An Introduction to Modeling with GAMS Py

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - An Introduction to Modeling with GAMS Py

Steven Dirkse, GAMS Development Corporation, Fairfax, VA, United States, Adam Christensen

GAMS execution system with the flexible Python language, creating a powerful mathematical optimization package. It acts as a bridge between the expressive Python language and the robust GAMS system, allowing you to effortlessly create complex mathematical models and applications. Join us to explore GAMS Py's fundamental functionalities through practical, interactive exercises. We'll cover everything from defining sets, parameters, variables, and equations to solving models and retrieving results, all within a familiar Python environment. Beyond the basics, we'll also provide a glimpse into more advanced features, demonstrating how GAMS Py can streamline complex modeling workflows and enhance your analytical capabilities. Whether you're a seasoned GAMS user looking to integrate with Python or a Python user curious about optimization, this workshop will equip you with essential skills needed to get started and demonstrate what is possible with GAMS Py.

Saturday, October 25, 11:30 AM - 12:45 PM

Building A Level 3 A315

The Benefits of Certifying your Data Team

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - The Benefits of Certifying Your Data Team

Nicole Janeway Bills, Data Strategy Professionals, Alpharetta, GA, United States

Certification elevates a data team's capability, credibility, and business impact. Data Strategy Professionals will explore how recognized credentials in Data Strategy, Data Governance, Data Analytics, and related disciplines strengthen technical skills, improve cross-departmental trust, and support regulatory compliance. Participants will learn how certification fosters a shared vocabulary, boosts productivity, and aligns data work with strategic objectives—resulting in higher quality outcomes and measurable business value.

Building A Level 3 A316

SAS Analytics

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - SAS Analytics

Rob Pratt, SAS, Cary, NC, United States

SAS offers extensive analytic capabilities, including machine learning, deep learning, natural language processing, statistical analysis, optimization, and simulation. SAS analytic functionality is also available through the open, cloud-enabled design of SAS® Viya®. You can program in SAS or in other languages – Python, Lua, Java, and R. This workshop will review the SAS analytics portfolio, highlight recently added optimization features, and explore several optimization examples. Academic faculty, staff, and students can access the latest SAS software through our free academic software platforms SAS Viya for Learners and SAS Viya Workbench for Learners. Access instructions and learning resources will be provided.

Saturday, October 25, 1:00 PM - 2:15 PM

Building A Level 3 A315

How to Advance your Optimization Game with FICO® Xpress Solver

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - How to Advance Your Optimization Game with FICO(R) Xpress Solver

Tristan Gally, FICO, Xpress Optimization, Birmingham, United Kingdom, Michael Perregaard, Susanne Heipcke, Dinakar Gade

In this workshop, we will give an overview of the different solvers in the FICO Xpress Optimization suite, their features, and how to interact with them through the different APIs. Find out how Xpress can solve LPs, MIPs, NLPs, and general MINLPs to global optimality, get an overview of different cuts, heuristics, and other features and learn how to influence the solve using callbacks. We will also give an overview of recent advances to all the different solvers from MIP over hybrid gradient to the FICO Xpress Global solver.

Building A Level 3 A316

5 Pillars of OR Project Success: A DecisionOps Tutorial with Nextmv

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - 5 Pillars of OR Project Success: a DecisionOPS Tutorial with Nextmv

Tiffany Bogich, Nextmv, Salt Lake City, UT, United States, Carolyn Mooney

Why do OR projects fail? Why do they succeed? The way a project unfolds often comes down to how a project is run. DecisionOps (yes, it's like MLOps, but for decision science) makes all the difference because: People don't trust decisions they can't understand. Every optimization run needs to be logged, tracked, and explainable Testing reduces rollout risk and increases revenue opportunities Structured workflows across a diverse, integrated ecosystem provides choice and resilience These four things amount to: observability, explainability, systematic testing, and consistency in support of diversity. And they all depend upon a robust platform that facilitates collaboration across modelers, engineers, and business users. In this interactive workshop, you'll learn how to efficiently operationalize open source and commercial decision models, create workflows that link to up and downstream processes like ML forecasting and result visualization, perform robust scenario testing to explore what

if questions, and manage model versions and run data. What's more: You have the opportunity to see all of this in action — and do it yourself live. This session is relevant to data science and OR practitioners using tooling such as OR-Tools, Pyomo, HiGHS, VROOM, Gurobi, AMPL, FICO Xpress, Hexaly, Statsmodels, scikit-learn, Databricks, Snowflake, and more.

Saturday, October 25, 2:30 PM - 3:45 PM

Building A Level 3 A316

AI + Monte Carlo Simulation: Transforming Risk Analysis with GenAI

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - AI + Monte Carlo Simulation: Transforming Risk Analysis with GenAI

Gustavo Vinueza, Ferryfield, Ithaca, NY, United States

Learn how to integrate Generative AI into Monte Carlo Simulation to build smarter, and more understandable risk models. This session will showcase how to enhance their risk analysis workflows by integrating the power of Generative AI (GenAI) into Monte Carlo Simulation (MCS). You'll gain practical skills and insights that bridge the gap between modern AI tools and traditional quantitative risk methods. Main cases to be analyzed: 1) Selecting the Right Distribution, 2) Use Case 2 – Creating Risk Registers, 3) Explaining a Histogram to Non-Experts, 4) Writing Executive Summaries.

Building A Level 3 A315

Part 1: Pushing the Boundaries of Optimization: What's New in Gurobi 13 and Beyond

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - Part 1: Pushing the Boundaries of Optimization: What's New in Gurobi 13 and Beyond

Robert Luce, Gurobi, Beaverton, OR, United States, Ed Klotz, Dan Steffy

Join Gurobi's expert team for a deep dive into the latest advancements in mathematical optimization. This workshop will explore new features in Gurobi 13, including a CPU-based PDHG solver and a local nonlinear solver. Gain insights into emerging technologies like generative AI for optimization, quantum computing, and our progress on GPU acceleration. The session will conclude with a dynamic panel discussion on the future of optimization and AI. Whether you're an academic, practitioner, or student, this is your chance to engage directly with Gurobi's developers and expand your understanding of cutting-edge optimization tools.

Building A Level 3 A304

No-code Machine Learning with JMP Pro and JMP Student Edition

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - No-Code Machine Learning with JMP Pro and JMP Student Edition

Ross Metusalem, JMP Statistical Discovery, Tampa, FL, United States

Building and deploying machine learning models doesn't have to require expertise in Python or other coding languages. JMP Student Edition (free for academic use at jmp.com/student) and JMP Pro offer interactive, point-and-click tools for building powerful machine learning models for regression and classification, from basic decision trees and neural nets through XGBoost and deep learning models. Join this workshop to learn how to use these no-code tools for: Training machine learning models for regression and classification, including image classification Automated cross-validation and hyperparameter tuning. Model comparison and deployment.

Building A Level 3 A303

Timefold: The Open Source Solver for Java

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - Timefold: The Open Source Solver for Java

Jeroen Colin, Timefold BV, Gent, Belgium, Geoffrey De Smet

Timefold Solver is a metaheuristics solver for vehicle routing, shift rostering, job scheduling and other planning problems. It's designed for ease of use, scalability and enterprise usage. But unlike other solvers, it doesn't require you to input your constraints/objectives as math equations. It accepts them as plain Java code. They can reuse existing code, for example from date and time libraries. And you don't face any linear or quadratic limitations. In this session, we'll introduce the open source solver, explain the basics and live code a solution for school scheduling.

Saturday, October 25, 4:00 PM - 5:15 PM

Building A Level 3 A315

Part 2: Pushing the Boundaries of Optimization: What's New in Gurobi 13 and Beyond

Vendor Workshop

MDPI Academic Publishing Workshop

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - MDPI Academic Publishing Workshop

We invite you to join MDPI for an Academic Publishing Workshop, where we will provide a detailed overview of MDPI's open access publishing model, covering important topics such as selecting the right journal, understanding the editorial process, and adhering to key principles of publication ethics. Attendees will also receive practical tips on enhancing their scientific writing and responding to reviewer feedback. Led by experienced Assistant Editor, Antigona Ulndreaj, this session is designed to equip participants with the knowledge and skills needed to strengthen their publication efforts.

Building A Level 3 A316

Enhancing Qualitative and Quantitative Text Analysis with Transparent Generative AI

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - Enhancing Qualitative and Quantitative Text Analysis with Transparent Generative AI

Normand Peladeau, Provalis Research, Montreal, QC, Canada

This workshop introduces the integration of GenAI features in WordStat text analytics and QDA Miner qualitative analysis software, showing how generative methods can be combined with traditional approaches for more robust insights. We will highlight how high transparency was achieved to enhance reliability and trust. Participants will explore options for choosing AI engines, working with visible prompts, and integrating user-created or predefined scripts. Examples will range from simple tasks such as sentiment analysis, translation, text extraction, and preprocessing, to more advanced applications, including the fully automated analysis of open-ended responses and customer feedback—while still offering the flexibility to keep the human in the loop when interpretation and judgment matter most.

From Classroom to Industry: Modern Optimization with AMPL for Energy, Finance, Supply Chain, and Beyond

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - From Classroom to Industry: Modern Optimization with AMPL for Energy, Finance, Supply Chain, and Beyond

Marcos Dominguez Velad, AMPL, Plasencia, Spain, Gleb Belov

Optimization has never been more critical – or more accessible. This talk will show how students and applied researchers can bridge the gap between academic learning and real-world impact using AMPL in modern workflows. With free academic licenses now including commercial-grade access to leading linear solvers (Gurobi, CPLEX, Xpress, Mosek, COPT, HiGHS and more), AMPL offers an unmatched opportunity to develop and apply optimization skills directly in industry contexts. We will explore how AMPL integrates seamlessly with the tools you already know – Python, R, Jupyter, Colab, VS Code, cloud platforms, and modern data pipelines – making it a “set it and forget it” system for building models that stay faithful to the real problems you’re solving. Attendees will see how AMPL powers large-scale, mission-critical applications in energy, finance, transportation, and supply chain, enabling companies to save costs, increase efficiency, and improve decision-making. By combining intuitive modeling with cutting-edge solver technology, AMPL empowers students and researchers not just to learn optimization, but to contribute immediately to high-impact, industry-grade projects. Join us to discover how AMPL can position you, or your students, at the forefront of applied optimization.

Advancing Optimization Excellence: How FICO® Xpress's Latest Features Scale Decision Intelligence

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - Advancing Optimization Excellence: How FICO® Xpress's Latest Features Scale Decision Intelligence

Michael Perregaard, FICO, Birmingham, United Kingdom, Tristan Gally, Susanne Heipcke, Dinakar Gade, Carlos Zetina, Alexander Biele

Join our workshop to discover the cutting-edge innovations in Xpress Solver 9.8 and our updated APIs! Get a firsthand look at how Xpress Insight empowers business users to harness the full potential of analytical models faster than ever before. Experience the latest features and performance enhancements in FICO® Xpress Solver, including groundbreaking advances to our mixed-integer linear solver, the latest enhancements to our primal-dual hybrid gradient solver, and the newest features of FICO Xpress Global solver. We will present advancements in the Solver APIs and Xpress Mosel, outlining recent updates to modelling capabilities. In the second half of this presentation, we showcase how to accelerate Optimization Workflows with Xpress Workbench & Insight using Docker. We will demonstrate the ease of setup and minimal configuration required to achieve a unified development experience across Workbench and Insight using automated Docker-based workflows. Hear from Rusty Burlingame, Principle Operations Research Advisor of Southwest Airlines, speak about how Southwest is leveraging advanced analytics to improve customer experience, enhance employee engagement, and streamline operations to maximize revenue and support growth.

Hexaly, a New Kind of Global Optimization Solver

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - Hexaly, a New Kind of Global Optimization Solver

Fred Gardi, Hexaly, Brooklyn, NY, United States

Hexaly is a new type of global optimization solver. Its modeling interface is nonlinear and set-oriented. It also supports user-coded functions, enabling seamless integration of simulation with optimization or machine learning with optimization. The Hexaly API unifies modeling concepts from mixed-integer programming, nonlinear programming, and constraint programming. Under the hood, Hexaly combines various exact and heuristic optimization methods: spatial branch-and-bound, simplex methods, interior-point methods, propagation, automatic branch-cut-price, local search, and surrogate modeling. Hexaly stands out from traditional solvers like Gurobi, CPLEX, and OR-Tools by delivering super-fast solutions to problems such as routing, sequencing, scheduling, packing, clustering, matching, assignment, and location. For example, Hexaly provides solutions that are close to the best-known results in the literature for vehicle routing problems with thousands of points and scheduling problems with millions of tasks, achieving this in just one minute of runtime on a basic computer. In addition to the Optimizer, Hexaly offers an innovative platform called Hexaly Studio, designed to prototype, develop, and deploy optimization applications quickly in a low-code fashion. This web-based platform is also well-suited for educational purposes; like all other Hexaly products, it is free for faculty and students.

Building A Level 3 A304

Littlefield 2.0: A Factory Management Simulation for Teaching Operations Management

Vendor Workshop

Vendor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - Littlefield 2.0: A Factory Management Simulation for Teaching Operations Management

Samuel Wood, Responsive Learning Technologies, Los Altos, CA, United States

Littlefield for Operations is a competitive online simulation of either a factory or a medical laboratory that has been used by more than half a million students in 500+ universities in 60+ countries. Professors use the simulation as a pair of graded assignment to engage and excite and students in studying operations management topics like process analysis and inventory control. This presentation will introduce Littlefield 2.0 and allow participants to play a very fast and challenging scenario in the new student interface. Participants are encouraged but not required to bring a laptop or tablet to play the game.

Building A Level 3 A301

Daniel H. Wagner Prize

Award Session

Daniel H Wagner

Chair: Konstantina Mellou, Microsoft Research, Redmond, WA, United States

1 - Analytics for Urban Bike Infrastructure Planning: A Multi-Year Collaboration with the City of Toronto

Bo Lin, University of Toronto, Toronto, ON, Canada, Madeleine Bonsma-Fisher, Shoshanna Saxe, Timothy Chan

Cycling promotes healthy living, reduces traffic, and combats climate change, but safety and comfort concerns remain key barriers to cycling uptake globally. In collaboration with the City of Toronto, we developed a suite of descriptive, predictive, and prescriptive analytics tools to support data-driven planning of urban bike infrastructure. As cities strive to promote sustainable transportation solutions, our work offers a user-friendly, scalable, and adaptable model for leveraging analytics to achieve these goals, paving the way for future research and collaboration in this critical area.

2 - Deepstock: Inventory Management with Policy Regularizations

Will Ma, Columbia Business School, New York, NY, United States, Xinru Hao, Jiayi Liu, Yaqi Xie, Linwei Xin, Lei Cao, Yidong Zhang

Deep Reinforcement Learning (DRL) is hard to deploy off-the-shelf for OR problems, due to imprecise data and computational difficulties. To overcome these issues, we show how to regularize DRL using well-established policy structures from OR, in particular for inventory management. We extensively analyze regularized vs. off-the-shelf DRL, demonstrating the power of policy regularizations when we understand the structure of near-optimal policies. We deploy our regularized DRL algorithm to replenish inventory at Alibaba's Tmall Supermarket, observing Pareto improvement across inventory metrics.

Innovations in AI And Machine Learning for Impact

Panel Session

Practice Track

Co-Chair: Raghu Kulkarni, Equifax, Alpharetta, United States

1 - Moderator Panelist

Raghu Kulkarni, Equifax, Alpharetta, GA, United States

As artificial intelligence and machine learning continue to evolve, so does their potential to drive transformative change across industries. This panel explores cutting-edge innovations that move beyond experimentation to deliver real-world impact. Featuring expert insights from Raghu Kulkarni and fellow leaders in data science, we will examine the intersection of emerging techniques, scalable deployment, and ethical responsibility. Key topics include next-generation model development, responsible AI, cognitive computing, and frameworks for ensuring measurable outcomes. Join us for a thought-provoking conversation on how organizations can harness innovation in AI/ML not just for advancement, but for lasting value.

Frontiers in Data-Driven Finance

Invited Session

Finance

Chair: Kay Giesecke, Stanford University, Stanford, CA, United States

Co-Chair: Junting Duan, Stanford University, Stanford, CA, United States

1 - Bi-Causal Optimal Transport and Application in Financial TIME Series Generation

Renyuan Xu, New York University, New York, NY, United States

In this talk, we present a foundational framework for bi-causal optimal transport between Markov processes defined on general state spaces. Building on this foundation, we develop a gradient-based learning algorithm grounded in the Dynamic Programming Principle, along with a novel policy gradient theorem tailored to the bi-causal setting. This framework is particularly suited for generating financial time series, especially in challenging scenarios involving missing data or heterogeneous data observation frequencies.

2 - Estimation of Out-of-Sample Sharpe Ratio for High Dimensional Portfolio Optimization

Weichen Wang, The University of Hong Kong, Hong Kong, Hong Kong, Xuran Meng, Yuan Cao

Portfolio optimization aims at constructing a realistic portfolio with significant out-of-sample performance, which is typically measured by the out-of-sample Sharpe ratio. However, due to in-sample optimism, it is inappropriate to use the in-sample estimated covariance to evaluate the out-of-sample Sharpe, especially in the high dimensional settings. In this paper, we propose a novel method to estimate the out-of-sample Sharpe ratio using only in-sample data, based on random matrix theory. Furthermore, portfolio managers can use the estimated out-of-sample Sharpe as a criterion to decide the best tuning for constructing their portfolios. Specifically, we consider the classical framework of Markowitz mean-variance portfolio optimization under high dimensional regime of $p/n \rightarrow c \in (0, \infty)$, where p is the portfolio dimension and n is the number of samples or time points. We propose to correct the sample covariance by a regularization matrix and provide a consistent estimator of its Sharpe ratio. The new estimator works well under either of the following conditions: (1) bounded covariance spectrum, (2) arbitrary number of diverging spikes when $c < 1$, and (3) fixed number of diverging spikes with weak requirement on their diverging speed when $c \geq 1$. We can also extend the results to construct global minimum variance portfolio and correct out-of-sample efficient frontier. We demonstrate the effectiveness of our approach through comprehensive simulations and real data experiments. Our results highlight the potential of this methodology as a useful tool for portfolio optimization in high dimensional settings.

3 - Imputation-Powered Inference for Missing Covariates

Junting Duan, Stanford University, Stanford, CA, United States

A prevalent problem in empirical research is missing covariate data as an input for model estimation. This paper develops a novel framework for optimally using partially observed covariates data for estimation and inference in a downstream model. Commonly used approaches, that either discard all partially observed samples or naively treat imputed values as real observations, are generally inefficient or biased. Our novel approach combines a bias correction with an optimal weighting scheme for imputed values that balances the efficiency trade-off between imputation error and effective sample size. Our method ensures valid inference while improving statistical efficiency by leveraging all available data. Our framework accommodates general missing data patterns for large panels and can be combined with a broad class of imputation methods. We establish the asymptotic normality of the proposed estimator under general assumptions. In simulations and an empirical application, we demonstrate the superior performance of our method over the naive approaches, as it achieves both lower bias and variance, while being robust to the imputation quality.

4 - Risk Disclosure Premium in the Cross-Section of Stock Returns: A Generative Topic Modeling Approach

Steve Yang, Stevens Institute of Technology, Hoboken, NJ, United States, Beichen Zhang, Shanshan Yang

We examine the pricing implications of financial risk disclosures by applying generative topic modeling to Section 1A of 10-K risk factor filings for S&P 1500 firms from 2010 to 2023. Using embeddings from FinBERT, GTE-Qwen, and SFR-Mistral, we quantify firm-level exposure to specific risk narratives and compute corresponding risk scores. These scores are used to construct narrative-based risk factors through a two-step empirical asset pricing framework. First, we test the return predictiveness of these factors using the Fama-French 5 factor model via long-short portfolio sorts. Second, we implement Fama-MacBeth cross-sectional regressions to evaluate their risk premia alongside the standard market, size, value, profitability, and investment factors. Our results reveal a robust risk premium in operational risk disclosure - which remains statistically significant even after applying the Bonferroni correction for multiple tests. In addition, several other disclosure factors, such as funding risk, intellectual property risk, and infrastructure risk, also show some level of significance. These findings suggest that firm-disclosed forward-looking risks, as identified through generative embedding model on firm risk disclosures, offer economically meaningful and statistically robust insights into cross-sectional return variation.

INFORMS Case Competition

Award Session

Case Competition

Chair: A. Cecilia Zenteno, Massachusetts General Hospital, Boston, MA, United States

1 - Calyber: a Ridesharing Game

Chiwei Yan, University of California Berkeley, San Francisco, CA, United States, Yifan Shen, Julia Yan

Motivated by the persistent challenges that ridesharing platforms face in offering shared rides (a service that pools riders into a single vehicle), this case offers a hands-on and engaging experience in developing real-time analytics solutions. Using a rich historical ridesharing dataset, students design and test policies for quoting prices and matching riders, competing for top performance on a test set. By completing this case, students gain a practical understanding of stochastic dynamic optimization, a concept often difficult to teach through traditional instruction.

2 - Reinforcement Learning for Clinical Decision Support

Dessislava Pachamanova, Babson College, Wellesley, MA, United States, Angela Lin, Georgia Perakis

This case, based on a project with a U.S. academic medical center, addresses real-world challenges in developing AI-augmented decision support for patient treatment. It highlights the application of reinforcement learning to personalize care, contrasting it with a static segmentation approach. The case covers problem framing, data preprocessing, supervised/unsupervised/reinforcement learning, stakeholder engagement, and AI ethics. Python code and realistic data are included.

3 - Routing for Social Good: Optimizing Human Milk Bank Logistics

Natalia Summerville, Memorial Sloan Kettering Cancer Center, New York, NY, United States, José Antonio Carbajal

This case challenges students to optimize donor milk collection for a human milk bank using real-world data. Students develop routing and scheduling models to minimize travel time while ensuring timely pickups. Variations of the case introduce predictive time series models to forecast donation volumes, enabling smarter collection plans. Ideal for analytics, OR, or supply chain courses, the case blends logistics, forecasting, and public health impact.

Strategic Considerations in Transportation

Job Market Showcase

Job Market Showcase

Chair: Kyle Bathgate, The University of Texas at Austin, Austin, 78751, United States

1 - Bridging Transportation Infrastructure Design, Operational Policies, and User Interactions: a Mathematical Framework for Curb Space Management

Jisoon Lim, University of Michigan, Ann Arbor, MI, United States

Today's transportation systems are undergoing transformative change, driven by advances in connectivity, autonomy, shared mobility, and electrification. These innovations create new opportunities for enhanced mobility and multimodal integration but also call for a fundamental rethinking of infrastructure design and operational strategies to ensure accessibility, efficiency, and equity. My research addresses this challenge by focusing on the dynamic interplay among three interdependent pillars: infrastructure design, operational policies, and user interactions. I develop mathematical frameworks that integrate these pillars, capturing their interactions while balancing model efficiency and granularity. This tripod approach offers structured and scalable tools for analyzing transportation operations that are both socially responsive and practically implementable. I highlight curb space as a key example of this evolving landscape, where demand has grown in both diversity and intensity. As a vital interface for urban activities, curb space must accommodate both traditional and emerging mobility needs, providing equitable and proximate access to key urban functions. My research employs mathematical solutions - drawing from optimization, scalable algorithms, game theory, simulation, and behavioral science - to construct technology-enabled infrastructure models, design efficient operational policies, analyze user behaviors through data, and develop solution algorithms and software tools that capture the dynamic nature of curb space. These approaches aim to identify socially optimal solutions and guide user adaptation to emerging curb management strategies. By bridging technology, operations, and behavior, my work contributes to the design of integrated, user-centered, and future-ready mobility systems that can serve as models for other societal infrastructure challenges.

2 - Equitable Transit Design in the Era of Telework

Tianxing Dai, Northwestern University, Evanston, IL, United States, Marco Nie

Transit ridership in the US has plunged due to the COVID-19 pandemic and has yet to recover to the pre-pandemic level primarily due to the wide adoption of telework. Not only do previous transit commuters choose to telework a few days a week, but they also tend to drive more than before on the days they do commute. For transit agencies, the structural reduction of transit ridership means a loss in the farebox revenue needed to sustain their services. When the COVID-19 relief funds expire, transit agencies need to seek other means to cover the budget deficit. If they end up with cutting service, the disadvantaged population who rely heavily on public transit would be disproportionately affected. To help transit cope with telework, we developed a microeconomic model of transit design under the monocentric city setting, and endogenized travelers' commute mode (driving, transit or telework) and housing location choices, as well as traffic congestion. To understand the equity implications of telework on transit, our model features heterogeneous travelers who have different income levels. The transit design model permits adjustments in transit services and finance policies including fare, tax and congestion charges, and we adopt both a utilitarian objective and a Rawlsian objective to study the efficiency-equity trade-off. When analyzing and solving the location-mode choice equilibrium, we capture both the spatial mode sorting effect and the income mode sorting effect, where residents living farther from the city center and with higher income are more likely to telework.

3 - The Transportation Network Efficiency Effects of Congestion Pricing

Huahua Zhu, Indiana University, Bloomington, IN, United States

Traffic congestion remains a persistent challenge in modern urban areas, contributing to longer travel times, increased travel costs, higher gasoline consumption, and network inefficiency. To evaluate the impacts of congestion pricing on mitigating these negative externalities, this paper develops a structural decision-making framework that models agents' optimal travel route and mode choice behavior under uncertainty, accurately capturing the resulting traffic equilibrium conditions. Within this framework, two user optimization problems are formulated—one without congestion pricing and one incorporating it—allowing for the establishment of equilibrium existence and uniqueness, as well as the derivation of closed-form expressions of the equilibria for both cases. Additionally, a system optimization problem is introduced from a social planner's perspective, providing a benchmark for evaluating network efficiency in response to transportation policy interventions. Empirical evidence from New York City's cordon-based congestion pricing policy demonstrates that such interventions significantly alter traveler distribution patterns, reduce travel times and travel costs, and lower gasoline consumption at the main entry links. However, this policy only improves the overall network efficiency by 4% within a monocentric city structure. Furthermore, an ex-ante policy analysis suggests that increasing the congestion pricing from 9 dollars to 12 dollars would reduce the network efficiency improvement to 3%.

4 - Methods for Assessing the Resilience of Maritime Freight Transportation Systems

Kyle Bathgate, The University of Texas at Austin, Austin, TX, United States

Resilient systems are critical for business continuity and effective supply chain management. In this work, new methods for measuring the resilience of maritime freight infrastructure facilities are developed. The metrics are derived using anchorage queue lengths and wait times, and relate to the system robustness and recoverability. Applications of the metrics are presented using historic vessel tracking automatic identification system (AIS) data at the Port of Houston, Texas to demonstrate the resilience of the system to disasters such as hurricanes and recurring fog events.

When coupled with discrete-event simulation approaches, the metrics allow for the testing of hypothetical disasters and scenario planning, allowing stakeholders to observe the potential resilience implications of a given infrastructure investment or operational adjustment. These findings are relevant to public and private sector maritime industries as they allow for increased awareness of system response under distress and provide tools for increased supply chain resilience.

Managing Emerging Technologies: AI, Blockchain, and Digital Markets

Invited Session

Information Systems

Chair: Xue Tan, Southern Methodist University, Dallas, United States

1 - Resalable Bytes: Unlocking Digital Ownership in Content Markets Through Blockchain

Zixuan Meng, The University of Texas at Dallas, Richardson, TX, United States, Yi Gao, Ming Fan

The proliferation of non-fungible tokens (NFTs) has sparked both public skepticism and institutional interest. While critics dismiss NFTs as speculative assets, leading firms increasingly adopt NFT-based strategies that promise transferable digital ownership, particularly in markets historically dominated by licensing restrictions and Digital Rights Management (DRM). Our work develops an analytical model to investigate how blockchain-enabled ownership, through granting resalable rights, reshapes digital market dynamics. Specifically, we compare three distinct market architectures: (1) a benchmark model without ownership, (2) a creator-initiated blockchain (CIB) model, and (3) a platform-initiated blockchain (PIB) model. Our findings show that both blockchain models enhance consumer surplus and social welfare when initiator's operating costs and user adoption frictions are relatively low. However, who initiates still matters, leading to distinct (1) changes in equilibrium price, (2) shifts in market demand, and (3) the specific channels through which ownership value is realized. This asymmetry between creator- and platform-initiated models is also reflected in their incentives. Creators are more likely to initiate blockchain, even under high operating and consumer adoption costs. This asymmetry in incentives leads to strategic responses by platforms, which may preemptively adopt blockchain despite short-term revenue losses, in order to mitigate long-term disadvantages associated with being a second mover.

2 - Civic Monitoring Through Internet-of-Things

Brian Lee, Pennsylvania State University, University Park, PA, United States

Internet-of-Things (IoT) devices are technological artifacts that integrate sensors, data, and automation to support decision-making. While widely adopted in areas such as marketing, manufacturing, and logistics, IoT is increasingly being used to promote community safety. However, its effectiveness remains uncertain due to the longstanding presence of traditional regulatory monitoring practices. This study focuses on consumer-grade air quality sensors as a form of IoT and examines whether their adoption can enhance community safety by reducing air pollution, even in areas already served by EPA air monitoring stations.

3 - AI Algorithms and Collusion in Ad Auctions

Subrahmanyam Aditya Karanam, National University of Singapore, Singapore, Singapore, Ashish Agarwal, Anitesh Barua

The rapid growth of Artificial Intelligence (AI) has led to its widespread deployment in automating decision-making and growing concerns about tacit collusive behavior among AI algorithms. One application involves real-time bidding for display advertisements, where collusion among bidders can negatively impact auctioneer revenues. Our study investigates this issue by analyzing the behavior of budget-constrained deep Q-learning algorithms in First-price auctions (FPA) through simulated computational experiments. We also examine how the advancement of AI technology and data policies affect the competitiveness of the auction. Overall, we find collusion among algorithmic bidders to be prevalent in FPA. The competitiveness of auctions further diminishes with more advanced AI algorithms. Contrary to findings in the literature on AI bidding with no budget constraints, our results suggest that when advertising platforms provide more detailed information about the auctions, it facilitates collusive behavior among budget-constrained AI bidders. Our results highlight the impact of using AI-powered algorithms on the outcomes in FPA and call for revisiting their design.

4 - Sell Data to AI Algorithms Without Revealing It: Secure Data Valuation and Sharing via Homomorphic Encryption

Michael Yang, University of Texas at Dallas, Richardson, TX, United States, Ruijiang Gao, Zhiqiang Zheng

Traditional data-sharing practices requires data owners to reveal the data to buyers to determine its value before they can negotiate a fair price, creating legal exposure, privacy risk, and asymmetric information that discourages exchange. We propose a homomorphic-encryption (HE) framework that enables prospective buyers to quantitatively assess a dataset's utility to AI algorithm while the data remain fully encrypted end-to-end. This approach tackles the last-mile problem in building modern AI data marketplaces: Efficient Encrypted Utility Estimation. We designed a lightweight data utility evaluation method using HE protocols that allows buyers to score different data samples without actually having to obtain the raw data. The proposed method can work with popular gradient-based data valuation methods and can scale to large foundational models such as Large Language Models (LLMs). By allowing organizations to determine the value of their data, without disclosing the data itself before the transaction, our work provides a practical path toward safer data monetization in modern AI data marketplaces.

5 - The Impact of Generative AI on Open-Source Community Engagement

Karthik Babu Nattamai Kannan, Southern Methodist University, Allen, TX, United States, Narayan Ramasubbu

Emerging research highlights significant productivity gains from generative AI tools like GitHub Copilot in software development. However, the specific mechanisms behind these gains, especially in distributed development settings, remain underexplored. This study examines GitHub's trial of "Copilot for Pull Requests (PR)" to assess its effect on PR latency—the time taken to close PRs. Analyzing over 100 open-source repositories and approximately 200,000 PRs using Propensity Score Matching and panel data analysis, we find that Copilot usage reduces PR latency by up to 4 days on average. This improvement is primarily due to a reduced need for multiple reviewers, streamlining the review process. Repository-level data shows that higher Copilot adoption leads to cumulative latency reductions, highlighting its scalable impact. Further investigation suggests that Copilot-generated summaries enhance collaboration by providing precise and comprehensive documentation at the time of PR creation, decreasing the number of review iterations. These findings offer key insights into how AI can optimize collaborative software workflows. Copilot not only boosts individual productivity but also mitigates systemic inefficiencies in the pull-based development model. The study underscores the value of integrating AI tools into the software development lifecycle and highlights the need to address potential challenges such as workflow friction and information gaps. This research advances understanding in AI-driven productivity and provides actionable guidance for practitioners aiming to improve project performance through AI-enabled development tools.

Novel Empirical and Experimental Analysis

Job Market Showcase

Job Market Showcase

Chair: Mohammad Fili, Oklahoma State University, Stillwater, OK, United States

1 - AI-Driven Predictive Analytics for Strategic Decision-Making in Industry and Public Health

Mahima Naznin, University Of Missouri- Columbia, Columbia, MO, United States

In the industrial domain, a predictive framework was developed in one project for forecasting steel prices, which are notoriously volatile due to fluctuating global market conditions. Through rigorous correlation and covariance analysis, novel economic indicators were identified that influence price shifts. These insights were integrated into a machine learning-enhanced time series model—capable of predicting steel prices up to 12 weeks ahead with high accuracy. The model was operationalized in an interactive dashboard to support procurement strategies, enabling data-driven decisions that mitigate financial risk and improve supply chain efficiency.

In another project in the healthcare domain, the critical need was addressed for early detection of Type 2 Diabetes (T2D) risk among adolescents. A machine learning-based screening tool was developed, incorporating socioecological, behavioral, psychological, and physiological factors. After benchmarking multiple algorithms, XGBoost demonstrated the strongest performance with an AUC-ROC of 0.72, enabling early identification of high-risk individuals up to 15 years in advance.

Together, these projects illustrate my ability to build end-to-end, impactful AI-driven solutions—from feature discovery to model deployment—in high-stakes environments. My work emphasizes practical implementation, interpretability, and domain relevance, contributing to smarter decision-making in both business and health sectors.

2 - Decoding Cognitive Aging

Mohammad Fili, Oklahoma State University, Stillwater, OK, United States

Accurately identifying individuals at risk of cognitive decline and those who demonstrate exceptional cognitive resilience is critical for advancing early intervention strategies and understanding the neural basis of healthy aging. This work develops and evaluates computational frameworks to distinguish between cognitive aging trajectories using neuroimaging and longitudinal cognitive data. Specifically, it focuses on characterizing individuals with superior cognitive performance, referred to as "Positive-Agers", in contrast to their age-matched peers exhibiting cognitive decline (i.e., "Cognitive Decliners"). Drawing on large-scale datasets from the UK Biobank, two algorithms are introduced: Optimal Labeling with Bayesian Optimization (OLBO), which integrates neuronal functional connectivity networks; and Optimal Cognitive Scoring (OptiCS), a predictive pipeline that leverages diffusion MRI to assess and distinguish cognitive groups. Both methods demonstrate strong performance (AUC 83–88%) and identify key neuroanatomical substrates associated with cognitive resilience. In addition, a labeling mechanism is proposed for cognitive assessment and monitoring. These findings enhance early detection of cognitive decline and offer insights into the neural correlates of cognitive aging.

3 - Drivers of Customers' Preferences for AI Service Agents

Chia-Chun Yang, University of Cincinnati, Cincinnati, OH, United States, Craig Froehle, Yinghao Zhang

The use of artificial intelligence (AI) in customer service roles is evolving rapidly across diverse industries such as finance, retail, education, and healthcare. Leveraging advanced language processing algorithms, AI-powered service agents (AISA) are increasingly capable of engaging in service tasks such as checking order statuses, facilitating food orders, recommending personalized items, and providing mental health support. Additionally, recent studies suggest that AISA has the potential to outperform human service agents not just in efficiency and consistency, but also potentially empathy and other overtly "human" traits. However, despite their growing capabilities and many associated benefits, AISA still faces challenges in customer acceptance. Much is still unknown about the determinants of customers' preference for using AISA, and how much this technology shapes the customer service experience. A better understanding of these issues can enable organizations to make substantive operational advancements: improve service process designs, increase efficiency, and enhance customer satisfaction. This study investigates two research questions: (1) How do trust and perceived performance risk influence customers' preference for AI-powered service agents? (2) What factors drive customers' perceptions of human-like trust and perceived performance risk? Specifically, we examine how these perceptions are influenced by two factors: the complexity of the customer's task and the degree of anthropomorphism embedded in AI-powered service agents. Experimental methods are conducted over multiple studies to gain insights into these questions.

1 - Robust Optimal Strategies for Two-Period Liquidation in Financial Systems

Hongyi Jiang, The Chinese University of Hong Kong, Hong Kong, China, People's Republic of

We study the problem of asset liquidation in financial systems. During financial crises, asset liquidation is often inevitable but can lead to substantial losses if a significant amount of illiquid assets are sold simultaneously at depressed prices. To tackle this challenge, we consider a two-period liquidation model that allows for preemptive liquidation before maturity and propose a worst-case approach to the associated liquidation problem. Specifically, we propose a robust optimal strategy—a tractable liquidation approach that maximizes the worst-case terminal value of liquid assets, taking into account the uncertainty of other banks' liquidation decisions. In addition, we find that the unique Nash equilibrium is attained when all banks adopt our proposed strategy. We further demonstrate that the robust optimal strategy retains a similar form even when interbank liabilities are involved, where we consider both scenarios of full and partial network information. While our analysis builds upon a stylized model, our findings offer valuable guidelines for developing robust liquidation strategies that mitigate losses resulting from asset liquidation.

2 - On Gpo Changes Within the Healthcare System

Andrew Hildebrandt, Auburn University, Auburn, AL, United States

Within our healthcare network, a significant transformation is underway—hospitals are rapidly shifting their procurement strategies in a dynamic and increasingly cyclical pattern. Rather than maintaining long-standing affiliations, many hospitals are now engaging in a process of joining, dropping, and even rejoining group purchasing organizations (GPOs). This behavior reflects a broader reevaluation of how hospitals manage supply chain efficiency, cost control, and strategic sourcing in response to evolving external pressures.

The traditional model of stable, long-term GPO participation is giving way to a more flexible and performance-sensitive approach. Hospitals are no longer viewing GPO membership as a static commitment but as a strategic lever that can be adjusted based on changing market conditions, policy environments, and internal performance metrics. Some hospitals drop out in pursuit of direct contracting opportunities or greater autonomy, only to rejoin a GPO later when the benefits—such as aggregated buying power or access to specific supplier networks—become more compelling again.

This cyclical pattern of GPO engagement signals a move toward more adaptive procurement behavior. It also reveals how hospitals are leveraging procurement decisions not only to reduce costs but also to respond to new operational challenges, shifts in payer mix, regulatory uncertainty, and technological change. Ultimately, this loop of entry, exit, and re-entry into GPO arrangements underscores the increasing complexity and strategic importance of supply chain management in healthcare today.

3 - Taking My Time to Perfect the Beat: A Behavioral Analysis of Product Launch Delay Decisions

Hyunsuk Baek, Arizona State University, Tempe, AZ, United States, Huseyn Abdulla, Seongkyoon Jeong

A product launch is a crucial event in the new product development process, and the timing of a product launch is a crucial decision in many innovation-driven industries. More often than not, product launches are delayed. The impetus behind many well-publicized product launch delays has been the aspiration of achieving high product quality given ever-increasing market expectations. Even products with pre-announced launch dates are often delayed to accommodate continued or final quality improvements. However, by delaying product launches beyond pre-announced dates, managers and entrepreneurs face risks associated with shifting market expectations due to technological innovations and new competitive entries, as well as additional development costs with typically diminishing returns. Recognizing these trade-offs, we conduct a behavioral analysis of decision-making regarding a product launch delay beyond a pre-announced launch date. We develop an analytical model and derive a rational benchmark for launch delay decisions. Then, we conduct a behavioral experiment to test the extent to which individuals' actual delay decisions are aligned with this rational benchmark. We find that most individuals largely deviate from the rational benchmark, exhibiting what we term as under-delay and over-delay biases. This results in, on average, 24.25% of relative profit loss to the rational benchmark. Given this salience, we propose a behavioral model to explain the launch delay decisions. Estimating the behavioral model, we find that a delay-dependent status quo effect and loss-aversion effect together can explain individuals' decisions in the experiment.

4 - Regulatory Intervention in Automotive Recalls

Ramin Sepehrirad, Washington State University, PULLMAN, WA, United States, Kevin Mayo, George Ball

Despite extensive research on automotive recalls, the actual effectiveness of remedial actions—how well firms repair faulty products—is largely unknown, even as millions of unrepaired defective vehicles pose significant safety risks on U.S. roads. We address this gap by examining how regulatory intervention by the National Highway Traffic and Safety Administration (NHTSA) impacts automakers' remedial performance. Using an attention-based view, we posit competing effects: NHTSA-initiated recalls may heighten managerial focus due to increased scrutiny, yet prolonged investigations and repair complexities associated with such recalls could divert decision makers' attention. Employing a quasi-experimental design on a dataset of over 4,200 U.S. passenger vehicle recalls (2009-2024), we surprisingly find that regulator-initiated recalls significantly reduce repair rates—by as much as 5%. We further explore explanatory mechanisms, such as recall complexity and repair procedures. Our findings offer crucial implications for NHTSA's policies and industry practices to improve recall outcomes and public safety.

Scheduling and Staffing in Healthcare Applications

Job Market Showcase

Job Market Showcase

Chair: Yiqi Tian, University of Pittsburgh, Pittsburgh, PA, United States

1 - Stochastic Programming Approaches for Medical Residents' Shift Scheduling Under Residents Absenteeism and Surging Demand

Shutian Li, Lehigh University, Bethlehem, PA, United States, Karmel Shehadeh

Motivated by our collaboration with a general residency program, we present a new two-stage stochastic mixed-integer programming approach for resident shift scheduling, considering residents' absenteeism and demand uncertainty. We proposed an enhanced Logic-Benders-based decomposition algorithm to solve the proposed model. We also developed a user-friendly tool that implements the proposed approach. Numerical results demonstrate the computational efficiency of our proposed algorithm over state-of-the-art decomposition algorithms and provide valuable practical insight.

2 - Early Intervention for Chronic Pain: Reducing Healthcare Utilization, Surgeries and Healthcare Costs

Buyun Li, Kelley School of Business, Indiana University, Bloomington, IN, United States, Mohammad Zhalechian, Christopher Chen

Chronic pain imposes significant clinical and economic burdens, yet optimal care pathways remain contested. We estimate the causal impact of early interventional pain management (IPM) on healthcare utilization, surgeries, and costs using a natural experiment from a 2019 insurer policy eliminating co-pays for conservative care in select regions. Leveraging administrative claims data and a difference-in-differences instrumental variable approach, we find that early IPM reduces downstream costs, surgeries, and service use. These findings provide the first causal evidence supporting early IPM access as a high-value strategy and inform benefit design and payment models promoting efficient pain care.

3 - Primary Care Panel Optimization

Dilara Sonmez, The University of Chicago Booth School of Business, Chicago, IL, United States, Daniel Adelman, George Weyer

The method to achieve financial success under value-based contracts remains unclear, but recent studies suggest that tailoring patient visit patterns could be the key. With CMS aiming to have all Medicare beneficiaries in an accountable care relationship by 2030, optimizing primary care visit for patients is crucial for the success of this initiative for both provider organizations and health policymakers. Despite having evidence that primary care visit patterns and having a large primary care network are important to financial success under value-based contracts, no one has yet provided a framework to model the effect of visit patterns and to implement them as decision variables in an optimization problem in a realistic setting with resource constraints. We address this gap in the literature by formulating the problem of finding physicians' optimal patient panels and prescribing patients with a primary care dosage as a mixed-integer nonlinear optimization problem. Central to our method is a dynamic programming model that captures the physician's decision-making process for scheduling follow-up visits. Our approach also accounts for the complex dependencies

among key visit pattern metrics: frequency, regularity, and continuity of care. To ensure scalability, we introduce a technique that enhances computational efficiency in large-scale applications while maintaining solution quality.

4 - Modeling Human-Centric Healthcare Scheduling with Decision-Dependent Uncertainty

Yiqi Tian, University of Pittsburgh, Pittsburgh, PA, United States, Bo Zeng

This talk introduces decision-dependent uncertainty to capture human behavior in healthcare scheduling tasks, including blood drives and radiologist staffing. By human behavior in contexts, the proposed models enhance the reliability and robustness of operational plans, ultimately improving resource allocation and outcomes in these critical, human-centric decision processes within healthcare domain.

Topics in Scheduling

Job Market Showcase

Job Market Showcase

Chair: Jorge Huertas, Georgia Tech - ISyE / AI4OPT, Atlanta, GA, United States

1 - Flow Shops with Reentry: a Theoretical and Computational Analysis

Nicklas Klein, University of Bern, Bern, Switzerland, Michael Pinedo

Scheduling manufacturing processes efficiently is a key challenge in many supply chains. We consider manufacturing processes in which the jobs traverse and reenter a flow shop multiple times, i.e., after a job has traversed the shop and completed its processing on the last machine, it must return to the first machine and traverse the shop again until it has completed all its required loops. Such a setting is referred to as a flow shop with reentry and has numerous industrial applications, e.g., in the electronics industry. The planning problem is to schedule all loops of all jobs so that an objective related to customer satisfaction or resource utilization is optimized. We propose several algorithms and analyze their theoretical properties and computational performance.

2 - Three Essays on Multiple-Orders-Per-Job Scheduling Problems in a Two-Stage Flow Shop

Rohan Korde, Arizona State University, Tempe, AZ, United States

Motivated by semiconductor manufacturing, in my PhD research, I study single-objective and bi-criteria job scheduling problems at a 300-mm wafer foundry fabrication (fab) facility. Customers send their orders to a fab in terms of number of 300-mm wafers. At a fab, the chip manufacturing involves hundreds of reentrant processing steps on many machines. The wafers are moved between machines using front opening unified pods (FOUPs or jobs) using an overhead hoist transportation (OHT) system. When the customer orders increase, the fab is constrained by the number of jobs available because by increasing the jobs can lead to congestion in the OHT. This can cause tardy orders, which the fab wants to minimize. One way to address this is to pack orders from different customers in the same job and then schedule the jobs to be processed on the machines. This class is called “multiple orders per job” (MOJ) scheduling problems. I model the fab as a two-stage permutation flow shop. In the first paper, I study single-objective MOJ problems (each to minimize a single regular performance measure) where the orders are released to flow shop at the same time. In the second paper, I study single-objective MOJ problems where the orders are released to the flow shop at different times (unequal release time). In the third paper I study bi-criteria MOJ problems. I use mixed integer linear programming, heuristics, and metaheuristics to solve these problems. I use full-factorial computational experiments to compare the solution quality.

3 - Safety-Driven Scheduling via Online Multi-Agent Reinforcement Learning

Pavithra Sripathanallur Murali, George Mason University, Fairfax, VA, United States

Scheduling in multi-component networks must balance performance with safety considerations, particularly in safety-critical systems. While existing decisions approaches either rely on model-based techniques like reachability analysis requiring precise system safety dynamics or implement model-free methods with simplistic binary safety measures and constraints falling short in capturing the gradients of safety. To this end, we propose a novel approach for decentralized scheduling in multi-component networks with interdependencies that incorporates continuous safety indicator measures for each schedule, enabling more nuanced safety assessment to classify and eliminate them during learning process. We specifically utilize decentralized markov decision process to model the decision process of network scheduling. Our method demonstrates superior performance in identifying and eliminating unsafe schedules while maintaining finite time guarantees. We validate our approach through numerical experiments and a real-world case study of a Water Distribution Network in Tampa, FL, where we optimize restoration scheduling under contamination risks. This work provides infrastructure managers with a practical framework for evaluating resilient strategies under simulated disruptions.

4 - Scheduling for Semiconductor Manufacturing

Jorge Huertas, Georgia Tech - ISyE / AI4OPT, Atlanta, GA, United States, Pascal Van Hentenryck

Recent disruptions in the semiconductor supply chain—such as the global chip shortage—highlight the urgent need for resilient scheduling tools within wafer fabrication facilities. These tools must incorporate a range of operational complexities, including the diverse batching regimes employed across different fab areas. This talk introduces novel constraint programming models for parallel and serial batching with incompatible job families, common in critical steps such as the diffusion and ion implantation stages in semiconductor manufacturing. Evaluated on standard testbeds, the proposed models outperform existing approaches from the literature. Furthermore, they effectively scale to replicated industrial instances, where exploiting the problem's structure further enables rapid schedule adjustments. Overall, these advancements offer a powerful foundation that paves the way for robust and adaptive planning under uncertainty.

Job Market Showcase

Chair: Yunbei Xu, National University of Singapore, Singapore, Singapore

1 - When Worst-Case Isn't Robust: on the Limitations of Distributionally Robust Formulations in Secretary Problems

Anas Abdelhakmi, National University of Singapore, Singapore, Singapore, Andrew Lim

We formulate and solve a Distributionally Robust Optimization (DRO) version of secretary problems, revealing a surprising phenomenon: the optimal robust decision coincides exactly with the nominal decision across various secretary problem variants and for different uncertainty sets (e.g., Kullback-Leibler divergence, Wasserstein distance\dots). We show that this result emerges because genuine robustness against distributional misspecifications is fundamentally unattainable in secretary problems without altering the problem structure itself. We illustrate how in this case, traditional DRO approaches yield only an illusion of robustness, leaving decisions equally sensitive, or even more vulnerable to distributional shifts if decision-makers misinterpret the ‘robust’ label. To address these vulnerabilities, we propose ‘Hedging for Robustness’, a managerial framework enabling practitioners to achieve robustness beyond conventional worst-case strategies. More generally, these results offer new intuitions of what it means for sequential decision to be truly robust and show how practitioners can achieve robustness beyond mere worst-case strategies.

2 - On the Minimax Regret of Sequential Probability Assignment via Square-Root Entropy

Zeyu Jia, Massachusetts Institute of Technology, Cambridge, MA, United States

We study the problem of sequential probability assignment under logarithmic loss, both with and without side information. Our objective is to analyze the minimax regret -- a notion extensively studied in the literature -- in terms of geometric quantities, such as covering numbers and scale-sensitive dimensions. We show that the minimax regret for the case of no side information (equivalently, the Shtarkov sum) can be upper bounded in terms of sequential square-root entropy, a notion closely related to Hellinger distance. For the problem of sequential probability assignment with side information, we develop both upper and lower bounds based on the aforementioned entropy. The lower bound matches the upper bound, up to log factors, for classes in the Donsker regime (according to our definition of entropy).

3 - Statistical Methods for Benchmarking Quantum Random Circuits**Tudor Manole, Massachusetts Institute of Technology, Cambridge, MA, United States**

Random circuit sampling (RCS) is a technique for benchmarking quantum computers that was popularized by Google Quantum AI, and formed the basis of their quantum advantage demonstration in 2019. This task consists of sampling bitstrings from a randomly-generated quantum circuit, and is considered to be intractable on a classical computer when the circuit size is sufficiently large. An important step for carrying out RCS experiments is to estimate the fidelity of the circuit, which is roughly the probability that it runs without errors. Typical approaches to fidelity estimation require knowledge of the probability distribution of bitstrings generated by the quantum circuit, which is usually obtained via classical computation for small system sizes. In this work, we instead consider obtaining side information in the form of bitstring samples from a clean quantum computer. We derive sharp bounds on the sample complexity of fidelity estimation, showing that it improves polynomially in the number of clean bitstring samples available. As a special case, we also obtain the sharp sample complexity of fidelity estimation in the absence of side information, which scales exponentially in the number of qubits. These sample complexity bounds are achieved by practical statistical estimators, which we illustrate on real RCS data.

This talk is based on joint work with Daniel Mark, Wenjie Gong, Bingtian Ye, Soonwon Choi, and Yuri Polyanskiy.

4 - Adaptive Learning to Prevent Spiral-Down in Branded-Fare Revenue Management**Lan Wu, National University of Singapore Business School, Singapore, Singapore, Changchun Liu, Chung Piau Teo, Xun Zhang**

Airline revenue management increasingly relies on branded fares, which organize ticket options into structured families with tiered services. Traditional RM models assume static, exogenous arrival rates and homogeneous choice behavior, neglecting dynamics such as competition-driven price shifts and context-dependent passenger decisions. A prominent example is the “buy-down” phenomenon, where customers qualified for premium fares opt for lower-tier options, triggering a spiral-down effect that erodes revenue.

Unlike “blind” RM—which treats every no-sale as an observed rejection and assumes a single choice model for all arrivals—our method infers both latent arrival intensity and heterogeneous choice parameters directly from the censored booking curve. We introduce a framework that combines a dynamically adjusted marginal-fare transformation with an online Bayes–Selector learning scheme. Under mild separation conditions on purchase probabilities and revenue differentials, the algorithm requires only an $O(\log T)$ exploratory phase to learn context-dependent parameters; if prior information or historical data already yield sufficiently accurate estimates, exploration is skipped and the regret is $O(1)$.

Crucially, by continuously updating estimates of each segment’s willingness-to-pay and buy-down propensity, this anticipatory pricing prevents customers from systematically trading down for minimal savings, thereby breaking the spiral-down feedback and preserving premium fare revenue. In the exploitation phase, LP-based bid-price controls optimize fare levels and seat allocations in real time. Extensive simulations and a real-world airline case study confirm that our approach not only outperforms classical RM heuristics in overall revenue but also significantly mitigates the buy-down effect by aligning fare offerings with evolving customer choices and competitive actions.

Platform Operations

Job Market Showcase

Job Market Showcase

Chair: Emin Ozyoruk, University of Chicago, Chicago, United States

1 - Incentive Design on Digital Platforms: from Principal–Agent Theory to Livestreaming Commerce**Hang Jiang, National University of Singapore, Singapore, Singapore, Chen Jin, Luyi Yang**

This talk presents two studies bridging principal-agent (PA) theory and platform operations, focusing on livestreaming commerce.

The first paper revisits the classical first-order approach (FOA) for simplifying PA problems. We show the most celebrated Mirrlees-Rogerson condition validating FOA does not generalize to risk-neutral agents with limited liability. Motivated by our finding that quota-bonus contracts are optimal for the relaxed problem, we propose FOA validity specifically for quota-bonus contracts (FOAVQB). We provide general, economically intuitive, and easily verifiable conditions ensuring FOAVQB, thus guaranteeing quota-bonus contracts’ optimality.

The second paper analyzes optimal pricing, refund policies, and influencer contracts in livestreaming commerce under moral hazard. We demonstrate that the optimal refund policy is either full-refund or no-refund policies, contingent on product value. High-value products benefit from full refunds, which incentivizes more customer purchases and thus increases net sales. For low-value products, thin margins make no-refund policies desirable, as they ensure committed purchases and reduce inefficient production and return costs. Under no-refund policy, practically-used commission contracts (based on either gross or net sales) always achieve the theoretical global optimum. Under full-refund policies, however, gross and net sales commissions expose agents to different levels of uncertainty, making their effectiveness dependent on the agent’s risk aversion. Additionally, influencer misconduct (brushing) complicates gross-sales-based contracts under full refund policy. We then characterize optimal brushing-proof refund policies and contracts. Our findings provide strategic guidance for firms navigating livestreaming platforms’ nuanced operational challenges.

2 - Seller Inventory Competition Under Platform’s Algorithmic Demand Allocation**Shengyu Cao, Rotman School of Management, Toronto, ON, Canada, Ming Hu**

We explore how platform allocation rules influence seller behavior and shape inventory-based competition within online marketplaces. Through a detailed analysis of multiple sellers offering identical products on a platform, we investigate the effects of different allocation rules on seller inventory levels and platform payoff in the equilibrium. Contrary to expectations, findings reveal that inventory-agnostic priority rules can mirror sole-sourcing decision-making scenarios, suggesting that these allocation methods do not influence the platform’s optimal payoff. In contrast, incorporating randomness in demand allocation intensifies competition among sellers and increases the platform’s payoff. Moreover, the introduction of inventory-aware allocation rules offers a novel approach to demand allocation and further promotes competitive inventory strategies among sellers. We extend our analysis in two extensions. First, we examine how different platform allocation rules influence sellers, highlighting the trade-offs between platform payoff, customer fill rates, and both inter-temporal and cross-sectional profit disparities. This provides an alternative perspective on the design of allocation mechanisms. Second, we investigate a scenario where sellers must learn the allocation rules through reinforcement learning algorithms, which can lead to algorithmic collusion. We propose mitigation strategies and demonstrate how the discussed allocation rules can be adapted to sustain competitive marketplace in a dynamic environment.

3 - Risk and Management of Talent Drain: a Mixed Methods Approach

Nuo Yuan, Boston University, Boston, MA, United States, Mohamed Zaki Balboula, Yuze Li

Talent drain matters to firms as it disrupts operational stability, exacerbating financial performance variability to the detriment of shareholder value. Therefore, a precise understanding and management of imminent talent drain risk is essential to investors and firms themselves. Online crowd-sourcing platforms such as Glassdoor provide a centralized place for employees to reflect on their workplace experience (i.e., Glassdoor employee reviews) at their respective employers, providing investors and firms themselves with an alternative information intermediary to gauge talent drain risk. As such, we 1) empirically assess the extent to which investors detect and price in such risk by exploiting the timing a firm receives its first Glassdoor review (i.e., Glassdoor coverage initiation) as an exogenous shock and 2) employ an interpretable ML paradigm to identify operational "hotspots" most associated with a future talent drain event and propose a text-based future talent drain prediction algorithm. We contribute to the social media as information source for financial market literature by disputing prior finding via our finding that Glassdoor coverage initiation incurs an instantaneous spike in a firm's talent drain risk. We also contribute to the talent recruitment and retention literature by identifying salient operational drivers/remedies of future talent drain events and demonstrating the incremental predictive power of Glassdoor employee review text in predicting future talent drain events.

4 - Pricing and Capacity Decisions in Platform Competition with Network Externalities

Emin Ozyoruk, University of Chicago, Chicago, IL, United States, John Birge

The structure of network externalities influences platform competition and can determine whether a two-sided market is winner-takes-all or highly contestable. Yet, because of analytical challenges, relatively little is known about these structures in different markets. This paper investigates how the structure of externalities impacts the performance of platforms and competitive outcomes. We propose a model of platform competition in ride-hailing, identifying the structure of externalities that arise from congestion. After finding representations of congestion, which serve as micro-foundations for platform competition, we provide general conditions for the existence and uniqueness of equilibrium. Our results demonstrate that ride-hailing platforms benefit from economies of scale, becoming more efficient as they attract more riders and drivers. This could lead to winner-takes-all scenarios in markets with low demand or attractive outside options. However, service variability arising from differing distances between riders and drivers introduces differentiation, enabling multiple platforms to coexist in suitable markets. In such cases, entrants can leverage service variability to enter, potentially driving profits to zero and making the market highly contestable. The results challenge conventional wisdom, suggesting that having a large network may no longer guarantee survival and that platforms need credible commitment mechanisms to retain users. We discuss the reasons behind, shedding light on potential strategies that platform managers can follow while avoiding the ones that can inadvertently harm competition.

Operational Optimization for Delivery Logistics in Urban Air Mobility and Commercial Aviation

Invited Session

Air Transportation Section

Chair: Shangqing Cao, University of California, Berkeley, Emeryville, CA, 94608, United States

Co-Chair: Shangqing Cao, University of California, Berkeley, Emeryville, CA, 94608, United States

1 - Map Partitioning for Same-Day Delivery Logistics System

Jianhua Liang, University of Texas at Austin, Austin, TX, United States

Same-Day Delivery (SDD) is a critical component of the logistics and transportation ecosystem, which garnered significant interest in the context of advanced air mobility (AAM) enabled E-commerce. Current research on SDD primarily addresses challenges in operational dispatch, leaving system design considerations largely unexplored. Previous studies on SDD system design usually considered a specific case with assumptions such as vehicle capacity and depot locations, which limit the implications of the models. These constraints also prohibit the exploitation of SSD with a single vehicle. In this work, we introduce a same-day delivery framework that incorporates vehicle capacity constraints and time guarantees, confirming a necessary schedule structure and bridging time and area constraints to ensure profitability. Tactically, we address the problem of what schedule and zone a vehicle should be responsible for to maximize the number of deliveries. We extend and generalize the existing same-day delivery model by including the vehicle's capacity constraint, as well as providing a set of comprehensive proofs for the necessity of optimality for the optimization problem. Besides, we also provide a straightforward implementation to convert the numerical optimization problem to one for maximizing profit. Finally, we provide an example demonstrating how system designers can achieve profitability while adhering to time guarantee SDD standards. This research helps reducing operational costs, improving delivery efficiency, while maximizing profitability. Further advancements based on this research, such as scaling to complex scenarios and optimal region partitioning, will further enhance the usage and enable real-world industry applications.

2 - From Voice to Safety: Language AI Powered Pilot-ATC Communication Understanding for Airport Surface Movement Collision Risk Assessment

John-Paul Clarke, University of Texas at Austin, Austin, TX, United States

Surface movement collision risk models are essential for airport safety, providing early warnings for near-miss incidents and reducing the risk of accidents. However, most existing models were developed decades ago and have not fully integrated recent advances in machine intelligence. To address this gap, we propose a language AI-based framework that enhances current Airport Surface Surveillance Capability (ASSC) by incorporating voice communication understanding for collision risk assessment.

Our framework has two components: (a) rule-enhanced Named Entity Recognition (NER) and (b) surface collision risk modeling. The NER module processes pilot-Air Traffic Controller (ATCo) voice transcripts to generate structured information tables, which inform taxi plans and collision risk calculations. We created and annotated a dataset from open-source recordings and safety reports, supplementing it with heuristic rules from FAA Order JO 7110.65W and FAA Order JO 7340.2N. Building on this, we developed the ATC Rule-Enhanced NER method, a hybrid model integrating heuristic rules into both training and inference, which outperforms baseline embedding models.

For risk modeling, we adopt a node-link airport layout graph (from NASA FACET) and model aircraft taxi speed as a log-normal distribution to estimate taxi times. We then propose a spatiotemporal formulation for collision probability when two aircraft approach conflict nodes. Case studies—including the January 2024 Haneda runway accident and September 2024 KATL taxiway collision—demonstrate that our model can estimate collision probabilities in real time. By combining voice communication understanding with surface movement analysis, our approach enables proactive measures to mitigate incursions and enhance airport safety.

3 - Scheduling and Routing for Multi-Modal Last-Mile Delivery Under Multiple Uncertainties

Minghao Chen, Columbia University, New York, NY, United States, Ang Li, Max Li

This research introduces a novel optimization framework for last-mile delivery using a tri-modal system that integrates trucks, drones, and tricycles. The proposed Stochastic Heterogeneous Vehicle Scheduling and Routing Problem (SHVSRP) addresses the operational complexities and synchronization risks arising from uncertain urban conditions such as traffic congestion and variable weather. We formulate SHVSRP as a mixed-integer program with dual objectives: minimizing expected delivery time and synchronization failures across modes. To solve this problem efficiently, especially at scale, we develop a two-phase parallel heuristic combining capacitated routing and time-aware scheduling. Simulation results across various traffic and wind conditions demonstrate that the tri-modal system significantly outperforms traditional truck-only and truck-drone models. Notably, it reduces makespan and failure rates, particularly under high uncertainty, thereby enhancing reliability and efficiency. Our study offers operational insights on optimal fleet composition and dynamic route planning, paving the way for resilient, scalable, and sustainable urban logistics.

4 - The UAM Fleet Scheduling Problem with Non-Linear Charging Time

Shangqing Cao, University of California, Berkeley, Emeryville, CA, United States

To better assess the economic feasibility of a UAM service, we introduce a vehicle-routing formulation of the Urban Air Mobility (UAM) fleet scheduling problem. The proposed model, electric urban air mobility vehicle routing problem with non-linear battery charging time (eUAMVRP-NL), studies the optimal flight scheduling and charging policy for a given fleet of eVTOL vehicles to maximize the operating revenue with the assumption of a non-linear charging model for the aircraft batteries. We design a Cluster-First Route-Second (CFRS) solution heuristic that first decomposes the k-vehicle problem into k number of 1-vehicle problems before optimizing the flight scheduling and charging decisions for each aircraft in the fleet. We validate our CFRS algorithm on a small, two-vertiport instance in which an optimal solution can be obtained. We found a loss of optimality less than 2%. Finally, we demonstrate the use of eUAMVRP-NL in obtaining meaningful metrics for the estimation of capital cost and operating cost by considering the airport access use case of UAM at Los Angeles International Airport (LAX).

5 - UCAirSim: Designing and Evaluating Cross-Campus UAM Network

Andrew Park, University of California, Berkeley, Berkeley, CA, United States

Urban Air Mobility (UAM) is emerging as a transformative mode of intra-regional transportation, enabled by electric vertical takeoff and landing (eVTOL) aircraft. This study presents UCAirSim, a discrete-event simulation framework designed to evaluate the performance of an inter-campus air taxi network connecting CITRIS campuses and major research hubs in Northern California. The framework integrates a Campus Interconnectivity Simulation (CIS)—a macroscopic, event-driven model of fleet scheduling, demand balancing, and energy dynamics—with a Guidance, Navigation, and Control (GNC) simulator that validates flight trajectories, aeropropulsive performance, and noise impacts using high-fidelity NASA eVTOL models.

The analysis evaluates system capacity, fleet sizing, and performance under fluctuating demand and varying flight paths. Results show that a fleet of 31 aircraft could serve approximately 400 passengers per day under nominal conditions, with scalability up to 1,600 passengers under optimized scheduling. Average wait times were reduced by incorporating repositioning strategies, while nonlinear battery charging dynamics constrained operational efficiency. Environmental and stakeholder considerations were also addressed, including vertiport siting, multimodal connectivity, and static noise policies. By combining network-level scheduling with vehicle-level dynamics, UCAirSim provides a scalable platform for analyzing operational strategies, environmental impacts, and future optimization approaches. This dual-layer simulation offers decision support for fleet operators, policymakers, and researchers in planning sustainable and efficient UAM systems for intraregional connectivity.

AI: From Prototype to Production

Invited Session

The Practice Section of Informs

Chair: Ram Kumar Nimmakayala, WGU, Plano, TX, 75024, United States

1 - Bridging the Gap: Product-Led Execution for Enterprise AI Delivery

Ram Kumar Nimmakayala, WGU, Plano, TX, United States

Bridging the Gap: Product-Led Execution for Enterprise AI Delivery Despite rapid advancements in AI capabilities, many enterprise initiatives struggle to translate prototypes into scalable, value-generating solutions. This session focuses on a product-led execution framework that bridges the gap between experimentation and enterprise-grade AI delivery. It highlights how applying core product management principles—such as iterative validation, stakeholder alignment, user-centric design, and outcome-driven roadmaps—can transform fragmented AI efforts into cohesive, production-ready solutions. The discussion will explore real-world case studies, execution challenges in cross-functional environments, and techniques for aligning data science, engineering, and business teams around shared goals. Attendees will walk away with a pragmatic blueprint for operationalizing AI at scale, accelerating time-to-value, and embedding accountability throughout the AI lifecycle.

2 - Intelligent Automation of Data Engineering Workflows with AI

Manohar Sai Jasti, Workday, Cumming, GA, United States

Most data teams spend days turning a helpful query into a production-grade pipeline—refactoring code into dbt models, adding data-quality tests, writing documentation, and scheduling the flow in Airflow. These manual steps slow insights and tie up scarce engineering time.

This talk shows how large language models remove much of that toil. An LLM can

- Generate modular dbt models (staging, intermediate, mart) from draft SQL
- Insert freshness, null-check, and uniqueness tests
- Write concise model documentation and lineage notes
- Build a ready-to-run Airflow DAG

Attendees will see how automating these routine tasks speeds delivery of reliable data products and frees engineers to focus on higher-value analysis.

3 - Running Away from Demo Hell: Shipping AI Beyond the Prototype with Eval-Driven Development

Albert Lie, Forward Labs, San Francisco, CA, United States

Many AI projects shine in demos but fail in production, trapped in what we call "Demo Hell." The transition from a promising prototype to a reliable, real-world AI system is riddled with unseen pitfalls, from brittle prompts to unpredictable model outputs. In this talk, we'll explore Eval-Driven Development (EDD) as the key to escaping Demo Hell and building AI that actually works beyond controlled environments. Using a few open-source frameworks for evaluating LLM applications, we'll dive into: Why traditional AI development often breaks down in real-world use cases How Eval-Driven Development ensures continuous, measurable improvement Setting up automated evaluations to diagnose failures before they reach users Case studies of teams that successfully shipped AI from prototype to production using EDD

4 - A Framework for Generative AI Operation Evaluation

Cigil Achenkunju, Northern Illinois University, Boston, MA, United States

How do we know if the investment in generative artificial intelligence (GenAI) is moving the needle? It is a question heard almost daily across finance, healthcare, and retail sectors. And honestly, it is the right question to ask. On top of that, should we continue to invest in AI at the same rate or optimize? How can a stakeholder show that solution usage has a positive or negative impact on their operation?

Survey results indicate that up to 85% of AI initiatives eventually fail to deliver their promises. Organizations using gen AI want to understand the impact of such

solutions clearly. Can you blame them? So, let's define a strategic decision-making framework that broadly answers these business questions in an operational setting that balances the benefits of business value and AI integration.

An analytical framework for operations measurement 2S/2E: Think of it as four pillars used together to tell a complete story of your gen AI-enabled operation's health: Each pillar reveals a different facet of your performance, and I'll show you exactly how to measure them. These pillars offer valuable insights to measure your operations. What makes this framework powerful is its systematic approach and adaptability.

Labor Planning and UTR Process Optimization

Invited Session

Practice Track

Chair: Elcin Cetinkaya, Amazon.com, Seattle, WA, United States

1 - Optimizing the Allocation of Outbound Work to Constrained Resources in Amazon Fulfillment Centers

Kevin Bunn, Amazon, Bellevue, WA, United States

In Amazon Fulfillment Centers, there are multiple options for how to prepare a shipment to be sent to a customer. Each of these processing options is called an outbound process path. Every process path has a planned throughput, which can be used to determine the capacity available for how many shipments can be processed on that process path in a given amount of time. In this presentation, we will discuss an optimization-based planning model which is used to plan the allocation of shipments to each process path, given the set of process path options for those shipments. We will discuss the main objectives of this optimization model, and the factors which led to the decision to use an optimization model to solve this problem.

2 - Prior Day Labor Planning in Amazon Fulfillment Center

Yingqi Zhang, Amazon, Bellevue, WA, United States, Andy Johnson

This paper presents an innovative optimization approach to Prior Day Planning (PDP) in large-scale operations management. While labor planning typically spans multiple weeks, we specifically address the critical 24-hour window before execution, where site operators must finalize staffing decisions to meet committed volume targets. The existing PDP process, traditionally conducted through manual collaboration among department leaders, lacks systematic technological support for optimal decision-making. To address this gap, we introduce a mixed-integer programming (MIP) model that generates optimal labor allocation plans at granular working period and process levels. The model systematically evaluates cross-departmental labor sharing opportunities and staffing requirements, providing data-driven recommendations for resource allocation. Our solution integrates four key operational services into a streamlined planning framework, designed to enhance operational efficiency, optimize workforce utilization, and maintain service quality standards while responding to dynamic market conditions. This automated approach represents a significant advancement from manual planning methods, offering a more robust and systematic solution to daily labor optimization challenges.

3 - Optimizing Order Picking for Amazon Robotics Fulfillment Centers

Ignacio Neira, Amazon.com, Bellevue, WA, United States

Fulfilling orders at the scale and speed that Amazon does is a challenging task that requires optimized processes throughout an order's life cycle. Amazon Robotics (AR) Fulfillment Centers (FC) have proved to be more efficient and ergonomics-friendly than its traditional counterparts, empowered by the robotic technology that enables stationary and continuous picking from inventory pods that are brought to pickers by robotic drives. AR FCs face different challenges than traditional FCs and requires innovative ways to solve for a pick execution plan quickly while accounting for associate safety. Today's pick planning in AR FCs is driven by a heuristic that can quickly create short-term pick execution plans to meet upstream targets; however, its greedy nature has shown to be very limited in leveraging all the data and optimizing for multiple objectives. In this talk, we present a new optimization-based, scalable, and flexible framework for AR pick planning and execution that coherently optimizes for upstream targets adherence, pick productivity and associate safety.

4 - Robust and Interpretable Outbound Resource Plans

AARON HERMAN, Amazon, Seattle, WA, United States

A high quality, interpretable resource plan is a crucial component for a successful shift in Amazon Fulfillment Centers (FCs). A plan is high quality if it meets key objectives such as processing shipments in time and maximizing labor efficiency, while being robust to the uncertainty which is an inherent feature of warehouse operations. It must also be interpretable for managers in warehouses who are responsible for executing the decisions of the plan. In this talk we will describe components of a modeling strategy that meets the goals of being robust and interpretable.

5 - Computer Vision Integrated Warehouse Emulation for Bulk Package Flow

Sumant Joshi, Amazon.com, Bellevue, WA, United States, Chin-Yuan Tseng

Material flow simulation and emulation serve as cornerstone technologies in automated warehouse design, providing environment for digital twin development and control logic validation through production system integration. With recent years rapid growth in computation power and graphic processing algorithms, vision systems that capture real-time images and videos are massively deployed in robotic pick/place and bulk flow control applications. One of the key areas where Material flow simulation and emulation gap exists, is modeling vision systems to estimate volumetric information for bulk flow applications. In most simulation software, the image captured by vision camera cannot be analyzed locally for which simplified sensors are used which may not represent real system behavior. To enhance controls emulation, real-time vision data must be processed by AI/ML algorithms, with resulting insights driving decision-making in PLCs or industrial PCs. This research presents a novel integration framework between Emulate3D and computer vision algorithms, enabling real-time bidirectional communication for vision-based control. Our approach seamlessly transfers actual visual data from warehouse to Emulate3D using advanced image processing. Based on actual image processing, similar package setup is generated in Emulate3D for further emulation based on PLC logic. This integrated approach significantly enhances emulation fidelity and control system reliability as well as providing a platform for computer vision development.

Intelligent Transportation Systems and Cybersecurity

Invited Session

TSL: Intelligent Transportation Systems

Chair: Mohamadhossein Noruzoliaee, University of Texas, Rio Grande Valley, Edinburg, TX, United States

1 - Digital Twin-Based Driver Risk-Aware Intelligent Mobility Analytics for Urban Transportation Management

Zilin Bian, Rochester Institute of Technology, Rochester, NY, United States

Traditional mobility management strategies emphasize macro-level mobility oversight from traffic-sensing infrastructures, often overlooking safety risks that directly affect road users. To address this, we propose a Digital Twin-based Driver Risk-Aware Intelligent Mobility Analytics (DT-DIMA) system. The DT-DIMA system integrates real-time traffic information from pan-tilt-cameras (PTCs), synchronizes this data into a digital twin to accurately replicate the physical world, and predicts network-wide mobility and safety risks in real time. The system's innovation lies in its integration of spatial-temporal modeling, simulation, and online control modules. Tested and evaluated under normal traffic conditions and incidental situations (e.g., unexpected accidents, pre-planned work zones) in a simulated testbed in Brooklyn, New York, DT-DIMA demonstrated mean absolute percentage errors (MAPEs) ranging from 8.40% to 15.11% in estimating network-level traffic volume and MAPEs from 0.85% to 12.97% in network-level safety risk prediction. In addition, the highly accurate safety risk prediction enables PTCs to preemptively monitor road segments

with high driving risks before incidents take place. Such proactive PTC surveillance creates around a 5-minute lead time in capturing traffic incidents. The DT-DIMA system enables transportation managers to understand mobility not only in terms of traffic patterns but also driver-experienced safety risks, allowing for proactive resource allocation in response to various traffic situations. To the authors' best knowledge, DT-DIMA is the first urban mobility management system that considers both mobility and safety risks based on digital twin architecture.

2 - Certifiable Hybrid Cyber Attack and Defense on Learning-Based Traffic Signal Control

Mohamadhossein Noruzoliaee, University of Texas Rio Grande Valley, Edinburg, TX, United States, Mark Hernandez, Fatemeh Nazari

Learning-based control methods, such as deep reinforcement learning (DRL), have gained traction in intelligent transportation systems (ITS) control due to their computational efficiency in dealing with the scale and dynamics of ITS. Despite growing popularity, DRL has been recently found to be vulnerable to cyber-attacks, rendering its deployment challenging in safety-critical ITS unless its adversarial vulnerabilities are mitigated. This research aims to robustify DRL-based traffic signal control (i.e., victim) against "hybrid" cyber-attacks on both the input state observations (e.g., traffic queue length at an intersection) and output actions (e.g., traffic signal phase selection) of the victim.

3 - Distributed Versus Centralized Optimization Frameworks for Maximum-Stability Dispatch of Shared Autonomous Electric Vehicles

Jake Robbennolt, University of Texas at Austin, Austin, TX, United States, Stephen Boyles, Javad Mohammadi

As shared autonomous electric vehicle (SAEV) fleets scale, centralized dispatch strategies face increasing computational burdens and communication bottlenecks. This is particularly problematic when optimal dispatch strategies incorporate time-varying factors including passenger demand patterns, vehicle battery states, electricity pricing fluctuations, and charging station availability which necessitate model predictive control frameworks to ensure future conditions are accounted for. With these concerns in mind, this research investigates the fundamental trade-offs between centralized and distributed optimization approaches for SAEV fleet management while maintaining maximum-stability guarantees—ensuring passenger queues remain bounded for any feasible demand pattern. We propose a distributed consensus+innovations method where individual vehicles and charging stations operate as computational agents in a multi-agent network, collaboratively solving the dispatch optimization problem without requiring a central controller. The proposed method maintains theoretical maximum-stability guarantees—ensuring passenger queues remain bounded for any feasible demand pattern—while distributing computational load across the network. Through rigorous mathematical analysis, we establish connections between communication burden, network topology, and system-level performance, identifying conditions where distributed approaches outperform centralized alternatives. Simulation experiments demonstrate that our distributed approach scales better with fleet size while maintaining or improving performance metrics compared to centralized dispatch policies.

4 - From Openlka to Lkalert: An End-to-End Pipeline for Real-World Lane-Keeping Safety

Yuhang Wang, Univeristy of South Florida, Tampa, FL, United States, Hao Zhou, Abdulaziz Alhuraish

Lane-Keeping Assist (LKA) is now standard on most market vehicles and has measurably reduced lane-departure crashes, yet production systems still disengage without warning in adverse conditions, forcing instantaneous driver take-overs and leaving researchers without holistic evidence of failure modes. We address these gaps with an end-to-end pipeline that unites open data, failure analytics, and proactive warning system. The OpenLKA dataset, released by us, is the first public corpus devoted to LKA evaluation, offering 400 h of time-aligned CAN telemetry, front-view video, perception outputs, and vision-language annotations from 62 vehicle models across varied weather, illumination, and geometry. Using this resource, we deliver the first comprehensive field study of LKA behaviour, catalogue high-risk scenarios, and verify their impact via statistic analysis; the derived features power a supervised model that assigns an infrastructure safety index to road segments, highlighting maintenance priorities. To restore reaction time for drivers, we curate OpenLKA-Alert, a 55 k-frame expert-labelled subset of imminent disengagements, and develop LKAAlert, a multimodal early-warning system built on Qwen2.5-VL-7B with surrogate-feature guidance and LoRA fine-tuning. LKAAlert forecasts LKA failures 1-3 s ahead with 69.8 % accuracy, operates at real-time 2 Hz on embedded hardware, and produces natural-language rationales scoring 71.7 ROUGE-L, demonstrating strong predictive power and interpretability in tandem. Collectively, OpenLKA, its analytical toolbox, and LKAAlert constitute the first integrated benchmark, diagnostic framework, and mitigation suite for real-world lane-keeping safety.

5 - Usage-Based Insurance in the Era of Connected Vehicles: Competition and Data Differentiation

Sen Yan, New York University, New York City, NY, United States, Daniel Vignon

Traditional auto insurance models have long relied on socio-demographic proxies to assess risk, a method that inadequately captures the true determinants of accident risk-driving behavior. With telematics technology, insurers can capture real-time driving data to offer usage-based insurance (UBI). In addition, direct access to extensive vehicle and driving behavior data incentivizes automakers to enter the market. Since the latter potentially possess better information on drivers than insurers, one rightfully wonders about (a) the extent to which this difference in consumer data affects the market and (b) policies to remediate potential distortions in this context. To answer these questions, we model competition between insurers whose costs of collecting consumer behavior data differ. We explore how this difference affects not only the equilibrium distribution of customers across firms, but also the overall welfare. We find that, though monitoring itself is welfare improving in the case of a monopoly, it may reduce welfare in the case of a duopoly. While requiring data-sharing might be welfare improving, it is only so when (a) investment in data collection technology is low or (b) when sharing is priced. These findings provide key insights into the welfare benefits of UBI, the competitive dynamics between traditional insurers and automakers, and policy implications regarding data sharing in the connected vehicle era.

1 - Endogenous Entry in Networked Markets with Production and Edge Capacity Constraints

Cheng Guo, Clemson University, Clemson, SC, United States, Ozan Candogan, Jiayi Wang

Motivated by electricity markets, we investigate the key drivers of firm entry and investment in multi-regional markets with elastic demand, incorporating capacity constraints for both firms and transportation. These constraints introduce externalities due to the coupling of decisions across firms and regions. To address such complication, we develop a novel convex optimization model for networked Cournot competition, which is substantially more tractable than the commonly-used mixed complementarity problem formulations. This model enables us to prove the uniqueness of the equilibrium, analyze how factors such as entry locations and tariffs shape investment decisions, and carry out a case study on a realistic electricity markets dataset. We find that a well-chosen firm entry location not only benefits the firm's own profit, but may also bring positive externalities for incumbent firms and consumers. Additionally, we show that import tariffs may, counterintuitively, encourage the expansion of more efficient foreign firms. Our results offer both novel analytical frameworks and scalable computational tools for practitioners, guiding efficient investment of capacity and infrastructure in networked markets.

2 - Optimal Mechanisms for Demand Response: An Indifference Set Approach

mohammad mehrabi, Stanford GSB, Stanford, CA, United States, Omer Karaduman, Stefan Wager

The time at which renewable (e.g., solar or wind) energy resources produce electricity cannot generally be controlled. In many settings, consumers have some flexibility in their energy consumption needs, and there is growing interest in demand-response programs that leverage this flexibility to shift energy consumption to better match renewable production—thus enabling more efficient utilization of these resources.

We study optimal demand response in a model where consumers operate home energy management systems (HEMS) that can compute the “indifference set” of energy-consumption profiles meeting pre-specified consumer objectives, receive demand-response signals from the grid, and control consumer devices within the indifference set.

For example, if a consumer asks for the indoor temperature to remain between certain upper and lower bounds, a HEMS could time the use of air conditioning or heating to align with high renewable production when possible.

Here, we show that while price-based mechanisms do not generally achieve optimal demand response—i.e., dynamic pricing cannot induce HEMS to choose optimal demand-consumption profiles within the available indifference sets—pricing is asymptotically optimal in a mean-field limit with a growing number of consumers. Furthermore, we show that large-sample optimal prices can be efficiently derived via an algorithm that only requires querying HEMS about their planned consumption schedules under different prices. Finally, we study learning the optimal price passively (when frequent queries to HEMS are not possible) as an online learning problem over a series of days, using only the day's forecasts—i.e., weather, temperature, and weekday conditions—as context, and by observing only consumer consumption profiles.

3 - Mallows Model with Learned Distance Metrics: Sampling and Maximum Likelihood Estimation

Yeganeh Alimohammadi, USC, Los Angeles, CA, United States

The Mallows model is a widely-used probabilistic framework for learning from ranking data, with applications ranging from recommendation systems and voting to aligning language models with human preferences [1]. Under this model, observed rankings are noisy perturbations of a central ranking σ , with likelihood decaying exponentially in distance from σ , i.e., $P(\pi) \propto \exp(-\beta \cdot d(\pi, \sigma))$, where $\beta > 0$ controls dispersion and d is a distance function.

Existing methods mainly focus on fixed distances (such as Kendall's τ distance), with no principled approach to learning the distance metric directly from data. In practice, however, rankings naturally vary by context; for instance, in some sports we regularly see long-range swaps (a low-rank team beating a high-rank one), while in others such events are rare.

Motivated by this, we propose a generalization of Mallows model that learns the distance metric directly from data. Specifically, we focus on L_α distances: $d_\alpha(\pi, \sigma) = \sum_{i=1}^n |\pi(i) - \sigma(i)|^\alpha$.

For any $\alpha \geq 1$ and $\beta > 0$, we develop a Fully Polynomial-Time Approximation Scheme (FPTAS) to efficiently generate samples that are ϵ -close (in total variation distance) to the true distribution. Even in the special cases of L_1 and L_2 , this generalizes prior results that required vanishing dispersion ($\beta \rightarrow 0$).

Using this sampling algorithm, we propose an efficient Maximum Likelihood Estimation (MLE) algorithm that jointly estimates the central ranking, the dispersion parameter, and the optimal distance metric. We prove strong consistency results for our estimators, and we validate our approach empirically using datasets from sports rankings.

4 - Effectiveness of Interventions in Epidemic Spread

Karissa Huang, University of California, Berkeley, Berkeley, CA, United States

As the world grows increasingly connected, infectious disease transmission and outbreaks become a pressing global concern for public health officials and policymakers. While policy interventions to contain and prevent the spread of disease have been proposed and implemented, there has been little rigorous quantitative analysis of the effectiveness of such interventions. In this talk, we discuss the susceptible-infected-recovered (SIR) infection process on a dynamic network model that models two communities with travel between them. In particular, we consider two Erdos-Renyi graphs where edges are dynamically changing in each graph based on node travel between the graphs. We characterize the time evolution of the outbreaks in both communities and pin down the time for when the infection first reaches the second community. Finally, we analyze two interventions—social distancing and travel bans—and show that while social distancing is effective at reducing the burden of the disease in the second community, travel bans are not.

1 - Data-Driven Dynamic Modeling of Chaotic Systems Using Local Maximum Entropy Expansion

Nazia Raza, Lehigh University, Bethlehem, PA, United States, Farrah Moazeni

Learning the dynamics of real-world systems without prior knowledge remains a fundamental challenge across engineering disciplines. Traditional identification techniques often rely on strong assumptions or detailed physical models, limiting their applicability in chaotic, complex, or partially observed environments. Meanwhile, the rise of sensor networks and IoT infrastructure has led to abundant high-resolution time-series data, much of which remains underutilized. This work introduces a novel data-driven framework for chaotic system identification based on Local Maximum Entropy (LMaxEnt) modeling, which requires no structural assumptions and integrates principles from information theory and polynomial interpolation. The method learns time-resolved system derivatives using locally weighted basis functions, forming a flexible nonparametric surrogate model. To control locality and smoothness, we incorporate three prior kernels (Gaussian, Laplacian, and Cauchy) and introduce a tunable locality parameter that governs each basis node's influence, enabling accurate approximation of both smooth and stiff dynamics. We validate the proposed framework on the classical quadruple tank process (QTPS) and a modified QTPS with additional coupling, against the chaotic Lorenz system as a benchmark. Across all studied systems, LMaxEnt demonstrates high-fidelity reconstruction of system trajectories and derivatives. The approach is experimentally validated using real-time data from a lab-scale QTPS and a water distribution network testbed, highlighting its robustness to noise and practical deployment. This study presents a generalizable, interpretable, and assumption-free pathway for modeling complex, chaotic dynamical systems, with promising applications in control, monitoring, and digital twin development for cyber-physical systems.

2 - Towards a Generalized Network Optimization Model for Community Resilience Decision Support

Kenneth Harrison, National Institute of Standards and Technology (NIST), Gaithersburg, MD, United States, Tasnim Faiz, William Hughes

Natural disasters, like floods, tornadoes, earthquakes, and wildfires, wreak havoc on a community's interdependent physical, social, and economic systems, or networks. These natural hazards present loadings (e.g., winds, inundation, ground acceleration) that cause network components to fail, in turn triggering outages impairing the social functions of the community (e.g., housing, businesses, and healthcare); importantly, a protracted period of recovery typically follows. NIST has developed several network optimization models to support community resilience decision-making. Recent advances include modeling the voluntary uptake of mitigation actions (e.g., new building retrofits) under incentive programs, addressing the extended implementation period of mitigation decisions, modeling access to healthcare services, and giving decision-makers tools for addressing risk. This talk describes work towards a generalization of the model for application to multiple communities confronting a range of hazards. Various complicating issues are addressed, including network component failure modeling differences across hazards, aligning with the community's other planning objectives, and satisfying multiple stakeholders. Case studies of communities facing various hazards demonstrate this work towards a common decision support framework for community resilience planning.

3 - Restoring Complex Flow Networks Using Deep Reinforcement Learning

Amir Shahlaee, Department of Civil Engineering, University of Texas at Arlington, Arlington, TX, United States, Xudong Fan, Wang Yu, Jin-Zhu Yu, Jianxi Gao

Ensuring the rapid and efficient recovery of large-scale complex flow networks following disruptions is critical to the resilience of those networks. While optimization models such as Mixed Integer Programming (MIP) offer accurate solutions, their computational intractability on large-scale, flow-constrained networks hinders practical application. This paper presents a Deep Reinforcement Learning (DRL) framework, guided by MIP during training, to learn optimal restoration sequences for damaged infrastructure. Our proposed MIP-guided Deep Q-Network (DQN) agent, equipped with a prioritized replay buffer, achieves fast and robust performance. The agent is trained on 60 small synthetic networks and evaluated on larger ones, demonstrating superior performance over traditional optimization approaches in both efficiency and solution quality. This work contributes a scalable, DRL-based methodology for enhancing the resilience of infrastructure systems subject to complex physical constraints such as flow conservation and traffic assignment.

Advances in Learning-Enhanced Combinatorial Optimization for Operations

Invited Session

Transportation Science and Logistics (TSL)

Chair: Yu Yang, University of Florida, 401C, Weil Hall, Gainesville, FL, 32611-0001, United States

Co-Chair: Ricky You, The University of Florida, Bellevue, WA, United States

1 - Two-Stage Learning to Branch in Branch-Price-and-Cut Algorithms for Solving Vehicle Routing Problems Exactly

Yu Yang, University of Florida, Gainesville, FL, United States

Branching is one of the most important components in branch-price-and-cut (BPC) algorithms for solving vehicle routing problems (VRPs) exactly. However, learning to branch is much more challenging in BPC than in branch-and-cut algorithms that are used for solving general mixed integer programs. To address such challenges, we propose the first effective learning-to-branch framework in BPC algorithms, leading to a novel two-stage learning-based branching (2LBB) strategy. Moreover, we propose a novel theoretical model characterizing the fundamental trade-off between time spent making a single branching decision and the resulting branching quality. Through an extensive numerical study, we demonstrate that a dynamic version of the 2LBB, denoted by 2LBB-dy, achieves approximately 45% and 50% time reduction, respectively, compared to the state-of-the-art (SOTA) hand-crafted branching strategy in solving the capacitated vehicle routing problem (CVRP) and vehicle routing problem with time windows (VRPTW). In addition, our RouteOpt (an exact VRP solver available at <https://github.com/Zhengzhong-You/RouteOpt>), when equipped with the 2LBB-dy, achieves a 47% time reduction compared to the SOTA VRPSolver from Pessoa et al. (2020) for the CVRP.

2 - Accelerating Column Generation for Vehicle Routing Problems Using Graph Neural Network-Predicted Dual-Optimal Inequalities

Ricky You, University of Florida, Gainesville, FL, United States, Bo Tang, Yu Yang

Column generation (CG) is widely used for solving combinatorial optimization problems due to strong dual bounds provided, but it often suffers from slow convergence caused by fluctuations in dual variables, especially early in the solution process. To stabilize CG, previous works introduced dual-optimal inequalities (DOIs) for structured problems like vector packing. However, vehicle routing problems (VRPs) lack the explicit structure required for deriving these inequalities analytically. We propose using graph neural networks (GNNs) to predict potential DOIs for customer pairs, effectively generating learned dual constraints. A graph-based reduction method further simplifies these constraints, preserving same dual feasible region while substantially reducing the formulation size. Computational experiments on standard VRP benchmarks demonstrate significant speedups; notably, our method reduces root-node computation time for a large-scale VRP instance (X-n1001-k43) from hours to minutes.

3 - Optimizing on-Demand Flexible Transit Services via Graph-Attention Multi-Agent Proximal Policy Optimization

Wen Zhang, The State University of New York at Buffalo, Buffalo, NY, United States, Jee Eun Kang

This study proposes a data-driven, real-time optimization framework for on-demand flexible transit services by integrating Graph Attention Networks (GAT) with Multi-Agent Proximal Policy Optimization (MAPPO). In contrast to traditional Vehicle Routing Problem with Pickup and Delivery (VRPPD) and Dial-A-Ride Problem (DARP) models, which assume static and pre-scheduled trips, our method models each vehicle as an autonomous agent operating within a Semi-Markov Decision Process. Tasks are dynamically allocated based on real-time system states and historical travel demand patterns. Vehicle states along with inter-vehicle dependencies are encoded via a shared graph-based critic, while decentralized agents select actions individually from a shared actor policy based on their local observations. The framework is trained end-to-end using Automated Fare Collection (AFC) data from Seoul with the explicit objective of minimizing fleet-wide total travel time and demonstrates significant improvements in operational efficiency. The proposed approach offers a scalable, adaptive solution for real-time transit operations.

4 - Deep-Learning Aided Crowdsourcing Network Design with External Delivery Vehicles

Baris Yildiz, Koc University, Istanbul, Turkey, Ramazan Cevik, Ali Sardag

Crowdsourcing has gained traction for its economic and environmental benefits, offering cost-effective deliveries while reducing traffic and emissions. However, the sporadic arrival of crowdsourcers limits reliability, especially on routes with heavy package flows. To address this, we propose a hybrid delivery model that integrates crowdsourcing with dedicated delivery vehicles along selected routes to improve system efficiency. Our goal is to identify which segments of the delivery network should be supported by external vehicles, determine the optimal number of vehicles, and design their routes. We formulate the problem on a time-extended network and solve it in two stages. In the first stage, we develop a Dynamic Programming (DP) algorithm that determines the optimal routing and compensation for crowdsourcers, given the locations of the supported routes. This problem is modeled as a Markov Decision Process (MDP), which we solve efficiently by leveraging the acyclic structure of the network. In the second stage, we generate multiple random network configurations and solve the MDP for each, creating a dataset of total crowdsourcing costs. A Feedforward Neural Network (FNN) is then trained to predict these costs based on network characteristics. This FNN is embedded into a Mixed Integer Programming (MIP) model to jointly optimize route selection and vehicle planning. We demonstrate that the FNN achieves competitive performance in cost prediction. Under mild conditions, it can be incorporated into a Mixed Integer Quadratic Programming (MIQP) model through appropriate transformations without compromising model performance.

5 - Regularized Langevin Dynamics for Combinatorial Optimization

Shengyu Feng, Carnegie Mellon University, Pittsburgh, PA, United States

This work proposes a simple yet effective sampling framework for CO. Our method builds on discrete Langevin dynamics (LD), an efficient gradient-guided sampling algorithm. However, we observed that directly applying discrete LD often leads to limited exploration. To overcome this limitation, we propose the *Regularized Langevin Dynamics (RLD)*, which enforces an expected distance between the sampled and current solutions, effectively avoiding local minima. We develop two CO solvers on top of RLD, one based on simulated annealing (SA) and the other one based on neural network (NN). Empirical results on three classical CO problems demonstrate that both of our methods can achieve comparable or better performance against the previous state-of-the-art (SOTA) SA and NN-based solvers. Our SA algorithm reduces the running time of the previous SOTA SA method by up to 80%, while achieving equal or superior performance. And our NN solvers achieve a comparable performance to the previous SOTA NN methods with only 5% training time due to its lightweight training objective. The extension of RLD also demonstrates its applicability to more general CO problems such as mixed integer programs or the ones with global constraints. In summary, RLD offers a promising framework for enhancing both traditional heuristics and NN models to solve CO problems.

Frontiers in Data-Driven Resource Allocation and Inventory Management

Invited Session

Applied Probability Society

Chair: Sean Sinclair, Northwestern University, Evanston, IL, United States

1 - Sample Complexity of Policy Learning for Inventory Control with Censored Demand

Xiaoyu Fan, Stern School of Business, New York University, New York, NY, United States, Boxiao Chen, Zhengyuan Zhou

Traditional offline-learning in inventory control assumes access to uncensored demand samples, which are often not available, as the firm can only access sales data (i.e. censored demand data). In this paper, we study the classic newsvendor problem in an offline learning setting with censored demand. We design an offline algorithm that achieves the optimal sample complexity under both iid data and adaptive data. We also extend our results to the infinite-horizon setting.

2 - Online Learning for Lost-Sale Inventory Systems with Product Returns

Qi Luo, University of Iowa, Iowa City, IA, United States, Boxiao Chen, Stefanus Jasin, Mengxiao Zhang

Product returns pose a significant challenge to supply chain sustainability and efficiency, as evidenced by \$744 billion worth of returned merchandise in 2024. To address this, we propose an online learning algorithm for single-item inventory control that adapts to demand censoring and unknown return rates over a horizon of T periods. The algorithm sequentially updates the base-stock policy, achieving asymptotic optimality with a worst-case regret bound of $O(T^{0.5})$. Our approach addresses the technical challenges and practical importance of incorporating return behavior into learning-based inventory control policies.

3 - Online Allocation of Throughput-Constrained Resources Using Proxy Assignments

Chamsi Hssaine, University of Southern California, Marshall School of Business, Los Angeles, CA, United States, Kamessi Zhao, Daniel Freund

Effective load balancing is at the heart of many applications in operations. Frequently tackled via the balls-into-bins paradigm, seminal results established the power of two choices in load balancing: a limited amount of costly flexibility goes a long way to maintain approximately balanced loads throughout the decision-making horizon. This paper is motivated by the fact that balance across time is too stringent a requirement for some applications; rather, the only desideratum is approximate balance at the end of the horizon. Thus motivated, in this work we design "delayed-flexibility" algorithms for such settings. For the canonical balls-into-bins problem, we show that a simple policy that begins exerting flexibility toward the end of the time horizon (i.e., when $\Theta(\sqrt{T \log T})$ periods remain), suffices to achieve an approximately balanced load (i.e., a maximum load within $O(1)$ of the average load). Moreover, with just a small amount of adaptivity, a threshold policy achieves the same result, while only exerting flexibility in $O(\sqrt{T})$ periods, thus matching a natural lower bound. We leverage these results to study the design of opaque selling strategies in retail settings, which have recently been found to be a prime application of the power of two choices in balls-into-bins. For this problem, we prove that late-stage opaque selling strategies achieve the optimal trade-off between exerting costly flexibility (i.e., the revenue loss from offering the opaque product at a discount) and achieving strong inventory cost savings due to load balancing. We demonstrate the robustness of our insights via extensive numerical experiments.

4 - Managing Inventory Systems with Stochastic Lead Times and Impatient Customers

Jinzhi Bu, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Guangyu Li

In today's global supply chain, lead time uncertainty presents significant challenges for online retailers, especially in managing inventories while facing impatient customers. We address this by studying a periodic-review inventory system with stochastic lead times and partial backorders in an online retail environment. The optimal policy for this system is in general very complex. We propose simple heuristic replenishment policies and analyze their performances. In the full distributional-information setting, we establish the asymptotic optimality of these policies with large unit shortage penalty costs. In the data-driven setting, we develop online learning algorithms that achieve tight regret bounds.

5 - Retail on Wheels: A Time-Sensitive Travelling Salesman Problem

Zhuolun Dong, University of Texas at Austin, Austin, TX, United States

Rapid advancement in self-driving technology has brought mobile retail into the spotlight. Motivated by its tremendous potential, we present a model, theory, and insights into the operations of the business model, where a fleet of wheeled stores traverses a service region, selectively seeks locations in which to perch, and fulfills local customer demand. The goal of retailers is to balance between perching and migrating to maximize total revenue. To dispatch such stores, retailers need to consider the following time-sensitive factors: (i) How busy the service is, (ii) how soon customers come to the store, and (iii) how fast the product decays. We propose and analyze a model that incorporates these factors into the classical traveling salesman problem (TSP), which we call the "time-sensitive TSP" (TSTSP). Using the continuous approximation approach, we derive the optimal revenue as well as the upper and lower bounds in the asymptotic regime as candidate locations increase to infinity. The tightness of the bounds is validated. Our analytical and numerical analysis demonstrates that store mobility creates value by bringing proximity to customers and by taking advantage of flexible repositioning to reach high-profit areas. We further uncover the effects of these time-sensitive features on decision-making. Specifically, the scaling relationship between revenue and fleet size is affected by customer tardiness and busyness. Busyness determines stores' ability to expand their service, whereas tardiness affects how effectively stores can utilize the initial high-freshness period. Our findings demonstrate the potential of mobile retail to emerge as a new competitive retail form.

Analytics for the Great Good

Invited Session

Minority Issues Forum

Chair: M Gabriela Sava, Bowling Green State University, Bowling Green, OH, United States

1 - Continuity of Hospital Care and Patient Outcomes: Evidence from Cabg Cases

Dawson Maddox, University of Tennessee, Knoxville, TN, United States, Bogdan Bichescu, Haileab Hilafu

We examine the relationship between continuity of hospital care (CoHC) and outcomes for patients undergoing coronary artery bypass grafting (CABG). Using linked inpatient and outpatient data, we define CoHC as receiving care from the same hospital across both settings. We find that greater CoHC is associated with shorter lengths of stay and lower readmission risk, though it has no significant effect on total charges. These relationships are moderated by physician utilization intensity and procedural focus.

2 - Bias in Predictive Models that use Electronic Health Record (EHR) Data

M Gabriela Sava, Bowling Green State University, Bowling Green, OH, United States, Azeez Kunle Akinbode, Jerrold May, Ronald Pirrallo

Methods for predictive modeling typically assume that all patient records are complete. However, EHR records may be incomplete, especially for groups of patients, such as for minorities and for those in lower socioeconomic groups who have only sporadic interaction with the healthcare system. We investigate, in the context of preventive screening, the impact of incomplete information on modeling, and the biases that might be introduced by predictive models created from, or applied to, incomplete patient records. From a clinical perspective, our research is of interest, because some best practice alerts need to be triggered even when only partial patient information is available.

3 - Identifying Illicit Drug Trafficking Patterns Using Geographical Weighted Regression: a Case Study with Colombian Cocaine Data

Eunseong Jang, University of Maryland, College Park, MD, United States, Margret Bjarnadottir, Marcus Boyd, Galia Benítez

Despite extensive efforts to curb cocaine trafficking, global cocaine production has increased for over a decade. Cocaine seizures have risen in tandem with production, but this has not translated into a reduction in cocaine consumption over the same period. This underscores the need for more effective strategies to enhance cocaine seizure

operations. Efficiently disrupting cocaine supply chains would begin with accurate predictions of trafficking routes. In this study, we aim to identify previously unrecognized trafficking nodes—both sources and destinations—by analyzing Colombian cocaine data. By examining the relationship between these observations and trafficking nodes inferred from anecdotal data, we seek to uncover unknown trafficking routes by narrowing the set of probable sources and destinations. Since trafficking nodes can be represented as a binary variable, we employ logistic regression to identify key factors that influence the likelihood of a location serving as a source or destination. However, applying a single regression model across all Colombian municipalities may be overly simplistic, as the cocaine trade is not controlled by a single entity. Consequently, certain factors may be associated with trafficking routes only in specific regions rather than nationwide. To address this issue, we employ a localized spatial analysis method—local geographically weighted regression (GWR), which only includes neighboring data when fitting the regression model of a focal point. Our results show geographical dynamic influence of factors associated with the trafficking nodes while overcoming limitations in the conventional GWR framework, which provide better understanding of clandestine cocaine network in Colombia.

4 - Optimizing Treatment Strategies for Small Renal Masses Using a Markov Decision Process Framework

Wendy Qi, University of Virginia, Charlottesville, VA, United States

Small renal masses (SRMs) are increasingly diagnosed due to widespread imaging, yet no consensus exists on optimal treatment strategies that balance cancer control and long-term renal function preservation. Clinical decisions are often made under uncertainty due to limited long-term data and variability in disease progression. Decision-making is further complicated by patient heterogeneity, tumor characteristics, and the evolving nature of tumor growth and kidney function decline.

To address these challenges, we develop a finite-horizon Markov Decision Process (MDP) model to simulate patient health trajectories and evaluate treatment strategies. The model incorporates key clinical factors, including tumor progression, chronic kidney disease (CKD) stages, recurrence, metastasis, and competing mortality risks. It evaluates treatment actions - active surveillance, ablation, partial nephrectomy, radical nephrectomy, and secondary treatment - based on their long-term effects on renal function, cancer control, and cause-specific mortality.

Using the PRISM model checker, we perform probabilistic model checking to compute optimal treatment policies based on expected cumulative rewards, reflecting quality-adjusted life years (QALYs) tied to each health state and action. The model supports patient-specific simulations from ages 65 to 85, allowing us to identify the timing and type of intervention that maximize clinical outcomes.

Our findings show that optimal strategies vary by patient characteristics, including age, sex, CKD stage, and tumor size. The proposed modeling framework supports personalized planning by allowing the objective function to be adapted to patient preferences or clinician priorities. This enables tailored recommendations that enhance shared decision-making between patients and providers and support improved long-term outcomes in SRM management.

5 - Predicting Substance use Risk in Youth: Associations Between Mental Health and Environment in ABCD Data

Viviana Milla Angeles, University of Virginia, crozet, VA, United States, Daniel Otero Leon

Early substance use is associated with long-term negative health and behavioral outcomes. This project examines how mental health conditions and environmental influences relate to early substance use among adolescents, where alcohol, nicotine, and cannabis are among the most used substances in this age group.

We use the comprehensive Adolescent Brain Cognitive Development (ABCD) dataset, which offers a robust, longitudinal dataset tracking biological, psychological, and social development in youth across the United States.

We propose a two-stage stacking prediction model that incorporates five years of longitudinal data that includes demographic variables, social context (including family dynamics, peer interactions, and socioeconomic indicators), and diagnosed mental health disorders to uncover patterns and estimate the likelihood of substance use initiation. For the base level, we employ a non-linear model which allows us to capture complex, non-linear relationships in the data. At the second level, a logistic regression meta-model, which assumes linearity and serves as a robust aggregator. Using a non-linear base model helps uncover intricate patterns, while the logistic regression meta-model reduces the risk of overfitting, especially when trained on out-of-fold predictions from the base models. This architecture enables the final output, probability estimates, to combine the strengths of diverse predictive models.

The goal of our project is to support early identification by recognizing which children are most at risk of initiating substance use. Our findings aim to inform public health strategies and clinical decision-making focused on youth mental health and substance use prevention.

6 - Polysubstance Overdose Deaths Involving Fentanyl

Hyojung Kang, University of Illinois at Urbana Champaign, Champaign, IL, United States, Moe Toyoda, Aaliyah Ali, Stanley Ratemo, Bryan Miller

Fentanyl continues to drive a significant portion of overdose mortality in the United States, often in combination with other substances. Employing toxicology records from medical examiner data in Illinois from 2016 to 2024, this study aims to identify frequently co-used substances with fentanyl and examine how these combinations vary over time, across demographic groups and by geographic regions. Using association rule analysis, we systematically explore the prevalence, correlations, and conditional probabilities of frequently co-used substances. The findings provide a comprehensive understanding of polysubstance use behaviors surrounding fentanyl-related overdoses and demonstrate the value of data mining techniques in public health surveillance. Also, results can inform targeted harm reduction strategies and guide resource allocation to address the evolving dynamics of the overdose crisis.

Building A Level 4 A410

Applications of Statistical Reinforcement Learning

Invited Session

Applied Probability Society

Chair: Kelly Zhang, Imperial College London, London, N/A

1 - Statistical Inference for Misspecified Contextual Bandits

Yongyi Guo, University of Wisconsin Madison, Madison, WI, United States

We study statistical inference following adaptive experiments in contextual bandit settings—a framework widely used in practice. Real-world environments often involve model misspecification, which can undermine both decision quality and the validity of post-hoc inference.

We develop valid inference procedures for data collected by adaptive algorithms, without assuming a correctly specified reward model. We characterize general conditions under which inference remains valid and highlight *policy convergence* as a key requirement. This condition is broad and holds for many online algorithms, but is notably violated by standard contextual bandit methods such as LinUCB and Thompson Sampling when they rely on a misspecified model.

Our results offer new insights into the interplay between model misspecification and statistical inference in adaptive decision-making, addressing common challenges posed by structural mismatch and limited data.

2 - Reinforcement Learning for Real-World Inventory Management

Omer Gottesman, Amazon, New York, NY, United States

Managing inventory across a large, dynamic supply chain presents a wide array of interdependent challenges. At Amazon, we develop reinforcement learning methods to help make better decisions for problems such as how much inventory to buy and where to place it across our network of fulfillment centers. Our systems must navigate complex trade-offs under uncertainty, including variable vendor lead times, capacity constraints, correlated customer demand, and the risk of lost sales. In this talk, we will highlight how reinforcement learning can enable us to address these challenges in a unified framework. We will share practical lessons from developing realistic simulators from historical data and discuss how we evaluate and deploy policies in high-stakes, real-world environments.

3 - Dynamic Contextual Pricing with Doubly Non-Parametric Random Utility Models

Jiayu Li, New York University, New York, NY, United States

In the evolving landscape of digital commerce, adaptive dynamic pricing strategies are essential for gaining a competitive edge. This paper introduces novel doubly nonparametric random utility models that eschew traditional parametric assumptions used in estimating consumer demand's mean utility function and noise distribution. Existing nonparametric methods like multi-scale Distributional Nearest Neighbors (DNN and TDNN), initially designed for offline regression, face challenges in dynamic online pricing due to design limitations, such as the indirect observability of utility-related variables and the absence of uniform convergence guarantees. We address these challenges with new population equations that facilitate nonparametric estimation within decision-making frameworks and establish the first analytical results on the uniform convergence rates of DNN and TDNN, enhancing their applicability in dynamic environments.

Our theoretical analysis confirms that the statistical learning rates for the mean utility function and noise distribution are minimax optimal. We also derive a regret bound that illustrates the critical interaction between model dimensionality and noise distribution smoothness, deepening our understanding of dynamic pricing under varied market conditions. These contributions offer substantial theoretical insights and practical tools for implementing effective, data-driven pricing strategies, advancing the theoretical framework of pricing models and providing robust methodologies for navigating the complexities of modern markets.

4 - Contextual Bandits for Enhancing User Engagement in the Drink Less App

Xueqing Liu, Harvard University, Boston, MA, United States

Mobile health (mHealth) interventions often seek to improve long-term outcomes by delivering timely, personalized support that optimizes short-term engagement. Contextual bandits provide a promising framework for such just-in-time adaptive interventions, yet their use in mHealth has been limited by challenges in modeling count-based outcomes. This study introduces methods that integrate count data models (Poisson, negative binomial, zero-inflated Poisson, and zero-inflated negative binomial regressions) with Thompson sampling to address this gap. Using data from the Drink Less trial, we demonstrate that these approaches can improve user engagement with the app. Results from simulated datasets further confirm performance gains, showing higher cumulative proximal outcomes compared to existing algorithms. We also provide theoretical results on regret bounds to support the robustness of the proposed methods.

5 - Jitai-Twins: a Digital Twin Framework for Reinforcement Learning Algorithms and Just-in-TIME Adaptive Interventions

Susobhan Ghosh, Harvard University, Cambridge, MA, United States, Asim Gazi

Recent work on just-in-time adaptive interventions (JITAI) -- nascent precision medicine systems that deliver just-in-time healthcare support during daily life that adapts to the changing state of an individual -- have leveraged reinforcement learning (RL) algorithms to optimize support. A challenge in designing JITAI that leverage RL algorithms is that RL algorithm design can require numerous non-trivial decisions that must be made before deploying a JITAI in the real world (e.g., hyperparameter selection). Additionally, each deployment can be costly, precluding the use of A/B testing for every design decision. How should design decisions be made strategically before (and between successive) JITAI deployments? In this talk, we will discuss our proposed framework, digital twins for just-in-time adaptive interventions (JITAI-Twins), to address this question. JITAI-Twins are "digital twins of a subpopulation" that are used to virtually simulate the potential outcomes of a JITAI's design decisions for an upcoming deployment. Based on simulation results, design decisions are made for the deployed JITAI. To continually improve the JITAI, data collected during deployment is used to update the JITAI-Twin -- and this bidirectional feedback between deployments and simulation environments continues. JITAI-Twins are thus fit-for-purpose instantiations of the digital twin concept. Importantly, JITAI-Twins highlight continuity over the course of a JITAI's optimization and continual improvement, emphasizing the need for bidirectional feedback between versions of a simulation environment and a JITAI's real-world deployments.

Reliable and Resilient Facility Logistics

Invited Session

TSL: Facility Logistics

Chair: Ritesh Ojha, Amazon, Redmond, WA, 98052, United States

1 - Deep Reinforcement Learning for Joint Location-Inventory Problems with Unknown Demand in Mobile Retail

Jiayin He, Tsinghua University, Beijing, China, People's Republic of, Wei Qi

The retail sector is rapidly transforming, with autonomous mobile stores (MFs) emerging as a novel format combining mobility's convenience with physical retail's engagement, particularly potent in addressing service equity issues like food deserts. However, effectively managing a fleet of MFs presents significant challenges, primarily the need to make high-frequency, dynamic joint location-inventory decisions under uncertain spatiotemporal demand. Traditional methods often struggle with the scale, dynamism, and rich features inherent in this problem. This research addresses the joint location-inventory problem for a central retailer managing MFs serving dynamically partitioned urban areas (Voronoi blocks based on grids). Demand is uncertain but characterized by grid-level features. We propose a data-driven Deep Reinforcement Learning (DRL) framework, specifically employing an Actor-Critic architecture enhanced with a spatial-temporal attention mechanism inspired by the Transformer. This approach learns an end-to-end policy directly from simulated or historical data, capturing complex dependencies without restrictive assumptions. The attention mechanism is crucial for effectively processing high-dimensional spatial and temporal inputs to inform better replenishment and relocation actions for each MF. Our approach provides valuable enhancements and partially achieve superior performance compared to traditional benchmarks (e.g., base-stock, myopic policies, static planning) and baseline DRL methods in extensive numerical experiments, including reductions in operational costs, improved service and fairness across different service blocks, and demonstrated scalability. Beyond practical implications for retailers seeking efficient and adaptive MF management strategies, this work contributes academically by showcasing advanced DRL applications in dynamic logistics and offers insights into balancing economic efficiency with social equity in modern retail operations.

2 - Optimizing Facility Layout and Vehicle Fleet Decisions for the Strategic Assembly Line Feeding Problem

Hannah Verplancke, Ghent University, Ghent, Belgium, Veronique Limère, El-Houssaine Aghezzaf, Emmanouil Thanos

The Strategic Assembly Line Feeding Problem (SALFP) aims at designing a robust internal logistics system for manufacturing companies to carry out their operations in an efficient manner over a long period of time. The SALFP consists of two core subproblems: the Supermarket Location Problem (SLP) and the Transport Vehicle Selection Problem (TVSP). In addition, SALFP also considers the influence of the tactical operating conditions by incorporating the tactical Assembly Line Feeding Problem (ALFP) decisions dealing with part feeding policy assignment in the strategic framework. The SLP decisions include locating and sizing supermarkets where parts are prepared according to their assigned policy. Positioning these supermarkets closer to the warehouse or the assembly line will influence the transportation decisions made by the TVSP component. The TVSP decides on the number and type of transportation vehicles to be purchased by the manufacturing company, limiting the purchasing cost. Those vehicles will subsequently be utilized to transfer all parts from the warehouse to the assembly line while maintaining a feasible routing schedule. By integrating these two correlated problems, we aim at providing an overall optimized solution for the internal logistics in high variability and low volumes manufacturing companies. We evaluate the performance of the solutions based on multiple scenarios in order to create robust solutions that can be put to use for multiple years in practice.

3 - Robust Outbound Load Planning with Volume Splitting for Parcel Carriers

Ritesh Ojha, Amazon, Redmond, WA, United States

In this work, we focus on the middle-mile consolidation networks of large parcel carriers where a flow plan specifies the primary and alternate flow paths for the commodities in the network, and a load plan specifies the number of trailers to operate between hubs, to move packages between their origin and destination hubs through intermediate sorting hubs. The joint optimization of flow and load planning decisions in large-scale networks is intractable. Therefore, we consider a simpler subproblem focused on specifying a low-cost load plan outbound from a single hub, for a series of consecutive sorting periods, given pre-specified flow plans for commodities. As this problem is solved a few days before the day of operations, we propose the robust outbound load planning problem and model it as a two-stage robust optimization model with relatively complete recourse. We solve the robust problem using a master-subproblem framework embedded in an exact column-and-constraint (CCG) algorithm. We propose heuristic scenario generation ideas that leverage the structure of the problem to provide tight lower bounds to the optimal objective without having to solve the computationally intensive MILP formulation of the subproblem. We integrate these ideas with a mountain climbing heuristic to efficiently generate local optimal solutions to the computationally-intensive subproblem in the CCG algorithm. On average, the local optimal solutions are within 11%-17% of the best bound obtained at the root node of the branch-and-bound tree when solving the subproblem using a commercial solver. An extensive computational study on real-life data shows that having

4 - A Dynamic Location and Routing Problem for Same-Day Delivery Using Autonomous Modular Vehicle as Mobile Parcel Stations

Amir Shafiee, University of Illinois Chicago, Chicago, IL, United States, Hanieh Rastegar Moghaddam Bajestani, Mostafa Ameli, Jane Lin

The rapid expansion of e-commerce and customer expectations for faster and flexible deliveries have intensified the challenges in last-mile logistics. Traditional systems often result in high costs, traffic congestion, and inefficiencies under fluctuating demand. In this study, we introduce a new last-mile delivery system using Mobile Automated Parcel Stations (MAPS), operated by Autonomous Modular Vehicles (AMVs) or pods. These delivery pods can station and move themselves in the neighborhoods; they can also join and disjoin in real time, forming energy-efficient platoons that reduce travel costs during shared route segments. We develop a location and routing optimization model formulated as a mixed-integer program (MIP) to determine optimal MAPS placement and pod routing. The model considers both pre-scheduled and real-time delivery or pickup requests, incorporating time windows, customer walking distance thresholds, pod capacity, and platoon-based cost reductions. Initial routes are planned at the start of the day, and dynamically updated as new requests arrive. The system decides whether to reroute existing pods or deploy a new pod without requiring returns to the depot. The framework integrates predictive planning for known requests with flexible route adjustments to accommodate dynamically arriving same-day pickups and deliveries. In the numerical experiments, we analyze the benefits of modularity and mobile stationing in different locations. The results are compared against an idealized scenario in which all customer requests are available at the beginning of the day. This comparison highlights the value of AMV-enabled modularity and dynamic planning in narrowing the performance gap between real-world uncertainty and full-information scenarios.

Location Analysis for Electric Vehicle Charging Under Uncertainty

Invited Session

Location Analysis

Chair: Xian Yu, The Ohio State University, COLUMBUS, OH, United States

Co-Chair: Huangrong Sun, The Ohio State University, Columbus, OH, United States

Co-Chair: Huangrong Sun, The Ohio State University, Columbus, OH, United States

1 - Maximum Flow-Based Formulation for the Optimal Location of Electric Vehicle Charging Stations

Miguel Anjos, University of Edinburgh, Edinburgh, United Kingdom

We consider the problem of optimal expansion of EV charging infrastructure to provide a greater quality of service in terms of user satisfaction (via the availability of charging stations). With a focus on urban areas, we first propose a model for the assignment of charging demand to stations, framing it as a maximum flow problem. This model is the basis for the evaluation of user satisfaction with a given charging infrastructure. Secondly, we incorporate the maximum flow model into a mixed-integer linear program, where decisions on the opening of new stations and on the expansion of their capacity through additional outlets is accounted for. We showcase our methodology for the city of Montreal, demonstrating the scalability of our approach to handle real-world scenarios. We conclude that considering both spatial and temporal variations in charging demand is meaningful when solving realistic instances. This is joint work with Pierre-Luc Parent, Margarida Carvalho, and Ribal Atallah.

2 - Contextual Distributionally Robust Optimization Under Multi-Modal Decision-Dependent Uncertainty with An Application to EV Charging Station Location

Huangrong Sun, The Ohio State University, Columbus, OH, United States, Beste Basciftci, Xian Yu

We study a two-stage electric vehicle (EV) charging station location problem under uncertain customer demand, where the demand may depend on the EV charging station location decisions and exhibit distinct patterns in different regions. To calibrate this decision-dependent and multi-modal uncertainty based on some historical data, we first formulate a mathematical optimization program to jointly optimize the number of modes, the assignment of data points to modes, and the regression function in each mode. Given the complexity of this optimization model, we apply cluster-wise regression algorithms to solve it more efficiently, which can converge to locally optimal solutions under mild conditions. Leveraging the estimated mode probabilities, regression functions, and the empirical residuals obtained from the regression step, we formulate a two-stage distributionally robust optimization (DRO) model for the EV charging station location problem with both moment-based and Wasserstein ambiguity sets and derive their tractable reformulations. We compare the performance of our cluster-wise regression algorithms with various regression benchmarks through extensive numerical experiments using synthetic datasets and real-world data from New York State. We also illustrate the benefit of considering decision-dependency and multi-modality by comparing our DRO model with decision-independent or single-modal counterparts.

3 - Large-Scale Location-Allocation Problem with Sinkhorn-Augmented Benders Decomposition

Nanshan Chen, The Ohio State University, Columbus, OH, United States, Cathy Xia, Guzin Bayraktan

Electric vehicle (EV) adoption continues to accelerate despite significant uncertainties. In 2025, over 25% of global car sales is electric. To support this transition, the expansion of public charging infrastructure is essential, and determining optimal locations for charging stations is a critical and challenging task. This problem is typically modeled as a location-allocation problem. However, as the number of locations and demand scale, conventional solution methods become computationally infeasible, even when decomposition techniques are applied.

This work proposes an efficient approximation approach based on the Sinkhorn algorithm to address the allocation subproblem under dense-demand cases. The overall framework models the location-allocation problem as a two-stage mixed-integer nonlinear program, which is solvable through a tailored Benders decomposition scheme.

We provide a theoretical analysis of the proposed method, including (i) the validity of custom Benders cuts adapted to the entropic regularization introduced by the Sinkhorn approximation, and (ii) the convergence properties of the resulting decomposition algorithm.

Computational experiments demonstrate that our algorithm effectively solves large-scale instances where commercial solvers fail, highlighting its potential to support the strategic deployment of EV charging infrastructure and, ultimately, to facilitate broader EV adoption. This framework can also be used in other facility location problems with high demand, such as bike-sharing systems, micro-transit services, etc.

4 - Urban Electrification Policy in NYC

Daniel Vignon, New York University, Brooklyn, NY, United States, Yanchao Li, Prakrith Raja, Zhengtian Xu

While most EV charging occurs at home, this relies on private, dedicated parking—a luxury in dense, urban settings like NYC, where private spaces are scarce. The resulting inconvenience for current and prospective EV owners has spurred cities nationwide to install, mandate, facilitate, or subsidize charging stations in garages, residential units, and curbside spots. Yet these well-meaning policies carry effects beyond boosting EV uptake: they reshape when and where people travel, alter parking

search costs, and influence how parking operators set prices and allocate spaces. Assessing their full welfare impact therefore requires a model bringing together travel-mode choice, individual activity and charging behavior, and parking market dynamics.

We fill this gap with an empirically calibrated framework for NYC. First, we integrate mode choice—EVs versus gasoline vehicles or non-driving options—with activities and charging decisions. Second, we model parking operators' decisions on pricing and supply as a game constrained by drivers' activity and parking behavior. We address computational complexity by leveraging the problem's convex structure to compute the Nash equilibrium among operators efficiently. We also combine proprietary industry data on parking availability and prices with inversion techniques to recover key parameter distributions.

Our approach enables simulation of counterfactual electrification policies—ranging from curbside charging mandates to garage subsidy schemes—and predicts their impacts on parking search times, EV adoption rates, and space availability. These insights will help policymakers better allocated limited funds for EV adoption, ensuring that expansions both accelerate urban electrification and maintain efficient parking markets.

Recent Advances in Integer and Low-Rank Optimization

Invited Session

Computing Society

Chair: Ryan Cory-Wright, Imperial, London, United Kingdom

1 - Improved Approximation Algorithms for Low-Rank Problems Using Semidefinite Optimization

Ryan Cory-Wright, Imperial, London, United Kingdom, Jean Pauphilet

Inspired by the impact of the Goemans-Williamson algorithm on combinatorial optimization, we construct an analogous relax-then-sample strategy for low-rank optimization problems. First, for orthogonally constrained quadratic optimization problems, we derive a semidefinite relaxation and a randomized rounding scheme, which obtains provably near-optimal solutions, mimicking the blueprint from Goemans and Williamson for the Max-Cut problem. We then extend our approach to generic low-rank optimization problems by developing new semidefinite relaxations that are both tighter and more broadly applicable than those in prior works. Although our original proposal introduces large semidefinite matrices as decision variables, we show that most of the blocks in these matrices can be safely omitted without altering the optimal value, hence improving the scalability of our approach. Using several examples (including matrix completion, basis pursuit, and reduced-rank regression), we show how to reduce the size of our relaxation even further. Finally, we numerically illustrate the effectiveness and scalability of our relaxation and our sampling scheme on orthogonally constrained quadratic optimization and matrix completion problems.

2 - The Augmented Factorization Bound for Maximum-Entropy Sampling

Yongchun Li, University of Tennessee Knoxville, Knoxville, TN, United States

The maximum-entropy sampling problem (MESP) aims to select the most informative principal submatrix of a pre-specified size from a given covariance matrix. This paper proposes an augmented factorization bound for MESP based on concave relaxation. By leveraging majorization and Schur-concavity theory, we demonstrate that this new bound dominates the classic factorization bound of Nikolov (2015) and a recent upper bound proposed by Li et al. (2024). Furthermore, we provide the theoretical guarantees that quantify how much our proposed bound improves the two existing ones and establish sufficient conditions for when the improvement is strictly attained. These results allow us to refine the celebrated approximation bounds for the two approximation algorithms of MESP. Besides, motivated by the strength of this new bound, we develop a variable fixing logic for MESP from a primal perspective. Finally, our numerical experiments demonstrate that our proposed bound achieves smaller integrality gaps and fixes more variables than the tightest bounds in the MESP literature on most benchmark instances, with the improvement being particularly significant when the condition number of the covariance matrix is small.

3 - The Surprising Performance of Random Partial Benders Decomposition

Yupeng Wu, London Business School, London, United Kingdom, Jean Pauphilet

Benders decomposition is a technique to solve large-scale mixed-integer optimization problems by decomposing them into a pure-integer master problem and a continuous separation subproblem. To accelerate convergence, we propose Random Partial Benders Decomposition (RPBD), a decomposition method that randomly retains a subset of the continuous variables within the master problem. Unlike existing problem-specific approaches, RPBD is simple to implement and universally applicable. We present both computational and theoretical evidence to support its effectiveness. For example, in extensive numerical experiments on network design and facility location problems, we find that (i) RPBD accelerates the convergence of Benders decomposition for problems with and without relatively complete recourse; (ii) RPBD usually halves the optimality gap at termination compared with a standard Benders approach; (iii) a random retention strategies is just as effective as problem-specific approaches proposed in the literature.

4 - Implicit Regularization of Infinitesimally-Perturbed Gradient Descent Toward Low-Dimensional Solutions

Jianhao Ma, University of Pennsylvania, Philadelphia, PA, United States, Geyu Liang, Salar Fattahi

Implicit regularization refers to the phenomenon where local search algorithms converge to low-dimensional solutions, even when such structures are neither explicitly specified nor encoded in the optimization problem. While widely observed, this phenomenon remains theoretically underexplored, particularly in modern over-parameterized problems. In this paper, we study the conditions that enable implicit regularization by investigating when gradient-based methods converge to second-order stationary points (SOSPs) within an implicit low-dimensional region of a smooth, possibly nonconvex function. We show that successful implicit regularization hinges on two key conditions: (i) the ability to efficiently escape strict saddle points, while (ii) maintaining proximity to the implicit region. Existing analyses enabling the convergence of gradient descent (GD) to SOSPs often rely on injecting large perturbations to escape strict saddle points. However, this comes at the cost of deviating from the implicit region. The central premise of this paper is that it is possible to achieve the best of both worlds: efficiently escaping strict saddle points using infinitesimal perturbations, while controlling deviation from the implicit region via a small deviation rate. We show that infinitesimally perturbed gradient descent (IPGD), which can be interpreted as GD with inherent "round-off errors", can provably satisfy both conditions. We apply our framework to the problem of over-parameterized matrix sensing, where we establish formal guarantees for the implicit regularization behavior of IPGD. We further demonstrate through extensive experiments that these insights extend to a broader class of learning problems.

1 - Expectation, Risk-Averse, and Distributionally-Robust Optimization for the Real-World Challenges in Emergency Medical Services

Yu-Ching Lee, National Tsing Hua University, Hsinchu, Taiwan

Emergency Medical Services (EMS) systems face significant operational challenges due to inherent uncertainties in demand, resource availability, and response times. Traditional optimization models often fall short in addressing these complexities, particularly when considering the variability and risks associated with real-world EMS operations. This research studied the frameworks of three key approaches: expectation optimization, risk-averse optimization, and distributional-robust optimization, to improve decision-making in EMS under uncertainty. The expectation optimization approach, or the stochastic programming, aims to minimize the average response time or cost while managing resource allocation across multiple service scenarios. The risk-averse optimization framework introduces tools to minimize the worst-case

outcomes, catering to situations where high-risk scenarios (e.g., critical patient cases) require robust and fail-safe planning. Lastly, distributional-robust optimization addresses uncertainty in both the probability distribution of future demands and service parameters, without assuming a specific underlying distribution, providing more flexibility and reliability in complex environments.

2 - Analyzing Manufacturer Channel Encroachment and Retailer Service Strategies Under A Carbon Emissions Trading Scheme

Jen-Yen Lin, National Cheng Kung University, Taiwan, East Dist., Taiwan

With the global push toward carbon neutrality, enterprises are facing increasingly stringent carbon reduction regulations. Achieving environmental sustainability while maintaining operational efficiency has become a critical issue in supply chain management. This study investigates a two-tier sustainable supply chain composed of a manufacturer and a retailer and develops a decision-making model that incorporates a carbon emissions trading scheme. In the proposed model, the manufacturer can sell directly to end consumers through an online platform, while the retailer responds to the resulting competition by enhancing its service level. The study further analyzes the optimal pricing and operational strategies for both the manufacturer and the retailer under this setting.

Three decision-making scenarios are analyzed: (1) the manufacturer does not engage in direct sales and the retailer does not enhance service (ND); (2) the manufacturer does not engage in direct sales while the retailer improves service (NS); and (3) the manufacturer engages in direct sales while the retailer does not improve service (ED). A Stackelberg game framework is employed to derive the optimal pricing strategies and corresponding profit for both players under each scenario. Numerical results reveal that when consumers exhibit a high psychological discount toward direct channels, the manufacturer tends to adopt a direct-selling strategy, and the advantage of doing so increases as the unit carbon emission decreases. Conversely, when the carbon trading price is relatively low or consumers perceive only a minor discount toward direct channels, refraining from direct sales may yield higher profits for the manufacturer.

3 - XGBoost with Missing Data Penalty for Multimodal Alzheimer's Disease Classification

Chen-ju Lin, Yuan Ze University, Taoyuan, Taiwan, Yu-chen Chiu

Multimodal clinical datasets are common in Alzheimer's disease (AD) diagnosis but often contain missing data due to incomplete testing or patient dropout. Traditional strategies, such as listwise deletion or imputation, may degrade classification performance, especially when the missingness mechanism is complex. This study proposes a new objective function for the XGBoost algorithm by incorporating the penalty of having missing data. Feature weights are iteratively optimized to minimize a composite loss function that reflects prediction performance, regularization, and data presence. The method was evaluated on a cohort of 517 subjects, comprising four data modalities: demographics together with APOE4 gene and cerebrospinal fluid biomarkers, magnetic resonance imaging (MRI), cognitive test scores, and the neuropsychological assessment battery. Compared to standard XGBoost, the proposed approach achieved higher F1 scores, improving by 0.02, 0.09, and 0.11 as the missing data rate increased from 20% to 30% and 40%, respectively. Feature importance analysis indicated MRI as the key predictor. This work demonstrates that augmenting XGBoost with a tailored penalty structure that models missingness in the learning objective enhances classification performance. The proposed algorithm offers a robust solution for healthcare applications with incomplete multimodal data.

4 - Minimizing Worst-Case Forest Fire Damage Through Optimal Prescribed Burning Strategy

I-Lin Wang, National Cheng Kung University, Tainan, Taiwan

Forest fires threaten ecosystems, with over 51,320 incidents burning 8 million acres in 2024. Prescribed burning mitigates wildfire risk, but optimizing burn locations remains a challenge. We model this as a Stackelberg game using bilevel programming, where the forest manager selects burn sites while an adversary chooses ignition points to maximize damage. Our approach considers worst-case scenarios, incorporating fire spread dynamics and cost-effective treatment areas. By reformulating the model into a single-level integer program, we improve efficiency and develop heuristics for faster solutions. Numerical results show our strategy significantly reduces fire damage, enhancing wildfire defense and broader risk mitigation planning.

Optimizing Distributed Energy Generation Systems

Invited Session

ENRE: Energy

Chair: Alexandra Newman, Colorado School of Mines, Golden, CO, United States

1 - Sizing of Stand-Alone Residential Battery Energy Storage Systems

Andrew Aikman, Colorado School of Mines, Golden, CO, United States, Karlyle Munz, Paulo Tabares, Alexandra Newman

Lithium-ion battery energy storage systems (BESS) can provide cost and CO₂ emissions savings to residential stakeholders by shifting energy usage from peak to off-peak hours. Lifetime cost savings can now be achieved without co-located generation due to the emergence of storage-based incentive programs. This work offers two methodologies for the sizing of stand-alone residential BESSs. Our life-cycle-cost approach uses incentive programs to balance upfront capital expenditures against lifetime electricity cost savings. The iterative-heuristic approach adds modules until the marginal benefit reaches a specified tolerance. We consider five control strategies to address both electricity cost and emissions goals. In a case study, we select systems for 29 low-income homes located in Lake County, Colorado, based on electrified and retrofitted electric demand profiles and local grid emissions rates. We isolate the cost and CO₂ emissions effects of electricity pricing by applying structures from across the United States. Both sizing methodologies achieve electricity cost savings of -50 to 40% and emissions savings of -12 to 23%. In another study, we create electric load profiles for the Lake County homes as if they were relocated to California, New York, Texas, Florida, and Nebraska. The new electric loads are paired with local emissions rates and pricing structures to create real home-pricing-emissions combinations. These cases produce electricity cost savings of -50 to 45% and emissions savings of -20 to 72%. Cost savings are highest in locations with pricing structures for electrified buildings while emissions saving potential depends on annual energy usage and grid-based emission rates.

2 - Minimizing Unmet Demand in Small-Volume Heat Pump Water Heaters

Janelle Domantay, School of Mines, Golden, CO, United States

Heat pump water heaters leverage the heat from ambient air temperature to heat water without using electric resistors. This method is up to four times more efficient than the commonly used electric water heaters and have been proposed to reduce energy costs. It is necessary to manually indicate a heating setpoint that determines the minimum temperature to maintain in the internal tank. However, depending on water usage and setpoint temperature, the hot water outlet temperature can fluctuate greatly. In order to maximize the cost efficiency of heat pump water heaters (HPWH), it is desirable to minimize the setpoint while still maintaining comfortable hot water outlet temperatures. Here we show that based on 220 days of minute-level draw data from a single HPWH site, we can accurately predict outlet temperatures for additional sites within a 2°C (1.8°F) margin of error across a two hour prediction horizon. This level of forecasting allows us to maximize the amount of delivered hot water for 120 V HPWHs and capitalize on variable electricity prices by maximizing preheating during times of the day with the lowest electricity demand.

3 - Optimizing Design and Dispatch of a Microgrid with Heterogeneous Heating Loads and Air-Sourced Heat Pumps

Alexander Zolan, National Renewable Energy Laboratory, Golden, CO, United States

The adoption of distributed energy resources to serve all or part of a building's electrical load is growing in response to the declining cost of onsite renewables and energy storage. In addition to this, electrification of the built environment motivates the inclusion of thermal loads when considering technology selection to meet a building's combined energy needs. We introduce REopt, an open-source web tool that obtains cost-minimizing distributed energy resource designs subject to meeting electrical, heating, and cooling loads with or without a utility connection for residential and commercial customers. We present an extension to include multiple heating loads of

different quality and the availability of air-sourced heat pumps as an option for meeting either space heating or domestic hot water needs. We demonstrate the impact of these extensions on design selection. We then present case studies showing the impact of technology availability, costs, and emissions reduction goals on technology selection.

4 - Enhancing Energy Resilience on Military Installations: a Heuristic Optimization Approach Using Genetic Algorithms

James Grymes, United States Military Academy, West Point, NY, United States, Jake Moffat

Functioning energy infrastructure on military installations is essential in executing daily operations. From powering ranges to maintaining communication systems, energy is a driving factor, and a failure has dramatic consequences. The research conducted by the Energy Resilience team at the United States Military Academy is directed toward enhancing the resilience of the Army's energy infrastructure through a heuristic optimization approach. Deliverables include innovative, sustainable, and actionable design solutions that address resilience, cost, and emissions. Improving resilience, or how quickly a system can return to a satisfactory state after a failure, is the primary focus. The research presented will be the analysis of the heuristic optimization method, recommendations to the algorithm, and current progress. The model incorporates a genetic algorithm to produce a Pareto frontier of micro-grid configurations. The genetic algorithm is coded in MATLAB and works to optimize the defined fitness function. The current results of the model analysis have led to recommendations for implementing adaptive mutation and elitism and adding resilience to fitness functions. The model produced will provide insight into improving energy infrastructure on military installations with a focus on resilience.

5 - Design of a 200-Kw Scale Solar Receiver Test Facility Using An Available Tower

Sebastian Dogue, Colorado School of Mines, Golden, CO, United States, Andrew Aikman, Alexandria Newman, Gregory Jackson

The scale-up of concentrating solar technologies requires adequate on-sun test facilities at or above the 100-kWth scale to demonstrate components and economically evaluate new concepts at plant-scale performance conditions. Adaptation of available tower structures provides a low-cost pathway to satisfy this need. This study examines the possible conversion of an existing 60-m high tower facility in the Front Range region of Colorado to a 200-kWth scale solar receiver and heliostat field test facility. We use NREL's SolarPILOT to examine the viability of the tower, surrounding environs, and weather to offer up to 500 kW of thermal power over enough days per year to support effective research and development. We use two sizing approaches to generate heliostat fields which achieve the desired mean receiver flux and uniformity. The 200-kW layout method creates a densely packed field of heliostats with focused aiming strategy, and the max-power layout method selects more heliostats but uses a dispersed aiming strategy. The max-power layout method obtains much greater flux uniformity at the expense of optical efficiency, which is necessary for receiver demonstration tests. Available receiver locations on the top half of the tower offer a suitable range of conditions to test 1x1m receivers with mean fluxes of 250 kW/m², from which final location can be selected based on demonstration test objectives.

Navigating Future Uncertainties in Energy System Planning

Invited Session

ENRE: Electricity

Chair: Sheng Lun Cao, University of Calgary, Calgary, AB, Canada

1 - Representative Period Selection for Incorporating Future Weather Data in Capacity Expansion Modeling

Sheng Lun Cao, Carnegie Mellon University, Pittsburgh, PA, United States

Long-term capacity expansion planning needs to account for future weather uncertainties to ensure renewable resource adequacy and grid reliability. Global climate modeling can forecast future weather dynamics to the end-century, but capacity expansion models cannot leverage the full spatiotemporal data resolution due to computational tractability. Thus, representative period selection become a necessary step to select some future weather periods to simulate "typical" grid operations in the future. We evaluated four hard and fuzzy k-medoids clustering-based and one tree-based representative period selection methods to assess their impact on the final capacity expansion planning outcomes for the ERCOT grid in Texas during mid-century (2045 – 2054) and end-century (2085 – 2094). Through 1120 capacity expansion cases, we determined that the cluster size-weighted hard k-medoids clustering method (UHKM) is the best-performing representative period selection method, in terms of estimated total system cost. The fuzzy clustering methods systematically overbuilds wind capacity and underbuilds PV capacity by selecting representative periods with high wind and low PV availability. Representative period selection, despite being one step in capacity expansion modeling, can have a significant financial impact on long-term system planning, leading up to \$7.2 billion in total system cost underestimation.

2 - Explaining Variation in Emissions and Health Impacts from SO₂ Control Technologies Installed at U.S. Coal Power Plants

Joanna Slusarewicz, Carnegie Mellon University, Pittsburgh, PA, United States, Valerie Karplus, Nicholas Muller

When predicting outcomes of future environmental policy in the electricity sector, analysts must make assumptions about investment in and use of adopted technologies that may critically determine ex-ante estimates of costs to households and regulated firms as well as the resulting benefits to society. To illustrate the importance of such assumptions to environmental policy analysis, this work examines U.S. coal power plant operational decisions that affect the SO₂ removal efficiency of flue gas desulfurization (FGD) units in response to environmental and market regulation. It has often been assumed that plants installing FGDs will reduce pre-FGD SO₂ emissions by a factor of the equipment's rated removal rate. However, plants often have financial incentives to (a) burn cheaper, higher sulfur coal after installing SO₂ scrubbers, and (b) operate outside of the standard conditions under which pollution control equipment is rated. This study compares the effects of each behavior by decomposing SO₂ emissions as a function of coal sulfur content and SO₂ removal efficiency across plants from 2008 to 2021. The study finds that SO₂ emissions declined by 90.0% after FGD installation relative to the 95.6% predicted from the rated removal rates. This discrepancy is in part due to a 58% increase on average in percent sulfur by weight of coal combusted post-FGD installation. Furthermore, total SO₂ tonnage capture rates were 2.4% lower than predicted from the rated removal rates, resulting in 740 additional deaths per year on average as estimated by the Air Pollution Emissions Experiments and Policy version 4 (AP4) model.

3 - A Comparative Evaluation of Machine Learning Algorithms for Disaggregating Outages from Disconnections in Smart Meter Data

Akua McLeod, Carnegie Mellon University, Pittsburgh, PA, United States, Destenie Nock, Amritanshu Pandey

Electricity service disruptions compromise households' ability to meet energy demand and thus increase energy insecurity. Disruptions can take the form of power outages, or involuntary disconnections due to nonpayment. To achieve equitable energy access, guide targeted grid modernization efforts, and facilitate utility performance regulation, we must understand how electricity reliability varies spatially and across demographics. Advanced metering infrastructure (AMI) data offers a unique opportunity to evaluate electricity access at the ZIP code level, in the absence of utility published datasets, however we must first disaggregate periods of zero energy consumption into outages and disconnections. Building on our previous work which presented a novel method of classifying disruptions in AMI data using logistic regression, we compare the performance of several machine learning methodologies, using the Commonwealth Edison territory in Illinois as a case study.

To identify the superior classifier, we evaluate three models (logistic regression, a support vector machine and a neural network) using both standard accuracy metrics such as the F1 score and Cohen's Kappa, as well as by validating our aggregate results against known disruption statistics for the service territory. Leveraging our model results, we find that the most outage-burdened regions are concentrated in rural counties, and that regions with a higher percentage of low-income residents and people of color often carry higher outage burdens than the rest of the service territory. Ultimately, this work enables more granular metrics for electricity reliability, highlighting gaps in energy accessibility and informing the identification of energy-insecure communities.

4 - Mortality and Distributional Effects of Air Pollution from Integrated Steelmaking in the United States

Judy Park, Carnegie Mellon University, Pittsburgh, PA, United States, Nicholas Muller, Valerie Karplus

32% of iron and steel production in the US comes from Integrated Iron and Steel (IIS) plants, which, along with the metallurgical coke plants upstream of them, are major sources of air pollution. We modelled the atmospheric PM_{2.5} concentrations attributable to these plants' pollution emissions and estimated the magnitude of their premature mortality effects, plus their distribution across racial/income groups. Annual Scope 1 emissions of five PM_{2.5}-precursor pollutants were determined using data from all existing IIS plants (n=9) and metallurgical coke plants (n=13) in the US in 2017, and Scope 2 emissions were modeled using the average of projected electricity generation emission factors from 2026-2065 (reflecting a 40-year plant life). Atmospheric dispersion and secondary pollutant formation were modeled with a Reduced-Complexity Model (AP4T) to determine the resulting ambient PM_{2.5} concentrations at a census-tract resolution, from which the premature mortality risk was calculated using age-differentiated dose-response functions from a large cohort study. Results show that air pollution from IIS and coke plants in the US may be responsible for 700 deaths per year, equivalent to damages of \$7 billion/year (\$2020) or 30% of the total value of steel produced with integrated steelmaking. 333 of these deaths occur in the top 10% of most affected tracts (by pollution level), where the population-weighted mortality risk is 11.6 per 100,000 people, and Black, Other Nonwhite, AAPI, and Hispanic residents face higher-than-average mortality risks. Additionally, mortality risks increase slightly with increasing household incomes, especially for residents who are Hispanic, Other Nonwhite, or 2+ Races.

5 - Modeling Spatial Health Damage Disparities from CCS Under Atmospheric and Policy Uncertainty

Nexus Attiogbe, UMass Amherst, Amherst, MA, United States, Erin Baker, Paola Furlanetto, Michael Ash

Recent U.S. policies, including the Inflation Reduction Act's 45Q Tax Credit and the EPA's CO₂ Performance Standards, aim to incentivize carbon capture (CC) in the power sector. This study evaluates how these individual policies and their combinations affect CC deployment, co-pollutant emissions (NO_x, SO_x, PM_{2.5}, NH₃, and VOCs), and the distribution of health damages across socioeconomic groups. Using a stylized three-node model, we optimize the generation investment and dispatch. We apply this regional case studies in Alabama and Texas to investigate health disparities. Air pollution exposure modeling is paired with census tract-level data to assess disparities in per-capita monetized health damages. Regional variation in co-pollutant dispersion patterns due to atmospheric conditions is incorporated to reflect climate-based uncertainties. This study highlights the importance of considering environmental injustice when designing policy by analyzing trade-offs between CC adoption, co-pollutant exposure, and equity outcomes. Results emphasize the need for decarbonization strategies that remain robust under uncertainty and prioritize equitable emission reductions.

Corporate Sustainability and ESG

Contributed Session

Contributed

Chair: Andy Buschmann, University of Michigan, Ann Arbor, Ann Arbor, MI, United States

1 - Environmental Shareholder Proposals and Firm Strategic Responses

Marilyn Lucas, University of Vermont, Burlington, VT, United States, Hung Do, Thomas Noordewier

We develop an economic model to study how firms decide on R&D and marketing investments in response to environmental shareholder proposals. To complement our analytical findings, we conduct an empirical study, using a dataset that combines financial data and shareholder resolution information.

2 - Impact of Epr on Circular Strategy for Electric Vehicle Batteries: Recycle or Refurbish?

Vikash Kumar, Ivey Business School, London, ON, Canada, Jason Nguyen

We study how implementation of extended producer responsibility (EPR) legislation for green products, such as EV batteries may impact their economic and environmental outcomes. EV batteries are critical to viability of EVs, which in turn is critical to meeting the emission targets. However, these EV batteries are equally environmentally detrimental to make as well as dispose. EPR regulations for EV batteries are policy tools that force EV manufacturers to choose different circular economic (CE) strategies to implement EPR standards. However, conspicuously there are no studies in academia that explores the unique nature of EV batteries, which make designing EPR implementation challenging. We develop an analytical model to analyze the different CE strategies of EV manufacturers under EPR and analytically reveal its economic and environmental impact. The impacts of EPR are not intuitive for EV batteries, on one hand it reduces the environmental degradation through recycling by mandating minimum proportion for input substitution from virgin material to recycled material; however, on the other hand this reduces the reuse of EV batteries which in turn aggravates environmental degradation. Furthermore, it may also reduce new production of EVs, which in turn slows down transition to green transportation, impacting the environment negatively. We offer insights into how the EPR regulations impact the environmental and economic welfare and reveal parameters of interest that the policy makers may target to nudge the EV manufacturers towards the optimal outcome.

3 - Modeling the Interplay Between ESG Dynamics and Corporate Financial Decisions

Jingwei Chen, University of Tennessee, Knoxville, Knoxville, TN, United States, Mingzhou Jin

As Environmental, Social, and Governance (ESG) considerations become central to corporate finance, decision-makers face growing challenges in aligning long-term sustainability goals with financial performance. This research develops a multi-period optimization framework that captures the dynamic interaction between ESG trajectories, investment portfolios, and debt financing decisions. The model integrates ESG score depreciation, asset deterioration, project-level sustainability impacts, and ESG-linked financing conditions, enabling firms to navigate both market-driven expectations and regulatory ESG targets. Each investment option is characterized by its financial return, long-term asset contribution, and ESG performance, and must be evaluated under liquidity and leverage constraints. Interest rates are endogenously defined as a function of firm size, leverage, and ESG score, linking sustainability performance to the cost of capital. The model tracks firm-level ESG scores and financial health over time and supports scenario analysis on strategic investment behaviors. Early-stage results from simulation-based evaluation highlight trade-offs between ESG impact and financial efficiency, and reveal how ESG-oriented capital structures affect long-term asset growth and interest rates. By incorporating ESG dynamics into corporate financial decision-making, this work aims to support transparent, robust, and actionable planning tools for firms transitioning toward sustainable operations. The proposed model also offers a foundation for future research exploring ESG-related financial incentives, policy instruments, and portfolio classification.

4 - Integration of Circulatory and Innovation Investments for Consumer Electronics Companies

Ece Zeliha Demirci, TED University, Ankara, Turkey, Emre Nadar, Zeynep Ece Livaoglu

We consider electronics companies that aim to allocate their limited financial resources along two critical dimensions: investments for research and development (RD) to improve the new product design and customer base, and investments for circularity technologies to increase the sales of remanufactured items. The volume of used items collected for remanufacturing can be controlled by the acquisition price set for the used item. We formulate the problem of such an electronic company with a bilevel programming model that takes into account demand uncertainty and supply-loop constraints. We characterize the optimal solution structure and derive managerial insights on how such companies can strategically allocate their resources.

5 - Does Corporate Sociopolitical Activism Oriented Market Exits Benefit Corporate Brand Equity and Firm Profitability? Evidence from Corporate Exodus from Russia Amidst the 2022 Russo-Ukrainian War

Wenjun SHU, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Di Fan, Xiao Zhang, Maggie Dong

Problem definition: With the rise of political consumerism, stakeholders increasingly pressure firms to take stands on sociopolitical issues. In response, multinational corporations (MNCs) engage in corporate social activism (CSA), such as publicly supporting or opposing sociopolitical issues. During the 2022 Russo-Ukrainian War,

many MNCs withdrew from the Russian market as a form of CSA, differing from traditional economically driven market exits and raising questions about their impact on firm performance. **Methodology/results:** We investigate whether CSA-driven market exits benefit firm performance in terms of corporate brand equity and profitability. Focusing on U.S.-listed MNCs that exited Russia during the 2022 Russo-Ukrainian War, we conduct a quasi-natural experiment comparing firms that announced withdrawal with those that did not. Our analysis reveals significant increases in corporate brand equity and profitability following the CSA decisions. Furthermore, the benefits are amplified when the firms' actions align with target market values and when social media sentiment is more positive. We address potential endogeneity issues through additional robustness tests, confirming the stability of our findings. **Managerial implications:** Our findings offer valuable insights for MNCs operating in global markets on how CSA-oriented market exits may affect their brand and profitability. The study provides guidance on effectively managing market exits amidst complex sociopolitical issues. Additionally, our results can inform policymakers about the quantitative effects of CSA-driven market exits and their potential economic impact, serving as important references for future policy-making.

6 - Do Firms Walk the Circular Talk? Multimodal Signals, Supplier Trust, and Dynamic Collaboration in the Circular Economy

Nan Liu, University of Birmingham, Birmingham, United Kingdom, Yufeng Zhang, Wanhong Li

As the Circular Economy (CE) becomes increasingly integral to sustainable operations, firms face intensified pressure to credibly signal their green commitments and secure long-term supplier collaboration. Traditional ESG disclosures provide retrospective insights with limited predictive capability, necessitating more forward-looking approaches in supply chain management. Building on signaling theory and organizational trust theory, we examine how firms' **multimodal data consistency**—integrating verbal, vocal, and visual expressions, dynamically shapes supplier trust formation and subsequent collaboration behaviors within sustainable supply chain contexts. We propose a **human-AI hybrid** methodology combining multimodal analytics with dynamic **agent-based modeling (ABM)**. Corporate executives' CE-related speeches are analyzed using multimodal tools (e.g., Whisper, openSMILE, OpenFace), generating **Multimodal Congruence Scores (MCS)**. Supplier trust perceptions and collaboration intentions are assessed through scenario-based surveys, embedding CE-specific constructs. To validate MCS, we implement human-AI alignment testing via the *Epitome* platform, where real suppliers rate trustworthiness of identical video content. Robust alignment between human and AI-derived ratings confirms MCS validity. Subsequently, we implement an **ABS** featuring adaptive supplier–firm interactions, dynamically capturing reciprocal trust updates and strategic communication adjustments. We pioneer the integration of multimodal expression congruence into the supply chain management literature, advancing signaling theory by redefining corporate signals as dynamic and interactive rather than static cues. It expands organizational trust theory by illustrating trust formation as an adaptive, feedback-driven process between firms and suppliers. Practically, our framework provides enterprises with scalable tools to strategically align organizational communication practices, thereby fostering resilient, trust-based supplier partnerships essential for sustained competitive advantage in circular supply chains.

7 - When Does Hedging Backfire? How Corporate Political Connections Affect Firm Survival Following Democratic Breakdown, Insights from the 2021 Coup in Myanmar

Andy Buschmann, University of Michigan, Ann Arbor, Ann Arbor, MI, United States

Firms frequently engage in political hedging—cultivating ties with competing political actors—to mitigate risks arising from regime turnover or policy shifts. While such strategies have been found effective in consolidated and new democracies, this study argues that political hedging may backfire in transitional regimes where democratic institutions remain fragile and the autocratic elite is still politically powerful. In such contexts, finite resources and costly commitments make political hedging not only more contentious but also potentially dangerous. When democratic transitions stall or reverse, autocratic elites may interpret ties to opposition actors as disloyalty or betrayal, triggering exclusion from strategic resources or political repression. To investigate this argument, I analyze firm survival following the 2021 military coup in Myanmar, which abruptly reversed a decade-long democratic transition. Based on data from a large-scale data leak of Myanmar's corporate registry and various other original datasets on firms' political ties, I explore the quasi-causal effect of the coup on firm survival conditional on different pre-coup corporate political connections (CPC). Within a factorial DiD framework, I classify firms by their network distance to opposing political camps prior to the coup. I supplement my causal analysis with data on post-coup repression to distinguish firm death due to market vis-à-vis non-market mechanisms. This study contributes to the nonmarket strategy literature by identifying critical boundary conditions under which political hedging ceases to function as an optimal strategy. I highlight the distinct political hazards firms face when pursuing CPC in politically uncertain regimes.

1 - Unlocking Demand-Side Flexibility with Dynamic Operating Envelope Market and AI Agent

Cong Chen, Cornell University, Ithaca, NY, United States

The global energy transition is transforming power systems through the rapid growth of renewables, data centers, and electrification across transportation, infrastructure, and industry. This talk highlights two critical challenges and our proposed solutions. First, distributed energy resources (DERs)—such as rooftop solar, home batteries, and electric vehicles—along with large new loads like data centers, require reliable and fair access to the distribution network. We introduce a dynamic operating envelope market, implemented through a forward auction, to allocate network injection and withdrawal rights. This mechanism enhances grid reliability while enabling equitable participation of diverse resources. Second, unlocking demand-side flexibility requires energy service providers to better understand customer behaviors and preferences in order to design sustainable and profitable business models. We develop AI agents powered by large language models that act as *homo silicus* for energy customers. These agents generate credible and diverse behavioral insights and capture responses to rare but high-impact events such as blackouts. Together, these approaches address renewable uncertainty, maintain competitive pricing, and advance demand-side participation in modern electricity markets.

2 - Reliability-Incorporated Optimization in Power Distribution via Multi-Source Weather Data and Ensemble Models

Gejia Zhang, Rutgers University, Piscataway, NJ, United States, Robert Mieth

Maintaining the reliability of modern power distribution systems is crucial, yet it is increasingly challenged by rising electricity demand, aging infrastructure, and the growing impact of unstable weather conditions. Recent studies have shown that operational decisions and environmental factors both play roles in determining component failure rates. This study integrates framework for enhancing power distribution system reliability by incorporating an array of meteorological factors from multiple measurement sources. To manage the resulting collinearity and computational challenges, we propose two ensemble tree-based models that systematically identify the most influential features and reduce the dataset's dimensionality based on each feature's impact on failure rate prediction. By weighting features according to their importance, critical variables exert a stronger influence on predicted failure rate, while each tree in the ensemble incorporate distinct feature subsets. These predictions are embedded within a sequential, non-convex optimization procedure, where operational decisions are dynamically updated in response to system states. We perform a numerical experiment that demonstrates the model's ability to integrate accurate reliability estimates derived from multi-dimensional data across multiple sources while co-optimizing operational costs.

3 - Data Driven Evaluation of Distribution Grid Upgrade Costs Under Utility Scale Smart Charging Strategies

Lusha Wang, University of Alabama, Tuscaloosa, AL, United States

Transportation Electrification will significantly reduce carbon emissions and reliance on fossil fuel. The world has seen an accelerating transition to electric vehicles (EVs) driven by environmental concerns, government promotions and battery technology advancements. On the one hand, this transition brings in great positive environmental impacts; on the other hand, it introduces enormous challenges to existing power systems which were designed and constructed without considering massive EV integration. It is thus imperative to understand the impact of EV charging on real-world power distribution networks and rethink the planning and operations of power grids. This talk will share key insights from a real-world smart charging management pilot program, evaluating strategies for optimizing EV charging loads and enhancing grid resilience. Leveraging real charging data from over 4,600 EV drivers and more than 2000 real-world distribution feeders, the study provides detailed feeder-level

analysis, revealing how factors like transformer rating and number, load profiles and infrastructure constraints influence smart charging performance. Data-driven methods are utilized to scale feeder-level insights to utility-wide estimates, yielding rapid yet precise results. These findings offer valuable guidance for stakeholders - including governments, utilities, third-party operators and consumers - on the role of feeder-specific smart charging in infrastructure planning and grid modernization.

4 - Energy Consumption of Limited Response to Weather

Fariba Farajbakhsh Mamaghani, Tulane University, River Ridge, LA, United States

The integration of smart technologies into electricity grids has enabled utilities to monitor consumption in real time and implement demand response (DR) programs that rely on dynamic pricing to balance supply and demand. Yet, recent experiences in the residential sector show mixed effectiveness, calling into question the assumption that households reliably adjust consumption in response to price signals. A key challenge is that prices must be set in advance and cannot adapt to random environmental factors such as weather. As a result, households often demonstrate limited ability to rationally modify their usage, leading to volatile demand patterns.

We address this gap by developing a novel framework that models households' decision-making under cognitive constraints, drawing on the concept of "rational inattention." Our model characterizes optimal consumption strategies that explicitly account for the trade-off between information processing costs and potential savings. This framework captures how random shocks in ambient conditions map into household consumption and identifies conditions under which households are responsive or unresponsive to demand fluctuations. We show that consumption is shaped by competing comfort-seeking and cost-saving incentives, yielding nontrivial demand patterns. Importantly, while higher prices reduce average demand, they may also increase sensitivity and variability. Likewise, reducing cognitive costs may unintentionally raise variability if prices are not set appropriately.

Using temperature data from New York City apartments, we calibrate the model and confirm its analytical predictions. Our findings provide insights into empirical demand patterns and offer actionable guidance for designing more effective DR programs and pricing policies.

Global Optimization Methods and Applications

Invited Session

OPT: Global Optimization

Chair: Sergiy Butenko, Texas A&M University, College Station, TX, United States

1 - Continuous Formulations for Combinatorial Optimization Problems Based on the Probabilistic Method

Miltiades Pardalos, Texas A&M University, College Station, TX, United States, Sergiy Butenko

We present a unified framework of exact continuous formulations for a wide range of classical graph optimization problems—minimum (double) dominating set, vertex cover, maximum independent set, clique, s-plex, and max-cut—by leveraging the probabilistic method. The approach yields multi-linear polynomial programs over the unit hypercube whose optimal values coincide with the corresponding combinatorial invariants, and introduces several novel weighted extensions. To assess practical performance, we solve these formulations on numerous networks using a modern global solver (Gurobi) and five state-of-the-art nonlinear solvers (CONOPT, IPOPT, KNITRO, LOQO, SNOPT). We find that high-degree multi-linear objectives can severely impede convergence, but that systematic degree reduction—via Boole's inequality—drastically improves solution quality and robustness. The obtained results are promising and encourage a more detailed investigation of continuous formulations based on the probabilistic method in the context of solving larger-scale discrete optimization problems.

2 - New Convex Relaxations of Dynamic Systems

Kamil Khan, McMaster University, Hamilton, ON, Canada

Global optimization problems arise in several engineering applications, such as worst-case uncertainty analysis and thermodynamic modeling. Typical deterministic methods for global optimization proceed by furnishing increasingly tighter upper/lower bounds on the unknown globally optimal value. In global minimization, lower bounds are typically constructed by minimizing an appropriate convex relaxation of the original problem. Hence, improvements in convex relaxation generation lead to improvements in global optimization overall.

We present recent advances in generating useful convex relaxations for dynamic systems, with dynamics represented by an embedded ordinary differential equation model. First, we show how optimal-value functions and kinematic intuition may be deployed to yield tighter, more versatile convex relaxations of ODE solutions. Second, we show how a new rigorous finite-difference bounding method can vastly reduce the number of ODE solves required when relaxing a dynamic system, without significant sacrifices in tightness.

3 - Gpu-Based Complete and Rigorous Search for Continuous Global Optimization

Guanglu Zhang, Carnegie Mellon University, Pittsburgh, PA, United States

Continuous optimization is of significance in many science and engineering fields. In many practical applications, it is desirable, and sometimes indispensable, to find the global optimum when solving continuous nonconvex optimization problems. However, popular gradient-based methods and heuristic methods often become trapped in local optima and do not take rounding errors into account, leading to inconsistent or incorrect assumptions and applications. Based on the research gap, we introduce a GPU-based, complete, and rigorous method that can efficiently enclose the guaranteed global optimum within a user-specified tolerance for continuous optimization problems, especially for large-scale continuous nonconvex optimization problems. Using interval analysis, coupled with the computational power and architecture of GPU, the method iteratively rules out the regions in the search domain where the global optimum cannot exist and leaves a finite set of regions where the global optimum must exist. The method is validated by enclosing the global optimum of 10 multimodal benchmark test functions with scalable dimensions. These test functions represent grand challenges of global optimization, and enclosing the guaranteed global optimum of these test functions with more than 80 variables has not been reported in the literature. Our method successfully encloses the global optimum for each of these 10 test functions with up to 10,000 variables using only one GPU in a reasonable computation time, demonstrating an approximately quadratic increase in computation time with the number of variables in these optimization problems. The method is also applied to solve several practical engineering optimization problems effectively and efficiently.

4 - Symmetry-Breaking and Bilinearity Reduction in the Global Optimization of the Multiperiod Blending Problem

Daniel Ovalle Varela, Carnegie Mellon University, Pittsburgh, PA, United States, Arsh Bhatia, Carl Laird, Ignacio Grossmann

The multiperiod blending problem (MPBP) generalizes the classical pooling problem by incorporating scheduling decisions across multiple time periods, requiring blending pools to operate dynamically rather than in steady state. While various formulations and solution methods have been proposed, existing decomposition approaches often suffer from inefficiencies due to symmetric solutions. In this work, we propose an enhanced decomposition method based on Generalized Disjunctive Programming (GDP) that resolves this symmetry issue. By eliminating redundant symmetric configurations, our approach improves computational efficiency and reduces the number of bilinear constraints in subproblems by approximately 90%, resulting in subproblem solve times that are up to two orders of magnitude faster. Computational experiments show that the proposed method consistently outperforms both existing GDP-based decomposition algorithms and standard monolithic formulations solved with state-of-the-art solvers like Gurobi. To support further research, we also introduce a publicly available library of 60 MPBP benchmark instances in JSON format, designed to provide a diverse and challenging testbed for future studies.

5 - Rotational Relaxations for Global Optimization of Quadratic Programs

Yehor Blokhin, KTH Royal Institute of Technology, Stockholm, Sweden, Jan Kronqvist, Martin ryner

In this talk, we investigate the global optimization of non-convex quadratic functions subject to linear constraints defining a bounded set. We introduce a novel family of relaxation methods obtained by linearly transforming the vector space using the constraints. Preliminary experiments indicate that the presented approaches, integrated with the α BB method and McCormick envelopes, produce significantly tighter convex bounds.

Fair and Dynamic Operations of Infrastructure Systems

Invited Session

Public Sector OR

Chair: Violet (Xinying) Chen, Stevens Institute of Technology, Hoboken, NJ, United States

1 - A Fairness Framework for Shared Electric Micromobility Systems: Conceptual Foundation and Case Studies**Tara Zibandehkhooy, Stevens Institute of Technology, Hoboken, NJ, United States, Violet (Xinying) Chen**

Shared Electric Micro-Mobility Systems (SEMS) are reshaping urban transportation by offering sustainable and convenient travel options. However, concerns about equitable access and usage have gained attention among policymakers and researchers. This study proposes a flexible framework for evaluating fairness in SEMS from the perspective of central decision-makers. Fairness is defined as the desirability of utility distributions—benefits or harms—across geographic or demographic stakeholder groups. The framework categorizes utilities into two types: *decision outcomes*, which capture static factors such as system supply and spatial context; and *system outcomes*, which reflect dynamic performance indicators such as vehicle availability, usage levels, and idle time. We demonstrate the applicability of this framework through two real-world case studies: a docked bike-sharing system and a dockless e-scooter system. Using operational SEMS and public infrastructure data, we compute relevant utility metrics and apply fairness measures to assess spatial equity. These case studies illustrate how the framework enables descriptive fairness analysis and supports data-driven insights for more equitable micro-mobility planning. The proposed framework serves as a foundation for systematic fairness evaluation across different SEMS types and urban contexts.

2 - Algorithmic Monoculture and Operational Hedging**Peter Zhang, Carnegie Mellon University, Pittsburgh, PA, United States, Hao Hao**

Problem. Large-model pipelines introduce a hidden single point of failure: predictions made by architecturally similar models tend to err in the same way, creating systemic risks that traditional i.i.d. assumptions or mean-squared-error metrics fail to capture.

Approach. We introduce *Algorithmic Concentration Risk* (ACR) to measure upstream prediction error alignment, and *Decision Concentration Risk* (DCR) to quantify the downstream, worst-case impact on decision-making. DCR is formulated as a distributionally robust optimization problem with a moment-based ambiguity set. To address this, we propose **RADIO** (Risk-And-Diversification Integrated Optimizer), which jointly minimizes the cost of deploying heterogeneous models and the DCR.

Novel Results.

- (i) This single, lightweight framework unifies three classical models from distinct domains: it reduces to the softmax/logit choice model under linear loss and Gumbel uncertainty; to the newsvendor model with piecewise-linear penalties; and to mean-variance (Markowitz) optimization under distributional ambiguity.
- (ii) In both heavy-tailed simulations and the public M5 retail dataset, RADIO reveals a novel “folded scaling-law,” showing how decision risk falls as investment in both accuracy and model diversity increases.
- (iii) This is the first decision-theoretic toolkit that quantifies the risk of model monoculture. It provides actionable guidance for hedging downstream decisions and pricing the value of added diversity and accuracy in predictive models.

3 - A Multi-Stage Dynamic Optimization Framework for Effective Epidemic Resource Allocation and Sustained Public Trust**Kimiya MohammadiJozani, Virginia Tech, Blacksburg, VA, United States, Sait Tunc, Esra Buyuktahtakin Toy**

Epidemics present urgent and complex decision-making challenges, where limited resources must be allocated under evolving and uncertain conditions. The stochastic nature of infection rates, driven by behavioral, environmental, and policy-related factors, adds significant complexity to planning effective interventions. Moreover, resource allocation strategies must consider efficiency and fairness to reduce the burden of epidemics while maintaining public trust. This work introduces an optimization-based framework for epidemic response, integrating disease dynamics with logistics planning under uncertainty. We formulate and solve stochastic epidemic-logistics models that enable equitable and effective allocation of critical resources, such as vaccines, across spatially and behaviorally heterogeneous populations over time.

4 - End-to-End Fairness Optimization with Fair Decision Focused Learning**Yu Wang, Stevens Institute of Technology, Hoboken, NJ, United States, Violet (Xinying) Chen**

We introduce Fair Decision-Focused Learning (FDFL), a principled framework for jointly optimizing predictions and downstream decisions under fairness constraints. Unlike traditional pipelines that treat fairness and decision-making as disjoint steps, FDFL integrates them into a unified, end-to-end learning objective. Our framework supports a broad class of fairness criteria, with a focus on differentiable decision-level objectives. We develop gradient-based training algorithms, and for a specific class of fairness measures—namely α -fairness with linear utilities—we derive closed-form optimization solutions that allow for exact gradient computation. This analytic approach significantly improves both computational efficiency and training stability.

Through healthcare resource allocation experiments, we demonstrate that FDFL yields lower decision regret and reduced prediction disparity compared to standard two-stage baselines. Moreover, using exact gradients via our closed-form solution yields better performance than approximate, perturbation-based methods.

Our results underscore the importance of aligning fairness objectives across the prediction-to-decision pipeline. FDFL offers a practical and scalable blueprint for building machine learning systems that are both effective and equitable, opening pathways for broader adoption in high-stakes domains.

5 - Tradable Equity Credits (Tecs) for Public Transit: a Dynamic Pricing Approach for Heterogeneous Travelers**Chenfeng Xiong, Villanova University, Villanova, PA, United States**

Public transit systems are vital for providing equitable access to jobs, education, healthcare, and other essential services. However, transit agencies face increasing challenges balancing financial sustainability with transportation equity, particularly in the wake of the COVID-19 pandemic. This paper introduces the Tradable Equity Credit (TEC) scheme, a novel market-based approach designed to incentivize transit agencies to enhance transportation equity while managing network demand and maximizing farebox revenue. The TEC scheme operates under a baseline-and-credit system, where transit agencies earn credits by surpassing equity targets and incur debts when they fall short. These credits are assigned monetary value and traded in an open market, providing financial incentives for agencies to adopt equity-focused policies without compromising revenue objectives. Unlike traditional subsidy programs, TEC dynamically allocates resources based on measurable equity improvements and promotes inter-agency collaboration. This paper develops a nonlinear programming (NLP) model to describe transit agencies' decision-making in the TEC market, integrating equity considerations into revenue management strategies considering heterogeneous travel demand. The model's equilibrium credit price is derived through Lagrangian dualization of the equity constraints and explored via variational inequality (VI) formulations. We propose a backpropagation-based iterative algorithm to solve the model efficiently. Case studies, including a real-world application in Sioux Falls, South Dakota, demonstrate the feasibility and effectiveness of the TEC framework. The findings show that TEC can serve as a revenue-neutral and scalable mechanism for improving transportation equity in public transit systems.

Co-Chair: Jimmy Zhang, 101 Main St, 47901

1 - A Modified Proximal Bundle Method Under Frank-Wolfe Perspective**Xu Sun, Massachusetts Institute of Technology, Cambridge, MA, United States, David Fersztand**

The proximal bundle method (PBM) is a fundamental and computationally effective algorithm for solving optimization problems with nonsmooth components. In this talk, we will present a theoretical investigation of a modified proximal bundle method, which we call the Modified Proximal Bundle with Fixed Absolute Accuracy (MPB-FA). MPB-FA modifies PBM in two key aspects. Firstly, the null-step test of MPB-FA is based on an absolute accuracy criterion, and the accuracy is fixed over iterations, while the standard PBM uses a relative accuracy in the null-step test, which changes with iterations. Secondly, the proximal parameter in MPB-FA is also fixed over iterations, while it is permitted to change in the standard PBM. These modifications allow us to interpret a sequence of null steps of MPB-FA as a Frank-Wolfe algorithm on the Moreau envelope of the dual problem. In light of this correspondence, we first extend the linear convergence of Kelley's method on convex piecewise linear functions from the positive homogeneous to the general case. Building on this result, we propose a novel complexity analysis of MPB-FA and derive an $O(\epsilon^{-4/5})$ iteration complexity, improving upon the best known $O(\epsilon^{-2})$ guarantee on a related variant of PBM. It is worth-noting that the best known complexity bound for the classic PBM is $O(\epsilon^{-3})$. Our approach also reveals new insights on bundle management.

2 - Primal-Dual Proximal Bundle and Conditional Gradient Methods for Convex Problems**Jiaming Liang, University of Rochester, Rochester, NY, United States**

This talk presents the primal-dual convergence and iteration-complexity of proximal bundle methods for solving nonsmooth problems with convex structures. More specifically, we develop a family of primal-dual proximal bundle methods for solving convex nonsmooth composite optimization problems and establish the iteration-complexity in terms of a primal-dual gap. We also propose a class of proximal bundle methods for solving convex-concave nonsmooth composite saddle-point problems and establish the iteration-complexity to find an approximate saddle-point. This talk places special emphasis on the primal-dual perspective of the proximal bundle method. In particular, we discover an interesting duality between the conditional gradient method and the cutting-plane scheme used within the proximal bundle method. Leveraging this duality, we further develop novel variants of both the conditional gradient method and the cutting-plane scheme.

3 - Nonopt: Nonconvex, Nonsmooth Optimizer**Frank E. Curtis, Lehigh University, Bethlehem, PA, United States, Lara Zebiane**

I will present my work with Lara Zebiane on an open-source C++ software package for solving locally Lipschitz minimization problems, primarily those involving objective functions that may be nonconvex and/or nonsmooth. The algorithms that are implemented in the software follow gradient-sampling and proximal-bundle methodologies. Quasi-Newton strategies with self-correcting properties play a central role in the algorithms' practical performance. In addition, a newly implemented interior-point subproblem solver greatly improves the scalability of software. I will discuss the various features of the software and present the results of numerical experiments on a variety of test problems.

4 - Linearly Convergent Algorithms for Nonsmooth Problems with Unknown Smooth Pieces**Jimmy Zhang, Purdue University, West Lafayette, IN, United States**

We propose efficient algorithms for optimizing piecewise smooth (PWS) functions, whose domain admits a finite (but unknown) partition into smooth pieces. When the objective function satisfies the quadratic growth condition, we propose a bundle level (BL) type [23] method to achieve global linear convergence. This appears to be the first global linear convergence result for any algorithm in the literature. We extend the method to handle approximately PWS functions and to solve weakly convex PWS problems, improving the current upper complexity bound by orders of magnitude to match that of smooth non-convex optimization. Moreover, we also propose the first verifiable and accurate termination criterion for optimizing the PWS function. Similar to the gradient norm for smooth optimization, it offers a tight characterization of the optimality gap under the strongly convex setting, and could be evaluated without the input of any problem parameters. A search subroutine for the certificate is developed, and we use it inside a guess-and-check scheme to improve the BL method to be almost parameter-free under both the strongly convex and the weakly convex settings.

Advances in Large-Scale Stochastic and Robust Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Anton Malandii, Stony Brook University, Stony Brook, 11790, United States

1 - Nonparametric Distributional Regression via Quantile Regression**Stanislav Uryasev, Stony Brook University, Stony Brook, NY, United States**

This paper estimates the distribution of a response variable conditioned on observing factors (features). We estimate the conditional quantile of the distribution as a mixture (weighted sum) of basis quantile functions with weights depending on factors. The suggested factor model has a closed-form expression. The calibration problem is reduced to conducting quantile regressions for all confidence levels simultaneously. However, the model does not suffer from "quantile crossing" by design. The calibration is equivalent to the minimization of Continuous Probability Ranked Score (CRPS). We prove asymptotic normality of the estimator. The approach allows for the application of neural networks for the calibration of the model. Numerical experiments demonstrated the high efficiency of the approach. In particular, we have used the factor model of mixtures for predicting horse-racing outcomes.

2 - Mean-Sensitivity Tradeoffs in Distributionally Robust Optimization**Jun-ya Gotoh, Chuo university, Bunkyo-ku, Tokyo, Japan, Michael Kim, Andrew Lim**

Distributionally Robust Optimization (DRO) is a worst-case approach to decision making when there is model uncertainty. Though formulated as a single-objective problem, we show that it is intrinsically multi-objective in that DRO solutions map out a near-Pareto-optimal frontier between expected cost and a robustness measure called worst-case sensitivity (WCS). We derive explicit expressions for WCS under common uncertainty sets, enabling a principled selection of uncertainty sets based on sensitivity control. More generally, this perspective provides a quantitative measure of robustness and a sensitivity-based approach to addressing important conceptual gaps in DRO—how to choose the family and size of uncertainty sets, and how this affects the solution.

3 - Proxstorm: a Stochastic Trust Region Algorithm for Nonsmooth Optimization**Aurya Javeed, Sandia National Laboratories, Albuquerque, NM, United States**

This talk is about minimizing a smooth term plus a convex nonsmooth term. We present a stochastic proximal Newton trust region algorithm that assumes models and estimates of the objective are sufficiently accurate, sufficiently often. Like STORM (work on stochastic optimization with random models), we use facts about martingales to prove our algorithm is globally convergent with probability one.

4 - Censored Feedback Learning for Stochastic Optimization**Zhengjia Zhuo, University of Michigan Ann Arbor, Ann Arbor, MI, United States**

Stochastic optimization traditionally assumes full knowledge of the underlying distributions, but in many real-world applications, these distributions are unknown and must be learned. We use a learning framework to address this shortcoming, where in each round the algorithm implements a policy and only observes samples from the selected random variables. In addition, we consider two practically motivated feedback models: censored feedback, where only values below the chosen thresholds are observed, and binary feedback, which indicates whether/not each realization exceeds its threshold. For both settings, we obtain a near-optimal regret bound as long as the stochastic problem satisfies a natural "monotone" property. Applications of our framework include fundamental problems such as single resource revenue management problem, prophet inequality and posted pricing.

5 - Adaptive Smoothing An Importance Sampling for Stochastic Optimization of the Conditional Value-at-Risk

Anton Malandii, Stony Brook University, Stony Brook, NY, United States

We present a novel method for solving conditional value-at-risk (CVaR) optimization problems based on the dual representation of CVaR. The algorithm is based on a Bregman proximal point algorithm and consists of alternating stochastic primal and dual stages. Every (inner) primal stage involves a subproblem solved by sampling from a probability distribution updated at each dual stage (outer iteration). The dual probability distributions relative to the distribution underlying the original problem converge to the risk identifier of the solution's CVaR. Thus, the dual probabilities provide the algorithm with a built-in importance sampling mechanism that draws from the tail of the underlying distribution. Because only samples in the tail influence the CVaR, and samples outside the tail are drawn with decreasing probability, the algorithm delivers exceptional performance over other stochastic approximation methods. We prove the algorithm's convergence for convex objective functions and present numerical evidence for solving non-convex problems.

Theory and Applications of Machine Learning and Optimization

Contributed Session

Contributed

Chair: Bhaskar Ray, North Carolina State University, Raleigh, NC, United States

1 - A New Mathematical Time Series Model: opt-ARIMAX

Yi-Hsuan Chu, Department of Information Management, National Chi Nan University, Nantou, Taiwan, Jing-Rung Yu, Chun-Yen Tsai, Donald Lien

Forecasting non-stationary and highly volatile financial data is critical for real-time trading and risk management, where delayed or inaccurate predictions can lead to substantial losses. The optimization-based autoregressive integrated moving average (Opt-ARIMA) method proposed by Bichescu and Polak (2023) uses a Haar wavelet transform and mathematical programming to isolate and retain white noise and automate lag terms. However, the forecasts tend to lag behind the actual data, limiting its ability to track trends accurately. To cope with this weakness, we propose an enhanced model called Opt-ARIMAX that integrates exogenous variables into the Opt-ARIMA model. This extension retains the core structure of ARIMA while improving responsiveness to real-time market changes. The Opt-ARIMAX model combines three key components: (i) using synchronous exogenous variables to capture rapid market shifts, (ii) incorporating forecast directional accuracy into the performance assessment offers a more interpretable metric, beyond conventional error measurements. Empirical results using 30-minute returns of the NASDAQ 100 indices and S&P 500 indices and corresponding index futures demonstrate that the Opt-ARIMAX offers a mathematically dynamic regression and interpretable forecasting approach. It consistently outperforms conventional ARIMA benchmarks, particularly during abrupt market regime shifts, while significantly enhancing predictive accuracy.

2 - From Vision to Optimization: AI Applications at Cargill

Madhushini Narayana Prasad, Cargill R & D, Houston/Minneapolis, TX, United States

Cargill, a global leader in food, agriculture, and industrial products, is leveraging the power of data science and artificial intelligence to drive innovation, efficiency, and sustainability across its diverse operations. In this session, we will explore how Cargill integrates cutting-edge AI technologies to solve complex business challenges and create value across the supply chain.

The presentation will begin with an overview of Cargill's mission and global footprint, followed by a deep dive into our data science strategy. We will showcase a series of project snippets that highlight the breadth and depth of our AI initiatives—from computer vision models that enhance food quality and safety, to time-series forecasting that optimizes supply chain logistics, to generative AI applications that streamline knowledge management and customer engagement, and mathematical optimization techniques that improve resource allocation and operational planning.

Attendees will gain insights into the practical deployment of AI in a global enterprise, the challenges of scaling data science solutions, and the collaborative culture that fuels innovation at Cargill. This session is ideal for data scientists, AI practitioners, and business leaders interested in real-world applications of AI in the food and agriculture industry.

3 - Dynamic Multi-Objective Optimization for Matching on a Crowdsourcing Platform

Weihang Ren, Walmart, Sunnyvale, CA, United States, Ou Sun, Hengchao Wang, Shanglin Zhou, Thomas Stiefel, Lijie Wan, Mingang Fu, Samuel Eldersveld

In this paper, we present a practical two-stage matching system designed to optimize driver-trip assignments on a crowdsourcing platform, addressing key operational challenges in real-time, multi-objective matching. Our system leverages a weighted-sum optimization approach that integrates driver preferences and efficiency constraints such as driver time-to-store to balance conflicting objectives. The platform's matching mechanism employs a flexible point-based scoring model to standardize and scale diverse metrics, enabling fair and effective comparison across objectives. Our findings highlight the system's adaptability to changing market conditions, resulting in enhanced operational efficiency and increased driver satisfaction. This applied approach offers valuable insights for scalable and adaptive matching algorithms in crowdsourced and on-demand service platforms. A switchback experiment was designed and implemented across diverse markets, revealing that our new matching system improved trip acceptance rates from 65.24% to 67.77% and matching effectiveness from 16.54% to 17.08%.

4 - Optimal Compensation Scheme when Salesperson's Environmental Knowledge is Limited: a Reinforcement Learning Simulation

Nanba Toshihiko, Kyoto University of Advanced Science, Kobe, Japan

This study revisits how firms should design sales incentives when launching a new product. Classic agency theory presumes that both the principal and the agent share, at least probabilistically, a common understanding of how effort converts into performance. At the outset of a new-product introduction, however, sales records are scant, and salespeople typically lack reliable knowledge of how their own effort will translate into revenue. We examine this information gap by embedding a reinforcement-learning algorithm within a single-period principal-agent framework. Concretely, we integrate a multi-armed bandit into the contract model and allow the salesperson to engage in soft-max exploration, progressively inferring the unknown effort-to-outcome mapping from experience.

The analysis delivers two main insights. First, relative to established products—where the effort–outcome relationship is already understood—it is profit-maximising for the firm to offer a higher commission rate for new products. Second, as learning proceeds and the salesperson refines their understanding of the underlying mapping, the optimal commission gradually converges toward the level used for existing products. These results provide a theoretical foundation for the widely observed managerial practice of offering generous launch commissions and then tapering them as market experience accumulates. The framework thereby links behavioural learning dynamics with optimal incentive design and enriches the toolbox for managing sales forces in uncertain, innovation-driven environments.

5 - Convex Clustering with Generalized Moreau Envelope Penalty

Zheming Gao, University of North Carolina Charlotte, Charlotte, NC, United States, ERIC CHI, Gal Mishne, Aaron Molstad, Chester Holtz

Convex clustering has attracted significant attention in unsupervised learning. In this research, we propose a novel convex nonconvex clustering model incorporating a generalized Moreau envelope (GME) penalty. Despite the nonconvexity introduced by the GME penalty, we establish an efficient parameter selection condition that ensures the overall convexity of the model. To solve the proposed formulation, we develop a fast forward-backward splitting algorithm. Numerical experiments on synthetic and benchmark datasets demonstrate the models effectiveness, showing advantages in clustering paths and key clustering metrics, including Adjusted Rand Index (ARI) and Variation of Information (VI). The proposed model provides reasonable and dominant clustering results in breast cancer subtype detection with TCGA data.

6 - Learning-at-Scale via RL-Enhanced Transformers and Decomposition

Seung Jin Choi, Virginia Tech, Blacksburg, VA, United States, Kimiya MohammadiJozani, Josh Cooper, Esra Buyuktahtakin Toy

This study introduces a novel Transformer-based deep learning framework for solving large-scale stochastic mixed-integer programs, with a focus on the Multi-item Capacitated Lot-Sizing Problem (MCLSP) under demand uncertainty. Our approach integrates Transformer architectures to predict optimal binary production decisions via supervised learning, followed by reinforcement learning (RL) fine-tuning that reduces infeasibility by penalizing constraint violations. To address scalability, we embed the Transformer within a decomposition framework that partitions the Single-item CLSP problem under uncertainty into a master problem and scenario-based subproblems. The model leverages Transformer parallelism to solve subproblems efficiently across multiple demand scenarios, while iterative cutting-plane generation maintains solution quality and feasibility. When integrated with the Gurobi solver, this hybrid approach significantly accelerates computation Gurobi alone, achieving near-zero optimality gaps and infeasibility rates post-RL tuning. Extensive computational experiments demonstrate that our Transformer-enhanced decomposition outperforms traditional Benders decomposition and direct MIP solvers in both speed and scalability. This work underscores the potential of combining deep learning with decomposition and cutting-plane techniques to solve complex stochastic combinatorial optimization problems at scale.

7 - L₁-Norm Regularized L₁-Norm Best-Fit Lines

Xiao Ling, Auburn University at Montgomery, Montgomery, AL, United States, James Brooks

We propose an optimization framework for estimating a sparse outlier-insensitive one-dimensional subspace. Our objective is to minimize both the representation error and a penalty on the loadings using an L₁-norm criterion for each. To our knowledge, computational methods for this pure L₁-norm formulation have not been previously proposed. Given that the problem is NP-hard, we introduce a linear relaxation-based approach. We present a novel fitting procedure, utilizing sortings of simple ratios. The proposed algorithm has a worst-case time complexity of $O(m^2 n \log n)$. We show that under certain circumstances, the method achieves global optimality. Compared to previously-proposed methods, the proposed algorithm often finds the subspace with the lowest discordance, and offers a smoother trade-off between sparsity and fit. We demonstrate the scalability with a parallel GPU implementation that provides a 16-fold improvement in computational speed for matrices of 2000x2000 over a serial CPU implementation. Furthermore, this method is distinguished by several advantages, including the lack of a need for initialization, and deterministic and replicable steps. An application to human microbiome data demonstrates the effectiveness of the algorithm in deriving meaningful and sparse solutions.

8 - Pace: Privacy Aware Collaborative Estimation for Heterogenous Glms

Bhaskar Ray, North Carolina State University, Raleigh, NC, United States, Srijan Sengupta, Aritra Mitra

With sensitive data collected across various sites, restrictions on data sharing can hinder statistical estimation and inference. The seminal paper on Federated Learning proposed Federated Averaging (FedAvg) to perform Maximum Likelihood estimation. However, FedAvg and other algorithms for parameter estimation can lead to erroneous estimation or fail to converge under model heterogeneity across sites. We propose a novel method of parameter estimation for a broad class of Generalized Linear Models with clusters of sites obtaining data based on the same distribution with possibly different values of the true parameters across clusters. It accounts for the uncertainty in the local ML estimator and that in the optimization algorithm iterates and leverages established concentration inequalities to provide non-asymptotic risk bounds. We conduct a hypothesis test-type classification based on one-shot estimation and utilize the inference to conduct a decentralized collaborative estimation, improving upon local estimation with high probability. We also prove asymptotic accuracy of the clustering algorithm and the consistency of the estimates. We validate our results with simulation studies.

Advances in Mixed-Integer Optimization for Power Systems

Invited Session

OPT: Integer and Discrete Optimization

Chair: Harsha Nagarajan, Los Alamos National Laboratory, Los Alamos, NM, United States

1 - Two-Stage Robust Optimization with Decision Dependent Uncertainty for Electric Vehicle Network Expansion

Haoxiang Yang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of

Electric vehicles (EVs) have taken over 20% of the new car sales globally. The rapid development of EVs requires expanding new charging stations, which would have a major impact on the operations of power systems. Establishing new charging stations affects EV users' behavior and determines the uncertainty of the charging demand. This talk discusses a two-stage robust optimization model for EV charging station expansion. The first stage decides the location and capacity of EV charging stations. We assume the random EV charging demand lies within a polyhedral uncertainty set, which depends on the first-stage decisions. Once the uncertain charging demand is realized, the second stage optimizes the power system operations with an optimal power flow problem. We show that such a two-stage robust optimization model can be reformulated as a mixed-integer linear program and propose a column-and-cut generation algorithm to solve this problem.

2 - Enforcing Binary Decisions in Time-Domain Optimal Switching of Power Grids

Amritanshu Pandey, University of Vermont, Burlington, VT, United States

Time-domain optimization problems are crucial for addressing operational challenges in power systems, particularly if the decisions are based on the grid's dynamic states. An important subset of these problems includes optimal switching of grid equipment in and out of service while satisfying dynamic AC network constraints. These problems include binary variables representing discrete decisions, such as equipment switching and protection operations, combined with nonlinear terms from grid physics, rendering them NP-hard mixed-integer nonlinear programs (MINLP). One such MINLP strategically allocates load-shedding locations during underfrequency load shedding (UFLS) events. Commercial optimization tools fail to handle such large-scale MINLP problems robustly, especially when the problem involves thousands of binary decision variables. We present a novel approach that reformulates the underlying MINLP problem into a nonlinear programming problem (NLP) by relaxing the binary variables. To enforce binary behavior within NLP, we incorporate a penalty term, transforming the problem into a concave minimization problem with multiple local minima, each potentially corresponding to feasible binary solutions, complicating the optimization trajectory. Therefore, initially, we add a weighted smoothing function to transform the original concave problem into near-convex optimization. Subsequently, following a homotopy approach, we solve a series of subproblems systematically canceling the smoothing term while incrementally introducing the penalty term to drive toward an integer feasible solution. We demonstrate the algorithm's efficacy by solving a time-domain optimization on power system dynamic models with around 6k+ binary decision variables and 180k+ non-linear equations, to select optimal load-shedding locations to arrest frequency decline during an underfrequency event.

3 - Tightening Quadratic Convex Relaxations for the Ac Optimal Transmission Switching Problem

Harsha Nagarajan, Los Alamos National Laboratory, Los Alamos, NM, United States, Cheng Guo, Merve Bodur

The Alternating Current Optimal Transmission Switching (ACOTS) problem enhances the AC Optimal Power Flow framework by incorporating line-switching decisions, enabling cost reductions and improved system reliability. However, ACOTS involves discrete variables and nonlinear, non-convex constraints, making it computationally challenging. In this work, we propose the tightest quadratic convex relaxation for ACOTS to date by introducing several new valid inequalities, including a novel class of on/off cycle-based polynomial constraints that leverage network structure. We linearize on/off trilinear terms using a theoretically tight extreme-point representation and embed the cycle-based constraints efficiently via disjunctive programming-based cutting planes. An optimization-based bound tightening (OBBT) procedure further tightens the relaxation. To accelerate solution times, we introduce a heuristic based on a maximum spanning tree that fixes a subset of lines to remain active. Extensive

experiments on medium-scale PGLib instances show substantial improvements in relaxation bounds, while large-scale tests (up to 2,312 buses) demonstrate significant performance gains. To our knowledge, this is the first ACOTS relaxation framework to achieve near-optimal switching solutions on realistic, large-scale power grid models.

4 - Second-Order-Cone Formulations of Power Flow for Topology Optimization

Noah Rhodes, Los Alamos National Laboratory, Los Alamos, NM, United States, Jim Luedtke, Line Roald

Optimization problems that involve topology optimization in scenarios with large scale outages, such as post-disaster restoration or public safety power shutoff planning, are very challenging to solve. Using simple power flow representations such as DC power flow or network flow models results in low quality solutions which requires significantly higher-than-predicted load shed to become AC feasible. Recent work has shown that formulations based on the Second Order Cone (SOC) power flow formulation find very high quality solutions with low load shed, but the computational burden of these formulations remains a significant challenge. With the aim of reducing computational time while maintaining high solution quality, this work explores formulations which replace the conic constraints with a small number of linear cuts. The goal of this approach is not to find an exact power flow solution, but rather to identify good binary decisions, where the power flow can be resolved after the binary variables are fixed. We find that a simple reformulation of the Second Order Cone Optimal Power Shutoff problem can greatly improve the solution speed, but that a full linearization of the SOC voltage cone equation results in an overestimation of the amount of power that can be delivered to loads.

5 - Sparse Neural Approximations for Bilevel Adversarial Problems in Power Grids

Young-Ho Cho, The University of Texas at Austin, Austin, TX, United States, Mohamad Chehade, Hao Zhu

The adversarial worst-case minimum load shed (MLS) problem is pivotal for identifying critical power system contingencies under line failures. This challenge is represented as a bilevel optimization problem, where the upper level simulates an attacker determining line failures, and the lower level corresponds to the defender's generator redispatch operations. However, standard reformulation techniques using optimality conditions render the bilevel, mixed-integer formulation computationally prohibitive due to the exponential growth of candidate topologies and the non-convex nature of AC power flow physics. To address these challenges, we propose a data-driven approach that replaces conventional reformulation methods with a novel value function-based neural network (NN) model. By leveraging a sparsified, area-based partitioning of its architecture constructed via spectral clustering, the NN size is made to scale linearly with system size without compromising its accuracy in load-shed predictions. Embedding the trained NN, that approximates the value function, as a mixed-integer linear program (MILP) transforms the adversarial worst-case MLS problem into a single-level reformulation, and enables near-optimal solutions with significant computational gains. Notably, our approach ensures accurate solutions across different loading conditions, facilitating the rapid online recomputation of worst-case failures during operations. Numerical experiments on the IEEE 14- and 118-bus systems demonstrate the method's scalability and solution quality for large-scale contingency analysis, an average optimality gap of 5.8% and a maximum gap below 22.3% compared to conventional methods, while maintaining computation times under one minute.

1 - Geopro-Net: Learning Interpretable Spatiotemporal Prediction Models Through Statistically-Guided Geo-Prototyping

Bang An, University of Akron, Akron, OH, United States, Xun Zhou, Ronilo Ragodos

The problem of forecasting spatiotemporal events such as crimes and accidents is crucial to public safety and city management. Besides accuracy, interpretability is also a key requirement for spatiotemporal forecasting models to justify the decisions. Interpretation of the spatiotemporal forecasting mechanism is, however, challenging due to the complexity of multi-source spatiotemporal features, the non-intuitive nature of spatiotemporal patterns for non-expert users, and the presence of spatial heterogeneity in the data. Currently, no existing deep learning model intrinsically interprets the complex predictive process learned from multi-source spatiotemporal features. To bridge the gap, we propose GeoPro-Net, an intrinsically interpretable spatiotemporal model for spatiotemporal event forecasting problems. GeoPro-Net introduces a novel Geo-concept convolution operation, which employs statistical tests to extract predictive patterns in the input as Geo-concepts, and condenses the Geo-concept-encoded input through interpretable channel fusion and geographic-based pooling. In addition, GeoPro-Net learns different sets of prototypes of concepts inherently, and projects them to real-world cases for interpretation. Comprehensive experiments and case studies on four real-world datasets demonstrate that GeoPro-Net provides better interpretability while still achieving competitive prediction performance compared with state-of-the-art baselines.

2 - Lonely Voices Online: Predictive Inference of Loneliness Behaviors from Social Media Using Decoder-Based LLMs

Jiyuan Yu, University of Iowa, Iowa city, IA, United States

Loneliness is deeply connected to a range of mental health conditions, including depression, anxiety, and suicidal ideation. As digital platforms become a primary space for emotional expression, social media provides a rich but underutilized source for understanding psychological distress at scale. However, existing computational approaches often rely on simple binary classification—determining whether a post reflects loneliness—while lacking interpretability and contextual reasoning.

This study introduces a novel inference pipeline that leverages decoder-based large language models (LLMs) to enhance both the detection and explanation of loneliness expressions in social media posts. Our method combines zero-shot and few-shot prompting strategies to classify user-generated content while simultaneously generating natural language rationales that explain why loneliness is inferred. This dual capability enables more transparent, interpretable, and empathetic assessments of online discourse.

By moving beyond black-box predictions, the proposed framework offers a scalable and minimally supervised solution for early identification of emotional distress. It holds potential applications in digital mental health monitoring, user experience design, and platform-level interventions. Our work demonstrates how LLMs can serve as both predictors and interpreters of complex psychological phenomena in online environments, contributing to the development of socially aware and ethically aligned AI systems.

3 - How Does XAI Improve Medical Diagnostic Effectiveness? Mechanisms and Methods

Dongqi Wang, Zhejiang University, Hangzhou, China, People's Republic of, Weihua ZHOU

This study examines how explainable artificial intelligence (XAI) improves diagnostic effectiveness in clinical decision-making. We first develop and empirically validate a theoretical framework grounded in two key mechanisms: perceived trust and mental model alignment. Specifically, we distinguish between two forms of alignment—Human-to-AI mental model alignment, and AI-to-Human mental model alignment. Through a controlled experiment in transfusion medicine, we demonstrate that both trust and alignment are necessary to improve the quality of human-AI collaboration.

Building on this insight, we propose a novel XAI method that aligns directly with the reasoning paradigm of evidence-based medicine. Rather than emphasizing abstract feature attributions, our approach retrieves and presents similar historical cases to support clinical decisions—mirroring how physicians reason through precedent and evidence. To enhance clinical relevance, the method leverages a large language model to distill patient context and identify the most comparable case from the historical database.

We term this approach the Retrieval Augmented Tree (RAT). By grounding AI predictions in case-based explanations that reflect medical reasoning practices, RAT facilitates intuitive understanding, fosters trust, and improves diagnostic performance—without requiring clinicians to engage with technical model internals. Together, our findings highlight both the mechanisms through which XAI enhances clinical decision-making and a practical, cognitively aligned method for its implementation in real-world healthcare.

4 - Leveraging Graph Neural Networks and Language Models for Personalized Occupation Recommendation

Yikang Wang, University of Iowa, Iowa City, IA, United States

Effective job matching requires aligning a candidate's knowledge, skills, abilities (KSAs), and motivations/interests (MIs) with occupational requirements. Traditional approaches relying solely on keyword matching often neglect nuanced motivational factors, leading to suboptimal career decisions. In this study, we propose an innovative recommendation framework that integrates large language models (LLMs) with graph neural networks (GNNs) to provide holistic job recommendations. Specifically, we utilize O*NET occupational descriptions—comprising both skills and interests—to generate semantic embeddings via a pretrained Transformer model. Occupations are connected based on semantic similarity to form a homogeneous occupation graph. Candidate resumes are similarly embedded into this latent space, naturally capturing their KSAs and MIs. A GNN then propagates information through this graph, refining occupation and candidate representations. Finally, personalized occupation recommendations are generated by comparing embeddings in the learned space. Preliminary results demonstrate that our framework significantly improves recommendation quality and interpretability compared to conventional keyword-based methods, highlighting the potential of combining structured occupational data with advanced embedding techniques for personalized career guidance.

1 - Shift Effect and Its Impact in EDs: From Analytical Insights to Empirical Validation

Parvin Malekzadeh, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Dmitry Krass, Opher Baron, Simai He, Hongsong Yuan, Arik Senderovich

The “shift effect” in healthcare arises when patients require at least two interactions with the physician (service provider), and the provider's priorities shift depending on timing within their shift. A common instance occurs in emergency departments (EDs), where patients undergo an initial physician assessment (PIA), followed by diagnostic tests, and then a second reassessment (“disposition”). Physicians working fixed-length shifts often aim to complete care for all patients they assessed before their shift ends—driven by compensation incentives and continuity-of-care concerns. This leads to a prioritization of new patients early in the shift and in-system patients toward the end. However, this behavior may increase both the average and variability of patient waiting times, contributing to ED overcrowding. While anecdotal evidence for the shift effect is widespread, analytical investigations into its existence and impact have been limited. We address this gap through two approaches. First, a stylized queueing model shows that physicians seeking to maximize completed services naturally shift priorities over time, providing theoretical support for the shift effect. Second, using real ED data and our SiMLQ platform—an ML-based automated queueing simulator—we conduct counterfactual analysis to estimate its impact on key performance metrics, including Time to Physician Initial Assessment (TPIA) and total ED Length of Stay (EDLOS). Our findings reveal that the shift effect can significantly delay TPIA and increase EDLOS, affecting both average values and the 90th percentile. We conclude with some potential strategies to mitigate the impact of the shift effect.

2 - A 2-Stage Stochastic Programming Scheme for Online Facility Location Problems in Drone Delivery Systems

Kai Zhou, Tsinghua University, Beijing, China, People's Republic of, Michael Lingzhi Li, Kai Wang

This study addresses facility location problems in the context of drone delivery systems, which involves multiple stations and demand locations. Drones are deployed at selected stations to serve demand locations, with service time varying based on the distance between stations and demand locations. Each demand location has two attributes: demand level (indicating required service instances) and time-dependent service success probability (p-value). The p-values are heterogeneous across locations and time intervals, often initially unknown or uncertain, which exist in the objective of maximizing the sum of expected successful services across all agents. To handle the uncertainty in p-values, the problem is formulated as a combinatorial multi-armed bandit (CMAB) problem. Here, each agent servicing a demand location at a specific time represents a base arm, while the collective allocation strategy forms a super arm. In this paper, we develop a two-stage stochastic programming scheme to iteratively explore p-values and exploit optimal locations. To deal with the curse of dimensionality, we propose a novel grouping-based estimation algorithm that enhances computational efficiency while keeping the optimality gap below 5% generally. Experimental results demonstrate that this approach consistently outperforms baseline methods in balancing exploration-exploitation trade-offs and minimizing cumulative regrets. The framework effectively addresses dynamic environments where success probabilities require adaptive estimation through strategic sampling and allocation adjustments.

3 - Strategic Behavior and Uncertainty in Allocation Markets: Insights from Online Experiments

Moran Koren, BGU, Beer Sheva, Israel

We examine strategic behavior in allocation markets through three large-scale online experiments that isolate informational incentives from other effects. We investigate how individuals navigate tensions between private signals and collective decision-making across different market mechanisms. Our primary experiment (N=1,368) tests crowdfunding mechanisms in static contexts, varying signal accuracy (55% vs. 85%), group size (5 vs. 25), and participation thresholds (50% vs. 80%). Results confirm crowdfunding mechanisms induce distinct strategic behaviors compared to voting, with participants significantly less likely to follow private signals (odds ratio: 0.141, $p < 0.001$). We observe **risk aversion** and **mutual insurance**. Higher signal accuracy decreases risk aversion but increases mutual insurance reliance, validating theoretical predictions. However, contrary to theory, higher thresholds amplify risk aversion, suggesting cognitive constraints interact with strategic considerations unexpectedly. <Additional experiments examine competitive timing in organ allocation markets and herding versus delegation effects in sequential decision-making, providing complementary insights into strategic behavior across allocation contexts. Our findings advance theory by: (1) empirically validating pure informational effects in strategic behavior, (2) identifying systematic deviations highlighting cognitive limitations, and (3) demonstrating differential information aggregation across mechanisms. Crowdfunding shows comparable performance to voting under low signal accuracy but deteriorates significantly as signal quality improves. For practitioners, results offer insights for platform design around threshold mechanisms and information provision. The systematic relationship between mechanism parameters and strategic behavior suggests market designers must consider cognitive and psychological factors alongside economic incentives, with implications for crowdfunding platforms, organ allocation systems, and other collective decision markets.

4 - From Restless to Contextual: a Thresholding Bandit Approach to Improve Finite-Horizon Performance

Jiamin Xu, Cornell University, Ithaca, NY, United States, Ivan Nazarov, Aditya Rastogi, Africa Perianez, Kyrá Gan

Online restless bandits extend classic contextual bandits by incorporating state transitions and budget constraints, representing each agent as a Markov Decision Process (MDP). This framework is crucial for finite-horizon strategic resource allocation, optimizing limited costly interventions for long-term benefits. However, learning the underlying MDP for each agent poses a major challenge in finite-horizon settings. To facilitate learning, we reformulate the problem as a scalable budgeted thresholding contextual bandit problem. We carefully integrate the state transitions into the reward design and focus on identifying agents with action benefits exceeding a threshold. We establish the optimality of an oracle greedy solution in a simple two-state setting, and propose an algorithm that achieves minimax optimal constant regret in the online multi-state setting with heterogeneous agents and knowledge of outcomes under no intervention. We numerically show that our algorithm outperforms existing online restless bandit methods, offering significant improvements in finite-horizon performance.

5 - Solving for Welfare, Fairness, and Feasibility: Modern Computational Methods for the U.S. Organ Transplant System

Elijah Pivo, MIT, Somerville, MA, United States, Maura Hegarty, Thomas Athey, Nikolaos Trichakis, Dimitris Bertsimas

The U.S. organ transplant system has long contended with the challenge of fairly and effectively allocating an insufficient supply of transplantable organs. A national organ allocation policy defines how patients are prioritized for each donated organ. However, understanding the implications of an allocation policy, much less designing one capable of improving the system, is a formidable task. The waitlist consists of over 100,000 individuals spread across the country with compatible donor pools that vary drastically, each transplant involves complex and time-critical logistics, and policy changes may influence how patients and transplant centers judge transplant offers. This talk will focus on new analytical tools our group has been developing in partnership with UNOS and the OPTN, the main organizations that manage the national transplant system, in order to better support policymakers. These tools include clinical, logistical and behavioral models, a high-speed transplant system simulator, and multi-objective policy optimization. Together, these methods represent a major advance in the computational methods available for the design of organ allocation policy and an opportunity to improve the system for hundreds of thousands of patients.

1 - Using AI for Mental Health Treatment

Jingyuan Hu, UCLA Anderson School of Management, Los Angeles, CA, United States, Yican Liu, Junyou Chen

Can AI serve as a meaningful substitute for human psychologists, and how might it be integrated into everyday mental health care? We study these questions through a series of field experiments evaluating the use of an AI therapist and its broader behavioral and economic implications. In collaboration with a college population, we introduce an AI-based mental health tool, guide students through its use, and track their interactions and self-reported mental health over time. In the short run, we examine engagement and conversational patterns; in the longer run, we ask whether users develop emotional reliance on the AI and how it affects their help-seeking behavior.

2 - The Effect of Ambulance Response TIME on No-Show Behavior of Patients

Mohammadmahdi Tahergandomabadi, University of Texas at Dallas, Dallas, TX, United States, Behrooz Pourghannad, Guihua Wang, Nancy Wang

Ambulance response time is a critical performance metric in emergency medical services (EMS), with direct implications for patient outcomes and system reliability. While efforts often focus on improving speed, less is known about how response delays influence patient behavior during the wait. This study examines how ambulance response time affects the likelihood of a caller's no-show before the ambulance arrives. Using detailed operational data from a metropolitan EMS provider, we estimate the causal impact of response time on caller disengagement through an instrumental variable regression that accounts for endogeneity. After controlling for incident characteristics and location, we find that longer response times significantly increase the likelihood of caller no-show.

We also explore heterogeneity in delay sensitivity across patients with different characteristics. Older individuals and those located farther from emergency rooms show higher tolerance for delays, while younger patients are more likely to disengage. Notably, patients with more severe conditions are less patient to delays, exhibiting greater urgency and a higher likelihood of seeking alternatives when wait times are prolonged. These findings highlight the behavioral consequences of operational delays in EMS systems and offer implications for triage design, resource allocation, and targeted communication strategies aimed at reducing caller no-shows.

3 - The Double-Edged Effects of Extended Training Policies: Staffing Gains and Care Disruptions in Nursing Homes

Minyu Ye, University of Illinois Urbana-Champaign, Champaign, IL, United States, Yixin Iris Wang

In response to persistent nursing shortages in U.S. nursing homes, the federal government enacted a time-limited nurse aides in training (NAs) waiver policy. This regulation permitted nurse aides in training to remain in the workforce beyond standard 4-month certification deadlines. Although the policy aims to stabilize staffing level and improve care quality, we identify several unintended consequences that come from changes in staffing composition and care delivery. We find that although the policy increases the staffing levels of total nurse aides and improves behavioral oversight, as reflected by increased rating matrix and reduced use of antipsychotic medications, it also leads to a higher ratio of new NAs to certified nurse aides (CNAs), which negatively influences functional care. Specifically, the increased presence of new nurse aides in training disrupts consistent care routines, leading to greater reliance on catheters and wheelchairs, which in turn contributes to declines in residents' independent mobility. We also find that the policy induced greater CNA coworker variability, which leads to less efficient care in tasks that require teamwork, such as two-person mobility support and regular toileting assistance. Our results suggest that while staffing interventions can improve behavioral oversight, they may undermine functional care unless staffing schedules and team structures are adjusted accordingly. This study highlights the importance of anticipating both benefits and trade-offs when designing policies to address workforce shortages in long-term care settings.

4 - Fairness in Priority-Based Decisions with Imperfect Classification

Zhiqiang Zhang, The University of Chicago Booth School of Business, Chicago, IL, United States, Pengyi Shi, Amy Ward

We study priority-based admission decisions under the assumption that machine learning (ML) algorithms are used to generate priority scores that predict latent (unobserved) features. For instance, in the criminal justice setting—our original motivation for this work—ML algorithms predict an individual's risk of committing another crime, which can inform decisions about admission to rehabilitation programs during sentencing. As another example, in the healthcare context, ML algorithms predict a patient's underlying health condition, guiding ICU admission decisions. Under a priority-based policy, fairness can be defined in various, often conflicting ways: from the ML perspective, it includes notions such as statistical parity, predictive parity, and error rate balance; from the operations management (OM) perspective, it involves equitable allocation of limited resources. To investigate the trade-offs between fairness and efficiency, we impose various (potentially relaxed) fairness criteria and analyze their impact on admission decisions.

Improving Access in Healthcare Systems: Incentives and Efficiency

Invited Session

MSOM: Healthcare

Chair: Houyuan Jiang, University of Cambridge, Cambridge, United Kingdom

1 - An Exploratory Study on How to Manage and Reduce Cancer Waiting Lists: A Queueing Approach

Xinran Hao, University of Cambridge, Cambridge, United Kingdom, Houyuan Jiang, Feryal Erhun

In the United Kingdom (UK), prolonged waiting lists for cancer treatment remain a significant challenge, with over 26,000 patients awaiting their first treatment as of November 2024. Only 69.4% of these patients received treatment within the targeted 62-day window, underscoring the urgency of timely intervention. Delays in cancer treatment can have severe consequences on survival rates, making effective management of patient flow essential. To address these challenges, we develop a queueing network model with dynamic customer types to analyze the cancer treatment pathway. Using fluid approximations of a stochastic queueing network, we derive closed-form solutions for the number of patients at each phase over time and in equilibrium, demonstrating the global asymptotic stability of the system. These analytical

solutions allow us to assess the impact of various strategies on patient abandonment rates and transitions from early to late cancer stages. A key insight from our analysis is the identification of critical capacity thresholds in congested systems. We reveal that adding capacity does not always shorten waiting times; below these thresholds, additional capacity can paradoxically increase waiting times, highlighting crucial implications for managing service systems. Our findings offer practical guidance for optimizing capacity expansion to reduce backlogs and improve early treatment rates for cancer patients.

2 - Information Disclosure, Performance Incentives and Quality Competition In Healthcare Markets

Zhan Pang, Purdue University, West Lafayette, IN, United States

Healthcare markets face persistent challenges stemming from imperfect quality information and complex interactions between payers, providers, and patients. Policymaker have been advocating three key policy instruments to improve quality of and access to care: (1) information disclosure (e.g., public reporting), (2) performance incentives (e.g., pay-for-performance), and (3) quality competition. Yet the interactions between these mechanisms remain poorly understood. Grounded in principal-agent theory and stochastic queuing dynamics, this study bridges this gap by analyzing how these policy instruments interplay to shape outcomes in healthcare markets, particularly hospital quality investments and patient choice. Our analysis reveals strategic provider responses to competing policy pressures, patterns in patient choice, and emergent system dynamics, and when these instruments complement or substitute each other. These results demonstrate that the policy effectiveness depends crucially on proper coordination. The findings provide practical guidance for designing policy portfolios that account for both provider quality improvement incentives and patient choice.

3 - The NHS Blended Payment Scheme: Incentive Issues and Optimal Reform

Kenan Arifoglu, UCL School of Management, London, United Kingdom, Sara Mohammadi, Bilal Gokpinar

The National Health Service (NHS) in England introduced the blended payment scheme for emergency care in 2019, as a mixed prospective payment model that combines fixed lump-sum payments under block contracts with variable activity-based payments under Payment by Results (PbR). Under this scheme, hospitals receive a fixed lump-sum payment at the start of the year based on their planned activity or readiness, and a variable payment at year-end that adjusts for differences between planned and actual activity, scaled by a variable rate but capped by break-glass provisions that limit extreme financial adjustment. We develop a game-theoretic model to analyze hospitals' treatment cost and planned activity decisions under the blended payment, considering information asymmetry between hospitals and regulator. Our analysis shows that while the blended scheme improves upon block contracts and PbR, it fails to fully align hospital incentives for cost reduction and readiness. We identify three key limitations: (i) information asymmetry makes it difficult for the regulator to set the appropriate variable rate, (ii) break-glass provisions may weaken hospital incentives for readiness, and (iii) hospitals may face long-term budget deficits. To address these issues, we propose a modified blended payment that retains the fixed payment but reforms the variable payment by: (i) setting the variable rate at 100%, (ii) adjusting payments based on deviations from average actual activity across hospitals rather than each hospital's own actual activity, and (iii) eliminating break-glass provisions. Our proposed payment model aligns hospital behavior with the social optimum and ensures a balanced long-term budget.

4 - Horizontal Consolidation in Healthcare Markets: Can Performance Incentives Preserve Access to Care?

Houyuan Jiang, University of Cambridge, Cambridge, United Kingdom, Zhan Pang, Sergei Savin

We study the effects of hospital consolidations on access to care in a competitive healthcare market in the presence of performance incentives. We consider a transition from a "pre-merger" market configuration where a payer delegates services to a market with two competing hospitals to a "horizontally consolidated" configuration under which the same entity manages two hospitals. We focus on two research questions: How should the payer set access-based performance incentives in response to a horizontal market consolidation? What are the effects of consolidation on patient access to care? We consider contracts where hospital compensation for delivering care includes a combination of fee-for-service payments and bonus components tied to the level of access to care patients receive. We derive the optimal bonus-type contracts that the payer can use to adapt to changes in market concentration, and we quantify the resulting impact on patient access to care and social welfare. In our analysis, we consider two alternative settings: the "fixed-FFS" setting, where the fee-for-service component cannot be altered, and the "flexible-FFS" setting, where both the fee-for-service and the bonus components can be adjusted in response to changes in the market composition. Our analysis shows that the bonus-type performance incentives provide payers with the ability to protect patient access to care upon hospital consolidation in a wide range of problem settings, provided that the intensity of competition between the hospitals is sufficiently strong. If, otherwise, the intensity of competition is relatively weak, horizontal consolidation may compromise access to care.

1 - Chief Sustainability Officers and Environmental Injustice: An Empirical Evaluation

Finn Petersen, Indiana University, Bloomington, IN, United States, Vibhuti Dhingra, Rachna Shah

Manufacturing facilities emit disproportionately high levels of toxic releases in underserved communities, exposing Black or African American populations to significant health risks, a phenomenon known as "environmental injustice." We study whether a firm governance reform, specifically, the appointment of a Chief Sustainability Officer (CSO), can reduce this disparity.

Using data on toxic releases from U.S. manufacturing facilities between 2000 and 2020, we find that facilities whose parent firms appoint a CSO reduce toxic emissions by up to 12% following the appointment. To identify causal effects, we employ a two-way fixed effects regression with matching, and conduct extensive robustness tests to rule out alternative explanations. We show that facilities in underserved communities experience greater reductions in toxic releases after CSO appointments, which reduces environmental injustice. This effect is driven, at least in part, by increased implementation of source reduction activities and the implementation of waste management processes by the treated facilities.

Our work sheds new light on how corporate governance reforms act as a control mechanism for addressing environmental injustice, an issue that has proven challenging to regulate effectively.

2 - Unveiling Operational Processes: The Impact of Real-Time Videos on Operational Outcomes

Zhanzhi Zheng, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Yuqian Xu, Bradley Staats

In the digital age, merchants are presented with an expanding range of resources to enhance operational transparency for customers. Moreover, the digital marketplace increasingly demands improved transparency due to the physical separation between merchants and customers. This paper explores a new method to enhance operational transparency for merchants on digital platforms: displaying real-time videos of their operational processes. Using a unique dataset about chain restaurants on a leading food delivery platform in China, we employ the difference-in-differences method with matching techniques for empirical analyses. Our results show that the display of real-time videos indeed improves restaurants' operational performance on the platform, including demand, customer average spending per order, and revenue. Furthermore, we find that reducing information asymmetry could be a key mechanism driving the positive effects of real-time videos. Specifically, these benefits are more pronounced for restaurants with less available information on the platform, such as those with fewer online reviews or lacking the premier label. Additionally, by leveraging advanced computer vision algorithms, we analyze the performance impact of key features in real-time videos through image mining, focusing on both the quality and content of the visual information that customers observe. Our findings indicate that both image quality and region of interest coverage play a crucial role in

enhancing the benefits of operational transparency. Specifically, we identify four key image attributes and operational areas detected in the videos, each significantly contributing to these benefits, though their impacts vary in magnitude.

3 - Improving Decision-Making in Resource Allocation: Evidence from Inpatient Admission Decisions

Harriet Jeon, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States, Song-Hee Kim, Hummy Song

Routing mechanisms are crucial for efficiently matching specialized resources to customer needs at the lowest cost. Improving allocation, then, is of first-order concern for many organizations. But when human decision-makers are tasked with allocation in a complex environment, it can be challenging to understand their decision processes and design systems that enhance their decision quality. Leveraging rich data derived from electronic medical records, we explore how, in the context of physicians making routing decisions of patients from the ED to inpatient medical units, decision-makers incorporate new information and adapt their decision-making processes.

4 - Crisis at the Core: Examining the Ripple Effects of Critical Incidents on Emergency Department Physician Productivity and Work Style

Lesley Meng, Yale School of Management, New Haven, CT, United States, Huifeng Su, Rohit Sangal, Edieal Pinker

Using the Emergency Department (ED) as a service setting, we study the impact of disruptive critical incidents (CIs) on worker productivity. Prior studies on CIs and worker performance predominantly focus on work environments with sequential task ordering and limited decision complexity. Since CIs occur daily in EDs but remain understudied from an operational perspective, we examine the impact of CIs in a setting with high degrees of multitasking and complex decision-making. We utilize four years of electronic medical records and administrative data from a large U.S. hospital and employ a difference-in-differences approach to analyze the impacts of CIs on worker behavior. Contrary to prior findings suggesting that CI exposure decreases worker productivity, our analysis reveals no significant reduction in the total number of patients signed and disposed of during shifts involving CIs. Physicians achieve this by working overtime, increasing reliance on diagnostic orders to facilitate decisions, and engaging in more parallel processing. However, patients discharged to home by CI-exposed physicians are 11.7% more likely to revisit the ED within seven days.

1 - Robustness in Adversarial and Non-Adversarial Environments

Arunesh Sinha, Rutgers University, Piscataway, NJ, United States

Robustness to adversaries (adversarial) and environment (stochastic) is important for high stakes decision-making. In this talk, I will present two recent works on robustness against adversaries and environment. The first proposes a defense in Reinforcement Learning, where policies are highly susceptible to adversarial noise in observations. The challenge inherent to adversarial perturbations is that by altering the information observed by the agent, the state becomes only partially observable. Existing approaches fail to account for partial observability directly; we introduce a novel objective called Adversarial Counterfactual Error (ACoE), defined on the beliefs about the true state and balancing value optimization with robustness. To make ACoE scalable in model-free settings, we propose the theoretically grounded surrogate objective Cumulative-ACoE. Our method significantly outperforms current state-of-the-art approaches. The second work explores robustness to uncertain time horizon in Markov Chains, which leads to uncertainty about the cost incurred based on the state distribution when the system stops. This is critical when one needs to estimate costs within finite wall clock time. Given past data samples of how long a system ran, we theoretically analyze a distributional robust cost estimation task in a Wasserstein ambiguity set. Towards this, we show an equivalence between a discrete-time Markov Chain on a probability simplex and a global asymptotic stable (GAS) discrete-time linear dynamical system, allowing us to base our study on a GAS system only. We provide various polynomial time algorithms and hardness results for different cases in our study, including a fundamental result about Wasserstein distance based polytope.

2 - Robust Optimization with Diffusion Models for Green Security

Lingkai Kong, Harvard University, Boston, MA, United States

In green security, defenders must forecast adversarial behavior, such as poaching, illegal logging, and illegal fishing, to plan effective patrols. These behaviors are often highly uncertain and complex. Prior work has leveraged game theory to design robust patrol strategies to handle uncertainty, but existing adversarial behavior models primarily rely on Gaussian processes or linear models, which lack the expressiveness needed to capture intricate behavioral patterns. To address this limitation, we propose a conditional diffusion model for adversary behavior modeling, leveraging its strong distribution-fitting capabilities. To the best of our knowledge, this is the first application of diffusion models in the green security domain. Integrating diffusion models into game-theoretic optimization, however, presents new challenges, including a constrained mixed strategy space and the need to sample from an unnormalized distribution to estimate utilities. To tackle these challenges, we introduce a mixed strategy of mixed strategies and employ a twisted Sequential Monte Carlo (SMC) sampler for accurate sampling. Theoretically, our algorithm is guaranteed to converge to an epsilon equilibrium with high probability using a finite number of iterations and samples. Empirically, we evaluate our approach on both synthetic and real-world poaching datasets, demonstrating its effectiveness.

3 - A Global Multi-Echelon High-Tech Supply Chain Network Equilibrium Under Trade-War Export Sanctions

Ting Zan, University at Buffalo, Buffalo, NY, United States

Export sanctions (ESs) have become prominent trade policies amid heightened geopolitical tensions, reshaping international trade and cross-border supply chain networks (CSCNs). This study investigates how ES affects firm-level decision-making and evaluates the effectiveness of government-subsidized research and development (R&D) innovations in mitigating these impacts. We first develop a comprehensive network equilibrium model that involves multiple suppliers, manufacturers, and demand markets in both Bertrand and Cournot competition. Subsequently, we derive equilibrium conditions using variational inequality theory, establish their qualitative properties, and implement the Euler algorithm to solve the model numerically. Extensive numerical experiments based on real-world scenarios illustrate that ES impacts vary significantly according to the network structure, geographical region, supply chain layer, and market parameters. Although R&D innovation does not entirely offset supply chain disruptions, it effectively mitigates the adverse effects of ES in targeted regions. Furthermore, our findings indicate conditional misalignment in preferences regarding R&D outcomes among suppliers, manufacturers, and government entities.

1 - From Knowledge to Open Innovation: Unlocking Circular Economy Potential in Smes Through Intellectual Capital and CSR

Bilal Iftikhar Makki, University of science and technology of China, Hefei, China, People's Republic of, Nabeel Rehman, feng feng

The transition from a linear "take-make-waste" approach to a circular economy is no longer an option but a need for sustainable economic development.

However, for SMEs in developing economies, this transformation is challenging. Overcoming the challenges requires a strategic approach like open innovation, a key enabler of circular economy principles for sustainable value creation. This study examines how knowledge management impacts open innovation through the sequential role of intellectual capital and corporate social responsibility. Additionally, it explores the moderating role of organizational and employee-level behavioural factors, such as resource efficiency practices and employee readiness for organizational change. Data was collected from 402 employees working in SMEs within the manufacturing sector of a developing country. The study employed partial least squares structural equation modeling (PLSSEM) to test the hypothesized relationships. The results confirm that knowledge management significantly influences intellectual capital and CSR, both of which sequentially enhance open innovation. Additionally, resource efficiency moderates the relationship between intellectual capital and open innovation but not between CSR and open innovation. Conversely, employee readiness for change moderates the CSR-open innovation relationship but does not moderate the intellectual capital-open innovation relationship. This research presents a novel contribution by combining knowledge management, intellectual capital, corporate social responsibility, and behavioral elements within a single framework, particularly regarding small and medium-sized enterprises in developing countries. It emphasizes the sequential and moderating factors that influence open innovation, providing practical recommendations for companies seeking to shift towards sustainable and resource-efficient practices

2 - Long-Term and Intra-Day Learning and Forgetting in Gig Work: Evidence from Online Grocery

Reeju Guha, CUNEF University, Madrid, Spain, Daniel Corsten, Maqbool Dada

Online platforms operating on a gig-contractor model rely on self-scheduling gig workers to meet real-time demand, while maintaining the desired productivity and service quality levels. In a gig-work setting, learning takes place primarily through task repetition and familiarity with the work environment. A factor that can deter learning in this setting is gaps in the continuity of service. Since gig workers can choose when and for how long to work, there is a high likelihood that service gaps lead to 'forgetting'. Drawing from theories of learning and forgetting, we investigate whether intra-day experience can mitigate the detrimental effects of forgetting on picking performance. Using data from an online grocery platform, we develop an econometric model to analyze productivity and service quality, based on the intra-day and long-term learning and forgetting of workers, while accounting for sample selection bias and endogeneity. Our findings reveal that as intra-day learning increases, productivity and service quality improves. We further examine the role of task batching and task complexity on performance and observe that when workers batch orders, higher intra-day learning reduces picking time but increases delays. For complex tasks, higher intra-day experience is beneficial up to a threshold, beyond which it improves productivity but reduces substitutions. Finally, we develop a task allocation algorithm that utilizes intra-day and long-term learning to allocate tasks to workers based on the nature and complexity of the tasks. We demonstrate that assigning tasks to workers based on task type, accounting for recent and long-term learning, leads to performance improvements.

3 - Does Helping Hurt? How Food Delivery Wage Protections Disrupt Ride-Sharing

Yunmin Choi, Korea University Business School, Seoul, Korea, Republic of, Kyeongsu Min, Jiye Baek

This study investigates the unintended cross-platform spillover effects of government regulations designed to protect platform workers. Specifically, we examine how the introduction of minimum hourly wage standards, which shift compensation from per-task to hourly pay for app-based food delivery workers, affects ride-sharing usage. As location-based gig platforms become increasingly interconnected, targeted regulations can disrupt labor allocation across sectors and alter the matching process between clients and workers. We argue that labor protections targeting a specific platform can produce spillover effects on adjacent platforms not directly subject to the regulation, thereby impacting the broader economy. Using a counterfactual estimation approach, we provide empirical evidence that implementing hourly pay for delivery workers reduces the availability of ride-sharing drivers, as indicated by a decline in ride-sharing trips and an increase in average fares. This study contributes to the literature on platform governance and labor market dynamics in multi-sided platforms. Our study also offers practical insights for policymakers and platform businesses facing growing pressure to improve working conditions.

4 - Short-Term Rentals and Their Dual Impact in College Towns: A Multi-Site Panel Study on Housing Affordability and Hotel Market Displacement

Aadi Kulkarni, UVA, Nashua, NH, United States

This study measures how the rapid rise of short-term rentals (STRs), such as Airbnb listings, affects both long-term housing costs and hotel performance in U.S. college towns. We merge monthly data from AirDNA, Zillow, STR Global, the Bureau of Labor Statistics, and the National Center for Education Statistics for ten college communities between January 2020 and December 2021. Using a difference-in-differences design and two-way fixed-effects panel regressions, we relate changes in STR density to city-level median rents and hotel revenue per available room (RevPAR), while controlling for employment, income, enrollment, and event weeks. Results show that adding one STR for every 1,000 housing units raises median rent by just over four percent, with the effect climbing to six percent in towns where new construction is

slow. In parallel, a one-unit increase in STR density is linked to a 1.8 percent drop in hotel RevPAR, a decline that grows during football and graduation months. These findings suggest that STR growth squeezes renters and trims hotel windfalls in college markets. Cities may therefore need locally tailored caps or licensing rules, while universities should expand student housing and open dorms during peak events to ease market pressure.

5 - Privacy-Preserving Location Sharing in Crowd-Sourced Shipping

Amin Rahimian, University of Pittsburgh, Pittsburgh, PA, United States

In applications involving volunteer delivery of food and other supplies to resource-limited locations as well as crowd-shipping of deliveries from a depot, a central dispatcher relies on location sharing from crowd-shippers to design optimal matching of deliveries to potential crowd-shippers and volunteers. However, this poses privacy concerns in sharing sensitive location and destination information between the dispatcher and shippers that can disrupt the dispatch operations if crowd-shippers are not afforded reliable privacy protections. We investigate privacy-preserving dispatch algorithms that protect destination location information shared by the shippers while maintaining the overall performance and the quality of matched deliveries. We investigate the cost of privacy in both local and central privacy regimes, where the destination information is protected either at the user-level locally or the matched deliveries are randomized centrally at the dispatch to protect the location information. We investigate managerial insights and policy implications that determine who bears the cost of added privacy protections and how the compensations to crowd shippers should vary accordingly.

1 - Centralized vs. Host-Set Pricing: Lessons from a Car-Sharing Marketplace

Christopher Dragomir, University of Pennsylvania, Philadelphia, PA, United States, Neha Sharma, Ioannis Stamatopoulos

Platforms now mediate most peer-to-peer transactions, yet price frictions persist. Determining who should set prices on two-sided marketplaces is unclear: platforms hold superior information on demand and supply, while hosts best understand their own costs. We explore the tradeoffs with these pricing mechanisms through data from a natural experiment wherein a large car sharing platform let hosts decide prices for their cars or accept the platform's smart pricing.

2 - Interpretable Feature Engineering Through Clustering: from Healthcare to Retail

Matea Gjika, Massachusetts Institute of Technology, Cambridge, MA, United States, Alessandro Morosini, Georgia Perakis, Marc Saouda

High dimensionality, multicollinearity, and noise in datasets can significantly hinder the interpretability and performance of predictive models. We address these challenges by introducing a clustering-based approach on the feature space to construct more meaningful features that preserve essential information while reducing granularity. Our method leverages domain knowledge to identify the appropriate clustering criteria and harnesses the power of mixed-integer optimization to make the clustering problems tractable. We present two case studies: in healthcare, we show that correlation-based gene-clustering improves the interpretability and predictive power of cancer treatment models, while providing actionable insights for personalized treatment. In retail, we present a weather state clustering framework that allows us to quantify and understand the impact of weather on sales for one of the world's largest fashion retailers, with the goal of improving their distribution decisions. Our approach leads to models that are more robust and interpretable, ultimately creating the opportunity for more effective data-driven decision making.

3 - Increasing Parents' Engagement on Ed-Tech Platforms: Evidence from the Field

Alex Akira Okuno, NYU Stern, New York, NY, United States, Divya Singhvi, Somya Singhvi

Ensuring universal access to quality education remains a formidable challenge in developing countries. A key issue affecting educational outcomes among low-income households is limited parental involvement in their children's education. EdTech platforms can help build cost-effective and impactful solutions to address this problem. In collaboration with Rocket Learning, one of India's leading non-profit EdTech organizations, we design, implement, and optimize nudges to increase parent engagement in digital educational communities. We conduct a large-scale Randomized Control Trial (RCT) with nearly 154,000 parents to investigate the effectiveness of peer comparison and self-comparison nudges in improving engagement. Our results demonstrate that nudges can significantly increase the number of engaged users by 8% to 13.5%. We find heterogeneous effects influenced by teachers' activity levels, parents' pre-treatment engagement, and potential benefits from targeted nudging. Leveraging RCT data, we develop machine learning-based targeting policies to optimize nudge assignments. A second RCT with 122,000 parents reveals that while targeted nudging performs comparably to the best uniform policy on average, it identifies a substantial sub-population (8.8% of parents) for whom targeted nudges improve engagement by 5.4% over the uniform policy. These findings have significant implications for policymakers and non-profits focused on improving educational outcomes in Low and Middle-Income Countries (LMICs), demonstrating the effectiveness of nudges in increasing parental engagement, revealing significant heterogeneity in their impact, and highlighting the nuanced benefits and challenges of ML-based targeting strategies in educational interventions.

4 - Grid-Scale Mobile Battery Energy Storage Systems

Vishrut Rana, The Wharton School, Philadelphia, PA, United States, Christian Kaps, Serguei Netessine

The rapid rise of renewable energy introduces operational challenges for electric grids due to the intermittent nature of solar and wind generation. To manage this intermittency, energy storage technologies have seen considerable interest, and among the many technologies, Battery Energy Storage Systems (BESS) have emerged the most commercially viable. BESS store excess energy when renewable supply is high, and thus price of electricity is low, and release it when demand, and thus price, spikes. Profitability of BESS depends largely on nodal electricity price volatility. However, this price volatility can diminish over time due to grid expansion or increased investment in storage and generation capacity in a region. This makes long-term investment in fixed-location BESS increasingly uncertain, especially as grid conditions evolve year over year. Mobile Energy Storage Systems (MESS) offer a promising alternative. Unlike stationary systems, MESS can be relocated between grid nodes to follow shifting price signals and better align with short-term market conditions or long-term infrastructure changes. This flexibility allows MESS to maintain financial viability while also providing grid operators with a dynamic tool to address localized reliability and congestion challenges. In this paper, we measure the financial performance of MESS using market data from the PJM Interconnection and empirically identify the scaling opportunity for MESS fleets.

5 - Tractable Approximation to Choice Models for Multiple Product Pricing

Xuening Wang, Massachusetts Institute of Technology, Cambridge, MA, United States, Georgia Perakis

In price optimization, demand models must balance behavioral interpretability with computational tractability. While discrete choice models like the Mixed Multinomial Logit (MMNL) offer behavioral realism, they are often intractable for price optimization. On the other hand, price optimization literature often assume a much simpler model that admits minimal behavioral structure for computational ease. Motivated by practical needs in retail settings, this paper proposes a class of piece-wise linear functions to approximate the demand function from discrete choice models. We introduce the Contracting Localization Update (CLU) algorithm to efficiently estimate these functions from historical transaction data. We provide analytical guarantees for our methodology and validate the performance of our approximation through numerical experiments, achieving on average over 86.9% of optimal revenue under MMNL ground truth. Our method bridges the gap between interpretable modeling and efficient optimization and is adaptable to broader choice structures, including complementarity and multi-purchase behavior.

1 - Thompson Sampling for Repeated Newsvendor

Weizhou Zhang, National University of Singapore, Singapore, Singapore, Li Chen, Hanzhang Qin, Yunbei Xu, Ruihao Zhu

We investigate the performance of Thompson Sampling (TS) for online learning with censored feedback, focusing primarily on the classic repeated newsvendor model—a foundational framework in inventory management—and demonstrating how our techniques can be naturally extended to a broader class of problems. We model demand using a Weibull distribution and initialize TS with a Gamma prior to dynamically adjust order quantities. Our analysis establishes optimal (up to logarithmic factors) frequentist regret bounds for TS without imposing restrictive prior assumptions. More importantly, it yields novel and highly interpretable insights on how TS addresses the exploration-exploitation trade-off in the repeated newsvendor setting. Specifically, our results show that when past order quantities are sufficiently large to overcome censoring, TS accurately estimates the unknown demand parameters, leading to near-optimal ordering decisions. Conversely, when past orders are relatively small, TS automatically increases future order quantities to gather additional demand information. Extensive numerical simulations further demonstrate that TS outperforms more conservative and widely-used approaches such as online convex optimization, upper confidence bounds, and myopic Bayesian dynamic programming. This study also lays the foundation for exploring general online learning problems with censored feedback.

2 - Llm-Based Choice Prediction: a Generalized Direct Preference Optimization Approach

Jinsong Liu, Cornell University, Ithaca, NY, United States, Li Chen, Dongdong Ge, Ruihao Zhu

In this talk, we propose a LLM-based approach for customer choice prediction. We develop the Generalized Direct Preference Optimization (GDPO) method that can effectively utilize the customers' historical choice data to fine-tune a pre-trained LLM. GDPO extends the conventional DPO method by additionally incorporating the crucial tie information in the data. We not only establish a theoretical performance guarantee for our approach, but also demonstrate its excellent performance through extensive numerical experiments on both synthetic and real-world datasets.

3 - Policy Learning with Switch Estimators: Statistics, Optimization and Computation

Hanzhang Qin, National University of Singapore, Singapore, Singapore, Jingren Liu, Junyi Liu, Mabel C. Chou, Jong-Shi Pang

We study an offline policy learning problem: Given an offline data set generated by a historical policy, we are interested in (i) evaluating the counterfactual outcomes had a target policy been implemented during the time of data collection, and (ii) learning the optimal policy. We employ a sample-dependent adaptive evaluator (SDAE) that interpolates between the direct regression and the augmented inverse propensity weighting (AIPW) estimator to balance the bias-variance tradeoff in policy evaluation. Unfortunately, the SDAE-based policy learning problem is nonconvex and nondifferentiable, posing significant challenges for optimization. We reformulate the policy learning problem as a Heaviside composite optimization problem (HSCOP), which can efficiently solved by the progressive integer programming (PIP) method. Beyond the computational efficiency guarantees, we show that the SDAE achieves minimax rate optimal regret in learning the optimal policy.

4 - A Variational Inference Method for Bayesian Dynamic Control

Li Chen, Cornell University, Ithaca, NY, United States, Jiachun Li, Jue Wang

In this talk, we introduce a variational inference method for a class of Bayesian dynamic control problems involving either exact or censored observations, with common applications in operations management. We show that this method is asymptotically optimal under some mild conditions. Finite-horizon performance bounds for this method are also obtained and numerically illustrated.

5 - Fairness-Aware Static and Dynamic Assortment Optimization: Optimal Selection with Balanced Market Share

Qing Feng, Cornell University, New York, NY, United States, Omar El Housni, Huseyin Topaloglu

Assortment optimization plays an important role for many online retailers in maximizing their revenue. However, assortment decisions exclusively for revenue maximization often create significant disparity in sales among products offered by the retailer. To address the fairness concerns in assortment optimization, we introduce a market share balancing constraint to guarantee fairness among offered products, ensuring that the expected sales of any two offered products differ by at most a factor of α given exogenously. We consider both the static and dynamic assortment optimization problem under MNL with market share balancing constraint. In the static problem, the seller chooses a distribution over assortments such that the market share balancing constraint is satisfied in order to maximize the expected revenue. We show that the problem can be solved in polynomial time. Specifically, we show that a product is offered in the optimal solution if and only if both its revenue and preference weight exceed certain thresholds. As an extension, we also consider the setting where besides market share balancing constraint, there are additional constraints on the set of offered products. We also study the dynamic problem, where each product has an initial inventory, and the seller chooses a dynamic control policy to maximize the total expected revenue such that the realized sales of each product do not exceed its initial inventory, and the market share balancing constraint is satisfied in expectation. We establish an asymptotically optimal policy for the dynamic problem, whose approximation ratio converges to one as the initial inventories increase.

Chair: Jing Wang, Rutgers University, 132 Yale Ave, East Newark, 07304, United States

1 - Hierarchical Risk Parity Portfolio Optimization with Constant Absolute Risk Aversion

Kwame Addey, Minnesota State University Moorhead, Moorhead, MN, United States

Diversification is the typical investment strategy of risk-averse agents. However, most portfolio optimization models often ignore the importance of investor's degree of risk aversion. This paper proposes an investment strategy based on the hierarchical risk parity (HRP) optimization model under constant absolute risk aversion (CARA). The HRP model innovatively employs graph theory and machine learning algorithms to optimally utilize hierarchically hidden information to create well-balanced and resilient investment portfolios. The results reveal better performance for HRP in annualized returns, Sharpe, Calmar, and Sortino ratios. However, the higher order risk aversion HRP outperforms the HRP in terms of volatility, tail risk-adjusted returns, and maximum drawdown. The proposed model is important for portfolio managers because it presents the leverage of choosing an investment strategy based on objectives, risk tolerance, market conditions, and investment horizon.

2 - Penalized Quantile Regression from An Optimization Perspective

Cezareo Rodriguez, SimpleRose, Saint Louis, MO, United States

In real-world data settings, especially those with skewed distributions, heteroscedasticity, or outliers, standard least squares regression often yields misleading results. Penalized quantile regression offers a robust alternative to classical least squares estimation by modeling conditional quantiles of the response variable while controlling for model complexity. In this talk we investigate LP and MIP formulations of penalized quantile regression under certain penalty functions, and how one can leverage parallelism and primal-dual relationships to create robust statistical models of entire distributions. We also present novel algorithmic strategies that exploit the structure of the optimization formulations to further enable scalable computation. Empirical results demonstrate the effectiveness of our methods on both synthetic and real-world datasets, and offer insight into how optimization-based techniques can be useful for scaling up robust regression models.

3 - Lie Theory-Based Explanation of Neural Network-Generated Quantum Gate Parameters for Barren Plateau Mitigation

Zhehao Yi, The University of Alabama in Huntsville, Huntsville, AL, United States, Rahul Bhadani

Barren plateaus describe the phenomenon in variational quantum algorithms where gradients vanish exponentially with the increase number of qubits, causing training to stall due to ineffective parameter updates. Our work offers a mathematical explanation for why neural networks, when generating quantum gate parameters, can effectively mitigate the barren plateaus problem in variational quantum algorithms. By applying tools from Lie theory, we map the single-qubit quantum gates into a geometrically structured group $SU(2)$, where the evolution of parameters can be more naturally analyzed. Our results show that the updated trajectories of neural network-generated parameters are one of the geodesics in the $SU(2)$ group, indicating a mapping between the parameter update process and the geometry of the quantum model. This finding provides a mathematical explanation for the success of neural networks in optimizing quantum circuit parameters. In particular, we reveal the mathematical principles underlying why parameter updates by neural networks significantly reduce the likelihood of gradient vanishing, which is that the optimization process is guided along the direction of geodesics to find the best parameters. This finding provides a mathematical groundwork for the class of methods that use neural networks to generate parameters mitigating barren plateaus, and also for future studies on hybrid quantum-classical architectures and their optimization procedure.

4 - Multitask Sufficient Dimension Reduction with Common Support

Jiaying Weng, Bentley University, Waltham, MA, United States

In this talk, we will focus on developing a new dimension reduction approach for multitask learning. Sufficient dimension reduction is a contemporary machine learning technique that reveals the underlying structure of high-dimensional data. Multitask learning, on the other hand, is a transformative approach that leverages shared information across multiple related tasks to enhance prediction accuracy and deepen feature understanding. Integrating sufficient dimension reduction within the multitask learning framework will markedly improve the analysis of complex, high-dimensional data across multiple tasks. We propose a multitask sufficient dimension reduction (MT-SDR) framework, starting with a multitask nonlinear regression model. We develop a novel optimization problem to estimate the central subspace for each task. We then establish the minimax lower bound of the sparse estimator for the multitask setting, generalizing the single-task result to this context. Furthermore, we show that the proposed MT-SDR estimator achieves a nearly optimal rate of convergence.

5 - Energy-Based Neural Surrogates to Guide Large-Scale Milp Solving

Niki Triantafyllou, Imperial College London, London, United Kingdom, Maria M. Papathanasiou

Solving large-scale mixed-integer linear programs (MILPs) remains a core challenge across industries due to their combinatorial complexity and high computational cost. While machine learning (ML) has shown promise in accelerating or approximating optimization, many approaches rely on directly predicting discrete decisions, which can violate feasibility or lead to poor-quality solutions when constraints are complex or tightly coupled.

We propose an energy-based learning (EBL) framework that integrates deep learning with structured optimization, enabling the efficient solution of large-scale MILPs while improving feasibility and solution quality. Rather than predicting discrete decisions directly, our approach trains neural networks to learn an energy function over the feasible space that assigns lower energy to high-quality, feasible solutions and higher energy to infeasible or suboptimal ones.

During inference, we minimize the learned energy subject to the original MILP constraints, combining the expressiveness of neural models with the rigor of exact optimization. Our method builds on earlier work using neural networks to approximate binary decisions in large-scale supply chain models, and addresses key limitations by ensuring constraint satisfaction through energy-based inference.

We apply our framework to a large-scale MILP model for investment and tactical planning in personalized medicine supply chains. Results show that the proposed approach consistently improves feasibility and objective performance compared to direct prediction methods. By embedding domain knowledge into the energy function and preserving optimization structure, our method bridges data-driven learning and combinatorial optimization, offering a scalable solution for complex decision-making problems.

6 - On Representing Optimization Problems with Graph Neural Networks

Jialin Liu, University of Central Florida, Orlando, FL, United States

The recent era has witnessed the success of machine learning models across various domains, including optimization. In these applications, ML models typically capture key features of problem instances to suggest adaptive configurations or provide effective warm-starts, thereby accelerating the solving process. This talk will focus on graph neural networks (GNNs), discussing their expressive power in approximating key mappings from problems to their features—such as feasibility and boundedness—or their solutions. We will explore what GNNs can and cannot do in this context.

7 - Integrating Neural Network Forecasts into Regional Power System Planning Models

Jing Wang, Rutgers, Jersey City, NJ, United States

This study explores a modeling framework that embeds trained neural networks (NNs) into a multi-regional generation expansion planning (GEP) model to support long-term electricity system planning. The optimization problem is formulated as a mixed-integer linear program (MILP) that jointly captures investment decisions, inter-regional power exchanges, and operational constraints under a cost-minimization objective.

A feedforward neural network with ReLU activation is incorporated into the GEP model using a piecewise-linear representation. This allows the model to utilize learned nonlinear relationships—such as demand or cost forecasts—while preserving mathematical compatibility with MILP solvers. We begin with a simplified architecture inspired by prior work, in which all network weights are nonnegative. This structural constraint reduces modeling complexity and facilitates initial testing, though it also limits the network's expressiveness.

We investigate whether embedding NN-based predictions alters key model outputs—including investment choices, regional generation mix, and total system cost—or primarily affects solution convergence. Comparative scenario analysis is conducted to assess the impact of network predictions under varying demand and transmission assumptions.

This research contributes to the broader integration of machine learning and energy systems optimization by evaluating practical approaches for combining neural forecasts with structured decision models. It also sets the stage for future work involving more expressive networks and broader classes of uncertainty representations in large-scale optimization frameworks.

1 - The Impact of Prescription Drug Monitoring Programs on the Structure of the Opioid Supply Chain

Elaheh Alimohammad, University of Oregon Lundquist College of Business, Eugene, OR, United States, Behrooz Pourghannad, Guihua Wang

The opioid epidemic has resulted in over one million deaths in the U.S. since 1999. While Prescription Drug Monitoring Programs (PDMPs) have been implemented nationwide to mitigate misuse by tracking opioid prescriptions, little is known about their impact on the underlying supply chain structure. This study utilizes a difference-in-difference design to investigate the impact of must-access PDMP mandates on the decisions and behaviors of key supply chain actors.

2 - Is Continuity All We Need? a Modeling Approach to Evaluating Relational Continuity in Primary Care

Naireet Ghosh, London Business School, London, United Kingdom, Nicos Savva, Yueyang Zhong

Relational continuity of care – the ongoing therapeutic relationship between a patient and the same physician – has been repeatedly linked to lower mortality, fewer hospitalizations, and reduced consultation demand. Yet strict continuity is operationally challenging as it constrains resource pooling among physicians, consequently lengthening queues and raising waiting times. To analyze this tradeoff, we develop a multi-server queueing model in which each patient chooses (or is routed to) either their regular physician or the earliest available physician, capturing the dynamic feedback whereby disrupted continuity leads to poorer health outcomes leading to increased visit rates in the future. We show that, from the perspective of a social planner, it is optimal to maintain intermediate levels of continuity wherein patients with the most complex needs visit their regular physician most of the time while those with lower complexity always visit the earliest available physician. This balance depends on factors such as the size of the practice, the patient mix, and the level of congestion. Leaving the decision to patients alone produces extreme Nash equilibria – either always maintain continuity or always abandon it – both of which can be far from the social optimum, highlighting the need for central coordination. We calibrate the model to data from NHS general practices and numerically analyze the optimal and equilibrium continuity policies in those contexts. The case study provides quantitative guidance for NHS administrators deciding how much continuity to prioritize at different practices and when to retain control over patients' appointment scheduling.

3 - To Each Their Own (Shifts): Incorporating Heterogeneous Worker Preferences into Shift Work Schedules

Hummy Song, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States, Harriet Jeon, Song-Hee Kim

Shifts are the dominant way to work in many contexts requiring 24/7 coverage, including call centers, police departments, and hospitals. While the detriments of shift work are well-documented both at the individual and organizational levels, its deployment is often unavoidable given round-the-clock staffing needs. We explore a potential organizational lever – incorporating preferences over shift design – to mitigate ramifications of shift work in the context of acute care bedside nurses. Using survey, administrative, and shift data, we examine whether and the extent to which individual choice over dimensions of their shifts mitigates the impact of shift work on work (dis)satisfaction and turnover of nurses.

4 - Feature-Driven Priority Queuing

Simrita Singh, Santa Clara University, Santa Clara, CA, United States

Traditional queuing theory assumes that customer types are perfectly observed, assigning each customer to a type-specific priority queue – this is known as type-driven priority queuing. We study feature-driven priority queuing, where types are not perfectly observed but inferred from features using a classifier. Our work introduces an explicit modeling of the classifier within the queuing system design, which is novel in this context. We analyze the optimal queue classification that minimizes queuing delay costs and compare a plug-and-play, type-first approach – where type probabilities are predicted by a classifier and then used to optimize queuing – with a direct approach that optimizes the classifier to predict queue probabilities directly from features.

Our primary contribution is proving that the direct approach outperforms the type-first approach, except when the type classifier perfectly predicts the Bayes posterior. To illustrate how the direct approach achieves this improvement, we use a combination of analytical results, numerical examples, and simulations on a large real-world dataset. In our numerical study using state-of-the-art image classifiers on a dataset of medical images used in radiology triage, the direct approach reduces delay costs by 30-60% relative to the type-first approach, particularly in high-utilization scenarios.

1 - (Machine) Learning Preferences from Complex Choice Sets: An Application to Service Networks

Kenneth Moon, Cornell University, New York, NY, United States

Hidden complexity pervades commonplace choices. For instance, at everyday venues such as supermarkets and amusement parks, customers routinely consider astronomically many possible choices of paths through some or all of the venues' stations (e.g., sections or rides). Rich data now capture such customer choices, but the complexity remains a challenge for empirical research. Firstly, it is unclear how customers assess such complex decisions. Secondly, choice estimation methods exhibit fundamental issues ranging from intractability to inconsistency when estimating consumer preferences from such data. Under commonplace conditions, we show that a hidden but provably low-dimensional fraction of relevant choice comparisons suffices to capture all customer preference information from data and can be automatically learned and exploited by machine learning (ML). The same low dimensionality further justifies simple shopping heuristics for customers. We develop a neural network-based estimator of customer preferences and demonstrate it on data tracking shoppers at a hypermarket serving over 1M customers annually. Such estimation uncovers the hypermarket's demand structure, and modest capacity reallocations counterfactually raise equilibrium service throughput by 5-25% through. Addressing a long-standing challenge in marketing and operations, we identify complementary stations from congestion levels at one station producing cross-station demand effects.

2 - Words Matter! Predicting Freelance Job Success Through Conversational Analytics

Jiannan Xu, Robert H. Smith School of Business, University of Maryland, College Park, MD, United States, Ashish Kabra, Kunpeng Zhang, Wedad Elmaghraby

As digital labor platforms become an increasingly important source of employment, understanding the factors that drive successful freelancer-client interactions is essential for promoting fair access to opportunities and improving labor market efficiency. This study applies conversational analytics and machine learning to analyze a unique dataset of tens of millions of messages exchanged between freelancers and clients. Drawing on Grice's Maxims (1975) from communication theory, it uncovers linguistic and behavioral patterns that influence freelance success. By developing AI-driven predictive models, this research advances natural language processing (NLP) applications in labor markets and provides actionable insights to help freelancers enhance their communication strategies.

3 - Real-Time Performance Feedback and Its Impact on Worker Performance

Zhi Chen, Zhejiang University, Hangzhou, China, People's Republic of, Yuqian Xu, Jayashankar Swaminathan, Weihua ZHOU, Yanbing Zhou

As digital technologies reshape the modern workplace, real-time performance feedback systems have gained traction as tools for enhancing productivity. While traditional feedback mechanisms provide periodic and infrequent updates, real-time systems leverage technology to deliver continuous, immediate performance updates throughout the workday. Although these systems hold promise and are increasingly adopted across industries, the rise of new technologies enabling real-time performance feedback raises critical and underexplored questions about how such continuous, data-driven systems influence employee behavior. Leveraging a unique dataset and quasi-experimental setting from Alibaba's Cainiao logistics warehouses, this study provides empirical evidence on the effects of real-time relative performance feedback systems. We find that real-time feedback led to a 7.0% improvement in efficiency without compromising quality. Notably, low-performing employees exhibited the largest gains, suggesting that frequent performance updates create stronger incentives for improvement among those with greater room for growth – potentially narrowing workplace performance gaps through upward productivity gains. At the same time, overall performance variability declined by 18.7%, though low performers experienced increased fluctuations. To explore the mechanisms behind these effects, we examine the system's dual role as both a feedback and monitoring tool. Importantly, we focus on the unique nature of feedback enabled by real-time systems, characterized by continuous updates on workers' rankings, individual efficiency, and comparisons to

warehouse averages. Positive feedback, such as improved ranking or exceeding the warehouse average, boosts effort and enhances performance, while negative feedback can discourage workers. Beyond feedback content, the awareness of being continuously observed fosters sustained improvements regardless of specific feedback signals.

4 - Eliminate Gender Wage Gap in the Gig Economy: a Solution from a Customer Service Platform

Xiao Ni, Fudan University, Shanghai, China, People's Republic of, Qiuping Yu, TIANJUN FENG

Job flexibility is a significant factor in gender wage gaps, yet wage disparities persist even in flexible gig work. While previous research has examined this issue in male-dominated, location-specific occupations like Uber driving, less is known about gender wage gaps in female-dominated or fully remote gig work. This study investigates gender wage differences among gig workers at an online chat center for a major retail platform, where pay is set by a transparent, gender-neutral algorithm. We find a gender pay gap in this female-dominated industry, with men earning 20% more per week and 2.4% more per hour. The hourly earning gap is primarily driven by men's faster work pace and higher chat concurrency, despite delivering lower service quality. However, once adjusted for experience, the gender pay gap disappears due to performance-based metrics (unbiased by gender) and the equalizing effect of remote work, which standardizes work timing across genders.

5 - Explain Worker Schedule Quality Disparities: Evidence from An American Restaurant Chain

Qiuping Yu, Georgetown University, Washington, DC, United States, Xiaoxuan Hou

While labor market disparity research has extensively explored racial and gender disparities in hiring, wages, benefits, and promotions, the disparities in the temporal quality of work schedules has largely been overlooked, despite its significant economic and social consequences for workers. Using large and granular shift data with roughly half a million unique shift records for over 2,400 unique customer-facing workers from an American casual restaurant chain, we examine gender and racial disparities in scheduling quality across two key dimensions: (1) sufficiency, which assesses the number of hours workers receive, and (2) predictability, which examines the frequency of last-minute shift changes. We address two main questions: (1) Are there gender and racial disparities in scheduling quality, and if so, what are they? (2) What mechanisms drive these disparities? Our findings reveal that women and minority workers are initially offered 3.3% to 10.7% fewer hours, and are 7.2% to 23.9% more likely to experience last-minute additions compared to White men, after accounting for human capital factors including role, tenure, intrinsic abilities, and absenteeism. We also show that classic explanations, such as workers' preference and availability, either do not hold true or only partly explain the observed disparities. By leveraging detailed field data, analyzing multiple dimensions of schedule quality, and systematically examining the mechanisms, we deepen the understanding of the drivers behind the gender disparities in schedule quality and underscore the importance of addressing these issues.

6 - Explain Worker Schedule Quality Disparities: Evidence from an American Restaurant Chain

1 - Fair Online Hospital Diagnostic Service Scheduling: Helping Both Patients and Providers

Joyce Luo, Massachusetts Institute of Technology, Cambridge, MA, United States, Maureen Canellas, Dessislava Pachamanova, Georgia Perakis

The management of diagnostic services is a challenging and important task for hospital systems. Suboptimal scheduling of diagnostic services increases patient wait times and reduces the availability of overnight beds that could otherwise be utilized by incoming patients. Patients are served by a limited number of diagnostic technicians, who frequently experience uneven workload distributions and disproportionate workload demands that contribute to higher rates of exhaustion and burnout. We propose a framework for analyzing and addressing workload imbalances by developing algorithmic solutions to target contributing factors. In collaboration with a large academic medical center in the Northeastern US, we identify key factors related to total workload, load difficulty, perception of load fairness, and workload variability, and develop an online algorithm that optimizes daily diagnostic technician schedules to mitigate these specific factors. Our proposed algorithm balances technician workload considerations with patient and hospital needs, simultaneously incorporating considerations for patient urgency levels and characteristics. We provide analytical guarantees and analyze the algorithm's performance using echocardiogram order data from our hospital partner. Computational studies show that our online load-balancing algorithm effectively mitigates all identified workload imbalance contributors by improving load fairness for technicians by up to 28%, limiting difficult scan load, and reducing daily workload variability compared to current hospital policy – all without compromising operational performance in terms of patient throughput and wait time. Our algorithm's policy shortens patient wait time and improves throughput for certain patient types, especially for high demand scenarios.

2 - When Nonmateriality is Material: Impact of ESG Emphasis on Firm Value

Yakov Bart, Northeastern University, Boston, MA, United States, Sonam Singh, Ashwin Malshe, Serguei Netessine

This study examines the presence and the impact of emphasizing nonmaterial ESG factors on firm value. ESG factors are considered nonmaterial (or material) when excluding them from corporate disclosure would not (or would) significantly alter the overall information available to a reasonable investor. Drawing on agency theory, the authors argue that managers may divert their attention from firm value-maximizing activities by emphasizing nonmaterial ESG factors to enhance their reputations. The authors measure ESG emphasis by applying a deep learning model to earnings call transcripts of 5,079 firms from 2005 to 2021. They demonstrate that, on average, managers emphasize nonmaterial ESG issues more than material ESG issues. Furthermore, they find a positive association between nonmaterial ESG emphasis and media mentions of the firms. Notably, a 10% higher emphasis on nonmaterial ESG factors leads to a significant 10.7% decline in firm value. This negative association intensifies over time, is stronger for firms with higher free cash flow, and is weaker for firms with higher market share. Finally, the authors develop an interactive web app (https://bit.ly/esg_app) to assist executives and investors in comparing companies against competitors and quantifying the impact of shifting ESG emphasis on the firm value.

3 - The Value of Time- and Location-Commitment for Decentralized Emergency Medical Services

Pieter van den Berg, Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands, Andre Calmon, Andreas Gernert, Stef Lemmens, Maria Rabinovich, Gonzalo Romero

Emergency medical services (EMS) in many low- and middle-income countries utilize decentralized platforms coordinating independent ambulance providers. However, significant operational challenges arise from uncertainty in provider time availability and unpredictable idle locations. These uncertainties hinder reliable service coverage and negatively impact patient outcomes. Using data from our partner Flare in Nairobi, Kenya, we investigate the relative effectiveness of enhancing provider temporal

commitment versus spatial commitment to improve system coverage. We employ optimization models adapted for ambulance commitment uncertainty, a detailed case study analysis, data-driven simulations, and a game-theoretic model. Our findings quantify a stark "cost of decentralization": the coverage provided by Flare's 340 loosely committed ambulances could potentially be matched by fewer than 15 optimally deployed fully committed units. We find that enhancing spatial commitment generally yields higher marginal returns for improving coverage than solely increasing time availability. Adding just five optimized, location-flexible ambulances increased coverage substantially in simulation (e.g., by 5% over the baseline fleet) and reduced service variability. Simulations confirm the practical impact of interventions and validate model assumptions. For managers and decision-makers overseeing decentralized EMS platforms, prioritizing strategies that improve spatial coordination offers an efficient path to enhancing service reliability and performance. Actionable strategies include targeted incentives that encourage providers to relocate strategically or deploy a small fleet of location-flexible, platform-controlled units to fill critical coverage gaps. Our framework offers practical tools for managers to identify coverage gaps and assess the potential impact of such interventions in resource-constrained settings, ultimately aiming to enhance emergency response.

4 - Electric Vehicle Charging Station Access Sharing and Economics Implication

Yuan Ma, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, Roman Kapuscinski, Ozge Sahin

This paper presents a comparative analysis of Tesla's Supercharger access strategies in the European Union (EU) and the United States (US), focusing on the expansion of access to non-Tesla electric vehicles (EVs). By developing a micro-foundation modeling framework, this research examines how these regional variations in charging infrastructure accessibility influence consumer utility, EV adoption rates, and competitive dynamics within the EV market.

5 - Mitigating Shortages of Generic Drugs: the Role of Reliability Certification

Xiaoyu Wu, Duke University, Durham, NC, United States, Robert Swinney, Can Zhang

Generic drugs play a vital role in the healthcare system. However, generic drugs have experienced severe shortages due to supply disruptions, caused by a number of factors, including low profit margins and a lack of information available to buyers about manufacturers' reliability, leading manufacturers to underinvest in supply reliability. Shortages result in numerous negative consequences for patients as well as institutional buyers of generic drugs, who may be forced to use more expensive alternative drugs when a shortage occurs. In this paper, we investigate the effectiveness of such a certification system. We propose a game theoretic model that captures the effects of generic drug manufacturer reliability certification on manufacturers, buyers, a GPO and patients. We find that certification may motivate manufacturers to improve their reliability; however, this may increase patients' shortage cost once the manufacturers adjust their wholesale prices and the buyers adjust their sourcing strategies in response. Nevertheless, we also identify conditions under which certification can benefit all stakeholders compared to the status quo with no certification. Finally, we find that combining certification with subsidies can further reduce the shortage cost when the subsidy level is sufficiently high, but it may backfire if the subsidy level is too low. Our findings offer insights for policymakers and nonprofit organizations in designing reliability certifications to mitigate generic drug shortages, highlighting when and why certification can benefit various stakeholders in the supply chain, while cautioning against unintended consequences arising from its impact on manufacturers' price competition and buyers' sourcing strategies

1 - Enhancing Efficiency and Robustness of Switchback Experiments: a Practical Model-Assisted Design

Tu Ni, Harvard Business School, Boston, MA, United States, Iavor Bojinov

Switchback experiments have become a popular alternative when conventional A/B testing is hampered by limits on user-level randomization or by interference between experimental units. In the presence of carryover effects, however, current switchback designs typically suffer from low statistical power and an unpredictable yield of observations, posing challenges in execution. This paper presents a novel model-assisted design framework for switchback experiments that guarantees a fixed number of valid observations, enabling more reliable and consistent experimentation. The proposed design introduces an adaptive mechanism that uniformly distributes observations across seasonal cycles, ensuring treatment-control balance and reducing sensitivity to peak periods. Additionally, the design incorporates refinements that adapt assignments more to past periods, creating temporal coupling between treatments and controls to enhance robustness, even in less predictable dynamic systems. We provide a comprehensive analysis of the design's bias and variance and develop tools to support statistical inference. Numerical studies indicate that our new design is markedly more efficient than existing approaches; in a realistic ride-sharing simulation environment, it reduces the mean-squared error by nearly 30%. This work contributes broadly to the field of experimental design under interference, bridging practical considerations with robust statistical methodologies.

2 - Optimal Targeting in Dynamic Systems

Yuchen Hu, Stanford University, Stanford, CA, United States, Shuangning Li, Stefan Wager

Modern treatment targeting methods often rely on estimating the conditional average treatment effect (CATE) using machine learning tools. While effective in identifying who benefits from treatment on the individual level, these approaches typically overlook system-level constraints that may arise when treatments induce strain on shared capacity. We study the problem of targeting in dynamic systems, where treatment decisions must be made one at a time as units arrive, and early decisions can impact later outcomes through delayed or limited access to resources. We show that optimal policies in such settings compare CATE values to delay-specific thresholds, where each threshold reflects the expected cumulative negative impact on the system of treating an additional individual at that delay level. We propose an algorithm that augments standard CATE estimation with off-policy evaluation techniques to approximate these thresholds from observational data. Theoretical results establish consistency and convergence guarantees, and empirical studies demonstrate that our method improves long-run outcomes considerably relative to individual-level CATE targeting rules.

3 - When Does Interference Matter? Decision-Making in Platform Experiments

Anushka Murthy, Stanford University, Stanford, CA, United States, Ramesh Johari, Hannah Li, Gabriel Weintraub

This paper investigates decision-making in A/B experiments for online platforms and marketplaces. In such settings, due to constraints on inventory, A/B experiments typically lead to biased estimators because of interference; this phenomenon has been well studied in recent literature. By contrast, there has been relatively little discussion of the impact of interference on decision-making. We focus on the commonly used frequentist hypothesis testing approach for making launch decisions based on data from customer-randomized experiments, and we study the impact of interference on (1) false positive probability and (2) statistical power. We obtain three main findings. First, we show that for monotone treatments -- i.e., those where the treatment changes booking probabilities in the same direction relative to control in all states -- the false positive probability of the naïve difference-in-means estimator with classical variance estimation is correctly controlled. This result stems from a novel analysis of A/A experiments with arbitrary dependence structures. Second, we demonstrate that for monotone treatments, when the state space is large, the statistical power of this naïve approach is higher than that of any similar pipeline using a debiased estimator. Taken together, these two findings suggest that platforms may be better off not debiasing when treatments are monotone. Finally, we numerically investigate false positive probability and statistical power when treatments are non-monotone, and we show that the performance of the naïve approach can be arbitrarily worse than a debiased approach in such cases.

4 - Experimenting on Markov Decision Processes with Local Treatments

Chonghuan Wang, Massachusetts Institute of Technology, Cambridge, MA, United States, Shuze Chen, David Simchi-Levi

Utilizing randomized experiments to evaluate the effect of short-term treatments on the short-term outcomes has been well understood and become the golden standard in industrial practice. However, as service systems become increasingly dynamical and personalized, much focus is shifting toward maximizing long-term cumulative outcomes, such as customer lifetime value, through lifetime exposure to interventions. To bridge this gap, we investigate the randomized experiments within dynamical systems modeled as Markov Decision Processes (MDPs). Our goal is to assess the impact of treatment and control policies on long-term cumulative rewards from relatively short-term observations. We first develop optimal inference techniques for assessing the effects of general treatment patterns. Furthermore, recognizing that

many real-world treatments tend to be fine-grained and localized for practical efficiency and operational convenience, we then propose methods to harness this localized structure by sharing information on the non-targeted states. Our new estimator effectively overcomes the variance lower bound for general treatments while matching the more stringent lower bound incorporating the local treatment structure. Furthermore, our estimator can optimally achieve a linear reduction with the number of test arms for a major part of the variance. Finally, we explore scenarios with perfect knowledge of the control arm and design estimators that further improve inference efficiency.

Bridging Theory and Practice: New Insights in Optimizing Operational Decisions

Invited Session

Revenue Management

Chair: Mingliu Chen, The University of Texas at Dallas, Richardson, TX, United States

1 - Mergers and Product Repositioning: Theory and Empirical Evidence

Soo-Haeng Cho, Carnegie Mellon University, Pittsburgh, PA, United States, Zijun Shi, Xin Wang, Yushu Zeng

This paper investigates how mergers affect firms' decisions on product quality, variety, and pricing, as well as the subsequent implications for consumer welfare. We develop a game-theoretical model of a vertically differentiated oligopoly in which firms compete on both quality and price. Post-merger, the combined firm may consolidate its product lines to achieve cost synergies, potentially altering market outcomes. We show that the welfare impact of a merger critically depends on the quality tiers of the merging firms. Mergers between top- and mid-tier firms can enhance consumer surplus if quality improvements offset price increases. In contrast, mergers involving bottom-tier firms tend to reduce consumer welfare due to limited consumer valuation of quality upgrades and reduced variety. These findings challenge the conventional focus on price effects in merger analysis and highlight the importance of product repositioning. Empirically, we analyze mergers in the airline industry using a Multinomial Logit demand model and a coarsened exact matched difference-in-differences design. Our results validate the theory: mergers between top-tier carriers increase consumer surplus, while those involving bottom-tier airlines often diminish it.

2 - Price and Assortment Optimization Under the Multinomial Logit Model with Opaque Products

Jiaqi Shi, Columbia University, New York, NY, United States, Omar El Housni, Adam Elmachetoub, Harsh Sheth

An opaque product is a product for which only partial information is disclosed to the buyer at the time of purchase. Opaque products are common in sectors such as travel and online retail, where the car type or product color is hidden in the opaque product. Opaque products enable sellers to target customers who prefer a price discount in exchange for being flexible about the product they receive. In this paper, we integrate opaque products and traditional products together into the multinomial logit (MNL) choice model and study the associated price and assortment optimization problems. For the price optimization problem, we surprisingly show that uniform pricing is optimal which implies it has the same optimal pricing solution and value as the traditional MNL model. While adding an opaque product priced at the revenue-maximizing price may enhance revenue given arbitrary traditional product prices, this advantage disappears when all prices are optimized jointly. For the assortment optimization problem, we show that the revenue-maximizing assortment is nested-by-valuation for uniformly priced products. For non-uniformly priced cases, we propose a natural nested-by-revenue-and-valuation heuristic that performs extremely well in an extensive numerical study.

3 - Shared OR Solo? Platform Operations and Social Choices in Ride-Hailing

Jianfu Wang, College of Business, City University of Hong Kong, Kowloon, Hong Kong, Ming Hu, Zhoupeng Zhang, Hengda Wen

Ride-hailing platforms provide pooling services, allowing riders to share trips, which can alleviate driver shortages and reduce wait times—particularly during peak hours—but may compromise privacy, space, and security. We analyze a queueing model where riders decide whether to join the queue and, if so, choose between shared or solo rides based on past wait-time experiences. Shared riders may face additional delays while waiting for a carpooling match. We derive optimal pricing strategies to incentivize riders toward joining rates and sharing probabilities that maximize throughput, revenue, or social welfare. Our findings show that revenue-maximizing joining rates and sharing probabilities are consistently lower than those under social welfare or volume maximization. As the shared-ride experience improves (i.e., stochastic increases in sharing externality) while sharing likelihood remains stable (aligned with Chicago data), the revenue-optimal shared price rises, while the solo price surprisingly decreases—compensating solo riders for increased system congestion. Under social welfare maximization, the solo-shared price gap narrows compared to revenue maximization, yet prices are not necessarily lower. Finally, we validate our theoretical insights using ride-hailing data from Chicago in August 2019.

4 - Pricing Roses in Online Dating

Kasra Ganjizadeh Tari, University of Pittsburgh, Pittsburgh, PA, United States, Arian Aflaki, Michael Hamilton, Enfeng Xing

Dating platforms provide an opportunity to match with a partner. Many of these platforms monetize this interaction by offering virtual products that enhance a user's chances of matching. For instance, Hinge allows users to send virtual roses to others, and Tinder offers Super Likes. These virtual products can increase the likelihood of a successful match by placing the user's profile at the top of the recipient's match list and signaling strong interest in the candidate.

We study the problem of pricing these virtual products, which we refer to as “roses,” in a multi-period setting. Users decide whether to send a match request upon observing a candidate and whether to accompany their request with a rose. We consider three selling mechanisms: offering roses separately in each period, as a bundle, or through both options. In this context, we characterize user behavior and derive the revenue-maximizing pricing and design for offering roses. For each scenario, we examine platform revenue, customer surplus, and social welfare, and compare outcomes across these metrics.

5 - Ride-Hailing Platforms: A Near-Optimal Policy for Pricing, Matching, and Spatial Routing

Yang Bo, University of Toronto, Toronto, ON, Canada, Guangwen Kong

We study an infinite-horizon, stochastic, dynamic optimization problem for an on-demand ride-hailing platform. The decisions include a one-time service pricing decision at the beginning of the horizon, and the real-time driver-customer-matching and driver-routing decisions during the planning horizon. The objective is to minimize the long-run average profit across time. We first establish a theoretical upper bound on the average profit under any policy. We then design a near optimal policy whose theoretical performance gap with respect to this upper bound vanishes in a meaningful asymptotic regime. Numerical results corroborate the near-optimal performance of our policy.

TBD

2 - Electric Vehicle Mobility and Charging Behavior

Christian Kaps, Harvard Business School, Cambridge, MA, United States

The rapid adoption of electric vehicles (EVs) is transforming mobility patterns and creating new dynamics in energy systems. This paper investigates the interplay between EV user mobility behavior and the strategic value of flexible charging. Using empirical data, we analyze how driving routines, charging preferences, and spatial-temporal demand patterns influence both individual driver and utility-level outcomes.

3 - Delivery Terms for Voluntary Carbon Offsets

Safak Yucel, Georgetown University, Washington, DC, United States, Vishal Agrawal, Gokce Esenduran

In addition to abating their emissions, to reach voluntary decarbonization goals, corporations purchase carbon offsets under two delivery terms. The first is forward delivery, where the buyer orders a certain quantity before the seller undertakes the investment and yield uncertainty realizes. The second is prompt delivery, where the seller invests and uncertainty realizes, before the buyer orders offsets. Motivated by the importance of choosing the right delivery term for buyers and sellers, in this paper, we investigate economic and environmental implications of these delivery terms. Our results offer several managerial insights: First, a seller should prefer forward delivery if investment cost is low, but prompt delivery otherwise. Although one would expect that the delivery term that enables the seller to make a higher investment results in a higher profit, we find that prompt delivery may lead to a higher profit despite lower investment. Second, a buyer should prefer forward delivery only for a project with either a low or high investment cost. Interestingly, the delivery term that leads to a lower cost for the buyer may actually require higher abatement. Finally, environmental groups should promote forward delivery only for a project with a low investment cost. Moreover, when the buyer and seller prefer different delivery terms, the one preferred by the seller leads to greater emissions reduction, and should be promoted by environmental groups.

4 - Market Fragmentation and Inefficiencies in Maritime Shipping

Giacomo Mantegazza, USC Marshall, Los Angeles, CA, United States, Kostas Bimpikis, Salomon Wollenstein-Betech

Maritime transportation accounts for 90% of global trade, but ballasting—vessels traveling without cargo—imposes substantial economic and environmental costs. This paper examines the oil transportation industry, where approximately half of all miles traveled are sailed empty. While some ballasting is necessary due to inherent supply-demand imbalances in oil markets, our analysis demonstrates that market structure, specifically the fragmentation of vessel ownership, is also a primary driver, accounting for 10-20% of the total empty miles traveled depending on the market segment. In addition, we show that consolidating vessels into small shipping pools—sets of vessels operated under unified management—can reduce ballasting-related carbon emissions by up to 15%. This market-driven approach, which is gaining industry adoption, maintains competitive dynamics, given the limited scale of consolidation, while significantly improving efficiency. The gains arise from enhanced coordination within larger pools and expanded port coverage, reducing unnecessary vessel repositioning. More broadly, our findings quantitatively demonstrate that organizational changes alone—specifically, the consolidation of vessel operations—can generate significant environmental improvements by reducing empty miles. This provides a practical path toward sustainability that can complement and amplify the benefits of technological innovation.

5 - Impact of the Maintenance in Power Plants and Data-Driven Optimal Maintenance Scheduling

Abdullah Coskun, Stanford University, Menlo Park, CA, United States

This study examines efficiency degradation and maintenance optimization in U.S. coal power plants using comprehensive hourly production, efficiency, and maintenance data. Through a difference-in-differences analysis, we demonstrate that coal generators experience significant efficiency decline prior to maintenance, followed by approximately 1% efficiency improvement post-maintenance. We develop a theoretical maintenance model that establishes the optimality of constant-control policies under stationary parameters and provides adaptive strategies for non-stationary conditions through production cycle clustering. Our analysis reveals that corporate consolidation through mergers and acquisitions has led to a 30% improvement in maintenance scheduling accuracy. The findings advance our understanding of power plant operational optimization and maintenance effectiveness in the U.S. electricity sector, while contributing to the empirical literature on real-world efficiency metrics in maintenance policy evaluation.

Social Media Analytics

Chair: Lingshu Hu, Washington and Lee University, Lexington, VA, United States

1 - From Self to Other: Customer Reactions to Firm DEI Promotions on Social Media

Chen Jing, Boston University, Boston, MA, United States, Priyanga Gunarathne, Shuba Srinivasan, Abraham Seidmann

We examine how firms' DEI promotions on social media affect customer complaints. Analyzing millions of interactions from 15 U.S. firms on Twitter, we find that DEI promotions raise customer complaints and weaken the benefits of responsive service, unless aligned with customer identities. Our findings reveal tensions in digital DEI strategy and offer guidance for managing online customer relationships.

2 - Emotional Dynamics—the Nonlinear Impact of Sentiment Volatility on Review Helpfulness

Jiaqi Ren, Zhejiang University, Hangzhou, China, People's Republic of, Xixian Peng, Yifan Yu, Yutong Guo

This study introduces sentiment volatility as a novel affective cue in online reviews. Drawing on EASI theory and multi-method evidence, we reveal an inverted U-shaped effect on perceived review helpfulness, mediated by emotional contagion and conceptual processing fluency. Our findings offer insights for online platforms, reviewers, and merchants.

3 - Reuniting Forcibly Separated Families Through Shared Memories-

Huifeng Su, Yale School of Management, New Haven, CT, United States, Lesley Meng, Edieal Pinker

Social media is a critical channel for separated families seeking reunification but faces vast search spaces, incomplete data, and inaccurate memories. Using a large crowd-sourced social forum dedicated to family reunification, our proposed language model pipeline reduces search complexity and offers practical, scalable solutions for social media-based family matching.

4 - Optimizing Influence Campaigns: Nudging Under Bounded Confidence

Yen-Shao Chen, Yale University, New Haven, CT, United States, Tauhid Zaman

Online influence campaigns often fail because audiences resist messages outside their comfort zones due to bounded confidence. This research reveals how “nudging”—gradually shifting opinions—overcomes this resistance. Using control theory and Twitter data, we demonstrate how multi-agent systems can effectively polarize or unite audiences.

Chair: Poyraz Kayabas, Purdue University Fort Wayne, Fort Wayne, IN, United States

1 - Adaptation Strategies-Based Supply Chain Viability Optimization Under Long-Time Disruption Risks

Wei Pu, School of Business, Guangdong University of Foreign Studies, Guangzhou, Guangdong, China, People's Republic of

With the accelerated globalization of the appliance industry, an intertwined supply chain network has emerged through resource integration. However, the multi-tiered and interactive nature of this network significantly amplifies the risk of cascading failures across supply chain nodes, thereby exacerbating systemic vulnerability. To mitigate the adverse effects of long-term disruptions—such as economic losses and customer dissatisfaction—an efficient optimization model is required to enhance the viability of intertwined supply chains (SCV) by integrating agility, resilience, and sustainability.

This model aims to improve the viability of appliance supply chains through resource allocation optimization and adaptive strategy selection, focusing on the following key components:

- (1) Analyzing the dynamic leader (appliance firms)–follower (suppliers) and coopetitive decision-making structures in intertwined supply chains to identify viability measurement indicators from a complex network perspective;
- (2) Generating stochastic dynamic disruption scenarios using dynamic Bayesian networks and developing a multi-objective stochastic programming model;
- (3) Implementing strategies such as fourth-party logistics (4PL), backup facilities, safety stock, and self-healing mechanisms to enhance viability.

Using real-world data from China's small appliance industry during the COVID-19 pandemic, this study demonstrates the practical applicability of the proposed approach in improving SCV and addressing multi-objective stochastic programming challenges. The optimal results indicate an 11.23% reduction in costs and a 13.72% decrease in order fulfillment time. These findings contribute to the theoretical and methodological foundations of supply chain resilience optimization and offer theoretical insights and practical tools to enhance SCV under disruption risks in appliance supply chains, thereby promoting their sustainable development.

2 - A Framework for Retailers and Manufacturers to Maximize Their Profits Through the Utilization of Food Shelf-Life Extension Technology

Yue Yao, University of Tennessee, Knoxville, TN, United States, Mingzhou Jin

Our research addresses the critical gaps in understanding the economic trade-offs and operational adjustments required for the adoption of shelf-life extension technology. By analyzing the potential impact of shelf-life extension on production batch size, frequency, and associated costs, this research seeks to provide actionable insights for food manufacturers and retailers. Through modeling the relationship between manufacturers and retailers as a Stackelberg game, our research underscores the strategic interplay between these two entities. The manufacturer, acting as the leader, determines the extended shelf-life and wholesale price to maximize profit, while the retailer, as the follower, calculates the inventory cycle length and optimal order quantity to balance profitability against expiry losses. The analysis delves into the impacts of shelf-life extension on production batch size, frequency, and costs, providing actionable insights for stakeholders. The findings aim to inform policy and decision-making, demonstrating conditions where shelf-life extension technology can maximize the profits for manufacturer and retailer, thereby advancing sustainability in the food industry.

3 - Proposed Modification of Lithium Reverse Logistics Supply Chain Network: An Optimization Outlook

Oluwatosin Atitebi, University of Texas at Arlington, Arlington, TX, United States, Erick Jones

Increasing demand for renewable energy technologies to advance growing push for transition from carbon-intensive energy system to non-carbon-intensive energy system has brought to fore the overwhelming demand for lithium-ion batteries, one of the current viable energy storage alternatives. This alternative energy system however is material intensive, therefore, the continuous demand for lithium, consequently increasing mining activities for these materials while also creating an unintended environmental/health crisis due to increasing rate of end-of-life lithium-ion batteries (LIBs) and their accumulation. Lithium reverse logistics network is on an uptick trend in recent decade geared towards facilitation of lithium recycling from end-of-life and other sources of scrap LIBs to minimize cost, enhance recovery efficiency, and ensure resilience of the network. This paper is a concerted effort towards ensuring an optimized lithium reverse logistics network by understudying the comparative analysis between the traditional reverse logistics network and the proposed modified reverse logistics network using 2 deterministic optimization models of the reverse logistic network variants. Overall, the proposed modified reverse logistics network showed a tremendous cost reduction compared to the traditional reverse logistics network over the planning period of consideration, while carbon emissions of both networks is comparatively the same.

4 - Enhancing Semiconductor Supply Chain Resilience and Reliability: a Quantitative Modeling Approach Under Uncertainty

Poyraz Kayabas, Purdue University Fort Wayne, Fort Wayne, IN, United States

This study presents a quantitative modeling approach to address the resilience and reliability challenges of semiconductor supply chains. Due to their complexity, global geographical distribution, and vulnerability to disruptions, designing resilient and reliable semiconductor supply chains requires a strategic balance between cost efficiency and operational robustness. The proposed approach evaluates various disruption scenarios and analyzes system response behaviors to identify optimal supply chain configurations.

Social Media and Behavioral Modeling for Public Health Decision-Making

Invited Session

Social Media Analytics

Chair: Hongru Du, Johns Hopkins University, Baltimore, MD, United States

1 - An LLM-Based Framework to Evaluate the Impact of Digital Media Exposure on Vaccination Choice

Shaochong Xu, Johns Hopkins University, Baltimore, MD, United States, Liyue Zhang, Amelia Jamison, Abe Hou, Hongru Du, Lauren Gardner

The digital information ecosystem plays a vital role in shaping public health behaviors, but the influence of social media–amplified exposure on individual health decision-making remains poorly understood. This study introduces a Large Language Model (LLM)–based framework to assess how health-related content consumed via social media informs vaccination attitudes and behaviors. Drawing on individual-level survey data and real-world news content from online platforms, our approach directly maps media preferences to vaccine attitudes, with applications demonstrated in both COVID-19 and MMR contexts. At the core of the framework is the hypothesis that individuals' attitudes and beliefs are reflected in the media content they consume. To test this, we create diverse "media diets" spanning the ideological spectrum, including politically extreme perspectives and verified misinformation, using actual circulating articles. The experiment proceeds in two steps: first, an LLM matches each participant to a personalized media diet based on their demographics and surveyed beliefs. Next, we evaluate whether this simulation allows the LLM to accurately predict vaccination choices as a function of individualized media exposure. Our findings reveal that LLMs using simulated media diets can closely replicate vaccine-related behaviors at the individual level, especially for those with well-articulated beliefs, underscoring a strong connection between personal beliefs and media consumption. These results significantly advance infodemiology by uncovering how information exposure mirrors underlying belief systems that shape health choices, offering valuable insights for designing targeted health communication. The generalizable framework provides a robust means to model debate and hesitancy around vaccination decisions beyond the current pandemic.

2 - Internet Search Trends and Infectious Disease Outbreaks & Understanding Spatial Variations In Relationship

Srikar Velichety, University of Memphis, Memphis, TN, United States, Utkarsh Shrivastava

Internet search trends (IST) are crucial for real-time surveillance of new cases of diseases (NCD). The predictive models based on IST are highly susceptible to the users' online search behavior, which bears similarities at the geographical level. The digital divide in underdeveloped nations has the potential to significantly skew the online search and disease outbreak correlation across geographical regions. This study investigates spatial variations in the association between IST and NCD, what factors contribute to this difference and how they can be incorporated to improve disease surveillance. We utilize a multilevel modeling approach to model the weekly data on

new cases of five infectious diseases in 48 states of the USA over five years. We consider the weather, state demographic, insurance coverage, tourism, and outbreaks in neighboring states. Our initial results suggest that internet search trends have a differential relationship to disease outbreaks across different geographies.

3 - Assessing Mmr Vaccination Strategies in Texas: A Scenario-Based Modeling Study of Measles Outbreaks

Kaiming Bi, UT Health Houston, Houston, TX, United States, Thuy Nguyen, Boya Peng

Measles, once common in the U.S., declined sharply after the MMR vaccine's adoption in 1971 and was declared eliminated in the U.S. in 2000. Measles has reemerged due to waning vaccination coverage and case importation and more than 200 cases reported in the past few months in West Texas. We used a calibrated mathematical model and stochastic simulations to assess the impact of vaccination on the expected number of cases. Raising vaccination coverage by 5% could prevent 133 cases (95% CI: 97–169), while a 5% reduction may result in 190 additional cases (95% CI: 133–273) in Gaines County. These findings highlight the critical need for robust vaccination strategies to mitigate measles outbreak risks.

4 - Identifying and Forecasting Importation and Asymptomatic Spreaders of Multi-Drug Resistant Organisms in Hospital Settings

Jiaming Cui, Virginia Tech, Blacksburg, VA, United States

Healthcare-associated infections (HAIs) from multi-drug resistant organisms (MDROs) pose a significant challenge for healthcare systems. Patients can arrive at hospitals already infected ("importation") or acquire infections during their stay ("nosocomial infection"). Many cases, often asymptomatic, complicate rapid identification due to testing limitations and delays. Although recent advancements in mathematical modeling and machine learning have aimed to identify at-risk patients, these methods face challenges: transmission models often overlook valuable electronic health record (EHR) data, while machine learning approaches typically lack mechanistic insights into underlying processes. To address these issues, we propose NeurABM, a novel framework that integrates neural networks and agent-based models (ABM) to leverage the strengths of both methods. NeurABM simultaneously learns a neural network for patient-level importation predictions and an ABM for infection identification. Our findings show that NeurABM significantly outperforms existing methods, marking a breakthrough in accurately identifying importation cases and forecasting future nosocomial infections in clinical practice.

1 - Scalable Metadata Curation via Context-Enriched LLMs and Semantic Term Guidance: A Case Study in Anatomical Standardization

Minoo Ahmadi, University of Southern California, Los Angeles, CA, United States, Minoo Ahmadi

Scientific data repositories face critical challenges in metadata standardization, particularly for domain-specific terminology that varies across research groups and experimental contexts. We present a novel automated framework that leverages large language models (LLMs) enhanced with contextual metadata to enable high-accuracy term curation. Each prompt incorporates information from multiple data fields within a record, providing rich semantic context that informs curation decisions and reflects the complex structure of scientific data.

We evaluate two guidance strategies that build on a shared foundation of contextual enrichment. The first, standard vocabulary prompting, appends the complete reference terminology to ensure comprehensive coverage. The second, similarity-guided prompting, uses semantic embeddings to retrieve the top-k most relevant vocabulary candidates. This similarity-based approach introduces a key innovation, offering substantial scalability advantages in repositories with large or expanding vocabularies. Building on these strategies, we develop a confidence-based hybrid method that dynamically selects the optimal prompting approach for each term based on semantic coherence assessment.

Evaluated on anatomical terms from the FaceBase craniofacial data repository, our proof-of-concept demonstrates that both approaches achieve high standalone accuracy, with the similarity-guided method exhibiting superior performance in capturing nuanced semantic relationships. The hybrid strategy further improves accuracy by intelligently combining both approaches. The framework effectively addresses terminology challenges, including synonyms, descriptive variants, and structural inconsistencies common in multi-source scientific repositories.

These results demonstrate that context-aware, LLM-guided semantic curation achieves robust accuracy in heterogeneous scientific databases, offering scalable solutions for metadata standardization with implications for data integration, interoperability, and research reproducibility.

2 - Synthetic Training for Assessment in Real-Time(Star): Enabling AI-Powered Patient Surveillance

Annajirao Challa, Binghamton University, Binghamton, NY, United States, Wen Cao, Sreenath Chalil Madathil, Mohammad Khasawneh

This research presents a novel AI-powered surveillance framework for monitoring oxygen therapy patients, with a dual focus on detecting mask dislodgement and early signs of perioral cyanosis. In clinical settings, visual cues often go unnoticed due to limited supervision. However, data scarcity, along with privacy, regulatory, and variability constraints, presents a major challenge to developing robust computer vision models. The Synthetic Training for Assessment in Real-Time (STAR) framework was designed to address these challenges. It introduces a hybrid synthetic data generation pipeline that combines procedural 3D modeling in Blender, GAN-based face generation via StyleGAN3 and CLIP, and digital illustration using Krita to simulate cyanotic symptoms. The visual fidelity was validated using Fréchet Inception Distance (FID), confirming their utility in downstream training. Semi-supervised annotation was employed to reduce manual labeling. Two state-of-the-art object detection models, YOLOv12 and YOLO-NAS were trained to detect oxygen masks. Eight lightweight CNNs were employed for cyanosis identification. Both detection and classification models were evaluated through baseline testing and k-fold cross-validation. YOLOv12 achieved a mean mAP@50 of 0.9859 ± 0.0019 while models like ShuffleNetV2 and ResNet18 exceeded F1-scores of 0.94. The results show that hybrid datasets, paired with these efficient neural architectures and robust evaluation, enable AI systems for patient monitoring. The STAR framework fuses generative and perception models, paving the way for ethical, scalable, and accessible AI solutions in data-sensitive environments.

3 - Llm-Augmented Medical Query Intention Detection with Interactive Bert

Shaochun Li, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Xuan Wei, Pengzhu Zhang

The proliferation of online medical platforms has fundamentally transformed patient consultation patterns, creating a critical need for accurate matching between patient queries and physician expertise. Each patient inquiry carries distinct medical requirements, making precise intention detection essential for optimal patient-provider pairing. This paper presents a novel framework that employs question answering (QA) data augmentation to enhance query intention detection in online medical systems. Our approach utilizes Large Language Models (LLMs) to generate semantically enriched answer data for patient inquiries, thereby augmenting the contextual information embedded within original questions. A modified BERT architecture, enhanced with an interactive attention mechanism, then integrates the generated answers with corresponding queries to capture nuanced semantic relationships and complex interactions. This methodology significantly improves medical query intention classification accuracy while maintaining adaptability to intention detection tasks across diverse online platforms. Comprehensive experiments on real-world medical platform data validate our method's effectiveness in enhancing both classification performance and service matching efficiency, providing a robust solution for understanding user intent in digital inquiry systems.

4 - Agentic AI Framework for Autonomous Clinical Trial Cohort Identification

Supraja Krovvidi, CapsicoHealth, Inc., San Mateo, CA, United States, Shloke Meresh, Siham Belgadi, Ramesh Jakka, Laurent Hasson

Clinical trial cohort identification remains a critical bottleneck in the pharmaceutical industry. Researchers must manually navigate complex medical coding systems, such as ICD-DX, ICD-PR, HCPCS/CPT, and DRG classifications, to define study populations. This manual approach to cohort definition is time-consuming, error-prone, and often lacks comprehensive coverage of relevant diagnostic and procedural codes. Recent developments in agentic AI have shown promise for drug development processes, but few implementations address the foundational challenge of accurate patient population definition. We hypothesize that an agentic AI framework integrating natural language processing, medical code validation, and automated cohort creation can significantly enhance the efficiency and accuracy of patient population definition for clinical research. We developed an agentic AI framework that integrates natural language processing, medical code validation, and automated cohort creation to enhance the efficiency and accuracy of patient population definition for clinical research. This work contributes to the expanding landscape of agentic AI in healthcare, addressing critical needs in integrating AI with clinical decision-making while incorporating safety and accountability considerations. Future research directions include expanding the framework to incorporate real-time clinical data integration, developing predictive models for cohort outcome assessment, and implementing advanced multi-agent architectures for autonomous study design optimization. Empirical evaluation demonstrates substantial improvements across key metrics. The framework achieves broader code coverage compared to manual methods, reducing cohort definition time by 95% while improving relevant patient capture by around 80%. Notably, for rare disease cohorts, the system attains 91% concordance with expert-curated definitions while discovering additional relevant codes overlooked by traditional approaches.

5 - Augmenting FDA Expert Committee Recommendations Using Large Language Models

Oliver Schaer, Drexel University, Philadelphia, PA, United States, Simon Spavound, Panos Markou, Nikolaos Kourentzes, Matthew Schneider

Institutions heavily rely on expert committees to advise on decisions requiring specialized knowledge by holding majority votes. However, by imposing binary decisions, nuanced information, such as uncertainty and emotion, is lost, which is integral to the experts' decision-making processes. For example, a member might vote in favor of a question but add a caveat or other important context that does not make it to the decision table where votes are presented. In this research, we utilize LLMs to capture advisory committee members' levels of uncertainty and emotion. Within the context of the FDA Advisory Committee, we specifically examine the decision to reject or approve the sale of drugs in the United States. We empirically test the incorporation of these nuances for improved decision-making to prevent costly product withdrawals after approval.

6 - Agentic Network and Knowledge Tree Based Medical Record and Multi-Modal Document Analyses and Comparison Across LLM Models for Pharmaceutical Sector in Areas Such as Patient Journey Analyses, Drug Development and Market Access

Jakka Sairamesh, CapsicoHealth, Inc, Palo Alto, CA, United States, Supraja Krovvidi, Siham Belgadi, Laurent Hasson, Shloke Meresh

Agentic-AI tools and Methods are fast becoming the foundation for automated decision making driven by the specific context-driven and task-based analyses and reasoning. In this presentation, we will focus on clinical medical record and document analyses using knowledge-networks and task-based reasoning and compare multiple LLMs (including LLAMA3, GPT4, Mistral, Gemini) on their performance to analyze and extract critical insights from records and documents. Such analyses has strong implications in the Pharmaceutical sector that deals with thousands of documents for drug-development, research, trials, applications for drug-approval, post-launch outcomes and more. We found that depending on domain and contextual searches (including text and image data) agentic methods combined with LLM accuracy can enable better research and improve clinical and pharmaceutical research and operations (e.g. MSLs, clinical affairs, clinical operations and more). We found over 85% accuracy when using agentic AI methods with reasoning when compared to RAG based context-specific searches. Our studies have shown that Agentic-AI based content-aware reasoning helps build automated systems of the future to drive better research and clinical operations, and improve healthcare outcomes.

7 - Enhancing Cross-Border Healthcare Data Exchange with LLMs, Genai, and Blockchain

Khaled Salah, Khalifa University, Abu Dhabi, United Arab Emirates

Healthcare systems across countries struggle to securely and efficiently exchange patient data due to fragmented regulations, lack of interoperability, inconsistent consent management, and limited trust among institutions. Existing solutions are unable to dynamically adapt to diverse legal, linguistic, and technical requirements, especially in cross-border scenarios. We propose a novel framework that uses LLMs, GenAI, and Blockchain technology to enable secure, regulation-aware sharing of healthcare data between institutions and across borders. LLMs and GenAI autonomously handle critical tasks such as interpreting local and international healthcare regulations (e.g., GDPR, HIPAA), verifying patient consent, selecting shareable data fields, harmonizing medical codes (e.g., ICD, SNOMED), and translating clinical content. Data is structured using FHIR standards, encrypted, and exchanged via a blockchain-governed access layer, which ensures traceability, policy enforcement, and tamper-proof auditability. The system addresses key challenges in global health data exchange: interoperability, compliance, privacy, and trust.

Modeling and Uncertainty in Large Language Models

Invited Session

Quality, Statistics and Reliability

Chair: Raed Al Kontar, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Naichen Shi, University of Michigan, Ann Arbor, MI, United States

1 - Speak to the Policy: Refining Policies with Language Feedback

Qiyuan Chen, University of Michigan, Ann Arbor, MI, United States, Raed AlKontar

We propose a novel framework for refining decision-making policies using natural language feedback. In our approach, we have running statistical policy whose behavior can be continuously critiqued via language. This feedback is then encoded and grounded using a Large Language Model (LLM), which acts as an intermediary that interprets and distills the feedback into actionable policy updates. Our method bridges the gap between symbolic feedback and statistical learning, allowing policies to evolve through language-guided interaction.

2 - Inv-Entropy: a Fully Probabilistic Framework for Uncertainty Quantification In Language Models

Haoyi Song, University of Michigan, Ann Arbor, MI, United States

Large language models (LLMs) have transformed natural language processing, but their reliable deployment requires effective uncertainty quantification (UQ). Existing UQ methods are often heuristic and lack a fully probabilistic foundation, largely due to model limitations and knowledge gaps. This work begins by providing a theoretical justification for the role of perturbations in UQ for LLMs. We then introduce a dual random walk perspective, modeling input-output pairs as two Markov chains with transition probabilities defined by semantic similarity. Building on this, we propose a fully probabilistic framework based on a novel inverse model, which quantifies uncertainty by evaluating the diversity of the input space conditioned on a given output through systematic perturbations. Within this framework, we define a new uncertainty measure, Inv-Entropy, implemented using bootstrapping and Monte Carlo estimation. A key strength of our framework is its flexibility: It supports various definitions of uncertainty measures, embedding functions, perturbation strategies, and similarity metrics. We also propose GAAP, a perturbation algorithm based on genetic algorithms, which significantly enhances UQ performance in empirical studies. Extensive experiments show that Inv-Entropy outperforms existing semantic UQ methods. Finally, we introduce a new evaluation metric, TSU (Temperature Sensitivity of Uncertainty), which directly assesses raw uncertainty values, unlike traditional accuracy-based metrics that rely on correctness as a proxy.

3 - Trustworthy LLM-in-the-Loop Bayesian Optimization

Raed Al Kontar, University of Michigan, Ann Arbor, MI, United States

Bayesian optimization (BO) is a sequential decision-making tool widely used for optimizing expensive black-box functions. Recently, Large Language Models (LLMs) have shown remarkable adaptability in low-data regimes, making them promising tools for black-box optimization by leveraging contextual knowledge to propose high-quality query points. However, relying solely on LLMs as optimization agents introduces risks due to their lack of explicit surrogate modeling and calibrated uncertainty, as well as their inherently opaque internal mechanisms. This structural opacity makes it difficult to characterize or control the exploration–exploitation trade-off, ultimately undermining theoretical tractability and reliability. To address this, we propose LLMIBO: LLM-in-the-Loop BO, a hybrid framework for BO that combines LLMs with statistical surrogate experts (e.g., Gaussian Processes ($\mathcal{GP}$)). The core philosophy is to leverage contextual reasoning strengths of LLMs for early exploration, while relying on principled statistical models to guide efficient exploitation. Specifically, we introduce three mechanisms that enable this collaboration and establish their theoretical guarantees. We end the paper with a real-life proof-of-concept in the context of 3D printing.

4 - Iterative Reinforcement Learning for Inference Time Adaptation of Diffusion Models and LLMs

Rongbo Zhu, University of Michigan, Ann Arbor, MI, United States

Generative models, including diffusion models for visual synthesis and Large Language Models (LLMs) for text, show immense promise. However, efficiently guiding these models to produce outputs that adhere to complex criteria, such as underlying physical laws in video prediction, remains a significant challenge. This paper introduces Iterative Reinforcement Learning for Inference Time Adaptation of Diffusion Models (IRLIA), a versatile method using reinforcement learning to improve pre-trained generative models, with a primary focus on video diffusion and potential applications to LLMs, directly at inference time. IRLIA employs an iterative RL approach where a task-specific simulator (e.g., a physics experiment simulator) serves to construct the reward function. This guides the generation process via value functions and guided search, steering outputs towards desired characteristics like physical plausibility in videos. This method enhances model outputs without retraining the base model, offering an efficient performance boost. We plan to demonstrate IRLIA's effectiveness initially on physics-based video generation (e.g., fluid dynamics), showing clear improvements in physical plausibility and predictive accuracy. We will also discuss its potential applicability and preliminary investigations for guiding LLMs towards complex textual requirements.

Adaptive Sampling and Monitoring in Spatially Distributed Systems

Invited Session

Quality, Statistics and Reliability

Chair: Jiahui Zhang, University of Wisconsin-Madison, Madison, WI, United States

Co-Chair: Kaibo Liu, UW-Madison, Madison, WI, United States

1 - Adaptive Sampling for Automated Post-Disaster Rapid Damage Assessment via Level-Set Cost-Aware Bayesian Optimization

Boyang Xu, Arizona State University, Tempe, AZ, United States, Hao Yan, Mostafa Reisi Gahrooei, Mohammad Ilbeigi

Natural disasters frequently inflict severe damage to the built environment, which demands a rapid, reliable, and cost-effective damage assessment for emergency response. However, traditional methods for Post-Disaster Damage Assessment often rely on static, labor-intensive data collection strategies that can be prohibitively expensive and struggle to adapt to dynamic post-disaster conditions. In this study, we propose a cost-aware Bayesian optimization framework that continuously guides autonomous data collectors, e.g., an Unmanned Aerial Vehicle (UAV), toward the most informative regions. By dynamically updating damage estimates across different geographic zones, our approach systematically reduces uncertainty while minimizing human resource needs and other operational costs. The result of the algorithm provides accurate and timely damage estimates that support informative and fast emergency responses.

2 - Active Learning for Data Stream Monitoring

Christian Capezza, University of Naples Federico II, Napoli, Italy, Antonio Lepore, Kamran Paynabar

In spatially and temporally distributed environments, supervised statistical process monitoring approaches require labeled data to identify in-control and out-of-control states. However, acquiring labels—such as through physical inspections or destructive testing—is often expensive and infeasible at scale. This work introduces a stream-based active learning framework for adaptive labeling under a constrained budget. The method integrates partially hidden Markov models (pHMMs) to exploit temporal dependencies and efficiently combine labeled and unlabeled data for multi-state classification. A novel dual-criterion strategy balances exploration, to identify previously unseen process states, with exploitation, to improve boundary resolution among known states. Unlike traditional pool-based approaches, our method operates in real time, issuing labeling decisions for each incoming observation. An online pHMM fitting algorithm is also developed with a tailored initialization strategy for imbalanced settings. The proposed active learning framework is validated through an extensive simulation study and a case study on monitoring a resistance spot welding process in automotive manufacturing. In this setting, dynamic resistance curves are monitored continuously, but labels are acquired through costly ultrasonic tests. Results show that the proposed active learning strategy substantially improves classification accuracy while minimizing labeling costs.

3 - Active and Data-Efficient Spatiotemporal Monitoring via Adaptive Sampling Strategies

Jiahui Zhang, University of Wisconsin-Madison, Madison, WI, United States

Spatiotemporal data arise naturally in many physical and industrial systems, such as environmental sensing networks and distributed manufacturing processes, where sensor measurements are correlated both spatially and temporally. In real-world settings, sensor observations are often partial and sparse due to operational or resource constraints, making it challenging to monitor such systems in a timely and accurate manner. Existing approaches require either strong distributional assumptions or sufficient historical data, which limits their applicability in real-world applications where only sparse observations are available beforehand and the data distributions are unknown. In this work, we develop an online monitoring framework that integrates adaptive sampling with nonparametric modeling to efficiently and effectively detect abnormal behaviors under limited sampling budgets. A spatiotemporal Gaussian process is used to represent the system state, and is sequentially updated as new data arrive. An acquisition function inspired by Bayesian optimization principles guides sampling decisions at each time step, balancing uncertainty exploration and exploitation for potential anomalies. Simulation studies on synthetic spatiotemporal processes demonstrate the framework's ability to maintain high monitoring accuracy with constrained sensing resources and limited amount of historical data.

4 - Self-Expressive Generalized Linear Models for Federated Network Optimization

Mohammad Amini, University of Florida, Gainesville, FL, United States, Mostafa Reisi, Aleksandr Kazachkov

We propose a novel federated learning framework designed for decentralized networks with heterogeneous data, where each local client models its outcome variable using a generalized linear model (GLM). Unlike conventional federated learning, which assumes a global model shared across all nodes, our approach supports personalized model training while enabling localized cooperation. To do so, we leverage the topology of the underlying communication network to guide how models influence one another. This formulation allows our framework to interpolate smoothly between isolated local learning and centralized model fusion, depending on the network's structure and the degree of data heterogeneity. Moreover, the model includes self-tuning mechanisms that automatically adjust key federated learning parameters—such as regularization strength and neighbor influence—based on local and network-level signals. A key theoretical contribution is that we show standard federated learning is a special case of our framework when the network is fully connected. This positions our model as a strict generalization of classical FL, with added flexibility for personalization and structured collaboration. We develop a decentralized optimization algorithm based on the alternating direction method of multipliers (ADMM) to efficiently solve the problem without central coordination. Experimental results demonstrate that our method outperforms existing federated and personalized learning baselines in terms of predictive performance, adaptability, and robustness to network sparsity. Our framework is especially suited for applications such as precision agriculture, distributed healthcare, and sensor networks, where local models must adapt to their environment while benefiting from selective, topology-aware cooperation.

1 - A Multi-Stage Stochastic Optimization Approach for Maintenance Planning of Co-Located Infrastructures Under Deterioration and Budget Uncertainties

Bingjie Wang, University of South Florida, Tampa, FL, United States, Hung Nguyen, Qing Lu, Qiong Zhang, Mingyang Li

Deteriorating transportation infrastructure (TI) and water infrastructure (WI) are interdependent due to their co-location, with failures and degradation in one system influencing the performance of the other, while complex intra-system interactions further propagate deterioration impacts within each network. Given the inherent unpredictability of infrastructure deterioration and budget fluctuations, effectively managing these interdependent systems requires explicitly accounting for uncertainties. This research develops a network-wide, long-term joint maintenance planning framework for co-located TI and WI systems, capturing both intra-system and inter-system interdependencies. We further propose a multi-stage stochastic programming model to optimize maintenance planning, explicitly modeling uncertainties in deterioration rates of the co-located roads and pipes, as well as future budget variations over a defined planning horizon. A progressive hedging algorithm is employed to determine optimal maintenance decisions within this framework. A case study based on the Ybor City, Tampa testbed demonstrates the effectiveness of the proposed method, highlighting its capability for cost-efficient and proactive joint maintenance planning across interdependent infrastructure systems. Comparative analysis with alternative strategies further demonstrates the benefits of the proposed approach in reducing long-term costs and enhancing network reliability.

2 - Deep Neural Network for Predicting GPU Failure Time Distributions Under Competing Risks

Jie Min, University of South Florida, Tampa, FL, United States, Yueyao Wang

Time-to-event data, or lifetime data, are commonly seen in areas including biology, medical science, and engineering. In analyzing such data, one important topic is the prediction of the survival probability of units. This paper proposes a deep neural network for predicting the survival probability of units with censored data and competing risks without parametric assumptions. The neural network takes the sub-distribution hazard functions as outputs and uses likelihood loss with L0 smoothing penalty. The performance of the proposed neural network is evaluated and is compared with existing methods using simulated datasets. The advantages and disadvantages of the proposed and existing neural networks are discussed in terms of predictive discrimination and calibration. The proposed neural network is then applied to predict the survival probability of GPUs in the Titan supercomputer.

3 - An AI Enhanced Simulation Framework for Informing Nursing Home Staffing Decisions

Yulun Xu, University of South Florida, Tampa, FL, United States, Nazmus Sakib, Hongdao Meng, Nan Kong, Kelly Smith, Mingyang Li

Nursing homes (NHs) provide continuous care for frail older adults with complex needs, but rising demand due to population aging highlights the need for effective management strategies. Despite high costs, many NHs continue to face regulatory violations and workforce shortages, revealing systemic challenges in maintaining care quality.

Many of the existing works primarily assumed homogeneity among individual patients and analyzed service demand based on overall patient volume, overlooking the variation in care needs arising from diverse individual characteristics. To address these limitations and fill existing research gaps, we propose an AI-enhanced simulation framework for characterizing the heterogeneous service demand of NH residents over time and determining the appropriate staffing decisions. Specifically, deep learning methods will be integrated with digital simulation to predict service demand of a heterogeneous population of NH residents at both resident and facility levels, and further evaluate various types of staffing decisions, such as ratio-based and need-based staffing decisions. The effectiveness of the proposed work will be showcased via a real case study.

4 - A Comparative Analysis of Data-Driven Modeling Approaches to Forecast Cyanobacteria Algal Blooms in Eutrophic Lake Discharge Canals

Hung Nguyen, University of South Florida, Tampa, FL, United States, Mauricio Arias, Qiong Zhang, Osama Tarabih, Cassondra Armstrong, Detong Sun, Edward Philips

This research explores the use of data-driven models to develop forecasting tools for algal blooms (ABs) represented by the Chlorophyll-A (Chla) concentrations in the St. Lucie and Caloosahatchee canals in Lake Okeechobee, Florida. By different approaches, the study aims to understand the differences in Chla dynamics between the two canals, identify the main drivers of Chla concentration in each, and develop suitable Chla forecasting models for the canals' operation purposes. The findings not only contribute to improving understanding of water quality dynamics in Lake Okeechobee canals but also can provide flexible tools for the decision-makers in management strategies based on the waterbody's characteristics in general.

Behavior in Queueing and Service Systems

Invited Session

Behavioral Operations Management

Chair: Blair Flicker, University of South Carolina, Columbia, SC, United States

1 - Reference Dependent Preferences in Priority Services

Leon Valdes, University of Pittsburgh, Pittsburgh, PA, United States, Kaitlin Daniels

Service providers offer priority alternatives in a variety of settings, e.g., TSA lines at airports, faster pickup options in ride hailing, etc. In this work, we explore whether and how reference-dependent preferences affect customer choices in such settings, and as a result, how service providers should account for them when designing their menus of options. In particular, we consider the presence of multiple reference points---the quoted service times for the normal and fast service---and people's responses to them in priority settings, which are currently not well understood in the literature.

2 - Understanding Queue Abandonment: the Role of Wait-Time Communication and Distraction

Adam Arveson, University of Cincinnati, Cincinnati, OH, United States, Craig Froehle, Yinghao Zhang, Kanix Wang

Despite significant advancements in predictive analytics and service delivery enhancement, customers often still face long wait times in physical (e.g., retail, healthcare) and virtual environments (e.g., ridesharing, chatbots). Drawing on Maister's (1985) well-known principles, two predominant tactics have emerged: informing customers about their wait through clear communication, and employing distraction techniques to divert attention away from the wait. Any firm's attempt to find a balance by combining both tactics, but is this the best approach? We conduct a series of controlled experiments to examine how customer abandonment behavior is affected by how an organization informs or distracts its customers. We experimentally varied the ability to retrieve information and the frequency of information pushed amongst distractions.

3 - Silent Abandonment in Text-Based Contact Centers: Identifying, Quantifying, and Mitigating Its Operational Impacts

Antonio Castellanos, Hebrew University of Jerusalem, Jerusalem, Israel, Galit Yom-Tov, Yair Goldberg, Jae Park

To improve services, companies allow customers to interact with agents via text. Unlike traditional call centers, text-based contact centers face unique operational challenges due to information uncertainty, particularly in measuring customer experience proxies such as abandonment and patience. A major source of this uncertainty is *silent abandonment*, in which customers leave while waiting without notifying the system. As a result, the system is unaware that the customers left, and the agent's time is wasted. Furthermore, the system may not be aware (even retrospectively) whether a customer silently abandoned or was served.

We develop classification models to investigate the magnitude of silent abandonment. A sample of 17 companies shows that 3%-70% of the customers entering these contact centers abandon silently. A detailed text-based analysis of one company finds that 71.3% of abandoning customers do so silently, reducing agent efficiency by 3.2% and system capacity by 15.3%, incurring an estimated annual cost of \$5,457 per agent. Separate from this classification, we develop an expectation-maximization (EM) algorithm to accurately estimate customers' patience under information uncertainty and examine covariates influencing its value.

We find that companies should use classification models to estimate abandonment scope and our EM algorithm to estimate customer patience. We propose strategies to mitigate the operational impact of silent abandonment by predicting likely behavior or changing service design. Specifically, we show that while allowing customers to write while waiting in the queue creates missing data, it also significantly increases patience and reduces service time, leading to lower abandonment and staffing requirements.

4 - How a Wait's Presentation Affects Its Perceived Cost

Blair Flicker, University of South Carolina, Columbia, SC, United States

As virtual waits replace physical queues, managers today must decide how to communicate wait characteristics to customers. We experimentally demonstrate that this decision can substantially influence customer behavior. Clock-framed waits, like Uber, convey information accurately but are unappealing. Conversely, people systematically underestimate the duration and disutility of queues.

Building B Level 4 B405

Predictive and Constraint-Based Learning Techniques with Business Applications

Invited Session

Artificial Intelligence

Chair: Neta Rabin, Tel-Aviv University, Tel-Aviv, Israel

Co-Chair: Gonen Singer, Bar-Ilan University, Ramat-Gan, Israel

1 - Resource Allocation in Classification Task with Feature-Based and Sample-Based Constraints

Gonen Singer, Bar-Ilan University, Ramat-Gan, Israel

Efficient resource allocation in classification tasks presents a significant challenge across various domains. These tasks demand high predictive accuracy and require compliance with complex constraints arising from resource limitations. Traditional machine learning (ML) models primarily focus on improving prediction accuracy but often fail to incorporate decision constraints, resulting in suboptimal resource allocation in real-world settings. This project proposes a two-phase framework that integrates classification with optimization models to allocate resources effectively while addressing two primary constraint types: (1) Feature-based constraints, which set restrictions on predicted classifications for a specific class based on certain feature values, and (2) Sample-Based Constraints, which require grouped samples to be assigned to the same class. To illustrate these constraints, consider a retention resource allocation problem for efficient churn risk management in a telecom company. The goal is to classify customers based on their churn risk level and design targeted interventions to reduce churn rates. Each customer receives a churn risk score based on their usage patterns, demographics, and interaction history. The operational challenge lies in efficiently allocating limited retention resources: there is a fixed budget for customer retention efforts across different customer segments (feature-based constraint), and certain groups (e.g., families on shared plans) must receive the same retention efforts to maintain fairness and prevent negative impact on other group members (sample-based constraint). Addressing this challenge requires balancing the prioritization of high-risk customers with the constraints of budget and operational limitations, ensuring the highest return on investment for retention efforts.

2 - A Graph-Based Sparse Filter Feature Selection Method for Multi-Class and Ordinal Time Series Classification

Neta Rabin, Tel-Aviv University, Tel-Aviv, Israel

Feature selection is a key pre-processing step for high-dimensional datasets. Filter-based methods evaluate feature relevance independently of classifiers. This work introduces a graph-based filter approach for multi-class classification that significantly reduces the number of features while preserving class-separability information. The method integrates the Jeffries-Matusita distance with diffusion maps for nonlinear dimensionality reduction. Features are ranked based on their distribution in the reduced space, allowing the selection of a compact subset with complementary separation capabilities. A modified version is also proposed to handle ordinal feature selection. Experiments on public tabular and time-series datasets show the method outperforms existing filter-based techniques.

3 - Detecting Coordination Within and Across Encrypted Platforms

Shahar Somin, Bar Ilan University, Ramat Gan, Israel, Tom Cohen, Jeremy Kepner, Alex Pentland, Keeley Erhardt

Adversarial activity on networks is escalating rapidly, with cybercrime damages projected to reach \$9.5 trillion annually in 2024. While machine learning and deep learning have been widely applied in cybersecurity, they often depend on large volumes of clean, labeled data and struggle to adapt to encrypted, fragmented, and evolving environments. Graph-based methods offer a structural alternative, but typically focus on explicit, observable links—limiting their effectiveness when connections are hidden or obfuscated. This reflects a fundamental divide between the data plane, where actions are recorded, and the control plane, where coordination actually occurs. To bridge this gap, I present a scalable framework for detecting coordination within and across encrypted platforms by leveraging latent temporal patterns. We introduce temporal fingerprinting, which characterizes user behavior through bursty activity dynamics. These behavioral signals enable both identity matching and community detection across domains, even in the absence of structural links or content similarity. We further propose a generative model that links control-plane coordination to emergent data-plane correlations, revealing the conditions under which structure-based techniques fail. The approach is adaptable to large-scale, content-restricted environments and supports applications in pre-emptive cyber defense, fraud detection, and multi-platform surveillance—providing new tools for AI-driven decision-making in adversarial and data-sparse settings.

4 - Data-Driven Surrogate Simulation Optimization for Firefighting Resource Allocation

Yaniv Leuchter, Tel Aviv University, Pardes Hanna-Karkur, Israel

Efficient planning and resource allocation are vital for firefighting departments to ensure rapid emergency response and operational readiness. As urban growth, climate change, and unpredictable crises intensify service demands, data-driven strategies are increasingly essential. This study addresses limitations in current decision-support tools, such as business intelligence systems, which often overlook dynamic interactions between fire stations and incidents. We propose a simulation-optimization framework to enhance resource allocation, aiming to reduce response times and strengthen system resilience. Our multi-phase approach begins with a high-fidelity simulation model built on multidimensional historical data—incident locations, response times, resource use, and station dynamics. This model supports evaluating alternative resource configurations. We then implement a simulation-based optimization algorithm to identify more effective deployment strategies. To accelerate computations, a surrogate model is developed using supervised learning, and dimensionality reduction techniques are applied to isolate key drivers of response efficiency. The framework also allows for sensitivity analysis and demand forecasting based on urban growth and climate trends. A case study in one district of the Israeli Fire and Rescue Service demonstrates the framework's effectiveness. Using historical data, we assess operational performance across multiple scenarios. Preliminary results show reduction in the average response time. This work informs strategic decisions for policymakers, including the Fire Commissioner of Israel, supporting evidence-based resource planning. Funded by the Ministry of Science and Technology, this research showcases the value of academic-government collaboration in improving emergency response systems.

5 - An End-to-End Imputing Autoencoder Framework for Artifact-Aware Sleep Apnea Detection

Rahul Sharma, Georgia Institute of Technology, Atlanta, GA, United States

Physiological signals, such as those used in sleep studies, are often affected by artifacts arising from patient movement, sensor displacement, or external interference. These artifacts can significantly degrade the performance of automated diagnostic systems, such as those for sleep apnea detection. Conventional approaches to mitigate this issue typically rely on manual artifact removal or supervised filtering techniques that require prior knowledge or expert-labeled data. However, these methods can be labor-intensive, non-scalable, and often fail to generalize across datasets with varying noise characteristics. In this work, we propose a novel unsupervised deep learning framework that addresses the dual challenge of artifact removal and apnea detection in physiological signals through a unified architecture. The proposed method utilizes a dual-purpose convolutional autoencoder designed to decompose multichannel physiological signals into clean and artifact components without requiring labeled artifact data. Alongside this decomposition, an integrated apnea detection module is trained directly on the clean signal representation to accurately identify apnea events. This joint training approach ensures that the apnea detection model learns to rely only on artifact-free features, enhancing its robustness and predictive reliability. The model is rigorously evaluated on both synthetic and real-world datasets. By simultaneously performing artifact removal and classification, our approach eliminates the need for separate preprocessing pipelines and enables end-to-end learning from raw physiological signals. This unified model offers a scalable and generalizable solution for artifact-resilient biomedical signal analysis, with promising implications for real-time and automated diagnosis in clinical and home-based monitoring settings.

Pedagogical Design and Innovations for Analytics Education

Invited Session

INFORMS Committee on Teaching and Learning

Chair: Clara Novoa, Texas State University, San Marcos, TX, 78666, United States

1 - Teaching with the Burrito Optimization Game**Lawrence Snyder, Lehigh University, Bethlehem, PA, United States, Karmel Shehadeh, Luis Novoa**

Gurobi's Burrito Optimization Game is a fun, free, and interactive online game that aims to introduce learners to the basic ideas behind mathematical optimization (MO) in the operations research (OR), business analytics (BA), and supply chain management (SCM) fields. In the game, players drag and drop burrito trucks onto a city map in order to serve customers and maximize the profit of the burrito company. The underlying problem is a classic MO problem, a facility location problem. We conducted an experiment to explore the effectiveness of the game as an aid for teaching MO in a classroom environment. Our results show that the game is effective in both building understanding of and confidence in MO, as well as reinforcing players' prior knowledge of the concepts under proper instructor-guided discussion. In this presentation, we present an overview of the game, discuss its use in a classroom setting, and present our findings from this experiment.

2 - Purposeful Analytics Course Design**Julie Williams, University of West Florida, Pensacola, FL, United States**

The goals and benefits of prescriptive analytics assignments can be emphasized with innovative titles, scaffolded formats, and a template to guide students through the modeling process. In an online prescriptive analytics course, implementing these changes led to improved student engagement, with a higher percentage of participants submitting all modeling assignments—even when the lowest assignment grade could be dropped.

3 - Problem Solving and Panic Attacks: Teaching Analytics Without Frying Brains**Susan Palocsay, James Madison University, Harrisonburg, VA, United States, Luis Novoa, Scott Stevens**

In the never-ending quest to improve teaching and learning in our analytics classes, we are currently studying cognitive load theory (CLT). First introduced in the field of educational psychology almost four decades ago, CLT provides an architectural model of human cognition and processes for acquiring complex problem-solving skills. Based on this model, it identifies three types of cognitive load—intrinsic, extraneous, and germane—and gives guidance on ways to manage each type for optimal learning and retention of knowledge and skills. In this presentation, we will explain the core principles of CLT and explore their practical application in all three stages of teaching analytics, i.e., presentation, practice, and assessment. The goal is to foster *productive* cognitive effort, rather than “frying brains,” and enhance student performance outcomes while also maintaining mathematical rigor. We will consider how instructional methods that are informed by CLT have the potential to improve conceptual understanding and problem-solving ability in quantitative courses. Examples based on topics in introductory statistics and management science, where students typically struggle, will be used to illustrate these methods. We will also discuss ideas for pedagogical research to gather evidence in support of CLT in analytics classrooms.

4 - Build, Deliver, Showcase: Lessons from Scaling An Analytics Lab for Real-World Impact**Daniel Pirutinsky, UC Berkeley, Berkeley, CA, United States**

Teaching analytics effectively at scale demands innovative strategies for student engagement, real-world relevance, and pedagogical rigor. This talk outlines the evolution of the Master's of Analytics course, "Analytics Lab," a project-driven, capstone-style class emphasizing practical skills through the cycle of Build, Deliver, Showcase.

Launched in 2022, the course transitioned from traditional lectures to active-learning sessions, progressively refining student deliverables from basic reports to sophisticated dashboards and presentations. By integrating licensed industry datasets and structured external collaborations, the course enhances authenticity and professional relevance. A culminating public Showcase event—evaluated by alumni and industry judges—anchors student accountability and ensures high-quality outcomes.

This talk provides insights into structuring large-scale analytics education, fostering student professional development, and effectively leveraging real-world collaborations.

Data-Driven vs. Rule-Based: Bridging the Gap for Real-World Applications

Invited Session

Data Mining

Chair: Jiajing Huang, Kennesaw State University, Atlanta, GA, 30346, United States

Co-Chair: Feng (Ryan) Lin, University of Washington, Seattle, WA, United States

1 - Deepmide: a Multivariate Spatio-Temporal Deep Learning Model for Ultra-Scale Offshore Wind Energy Forecasting**Feng Ye, Clemson University, Clemson, SC, United States, Xinxi Zhang, Michael Stein, Ahmed Aziz Ezzat**

The hyper-increase in scale and capacities of modern offshore wind turbines—with altitudes approaching many of the world's tallest landmarks—motivates a departure from univariate wind energy forecasting methods that are only focused on a single representative height. In response, we propose DeepMIDE—a multivariate statistical deep learning method which—unlike existing time-series and space-time methods—jointly models the spatial, temporal, and vertical variations and dependencies in the offshore wind resource and corresponding power output. DeepMIDE is a multi-input, multi-output integro-difference equation model with a nonstationary multivariate kernel, for which key physically meaningful parameters are learnt via an advanced deep transformer architecture that extracts the governing dynamics of wind propagation and formation from streams of weather maps. Tested on real-world data from the offshore wind energy areas in the U.S. East Coast—where Giga-watt scale offshore wind

farms are in-development— DeepMIDE is shown to produce forecasts that are of higher accuracy and enhanced interpretability than prevalent statistical and deep learning-based forecasting methods.

2 - Visual Analytics to Assist Human-Machine Teaming

Jieqiong Zhao, Augusta University, Augusta, GA, United States

Artificial intelligence and machine learning (AI/ML) models have become powerful tools for decision support, capable of processing vast amounts of data that would be otherwise impossible to utilize. Yet, in high-stakes domains, human experts are still relied upon to validate model outputs and make final decisions as no AI/ML model is perfect. Therefore, effective human-machine teaming requires humans to understand, trust, and appropriately leverage AI/ML predictions. In this talk, I present a human-centered approach to developing visual analytics systems that integrate expressive visualizations with interpretable AI/ML algorithms. I will share both theoretical and practical advancements aimed at calibrating human adoption of AI/ML models, including systems that support domain experts in real-world applications. I will also present findings from a controlled experiment that investigates how uncertainty visualizations influence trust calibration in human-machine interactions, offering insights into the design of more reliable and transparent decision support systems.

3 - Structure-Independent Prediction of Protein-Protein Binding Affinity via Sequence-Based Deep Learning

Lingtao Chen, Kennesaw State University, Marietta, GA, United States, Yixin Xie

Protein-protein interactions (PPIs) are fundamental for biological functions and play key roles in health and diseases, including cancer, neurodegenerative disorders, and infectious diseases. Binding affinity, measured as changes in Gibbs free energy (ΔG), is crucial for identifying PPIs. Accurate prediction of ΔG between protein pairs is therefore important for understanding biological mechanisms. Traditional structure-based approaches are often limited by the availability of high-quality experimentally determined structural data. Here, we introduce a fully sequence-based deep learning framework that integrates rich protein embeddings with multiple neural architectures to predict ΔG directly from primary protein sequences. We systematically evaluate convolutional, transformer, and graph-attention architectures in combination with custom and pretrained sequence embeddings. The best model variant demonstrates substantial gains in predictive accuracy and generalization over earlier methods. Our models not only deliver robust performance across a diverse benchmark of protein complexes, but also exhibit stability under sequence perturbations, which show their practical utility when structural information is unavailable. By bypassing the need for three-dimensional structures and achieving state-of-the-art performance from sequence alone, this framework paves the way for scalable, structure-independent exploration of PPIs in drug discovery, protein engineering, and beyond.

4 - A Comprehensive Database Collection for Alzheimer's Disease: Organizing Key Research Domains to Enhance Diagnostics and Treatment

Johaam Kathilankal Jis, Kennesaw State University, Kennesaw, GA, United States

Alzheimer's Disease (AD) is a neurodegenerative disease that is progressive and mainly affects the brain causing a decline in cognitive ability in the regions of memory, reasoning, and language. According to a study conducted by the National Institute of Aging, AD is currently the 7th leading cause of death in the United States. Our research goal is to review existing computational methods and databases for further AD research. The work first starts with a brief introduction about AD and then goes to discuss different computational methods within AD research and then goes on to discuss databases. The computational methods part of the work will focus on different methods that are useful in AD research which includes talking about different machine learning, natural language processing, and molecular dynamic simulations procedures. Then we go on to talk about databases which are classified into 8 different categories. Each category is then defined followed by an explanation of how each individual database within the category can help play a role in AD research. Finally, in the application section, we will talk about different applications related to AD treatment. This research ultimate goal is to aid medical professionals, researchers, and pharmaceutical companies with valuable data to improve AD treatment and research.

5 - Bridging the Gap: Costar-a for Smarter Prompting in Localized Language Models

Nzubechukwu Ohalet, Kennesaw State University, Atlanta, GA, United States

As data-driven approaches continue to advance the capabilities of artificial intelligence, optimizing prompt design has emerged as a critical factor in improving the performance of large language models (LLMs). In this work, we present COSTAR-A, an enhanced prompt engineering framework that builds upon the existing rule-based COSTAR method—which incorporates Context, Objective, Style, Tone, Audience, and Response—by introducing an additional component: Answer. While the original COSTAR framework effectively improves clarity and alignment for general-purpose LLMs, it demonstrates limitations when applied to localized or fine-tuned models. Through a series of controlled prompt-response experiments, we show that the data-driven COSTAR-A framework leads to more structured and decisive outputs in localized LLMs, such as Llama 3.1. These findings highlight how a flexible, data-informed approach to prompt design can bridge the performance gap between generic rule-based methods and the nuanced demands of real-world, low-resource AI deployments.

Advancing Theories and Methodologies in Financial Data Mining: Quantile Models, Network Structures, Diagnostic Frameworks, and Social Signal Integration

Invited Session

Data Mining

Chair: Xiaorui Zhu, Towson University, ELLICOTT CITY, MD, 21252, United States

1 - Quantile Predictions for Equity Premium Using Penalized Quantile Regression with Consistent Variable Selection Across Multiple Quantiles

Shaobo Li, University of Kansas, Lawrence, KS, United States

This paper considers equity premium prediction, for which mean regression can be problematic due to heteroscedasticity and heavy-tails of the error. We show advantages of quantile predictions using a novel penalized quantile regression that offers a model for a full spectrum analysis on the equity premium distribution. To enhance model interpretability and address the well-known issue of crossing quantile predictions in quantile regression, we propose a model that enforces the selection of a common set of variables across all quantiles. Such a selection consistency is achieved by simultaneously estimating all quantiles with a group penalty that ensures sparsity pattern is the same for all quantiles. Consistency results are provided that allow the number of predictors to increase with the sample size. A Huberized quantile loss function and an augmented data approach are implemented for computational efficiency. Simulation studies show the effectiveness of the proposed approach. Empirical results show that the proposed method outperforms several benchmark methods. Moreover, we find some important predictors reverse their relationship to the excess return from lower to upper quantiles, potentially offering interesting insights to the domain experts. Our proposed method can be applied to other fields.

2 - Enhancing Bankruptcy Prediction: a Two-Layered Network Approach Using Latent Space Models

Tianhai Zu, University of Texas at San Antonio, San Antonio, TX, United States

In this study, we present a novel statistical approach to corporate bankruptcy prediction by leveraging complex network analysis. We introduce a two-layered network structure that captures both supply chain relationships and investment-co-investment patterns among companies, providing a more comprehensive view of corporate interdependencies than traditional methods. To analyze this complex structure, we develop a flexible multi-layered latent position model that efficiently extracts key features from the network. Our methodology employs advanced statistical techniques to estimate latent positions underlying this two-layered network, which are then utilized as predictors in a bankruptcy prediction model. Using the US public company data, we demonstrate that incorporating these network-derived features significantly enhances the predictive power of bankruptcy models. Our results reveal that these latent positions estimated from network structure capture crucial relational information that is highly relevant to a company's financial stability. This approach not only outperforms traditional prediction methods but also provides interpretable insights into the role of corporate interconnectedness in financial risk. Our work aims to offer a robust statistical framework for integrating complex relational data into predictive modeling for bankruptcy risk assessment.

3 - The Ripple Effect of Corporate Social Media: How Firm-Generated Content (FGC) Shapes Investor Sentiment from User-Generated Content (UGC) and Stock Performance

Xiaorui Zhu, Towson University, Ellicott City, MD, United States

The popularity of social media platforms has fundamentally transformed word-of-mouth communication, significantly impacting stock market dynamics. Using over 60 million posts from X.com (formerly known as Twitter), this study explores how the posts made by the company's official account (firm-generated content, FGC) versus those from general users (user-generated content, UGC) interact with firms' stock performance differently. With the computationally intensive framework that incorporates the panel vector autoregressive (PVAR) model, we find that UGC sentiment, particularly bullishness, has significant and positive influences on future stock returns, while FGC positive and negative sentiments do not exhibit strong direct effects on stock returns. However, our empirical findings confirm the significant indirect effects of FGC sentiments on the stock return mediated through UGC sentiment and engagement metrics. Specifically, a stronger positive tone in FGC significantly increases bullishness of UGC, which in turn raises stock returns. Likewise, negative sentiment from FGC does not directly influence stock returns but contributes to shaping bullish sentiment of UGC, which then negatively affects stock returns. The findings hold practical implications for both investors and firms, suggesting that strategic management of corporate social media communications can influence market perceptions and trading activities.

4 - A Unified Framework for Residual Diagnostics in Generalized Linear Models and Beyond

Zwei Lin, Texas State University, San Marcos, TX, United States

Model diagnostics is an indispensable component of regression analysis, yet it is not well addressed in standard textbooks on generalized linear models. The lack of exposition is attributed to the fact that when outcome data are discrete, classical methods (e.g., Pearson/deviance residual analysis and goodness-of-fit tests) have limited utility in model diagnostics and treatment. This paper establishes a novel framework for model diagnostics of discrete data regression. Unlike the literature defining a single-valued quantity as the residual, we propose to use a function as a vehicle to retain the residual information. In the presence of discreteness, we show that such a functional residual is appropriate for summarizing the residual randomness that cannot be captured by the structural part of the model. We establish its theoretical properties, which lead to the innovation of new diagnostic tools, including the functional-residual-vs-covariate plot and Function-to-Function (Fn-Fn) plot. Our numerical studies demonstrate that the use of these tools can reveal a variety of model misspecifications, such as not properly including a higher-order term, an explanatory variable, an interaction effect, a dispersion parameter, or a zero-inflation component. The functional residual yields, as a byproduct, Liu-Zhang's surrogate residual, mainly developed for cumulative link models for ordinal data (Liu and Zhang, 2018, JASA). In general, it considerably broadens the diagnostic scope, as it applies to virtually all parametric models for binary, ordinal, and count data, all within a unified diagnostic scheme.

Building B Level 4 B409

Empirical Research on Innovation and Technology

Invited Session

Technology, Innovation Management and Entrepreneurship

Chair: Ran Zhuo, University of Michigan, Ann Arbor, United States

1 - How Big is too Big? the Competitive Effects of Shipping Technology Innovation

Anhua Chen, Cornerstone Research, Cambridge, MA, United States

Technological innovation drives economic progress but can also lead to unintended consequences, such as market over-consolidation. This paper examines the competitive effects of technological advancement in the container shipping industry, focusing on the relationship between vessel size and market structure, and its impact on welfare. Using a dynamic oligopoly model and proprietary data, we quantify the economies of scale associated with vessel size and explore how it interact with market competition and investment behavior. We find that a 10% increase in vessel size reduces operational costs by 3.4% but contributes to market concentration, potentially offsetting consumer benefits. Counterfactual analysis suggests that the welfare-optimal vessel size is around 20,000 TEU under current demand level, as larger vessels risk over-consolidating the market. Additionally, smaller innovation steps promote competition, while larger steps drive consolidation. These findings highlight the need for policymakers to balance the efficiency gains of technological advancements with their competitive impacts, particularly when designing infrastructure investments in industries with strong economies of scale.

2 - Human-Centric Perishable Inventory Management with AI-Assistance

Yu Nu, University of South Carolina, Chapel Hill, SC, United States, Meng Qi, Karan Girotra, Elena Belavina

Up to 20% of food purchased by restaurants is wasted before reaching customers, with commercial leftovers being the major contributor due to poor production planning. This study introduces two AI decision-making assistants that support perishable inventory management differently in human-centric commercial kitchens. We address the periodic review inventory control problem for perishable goods with a fixed shelf life and demand censoring in an offline, data-driven setting. One AI assistant leverages a data-driven prescriptive solution to the multi-period inventory control problem, directly telling how much a human decision maker should replenish for the upcoming season given past sales data. We justify this prescriptive co-pilot with associated performance guarantees. Building on the data-driven prescriptive solution, the second AI assistant is enhanced in terms of detecting potential human decision-making biases in managing perishable inventory. Using machine learning models, it identifies from past user behavior whether a human decision maker is biased in their inventory decision making, and (if so) what human bias likely accounts for. Through an online experiment with Prolific workers, we further investigate how human users react to the deployment of different forms of AI assistance and uncover factors influencing their effectiveness. Results show that both types of inventory co-pilots, whether providing data-driven prescriptive solutions or bias detection, improve perishable inventory management performance for human decision-makers. Additionally, integrating bias detection with prescriptive solutions could foster greater human adherence to algorithmic recommendations.

3 - The Effect of U.S.-China Decoupling on Investment in High-Tech Manufacturing

Ran Zhuo, University of Michigan, Ann Arbor, MI, United States

High-tech manufacturing is often characterized by rapid technology turnover, frequent and substantial investment, and significant economies of scale. Recent national policies emphasizing domestic self-reliance in the U.S. and China highlight potential interactions between these industry characteristics and national security considerations. In this paper, we study the effect of U.S.-China decoupling on investments in contract manufacturing capacity for semiconductor chips. Our unique dataset combines a comprehensive sample of worldwide plant-level capacity investments and a representative sample of global contract manufacturing orders for semiconductors on a quarterly basis from 2004 to 2015. We use these data to estimate key parameters in a structural model of contracting between manufacturers and their clients, as well as manufacturers' capacity investment decisions. Based on the estimated parameters and using counterfactuals, we explore a large global semiconductor manufacturer's potential responses to geographically specific national policies affecting investment incentives.

4 - Consumers Cart-Building Behavior in Online Grocery: a Structural Approach Using Generative AI

Sandeep Chitla, NYU Stern School of Business, Jersey city, NJ, United States, Srikanth Jagabathula, Vidyadhar Mudium

How do customers build their online grocery shopping carts across multiple product categories, and how do operational factors such as prices, delivery fees, and promotions influence their choices? Existing multi-category choice models in operations, marketing, and economics often overlook the dynamic and sequential nature of cart-building and struggle with scalability in real-world scenarios involving thousands of products. Machine learning models, while scalable, often function as black boxes with limited interpretability. Our approach bridges this gap by combining the scalability of machine learning with the interpretability of structural choice models. We model customers as agents who sequentially select product categories based on their needs and choose products within categories according to their preferences. Using Generative AI techniques, we estimate the utilities driving these choices, extending the application of generative AI beyond its conventional domains to build a customer digital twin that replicates behavior on online platforms. Our analysis leverages a dataset from a leading quick-commerce platform in India, comprising 8.5 million orders from 350,000 customers. Our model predicts the next product category added to the cart 6.6% of the time from approximately 2,000 categories, with the true category in the top-10 predictions 38.8% of the time. Structural insights reveal that customers respond more to delivery fee waivers than flat discounts of the same value, highlighting the behavioral tendency to avoid service fees. Counterfactual analyses show how increasing delivery thresholds impacts product demand, with discretionary items like chips and longer shelf-life items like onions seeing increased demand as thresholds rise.

5 - Dynamic Discrimination on Online Platforms

Peibo Zhang, Emory University, Atlanta, GA, United States, Xinyu Cao, Dennis Zhang, Ruomeng Cui

Research on discrimination has predominantly relied on audit studies, which provide clean causal estimates through randomized profile testing but offer only static snapshots of bias. We adopt a dynamic perspective to examine how racial discrimination evolves over time. Using observational panel data from an online educational platform, we find that African-American teachers receive 64.3% fewer daily bookings than White teachers during their first 12 weeks on the platform, despite offering a similar number of class openings. Employing individual fixed-effects models, we estimate how the booking gap between African-American and White teachers evolves over time. The results show a striking 954% widening of this gap over the 12-week period. Our mechanism analysis shows that new students are significantly less likely to book classes with African-American teachers than with White teachers, even when they have minimal or comparable reputation metrics. This initial disparity makes African-American teachers build their reputation metrics and customer base at a slower rate than White teachers. Over time, the growing gaps in reputation and customer base further exacerbate the booking gap, contributed by both new students and repeat students. Our findings suggest that traditional audit studies may significantly underestimate the extent of discrimination, and highlight how reputation and matching systems serve as discrimination amplifiers on online platforms.

Building A Level 4 Auditorium

Welcome and Opening Plenary - Operations Research and Social Policy: Models that Can Make a Difference

Plenary Keynote

Plenary

2 - Plenary - Operations Research and Social Policy: Models that Can Make a Difference

Margaret Brandeau, Stanford University, Stanford, CA, United States

The United States faces numerous complex, intertwined social challenges such as rising income inequality, lack of access to healthcare, lack of affordable housing, homelessness, opioid addiction, and mass incarceration. How can OR inform good policies for addressing these and other social problems? Decision makers deciding which programs to invest in face a number of challenges, including limited resources, incomplete information about the potential effects of programs, and objectives that include not only welfare maximization but also economic, social, and political considerations. This talk describes modeling efforts in which OR has played and can play a role in informing such decision making. By providing a structured framework that uses the best available evidence, imperfect as it may be, and that captures relevant uncertainties, complexities, and interactions, OR-based models can be used to evaluate the potential impact of alternative public programs. We describe models focusing on opioid, housing, and criminal justice policies. We conclude with a discussion of useful lessons and opportunities for OR modelers who wish to work on problems related to social policy.

Sunday, October 26, 11:00 AM - 12:15 PM

Daniel H. Wagner Prize

Award Session

Daniel H Wagner

Chair: Konstantina Mellou, Microsoft Research, Redmond, WA, United States

1 - Optimizing Multimodal Rideshare Pricing via Quasi-Convex Efficiency Objectives

Sajjad Taghiyeh, Lyft Inc., San Francisco, CA, United States, Hao Yi Ong, Zeyad Kassem

We introduce a novel optimization system developed at Lyft to automate strategic rideshare pricing. Replacing manual heuristics, the system uses a unique quasi-convex efficiency objective to align pricing across multiple product types with long-term financial goals like bookings uplift and ride growth. It generates granular price recommendations across all 300+ markets daily, balancing demand with supply and integrating causal inference models. This approach enhances pricing consistency and allows analysts to focus on strategy, yielding 1.7% incremental rides and significant efficiency gains.

2 - Rebalancing and Pricing of Near-Expiry Inventory in Online Grocery Retail

Long He, George Washington University, Washington, DC, United States, Ziyuan Zhou, Zhengling Qi, Guangrui Ma, Yuanbo Peng, Yushu Yao, Zhongyi Zha, Mingyong Zhao, Zhenyu Zhuo

We partnered with Meituan, China's largest on-demand service platform, to develop and deploy an integrated learning-and-optimization system for managing near-expiry inventory in online grocery retail. By coordinating nighttime transshipment and dynamic pricing across thousands of micro fulfillment centers, the solution reduced spoilage by 20% and improved profit contribution by 14%, delivering over 50 million CNY in net gains. This work demonstrates how advanced analytics can transform perishable inventory from a loss driver into a source of profit and sustainability.

Emerging Topics in Sustainable Operations

Invited Session

MSOM: Sustainable Operations

Chair: Wayne Fu, University of Michigan-Dearborn, Dearborn, MI, 48126, United States

1 - On-TIME by Design - Ride-Pooling Subsidies for Workers

Wayne Fu, University of Michigan-Dearborn, Dearborn, MI, United States, WEE MENG YEO

In this study, we explore a situation in which a manufacturing company subsidizes a ride-pooling service due to unreliable or insufficient bus services. We develop a stylized analytical model and apply a game-theoretical approach to analyze the decisions made by workers, the ride-pooling company, and the manufacturer. The findings aim to provide insights for the ride-pooling service on when to enter the market and how to operate effectively, as well as guidance for the manufacturer on how to subsidize the service.

2 - The Impact of Present Bias on Social Welfare

Zhixin Liu, University of Michigan-Dearborn, Dearborn, MI, United States, Nicholas Hall, Yun Shi

This work challenges the common perception that present bias predominantly has negative effects on decision outcomes. By examining the effects of present bias on social welfare in a stylized economy, we explore various decision-making environments where the impact of present bias is beneficial. One such environment involves dynamic pricing decisions. Additionally, we demonstrate how present bias can refocus decision-making that is otherwise compromised by other behavioral biases, including sunk cost bias and value sensitivity bias. Finally, in a duopoly non-cooperative game, present bias can lead to an improved equilibrium solution.

3 - Transition to Green Products: Taxing Emissions Versus Taxing Products

Gal Raz, Ivey Business School at Western University, London, ON, Canada, Paolo Letizia, Wangcheng Yan

Governments worldwide are implementing environmental tax policies to incentivize green product adoption and reduce emissions. This study compares two established taxation strategies: one based on emissions generated by all products, whether green or “dirty” (emission-based taxation), and another specifically targeting the “dirty” conventional product (product-based taxation). Using a game-theoretical framework with Cournot competition, we analyze the decisions of two competing manufacturers serving consumers with heterogeneous product consumption preferences. Our findings reveal that while both policies can motivate green production when fixed costs are low, emission-based taxation may inadvertently incentivize manufacturers to revert to the “dirty” conventional product. In contrast, taxing the “dirty” product consistently encourages manufacturers to offer, and consumers to adopt, green alternatives. Further, when emission intensity is low, product-based taxation emerges as the optimal strategy for reducing emissions and curbing the production of “dirty” conventional products. However, at high levels of emission intensity, the effectiveness of either policy is contingent upon the tax rate and market equilibria. Finally, we propose a consumer-focused tax policy based on individual emissions, aligning with principles of environmental personal responsibility, and demonstrate its superior potential for emission reduction. These insights provide guidance for governments in designing effective tax policies tailored to product emission intensities and minimizing unintended consequences during the transition to green products.

4 - Environmental and Economic Impacts of Pooled vs. Separate Carbon Targets

Guowei Dou, Shenzhen University, Shenzhen, China, People's Republic of, Christian Blanco, Gokce Esenduran

Some firms set separate targets for their Scope 1 and 2 emissions, and Scope 3 emissions, while others set one target for entire emissions. We try to identify when firms prefer one target type over the other, and the implications of the firm's preference and decisions regarding overall emissions.

Multi-objective Optimization: Theory, Algorithms and Applications

Invited Session

Multi Criteria Decision Making

Chair: Banu Lokman, University of Portsmouth, Portsmouth, United Kingdom

1 - Exploring Efficiency and Equity in Day-Ahead Electricity Auctions: a Multi-Objective Optimization Approach

Banu Lokman, University of Portsmouth, Portsmouth, United Kingdom, Gökhan Ceyhan, Murat Koksalan

European day-ahead electricity markets (DAMs) are two-sided auctions that determine next-day electricity prices by solving a market-clearing model to match supply and demand bids. These markets are conventionally designed to maximize total surplus across all participants. However, there is usually no market-clearing price that maximizes the surpluses of all participants simultaneously, leading to potential inequities. Specifically, some participants may incur negative surplus (losses) or forgo potential gains (opportunity costs). This study addresses these equity-efficiency concerns by developing a multi-objective optimization approach and derives insights that can inform more equitable market designs across all DAMs.

2 - Multi-Period Critical Resource Allocation via Mobile Facilities: a Multi-Objective Customer-Centric Approach

Ozlem Karsu, Bilkent University, Ankara, Turkey, Zehranaz Varol, Bahar Y. Kara, Francisco Saldanha-da-Gama

Allocation of critical and scarce resources is relevant in real-world applications such as disaster response operations, healthcare resource distribution, and long-term relief management. In such settings, fairness in service levels and accessibility to services or commodities are important criteria alongside efficiency-related ones. This problem is cast as a multi-criteria multi-period location-inventory problem with a coverage constraint. Three criteria are considered based on deprivation cost and distance or travel time. The model is then applied to an instance of an aid allocation problem following a disaster. The tradeoff between the different objectives is analyzed. The results show that the proposed models can better inform customer-centered decision-making processes in the face of limited critical resources.

3 - Local Upper Bounds for Polyhedral Cones

Firdevs Ulus, Bilkent University, Ankara, Turkey, Gabriele Eichfelder

The concept of local upper bounds plays an important role for numerical algorithms in nonconvex, integer, and mixed-integer multiobjective optimization with respect to the componentwise partial ordering, that is, where the ordering cone is the nonnegative orthant. In this study, we answer the question on whether and how this concept can be extended to arbitrary ordering cones. We define local upper bounds with respect to a closed pointed solid convex cone and study their properties. We show that for special polyhedral ordering cones the concept of local upper bounds can be as practical as it is for the nonnegative orthant.

4 - Convergence Rate Results for Stochastic Multi-Objective Linear Programs

Ziyu Liu, Purdue University, West Lafayette, IN, United States, Susan Hunter, Raghu Pasupathy

Consider a stochastic multi-objective linear program in which the “cost” matrix is the expected value of a random matrix, the constraints are known and fixed, and we have access to a dataset or stochastic oracle capable of producing an unbiased estimator of the cost matrix. In this setting, we show that the vertices of the feasible set which belong to the efficient set are identified exponentially fast in the sample size. This result appears in contrast to the behavior of the Pareto set estimator, which converges at a slower rate according to a Central Limit Theorem.

5 - Scalarization and Approximation Methods for the Multi-Objective Set Covering Problem

Lakmali Weerasena, University of Tennessee Chattanooga, Chattanooga, TN, United States, Chathuri ththanayake

This study addresses the **Multi-Objective Set Covering Problem (MOSCP)**, an NP-hard challenge in multi-objective combinatorial optimization. While norm-based scalarizations have shown promise in approximating multi-objective minimization problems, ϵ -approximation algorithms for MOSCP remain underexplored. Our contributions are twofold:

- (1) We investigate the effect of using a common set of weight vectors across two scalarization methods—**weighted sum** and **weighted max-ordering**—under various conditions, employing four distinct weight generation strategies and solving both scalarizations exactly.
- (2) We extend theoretical insights by analyzing the **cost-effectiveness vector** from previous work and proposing a new version, leading to new approximation properties. Results show that the proposed weight generation methods perform well with an equal number of weights, and **weighted max-ordering scalarization** is recommended for generating robust initial solutions in two-phase algorithms.

6 - Risk-Averse Decision-Making Under Decision and Objective Space Uncertainty in Multi-Objective Combinatorial Optimization

Chathuri Aththanayake, Department of Mathematics, University of Tennessee at Chattanooga, Chattanooga, TN, United States, Lakmali Weerasena, Damitha Bandara

Uncertainty in input data significantly affects the quality of solutions in mathematical optimization, particularly when the computed solutions are not realized exactly. This study introduces a novel risk-averse decision-making approach when objective function coefficients are uncertain, which causes the decision space uncertainty in multi-objective combinatorial optimization problems. We construct a sensitivity region in the objective space based on reference solutions obtained from the deterministic formulation. To address the uncertainty in the decision space, we identify neighborhood solutions around the reference solutions that lie within this region, from which the risk-preference solutions are derived. We propose indices to quantify the risk associated with neighborhood solutions by capturing both decision space and objective space uncertainty. Additionally, we propose two decision supportive indices to assess the performance and risk levels of both reference solutions and neighborhood solutions. The effectiveness of the proposed approach is demonstrated in an instance of the Set Covering Problem, highlighting in enhancement of risk-averse decision-making under uncertainty.

Keywords: Multi-objective Combinatorial Optimization, Neighborhood, Risk-averse Decision-Making, Sensitivity Region, Uncertainty.

Trading and Risk Management

Invited Session

Finance

Chair: Rita D'Ecclesia, Sapienza University, Rome, 00162, Italy

Co-Chair: Andrea Roncoroni, ESSEC Business School, Cergy-Pontoise, France

1 - Offsets vs. Calendar Spreads in U.S. Treasury Futures Markets

Michel Robe, University of Richmond, Richmond, VA, United States

Using regulatory data, we document that much of what is commonly labeled as “spreads” in U.S. Treasury futures (USTF) markets actually consists of non-canceling directional positions, known as “offsets.” For both leveraged funds and institutional asset managers, these offsets are substantial—roughly one tenth and one half, respectively, of their aggregate net exposures. Unlike calendar spreads, which are typically market-neutral, offsets carry directional risk and contract significantly during periods of market stress. This distinct behavior has important implications for prudential assessments and financial stability monitoring. To aid such analysis, we provide a table that allows market observers to approximate the gross exposures of four major USTF trader categories using public data.

2 - Integrating Energy-Related Risks In Bitcoin's Price

Rosella Castellano, University of Rome UnitelmaSapienza, Roma, Italy

Bitcoin's high return volatility and energy-intensive mining process raise growing concerns about energy costs and environmental impact. Since mining relies heavily on electricity, energy prices significantly affect both profitability and market dynamics. Understanding how energy fluctuations and investor sentiment interact with Bitcoin's fixed supply is key to modeling its price. We propose a framework integrating energy costs, sentiment, and protocol-driven supply into a market equilibrium model. On the demand side, investors allocate wealth across assets with sentiment and energy as shifters. On the supply side, miner behavior responds to price, energy, and network conditions. This model, supported by machine learning calibration, offers insights for policymakers and investors on how energy and sentiment shocks influence Bitcoin prices.

3 - The Effect of Accounting Restatements on Supply Chain Partner Acquisitions

Volodymyr Babich, Georgetown University, Washington, DC, United States, Gilles Hilary, Kai Wai Hui, Gouman She

Would accounting restatements, by revealing the true state of the firm, make the firm a more attractive acquisition target? Our empirical analysis shows that the answer is no for acquisitions in general, but yes for acquisitions by supply chain partners. Our model explains this finding by describing an equilibrium among firms in a supply chain, the investors, and auditors. The key feature is an asymmetry of information between supply chain insiders and outsiders that hides mismanagement at one of the firms in the supply chain. We explain how accounting restatements change investors' equilibrium beliefs and which forces may affect the likelihood of supply chain integration. The model allows features such as noise and bias in managers' reports, auditing technology investments, auditing efforts, and investors' bargaining power. Leveraging model predictions, we eliminate the alternative explanation that the market underpricing of the target firm is the major reason for such acquisitions. The difference in acquisition rates with versus without a restatement is greater when acquisition targets exhibit greater agency problems, when acquirers have better governance, and when acquirers cannot easily switch supply chain partners. Our paper guides managers in their relationships with supply chain partners and highlights the importance of accounting information in this context. In particular, managers should consider accounting information in their outsourcing and acquisition decisions.

4 - Fragility of Green Investments, An Analysis of the Risk Drivers

Rita D'Ecclesia, Sapienza University of Rome, Rome, Italy

This paper uses the FTSE Russell Green Revenues 2.0 model, aligned with the EU Taxonomy, to identify sustainable investments. We construct High and Zero Green Revenue (GR) portfolios within Climate Policy Relevant Sectors (CPRS) using data from 2013 to 2023 to examine the greenium—the premium for green assets—via a Green Minus Brown (GMB) factor. High GR portfolios outperform brown ones only during periods of market stress, with no consistent investor preference for sustainability. The greenium varies across sectors, underscoring the need for sector-specific analysis. We also compare GR-based portfolios with other ESG metrics, emphasizing the need for a consistent sustainability classification framework.

5 - Commodity Vendors: Operational Handling, Business Timing, and Integrated Risk Management

Andrea Roncoroni, ESSEC Business School, Cergy-Pontoise, France

Commodity businesses operate under exogenous market prices and product demand, and vendors seek to maximize performance by jointly optimizing order quantities and market timing. This study examines a stylized, risk-averse commodity vendor model and provides a comprehensive theoretical analysis of the decision-making problem, both in terms of standalone operational management and when combined with financial hedging (integrated risk management). Our analysis highlights the critical role of market timing as a valuable operational decision variable, which degenerates into a now-or-never outcome in the case of a conventional newsvendor. Furthermore, the study reveals an expansionary effect of integrated risk management on both quantity and timing decisions. Applications to the steel component industry motivate and illustrate the model.

1 - Co-Designing Solutions to Disrupt Sex Trafficking Recruitment with Lived Experts

Baris Tezcan, Northeastern University, Brookline, MA, United States

Using a transdisciplinary, community-based approach, we developed a Resource Allocation–Markov Chain model of how vulnerabilities dynamically influence sex trafficking recruitment. This provides determine how to most effectively invest in community programs to reduce recruitment. Our work has transformed counseling practices, influenced policy on survivor inclusion in research, and initiated the first longitudinal sex trafficking data collection—demonstrating how operations research can have meaningful social change when embedded in authentic community partnerships that value lived expertise.

2 - Learning Optimal and Fair Policies for Online Allocation of Scarce Societal Resources from Data

Bill Tang, University of Southern California, Los Angeles, CA, United States

We study the problem of allocating scarce societal resources to heterogeneous allocatees on a waitlist based on their covariates. Using historical data, our policy waitlists individuals for the resource maximizing the difference between their estimated outcomes and the resource dual-price. We show that our policy almost surely asymptotically achieves the expected outcome of the optimal out-of-sample policy. We evaluate our approach on allocating scarce housing in Los Angeles. Our policies can improve outcomes by 5.16% and that fairness notions can be achieved at a very low price of fairness.

3 - Swap: Empowering Community Collective Impact Through Innovative Resource Sharing

Weixiao Huang, Worcester Polytechnic Institute, Worcester, MA, United States, Andrew Trapp, Jennifer Pazour

The SWAP system enables nonprofits to efficiently share resources, addressing resource scarcity and fluctuating demands through multilateral-exchange optimization and virtual currency (re-)distribution algorithm. In practice, SWAP has facilitated over 65 exchanges, enhancing organizational effectiveness, and fostering community collaboration, which has pioneered a new model for nonprofit resource sharing. Nonprofits using SWAP report significant improvements in operational capacity and interorganizational trust, indicating its substantial potential for broader national adoption.

4 - Saving Lives: Data-Driven Optimization in Animal Shelter

Qiuxia Chen, The University of Texas at Dallas, Richardson, TX, United States

We worked with Dallas Animal Services to improve outcomes for shelter dogs. By analyzing patterns in how long dogs stay in the shelter and how different types of dogs are adopted, we developed a practical strategy to save more lives without requiring more space. Our approach helped increase the shelter's live release rate – defined as the proportion of dogs with positive outcomes - from 76% in 2023 to 86% in 2024. This framework is easy to follow, scalable, and can be adapted by animal shelters across the country.

Resilience on Networks

Job Market Showcase

Job Market Showcase

Chair: Pelin Kesrit, Texas A&M University, College Station, TX, United States

1 - Deep Learning Model for Predicting Urban Flood Risk of a Public Transit System

Mubarak Iddrisu, University of Massachusetts Boston, Quincy, MA, United States

Flooding significantly disrupts public transit systems and disproportionately affects vulnerable transit-dependent groups such as older adults and low-income residents. Given increased transit vulnerabilities to flooding driven by climate change and rapid urbanization, accurate prediction models are essential for effective adaptation planning and equitable emergency responses. This study presents a deep learning framework integrating Geographic Information Systems (GIS) and convolutional neural networks (CNN) to predict flood susceptibility specifically for public transit networks in Boston. By leveraging spatial data encompassing topographic, hydrologic, climatic, and socio-demographic features, our CNN predicts flood impacts at high spatial resolutions. The model is trained using labeled data from floodplain maps and transit infrastructure exposure with 70% training and 30% validation data split. Further, we applied traditional machine learning approaches, including Support Vector Machine (SVM) and Random Forest (RF), for comparative analysis. Preliminary results indicate our CNN model achieves over 80% accuracy with an Area Under the Receiver Operating Characteristic (AUROC) exceeding 0.90, outperforming the traditional ML models. Our results identify transit routes and stops at high flood risk and facilitate targeted adaptation strategies. The study underscores the importance of incorporating socioeconomic vulnerability into flood prediction models to support equitable transit planning decisions. This integrated approach advances precise and equitable flood risk assessment and provides actionable insights for transit planners and policymakers to enhance resilience in flood-prone urban areas.

2 - Fortifying Distribution Network Nodes Subject to Disruptions

Pelin Kesrit, Texas A&M University, College Station, TX, United States, Bahar Cavdar, Joseph Geunes

We consider a distribution network for delivering a natural resource or physical good to a set of nodes, each of which serves a set of customers, in which flow disruptions may occur at one or more nodes. Each node receives flow through a path from a source node, implying that a node is disrupted if one or more nodes on each path from a source node experience a disruption.

All network nodes are vulnerable to a future disturbance due to a potential natural or man-made disaster, the severity of which follows some measurable probability distribution. For each node in the network, we wish to determine a fortification level that enables the node to withstand a disturbance up to a given severity level, while

minimizing the expected number of customers who experience a service disruption under a limited fortification budget. We formulate this problem as a continuous, nonlinear knapsack problem with precedence constraints, demonstrate that this optimization problem is NP-Hard for general tree networks and general disturbance severity distributions, and provide a polynomial-time solution algorithm for serial systems, which forms the basis for an effective heuristic approach to problems on tree networks. Our computational test results demonstrate the ability of the proposed heuristic methods to quickly find near-optimal solutions.

The Economics of AI

Invited Session

Information Systems

Chair: Jisu Cao, Arizona State University, Gilbert, AZ, United States

1 - Rational Analysis of Curiosity and Information Modality in Video Representations

Jaewung Sim, University of Connecticut, Stamford, CT, United States, Eunsol Cho, Daegon Cho, Jiyong Eom

In the attention economy, capturing users' attention is crucial for promoting content on social media platforms, particularly for long-form videos where effective pre-consumption representation is vital. This challenge is complex due to numerous factors, including the interplay of multimodal information—how textual and image components in video representations influence users' decisions to consume content. In this paper, we address the question of how semantic congruence between image and text elements of video representations affects curiosity. To empirically examine this question, we collect and analyze video data from YouTube and elicit the semantic congruence between thumbnail images and titles using multimodal large language models. Our findings reveal that the impact of semantic congruence on video views varies based on the information format, such that the image-title similarity shows an inverted U-shaped relationship with viewership, while the text-title similarity presents a linearly decreasing impact. We conduct a randomized online experiment and find supporting evidence.

2 - Text-to-Image AI and the Novelty of User Generated Content on Social Media

Guangzhi Shang, Florida State University, Tallahassee, FL, United States, Jingchuan Pu, Yi Tong

Text-to-image AI tools enable social media users to transform their imaginative ideas into visual content in a wide range of visual styles. We argue that the AI tools also pose a spillover effect on the novelty of user-generated regular content on social media (i.e., content generated without an AI tool) because using AI tools could potentially change the reputation dynamics on social media platforms (i.e., reputation mechanism) and/or fundamentally reshape human cognitive processes and innovative thinking (i.e., AI-usage mechanism). Collaborating with an image-sharing social media platform, we employ a difference-in-differences (DID) approach to empirically demonstrate that using a text-to-image AI tool significantly reduces the novelty of user-generated regular images. That is, after using the text-to-image AI tool, AI users' regular images become more similar to the platform-wide recent images than those of non-AI users. We do not find evidence supporting the reputation mechanism. However, empirical evidence consistently validates the AI-usage mechanism.

3 - AI-Enabled Job Markets & Market Participation: AI Aversion and Jobseekers Expectations of How AI Shapes Competition

Sarah Bana, Chapman University, Orange, CA, United States, Kevin Boudreau

Artificial intelligence is increasingly mediating matching between employers and jobseekers, and potentially reshaping how labor markets function. In this paper, we investigate whether the use of AI alters jobseeker behavior—specifically, the willingness to participate in job markets. We argue that knowing AI is used to match candidates with jobs may change jobseekers' willingness to participate, insofar as it shifts their expectations about the job market competition they will face. To test this theory, we conducted a field experiment with 4,562 jobseekers, randomly assigning them to different disclosure conditions. When AI use was disclosed, jobseekers' participation was roughly 25% lower than both a human matchmaking treatment and a control group in which the source was not given. We find that participation responses varied systematically by the quality of match, and jobseekers' professional networks, in ways that are consistent with jobseekers forming expectations about how AI affects the scale of competition, match prediction quality, and the information and sources used to generate predicted matches. Thus, the “AI aversion” in this context appears to be related to how AI shifts expected payoffs from participating. We conclude with implications for platform design, policy, and the future of AI-mediated labor markets.

4 - Can Kindness be Matched? Dynamic Match and Goal Match in Civic Crowdfunding

Xue Tan, Southern Methodist University, Dallas, TX, United States, Haoyan Sun, Oliver Yao

Match funds, funds supplemented by private or public institutions (“matchers”) to match charitable contributions made by individual donors, are widely adopted in traditional fundraising practices. Two match fund schemes prevail: a dynamic match fund is a commitment to match each contribution at a given ratio, and a goal match is a commitment to supplement a pre-announced amount of funds upon goal attainment. Matchers have a natural tendency to choose dynamic match over goal match, especially on crowdfunding platforms, because dynamic match funds enable higher visibility – upon every individual donation, a dynamic match fund donation will be transacted and displayed for public consumption, while a goal match fund donation is usually a one-time lump-sum contribution. By leveraging over ten years of data from a civic crowdfunding platform that supports the United Nations' sustainable development goals (SDGs), we uncover the differential impacts of dynamic match and goal match on fundraising performance. While the added match funds could always guarantee a higher total pledge, only dynamic match but not goal match crowds out total individual contributions. A more granular analysis further revealed that dynamic match funds reduce both donor participation and average contribution size. Surprisingly, goal-match funds led to an increase in average contribution size, offsetting its negative impact on donor participation. These findings contribute both to the theoretical understanding of match funds and add insights to the fundraising literature in economics and the crowdfunding literature in information systems.

5 - Balancing Safety, Engagement, and Compliance: Evaluating the Impact of Nsfw Governance on User Behaviors for Gen-AI Platforms

Jisu Cao, Arizona State University, Tempe, AZ, United States, Keran Zhao, Xiaowei Liu, Che-Wei Liu, Jiang Duan

Generative AI (Gen-AI) technology has rapidly transformed the content creation industry, enabling users to produce text, images, and videos with unprecedented efficiency and accessibility. While the new technology unleashes human productivity and creativity, it also presents the risk of misuse, particularly in generating NSFW content. Strengthening NSFW content governance creates a tradeoff between fostering a safer digital environment and maintaining user engagement. On one hand, strict governance protects users from harmful, exploitative, or distressing material, ensuring legal compliance and preserving platform integrity. However, such governance may lead to reduced user autonomy and increased dissatisfaction among certain user groups who value creative freedom. By leveraging a natural experimental policy change, where a Gen-AI platform tightened its NSFW policy in March 2024, we investigate how users with prior NSFW content intentions responded to the increased moderation. We find that introducing a strict NSFW filter led to a 0.7% decline in the subscription rate for users with NSFW intention, indicating a potential economic cost for platforms. Our findings highlight the complexities of NSFW content governance and offer important managerial implications for Gen-AI platforms.

Preserving Privacy

Job Market Showcase

Job Market Showcase

Chair: Yuxin Liu, University of Pittsburgh, Pittsburgh, 15217, United States

1 - Joint Differential Privacy for Resource Allocation: Protection Capability, Price of Privacy and Algorithm Design

Du Chen, Nanyang Technological University, Singapore, Singapore, Geoffrey Chua, Victor Jose

Resource allocation is a fundamental problem in management science. Recent growth in privacy concerns has made this problem more challenging because private data might be inadvertently revealed through the optimal allocation decisions. While differential privacy (DP) limits data leakage in resource allocation, it often compromises decision utility substantially. To address this, we adopt joint differential privacy (JDP), another data privacy standard and provide a new comprehensive understanding of this approach. We formally show that JDP provides privacy protection as strong as DP if recipients do not disclose their allocations. Moreover, JDP achieves this with substantially lower utility loss, with per-recipient loss vanishing as the system scales. However, the direct application of existing JDP algorithms may not reap the full benefits of lower utility loss and could empirically underperform compared to DP. To address this, we exploit the primal-dual relationship and develop the Noisy Dual Mirror Descent (NDMD) algorithm, a minimax near-optimal approach for a large class of convex resource allocation problems. NDMD offers a practical solution for privacy-preserving allocation problems, including the long-debated public policy problem of allocating Title I US education grants with privacy. Our simulations using real-world data show that shifting from DP to JDP reduces nationwide misallocation by as much as 52% and significantly mitigates the disproportionate impact of privacy protection on historically disadvantaged and underrepresented minority groups. Our results highlight the importance of operational knowledge such as disclosure discretion, downstream operational tasks, and algorithm design in balancing privacy with utility.

2 - Privacy-Preserving Data-Driven Inventory Management

Lorraine Yuan, Cornell Tech/Cornell University, New York, NY, United States, Elena Belavina

Firms have access to increasing amounts of customer data, which facilitates better inventory management. However, security researchers have demonstrated that attackers can recover sensitive data by combining data-driven decisions with background information. This study develops and compares privacy-preserving approaches for data-driven inventory management that are robust to such attacks. We propose differential privacy-based adaptations of two leading data-driven methods—the two-step estimate-then-optimize and the one-step joint estimate-optimize paradigm—and establish theoretical guarantees on their performance. Our analysis characterizes a firm's tradeoff between privacy protection and profitability. It compares the three algorithms in terms of the difficulty of privacy preservation, profit losses from privacy, the optimal privacy protection levels, and customer surplus. We show that the one-step paradigm dominates the two-step paradigm by enabling lower-cost privatization through more targeted noise injection, achieving lower privacy exposure risk, higher profitability, and greater customer surplus. This reshapes our understanding of privacy protection—the costs and benefits of privacy preservation are not only driven by the privacy algorithms used but are also fundamentally shaped by the underlying data-driven decision making paradigm. This implies that privacy-conscious firms should deploy the private version of the one-step data-driven algorithm. We show that a firm that uses our methods and chooses an optimal privacy level will increase its demand, profit, and customer surplus (under most conditions)—challenging the notion that privacy protection necessarily comes at a cost. Our numerical analysis reveals that one-step algorithms offer 3 to 6 times stronger privacy protection and around 30% higher profits than two-step algorithms.

3 - Differentially Private Sequential Learning

Yuxin Liu, University of Pittsburgh, Pittsburgh, PA, United States, Amin Rahimian

In differentially private sequential learning, agents inject endogenous noise into their actions to preserve privacy. This leads to markedly different outcomes depending on whether signals are continuous or binary. For continuous signals under a finite privacy budget $\epsilon \in (0, 1)$, we propose a novel smoothed randomized response mechanism that adjusts the noise level based on a signal's proximity to a decision threshold. Unlike traditional randomized response, which applies uniform noise, our approach allows actions to more accurately reflect both private signals and public history. This enables faster information aggregation, achieving an accelerated learning rate of $\Theta(\epsilon \log(n))$, compared to the slower $\Theta(\sqrt{\log(n)})$ rate in the non-private regime where $\epsilon \rightarrow \infty$. Moreover, in the non-private setting, the expected stopping time for the first correct decision and the number of incorrect actions both diverge, while under privacy constraints, these metrics remain finite. This reveals a surprising efficiency gain in private continuous-signal settings, where the variable flipping probabilities amplify the log-likelihood ratio across time. In contrast, binary signals suffer under privacy: the use of constant randomized response before an information cascade reduces the informativeness of actions, significantly hampering learning. These findings highlight a counterintuitive insight—privacy can enhance learning with continuous signals but impairs it with binary ones.

4 - Privacy with Information Externalities and Complexity

Qingyi Wang, School of Information, University of Michigan, Ann Arbor, MI, United States, Eytan Adar, Yan Chen

Privacy decisions in social communication are complex in that they affect the individual making them and often everyone that person is connected to. Investigating information sharing with externalities in an abstract information-sharing game in the lab, in real life involving friends, and on a social media platform, we find that participants overshare relative to the Bayesian Nash equilibrium prediction in the game, and that externalities increase the likelihood of sharing in both the game and real-life sharing involving friends. When we exogenously reduce computational complexity in the game by providing an average payoff matrix, participants are 19.4 percentage points more likely to best respond, leading to a 24.4% increase in efficiency. Furthermore, more risk-averse individuals share less and therefore perform better in the game. The tendency to share sensitive information involving friends is negatively correlated with both risk aversion and ambiguity aversion. Our results highlight the potential to improve users' welfare by reducing the complexity in their privacy decisions.

Disease Screening and Treatments

Job Market Showcase

Job Market Showcase

Chair: Sayaka Ishizawa, The University of Texas MD Anderson Cancer Center, Houston, TX, 77030, United States

1 - Universal Lung Cancer Screening Guidelines Under Heterogeneous Patient Responses

Raul Garcia, Rice University, Houston, TX, United States, Andrew Schaefer, Iakovos Tournazis

Health organizations (*society*) generally prefer to recommend universal screening guidelines to at-risk individuals (*patients*) for various diseases, for which coverage is typically provided by insurers. However, patients are heterogeneous both in disease risk and disutility associated with screening, resulting in varying health outcomes. Infrequent recommendations leave at-risk patients to decide if to pay out-of-pocket in the interim, while frequent recommendations may result in unnecessary screening disutility for low-risk patients and unnecessary costs to society. Moreover, patient adherence to guidelines remains low for many diseases, further complicating the health benefits and costs realized in practice. We address these challenges in the context of lung cancer screening for eligible ever-smokers and employ a bilevel optimization model to compute universal lung cancer screening guidelines that maximize the societal net monetary benefit (NMB). With *society (leader)* determining the covered universal screening schedule, representative patient classes (*followers*) are modeled as partially observable Markov decision processes (POMDPs), maximizing their own NMB with respect to their smoking level, screening disutility, willingness-to-pay for out-of-pocket costs, and adherence rate. We provide analytical results for the POMDP and conduct numerical experiments.

2 - Optimizing Vascular Access Timing in Pre-Dialysis Patients: a Markov Decision Process Approach

Yiwen Cao, University of Southern California, Los Angeles, CA, United States, Sze-chuan Suen

Effective planning for vascular access (VA) is essential for initiating hemodialysis in patients with end-stage renal disease (ESRD). Currently, over 80% of patients begin treatment using a temporary access, which increases the risk of infection, complications, and mortality. Deciding when and which type of permanent access to initiate is challenging due to patient heterogeneity and uncertainty in access outcomes.

This study presents a finite-horizon Markov Decision Process (MDP) model to identify the optimal timing and choice of vascular access—arteriovenous fistula (AVF), arteriovenous graft (AVG), or wait at each epoch—for pre-dialysis patients. The model considers each patient's estimated glomerular filtration rate (eGFR), current access

status, access type, prior failures, age, and frailty. It accounts for uncertainty in access maturation and disease progression. The decision process ends when the access becomes functional or after repeated failures. The objective is to maximize expected discounted lifetime health outcomes.

We stratify the model by patient frailty and age to enable personalized decision support. Results demonstrate that optimal access initiation policies are sensitive to patient-specific characteristics and outperform heuristic approaches that follow static “fistula first” guidelines. This framework offers a tractable, policy-relevant tool for sequential medical decision-making under uncertainty, supporting personalized treatment recommendations.

3 - Optimizing Ovarian Cancer Early Detection Using Stochastic Modeling

Sayaka Ishizawa, The University of Texas MD Anderson Cancer Center, Houston, TX, United States, Maryam Eghbalizarch, Renu S Nargund, Andrew Schaefer, M. Soheil Hemmati, Seyyed Mostafa Mousavi Janbeh Sarayi, Karen Lu, Sharon H Giordano, Larissa A Meyer, Iakovos Toumazis

Background: Ovarian cancer is the second leading cause of death among all gynecologic cancers. Yet, no effective prevention program currently exists. Well-validated natural history models (NHMs) provide insights on the natural progression of diseases and can be used to assess the effectiveness of potential interventions in silico. Currently, no histology-specific NHM exist for ovarian cancer.

Study Design: We developed histology-specific NHMs for the seven most common ovarian cancer subtypes using discrete-time Markov models. We calibrated histology-specific model parameters using Adaptive Simulated Annealing such that model outcomes reliably reproduced the observations from the Surveillance, Epidemiology, and End Results (SEER) program. We assessed goodness-of-fit using the weighted sum of root mean squared error (RMSE). We validated the NHMs on data from the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial (PLCO) and the United Kingdom Collaborative Trial on Ovarian Cancer Screening (UKCTOCS). Moreover, the stage distribution at diagnosis was validated on PLCO data. Differences between observations and model estimates were evaluated using the Pearson’s chi-squared test.

Results: The calibrated NHM showed satisfactory goodness of fit to the SEER data, within 2% of RMSE. In model validation, none of our model estimates showed significant difference on UKCTOCS (p-value on incidence=0.399, death=0.377) or PLCO (p-value on incidence=0.207, death=0.513, stage distribution=0.498) observations.

Conclusion: The developed NHM accurately describes the histology-specific natural progression of ovarian cancer. This model could be used to assess the impact of future and emerging ovarian cancer preventive interventions, thus assisting policy makers developed effective prevention programs.

Resilience and Crisis Response

Job Market Showcase

Job Market Showcase

Chair: Amir Hossein Moadab, Washington State University, Pullman, WA, United States

1 - Generative Simulation: AI-Driven Predictive Modeling for Decision Support in Crisis Operations

Seung ho woo, Purdue University, Lafayette, IN, United States, Young-Jun Son

Crisis operations demand rapid decision-making in environments characterized by uncertainty, complexity, and data scarcity. Traditional simulation approaches often fall short in these contexts due to their reliance on extensive historical data and rigid model assumptions. This work introduces a novel paradigm, Generative Simulation, that leverages advanced artificial intelligence to create adaptive, knowledge-driven predictive models for crisis decision support. The framework integrates generative AI models with agent-based simulation to enable zero-shot scenario generation and adaptive agent behavior without requiring extensive predefined models or training data.

Our research makes three primary contributions including a zero-shot generative simulation architecture that autonomously constructs crisis scenarios from minimal inputs, LLM-embodied agents capable of realistic decision-making that adapts to evolving crisis conditions, and empirical validation comparing generative agent simulation against traditional approaches across multiple crisis domains. Experiments in disaster management, power grid failure response, and emergency resource allocation demonstrate that generative simulation achieves comparable or superior predictive accuracy while requiring significantly less domain-specific data engineering.

The implications extend beyond technical innovation by reducing the data and expertise barriers to sophisticated simulation, this approach democratizes access to advanced decision support tools. Communities with limited resources can leverage generative simulation to model complex crisis scenarios previously beyond their analytical reach. This research represents a fundamental shift in how simulation science approaches predictive modeling under uncertainty, with applications in disaster resilience, infrastructure protection, and humanitarian response operations.

2 - Machine Learning for Crisis Operations: Detecting Patterns of Vulnerability and Predicting Demand

Amir Jamali, Worcester Polytechnic Institute, Worcester, MA, United States, Renata Konrad

Crisis environments create dynamic and uncertain operational conditions, requiring fast, data-driven responses. This research investigates how machine learning (ML) algorithms can uncover hidden patterns in unstructured data and support real-time decision-making in humanitarian operations. We apply natural language processing (NLP) to identify suspicious recruitment patterns indicative of human trafficking, using multilingual social media (Telegram) and messaging data. Beyond detection, we extend our methods to operational tasks such as demand prediction and vulnerability estimating needs for shelter, transportation, or medical aid based on textual context from digital platforms. Our approach uses transformer-based algorithms using ensemble techniques to improve accuracy across tasks. We develop a model pipeline that can generalize across regions and crises by addressing key challenges like data imbalance, language diversity, and informal communication formats. This work contributes to building adaptive, pattern-based ML systems that enhance situational awareness and resource allocation in disaster response and humanitarian logistics.

3 - When Every Second Matters: Dispatching Drones After a Disaster to Locate Victims

Amir Hossein Moadab, Washington State University, Pullman, WA, United States, Chuck Munson, Arman Hosseini

The use of drones in humanitarian and disaster management operations has gained increasing attention due to their speed and reliability in data gathering and assessments, especially where road infrastructure is disrupted. Drones reduce risks for search and rescue teams by enabling efficient victim detection without exposing responders to hazardous environments. This study presents a two-phase optimization framework for drone-based search and rescue after major disasters.

In the first phase, K-means clustering identifies potential hub locations, followed by a heuristic approach to optimize hub selection and drone allocation, ensuring inter-hub connectivity within flight range constraints. The second phase formulates a team orienteering problem to design efficient drone routing strategies, maximizing coverage and search effectiveness.

To address disaster-related uncertainty and infrastructure disruptions, the model incorporates potential facility failures and integrates alternative hubs to enhance resiliency. These hubs enable on-time replanning of operations through real-time decision-making and contingency strategies, preserving connectivity when primary hubs are compromised.

A case study in San Fernando Valley, Los Angeles, incorporates earthquake-specific data and building density. Three operational policies are evaluated that offer valuable trade-offs for decision makers: unconstrained coverage (maximal utility), threshold-based coverage (equity), and maximal covering hub selection. Results show that inter-

connectivity and alternative hubs significantly improve performance, mitigate battery and range constraints, and extend operational endurance. The findings offer insights into resilient and efficient drone deployment for post-disaster response.

Queueing Systems

Job Market Showcase

Job Market Showcase

Chair: Deniz Simsek, Northwestern University, Evanston, IL, United States

1 - Join-the-Shortest Queue with Abandonment

prakirt jhunjunwala, Columbia Business School, Westbury, NY, United States

We consider a load balancing system comprised of a fixed number of single server queues, operating under the well-known Join-the-Shortest Queue policy, and where jobs/customers are impatient and abandon if they do not receive service after some (random) amount of time. In this setting, we characterize the centered and appropriately scaled steady-state queue length distribution (hereafter referred to as limiting distribution) in the limit as the abandonment rate goes to zero at the same time as the load either converges to one or is larger than one.

Depending on the arrival, service, and abandonment rates, we observe three different regimes of operation that yield three different limiting distributions. The first regime is when the system is underloaded, and its load converges relatively slowly to one. In this case, abandonments do not affect the limiting distribution, and we obtain the same exponential distribution as in the system without abandonments. When the load converges to one faster, we have the second regime, where abandonments become significant. Here, the system undergoes a phase transition, and the limiting distribution is a truncated Gaussian. Further, the third regime is when the system is heavily overloaded, and so the queue lengths are very large. In this case, we show the limiting distribution converges to a normal distribution.

2 - Socially Optimal Pricing of Downtown Parking Through the Lens of Cruising Delays

Xinyu Liu, University of Michigan, Ann Arbor, MI, United States, Vijay Subramanian, Yafeng Yin

Cruising is the search for parking spaces when a driver finds no vacancy near the desired parking location. This unpleasant experience of uncertainty and frustration is frequently encountered in downtown areas, aggravating the urban congestion and emission. Pricing has been long promoted as an efficient control to manage downtown parking, reduce cruising for parking, and enhance social welfare. Donald Shoup advocated parking pricing to meet a target occupancy of 85%, which has been widely accepted and implemented in demand-responsive parking pricing projects like SFpark project (launched by the San Francisco Municipal Transportation Authority in 2011). Despite its widespread acceptance, our literature search reveals that few studies have systematically examine the optimal target occupancy. Furthermore, with the advent of autonomous vehicles and their tendency to cruise as a substitution for parking, the optimal pricing and space allocation schemes with the mixed traffic is yet to be understood.

We formulate the parking-cruising system as a queueing network with price- and delay-sensitive arrivals and state-dependent retrial rates that are functions of congestion levels. We provide the stability conditions, propose a scalable approximation to the stationary distribution, show its equivalence to the exact solution in small systems, and validate its performance using a simulation. We leverage the estimated cruising delays to analytically and computationally characterize the target occupancy that optimizes the system welfare.

3 - Dynamic Transfer Policies for Parallel Queues

Jangwon Park, University of Toronto, Toronto, ON, Canada, Timothy Chan, Vahid Sarhangian

We consider the problem of load balancing in parallel queues by transferring customers between them at discrete points in time. Holding costs accrue as customers wait in the queue, while transfer decisions incur both fixed (setup) costs and variable costs that increase proportionally with the number and distance of transfers and vary by direction. Our work is motivated by inter-facility patient transfers to address imbalanced congestion and inequity in access to care during surges in hospital demand (e.g., pandemics). Analyzing the associated fluid control problem, we show that under general assumptions, including time-varying arrivals and convex holding costs, the optimal policy partitions the state-space into a well-defined *no-transfer region* and its complement, implying that transferring is optimal if and only if the system is sufficiently imbalanced. In the absence of fixed transfer costs, an optimal policy moves the state to the no-transfer region's boundary; in contrast, with fixed costs, the state is moved to its relative interior. Leveraging our structural results, we propose a simulation-based Approximate Dynamic Programming (ADP) algorithm to find good transfer policies for the stochastic system. We investigate the performance and robustness of the fluid and ADP policies in a case study calibrated using data during the pandemic in the Greater Toronto Area, which demonstrates that transferring patients between hospitals could result in up to 27.7% reduction in total cost with relatively few transfers.

4 - Large Service Systems with Patience- OR Delay-Dependent Service TIMES: Fluid Approximations, Design and Control

Deniz Simsek, Northwestern University, Evanston, IL, United States, Achal Bassamboo, Ohad Perry

We consider a single-pool many-server queueing system, assuming the service time of each customer depends on the delay of that customer in queue. Such dependence can be due to the customers having finite patience for waiting that depends on their individual service requirement, or due to having their service-time distribution be a function of the time spent in queue. We refer to the former dependence mechanism as “exogenous dependence” and to that latter as “endogenous dependence.” Since exact analysis of the stochastic system under either dependence mechanism is intractable, we propose a deterministic approximation for the (mean) queueing dynamics, referred to as a Unified Fluid Model (UFM). For constant arrival rates, we characterize conditions for the existence of a unique stationary point for the UFM and prove that those conditions always hold when the dependence is exogenous. However, the UFM may possess multiple equilibria, with each equilibrium point being either locally stable or unstable. The implication of the multi-stability of the UFM for the stochastic system is two-fold. First, the stochastic fluctuations in steady state may be an order of magnitude larger than the typical fluctuations in many-server queueing systems. Second, an underloaded or critically loaded system may experience congestion collapse, namely, it becomes severely congested. Finally, for systems with delay-dependent services, which are prone to multi-stability, we propose design and control mechanisms achieving the performance level of the most desirable equilibrium of the UFM while maintaining unique stationary behavior.

Design of Incentives and Allocations

Job Market Showcase

Job Market Showcase

Chair: Eklavya Sharma, ISE, UIUC, Urbana, IL, United States

1 - Bayesian Mechanism Design for Blockchain Transaction Fee Allocation

Zishuo Zhao, University of Illinois Urbana-Champaign, Urbana, IL, United States, Xi Chen, David Simchi-Levi, Yuan Zhou

In blockchain systems, the design of transaction fee mechanisms (TFMs) is essential for stability and satisfaction for both miners and users. A recent work has proven the impossibility of collusion-proof mechanisms that achieve both nonzero miner revenue and Dominant Strategy Incentive Compatibility (DSIC) for users. However, a positive miner revenue is important in practice to motivate miners. To address this challenge, we consider a *Bayesian game* setting and relax the DSIC requirement for users to Bayesian Nash Incentive Compatibility (BNIC). In particular, we propose an auxiliary mechanism method that makes connections between BNIC and DSIC

mechanisms. With the auxiliary mechanism method, we design a TFM based on the multinomial logit (MNL) choice model, and prove that the TFM has both BNIC and collusion-proof properties with an asymptotic constant-factor approximation of optimal miner revenue for i.i.d. bounded valuations. Our result breaks the zero-revenue barrier while preserving truthfulness and collusion-proof properties.

2 - Single-Sample and Robust Online Resource Allocation

Yifan Wang, Georgia Institute of Technology, Atlanta, GA, United States, Rohan Ghuge, Sahil Singla

Online Resource Allocation problem is a central problem in many areas of Computer Science, Operations Research, and Economics. In this problem, we sequentially receive n stochastic requests for m kinds of shared resources. Each request can be satisfied in multiple ways, consuming different amounts of resources and generating different values. The goal is to achieve a $(1 - \epsilon)$ -approximation to the hindsight optimum, where $\epsilon > 0$ is a small constant, assuming each resource has a large budget.

We investigate the learnability and robustness of online resource allocation. Our primary contribution is a novel Exponential Pricing algorithm with the following properties:

1. It requires only a single sample from each of the n request distributions to achieve a $(1 - \epsilon)$ -approximation for online resource allocation with large budgets. Such an algorithm was previously unknown, even with access to polynomially many samples, as prior works either assumed full distributional knowledge or was limited to i.i.d. or random-order arrivals.
2. It is robust to corruptions in the outliers model and the value augmentation model.
3. It operates as a simple item-pricing algorithm that ensures incentive compatibility.

The intuition behind Exponential Pricing algorithm is that the resource prices should adjust exponentially as it is overused or underused. It differs from conventional approaches that use an online learning algorithm for item pricing. This departure avoids running out of resources entirely, but loses the usual no-regret properties of online learning algorithms, necessitating a new analytical approach.

3 - Mission vs. Profit: The Interplay Between Social Service Agencies and Private Service Providers

Gulten Busra Karkili, University of Massachusetts-Amherst, Amherst, MA, United States, Senay Solak

Voucher-based subsidy programs are a key policy tool for improving access to essential services such as childcare and housing, but their success depends heavily on voluntary participation from private providers who face uncertainty and financial trade-offs. This paper presents an optimization framework capturing the strategic interaction between a mission-oriented agency and quality-differentiated providers within a voucher system. The agency invests in providers to increase service quality and encourage participation, while providers decide whether to participate and what portion of their capacity they expect to be used by voucher beneficiaries, balancing uncertain private-payer demand and capacity utilization risk.

We characterize how provider participation and planned participation levels respond to changes in agency investment, market competition, and provider characteristics. Our analysis reveals that under certain conditions, providers can be incentivized to participate even without direct funding, either through increased voucher payments or indirect competitive effects. We also identify operational scenarios where higher investments paradoxically lead to non-participation by service providers.

We apply the model using data from Massachusetts' C3 childcare grant program. Results show that optimized investments can increase service access by over 10% without additional funding, demonstrating how targeted financial strategies can significantly improve program outcomes. This work provides actionable insights for agencies designing more effective and efficient public-private partnerships in essential service delivery.

4 - New Fairness Concepts for Allocating Indivisible Items

Eklavya Sharma, ISE, UIUC, Urbana, IL, United States, Ioannis Caragiannis, Jugal Garg, Nidhi Rath, Giovanna Varricchio

For the fundamental problem of fairly dividing a set of indivisible items among agents, envy-freeness up to any item (EFX) and maximin-share fairness (MMS) are arguably the most compelling fairness concepts proposed until now. Unfortunately, despite significant efforts over the past few years, whether EFX allocations always exist is still an enigmatic open problem, let alone their efficient computation. Furthermore, today we know that MMS allocations are not always guaranteed to exist. These facts weaken the usefulness of both EFX and MMS, albeit their appealing conceptual characteristics. We propose two alternative fairness concepts, called epistemic EFX (EEFX) and minimum EFX share fairness (MXS), inspired by EFX and MMS. For both, we explore their relationships to well-studied fairness notions and, more importantly, prove that EEFX and MXS allocations always exist and can be computed efficiently for additive valuations. Our results justify that the new fairness concepts can be excellent alternatives to EFX and MMS.

coming soon

2 - Air Carrier Capacity Allocation for Collaborative Humanitarian Logistics

Micah Borrero, University of Michigan, Ann Arbor, MI, United States

Vulnerable communities are increasingly exposed to natural disasters due to global climate change. Coordinated humanitarian responses to impacted regions are often logistically complex and expensive. Given the high cost and potential infeasibility of a well-coordinated post-disaster response, the preemptive, strategic placement of humanitarian logistics assets could yield numerous benefits, including lowering potential operational costs, improving response times, and ensuring maximum coverage of disaster-impacted communities. We propose a bi-level optimization architecture in which the leader-level problem models the interaction between fleet operators and a logistics agency, while the follower-level problem models the interaction between the logistics agency and downstream aid delivery operations. Specifically, the leader model captures a fleet operator's decision process when weighing the cost of reserving air freight capacity against the risk of unmet humanitarian demand. The follower model subsequently responds to realized scenarios by routing aid through a potential multimodal air-ground network, combining reserved air capacity with pre-positioned trucks to minimize delivery time. Preliminary results from sensitivity analyses reveal tradeoffs between operator costs and humanitarian outcomes. These show how organizational priorities influence capacity reservation strategies and identify conditions where under- or over-reserving capacity becomes particularly costly. Ongoing work incorporates operational uncertainties, such as ad-hoc payload adjustments by airlines, that can significantly disrupt time-sensitive missions and historical air carrier data. We aim to develop robust optimization models that yield resilient capacity allocation strategies, strengthening the reliability of humanitarian supply chains under growing global uncertainty.

3 - Analyzing Inter-Airline Cooperative Coordination Mechanisms Under A Time-Varying Cost Function

Tolga Atabas, University of Michigan, Ann Arbor, MI, United States

Airlines frequently face delays from disruptions that reduce airport capacity, such as adverse weather. To balance constrained capacity with demand, air traffic managers reschedule flights, often causing widespread delays. Airlines model delay costs for each flight as a function of delay severity (e.g., hours) and prior work on intra- and

inter-airline slot swapping has applied such functions to minimize systemwide delay costs. However, an existing inter-airline swapping mechanism—the Delay Ledger (DELED), which uses a ledger-based system to coordinate scheduling decisions among airlines—assumes fixed-rate cost functions. This assumption fails to capture real-world cost surges arising from missed connections, crew disruptions, and tail-propagated delays.

This study introduces a convex, stochastically generated piecewise linear cost function that captures the time-varying nature of delay costs in the real world. We model surge events with a Poisson process and integrate the resulting functions into the DELED framework. This enhancement improves both the realism and robustness of delay management models.

Our results show that incorporating time-varying cost structures yields more efficient delay assignments compared to fixed-rate assumptions. Numerical experiments further demonstrate that DELED's ledger-based coordination outperforms a round-robin rotational mechanism in allocating delay across airlines. Finally, we conduct a sensitivity analysis to examine how parameter changes affect DELED's ability to reduce system-level delay costs, highlighting the framework's adaptability across diverse operating conditions.

4 - A Dynamic Model for Airline Fleeting and Scheduling

Jingxing Wang, University of California, Berkeley, Berkeley, CA, United States

The global airline industry slumped during COVID-19: demand was volatile, cancellations surged, and airlines struggled to align capacity with shifting demand, pushing load factors to historic lows. In the recovery, airlines have institutionalized several measures first adopted during the pandemic, such as offering passengers greater flexibility in booking and cancellation. As a result, airlines are increasingly required to be agile and adaptive in their operational decisions. We introduce a dynamic model to help airlines make adaptive fleeting and scheduling decisions based on stochastically evolving bookings. The model incorporates both arrivals (new bookings) and departures (cancellations). This significantly generalizes and strengthens previous modeling attempts. We develop a Lagrangian relaxation framework that decomposes the dynamic program on a large time-space network into separable flight-level problems, and we analyze the tightness of this relaxation under representative flight network structures. Owing to the complexities of this network, our Lagrangian dual problem is not straightforward to solve. We therefore develop a tailored yet simple projected subgradient algorithm that exploits the structure of this network for efficient solutions. We establish the correctness and convergence properties of this procedure. Our analysis yields new theoretical, algorithmic, and managerial insights into the dynamic fleeting and scheduling problem. We present computational experiments based on real-world airline booking data to demonstrate the potential benefits of this approach.

5 - Aircraft Trajectory Optimization for Combinatorial Sampling in the Airspace

6 - Penalty Functions for Truck-and-Drone Routing Problem

Ke Xu, University of Southern California, Los Angeles, CA, United States

Drones are increasingly being integrated into last-mile delivery networks to alleviate reliance on conventional ground trucks. This collaboration can involve various combinations of trucks and drones and incorporate diverse operational constraints tailored to specific delivery requirements. In previous studies, however, each problem variant is typically addressed by a specialized solution method. In this study, we introduce a versatile heuristic approach based on the Lin-Kernighan-Helsgaun algorithm with penalty functions to solve a wide range of drone-assisted delivery variants with a unified solution framework. Its flexibility and effectiveness are demonstrated through numerical experiments on benchmark instances designed for several representative problem variants, including the Flying Sidekick Traveling Salesman Problem (FSTSP), the Traveling Salesman Problem with Multiple Drones (TSP-MD) and the Vehicle Routing Problem with Drones (VRPD).

7 - Optimization Model for Large-Scale Long-Term Aircraft Maintenance Scheduling and Station Assignment

JohnPaul Adimonyemma, FAMU-FSU College of Engineering, Tallahassee, FL, United States, Yanshuo Sun

The primary focus of the existing aircraft maintenance optimization literature is on short-term aircraft maintenance routing. By contrast, only a few studies address long-term maintenance planning, which predominantly emphasize scheduling decisions: none of them have examined the critical aspect of assigning aircraft to maintenance stations, a key challenge for major airlines with a network of maintenance facilities. Additional research gaps include (1) insufficient consideration of practical maintenance-related constraints (e.g., station access limit and aircraft rotation requirement) and (2) the absence of scalable algorithms capable of solving real-world problem instances involving hundreds of aircraft and dozens of maintenance stations. To fill those gaps, this study introduces a joint optimization model for aircraft maintenance scheduling and station assignment to assist a U.S.-based airline in creating long-term plans for a fleet of over 800 aircraft of multiple subfleet types. To address the computational challenges, we propose two decomposition approaches: one based on decision types and the other on time horizons. Extensive computational experiments using real-world data from the collaborating airline demonstrate that these approaches can reduce computation time by up to 80% with a minimal increase in the optimization objective (less than 2%). The proposed model is expected to streamline maintenance planning efforts and enhance outcomes for aircraft maintenance professionals.

8 - Detecting Anomalous Bird Flock Patterns Using Coarse-Grained Complexity: Toward Safer UAS Operations Near Airports

9 - Optimizing Multi Team Agricultural Drone Deployment and Routing with Weather Aware Planning

Ethan Kolby, University of Michigan, Ann Arbor, MI, United States

UAS can service dozens to hundreds of fields on a county-scale, but real operations require routing that adapts to fast-changing weather while coordinating multiple teams. This work extends a prior facility-location→vehicle-routing (FLP→VRP) pipeline by making deployments weather-aware. For each rolling forecast horizon, gridded wind and precipitation products are interpolated to a continuous vector field when needed, thresholds are applied to polygonize exceedance regions, and a facility-time availability matrix is built. Availability enters the optimization as time-windowed closures: closed sites cannot open or dispatch during affected windows; open sites remain routable. The regional problem proceeds as FLP→VRP: fields are assigned to feasible facilities, and shortest tours over fields and required facility legs are computed for each team. As forecasts update, the solver re-optimizes, shifting workload to open sites and rerouting around transient closures with minimal manual intervention. We outline a practical ingest-to-optimization loop: (1) read forecast data; (2) interpolate sparse fields; (3) delineate exceedance polygons; (4) label facility-time pairs open/closed; and (5) pass the availability mask into the FLP→VRP solver for rolling-horizon updates. Ongoing work automates the weather ingest and interpolation, incorporates scenario-based wind uncertainty to harden availability labels, and evaluates regional service levels under realistic, time-varying closures. The result moves multi-team UAS operations toward robust, forecast-integrated planning and execution.

10 - Towards Efficient Aircraft Turnaround: a Mesoscopic Model for Equipment Routing and Scheduling

Marcus Koh, Singapore University of Technology and Design, Singapore, Singapore

Efficient aircraft turnaround relies on tightly coordinated ground operations carried out with limited Ground Service Equipment (GSE). As air traffic continues to grow, pressure on GSE allocation and scheduling intensifies, with poor management risking delays, higher fuel consumption, reduced passenger satisfaction, and even cancellations. To address this, we frame turnaround operations as a Vehicle Routing Problem (VRP), extending beyond classical VRP models by integrating aviation-specific complexities such as heterogeneous fleets, multiple task types, precedence constraints, reloading needs, and strict time windows.

We propose a decomposition approach where the turnaround process is structured into four interrelated subproblems—baggage operations, waste and water services, passenger-dependent operations, and aircraft pushbacks—each modelled and solved individually before integration into a master problem. Among these, the baggage subproblem is prioritized as the foundation, given its operational intricacy and strong interdependencies between the GSEs. By tackling baggage operations first, we thus establish a generalizable modelling framework that can be further extended to capture the full turnaround process.

11 - Bandit-Enabled Dynamic Vehicle Dispatch and Routing in Hazardous Environments

Jimin Choi, University of Michigan, Ann Arbor, MI, United States

Hazardous environments such as chemical spills, radiological zones, and bio-contaminated sites pose significant threats to human safety and public infrastructure. Rapid and reliable hazard mitigation in these settings often unsafe for humans, calling for autonomous systems that can adaptively sense and respond to evolving risks. This paper presents a decision-making framework for autonomous vehicle dispatch in hazardous environments with uncertain and evolving risk levels. The system integrates a Bayesian Upper Confidence Bound (UCB) sensing strategy with task-specific vehicle routing problems with profits (VRPP), enabling adaptive coordination of unmanned aerial vehicles (UAVs) for hazard sensing and unmanned ground vehicles (UGVs) for cleaning. Using VRPP allows selective site visits under resource constraints by assigning each site a visit value that reflects sensing or cleaning priorities. Site-level hazard beliefs are maintained through a time-weighted Bayesian update. UCB scores guide UAV routing to balance exploration and exploitation under uncertainty, while UGV routes are optimized to maximize expected hazard

reduction under resource constraints. Simulation results demonstrate that our framework reduces the number of dispatch cycles to resolve hazards by around 30% on average compared to baseline dispatch strategies, underscoring the value of uncertainty-aware vehicle dispatch for reliable hazard mitigation.

1 - From Complexity to Clarity: AI in Action for Resilient and Efficient Supply Chains

Bhubalan Mani, Garmin International, Inc., Olathe, KS, United States

The current global economy with its unpredictable nature and interconnected systems puts supply chains under continuous stress from unexpected disruptions, changing market demands and internal planning system inefficiencies. The ability of traditional rule-based systems to handle uncertainties is limited. The presentation “From Complexity to Clarity: AI in Action for Resilient and Efficient Supply Chains” demonstrates how AI and analytics solutions solve real business problems to create better decision-making processes. My two decades of experience working with enterprise supply chain systems and analytics allows me to share practical lessons from recent projects that integrated AI and machine learning into ERP-driven planning functions to optimize safety stock levels and balance inventory across multiple echelons and forecast demand under uncertain conditions. The implemented initiatives delivered better operational performance while moving supply networks toward predictive decision-making at a global level. The session will demonstrate how organizations can design and implement AI-enabled planning tools without having to overhaul existing systems by strategically layering intelligence over operational data. I will also discuss critical success factors, including cross-functional collaboration, data readiness, and change management. The participants will have a clear understanding of how to turn AI from a buzzword into a practical enabler of supply chain resilience and efficiency. This session will be useful for practitioners who want to know how to implement AI and decision makers who want to know if AI is a good fit for their operations.

2 - AI-Enabled Customer Sentiment Analysis in B2b Sales Operations

Jiaxi Zhu, Google, Mountain View, CA, United States

In complex B2B environments, sales effectiveness often relies on qualitative signals that are difficult to quantify or scale. This talk presents a case study on how AI-enabled sentiment analysis was operationalized within a large-scale B2B sales organization to improve customer engagement. We explore a hybrid framework that combines natural language processing (NLP) and large language models (LLMs) with structured sales pipeline data to surface sentiment trends, customer risk indicators, and emerging objections in real time. The system was deployed across global sales operations, with models trained on call transcripts and was integrated directly into frontline decision workflows. Key outcomes include improved deal prioritization and accelerated resolution of customer concerns. We also highlight lessons learned in implementation, including cross-functional buy-in, model interpretability, and feedback loops between AI outputs and sales strategy. This presentation offers practical guidance for analytics leaders and OR professionals working at the intersection of AI, sales, and customer insights.

3 - From Complexity to Clarity: AI in Action for Resilient and Efficient Supply Chains

The current global economy with its unpredictable nature and interconnected systems puts supply chains under continuous stress from unexpected disruptions, changing market demands and internal planning system inefficiencies. The ability of traditional rule-based systems to handle uncertainties is limited. The presentation “From Complexity to Clarity: AI in Action for Resilient and Efficient Supply Chains” demonstrates how AI and analytics solutions solve real business problems to create better decision-making processes. My two decades of experience working with enterprise supply chain systems and analytics allows me to share practical lessons from recent projects that integrated AI and machine learning into ERP-driven planning functions to optimize safety stock levels and balance inventory across multiple echelons and forecast demand under uncertain conditions. The implemented initiatives delivered better operational performance while moving supply networks toward predictive decision-making at a global level. The session will demonstrate how organizations can design and implement AI-enabled planning tools without having to overhaul existing systems by strategically layering intelligence over operational data. I will also discuss critical success factors, including cross-functional collaboration, data readiness, and change management. The participants will have a clear understanding of how to turn AI from a buzzword into a practical enabler of supply chain resilience and efficiency. This session will be useful for practitioners who want to know how to implement AI and decision makers who want to know if AI is a good fit for their operations.

Inventory Management at Amazon

Invited Session

Practice Track

Chair: Chun Ye, Amazon.com, Seattle, WA, 98101, United States

Co-Chair: Ishan Bansal, Amazon, Lynnwood, WA, United States

1 - Managing Inventory Flows in a Multi-Echelon Network - a Simulation Study

Zihao Li, Amazon, Bellevue, WA, United States

Inbound Network Simulation (INSim) is a Discrete Event Simulation (DES) tool designed to replicate and experiment with various inbound network structures and inventory control strategies. In a multi-echelon inbound network, inventory is received, stored, and distributed to different facilities. We demonstrate how INSim can be used to experiment with different inventory control strategies.

2 - Inventory Placement Planning - Overcoming the Limitations of Product Grouping

Ishan Bansal, Amazon, Bellevue, WA, United States

Online retailers face the critical challenge of optimally distributing inventory across fulfillment centers under demand uncertainty. While traditional approaches allocate each product independently based on regional demand patterns, ship and store capacity constraints create interdependencies across product placement decisions. Given extensive product catalogs, retailers commonly group similar products to make optimization problems tractable.

However, this product grouping introduces significant approximation errors, particularly for tail products with sparse demand. Existing literature often treats products within a group as fungible, resulting in overly optimistic placement strategies for low-demand items. This talk presents novel techniques to address these limitations and introduces an algorithm that effectively disaggregates group-level placement solutions into precise product-level allocation decisions. Our approach maintains computational efficiency while significantly improving inventory positioning accuracy for the full product spectrum.

3 - Optimizing Inventory Placement in Speed-Sensitive Fulfillment Networks with Consumer Substitution Behavior

Katja Meuche, Georgia Institute of Technology, Atlanta, GA, United States, Cristiana Lara, Louis Faugere, Benoit Montreuil

The traditional Newsvendor model, while analytically elegant, struggles with modern e-commerce fulfillment networks where consumer-driven substitution occurs due to stock-outs and long delivery times. This research develops a two-stage stochastic optimization framework that incorporates consumer substitution behavior for inventory

decisions across multiple fulfillment locations.

We extend the classical Newsvendor model by including both stockout-based and delivery speed-based substitution behaviors. Our model optimizes inventory placement across a fulfillment network, considering product substitutability, delivery time expectations, and capacity constraints to reduce operating costs.

Recognizing that temporal demand sequences drive real-world operations, we explore how to approximate consumer-driven substitution behavior through various constraint formulations and a comparative simulation study. By capturing the dynamics of consumer substitution in multi-location networks, we assess the impact of substitution-aware inventory placement on expected costs, service levels, and inventory levels.

Our preliminary experiments show that substitution-aware inventory placement can reduce inventory levels by 14% on average while maintaining service targets. This research enhances both the theoretical understanding of inventory models and their practical applications in retail. By accurately representing consumer substitution behavior, we help retailers manage the trade-off between costs and service levels in competitive omni-channel environments.

Transportation Safety, Security, and Sustainability

Invited Session

TSL: Intelligent Transportation Systems

Chair: Haitao Li, University of Missouri - St. Louis, Saint Louis, MO, United States

1 - Driving Renewable Integration: Dual-use Carshare Fleets for Mobility and Grid Services

Kevin Freymiller, Carnegie Mellon University, Pittsburgh, PA, United States, Haocheng Duan, Sean Qian

As institutions increasingly deploy renewable energy generation, they typically seek to reduce their energy costs and carbon emissions. Solar energy deployments continue to grow worldwide and so does the need for local energy storage alongside it. Fixed battery storage systems remain too expensive in most cases to provide significant savings on energy. Institutions also generate significant transportation demand, and many are transitioning to battery electric vehicles to meet these needs. These batteries can serve a dual use for energy storage and transportation when operated optimally, and can even serve to transport energy between multiple locations where energy costs and emissions vary, providing an additional benefit to the system. We investigate how an electrified carshare fleet providing mobility services within an institutional campus can provide mutual benefits beyond transportation by storing and moving energy in the vehicle battery. By utilizing vehicle-to-grid technology, vehicles charge and discharge as needed at different sites depending on site specific energy prices, generation, and demand, reducing energy costs, and increasing utilization of renewable energy. We show that charging vehicles at sites with excess solar generation reduces cost of energy for transportation and also sites where V2G delivers energy to offset building demand. This approach shows benefit increases when energy prices are highest, which coincides with increased travel delays. When energy costs are low and transporting energy has less benefit, travel delays are decreased. Thus we show that considering tradeoffs between the system leads to an overall systemwide benefit.

2 - Sensor-Enabled Intelligent Distribution for Perishable Food Products

Haitao Li, University of Missouri - St. Louis, Saint Louis, MO, United States

With the technology of rapid pathogen sensors being deployed throughout an end-to-end poultry supply chain, *Salmonella* testing results can be obtained and shared in real time, which makes it possible to improve processing, distribution and transportation operations. We develop a mixed-integer programming (MIP) model to automate and optimize the diversion decision in poultry processing, distribution of limited supply to the markets in need, and cold chain options, e.g., transportation modes, temperature setting, while satisfying supply capacity, market demand, and food safety standards. The novelty of our model is its ability to model diversion decision in poultry processing, and the consideration of pathogen growth and decrease of shelf-time and product value during cold chain transportation. A case study of an end-to-end poultry supply chain is conducted to show the type of decision support that can be provided by our model and how it simultaneously addresses food safety and operating efficiency.

3 - Energy and Emission Efficient Speed Suggestion System for Human Drivers: Simulation and Real-World Validation

Maziar Zamanpour, University of Minnesota, Minneapolis, MN, United States

Advancements in vehicle connectivity and automation have presented numerous opportunities in transportation, such as increased throughput, enhanced safety, and improved energy efficiency. While connected and automated vehicles (CAVs) offer significant energy savings, their widespread implementation faces substantial practical challenges. This study presents an energy-efficient speed suggestion system for human-driven connected vehicles (ESSCV), bridging the gap between conventional vehicles and fully autonomous ones. A Model Predictive Control (MPC), commonly used in eco-driving for CAVs, calculates optimal acceleration, providing speed advisories to human drivers. The driver's response to these advisories is modeled using an adaptive Intelligent Driver Model (IDM) calibrated in real-time. To validate the simulation results, a real-world road test was conducted in Minnesota using a connected vehicle communicating with a traffic signal. Initially, the system displayed speed suggestions to the driver, and the IDM was trained based on observed driver responses. Subsequently, an actual road test was performed, demonstrating practical feasibility and effectiveness. The road test confirmed that drivers could reliably follow the advisories, achieving energy savings consistent with simulation predictions. Overall, the integrated ESSCV framework, combining traffic prediction, MPC-based optimization, and real-time driver behavior modeling, achieves an average energy saving of up to 12% compared to conventional car-following behavior at signalized intersections, with minimal travel time impacts. This study demonstrates the practical viability and benefits of integrating ESSCV into existing speed control mechanisms, providing a cost-effective interim solution as the technology for fully automated vehicles continues to evolve.

Chair: Sophie Yu, The Wharton School of the University of Pennsylvania, Philadelphia, PA, United States

Co-Chair: Yeganeh Alimohammadi, USC, Los Angeles, CA, United States

1 - A Random Model of Supply Chain Networks

Georgina Hall, INSEAD, Fontainebleau, France, Philippe Blaettchen, Andre Calmon

Supply chain problems are frequently formulated as optimization problems over graphs representing complex networks of interlinked input-output relationships. Frequently, these problems are hard, so researchers rely on analyzing stylized structures or developing heuristic solutions. Yet, a scarcity of real-world data has hindered our understanding of how these exact and heuristic solutions perform in practice and whether managerial insights carry over from these simplified settings. We address this critical gap by introducing RG4SC, a versatile random graph model for creating "test tracks" for supply chain management research. RG4SC's simple micro-foundations and interpretable input parameters allow for systematically generating diverse and realistic network structures. We demonstrate its empirical validity and that it more adequately represents real-world supply chain networks than existing random models. We then showcase RG4SC's utility for research through a case study on the Guaranteed Service Model, a widely used framework for safety stock optimization. Our analysis shows how RG4SC can be central to uncovering novel managerial insights, analyzing the computational complexity of algorithms, benchmarking heuristics, and training machine learning models.

2 - Two-Sided Flexibility in Platforms

Jiayu (Kamessi) Zhao, MIT, Cambridge, MA, United States, Daniel Freund, Sebastien Martin

Flexibility is a cornerstone of operations management, crucial to hedge stochasticity in product demands, service requirements, and resource allocation. In two-sided platforms, flexibility is also two-sided and can be viewed as the compatibility of agents on one side with agents on the other side. Platform actions often influence the flexibility on either the demand or the supply side. But how should flexibility be jointly allocated across different sides? Whereas the literature has traditionally focused on only one side at a time, our work initiates the study of two-sided flexibility in matching platforms. We propose a parsimonious matching model in random graphs and identify the flexibility allocation that optimizes the expected size of a maximum matching. Our findings reveal that flexibility allocation is a first-order issue: for a given flexibility budget, the resulting matching size can vary greatly depending on how the budget is allocated. Moreover, even in the simple and symmetric settings we study, the quest for the optimal allocation is complicated. In particular, easy and costly mistakes can be made if the flexibility decisions on the demand and supply side are optimized independently (e.g., by two different teams in the company), rather than jointly. To guide the search for optimal flexibility allocation, we uncover two effects -- flexibility cannibalization and flexibility asymmetry -- that govern when the optimal design places the flexibility budget only on one side or equally on both sides. In doing so we identify the study of two-sided flexibility as a significant aspect of platform efficiency.

3 - Aligning Multiple Inhomogeneous Random Graphs: Fundamental Limits of Exact Recovery

Taha Ameen, University of Illinois Urbana-Champaign, Urbana, IL, United States, Bruce Hajek

We explore impacts of network heterogeneity and multiple networks on the graph matching problem, i.e. to recover the underlying correspondence between correlated unlabeled graphs. This problem captures essential challenges in operations: matching users across platforms for targeted advertising, aligning supply chains for merger analysis, correlating sensor networks for infrastructure monitoring, or aligning feature representations across different datasets for machine learning. The insight is that networks exhibit correlation (e.g. two friends on Facebook likely also follow each other on Twitter), but the correlation is obscured by unknown node correspondences.

Real-world networks have dense clusters, spatial correlations, and high degree superstar nodes. How do these factors influence thresholds for graph matching? Using inhomogeneous random graph models, we characterize phase transitions for exact recovery and show that heterogeneity can both help and hinder matching performance depending on the correlation structure, providing insight into which network features are most important for inference. Our multi-graph matching algorithm first partially matches graphs pairwise and then combines the partial matchings by transitivity. Its analysis yields a sufficient condition on the problem parameters to exactly match all nodes across all the graphs. In the setting of homogeneous (Erdős-Rényi) graphs, we show that this condition is also necessary, i.e. the algorithm works down to the information theoretic threshold. This reveals a scenario where exact matching between two graphs alone is impossible, but leveraging more than two graphs allows exact matching among all the graphs.

4 - The Uniformity Principle in Spatial Matching

Sophie Yu, The Wharton School of the University of Pennsylvania, Philadelphia, PA, United States, Taha Ameen, Flore Sentenac

Platforms matching mobile supply to spatially distributed demand face a fundamental design choice: given a fixed budget, how should service ranges be distributed among supply units? We model this via bipartite random geometric graphs with n supply and m demand nodes uniformly distributed on $[0,1]^k$ ($k \geq 1$), where an edge between a supply and demand node forms when the demand node is within the supply node's allocated service range. We seek to maximize the expected size of the maximum matching under a fixed total range budget. Our main result establishes that uniform allocation—equal ranges for all supply units—strictly dominates heterogeneous allocation for all dimensions $k \geq 1$. This dominance stems from diminishing marginal returns to range expansion and limited interference from bounded ranges fragmenting the graph. Additionally, for $k=1$, we characterize the size of maximum matching via Markov chain embedding and derive exact matching formulas for special cases. Our results provide theoretical justification for equalizing service territories in applications such as autonomous vehicles, drones, and emergency services.

5 - AI Supply Chains: An Emerging Ecosystem of AI Actors, Products, and Services

Sarah Cen, Massachusetts Institute of Technology, Cambridge, MA, United States

The widespread adoption of AI in recent years has led to the emergence of AI supply chains: complex networks of AI actors contributing models, datasets, and more to the development of AI products and services. AI supply chains have many implications yet are poorly understood. In this work, we take a first step toward a formal study of AI supply chains and their implications, providing two illustrative case studies indicating that both AI development and regulation are complicated in the presence of supply chains. We begin by presenting a brief historical perspective on AI supply chains, discussing how their rise reflects a longstanding shift towards specialization and outsourcing that signals the healthy growth of the AI industry. We then model AI supply chains as directed graphs and demonstrate the power of this abstraction by connecting examples of AI issues to graph properties. Finally, we examine two case studies in detail, providing theoretical and empirical results in both. In the first, we show that information passing (specifically, of explanations) along the AI supply chains is imperfect, which can result in misunderstandings that have real-world implications. In the second, we show that upstream design choices (e.g., by base model providers) have downstream consequences (e.g., on AI products fine-tuned on the base model). Together, our findings motivate further study of AI supply chains and their increasingly salient social, economic, regulatory, and technical implications.

1 - Political Districting to Minimize County Splits

Maral Shahmizad, Delta Air Lines, Atlanta, GA, United States, Austin Buchanan

When partitioning a state into political districts, a common criterion is that political subdivisions, like counties, should not be split across multiple districts. This criterion is encoded into most state constitutions and is sometimes enforced quite strictly by the courts. However, map drawers, courts, and the public typically do not know what amount of splitting is truly necessary, even to satisfy basic criteria, like contiguity and population balance. In this paper, we provide answers for all congressional, state senate, and state house districts in the United States using 2020 census data. Our approach is based on integer programming. The associated codes and experimental results are available on GitHub.

2 - The Driver-Aide Problem: Coordinated Logistics for Last-Mile Delivery

3 - Maximizing Engagement in Large-Scale Social Networks

Hamidreza Validi, Texas Tech University, Lubbock, TX, United States, Samuel Kroger, Illya Hicks

Motivated by the importance of user engagement as a crucial element in cascading leaving of users from a social network, we study identifying a largest relaxed variant of a degree-based cohesive subgraph: the maximum anchored k -core problem. Given graph $G=(V, E)$ and integers k and b , the maximum anchored k -core problem seeks to find a largest subset of vertices S that induces a subgraph with at least $|S|-b$ vertices of degree at least k . We introduce a new integer programming (IP) formulation for the maximum anchored k -core problem and conduct a polyhedral study on the polytope of the problem. We show the linear programming relaxation of the proposed IP model is at least as strong as that of a naïve formulation. We also identify facet-defining inequalities of the IP formulation. Furthermore, we develop inequalities and fixing procedures to improve the computational performance of our IP model. We use benchmark instances to compare the computational performance of the IP model with (i) the naïve IP formulation and (ii) two existing heuristic algorithms. Our proposed IP model can optimally solve half of the benchmark instances that cannot be solved to optimality either by the naïve model or the existing heuristic approaches.

The Present and Future of Operational Resilience in Air Transportation

Panel Session

Transportation Science and Logistics (TSL)

Co-Chair: Alexander Estes, University of Maryland, College Park, MD, United States

1 - Moderator Panelist

Alexander Estes, University of Maryland, College Park, MD, United States

Recent, high-profile events have disrupted the national airspace system, resulting in significant delays and cancellations. Examples include winter storms in the southeast and the CrowdStrike software outage. These events demonstrate the need for resilient air transportation operations. When extreme weather, infrastructure outages, and other disruptive events degrade operations, it is critical to contain these events and avoid system collapse. This panel will discuss present and future efforts to improve operational resilience. Panelists will discuss what resilience means to their organization and the current efforts that are being taken to improve resilience. Panelists will also discuss current and future challenges, and the potential for operations researchers and management scientists to contribute to this topic.

Chair: Brian Denton, University of Michigan, Ann Arbor, MI, United States

1 - The Role of Optimization in The Decarbonized Energy Systems of The Future

Miguel Anjos, University of Edinburgh, Edinburgh, United Kingdom

Energy is a fundamental need of human activity. Electricity in particular is a critical resource for society in the 21st century and its ubiquitous use in our houses and cities makes it an essential part of our daily life. As we aim to reduce the environmental impact of human activity, a historical energy transition is under way. This transition raises several major challenges for electric power systems. We begin with an overview of the general trends of change in power systems, followed by examples of real-world success of mathematical optimization techniques in practice. We then introduce the unit commitment problem and how to obtain commitment decisions that are robust in the context of large-scale penetration of renewables. This is followed by an aggregator-based optimization model to support the participation of so-called prosumers in the electricity markets and their potential to contribute flexibility to the power system. Next we consider several of the recent research developments concerning charging infrastructure for electric vehicles. We conclude with a summary of important future research opportunities for the optimization community in electric energy systems.

1 - Order Picking in Large-Scale Robotic Mobile Fulfillment Systems

Felipe Cordera, Massachusetts Institute of Technology, Cambridge, MA, United States, Alexandre Jacquillat, Cynthia Barnhart, Alexandria Schmid

Robotic process automation is transforming operations across various industries, with e-commerce warehousing increasingly reliant on Robotic Mobile Fulfillment Systems (RMFS) to enable efficient order picking. This paper addresses the challenges of jointly assigning multi-item orders, and the necessary pods, to multiple workstations in large-scale warehouses, through the Task Assignment Problem (TAP). We provide theoretical insights demonstrating that synergy opportunities in order picking expand as system scale increases, underscoring the need to develop scalable solution methods for TAP. To this end, we propose valid inequalities to strengthen its formulation, and we also introduce a family of simple, yet effective, variable-fixing heuristics to tackle large-sized instances. These heuristics, grounded in nearest-neighbors and greedy assignment principles, effectively reduce the dimension of the problem while retaining high quality solutions. Extensive experimentation demonstrates the superiority of our approach over existing benchmarks, further validated through a route planning module that evaluates downstream operational efficiency, specifically focusing on pod traffic bottlenecks. Finally, we introduce a novel optimization framework that integrates downstream operational effects into TAP, enabling more informed decision-making. Our results provide practical insights into challenging operating conditions and showcase the ability of our methods to capitalize on increased synergy opportunities in larger systems.

2 - Leveraging Large Language Models for Intelligent Supply Chain Decision Making

Yongzhi Qi, JD.com, Beijing, China, People's Republic of, Jiaheng Yin, Jianshen Zhang, Wei Qi

We present a novel framework that integrates large language models (LLMs) into intelligent supply chain decision-making, addressing the growing need for responsive, interpretable, and scalable planning systems. Our method has been developed and deployed in collaboration with JD.com, a leading e-commerce platform with highly complex supply chain operations. First, we introduce an LLM-based planning agent capable of autonomously decomposing business goals into executable subtasks across various planning horizons. It coordinates forecasting, inventory control, and replenishment operations by interfacing with external tools and validating output correctness, forming an adaptable and modular planning workflow. Second, we employ LLMs as auditors of traditional decision models. Recognizing that classical optimization methods often rely on unrealistic assumptions, we design prompt-based mechanisms where the LLM critiques decision outputs, surfaces modeling flaws, and suggests business-aligned refinements. This introspective capability improves the practical utility of models in uncertain, data-driven environments. Our experimental results and deployment experience at JD.com show that this hybrid decision-making framework enhances both planning quality and interpretability. It significantly reduces manual effort, improves solution feasibility, and bridges the gap between model-driven and context-aware decision processes. This work demonstrates the practical value of LLMs in enterprise-scale applications beyond text generation. It contributes a robust and extensible paradigm for AI-powered operations, offering new directions for applied research and intelligent system design in the supply chain domain.

3 - On-Demand Service Zone Design for Energy-Constrained Spatial Queueing Systems: Applications to Drones and Mobile Chargers

Peng Lin, Tsinghua University, Beijing, China, People's Republic of, Cheng Hua, Wei Qi, Kai Wang

This research proposes an energy-integrated spatial queueing system that extends the classical hypercube framework with stochastic energy tracking mechanisms. To address energy-constrained service operations, we formulate a semi-Markov process capturing each server's joint energy-position dynamics. Through an iterative approximation scheme with provable fixed-point properties, we numerically derive steady-state service satisfaction rates and operational metrics including system profitability. The implementation framework introduces a service zone design optimization model that simultaneously determines service region partitioning and facility placement under service radius limitations. By constructing the P-median-like problem as an upper bound for our system, we devise an improved branch-and-price algorithm to address the inherent combinatorial complexity. Numerical experiments demonstrate the model's capability in modeling spatial queueing systems with multiple energy-constrained servers operating concurrently, exhibiting resilient performance under server shortage. Specific implementations in multi-task drone operations and mobile charging pile deployment validate its effectiveness in capturing spatial-energy service interactions. The methodology offers systematic insights for designing resilient service networks with adaptive resource pooling capabilities, providing operational guidance for on-demand systems requiring concurrent energy and spatial management.

4 - Mobile Additive Manufacturing Factories with Drone Delivery to Supply Spare Parts to Offshore Platforms

Daniela Granados Rivera, Auburn University, Auburn, AL, United States, Daniel Silva, Alice Smith, Fabio Sgarbossa, Nils Knofius

This research explores a real-world mobile additive manufacturing (MAM) factory problem using uncrewed autonomous vehicles (i.e., drones), from both analytical and practical perspectives. We partner with FIELDMADE, a Norwegian company that provides mobile factories inside shipping containers equipped with additive manufacturing technology. We extend the Mobile Facility Location Problem (MFLP) to study spare parts supply to offshore platforms using MAM factories and delivery drones, enabling a flexible and adaptive supply chain. Our model assumes that MAM factories are located onshore and that delivery options comprise drones, trucks, and ships. The existing literature on MFLP lacks integration of delivery decisions and often limits facility relocation to direct customer locations, which is infeasible for offshore settings. Moreover, the few studies combining MFLP with distribution do not consider multi-modal transportation. Given the constraints of offshore environments, drones are a promising solution for spare parts delivery. The problem incorporates multiple decisions—relocation, production, distribution, and routing—that are rarely addressed together because of the complexity. To address this, we propose a two-stage matheuristic: the first stage focuses on relocation and production, while the second stage addresses distribution, including drone routing and truck/ship deliveries. The performance of the matheuristic proves to be within of 7% of optimal, with computational time up to 20 times faster than the complete mathematical model. Results show that relocation and drone use significantly reduce shipping times and help meet due dates. The proposed approach offers a practical and efficient solution for this novel offshore supply chain.

1 - Why is EV Charging so Unreliable? The Role of Competition in Supplementary Services

Yifan Liu, Georgia Institute of Technology, Atlanta, GA, United States

As companies increasingly offer sustainability-oriented supplementary services such as trade-in remanufacturing or hotel electric vehicle charging, understanding the circumstances under which firms can improve their service quality for these offerings is crucial for effective sustainable operations and policy decisions. While competition is widely known to drive improvements in core service quality, its effects on supplementary service quality remain unclear. In this study, we examine how competition influences the reliability of U.S. electric vehicle charging infrastructure, a key supplementary offering for businesses such as hotels, retailers, shopping centers, and parking facilities. Using a U.S. dataset of 66,228 EV charging stations spanning 2011 to 2024, we apply machine learning methods to measure service reliability in EV charging operations. While increased competition within the same core business is found to enhance charging reliability, surprisingly, greater competition from businesses in different core areas is associated with a decline in charging station reliability. This is critical because the vast majority of nearby providers are competing in different core businesses. We project that an average annual increase in competition is associated with a decrease in service reliability scores ranging from 11% to 23% across the most common establishment types over a 5-year period. We also find that the effects of competition attenuate within 10 miles and are not

statistically different from zero in rural or disadvantaged areas. We investigate whether relying on competition, or introducing targeted policies, can address the large-scale service reliability issues reported in the U.S. and globally in public EV charging infrastructure.

2 - Physician Networks in Accountable Care Organizations

Dimitrios Andritsos, HEC Paris, Paris, France, Claire Senot

Effectively coordinating a patient's health care services is critical for the delivery of high-quality and efficient care. Accountable Care Organizations (ACOs) are a prominent model for incentivizing more coordinated care delivery. Nevertheless, no consistent approach has emerged in terms of how different ACOs organize and coordinate care between participating providers. In aggregate, the evidence to date suggests that ACOs' success in achieving their stated objectives of lowering costs and improving quality has been modest. However, this hides the fact that there exists a wide disparity of performance across ACOs. Thus, they provide an excellent empirical setting for the study of care coordination. In this work, we exploit this variability to understand how the nature of care coordination across ACO-centered physician referral networks is associated with performance across both cost and quality dimensions. In our analysis, we put a particular emphasis on coordination between primary care providers and specialists. To characterize communication and care coordination among physicians we examine their patient-sharing relationships via network analysis.

Roundoff-Error-Free Algorithms in Optimization

Invited Session

Computing Society

Chair: Christopher Lourenco, US Naval Academy, Annapolis, MD, United States

1 - An Early Termination Criteria for Dixon's Method

Erick Moreno-Centeno, Texas A&M University, College Station, TX, United States

Dixon's p-adic lifting algorithm uses modular arithmetic to find exact solutions to systems of linear equations. Although this method is state-of-the-art for solving dense systems exactly, it often performs significantly more iterations than necessary to compute the solution. In order to avoid some of these unnecessary computations, a new early termination criteria is presented which is based on Cabay's criteria for congruence technique algorithms. This stopping procedure is predicated on a new version of rational reconstruction which partially reconstructs the modular image found at each p-adic lifting iteration. The complete algorithm maintains the same worst-case complexity as Dixon's original method but is more efficient in practice, as it performs only a small number of iterations beyond those which are necessary to compute the solution.

2 - Sparse Integer-Preserving Gram-Schmidt

Lorena Mejia Domenzain, SimpleRose, St Louis, MO, United States

QR factorization is widely used in mathematics, computer science, and operations research. The QR factorization of matrix A is given by $A=QR$, where Q is an orthogonal matrix, and R is an upper triangular matrix. Typically, QR factorizations are implemented using floating-point precision, which, though appropriate for the majority of applications, have been shown to lead to incorrect rank computation, loss of orthogonality, or incorrect solutions for highly ill-conditioned input matrices. The Round-off error free QR (REF QR) factorization and integer-preserving Gram-Schmidt (IPGS) orthogonalization provide a framework to compute exact QR factorizations of any dense rational input matrix, using integer arithmetic. The REF QR factorization factors matrix A as $A=QDR$, where Q is a left orthogonal matrix, R is an upper triangular matrix, and D is a diagonal matrix. This talk presents an efficient sparse IPGS-REF QR algorithm, that can be used to factorize matrices and determine the rank of rank-deficient matrices. This computation of rank is strongly grounded in exact linear algebra and does not rely on numeric or probabilistic approximations (as other methods for computing the rank of sparse matrices do).

3 - From Pits to Projects: Providing Good Options to Managers Through Computation of K-Best Closures

Andrew Plucker, Texas A&M University, College Station, TX, United States, Erick Moreno-Centeno

Rupert Resources discovered the Ikkari Mineral Reserve in Finland in 2020; their pre-feasibility study highlights a 20-year plan to mine 52 milled tons of earth for an expected gross revenue of \$7.2 billion. The first 10 years of the operation will include open-pit mining. In open-pit mining, the mine design involves selecting blocks of ore to extract while respecting precedence constraints derived from the stability of the pit's slope. When modeled, these constraints form a directed acyclic graph (DAG) where the best economic value corresponds to a maximum weight closure. While the maximum weight closure problem is solvable via a reduction to the minimum-cut problem, many managerial applications demand not just a single optimal solution but a *portfolio* of high-quality alternatives. Generating the k-best closure sets, ordered by total vertex weight, enables decision makers to explore trade-offs, evaluate solution robustness, and flexibly respond to input parameter changes. Despite the practical importance of such ranked alternatives, literature has largely focused on identifying a single optimal closure, with comparatively few tools available for computing and analyzing the k-best solutions. We introduce an algorithmic framework for computing and ranking the k-best closures in a DAG, with direct applicability to managerial problems where solution diversity and interpretability are as important as optimality. Our approach builds upon advances in combinatorial optimization, enhancing them with problem-specific pruning techniques. We demonstrate the utility of our method through instances of open-pit mining and daily-pricing project scheduling, highlighting different solutions that could significantly impact decisions within those respective domains.

4 - Expediting Exact Linear Programming Solvers via Integer Preserving Factorization

Christopher Lourenco, US Naval Academy, Annapolis, MD, United States, Ram Krishnamoorthy

Linear programming (LP) is foundational to operations research and LPs are widely solved using state-of-the-art commercial solvers. These solvers provide accurate solutions for the vast majority of instances; however, for approximately 3-5% of real-world problems, they may provide incorrect solutions. To remedy this issue, exact LP solvers exist, the forefront of which is the solver SoPlex. SoPlex guarantees exactness by performing rational basis validation; that is rational-arithmetic LU factorizations of LP bases. These rational factorizations are the bottleneck of SoPlex, in some cases occupying over 90% of the run time. We replace these rational factorizations with the SPEX factorization framework, an exact integral approach for LU factorization which is asymptotically more efficient than rational LU. On a test set of real-world LPs, our new approach utilizing SPEX for basis validation is a factor of 3.33 and 1.60 times faster than baseline SoPlex in terms of average and geometric mean, respectively.

5 - Stress Testing the Numerical Stability of Lp and Mip Solvers

Joshua Grassel, North Carolina State University, Raleigh, NC, United States, Adolfo Escobedo

Modern solvers for linear programming (LP) and mixed-integer programming (MIP) are indispensable tools in optimization, yet they can yield incorrect results due to roundoff errors from floating-point arithmetic. These errors, such as reporting suboptimal solutions as optimal or misidentifying problems as infeasible, cast doubt on solver reliability. Their impact is particularly acute in domains requiring high numerical precision, such as biochemical modeling, astrophysics simulations, compiler optimization, and mathematical proofs.

To mitigate these issues, various strategies have been developed, including presolve scaling, algorithm tuning, and exact arithmetic subroutines. However, current evaluation practices rely heavily on standard problem libraries, which may not expose numerical weaknesses in a consistent or generalizable way.

This research proposes a novel framework for generating synthetic LP instances that systematically stress test solvers' numerical robustness. Inspired by worst-case complexity constructions like the Klee-Minty cube, the framework allows control over key parameters, such as variable count and coefficient precision, enabling exploration of solver behavior under varying numerical stress. Each generated problem is guaranteed to have an exactly representable optimal solution in the floating-point standard used, ensuring that any observed errors originate from solver internals rather than input and output encoding.

This approach provides a systematic method for testing solver reliability and benchmarking numerical stability. The presentation showcases results from applying this framework to a range of commercial and open-source solvers, highlighting both their strengths and limitations when facing numerically challenging LP instances.

1 - Harnessing Technological Innovation Through Operational Customization: Virtual Triage Adoption in Acute Care

Jiatao Ding, Nanyang Technological University, Singapore, Singapore, Michael Freeman, Sameer Hasija

Effective technology management is crucial for organizations seeking to leverage technological innovation to improve decision-making and operational performance. While predictive technologies powered by advanced algorithms promise enhanced accuracy and efficiency, real-world evidence suggests that their benefits cannot be realized without proper operational customization – adapting tools to specific organizational contexts. This interplay between technological innovation and operational customization is particularly crucial in acute care, where virtual triage tools have been increasingly adopted to assist patients with self-triage and make informed decisions about the appropriate care options, i.e., primary care or emergency care. Despite their potential as scalable and cost-effective solutions, the impact of virtual triage on patient behavior and system performance remains underexplored. To address this gap, we develop a modeling framework to evaluate the effects of virtual triage adoption, focusing on the nuanced interaction between technological advancement and operational customization. Our analysis reveals a fundamental trade-off between the informativeness and volume of virtual triage recommendations, which significantly influences patient compliance. Additionally, we show that improvements in predictive performance of virtual triage may lead to adverse outcomes. Instead, tailoring virtual triage tools to align with system-specific characteristics offers a pathway to realizing their intended benefits. These findings emphasize the necessity of coupling technological advancements with operational customization to unlock the full potential of virtual triage. More broadly, our work underscores the importance of context-sensitive technology management, calling for regulatory oversight and collaborative efforts between technology providers and operational stakeholders to ensure effective implementations.

2 - Waiting Under Pressure: The Causal Impact of ED Wait Times on Diagnostic Decision-Making

Danqi Luo, UC San Diego, San Diego, CA, United States, Luxi Shen

Emergency department (ED) overcrowding and prolonged wait times pose critical challenges for healthcare systems, yet the direct effect of these waits on clinical decision-making remains unclear. This study combines a natural experiment with a controlled online experiment to investigate whether extended wait times causally influence physicians' diagnostic ordering. Drawing on detailed ED data, we exploit exogenous variation in wait times—conditioned on triage priority and ED congestion—to examine two assumptions: (1) that wait times are independent of underlying patient complexity, and (2) that wait times vary randomly within each acuity level. Empirical tests confirm the validity of these assumptions, showing no significant correlation between wait times and predicted patient complexity, and minimal demographic-based sorting within acuity strata. In a Two-Stage Least Squares (2SLS) analysis, leveraging a ransomware-induced disruption as an instrumental variable, we find that longer waits substantially increase the number of diagnostic tests ordered.

To further validate these findings, we conducted an online experiment on Prolific with practicing clinicians, randomly manipulating only the reported wait time before evaluation. Consistent with the natural experiment results, physicians who perceived a longer patient wait were more likely to order additional tests. These findings highlight the importance of managing ED wait times to optimize diagnostic decisions and improve resource allocation.

3 - What Can Online Personal Statements Tell us? Insights About Physicians's Personality Traits and Clinical Performance

Susan Lu, University of Toronto, West Lafayette, IN, United States, Jianing Ding, Wilson Lin, Karthik Kannan

We use NLP to extract personality traits from physicians' statements and examine how their personalities affect clinical performance.

4 - Explore Then Confirm: Investment Portfolios for New Drug Therapies

Zaile Li, INSEAD, Fontainebleau, France, Stephen Chick, Sam Deams, Shane Henderson

New medical technologies must pass several risky hurdles, such as multiple phases of clinical trials, before market access and reimbursement. A portfolio of technologies pools these risks, reducing the collective financial risk of such development while also improving the chances of identifying a successful technology. We propose a stylized model of a portfolio of technologies, each of which must pass two phases of clinical trials before market access is possible. Using ideas from Bayesian sequential optimization, we study the value of running response-adaptive clinical trials to flexibly allocate resources across technologies in a portfolio. We suggest heuristics for the response-adaptive policy and find evidence for their value relative to non-adaptive policies.

Sector Coupling for the Energy Transition

Invited Session

ENRE: Energy

Chair: Dharik Mallapragada, New York University, Brooklyn, NY, 11201, United States

1 - Industrial Heat Decarbonization Using Gas-Electric Sector-Coupled Models

Dimitri Saad, Stanford University, Stanford, CA, United States, Jacqueline Dowling, Mo Sodwatana, Steve Davis, Inês Azevedo, Adam Brandt

Carbon emissions from industrial heat sources are considered hard-to-abate emissions. Industrial processes generally utilize heat that is generated by combusting a fuel, such as natural gas. Moreover, reducing industrial heating emissions depends on the required process temperatures, which are specific to each industrial sector. Industrial heat electrification can provide net-zero heat at various temperature ranges, provided zero-carbon electricity is utilized. Thus, electrifying industrial heating could require significant expansion in the generation capacity of the electric power grid. Our work examines the role of thermal batteries - a flexible system that converts electricity to heat to store thermal energy - in reducing the process heat emissions of industrial facilities in California. We use BRIDGES: a sector-coupled gas-electricity capacity expansion model, which minimizes system costs over multiple investment years (2025-2045), subject to decreasing carbon emission targets that reach net-zero emissions in 2045. We model heat demands across 39 industrial manufacturing sectors in California, which add up to an equivalent baseload heat demand of 8.1 GW. Our results show that, without the option for carbon capture & storage (CCS) to abate industrial heat emissions, thermal batteries supply the majority of the industrial heat demand below 1000 C. The installation of thermal batteries leads to more built solar PV capacity to charge the batteries. Furthermore, in scenarios with CCS as an option for industrial emission abatement, natural gas usage for industrial heating continues till 2045. While thermal batteries are also built in this scenario, they serve a more substantial role when fuel costs are notably higher.

2 - U.S. Energy Transition Pathways: Insights from US-Regen Scenario Modeling

Aranya Venkatesh, EPRI, Palo Alto, CA, United States, John Bistline

The trajectory of U.S. energy sector emissions over the coming decades will be shaped by multiple dynamic factors, including uncertainties in recent climate legislation, shifts in global fuel trade driven by the energy transition, and the emergence of new technology pathways. In this study, we employ EPRI's US-REGEN—a detailed

energy-economy optimization model that captures the operations and interactions across the electric, fuels, and end-use sectors—to develop scenarios that explore how the U.S. energy system may evolve in response to these drivers. For each scenario, we analyze impacts on the electric sector, focusing on capacity and generation. We also examine key outcomes related to fuel supply, such as the regional distribution and cost of low-carbon fuel production, as constrained by infrastructure and resource availability. Additionally, we assess how end-use demands in the buildings, transportation, and industrial sectors respond to these evolving conditions. Finally, we highlight implications for energy-system CO₂ emissions and system costs.

3 - State-Dependent Non-Linearities in Large-Scale Multi-Sector Energy System Optimization for Capacity Planning

yu weng, Massachusetts Institute of Technology, Cambridge, MA, United States, Ruairidh Macdonald

Multi-sector energy systems; which integrate sectors such as electricity, hydrogen, and transportation; offer a promising pathway to efficiently meet rising energy demands while meeting reliability and decarbonization goals. Capacity expansion planning for such systems are large scale multi-sector co-optimizations of investment and operational decisions across a large number of technologies and resources. As a result, such models can typically only be solved with low temporal or spatial resolution, or simplified technology models - particularly when applied at a national level. To address this, existing methods often rely on clustering and decomposition techniques, along with linearized constraints. While these approaches reduce computational burden, they compromise modeling accuracy, making it difficult to capture the influence of nonlinear behaviors on investment decisions. This work presents an approach to effectively handle non-linear and state-dependent non-linear constraints in planning problems. State-dependent nonlinear constraints is a novel class of constraints that describe how the operational characteristics of technologies/devices change in response to varying levels of investment. These constraints capture important nonlinear properties of technologies that are often overlooked in conventional models. To solve such constraints in capacity planning problem, this work presents a novel envelope-based method for incorporating them within a Benders decomposition framework. The proposed approach approximates state-dependent nonlinear relationships using multiple linear constraints, preserving key nonlinear features without incurring large computational costs. Consequently, it enables a more accurate examination of how the unique properties of emerging technologies and energy carriers could affect future energy investment landscapes.

4 - Modeling Multisectoral Interactions in the Temoa Canadian Open Energy Model

Daniel Posen, University of Toronto, Toronto, ON, Canada, David Elder, Sylvia Sleep, Sean McCoy, Juan Moreno-Cruz, Heather L. MacLean, Sara Hastings-Simon, Andrew Leach, Cameron Wade

Energy system models provide a critical foundation for assessing technology pathways for a low-carbon future. Despite substantial progress in advancing sector-coupling in previously electricity-focused models, many continue to struggle to capturing the sector-specific constraints and multisectoral interactions – particularly in relation to the physical realities such as fuel supply chains, critical mineral and bulk material flows or infrastructure requirements of the energy transition.

This talk will present an overview of ongoing activities to construct and advance a novel energy system optimization model for Canada – the Canadian Open Energy Model (CANOE). Built on the TEMOA linear-programming framework, CANOE is a multi-sector capacity expansion model. It is being constructed in a highly modular format that allows for flexible choice in technological, spatiotemporal and sectoral resolution. The development team is a multi-university consortium with primary background in the tools of industrial ecology (life-cycle assessment, techno-economic assessment, material flow analysis and energy transitions) – enabling us to bring an uncommon perspective to the world of energy modeling. We have developed capabilities to track physical materials (e.g., critical minerals for battery cathodes and electrolyzers) through the energy system; assess the role of embodied carbon in the energy transition; analyze constraints imposed by the available fuel mix from petroleum refineries; incorporate empirical growth-rate constraints on new technologies; and embed results from detailed sectoral models such as transport sector traffic flows and infrastructure needs.

Although the current model remains a coarse representation of the real world, we look forward to discussing our ongoing and future efforts

5 - Domestic Energy System, Macroeconomic, and Distributional Impacts of Increased US Natural Gas Exports

Maxwell Brown, Colorado School of Mines, Golden, CO, United States

This study uses the linked USREP-ReEDS modeling framework to explore the domestic energy system, macroeconomic, and distributional impacts of expanded US natural gas exports. The integration of the computable general equilibrium capabilities of USREP with the detailed electric sector representation of ReEDS helps to capture the relationships between energy infrastructure, economic activity, and household welfare. The analysis explores scenarios of increased natural gas exports, driven by both/either demand and/or supply adjustments, under varying domestic policy conditions. Metrics of focus are energy prices, generation mix, emissions, and regional economic outcomes. Attention is given to the distributional effects across income groups and US regions, highlighting profit and economic welfare changes associated with shifts in energy costs to industrial and residential consumers, respectively. The open-sourcing of the linked model as well as other advancements in sectoral couplings (mostly focused on materials) are also briefly covered.

Understanding Electricity Markets through Enhanced Optimization

Invited Session

ENRE: Electricity

Chair: Alexandra Newman, Colorado School of Mines, Golden, CO, United States

1 - Optimizing Power Grid Expansion Planning to Promote Energy Transition

Yan-Shen Yang, Tianjin University, Tianjin, China, People's Republic of, Bai-Chen Xie

Interregional transmission lines represented by Ultra-High Voltage (UHV) are used to effectively utilize variable renewable energy (VRE) in resource-rich areas and accelerate the low-carbon transformation of the power system. However, considering its high construction cost, whether the transmission line expansion is cost-effective under high VRE penetration remains unknown. Besides, large amounts of power transmission may affect the locally distributed energy development causing the waste of renewable energy resources. Finding an optimal transmission expansion strategy has become a key issue that needs to be solved urgently. To address the above issue, we develop an hourly scale model to simulate power system operations and expansions under different VRE penetrations by 2050. The results show that: (1) Transmission line expansion will decrease the cost of power system under high VRE penetration. The expansion of transmission lines significantly reduces the installed generating capacity of the power system as well as the amount of VRE curtailment. (2) The inter-regional transmission lines have significantly promoted the construction of centralized wind and solar power in the provinces of the “three North” regions, especially in Inner Mongolia and Xinjiang. The distributed PV has developed rapidly in load-concentrated areas with no transmission line expansion. (3) The proposed optimal transmission line expansion can better balance the relationship between interregional power transmission and locally distributed consumption. It achieves cost-effectiveness while avoiding resource wastage. Our study contributes to pursue a smarter decision in the power sector for a sustainable development world.

2 - Grid’S Large Carbon-Abatement Potential Hindered by Interregional Power Market

Bai-Chen Xie, Tianjin University, Tianjin, China, People's Republic of, Yan-Shen Yang

Power transmission lines play an important role in integrating variable renewable energy (VRE) and realizing the low-carbon transformation of power sector. With the low-carbon transformation of power sector, making better use of UHV transmission lines for integrating VRE to decarbonize power sector has become an important issue to be solved urgently. In this study, we have proposed a high-resolution nonlinear programming model for power market that includes independent system operators (ISO),

producers, and consumers, this study finds that the existing transmission lines make no full use of their capacity to improve the utilization of renewable energy. Therefore, we propose two regulatory policies, volume-based and percentage-based, to improve renewable energy power transmission. The results show that (1) the regulatory policy can effectively promote interprovincial VRE transmission, achieving the clean and efficient utilization of power transmission lines. (2) The regulatory policy can optimize the layout of newly installed VRE capacity, as well as significantly promote low-carbon transformation of power sector. (3) The volume-based policy is more effective in promoting carbon emission reduction in the power system than the percentage-based policy. Valuable implications for policymakers are concluded in the end. Our study contributes to the smarter decision in power sector for sustainable development worldwide.

3 - Value-Oriented Forecast Combinations for Unit Commitment

Mehrnoush Ghazanfariharandi, Rutgers University, Piscataway, NJ, United States, Robert Mieth

Value-oriented forecasts for two-stage power system operational problems have been demonstrated to reduce cost, but prove to be computationally challenging for large-scale systems because the underlying optimization problem must be internalized into the forecast model training.

Therefore, existing approaches typically scale poorly in the usable training data or require relaxations of the underlying optimization.

In this talk, we present a method for value-oriented forecast combinations using progressive hedging, which unlocks high-fidelity, at-scale models and large-scale datasets in training.

We also derive a direct one-shot training model for reference and study how different modifications of the training model impact the solution quality.

Our method reduces operation cost by 1.8% on average and trains forecast combinations for a 2736-bus test system with one year of data within 20 hours.

1 - How to Operate Efficiently and Achieve Maximum Carbon Reduction Before Coal-Fired Power Plants Disappear? a Predict-Then-Optimize Approach

Huiting Hu, University of Science and Technology of China, Hefei, China, People's Republic of

Problem definition: In order to achieve the strategic goal of carbon peak and carbon neutrality in China as soon as possible, it is crucial for coal-fired power plants to effectively utilize the input coals available to improve their fuel costs and reduce carbon emissions. This paper studies the coal blending scheme of coal-fired power plant by mixing different types and corresponding quantities of coal, a coal blending scheme can be obtained under the condition of meeting the demand for power generation. **Methodology/Results:** We developed a data-driven optimal decision framework for coal blending that combines power demand forecasting with coal blending optimization. For this end, we first predict power demand by utilizing the approaches combined long short-term memory (LSTM) with machine learning on multi-modal data. Subsequently, we develop two coal blending optimization formulations, including stochastic optimization formulation and distributionally robust optimization (DRO-W) formulation. To make the formulation solvable, we perform a solvable equivalent reformulation on the proposed DRO-W formulation. By applying our data-driven approach in the numerical experiment based on the historical data of a coal-fired power plant (CPP), which performing significantly better in the worst-case than the stochastic formulation. Furthermore, the numerical results indicate that our data-driven coal blending approach can achieve approximately a 5% cost reduction for the firm. **Managerial Implications:** Interestingly, our findings suggest that the DRO-W approach under carbon trading policy can effectively reduce carbon emission, but the change of carbon price has a non-monotonic effect on the emission reduction.

2 - Structural Features and Formation Mechanisms of Global Co2 Transfer Network Driven by ICT Multinational Investment

Xiaoping Zhang, Tianjin University, Tianjin, China, People's Republic of, Tao Zhao, Rong Yuan, Liang Dong

The rapid expansion of ICT-related multinational enterprises (IMNEs) has introduced significant challenges in emissions mitigation. These IMNEs often manage complex global supply chains and outsource production through foreign direct investment (FDI) while transferring CO₂ emissions to other countries. This paper uses a multi-regional input-output model, social network analysis, and an exponential random graph model to examine the structural characteristics and formation mechanisms of the global CO₂ transfer network driven by IMNEs through FDI (GCNI) from 2000 to 2020. The results reveal that network density increased from 0.353 in 2000 to 0.471 in 2020, reflecting more intensive global CO₂ transfer. The average path length decreased from 1.681 in 2000 to 1.531 in 2020, indicating a shorter distance for embodied CO₂ transfers. The GCNI experienced dynamic cluster adjustments, leading to two distinct communities: the Asia-Africa community and the Europe-America community. China, Chinese Hong Kong, the United States, Japan, South Korea, Germany, and Chinese Taiwan occupied central positions within the GCNI. Larger and more open markets tend to attract CO₂ inflows. CO₂ transfer destinations have shifted from resource-rich nations to those with lower labor costs, and ultimately to regions with high-skilled labor. Countries with strict environmental regulations and high corporate tax rates exhibit a trend of CO₂ outflows. These findings highlight the need to strengthen international cooperation in addressing cross-border environmental challenges in the digital era, as well as the crucial role of FDI motivations in reshaping the geographical patterns of emissions transfers driven by ICT investment.

3 - The Effect of Carbon Prices on Economic Growth and Decarbonization Efforts

Benoit Chevalier-Roignant, emlyon business school, Lyon, France, Alain Bensoussan, Oluwadamilola Oyekan, Viswanath Ramakrishna

The introduction of carbon emission allowances was intended to affect firms' investment decisions (with a possible adverse effect on "economic growth") and allow the emergence and adoption of greener production technologies by incentivizing decarbonization efforts by firms. Empirical studies have stressed the impact of carbon prices' uncertainty on firms' decarbonization efforts. Using a stylized model in continuous time, our model studies when a firm should start operations given that production will imply carbon emissions and, so, the need to acquire certificates. This firm may also choose a production technology with a reduced carbon footprint (e.g., thanks to carbon capture) at the time of investment. In this context, the firm's investment decision is driven by its beliefs about the idiosyncratic profitability and the magnitude of carbon prices. This investment can be reduced to a two-dimensional optimal stopping problem. We characterize the structure of the optimal strategy and design an algorithm to price this real option following a study of a "penalized equation." We also provide comparative statics with respect to key parameters.

4 - Assessing the System Value of Emerging Technologies in A Multi-Sector Energy Model

David Elder, University of Toronto, Toronto, ON, Canada, Juan Moreno-Cruz, Cameron Wade, Heather MacLean, Daniel Posen

In this work, we use an early version of the multi-sectoral TEMOA Canadian Open Energy Model (CANOE) to demonstrate the power of System Value Assessment (SVA) for assessing emerging energy technologies. Rapid decarbonisation requires decisive policy action, which is impeded by risk and uncertainty. A major source of uncertainty in the coming energy transition is the role of emerging technologies like batteries, hydrogen, and direct air carbon capture and storage (DACCS). These technologies feature heavily in plans to reach net zero emissions but there remains deep uncertainty in the projections of their at-scale cost and performance parameters, which are the basis of energy system modelling. This uncertainty is exacerbated by the opacity of large energy systems models, where the interpretation of results can be difficult and often subjective.

Through applied examples exploring the role of grid-scale electricity storage, DACCS, and electrolytic hydrogen production, we demonstrate the use of SVA to assess the value that technologies provide to the energy system across the space of their uncertain parameters – identifying thresholds of price and performance and optimal deployment strategies to achieve and maximise economic viability. We break down the source of system value as a forensic tool to investigate model behaviour, uncovering generalizable insights into the cross-sectoral systemic effects of technology adoption.

5 - Supply Chain and Policy Design for Integrated SAF Production in Brazil: A Bilevel Optimization Approach

Madelynn Watson, University of Notre Dame, Notre Dame, IN, United States, Aline Veronese da Silva, Pedro Gerber Machado, Celma de Oliveira Ribeiro, Claudio Augusto Oller do Nascimento, Alexander Dowling

Sustainable aviation fuel (SAF) is expected to account for 65% of total emissions reductions in the aviation industry by 2050 due to its economic competitiveness and drop-in compatibility with existing aircraft and fuel systems. Brazil's historical government support of biofuels, large ethanol capacity, and existing biomass infrastructure create a unique opportunity for commercial SAF development. Bioethanol from the sugarcane industry in Brazil can be upgraded to SAF via the ASTM-certified pathway alcohol-to-jet (ATJ). Integration of SAF production in the Brazilian sugarcane industry presents complex multiscale optimization problems, including a strong dependence on sustainable energy policy, undeveloped SAF supply chains, and hierarchical interactions between supply chain managers and individual mill owners.

In this work, we propose a bilevel optimization formulation to design a two-stage SAF supply chain in Brazil to meet 50% of the country's international airport jet fuel demand. In this bilevel formulation, we consider the supply chain central planner as the leader. The leader sets the SAF incentive and decides the locations of mills that produce SAF to minimize system costs. Then, the sugarcane mill owners (the followers) determine the production amounts of sugar, ethanol, and SAF to maximize their profit. The optimal supply chain design allows us to determine break-even SAF incentive prices and quantify the impact of ATJ technological advances for successful SAF integration in the Brazilian sugarcane industry.

6 - Plant-Level Techno-Economic Assessment of Steel Sector Decarbonization Pathways in the United States

Robin Zou, Dartmouth College, Hanover, NH, United States, Erin Mayfield

The steel industry accounts for approximately 7% of global greenhouse gas emissions and is widely recognized as a "hard-to-abate" sector. Decarbonizing steel production is essential for meeting climate targets, yet existing analyses often lack plant-level resolution and do not reflect diversity in production technologies, regional material supply chains, and regional energy systems. This gap limits the ability to design tailored, actionable decarbonization strategies.

We develop a bottom-up modeling framework to evaluate the techno-economic pathways across 93 steel-producing plants in the U.S. The model integrates plant-level operational data, technology-specific performance and costs, regional energy system projections, regional material supply chains, and plant-level lifecycle greenhouse gas emissions. Our framework enables comparative assessment of incumbent production routes, such as blast furnace–basic oxygen furnace (BF–BOF), direct reduced iron–electric arc furnace (DRI–EAF), scrap–EAF, and emerging technologies, such as molten oxide electrolysis, carbon capture and storage (CCS), and substitution with low-carbon fuels (e.g., green hydrogen, sustainable biomass).

The framework captures the impact of site-specific variation on cost and emission tradeoffs associated with alternative decarbonization pathways, and examines the role of grid decarbonization, CCS deployment, and fuel switching in shaping feasible transition pathways. Results highlight significant variability in decarbonization potential and cost-effectiveness across plant types and regions.

Our work provides a high-resolution analytical tool for evaluating the economic and environmental implications of decarbonization strategies at the facility level. The framework supports data-driven policy development and strategic planning within the steel sector, helping accelerate industrial decarbonization while addressing operational, technological, and regional constraints.

7 - A Study on the Economic Impacts of Repurposing Plant Sites in Energy Transition

Jeongmin Shin, Kyung Hee University, Yongin-si, Korea, Republic of, Changeun Park, Jungwoo Shin

As coal-fired power plants are phased out globally to support decarbonization, South Korea faces both challenges and opportunities in repurposing the idle land left behind—often near urban centers. This study presents a comprehensive analysis of such repurposing by integrating three dimensions: social preference, economic value, and financial impact on public energy companies. A nationwide choice experiment using a Bayesian mixed logit model reveals that residents prefer tourism-oriented or hybrid redevelopment over simple power plant conversions, driven by factors like carbon reduction, job creation, and proximity. The zonal travel cost method, applied to the Mapo Saebit Culture Forest, estimates significant consumer surplus from nature-based tourism, projecting long-term benefits for nine closure sites. Financial analysis using a Korean-adapted O-score model shows that although closure compensation harms short-term financial stability, long-term recovery is achievable through electricity revenues, carbon savings, and tourism income. The study offers a novel framework combining stated preference data, economic valuation, and financial risk modeling to inform site-specific, regionally sensitive policy. While it delivers valuable insights, it acknowledges limitations, including the exclusion of site-specific constraints and fixed financial assumptions. Overall, the research highlights that repurposing idle energy infrastructure requires a multidimensional strategy that blends physical planning with socioeconomic and financial considerations, offering practical guidance for sustainable energy transition and regional resilience.

8 - Location-Based Power Planning with Aging Plant Sites for a Just Energy Transition: Coal Repurposing Opportunities in South Africa

Ziting Huang, Johns Hopkins University, Baltimore, MD, United States, Ben Hobbs, Debabrata Chattopadhyay

By 2045, 25% of the global operating coal power capacity will reach the end of 50-year design lifetime, presenting a critical crossroads for system operators and plant owners in making future decisions. However, plant sites remain valuable assets, as transmission lines typically have a much longer lifespan than generators. To explore the reutilization potential of plant sites, we propose a holistic model that compares the benefits across six alternatives regarding existing coal power: (1) limit operation, (2) mothball as a backup generator, (3) retrofit with carbon capture and storage, (4) repurpose with renewable energy and battery storage, (5) redevelop for non-power use, and (6) demolish completely. These decarbonizing alternatives often come along with different externalities, such as providing affordable generation, reducing carbon emissions, or increasing unemployment.

We incorporate multiple objectives with capacity expansion model to identify the plant redevelopment decisions while achieving system stability, emissions reduction, and local employment. Furthermore, system operators typically prioritize costs and system reliability, while plant owners are more concerned with profits and local community impacts, leading to discrepancies in objectives during the decision-making process. We also explore the interaction between system and plant owners through two distinct modeling frameworks -- multi-objective optimization and agent-based modeling simulation, to facilitate a comparison between top-down decisions and those incorporating with plant-level preferences. This research is useful in developing effective energy transition policies that balance both system stability and local community benefits.

We adopt this model in South Africa, a system dominated by aging coal, to discuss coal phase-out decisions.

1 - The Impact of Precipitation Forecasts on Small Business Performance

Weilong Wang, Columbia University, New York, NY, United States, Tim Sels, Abhishek Nagaraj, Vaibhav Anand

Weather forecasts are a critical tool for economic decision-making, yet systematic evidence on their real-world value remains limited. This study quantifies the economic impact of short-term precipitation forecasts on small business performance across the United States. Using a natural experiment framework, we exploit variation in forecast accuracy while holding actual weather constant to isolate the causal effect of forecast quality on business outcomes. Specifically, we examine how customer foot traffic and spending at over one million establishments vary when precipitation is predicted accurately versus when forecasts either over- or under-estimate rainfall. Drawing on high-frequency data from SafeGraph and anonymized transaction datasets, we find that forecast errors meaningfully influence small business activity. On days when rainfall is overpredicted, businesses see a measurable decline in visits and spending—even when actual conditions are favorable. Conversely, underpredictions lead to increased business activity, though often at the cost of preparedness. These effects are concentrated on days with moderate to heavy precipitation and vary significantly by industry, in particular, retail, food service, and entertainment. Our results highlight the economic cost of inaccurate forecasts and the value of reliable short-term predictions. Improvements in 1-day precipitation forecasts yield substantial returns in increased consumer activity during inclement weather, suggesting investment in forecast accuracy significantly benefits local economies. By providing causal evidence, this study offers a rigorous framework for evaluating forecasts and underscores the importance of incorporating user impact into forecasting system design and funding decisions.

2 - Facing Common Threats in a Polarized Environment

Cathy DiGennaro, MIT Sloan School of Management , Cambridge, MA, United States, Vicky Chuqiao Yang

When facing a common threat, conventional wisdom suggests that members of a society will be able to set aside their differences and work together towards a collective solution. However, that this axiom is universal has been disproven by the disjointed and highly polarized responses to COVID-19 and the threat of climate change in the United States. Previous research has suggested that conditions are unfavorable for collective response, citing high levels of affective polarization, low information and subsequent overreliance on social learning, and divisive influence of political elites. We synthesize these concepts into a mathematical model of opinion dynamics and evaluate different scenarios under which feedback between affective and ideological polarization may evolve. Under different specifications for social learning, initial polarization (representing, e.g., early influence by political elites), and inherent preferences between groups, the model predicts three behaviors. In a scenario with a high degree of social learning and high initial polarization, a common threat can deepen existing division, even when inherent preferences are equal between two groups. When initial polarization is lower, groups can reach consensus on the common threat, and when reliance on social learning is reduced and inherent preferences are more disparate, the consensus reached on the common threat can reduce polarization on pre-existing issues. This study helps solve the puzzle of why common, catastrophic threats like COVID-19 and climate change are not guaranteed to unite polarized groups and suggests potential high-leverage intervention points to facilitate collective problem-solving.

3 - Electrifying Away Climate Change: Interactions of Heat Pump Adoption, Installation Capacity, and Peak Grid Load in Massachusetts

Alexander Kuptel, MIT Sloan School of Management , Cambridge, MA, United States, John Sterman

The transition to electric heat pumps for residential heating is likely an effective step in addressing climate change. Despite their efficiency and emissions benefits, heat pump adoption remains limited due to high upfront costs and insufficient installer capacity. Moreover, their performance in cold climates raises concerns about grid load during peak winter demand, and subsidizing heat pumps has proven to be expensive. Using a dynamic behavioral model parameterized to Massachusetts, this paper identifies high leverage policies that spur heat pump adoption while limiting their effect on grid load and costs. Our results suggest subsidies for heat pump purchase costs and electricity use only minimally boost adoption due to limited installation capacity. Subsidizing electricity use also disincentivizes home energy retrofits, as homeowners face a lower effective heating cost. Homes under greater subsidies are subsequently less efficient, leading to greater energy use, peak winter load, and heating energy subsidies. On the other hand, a policy that targets operational and financial constraints of heat pump adoption, such as funding more installer training, improves adoption. This policy increases adoption especially in the short run and therefore reduces cumulative emissions significantly compared to the subsidy policy. However, higher short-run adoption also increases peak heating load and subsidies, highlighting a tradeoff of adoption and emissions with peak winter load and costs in the short term. Our results emphasize the importance of installation capacity and the interaction between energy costs and home energy retrofits to accelerate the energy transition in residential heating.

4 - Bilevel Analysis of Cost and Emissions Externalities from Data Center Load Shifting

Aron Brenner, MIT, Cambridge, MA, United States, Rahman Khorramfar, Nathan Engelman Lado, Line Roald, Saurabh Amin

Data centers are emerging as large, flexible electricity consumers capable of shifting computational workloads across locations in response to economic and environmental signals. While this flexibility has potential for emissions reduction, its impact on power system operations depends critically on how such behavior interacts with network constraints and market signals. We develop a bilevel optimization framework in which a data center minimizes a weighted combination of electricity cost and marginal emissions intensity (LME), while the system operator clears economic dispatch under transmission and generation constraints. Focusing on a stylized three-bus power system, we derive closed-form, piecewise-linear expressions for both the data center and system-wide objectives as functions of the data centers' load shift. These expressions capture threshold-driven regime changes due to congestion and renewable saturation. We identify sufficient conditions under which the data center's decentralized decisions align with or diverge from socially optimal behavior and characterize the resulting externalities. Our results reveal how system topology and generator asymmetry affect incentive alignment and provide insight into when marginal price or emissions signals may fail to guide flexible loads toward socially beneficial outcomes. Our results offer a tractable starting point for analyzing decentralized flexibility under carbon-aware incentives and suggest directions for improving coordination between flexible loads and system operations.

Healthcare NLP: Leveraging Language Models for EHR Insights

Invited Session

Health Applications Society

Chair: Muyan Jiang, UC Berkeley, Berkeley, CA, United States

Co-Chair: Anil Aswani, UC Berkeley, Berkeley, CA, United States

1 - A Large Language Model Based Pipeline for Review of Systems Entity Recognition from Clinical Notes

Zhuqi Miao, SUNY New Paltz, New Paltz, NY, United States, Hieu Nghiem, Hemanth Singareddy, Abdulaziz Ahmed, Jivan Lamichhane, Dursun Delen, William Paiva

The Review of Systems (ROS) is a critical component of clinical assessments, helping identify and differentiate symptoms across body systems. While ROS data are often documented as free text in clinical notes, this format poses challenges for analysis and contributes to physician documentation burden. Despite the promise of NLP for parsing such text, most existing research relies on complex, fine-tuned BERT models rather than more user-friendly large language models (LLMs). This study introduces a streamlined, cost-effective pipeline using open-source LLMs for ROS recognition, offering a scalable solution for improving medical documentation workflows.

2 - Uncovering Treatment Non-Adherence Bias in Clinical Machine Learning with LLMs: a Real-World Study on Hypertension Medication

Zhongyuan Liang, UC Berkeley, Berkeley, CA, United States

Machine learning systems trained on electronic health records (EHRs) increasingly guide treatment decisions, but their reliability depends on the critical assumption that patients follow the prescribed treatments recorded in EHRs. Using EHR data from 3,623 hypertension patients, we investigate how treatment non-adherence introduces implicit bias that can fundamentally distort both causal inference and predictive modeling. By extracting patient adherence information from clinical notes using a large language model (LLM), we identify 786 patients (21.7%) with medication non-adherence. We further uncover key demographic and clinical factors associated with non-adherence, as well as patient-reported reasons including side effects and difficulties obtaining refills. Our findings demonstrate that this implicit bias can not only reverse estimated treatment effects, but also degrade model performance by up to 5%, while disproportionately affecting vulnerable populations by exacerbating disparities in decision outcomes and model error rates. This highlights the importance of accounting for treatment non-adherence in developing responsible and equitable clinical machine learning systems.

3 - Scaling Clinical Note Understanding: An LLM-Guided Framework for Aspect-Based Sentiment Analysis

Muyan Jiang, UC Berkeley, Berkeley, CA, United States

We introduce a flexible, LLM-enhanced framework for aspect-based sentiment analysis of clinical narratives. Our approach begins by sampling representative note excerpts across specialties and time windows, then engages a large language model to define and illustrate key clinical aspects—such as empathy, uncertainty, patient-centered explanations, shared decision-making, and confidentiality. Leveraging few-shot prompting, the same LLM rapidly generates labeled examples, which we use to fine-tune a single transformer classifier. At scale, the trained model assigns sentiment scores for each aspect across entire clinical notes, handling long texts through intelligent segmentation. The result is a compact, per-note sentiment profile that reflects multiple dimensions of clinician language. This end-to-end pipeline strikes a balance between human-guided design and automated scalability, making it readily adaptable for large clinical corpora.

Logistics Under Stress

Invited Session

OPT: Global Optimization

Chair: Daniel Bienstock, Columbia University, New York, NY, 10027, United States

1 - A Column-Generation Approach for Resilient Logistics in Adversarial Environments

Gabriel Hake, Colorado School of Mines, Golden, CO, United States, Robert Provine, Justin Kilb, Alexandra Newman, Daniel Bienstock

This study integrates column generation into a multi-period contested logistics framework, allowing Blue forces to dynamically adapt to adversary actions. Traditional logistics models assume predictable movement, yet adversarial conditions introduce uncertainty and disruption beyond conventional forecasting methods. Our approach iteratively refines feasible solutions, leveraging Generative Adversarial Tactics for Engagement to assess adversarial behaviors without presupposing static distributions. By solving an adversary-aware routing and inventory management problem, we generate robust strategies that optimize resupply efforts while responding to emerging threats. Joint work with Bobby Provine, Justin Kilb, Blake Sisson, Alexandra Newman and Daniel Bienstock.

2 - RI for Logistics Under Stressed Conditions

Blake Sisson, Columbia University, New York, NY, United States, Daniel Bienstock, Justin Klib, Alexandra Newman

We consider a setup with sequential decision making where a logistics plan is stressed by a poorly understood adversary. We demonstrate a set of computational tools based on optimization and reinforcement learning, designed to obtain resilient decisions. Joint work with Justin Kilb, Alexandra Newman and Daniel Bienstock.

3 - A MIP-Based Planning Tool for Military Logistics Operations

Soochan Kim, University of Southern California, Los Angeles, CA, United States, Johannes Royset

In this presentation, we propose a mixed integer programming-based decision support tool that optimizes military logistics operations. The mathematical formulation aims to maximize the fulfilled transport requests, each defined by commodity type, quantity, and a priority factor, across an area of operations consisting of several nodes, while minimizing connector and crew usage cost. In addition, the proposed model considers complex real-world constraints such as capacity, range, refueling, and crew assignment. Computational experiments on real-scale instances indicate that the model efficiently produces sustainment plans within a reasonable computation time. We also explore alternative objective function mode and constraint settings to adapt the tool to varying operational situations and discuss implications of the results.

4 - Tactical Route Planning

Jakub Cerny, Columbia University, NYC, NY, United States, Christian Kroer, Garud Iyengar

We build a game-theoretic model for tactical-level route planning in contested environments with a strategic adversary. While basic deterministic logistics plans are already challenging to devise, they tend to be predictable, which can limit their effectiveness. By introducing calculated randomness into the route planning process, we compute immediately deployable plans that are diversified and harder to anticipate, while maintaining operational efficiency through computation times of just a few seconds. Joint work with Christian Kroer.

5 - Solving Large-Scale Military Logistics Planning Problems

Jeff Linderorth, University of Wisconsin-Madison, Madison, WI, United States

Dreamcatcher-Log (dclog) is a mixed-integer linear program that implements a multi-commodity flow model over a time-space network to propose best allocation and scheduling of connector resources to meet the force closure and sustainment requirements in the logistics plan to support operations meeting the commander's intent. In this talk, we outline the dclog mixed-integer programming model and discuss recent computational improvements.

Causal Inference: Data Corruption, Debiasing, and Fairness.

Invited Session

Public Sector OR

Chair: Jimi Kim, University of Texas at Dallas, Richardson, TX, United States

1 - Learning Interpretable Concepts: Unifying Causal Representation Learning and Foundation Models

Bryon Aragam, University of Chicago, Chicago, IL, United States

To build intelligent machine learning systems, there are two broad approaches. One approach is to build inherently interpretable models, as endeavored by the growing field of causal representation learning. The other approach is to build highly-performant foundation models and then invest efforts into understanding how they work. In this work, we relate these two approaches and study how to learn human-interpretable concepts from data. Weaving together ideas from both fields, we formally define a notion of concepts and show that they can be provably recovered from diverse data. Experiments on synthetic data and large language models show the utility of our unified approach.

2 - Prompting Fairness: Causality-Guided Debiasing of LLM Decisions

Zeyu Tang, Stanford University, Stanford, CA, United States

Large language models (LLMs), despite their remarkable capabilities, are susceptible to generating biased and discriminatory responses. As LLMs increasingly influence high-stakes decision-making (e.g., hiring and healthcare), mitigating these biases becomes critical. We propose a causality-guided debiasing framework to tackle social biases, aiming to reduce the objectionable dependence between LLMs' decisions and the social information in the input. Our framework introduces a novel perspective to identify how social information can affect an LLM's decision through different causal pathways. Leveraging these causal insights, we outline principled prompting strategies that regulate these pathways through selection mechanisms. This framework not only unifies existing prompting-based debiasing techniques, but also opens up new directions for reducing bias by encouraging the model to prioritize fact-based reasoning over reliance on biased social cues. Extensive experiments on real-world datasets across multiple domains have demonstrated the effectiveness of our framework in debiasing LLM decisions, even with only black-box access to the model.

3 - Unified Covariate Adjustment for Causal Inference

Yonghan Jung, University of Illinois at Urbana-Champaign (UIUC), Urbana-Champaign, IL, United States

Causal effect identification and estimation are two crucial tasks in causal inference. Although causal effect identification has been theoretically resolved, many existing estimators only address a subset of scenarios, known as the sequential back-door adjustment (SBD) (Pearl and Robins, 1995) or g-formula (Robins, 1986). Recent efforts for developing general-purpose estimators with broader coverage, incorporating the front-door adjustment (FD) (Pearl, 2000) and more, lack scalability due to the high computational cost of summing over high-dimensional variables. In this paper, we introduce a novel approach that achieves broad coverage of causal estimands beyond the SBD, incorporating various sum-product functionals like the FD, while maintaining scalability -- estimated in polynomial time relative to the number of variables and samples. Specifically, we present the class of UCA for which a scalable and doubly robust estimator is developed. In particular, we illustrate the expressiveness of UCA for a wide spectrum of causal estimands (e.g., SBD, FD, and more) in causal inference. We then develop an estimator that exhibits computational efficiency and doubly robustness. The scalability and robustness of the proposed framework are verified through simulations.

4 - Near-Optimal Reinforcement Learning in Dynamic Treatment Regimes

Junzhe Zhang, Syracuse University, Syracuse, NY, United States, Elias Bareinboim

A dynamic treatment regime (DTR) consists of a sequence of decision rules, one per stage of intervention, that dictates how to determine the treatment assignment to patients based on evolving treatments and covariates' history. These regimes are particularly effective for managing chronic disorders and is arguably one of the key aspects towards more personalized decision-making. In this paper, we investigate the online reinforcement learning (RL) problem for selecting optimal DTRs provided that observational data is available. We develop the first adaptive algorithm that achieves near-optimal regret in DTRs in online settings, without any access to historical data. We further derive informative bounds on the system dynamics of the underlying DTR from confounded, observational data. Finally, we combine these results and develop a novel RL algorithm that efficiently learns the optimal DTR while leveraging the abundant, yet imperfect confounded observations.

5 - Optimizing Policy Decisions in Interconnected Populations: a Spatially-Dependent Framework for Dynamic Decision-Making

Jimi Kim, University of Texas at Dallas, Addison, TX, United States, Yunan Wu

Dynamic decision-making is crucial in policy formation. In reality, states or countries typically make these decisions, and their effects are interdependent due to spatial relationships. However, conventional policy decision-making strategies often overlook these spatial effects, assuming no interference among individuals. In this project, we propose a novel framework to measure these interdependent effects across multiple stages. We also propose the methods to estimate the optimal policy regime taking the spatial effects in consideration for a series of time spots, as well as constructing confidence intervals for the coefficients indexing the optimal policy regime based on multiplier Bootstrap methods. We rigorously demonstrate the validity of the proposed estimation and inference methods. We apply the proposed method on a case study on COVID-19 school closing policies. By applying our methodologies to real-world data on state-level interventions and outcomes, we illustrate how this approach can optimize policy decisions. Our findings have substantial implications for enhancing the effectiveness of personalized intervention strategies in interconnected populations. This approach has the potential to revolutionize precision policy-making in spatially dependent contexts while maintaining a balance between public health and economic considerations.

Advances in Learning Dynamic Games

Invited Session

OPT: Nonlinear Optimization

Chair: Apurv Shukla, University of Michigan, Ann Arbor, MI, United States

1 - Capacitated Dynamic Pricing with Asymmetric Information

Apurv Shukla, University of Michigan, Ann Arbor, MI, United States

We consider the problem of capacitated dynamic pricing under information asymmetry. Our main contribution is to study the capacitated dynamic pricing problem under information asymmetry using the notion of sequential equilibria. We study sequential equilibria as such refinements are more credible in dynamic games than Bayes-Nash equilibrium. We establish the existence of this equilibrium for our problem and propose an efficient method to compute a subset of them. We study characteristics of the resulting pricing equilibrium, such as existence, uniqueness, and the effects of competition and information asymmetry. We conclude by examining the efficiency of the proposed equilibrium with respect to two benchmarks: the team problem which preserves information asymmetry and a mechanism design perspective which computes the transfers and utilities by soliciting information apriori. In addition to providing insights into the efficiency of the pricing equilibria, these benchmarks also shed light on the effect of information asymmetry on social welfare in such dynamic pricing problems.

2 - The Lagrangian Method for Solving Constrained Markov Games

Soham Das, Texas A&M University, College Station, TX, United States, Santiago Paternain, Luiz Chamon, Ceyhun Eksin

We introduce the conception of a Lagrangian game to solve general sum constrained Markov games (CMGs). CMGs model multiagent systems in dynamically evolving environments where agents optimize their individual utilities while also adhering to global system-level feasibility constraints. These constraints can model real world limitations, such as resource budgets, safety considerations, etc. CMGs provide the formal underpinning for safe multiagent reinforcement learning (safe-MARL), where agents must learn intrinsically safe policies through repeated interactions in a coupled environment. Applications are ubiquitous, including autonomous systems coordination, energy aware planning, etc. In our proposed algorithmic framework, given a general-sum CMG, agents construct the “dual” Lagrangian game, by augmenting their value functions akin to constructing the Lagrangian in constrained optimization. Agents solve the associated unconstrained Lagrangian game and simulate finite state-action trajectories to evaluate accumulated rewards and costs. The experience thus obtained is utilized to update the multipliers using a gradient step, generating a new Lagrangian game iteration. Our key result consists in showing that the sequence of policies thus generated constitutes a nonstationary approximate Nash for the original CMG. Our results guarantee feasibility for the policy sequence, with controlled accuracy, while handling constraints indirectly.

3 - Sharing with Frictions: Limited Transfers and Costly Inspections

Federico Bobbio, Northwestern University, Chicago, IL, United States, Randall Berry, Michael Honig, Thanh Nguyen, Vijay Subramanian, Rakesh Vohra

We study an optimal mechanism design problem for resource sharing between an incumbent noncommercial user and a commercial entrant. Motivated by applications such as wireless spectrum allocation and access to national resources, where noncommercial and commercial users compete for limited availability, the mechanism is subject to two key constraints. First, direct transfers cannot take place to compensate the incumbent for externalities caused by the activity of the commercial user. Instead, the incumbent reports a disutility for sharing to a regulator; the second constraint is that this disutility can only be verified via a costly inspection. The regulator optimizes total welfare by announcing a probability of shared resource assignment along with a probability of inspection. We show that in the optimal mechanism, both allocation and inspection decisions are binary: The regulator either fully allows or prohibits sharing, and inspections occur only for certain reported values when sharing is denied. We further reformulate the problem as a knapsack model to characterize threshold extremal points.

Complexity Analysis for Deterministic, Stochastic, and Robust Optimization Methods

Invited Session

OPT: Optimization Under Uncertainty

Chair: Hongcheng Liu, University of Florida, Gainesville, FL, United States

1 - A Single-Loop Spider-Type Stochastic Subgradient Method for Expectation-Constrained Nonconvex Nonsmooth Optimization

Yangyang Xu, Rensselaer Polytechnic Institute, Troy, NY, United States, Wei Liu

We consider nonconvex nonsmooth stochastic optimization problems with expectation constraints, for which we build a novel exact penalty model. We first show the relationship between the penalty model and the original problem. Then on solving the penalty problem, we present a single-loop SPIDER-type stochastic subgradient method, which utilizes the subgradients of both the objective and constraint functions, as well as the constraint function value at each iteration. Under certain regularity conditions (weaker than Slater-type constraint qualification or strong feasibility assumed in existing works), we establish an iteration complexity result that is better than the best-known results. Moreover, on solving two fairness-constrained problems, our method is significantly (up to 466 times) faster than the state-of-the-art algorithms, including switching subgradient method and inexact proximal point methods.

2 - Parameter-Free Gradient Sliding Methods

Yuyuan Ouyang, Clemson University, Clemson, SC, United States

The gradient sliding methods was developed for problems that has separable structures: sum of convex smooth and nonsmooth functions, convex smooth objective and constraint functions, etc. The core idea of gradient sliding-type methods is that the complexity of first-order algorithms should be adaptable to different problem structures. While several gradient sliding methods have been proposed in the literature, few of them are parameter-free; most sliding algorithms require the knowledge of Lipschitz constants. In this talk, we show that gradient sliding methods can be designed without any knowledge of Lipschitz constants. We propose novel gradient sliding algorithms for convex functional constrained minimization and monotone variational inequalities with convex functional constraints.

3 - Simple yet Effective Approximations for Optimization Under Uncertainty

Jianqiang Cheng, University of Arizona, Tucson, AZ, United States

In this talk, we present a novel and simple modeling method called harmonizing optimization (HO), which integrates SAA and DRO with moment by adaptively adjusting the weights of data and information based on sample size N . This allows HO to amplify data effects in large samples while emphasizing information in smaller ones. Moreover, we provide practical methods for determining these weights and demonstrate that HO offers finite-sample performance guarantee. As an application, HO can be used to enhance scenario reduction by retaining critical information from reduced scenarios, thereby improving approximation quality and reducing completion time. Numerical results show significant advantages of HO in solution quality compared to other benchmark modeling approaches, and highlight its effectiveness in scenario reduction.

4 - Metric Entropy-Free Sample Complexity Bounds for Sample Average Approximation in Convex Stochastic Programming

Hongcheng Liu, University of Florida, Gainesville, FL, United States

This talk is focused on sample average approximation (SAA) in solving convex or strongly convex stochastic programming (SP) problems. Under some common regularity conditions, we show that SAA's sample complexity can be completely free from any quantification of metric entropy (such as the logarithm of the covering number), leading to a significantly more efficient rate with dimensionality than most existing results. From the newly established complexity bounds, an important revelation is that SAA and the canonical stochastic mirror descent (SMD) method, two mainstream solution approaches to SP, entail almost identical rates of sample efficiency, lifting a current theoretical discrepancy of SAA from SMD by the order of $O(d)$.

Building B Level 2 B213

Online and Discrete Optimization: Methods and Applications

Invited Session

OPT: Integer and Discrete Optimization

Chair: Alexandre Jacquillat, MIT Sloan School of Management, Cambridge, MA, United States

1 - Online Rack Placement in Large-Scale Data Centers: Online Sampling Optimization and Deployment

Alexandre Jacquillat, MIT Sloan School of Management, Cambridge, MA, United States, Kayla Cummings, Sean Lo, Konstantina Mellou, Ishai Menache, Marco Molinaro

This paper optimizes the configuration of large-scale data centers toward cost-effective, reliable and sustainable cloud supply chains. The problem involves placing incoming racks of servers within a data center to maximize demand coverage given space, power and cooling restrictions. We formulate an online integer optimization model to support rack placement decisions. We propose a tractable online sampling optimization (OSO) approach to multi-stage stochastic optimization, which approximates unknown parameters with a sample path and re-optimizes decisions dynamically. We prove that OSO achieves a strong competitive ratio in canonical online resource allocation problems and sublinear regret in the online batched bin packing problem, and that it can outperform certainty-equivalent benchmarks. Our algorithm has been packaged into a software solution deployed across Microsoft's data centers, contributing an interactive decision-making process at the human-machine interface. Using deployment data, econometric tests suggest a positive and statistically significant impact of our solution on data center performance, leading to a 1--3 percentage point reduction in power stranding. At the scale of cloud computing, these improvements in data center utilization can result in multi-million-dollar annual cost savings and concomitant environmental benefits.

2 - Learning to Cover: Online Learning and Optimization with Irreversible Decisions

Michael Lingzhi Li, Harvard Business School, Boston, MA, United States, Alexandre Jacquillat

We define an online learning and optimization problem with discrete and irreversible decisions contributing toward a coverage target. In each period, a decision-maker selects facilities to open, receives information on the success of each one, and updates a classification model to guide future decisions. The goal is to minimize facility openings under a chance constraint reflecting the coverage target, in an asymptotic regime characterized by a large target number of facilities $m \rightarrow \infty$ but a finite horizon $T \in \mathbb{Z}^+$. We prove that, under statistical conditions, the online classifier converges to the Bayes-optimal classifier at a rate of at best $O(n^{-1/2})$. Thus, we formulate our online learning and optimization problem, with a generalized learning rate $r > 0$ and a residual error $1 - p$. We derive an asymptotically optimal algorithm and an asymptotically tight lower bound. The regret grows in $\Theta(m(1-r)/(1-r^T))$ if $p=1$ (perfect learning) or in $\Theta(m \max\{(1-r)/(1-r^T), 1/2\})$ otherwise; in particular, the regret rate is sub-linear and converges exponentially fast to its infinite-horizon limit. We extend this result to a more complicated facility location setting in a bipartite facility-customer graph with a target on customer coverage. Throughout, constructive proofs identify a policy featuring limited exploration initially and fast exploitation later on once uncertainty gets mitigated. These results uncover the benefits of online learning and optimization through pilot programs prior to full-fledged expansion.

3 - Sequential Testing with Subadditive Cost

Rayen Tan, University of Michigan, Ann Arbor, MI, United States, Blake Harris, Viswanath Nagarajan

In the classic sequential testing problem, we are given a system with several components each of which fails with some independent probability. The goal is to identify whether or not some component has failed. When the test costs are additive, it is well known that a greedy algorithm finds an optimal solution. We consider a much more general setting with subadditive cost functions and provide a $(4q+\gamma)$ -approximation algorithm, assuming a γ -approximate value oracle (that computes the cost of any subset) and a q -approximate ratio oracle (that finds a subset with minimum ratio of cost to failure probability). While the natural greedy algorithm has a poor approximation ratio in the subadditive case, we show that a suitable truncation achieves the above guarantee. Our analysis is based on a connection to the minimum sum set cover problem. As applications, we obtain the first approximation algorithms for sequential testing under various cost-structures: $(5+\epsilon)$ -approximation for tree-based costs, 9.5-approximation for routing costs and $(4+\ln n)$ for machine activation costs. We also show that sequential testing under submodular costs does not admit any poly-logarithmic approximation (assuming the exponential time hypothesis).

4 - New Optimization Approaches for Designing Experiments

Zulal Isler Ardic, Rensselaer Polytechnic Institute, Troy, NY, United States, Diego Moran, Burak Kocuk

Designing experiments is essential for drawing reliable conclusions in research. A key challenge lies in dividing participants into groups that are both balanced and representative of the population. This ensures that comparisons between treatments or controls are fair and meaningful. Traditional methods, such as randomization and re-randomization, are widely used to reduce bias. However, these approaches do not guarantee optimal group balance, particularly in studies with small or diverse samples. Optimization-based methods have emerged as a promising alternative, offering improved performance by directly targeting several balance criteria. In this talk, we present new optimization models that combine different metrics such as difference in moments, Wasserstein distance, variation distance, and a new bin-based approach. Through computational experiments, we evaluate the strengths and limitations of each approach in achieving group similarity and empirically show that our models have a promising performance.

5 - Rounding the Lovasz Theta Function with a Value Function Approximation

Rui Gong, Georgia Institute of Technology, Atlanta, GA, United States, Diego Cifuentes, Alejandro Toriello

The Lovasz theta function is a semidefinite programming (SDP) relaxation for the maximum weighted stable set problem, which is tight for perfect graphs. However, even for perfect graphs, there is no known rounding method guaranteed to extract an optimal stable set from the SDP solution.

In this paper, we develop a novel rounding scheme for the theta function that constructs a value function approximation from the SDP solution

and then constructs a stable set using dynamic programming.

Our method provably recovers an optimal stable set in several sub-classes of perfect graphs, including generalized split graphs, which asymptotically cover almost all perfect graphs.

To the best of our knowledge, this is the only known rounding strategy for the theta function that recovers an optimal stable set for large classes of perfect graphs.

Our rounding scheme relies on simple linear algebra computations;

we only solve one SDP.

In contrast, existing methods for computing an optimal stable set in perfect graphs require solving multiple SDPs.

Computational experiments show that our method produces good solutions even on imperfect graphs.

Chair: Mohammad Fili, Oklahoma State University, Stillwater, OK, United States

1 - Llm-Driven Preprocessing of Ehr and Survey Data for Medical Downstream Applications

Kihyuk Yoon, Georgia Institute of Technology, Atlanta, GA, United States, Lingchao Mao, Jing Li

In this study, we propose a preprocessing method that generates embedding vectors for downstream medical machine learning tasks using large language models (LLMs). This approach addresses common challenges in handling electronic health records (EHRs) and medical survey data, such as high rates of missing values and categorical variables with extensive, sparse categories like medications or comorbidities. Traditional preprocessing techniques often require dropping features with many missing values or converting categorical variables into high-dimensional one-hot encodings, which can lead to information loss and reduced data utility. Moreover, such transformations may obscure the clinical meaning of the data, particularly in the context of surveys with unstructured or multi-option responses. Our method mitigates these limitations by converting only the available patient-specific information into natural language text, which is then embedded using an LLM pre-trained on medical datasets. This allows for more comprehensive data utilization without the need to explicitly manage missing values or predefined categorical schemas. Additionally, the LLM can infuse domain knowledge into the embedding vectors, enhancing their clinical relevance and semantic richness. Furthermore, by grouping patient information by clinical theme (e.g., symptoms, medications, comorbidities) and generating separate embeddings, the method improves the interpretability of downstream tasks. The proposed framework enables robust, knowledge-informed feature representation from medical data, facilitating more accurate and explainable machine learning in real-world healthcare applications.

2 - Investigating Grey-White Matter Contrast Changes In Healthy Older Adults

Jonas Swope, Oklahoma State University, Stillwater, OK, United States, Mohammad Fili, Guiping Hu, Auriel Willette

Gray-white matter contrast (GWC) reflects the clarity of the boundary between gray and white matter and serves as a key marker of brain health. In this study, we analyzed regional changes in GWC using structural MRI data from the UK Biobank. Participants were categorized into two groups based on substantial increases or decreases in GWC using the Desikan-Killiany Freesurfer brain atlas. These two groups were named: “Contrast Gainers” and “Contrast Decliners”. We computed Pearson correlation coefficients between brain regions and employed Jennrich’s test to evaluate statistical differences in correlation structures between the two groups. The results revealed significant differences between the correlation matrices of Contrast Gainers and Decliners. Heatmaps highlighted clusters of strongly correlated brain regions within each group, and further analysis uncovered both shared and distinct correlation patterns between them.

Keywords: Cognitive aging, Correlation patterns, Grey-white matter contrast, Structural Magnetic Resonance Imaging (sMRI).

3 - Multimodal Learning for Embryo Viability Prediction in Clinical IVF

Yicong Li, Harvard University, Cambridge, MA, United States, Junsik Kim, Zhiyi Shi, Davin Jeong, Johannes Knittel, Helen Yang, Yonghyun Song, Wanhua Li, Dalit Ben-Yosef, Daniel Needleman, Hanspeter Pfister

In clinical In-Vitro Fertilization (IVF), identifying the most viable embryo for transfer is important to increasing the likelihood of a successful pregnancy. Traditionally, this process involves embryologists manually assessing embryos’ static morphological features at specific intervals using light microscopy. This manual evaluation is not only timeintensive and costly, due to the need for expert analysis, but also inherently subjective, leading to variability in the selection process. To address these challenges, we develop a multimodal model that leverages both time-lapse video data and Electronic Health Records (EHRs) to predict embryo viability. One of the primary challenges of our research is to effectively combine time-lapse video and EHR data, owing to their inherent differences in modality. We comprehensively analyze our multimodal model with various modality inputs and integration approaches. Our approach will enable fast and automated embryo viability predictions in scale for clinical IVF.

4 - Optimizing the Johns Hopkins Fall Risk Assessment Tool (JHFRAT) for Improved Fall Risk Identification

Emmett Springer, Johns Hopkins University, Baltimore, MD, United States, Fardin Ganjkanloo, Erik Hoyer, Daniel Young, Kimia Ghobadi

This study aims to enhance the predictive performance of the Johns Hopkins Fall Risk Assessment Tool (JHFRAT) using electronic health record data and advanced analytics. A retrospective analysis was performed on 54,209 inpatient admissions from three Johns Hopkins Health System hospitals between March 2022 and October 2023. Patients were labeled high-risk or low risk for falls based on the occurrence of a fall during hospitalization and the number of targeted fall prevention interventions received. JHFRAT scoring was refined using a mixed-integer optimization problem that maximized a weighted sum of sensitivity and specificity while adhering to clinical knowledge constraints. The MIP model was compared against a constrained logistic regression and XGBoost models, which also incorporate additional EHR variables. All model performances were validated using stratified 5-fold cross-validation. The optimized JHFRAT model accurately identified 79.1% of high risk patients, a substantial

improvement over the original JHFRAT's sensitivity of 31.7%, while maintaining a specificity of 93.7%. The area under the precision-recall curve increased from 0.44 for the original JHFRAT to 0.58 for the optimized model. The analysis highlighted the critical importance of impaired mobility and cognitive impairments in predicting falls. By controlling for fall prevention interventions and maximizing sensitivity and specificity, the accuracy and predictive performance of JHFRAT risk stratification were substantially improved. This evidence-based approach provides a robust foundation for health systems to systematically enhance inpatient fall prevention protocols and patient safety using data-driven optimization techniques, contributing to improved risk assessment and resource allocation in healthcare settings.

5 - Targeted Priority Mechanisms in Organ Transplantation

Ruochen Wang, Virginia Tech, Blacksburg, VA, United States, Sait Tunc, Burhaneddin Sandikci, Bekir Tanriover, Matt Ellis

The persistent imbalance between organ supply and demand poses a significant challenge for the life-saving treatment of transplantation. This study introduces innovative targeted priority mechanisms inspired by the Eurotransplant Senior Program (ESP), designed to bridge the supply-demand gap while optimizing the matching between organs and recipients without mandating offer acceptance. These mechanisms diverge from traditional prioritization by offering voluntary participation and granting explicit priority to disadvantaged patients for a specified range of organs provided they restrict their offer acceptance to this set. Using a comprehensive queueing model, our study analyzes the strategic decisions of waitlisted candidates under targeted priority mechanisms in equilibrium, establishing the optimal program design. Our findings reveal the capacity of these mechanisms to separate organ allocation across different patient classes, improving overall system efficiency. Our evaluation of these mechanisms' impact on social welfare underscores their potential to improve overall welfare without adversely affecting any patient group. The practical applicability and impact of these mechanisms are demonstrated through a case study within the U.S. kidney allocation system using a clinically detailed simulation model, targeting elderly patients aged 65 and above. Simulation outcomes reveal a significant participation rate even when the program offers priority over kidneys that are conventionally perceived as marginal. Furthermore, our findings highlight the mechanisms' potential to increase yearly transplants by 1,000 and prevent up to 200 waitlist deaths annually. Improvements in the outcomes of even nonelderly patients highlight the mechanisms' potential to comprehensively address organ underutilization and improve organ-recipient matching in a real-world context.

Bridging Research and Practice: The Role of Innovation, Regulation and Partnerships

Panel Session

Health Applications Society

Co-Chair: Kanix Wang, University of Cincinnati, Cincinnati, OH, United States

1 - Moderator Panelist

Kanix Wang, University of Cincinnati, Cincinnati, OH, United States

This year's panel will address challenges of integrating research into healthcare practice, focusing on interoperability, stakeholder alignment, and compliance. Discussions will emphasize the importance of multidisciplinary partnerships across academia, industry, and regulators, highlighting effective collaboration models to scale innovations. Additionally, the panel will explore how advancements in digital health, machine learning, and modeling influence clinical practices and shape future healthcare policies.

2 - Panelist

Maria Mayorga, North Carolina State University, Raleigh, NC, United States

3 - Panelist

Turgay Ayer, ISyE Georgia Tech, Atlanta, GA, United States

4 - Panelist

Tolga Tezcan, Rice University, Houston, TX, United States

5 - Panelist

Ramesh Johari, Stanford University, Stanford, CA, United States

1 - Machine Learning-Guided Cancer Screening: the Benefits of Proactive Care

Carri Chan, Columbia Business School, New York, NY, United States, Minje Park, Keith Boell, Elliot Mitchell, Abdul Tariq, David Vawdrey

With the advance of data analytics, many disease prediction models have been developed with the intent of detecting diseases earlier and improving patient outcomes through earlier treatment. The operationalization of interventions and care based on these predictive models is critical to attaining these goals. We study the real-world effects of a machine learning-guided colorectal cancer screening program deployed at a health system in Pennsylvania. Using a regression discontinuity design based on the predicted risk score for having cancer, we find that the program increases the likelihood of colonoscopy uptake in three and six months by 6.0 percentage points (214% increase relative to the control sample within the bandwidth) and 6.9 percentage points (117% increase), respectively. Importantly, we also find significant effects on mortality. We estimate that the program decreases 2-year mortality by 6.2 percentage points (43% decrease). Our finding suggests that a machine learning-guided proactive cancer screening program could significantly improve patient outcomes in addition to achieving higher disease detection rates. We argue that establishing unbiased estimates of the impact of machine learning-guided screenings is critical for capacity planning of screening resources, such as colonoscopies.

2 - A Tale of Two Eds: Demand-Inducing Effects of Opening New Emergency Departments

Hyun Seok Lee, Korea University Business School, Seoul, Korea, Republic of, Eric Park, Bob Batt, Timothy Rainer

Timely access to emergency care depends on both geographic proximity and wait times. While opening a new emergency department (ED) improves access, it may also induce demand by lowering the cost—time and effort—of seeking care. This study examines the demand-inducing effects of ED openings in two distinct contexts: a high-capacity urban area and an underserved rural region. Using comprehensive ED visit data from Hong Kong, we assess changes in ED visits within 5 km of newly opened facilities.

Overall, ED visits per district increased by 28.3% near the new urban ED and by 272.5% near the rural one. The impact was smaller in areas that already had nearby EDs before the new opening. The increase was most pronounced among younger populations. In the rural area, visits rose by 511.0% for individuals aged 0–19, declining progressively with age: 314.1% (20–39), 282.3% (40–59), 234.0% (60–79), and 103.4% (80+). A similar monotonic decreasing pattern by age was observed in the urban area, with a 47.6% increase for the youngest group and no significant change for the oldest. Low-acuity visits (triage levels 4–5) surged—by 44.8% in the urban and 406.3% in the rural area—while high-acuity visits (levels 1–2) increased more modestly.

These findings show that new ED openings substantially increase utilization—particularly among younger, lower-acuity patients—highlighting the need to account for induced demand in emergency care planning.

3 - From Delay to Disparity: Ethnic Gaps in Emergency Care Access and Outcomes Under a Universal Public Health System

Eric Park, Wake Forest University, Winston Salem, NC, United States, Timothy Rainer

This study examines racial and ethnic disparities in access to emergency medical care and the quality of care within Hong Kong's universal public healthcare system. Using 4.5 million patient-level emergency department (ED) visit records from 2013 to 2017, we analyze whether patients of different ethnic backgrounds experience unequal waiting times to be seen by a physician. We focus on five major non-Chinese ethnic groups—Pakistani, Filipino, Nepalese, Indian, and Indonesian—who represent the largest non-Chinese patient populations in the dataset.

Controlling for a wide range of patient, temporal, clinical, and hospital-level covariates, we find that these five ethnic groups consistently experience significantly longer waits compared to native Chinese patients, particularly among lower-priority triage levels (III–V). No disparity is observed among triage levels I and II, where clinical urgency mandates immediate or rapid attention. The observed differences suggest that racial and ethnic minority patients, often from marginalized labor sectors, may face systemic delays in receiving care even within a nominally equitable system.

These findings raise concerns about hidden barriers to equitable emergency care in Hong Kong's public hospitals and highlight the need for further investigation into potential sources of bias or structural inequities in ED operations. Ongoing work will examine differential rates of treatment abandonment by ethnicity to assess further implications for health outcomes.

4 - Early Birds Versus Last-Minute Arrivals: Empirical Evidence and Theoretical Analysis of Arrival Time Queueing Game

Xiangjie Zhao, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of, Yichuan Ding, Dongdong Ge, Xiaoqing Xie

We examine a scenario where each customer strategically selects their arrival times at a queue, aiming to minimize their total costs, which include waiting, tardiness, and earliness costs. Building on the mixed strategy framework characterized by Haviv(2013), which provides a closed-form arrival time distribution, our focus extends to the transient behavior of this system in presence of irrational customers, in which case it is not yet known whether an equilibrium exists or whether the system would converge to the equilibrium. We introduce a dynamic choice model to describe customers' behavior in a repeated game setting. We empirically validate this model using data from a large endoscopy department in China, operating on a first-come first-served basis. The empirical result supports the efficacy of this model in capturing the adaptive strategies of patients concerning their arrival times. Leveraging this model, we prove that there exists a unique equilibrium and the system converges to this equilibrium under both a fluid model and an M/M/1 queueing model. By analyzing the equilibrium arrival time distribution, we identify the optimal time for patients to arrive, which occurs either at the start or near the end of the morning session, depending on the model parameters. Furthermore, we formulate a dynamic control problem to characterize the optimal information sharing policy, suggesting that service providers may decrease social cost by deliberately modulating the communication of waiting time information to patients. Further examination of social cost unveils that increasing earliness cost can, counter-intuitively, detract from social cost at equilibrium.

Health Applications Society

Chair: Hussein El Hajj, Santa Clara University, Santa Clara, CA, 95053, United States

1 - Identifying Regions Vulnerable to Obstetric Unit Closures Using Facility Location Modeling with Patient Behavior

Meghan Meredith, Georgia Institute of Technology, Atlanta, GA, United States, Lauren Steimle

The U.S. has the highest maternal mortality rate among high-income countries. This is just the tip of the iceberg with many more women experiencing severe complications due to their pregnancy. One commonly cited challenge in maternal healthcare delivery is that many pregnant people lack access to obstetric care, and this has been exacerbated by widespread closures of obstetric units. In this talk, we present a framework for identifying regions that are vulnerable to obstetric unit closures using facility location modeling. When considering the impacts of closures, we incorporate patient care-seeking behavior as many pregnant people "bypass" their closest obstetric facility to deliver at a farther facility. Altogether, we consider a problem in which an adversary seeks to maximize a population's average distance traveled to obstetric care by closing obstetric units. After the adversary closes obstetric units, patients probabilistically select the facility that maximizes their utility under a random utility maximization framework. We demonstrate that this model can be represented as a mixed-integer nonlinear program. Unlike existing facility location models that incorporate consumer choice, our model's objective function is not concave in general and thus, the state-of-the-art algorithms for solving facility location models with choice are not applicable. We introduce reformulations of our problem that lend themselves to solution methods which can take advantage of their decomposable structure. We compare our solution methods in numerical experiments and illustrate our framework using a case study of obstetric care in the state of Georgia.

2 - Navigating Incentive Challenges in Capitation Payment Models

Tolga Tezcan, Rice University, Houston, TX, United States

Healthcare systems are increasingly adopting capitation payment models to reduce costs. In the conventional capitation payment model, insurance companies receive predetermined, risk-adjusted payments per patient to provide care over fixed time periods, regardless of actual healthcare utilization. Although this model encourages insurers to enhance cost efficiency in theory, the actual outcomes have not always aligned with this expectation, as evidenced by the increased healthcare costs experienced by Medicare following the introduction of Medicare Advantage Plans.

Motivated by this observation, we demonstrate, using a simple model, that the conventional capitation model may not effectively incentivize cost reduction in competitive insurance markets when patients can enroll in any available plan. This failure stems from insurers exploiting imperfections in risk adjustment to cherry-pick profitable patients by manipulating plan designs, especially when patients have the option to enroll in alternative plans like the fee-for-service-based traditional Medicare Plan. Additionally, we show that, even with perfect information about patient types, which eliminates patient selection, conventional capitation may not yield socially optimal outcomes due to externalities stemming from patient choice.

Next, we introduce an innovative retrospective capitation payment model that leverages actual healthcare utilization of each patient. This approach eliminates the need for risk-adjustment procedures and the requirement to predict future medical expenses, all while still incentivizing providers to enhance cost efficiency. Using a general model, we demonstrate that this approach yields identical outcomes to the conventional capitation model with perfect patient type information in a competitive equilibrium.

3 - Towards Enabling the Last-Mile Logistics of Vaccine Supply Chains: Learnings from COVID-19 Vaccine Administration

Bhupinder Juneja, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States, Ujjal Mukherjee, Kingshuk Sinha

Vaccine coverage can minimize the impact of the pandemic. However, there is a wide spatial disparity in vaccine coverage. While the significance of vaccine hesitancy and associated socio-economic factors are well-acknowledged, the factors related to vaccine delivery and administration from a supply-chain efficacy perspective are poorly understood. We analyze the effect of the enablers of the last mile of vaccine supply chains along 3-dimensions: logistical connectivity, delivery infrastructure, and informational connectivity. Our results suggest that all three dimensions of the last-mile delivery and administration of vaccines improve vaccine coverage. Further, we

demonstrate that improving enablers of the last mile of the vaccine supply chain is more beneficial for locations with relatively higher prevalence of socio-economic and demographic risk factors.

4 - A Patient Prospective on Treatments for Substance use Disorder

Zlatana Nenova, Wake Forest University, Winston-Salem, NC, United States, David Rea, Margret Bjarnadottir, Madeline Marks

We collected data from 578 U.S. residents who self-identified as having received individual therapy for alcohol use disorder. Across four surveys, we gathered background information as well as detailed data on their treatment experiences, personal goals, prior treatments, and perceived successes and failures. Our primary goal is to identify features of rehabilitation programs that help individuals with substance use disorder regain control over their lives. Through our analysis, we uncover major drivers of post-discharge success, including - but not limited to - group dynamics, therapy methodologies, and internal motivational factors. Our findings have the potential to help treatment centers better understand which practices, when properly reinforced, can significantly improve clients' chances of long-term success after discharge.

5 - Better Resource Allocations in the Criminal Justice System: Optimizing for the Long-Term Good

Chuwen Zhang, The University of Chicago Booth School of Business, Chicago, IL, United States, Pengyi Shi, Amy Ward

Incarceration diversion programs provide an alternative to incarceration, with a focus on rehabilitation over punishment. The goal is to prevent reoffense by providing treatment tailored to individual needs (for example, substance abuse problems). The hope is that such programs move society to a better place in the long term, with a smaller percentage of the population turning to crime. The question is: How do we decide which individuals are best suited for such programs?

To answer the question, we develop a framework that begins with survival models of individual reoffending behavior, incorporating both treatment effects and community-level interactions. We then derive a macro-level dynamical system that captures the mean behavior of individuals across different cohort groups. Theoretically, we establish uniform convergence of this dynamical system to a unique equilibrium under mild conditions on stationary policies. This allows us to study the effect of treatment policy decisions in the long term, and to highlight the inadequacy of myopic policies. We use a publicly available dataset together with an agent-based simulation to calibrate our dynamical system model, and validate our insights.

1 - Outpatient Appointment Scheduling with Waiting TIME Limits

Rachel Chen, University of California at Davis, Davis, CA, United States, Han Zhu, Min Zhang, Zhenzhen Zhang

The paper studies an outpatient appointment scheduling problem with waiting time limits, in the presence of uncertain service times, patient no-shows and unpunctuality. The presence of waiting time limit amplifies model complexity by significantly increasing problem scenarios. To address this challenge, we introduce the concept of virtual waiting time, representing the additional waiting time that a patient would have to wait to see the doctor after the waiting time limit is reached. Using this concept, we are able to unify the modeling of system dynamics of all different scenarios into one stochastic program. We develop a tailored integer L-shaped method to solve this model. We find that the presence of waiting time limits increases the job allowance between two adjacent patients, and the optimal schedule does not necessarily exhibit the well-known dome-shaped pattern.

2 - Sharing in Caring: Viewing Shared Medical Appointments Through An Operations Lens

Sundara Natarajan Panchanatham, HKU Business School, Hong Kong, Hong Kong, Enver Yucesan

Shared medical appointments (SMA), doctor-patient visits in which groups of patients are seen by one or more healthcare professionals in a concurrent session, are designed to achieve a more efficient use of medical resources and offer quicker –and less costly– access to healthcare services for patients. Moreover, for certain conditions, SMA can improve compliance and improve outcomes due to the learning effects from the peer group and the social benefits of meeting a group. Thus, the setup can potentially enhance patient experience, eliminate redundant work, and reduce costs for specific treatments. Our objective is to quantify the impact of SMA models on the cost and benefits for physicians and patients and characterize conditions under which SMA is a superior healthcare delivery model compared to the traditional care delivery models. On the methodology front, we mathematically model the operational trade-offs in SMAs and derive optimal capacity decisions for the healthcare providers using a game-theoretic framework.

3 - An Empirical Investigation of R&D Strategy and Clinical Trial Design

Kanix Wang, University of Cincinnati, Cincinnati, OH, United States, Zhaowei She, Liang Xu

This study examines the impact of eligibility criteria in clinical trials on drug approval, effectiveness, and inclusivity. Using AI-driven models, we analyze how criteria evolve across trial phases, their influence on FDA approval and post-market outcomes, and the role of firm size in balancing trial success with broader patient population.

4 - Dynamic Multi-Class Multi-Appointment Advance Scheduling: Approximate Policies and Lower Bounds

Vahid Sarhangian, University of Toronto, Toronto, ON, Canada, Yanbo Ding

We study a dynamic advance scheduling problem with multiple classes of customers and with each customer requiring several appointments. Our primary motivation is scheduling appointments for Radiation Therapy (RT) treatments for patients with different urgency levels which usually consist of multiple appointment sessions. We consider a Markov Decision Process (MDP) formulation of the problem and propose scalable approximate dynamic programming policies based on hindsight optimal policies. We evaluate the performance of the proposed policies using a related information-relaxation lower bound, and in comparison with other benchmarks. Finally, we conduct a case study using real data to illustrate the effectiveness and practicality of the proposed policies.

1 - Why the Best Machine May Not be the Best: Incentivizing Human-Machine Collaboration

Xiaotong Guan, The University of Texas at Dallas, Richason, TX, United States, Anyan Qi, Shouqiang Wang

Humans and machines need to work collaboratively to make operational decisions such as demand forecasts. In this paper, we study how the machine should be designed to incentivize human-machine collaboration and obtain a rich set of results.

2 - Persuasive Calibration

Wei Tang, Chinese University of Hong Kong, Hong Kong, Hong Kong, Yiding Feng

We introduce and study the persuasive calibration problem, where a principal aims to provide trustworthy predictions about underlying events to a downstream agent to make desired decisions. We adopt the standard calibration framework that regulates predictions to be unbiased conditional on their own value, and thus, they can reliably be interpreted at the face value by the agent. Allowing a small calibration error budget, we aim to answer the following question: what is and how to compute the optimal predictor under this calibration error budget, especially when there exists incentive misalignment between the principal and the agent? We focus on standard ℓ_1 -norm Expected Calibration Error (ECE) metric. We provide both algorithmic solutions and structural characterizations for optimal calibrated predictors.

3 - Best is Not Always First: Optimizing Offer Deadlines and Offer Sequence with Delayed Feedback

Wenjie Tang, University of Vienna, Vienna, Austria, Zhenyu Hu

We study a setting where a proposer (e.g., an employer) with a single offer to make sequentially approaches a set of responders (e.g., job candidates) each of whom is also searching for alternative offers. We are interested in the proposer's decision of which responder to offer to first, and the optimal deadline to set for the responder's reply. We provide a full characterization of the optimal deadlines. When the proposer's choice set is composed of only two responders, we also fully characterize the proposer's sequence decision: She should offer to the higher-utility responder first if and only if she approaches the responders later than a time threshold. Moreover, we show that, among exploding responders who are able to provide immediate feedback on the proposer's offer, the proposer should always prioritize the highest-utility one—as long as responders are homogeneous in the probabilities of their availability at any given time. In addition, when all but one of the responders are exploding responders, we show that as the proposer approaches this choice set later in the time horizon, the sole non-exploding responder should be prioritized over fewer exploding responders. Finally, our analysis of a static greedy policy that always prioritizes the highest-utility responder indicates that a greedy policy can be rather efficient when the market is not very competitive; otherwise, our numerical examples show that the proposer can incur substantial loss.

4 - Information Design of the Monty Hall Problem

Zhenyu Hu, National University of Singapore, Singapore, Singapore, Shouqiang Wang, Yangge Xiao

We consider the following variant of the Monty Hall Problem. There are n doors, behind each of which hides an a priori random reward, independently distributed according to a common prior. A clue box is attached to each door, which, if inspected, yields a clue about the rewards behind possibly all doors. The game host designs what clues to be put in each box and announces at the beginning of the game what each clue reveals about the rewards. Given the design, the player decides sequentially which clue box to inspect by paying an inspection fee and when to stop inspecting the boxes. Upon stopping, the player can then utilize the clues collected so far to open a door whose attached box has already been inspected and take the reward behind it. The player wishes to maximize the reward obtained from the opened door, while the host maximizes the fees collected from inspections. Under specific designs, the player's problem can be reduced to several classic sequential information acquisition problems, such as the Pandora's box problem or the Wald's sequential sampling problem. We study the optimal designs of the clue boxes when the host faces different informational constraints. These informational constraints arise from the potential applications in different settings such as product-page design on online platforms, information design in delegated search, and reward design in video games.

Platform Design

Contributed Session

Contributed

Chair: Tania Saha, S.P. Jain Institute of Management & Research (SPJIMR), Mumbai, India

1 - Shoulders of Little Giants: A Two-Stage Design to Assist Solution Providers in Innovation Contests

Sriram Sankaranarayanan, Indian School of Business, Mohali, India, Swanand Deodhar

Tournaments mediated by digital platforms have become a key mechanism for sourcing innovation, allowing seekers to solicit solutions from a distributed pool of providers. However, solution quality is uncertain, and platform mechanisms to assist providers often require greater seeker involvement, raising transaction costs. To address this, we propose a two-stage contest design. In the first stage, artifact-development (AD), providers create artifacts; in the second, solution-development (SD), they use these artifacts to develop final solutions. We model three types of artifacts: (i) expertise-enhancing, improving top providers; (ii) expertise-equalizing, aiding mid-and low-tier providers; and (iii) cost-reducing, lowering effort costs for all. We identify conditions for when this two-stage design offers better seeker return than a traditional one-stage design, and derive optimal split of the incentive budget between these two stages, resulting in meaningful takeaways for the seeker. For example, we show that when expertise-enhancing or expertise-equalizing artifacts are encouraged, it is optimal for them to have an AD stage and offer increasing larger share of reward to the AD stage, when the seeker expects a large participation in the SD stage.

2 - A Community Recharging Facility Sharing Program: Optimized Slot Assignment Considering Uncertain User Acceptance

Hongke Xie, University of Electronic Science and Technology of China, Chengdu, China, People's Republic of, Pengyu Yan

The rapid adoption of electric vehicles (EVs) has intensified the demand for accessible charging infrastructure, particularly in urban areas where private charging facility installation is often infeasible. While shared charging programs offer a potential solution, existing approaches suffer from low utilization due to mismatches between supply and demand, with only 1.57% of private charging facilities currently shared in China. This study proposes a novel community-based EV charging facility sharing program, where users with charging-equipped parking slots (C-users) temporarily exchange with users lacking such facilities (N-users) overnight. A key challenge is optimizing slot assignments without prior knowledge of users' walking distance-dependent acceptance probabilities, which are private and stochastic. To address this, we formulate the problem as a Sleeping Combinatorial Multi-Armed Bandit (CS-MAB) and develop a Sleeping Combinatorial Upper Confidence Bound (CS-UCB) algorithm that learns acceptance probabilities while maximizing fulfilled charging demands. Furthermore, we integrate a Structural Causal Model (SCM) framework to infer counterfactual feedback and accelerate learning during initial deployment stages. Numerical experiments demonstrate that our approach achieves near-optimal performance, with regret below 11.86% across varying demand-supply ratios, significantly outperforming benchmarks. Sensitivity analyses confirm robustness to stochastic user behavior, exploration parameter, and pricing schemes. The extension verifies one-to-one exchange mechanism proves more effective than many-to-many assignment, ensuring practical scalability and user satisfaction.

3 - Dynamic Random Bipartite Matching Under Spatiotemporal Heterogeneity for Mobility Services

Shiyu Shen, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Yanfeng Ouyang

This study explores a variation of the online bipartite matching problem that allows randomness in the spatiotemporal distribution of the vertices, referred to as the Spatio-Temporal Random Bipartite Matching Problem (ST-RBMP). This type of problem directly builds upon spatial location information of the vertices, and can be applied to services such as shared mobility (e.g., matching riders with drivers). Many strategies and algorithms have been developed to solve some form of ST-RBMP in different contexts. However, the inherent nature of dynamic and stochastic decision-making imposes notable challenges, such as the so-called wild goose chase (WGC) phenomenon. To address these challenges, this paper proposes a modeling framework to dynamically determine the optimal pooling intervals and matching radii for ST-RBMP to minimize the system-wide costs associated with matching distance and waiting for mobility services systems. At each matching epoch, the system state is represented by the spatial distribution of demand and supply points, referred to as a vertex distribution profile. Closed-form formulas for the expected matching distance and probability of static RBMPs are adapted into a time- and space- dependent decision framework, and now with consideration of max radii, to minimize the total expected matching distances. Following a continuum approximation scheme, the optimal functions of pooling intervals and matching radii over time and space are then derived from the Euler-Lagrange equations. This framework effectively addresses the spatiotemporal heterogeneity in demand and supply distributions in many real-world systems. Moreover, it is transferable and robust across diverse problem settings and varying decision-making scenarios.

4 - Exploring the Impacts of Mobilitycoins on Last-Mile Delivery Services

Anke Ye, Technical University of Munich, Munich, Germany, Maximilian Schiffer, Klaus Bogenberger

Logistics companies aim to improve user experience by offering a variety of personalized last-mile parcel delivery services. However, the additional mileage associated with these services can hinder efforts to achieve decarbonization goals. In order to promote sustainable ordering habits amongst users, we propose an innovative internalization of the services' environmental externalities by means of a Tradable Credit Scheme (TCS) known as MobilityCoins (MoCo). This work represents one of the first attempts to apply TCS in a logistics context, specifically focusing on the MoCo scheme design and its impacts on the logistics company and users. To derive tangible insights, we model the system using a three-layer programming approach. At the upper level, the MoCo agency optimizes the scheme design by determining the total MoCos in the initial allocation based on the predetermined per-kilometer MoCo charge. The middle level captures the pricing problem faced by logistics companies, which offer two service options, i.e., Express and Standard. These options differ with respect to delivery times and consolidation potential. A shift in demand from the faster service to the more energy-efficient alternative ultimately affects the amount of MoCos consumed for delivery. At the lower level, users with diverse price sensitivities choose their delivery service following the user equilibrium principles. We first investigate the system's features in a monopoly market and then extend the analysis to a competitive market with multiple logistics companies. The findings provide valuable managerial insights into the extended application of TCS.

5 - On Robust Inventory Optimization for Bike Sharing

Haixiang Wang, King's College London, London, United Kingdom, Dimitrios Letsios

We aim at enhancing service level in bike sharing systems under demand uncertainty. We develop a robust optimization approach for station-level inventory optimization. Although deterministic optimization models effectively evaluate past planning decisions with known demand, their performance is deteriorated when considering future bike allocations due to demand prediction errors. We consider demand realizations within Gamma uncertainty sets. We formulate a deterministic optimization model and express its robust counterpart as a bi-level optimization problem. Unlike previous inventory optimization approaches that rely on dualization techniques for computing robust solutions to the inventory rebalancing problem, we propose a novel approach based on Benders decomposition, including primal heuristic and adversarial relaxation components. The robustness of our approach is validated computationally.

6 - Slide or Feed: Content Recommendation with Creators' Incentives

Shu Zhang, the Chinese University of Hong Kong, Hong Kong, Hong Kong, Hongfan Chen, Renyu Zhang, Zhou Zhou

In online video platforms, optimizing recommendation systems is crucial for maximizing profit and incentivizing content creators. Our work delves into the comparative efficacy of two layout modes of recommendation systems in online content platforms: the single-column (slide) and double-column (feed) formats. We build up a gaming model to describe the dynamics between recommendation modes and their impact on platform economics, where the two modes are different in both recommendation accuracy as well as their monetization ability.

We illustrate how the performance of recommendation system is affected by both the modes and the users' interactions on the platform. The equilibrium results show that the strength of the recommendation algorithm plays an important role in this comparison. Platforms with robust algorithms benefit from the slide mode's efficiency, while those with weaker algorithms should leverage the feed mode to enhance usability and engagement. Several operational factors of the platforms also interplay in this comparison.

Insights from this study advance our understanding of how recommendation system modes affect user content consumption patterns, creator engagement, and the financial sustainability of online content platforms. These findings also offer actionable guidance for platform managers and market regulators seeking to optimize operations and policy-making.

7 - A Manufacturer's Pricing Format in A Dual-Distribution Channel of Retail and Rental Platforms

Tania Saha, S.P. Jain Institute of Management & Research (SPJIMR), Mumbai, India, Prasenjit Mandal

Many manufacturers use a dual-distribution channel strategy, offering products for purchase through retail platforms and sharing products through rental platforms. For example, Tommy Hilfiger partnered with rental platform MY Wardrobe HQ and also with the retail platform Kohl. While retail platforms enable consumers to get exclusive ownership of products, rental platforms facilitate temporary access to products. In the presence of both retail and rental platforms, consumers have the option to buy or rent. Furthermore, manufacturers are not only involved in wholesaling their products (the traditional wholesale pricing format) but also using retail/rental platforms as marketplaces where they sell/share the products directly with the consumers (the agency pricing format). The manufacturer can opt for the same pricing format with both platforms, i.e., either a wholesale pricing format or an agency pricing format. The manufacturer can also opt for a hybrid pricing format approach, where the manufacturer opts for different pricing formats with the two platforms (for example, wholesale with the retail platform and agency with the rental platform or vice versa). In the wholesale pricing format, the retail (rental) platform purchases products from the manufacturer for a wholesale price and then decides the retail (rental) prices for consumers. In the agency pricing format, the firm determines the retail (rental) prices and shares revenue with the retail (rental) platform. In this paper, we study the manufacturer's pricing format: agency or wholesale with the retail and rental platforms?

Data-driven Decision and Risk Analysis

Invited Session

Decision Analysis Society

Chair: Chen Mavis Wang, N/A

Co-Chair: Yifan Hong, Tsinghua University, Beijing, N/A

1 - Lamda: Large Language Models as Decision Analysts

Yifan Hong, Tsinghua University, Beijing, China, People's Republic of, Chen Wang

Influence diagrams help tackle the challenges of decisions under risk by structuring information, decisions and values, and explicitly representing uncertainties and probabilistic dependencies. However, constructing an influence diagram requires expertise in decision analysis and is further complicated by the need to process large amounts of contextual information. This work automates the construction of influence diagrams from natural language input with the help of large language models (LLMs). We design a workflow where LLMs are prompted to output elements of an influence diagram and resolve issues through verification and regeneration. We then construct a new dataset of typical decision problems under risk, and evaluations on this dataset demonstrate that our framework effectively identifies key factors and relationships in natural language and, therefore, makes better decisions than standalone LLMs and LLMs enhanced with standard techniques such as chain-of-thought (CoT). Furthermore, we extend the framework to aggregate opinions from multiple information sources, and apply the aggregation method to group discussions by disease control experts on a hypothetical pandemic scenario.

2 - Honesty, Deception, OR Secrecy? Optimally Disclosing Defensive Posture

Kyle Hunt, University at Buffalo, Buffalo, NY, United States, Sule Guney, Richard John

Due to the strategic and adaptive nature of adversaries, the deployment of new technologies is common practice in the arenas of security and defense. History has shown that the deployment of these technologies has often been disclosed to the public, allowing malicious actors to potentially understand which venues are defended, and how. Within this context, there is limited research examining how defenders should optimally disclose their deployment strategies -- a gap we fill in this work. To understand adversary decision-making in this setting, we first run behavioral experiments to understand how adversaries develop their attack plans in response to information

disclosed by a defender. Specifically, we address whether attackers (i) believe the information they receive from the defender and (ii) choose to attack after learning that new security measures may be deployed at their target(s) of interest. Then, utilizing the data from the experiments as a proxy for real adversary behavior, we optimize the disclosure strategy for the defender, where she can either be deceptive, secretive, or truthful. We compare these disclosure policies with those obtained when optimizing against different traditional models of adversary behavior that have long been adopted in the literature.

3 - The Role of Mental Simulation in Risk Decision-Making: Evidence from Air Traffic Management

Tong Deng, Tsinghua University, Beijing, China, People's Republic of

Effective risk decision-making is essential in high-stakes domains such as air traffic management (ATM), where safety outcomes depend on operators' ability to anticipate and mitigate evolving hazards. This study examines how mental simulation and environmental controllability jointly shape the causal basis of risk decisions among air traffic controllers. We develop an airspace simulation model to approximate controllers' mental simulations of future traffic states. Weather conditions serve as an exogenous proxy for environmental controllability, enabling a stratified analysis of decision-making under varying levels of environmental uncertainty. Using real-world operational data (including air traffic flows, weather, and controller operations), we uncover the underlying causal structure among air traffic risk features, controllers' mental simulations, and their risk decisions, and estimate the sizes of these causal effects. The results show that in good weather conditions with high controllability, mental simulation significantly contributes to decision-making, enabling proactive mitigation measures. In contrast, in bad weather conditions with low controllability, decisions are heavily influenced by static airspace structures and existing congestion, indicating an inclination toward reactive strategies. Our study presents a novel approach to leveraging real-world operational data and causal machine learning methods to elucidate the impact of simulation-based reasoning on safety-critical decision-making.

4 - Epidemic Mitigation Under Stochastic Contagion Models

Janne Kettunen, The George Washington University, Vienna, VA, United States, Miguel Lejeune

We propose a risk-averse prescriptive contagion model governed by stochastic time-varying transmission dynamics to guide epidemic mitigation. The model is a multi-period mixed-integer nonlinear chance-constrained stochastic programming problem that minimizes the burden of the mitigation actions whilst guaranteeing that the need for ICUs remains below their availability with high probability. The evolution of the pandemic is represented via a compartmental Susceptible-Exposed-Infectious-Recovered-Died model with a stochastic and mitigation-dependent transmission rate of the disease. We design a solution method that features the deterministic and equivalent reformulation of the nonlinear chance constraint using a Boolean method, quadratization of the set of nonconvex constraints using linearization methods for polynomial terms and exponential function with integer arguments, and construction of the envelope of bilinear terms defined on a specific domain with non-trivial upper bound on the product of the two variables. The proposed framework generalizes well to alternative problem formulations. Indeed, the reformulation is applicable to nonconvex polynomial chance-constrained problems outside the epidemic mitigation field. We apply the models to real COVID-19 data in four Nordic countries. The experiments confirm the computational efficiency and scalability of our approach and show that the solutions are stable, reliable and perform well out-of-sample, and robust even in the presence of uncertainties in other key model parameters. The results highlight the proper timing and stringency of mitigation actions. The optimal policy can include some alternations between periods of strict and lenient mitigation. Counterintuitively, mitigation can be optimal to forgo at early periods.

Supply Chain Management for Social Good

Invited Session

MSOM: Supply Chain

Chair: Xiajun Pan, University of Florida, Gainesville, FL, United States

Co-Chair: Shiwei Chai, University of Florida, GAINESVILLE, FL, United States

1 - Operational-Marketing Trade-Offs in Managing Social and Environmental Responsibility

Shiwei Chai, University of Florida, Gainesville, FL, United States, Asoo Vakharia, Anand Paul

This paper is motivated by observing the substantive interest in environmental stewardship by both regulators and individual firms. For regulators, key concerns relate to better management of public environmental risks by designing an incentive mechanism (comprising a fine and a fixed subsidy) for a firm to optimize social environmental welfare. The firm, on the other hand, maximizes its profit by choosing product prices, marketing (advertising) effort, and operational (audit/inspection or process improvement) effort expended to reduce environmental violations.

Through a rigorous analysis of a stochastic dynamic programming problem for a risk-neutral firm and a characterization of the corresponding fine and subsidy mechanism for the regulator, insights offered are as follows. While the fixed subsidy has no impact on the firm's decisions, increases in the fine levied by the regulator incentivizes the firm to expend: (a) higher marketing effort through an increase in advertising expenditures; and (b) higher operational efforts directed at reducing the possibility of environmental violations. From the regulator's perspective, the average costs associated with an environmental violation serve as a lower bound on the fine that should be levied. Interestingly, we also find that when either the social and environmental cost or the loss of brand image due to environmental violations is above a certain threshold, the regulator should not only impose a fine but simultaneously provide a fixed subsidy to the firm.

2 - Boxless Shipping: Balancing Sustainability and Security in Package Delivery

Stanley Lim, Michigan State University, East Lansing, MI, United States, Neda Mirzaeian, Shouqiang Wang

We explore optimal packaging strategies for online retailers, focusing on boxless shipping to address environmental waste and theft concerns. Using an information design framework, we demonstrate profit gains of up to 221% and environmental benefits. However, we highlight that outcomes depend on the sensitivity of customers to theft and privacy.

3 - Product Rollover Strategies: Dynamic Decision Model Motivated by the Hybrid Seed Agribusiness

Jian Li, Northeastern Illinois University, Chicago, Illinois, IL, United States, Panos Kouvelis

We study the optimal launch timing and rollover pattern selection for new product's launch. We consider two product rollover patterns: Solo-Rollover and Dual-Rollover. We examine two distinct timing strategies: the Static approach, which ex-ante plans the launch time and/or rollover pattern of the new product, and the Dynamic approach, which dynamically determines these decisions accounting for realized demand information over time. Our focus is on formulating an optimization model that integrates the above-mentioned decisions in managing product rollovers over a given lifecycle. We also study, as special cases, five other timing and rollover strategies that differ along the static/dynamic nature of the launch's timing and contingent execution of the rollover pattern selection.

4 - A Model of Tokenized Marketplaces

Jiong Sun, Purdue University, West Lafayette, IN, United States, Shiwei Chai

We develop an analytical model to rationalize the economic value of digital tokens as a means of reducing reliance on intermediaries and improving transactional efficiency. Specifically, we propose a token-based framework for decentralizing digital marketplaces. In this setting, utility tokens function as a coordination mechanism that mitigates underproduction and protects producers from adverse price pressures typically exerted by conventional intermediaries. This is achieved through decentralized controls, where transaction validation is delegated to independent contributors and commission fees are determined by producers themselves. Our findings are robust across various contexts involving multiple producers, whether they offer unrelated, complementary, or substitute products.

Overcoming the Challenges of Policy Optimization

Invited Session

MSOM: Service Operations

Chair: Hamsa Bastani, Wharton School, Philadelphia, PA, United States

Co-Chair: Bryce McLaughlin, University of Pennsylvania, Philadelphia, United States

1 - Inference-Aware Policy Optimization

Bryce McLaughlin, University of Pennsylvania, Philadelphia, PA, United States, Hamsa Bastani, Osbert Bastani

The traditional goal in machine learning is to build predictive models, which forecast outcomes that can be used to guide decision-making. When we attempt to optimize a decision-making policy using these models, it is hard to overcome the challenge that the model's accuracy varies significantly over the population. A naive approach that takes the decision associated with the best counterfactual outcome prediction will suffer as it will often act on noise, generating large variance in its observed performance.

This variance makes validating the policy using a hold-out test set extremely difficult, often preventing implementation of the policy. Essentially whatever estimate of policy improvement we produce will be yielded insignificant as the overconfident decisions made by some parts of the model drown out gains elsewhere. In settings where the outcomes following decisions are high-stakes, significant improvements are often needed to change the implemented policy, making the naive approach much less useful.

Our approach involves updating the objective of policy optimization from expected reward to a tradeoff between increasing expected reward and decreasing the variance induced by the policy. Our solution, Inference-Aware Policy Optimization (IAPO), traces out a Pareto frontier of policies, allowing the user to tradeoff between expected performance and stability. Using a large dataset of behavioral health nudges, we show that IAPO can identify and implement significant policy improvements while other common approaches deteriorate the policy almost as often as they improve it.

2 - Mind the Gap: Encouragement Policy Learning Balancing Take-up and Efficacy

Angela Zhou, University of Southern California, Los Angeles, CA, United States

In consequential domains, it is often impossible to compel individuals to take treatment, so that optimal policy rules are merely suggestions in the presence of human non-adherence to treatment recommendations. Under heterogeneity, covariates may predict take-up of treatment and final outcome, but differently. While optimal treatment rules optimize causal outcomes across the population, access parity constraints or other fairness considerations on who receives treatment can be important. For example, in social services, a persistent puzzle is the gap in take-up of beneficial services among those who may benefit from them the most. We study causal identification and robust estimation of optimal treatment rules, including under potential violations of positivity. We consider constraints such as demographic parity in treatment take-up, among others, via constrained optimization. Our framework can be extended to handle algorithmic recommendations under an often-reasonable covariate-conditional exclusion restriction, using our robustness checks for lack of positivity in the recommendation. We develop a two-stage algorithm for solving over parametrized policy classes under general constraints to obtain variance-sensitive regret bounds. We illustrate the methods in three case studies based on data from reminders of SNAP benefits recertification, randomized encouragement to enroll in insurance, and from pretrial supervised release with electronic monitoring. While the specific remedy to disparities in algorithmic allocation is context-specific, it requires studying both take-up of decisions and downstream outcomes of them.

3 - Designing AI-Human Supervision to Improve Worker Performance: a Field Experiment in Service Operations

Bing Bai, McGill University, Montreal, QC, Canada, Xueming Luo, Zheng Fang, He Peng

We study how firms can effectively integrate AI into supervisory roles to enhance worker performance. Using data from a randomized field experiment at a fintech firm, we compare the effects of different human-AI supervisory configurations on customer service agents. Workers received performance feedback from either human managers (human-solo), an AI bot (AI-solo), both in parallel (dual), or an AI system whose feedback was relayed by a human manager (shadow-AI). We find that AI-solo supervision improves worker performance relative to human-solo, but that combining both in a dual configuration backfires—leading to confusion, reduced feedback-seeking, and lower task performance. In contrast, the shadow-AI configuration improves performance by encouraging proactive learning and reducing customer frustration. Importantly, while AI-solo supervision exacerbates gender disparities, shadow-AI reduces the gap by improving performance for both genders. Our findings highlight that AI should not replace human managers, but rather work behind the scenes to support them, enabling more productive, equitable, and human-centered service operations.

4 - Large-Scale Personalization: Lessons from Behavioral Nudging in India

Divya Singhvi, New York University, New York, NY, United States

In this talk, I will share insights from recent work on designing and deploying a personalized behavioral nudging system to optimize user engagement at scale on an EdTech platform in India. I will present key findings from field experiments and highlight practical lessons for implementing personalization strategies in data-scarce environments. The discussion will focus on both methodological innovations and operational challenges, offering actionable guidance for researchers and practitioners working in similar contexts.

Advances in Empirical Platform Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Sidika Candogan, National University of Singapore, Singapore, Singapore

Co-Chair: Guang Cheng, National University of Singapore, Singapore, Singapore

1 - Platform Entry in Winner-Take-All Markets: An Empirical Investigation of Feature-Based Differentiation of a Microblogging Platform

Jonathan Gomez Martinez, Marshall School of Business - University of Southern California, Atlanta, GA, United States, Ramnath Chellappa, Emma Zhang

Theoretical work on platform competition emphasizes the importance of differentiated features and multihoming in determining market outcomes. However, empirical evidence of platforms competition in stable markets remains sparse. We analyze such a market through the introduction and growth of the Parler social media platform. Parler, offered similar features to other microblogging platforms with the addition of freedom from content moderation as its differentiated feature. Our work demonstrates that Parler's differentiated feature, both, expanded the market and increased competition with the dominant microblogging platform. We also identify periods when the salience of Parler and its differentiated feature were heightened. We find that competition was heightened with additional salience of Parler's differentiated feature while increased visibility of Parler, itself, resulted in market expansion. Our work concludes with a discussion of the events leading to Parler shutting down and the competitive issues therein.

2 - The Role of Contextual Information in Customer Reviews: a Field Experiment on a Mental Health Platform

Guang Cheng, National University of Singapore, Singapore, Singapore, Sidika Candogan, Joel Goh, Bilal Gokpinar

Online mental health platforms can increase the accessibility of mental health care by allowing customers to select a therapist from a large pool of vetted professionals. However, customers may find it difficult to choose a therapist best suited to their needs because therapists typically list multiple specializations that tend to overlap significantly. This makes it challenging for online mental health platforms to attract new customers and retain existing ones. Motivated by this challenge, we conducted a randomized field experiment in partnership with Singapore's largest online mental health platform. In this experiment, we empirically investigate whether a simple intervention on the customer reviews—revealing contextual information about the review writers—can improve the platform's ability to attract and retain customers. We

find that, relative to the control, treated customers were 15% more likely to book at least one therapy session, and they booked 36% more sessions in total during the experiment. Furthermore, treated customers who have the first therapy session booked 55% more follow-up sessions with their first chosen therapist. Overall, our results suggest that revealing contextual information about the review writers improves the informativeness of customer reviews on mental health platforms, and it is a simple and effective way to increase successful matches and foster long-term relationships between customers and the platform.

3 - 30 Million Canvas Grading Records Reveal Widespread Sequential Bias and System-Induced Surname Initial Disparity

Jiaxin Pei, Stanford University, Palo Alto, CA, United States, Zhihan Wang, Jun Li

he widespread adoption of learning management systems in educational institutions has yielded numerous benefits for teaching staff but also introduced the risk of unequal treatment towards students. We present an analysis of over 30 million Canvas grading records from a large public university, revealing a significant bias in sequential grading tasks. We find that assignments graded later in the sequence tend to (1) receive lower grades, (2) receive comments that are notably more negative and less polite, and (3) exhibit lower grading quality measured by post-grade complaints from students.

Furthermore, we show that the system design of Canvas, which pre-orders submissions by student surnames, transforms the sequential bias into a significant disadvantage for students with alphabetically lower-ranked surname initials. These students consistently receive lower grades, more negative and impolite comments, and raise more post-grade complaints as a result of their disadvantaged position in the grading sequence. This surname initial disparity is observed across a wide range of subjects, and is more prominent in social science and humanities as compared to engineering, science and medicine. The assignment-level surname disparity aggregates to a course-level surname disparity of students' GPA and can potentially lead to inequitable job opportunities. For platforms and education institutions, the system-induced surname grading disparity can be mitigated by randomizing student submissions in grading tasks. Education institutions should keep the workload of graders at a reasonable level to reduce fatigue and/or have multiple graders as a cross validation to enhance grading quality.

4 - Have You Walked in My Shoes? Mitigating the Cold Start Problem in Peer-to-Peer Platforms with Bilateral Reviews

Junghyun Maeng, National University of Singapore, Singapore, Singapore, Varun Karamshetty, Hyeokkoo Eric Kwon

Early-stage sellers on peer-to-peer (P2P) platforms often struggle to attract buyers due to the cold-start problem—a lack of performance feedback reviews that limits their ability to establish trust with prospective buyers. This study investigates whether and how bilateral review systems can mitigate this problem by enabling the transfer of reputation between roles. Using a unique panel dataset of Airbnb property listings in New York City from 2015 to 2019, we exploit the variation in the timing of when new hosts receive guest-side reviews (reviews they earned in their role as guests) to estimate the impact on their performance as a host (seller). We find that receiving guest-side reviews increases the monthly occupancy rates of early-stage hosts and the number of booked days by 11.2% and 13.6%, respectively. Interestingly, these effects are stronger for early-stage hosts who face higher baseline uncertainty in performance, such as belonging to racial minority groups or operating in high-crime neighborhoods. We also find that the positive effect on host performance is amplified when guest-side reviews contain host-relevant content, such as feedback on their cleanliness and communication (as a guest). Our findings contribute to the literature on bilateral review systems and cold-start problem by showing that trust in role-fluid P2P environments is not siloed – reputation earned as a buyer can meaningfully shape seller outcomes. Based on our findings, we offer actionable insights for early-stage sellers and P2P platforms seeking to design bilateral review systems.

MSOM: Sustainable Operations

Chair: Tim Kraft, North Carolina State University, Raleigh, NC, United States

1 - Getting to the Green: Should a Profit-Maximizing Firm Buy Carbon Offsets OR Invite Consumers to Buy Them?

Gokce Esenduran, Purdue University, West Lafayette, IN, United States, H. Sebastian Heese, Gil Souza

Many companies, including American Airlines, Patagonia, Google, and Apple have pledged to achieve carbon neutrality, pursuing initiatives such as renewable energy use, zero-emissions vehicles, and low-carbon materials. However, residual emissions often remain, requiring the purchase of carbon offsets, which raise costs. While environmentally conscious consumers may accept higher prices for low-emissions products, many climate-disengaged consumers will not. In this paper, we identify when it is optimal for a profit-maximizing firm to offer its consumers carbon-reduction offsets for purchase with the product, in addition to potentially purchasing offsets at the firm level. Through a stylized analytical model, we show that it is never optimal for firms to both buy offsets at the firm level and offer them to consumers for purchase simultaneously. Rather, when the offset cost is low enough, the firm buys enough offsets to compensate for all of its emissions at the firm level, resulting in a higher overall product price; when the offset cost is in the middle range, the firm offers offsets to consumers for purchase at an offset price lower than offset cost, ensuring that green consumers buy offsets; and when the offset price is high, offsets cannot be optimally used in any way. The thresholds depend on the green-segment size and disutility from emissions, and on the product's own carbon footprint. Providing offsets for purchase to consumers allows consumers to self-select into their preferred product/price bundle, thus providing the firm with a market-segmentation and price-discrimination mechanism that increases profits and reduces the firm's carbon footprint.

2 - Consumer Food Waste in Retail Operations

Seulchan Lee, Michigan Technological University, Hancock, MI, United States, Michael Ketzenberg, Han Oh, Nesim Erkip

Our research focus is on consumer food waste for sustainable retail operations. We specifically address the research question of how consumer food waste is affected by retail decision-making and the reciprocal, how food waste by consumers affects retail decision-making. We introduce a generic model of consumer utility with regard to food consumption and waste. From this granular level of heterogeneous consumer utility, we derive a stochastic, aggregate market demand function that drives retail inventory management. We do so in the context of a single period newsvendor problem. Several key observations arise from our analysis. For example, providing a higher quality product for sale may increase total waste. We also observe that increasing consumer disutility to waste may actually increase total food waste. In addition, we find that an increase in the unit salvage value of unsold inventory at the end of the period will also generally increase total waste. We contribute to the understanding of the behavioral mechanisms that explain how both food consumption and waste interact with and impact retailer decision-making. These findings have important implications with respect to potential regulatory actions and policy interventions to reduce food waste.

3 - Truth OR Dare? Managing Engagement and Verification Efforts Under Supplier Self-Reporting

Elif Kuscü, University of Zurich, Zurich, Switzerland, Tim Kraft, Tarkan Tan, Ozge Tuncel

To improve supply chain sustainability, buyers often rely on audits to assess performance and determine their engagement levels. However, traditional audits frequently fall short in uncovering the truth. Consequently, large firms such as health-technology provider Philips no longer use audits to ensure supplier compliance but instead require suppliers to self-report their sustainability performance. While novel, this practice has the potential to introduce new challenges, such as bias in suppliers' self-reports.

Motivated by this shift, we develop game-theoretic models to examine how a buyer should respond to a supplier's self-reported sustainability claims under information asymmetry. Specifically, we ask: How should buyers manage their efforts between engaging with suppliers and verifying their claims when reports may be strategically distorted? We analyze two settings: (1) a supplier self-reporting model in which the supplier may misrepresent their sustainability capability, and (2) a buyer verification model in which the buyer can adjust engagement based on supplier characteristics and invest in assessing the supplier's true capability.

Our analysis shows that supplier misreporting can induce higher buyer engagement and, counterintuitively, lead to improved sustainability outcomes. In some cases, the buyer achieves better results under asymmetric information than full transparency. These findings challenge the view that accurate reporting is an end in itself and highlight its role as a mechanism for driving improvement. From a managerial perspective, our findings illustrate the value of adaptive engagement strategies. Rather than focusing solely on verifying reports, buyers may benefit from a more nuanced approach that balances information gathering with proactive support.

4 - A Dynamic Multi-Agent Framework for Collective ESG Investment: Mitigation, Greenwashing, and Strategic Trade-Offs

Pengyu Wang, University of Washington, Foster School of Business, Seattle, WA, United States, Shi Chen

This paper develops a dynamic multi-agent decision framework to study collective ESG (Environmental, Social, and Governance) investment strategies in a setting where each firm's actions influence, and are influenced by, the broader population. We consider a large number of heterogeneous firms whose ESG-related decisions – ranging from genuine mitigation efforts to greenwashing – generate economic externalities such as climate risk and violations of sustainability standards in global supply chains. These externalities, in turn, affect the payoffs of all firms through their impact on an ESG-focused financial market. The systemic nature of ESG risks couples firms' decisions dynamically, making each firm's optimal strategy dependent on the collective behavior of others. Within this framework, we examine how firms' capital and ESG investment behaviors co-evolve over time. We highlight and analyze three key trade-offs: (1) the intertemporal tension between short-term costs and long-term ESG benefits; (2) the strategic balance between authentic mitigation and reputational greenwashing; and (3) the free-rider problem that emerges from shared mitigation efforts. Our findings provide insights into the design of effective ESG incentives that promote responsible investment and sustainable operations across global supply chains.

1 - Reducing Symbiosis Bias Through Better A/B Tests of Recommendation Algorithms

David Holtz, Columbia Business School, New York, NY, United States, Jennifer Brennan, Yahu Cong, Yiwei Yu, Lina Lin, Yajun Peng, Changping Meng, Ningren Han, Jean Pouget-Abadie

It is increasingly common in digital environments to use A/B tests to compare the performance of recommendation algorithms. However, such experiments often violate the stable unit treatment value assumption (SUTVA), particularly SUTVA's "no hidden treatments" assumption, due to the shared data between algorithms being compared. This results in a novel form of bias, which we term "symbiosis bias," where the performance of each algorithm is influenced by the training data generated by its competitor. In this paper, we investigate three experimental designs—cluster-randomized, data-diverted, and user-corpus co-diverted experiments—aimed at mitigating symbiosis bias. We present a theoretical model of symbiosis bias and simulate the impact of each design in dynamic recommendation environments. Our results show that while each design reduces symbiosis bias to some extent, they also introduce new challenges, such as reduced training data in data-diverted experiments. We further validate the existence of symbiosis bias using data from a large-scale A/B test conducted on a global recommender system, demonstrating that symbiosis bias affects treatment effect estimates in the field. Our findings provide actionable insights for researchers and practitioners seeking to design experiments that accurately capture algorithmic performance without bias in treatment effect estimates introduced by shared data.

2 - The Design and Analysis of Switchback and Panel Experiments

Iavor Bojinov, Harvard Business School, Somerville, MA, United States

Marketplaces often exhibit complex interference patterns that in the worst case, can not be directly modeled or even adequately described. In such settings, practitioners have opted to use switchback experiments whereby the whole market is randomly assigned to treatment or control conditions for a short period, some outcome is recorded, and the process is repeated for T time periods. Although these experiments alleviate the challenges posed by the population interference, they often suffer from temporal interference — or carryover effects — whereby past treatments affect current outcomes. In this talk, I will share recent advances in the design and analysis of switchback experiments and their generalization to multiple experimental units, known as panel experiments. The talk will highlight insights from several new research papers and offer practical guidance for applying these methods in real-world settings.

3 - On Experiment Design Under Network Interference

Yuwei Luo, Stanford University, Stanford, CA, United States, Mohsen Bayati, William Overman, Sadeh Shirani, Ruoxuan Xiong

Randomized experiments are a powerful methodology for data-driven evaluation of decisions or interventions. Yet, their validity may be undermined by network interference. This occurs when the treatment of one unit impacts not only its outcome but also that of connected units, biasing traditional treatment effect estimations. This talk discusses a new framework to accommodate complex and unknown network interference and produce practical estimators.

4 - Switchback Price Experiments with Forward-Looking Demand

Yifan Wu, Northwestern University, Evanston, IL, United States, Ramesh Johari, Vasilis Syrgkanis, Gabriel Weintraub

We consider a retailer running a switchback experiment for the price of a single product, with infinite supply. In each period, the seller chooses a price p from a set of predefined prices that consist of a reference price and a few discounted price levels. The goal is to estimate the demand gradient at the reference price point, with the goal of adjusting the reference price to improve revenue after the experiment. In our model, in each period, a unit mass of buyers arrives on the market, with values distributed based on a time-varying process. Crucially, buyers are forward-looking with a discounted utility and will choose not to purchase now if they expect to face a discounted price in the near future. We show that forward-looking demand introduces bias in naive estimators of the demand gradient, due to intertemporal interference. Furthermore, we prove that there is no estimator that uses data from price experiments with only two price points that can recover the correct demand gradient, even in the limit of an infinitely long experiment with an infinitesimal price discount. Moreover, we characterize the form of the bias of naive estimators. Finally, we show that with a simple three-price level experiment, the seller can remove the bias due to strategic forward-looking behavior and construct an estimator for the demand gradient that asymptotically recovers the truth.

Data-Driven Research in Revenue Management

Invited Session

Revenue Management

Chair: Zhiqi Zhang, Washington University in St. Louis, St. Louis, MO, United States

1 - Optimal Bundles in Land Freight Auctions

Yuetong Xu, MIT, Cambridge, MA, United States, Retsef Levi

Land freight is a critical transportation mode of shipping goods in the U.S., with trucks moving roughly 72.6% of total freight weight. This corresponds to \$940.8 billion of gross freight revenue, equivalent to 80.7% of the nation's freight bill in 2022. US Postal Services and many other agencies and companies employ freight delivery auctions with the goal of obtaining competitive market prices and maximize profits.

This work develops an optimization model to find the optimal bundles in second price freight auctions. An innovative and tractable integer program is provably able, for practically realistic size auctions, to identify bundles that ensure truthful bidding and minimize the overall payoff of the auctioneer.

2 - Bias-Variance Tradeoff of Matching Prior to Difference-in-Differences when Parallel Trends is Violated

Mingxuan Ge, University of Michigan - Ross Business School, Ann Arbor, MI, United States, Dae Woong Ham

The Difference-in-Difference (DiD) estimator is a popular estimator built on the "parallel trends" assumption. To increase the plausibility of this assumption, a popular and natural idea is to match treated and control units prior to a difference-in-difference. The intuition is that after matching, the matched set of treated units and control are more likely to have the same post-treatment outcome absent treatment, i.e., the parallel trends. While this issue has been studied previously, the focus was solely on the bias of such a practice. This paper generalizes prior bias results under weaker assumptions and further explores the variance and mean squared error (MSE) implications of matching DiD estimators. To assess the tradeoffs of matching prior to DiD, we compare the variances and MSE of three estimators: 1) classical DiD (no matching), 2) DiD after matching on observed covariates, and 3) DiD after matching additionally on pre-treatment outcome(s) under a linear structural equation model with unobserved time-varying confounders, allowing a breakage in parallel trends. Unlike previous studies that show matching on observed covariates X always reduces bias, this work shows matching on observed covariates X is not always recommended when considering variance due to a sample size tradeoff. We characterize full bias-variance tradeoffs among all three estimators and further give guidelines for determining to what extent the reduction in MSE from matching is likely to outweigh the associated costs.

3 - Data-Driven B2b Pricing

Ningyuan Chen, Rotman School of Management, Toronto, ON, Canada, Timothy Chan, Craig Fernandes

In B2B pricing, the price is typically determined through initial quote and subsequent bargaining. As a result, the prices in the transaction data are confounded by the customer's willingness-to-pay and thus endogeneous. To find the optimal (quoted) price and bargaining strategy, the approach adopted in the classical pricing literature, which first fits a demand function under the assumption that historical prices are exogeneous, does not apply. We develop a framework to learn the distribution of customer's willingness-to-pay and bargaining power from the data under confounding and then identify the optimal prices. We use the Nash bargaining to model the price forming process in the data. We identify the conditions of the dataset that lead to identifiable parameters, and show that even without identifiability, the optimal price can still be determined. We compare the efficiency of several methods with limited data.

4 - Bundling with Doubly Sparse Interactions: Estimation and Assortment Optimization for Bundling Under the Multivariate Mnl

Heng Zhang, Arizona State University, Tempe, AZ, United States, Mengxin Selene Wang

We study consumer choice behavior in bundling contexts, where customers may simultaneously purchase products across multiple categories. To capture both within-category substitution and cross-category complementarity, we present a reformulated multivariate multinomial logit (MVMNL) model. This framework extends the classical MNL model by modeling basket-level utility with Gumbel-distributed random variables, allowing us to account for complex interactions among products across different categories. A key innovation in our approach is to reduce the computational burden of this high-dimensional model by predicting choices in one category conditional on selections in others. This reformulation dramatically simplifies the full joint likelihood, making it more tractable for both estimation and optimization. We study the statistical properties of our approach. Recognizing that not all cross-category relationships are equally important, we impose a sparsity structure on interaction terms. This assumption enables us to develop efficient and scalable methods for parameter estimation. Building on our estimation procedure, we demonstrate how the learned interaction patterns can be directly exploited to design algorithms for operational decision-making. In particular, we illustrate the model's utility in assortment optimization and pricing strategies for high-dimensional retail settings.

5 - Balancing Act: Designing Sustainable Incentive Schemes for User Engagement and Revenue Optimization in Online Platforms

Xinyu Xu, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Qinlu Hu, Ni Huang, Renyu Zhang

User-generated content (UGC) platforms frequently use monetary incentives to boost user engagement, yet their impact on platform revenue remains under-explored. Our study addresses this gap by exploring the dual-sided effects of monetary incentives on both users and platforms and introduces and evaluates a novel monetary incentive scheme: ad-based incentives, where users receive rewards for watching advertisements. Unlike traditional monetary incentives (e.g., posting rewards), ad-based incentives generate direct platform revenue. Through two large-scale field experiments on a short-video platform, we analyze the effects of removing ad-based incentives and combined monetary incentives (a hybrid of traditional and ad-based schemes). Results show that removing ad-based incentives does not impact user engagement but significantly reduces platform revenue. Conversely, removing combined incentives reduces engagement but increases revenue, revealing a trade-off between user activity and profitability. Furthermore, Heterogeneous treatment effect analysis indicates greater impacts on women and older users (aged 50+). These findings provide actionable insights for designing balanced user acquisition and retention strategies.

Recommendations, Fairness and Human-AI Interaction

Invited Session

Revenue Management

Chair: Akshit Kumar, Yale University, Jersey City, NJ, United States

1 - The Feedback Loop of Statistical Discrimination

Jackie Baek, New York University, New York City, NY, United States, Ali Makhdoumi

We study a dynamic model of interactions between a firm and job applicants to identify mechanisms that drive long-term discrimination. In each round, the firm decides which applicants to hire, where the firm's ability to evaluate applicants is imperfect. Each applicant belongs to a group, and central to our model is the idea that the firm becomes better at evaluating applicants from groups in which they have hired from in the recent past. We establish the firm's initial evaluation ability for each group to be a critical factor in determining long-term outcomes. We show that there is a threshold for which if the firm's initial evaluation ability for the group is below the threshold, the group's hiring rate decreases over time and eventually goes to zero. If the group starts above the threshold, then the hiring rate stabilizes to a positive constant. Therefore, even when two groups are ex-ante identical, a marginal difference in the firm's initial evaluation ability can lead to persistent disparities that exacerbate over time through a feedback loop. Importantly, the dynamic nature of our model allows us to assess the long-term impact of interventions. Our analysis highlights the importance of interventions that meaningfully alter evaluation ability, and our results imply that drastic short-term interventions are more effective compared to milder long-term interventions. We also find that smaller groups face inherent disadvantages, requiring a higher initial evaluation ability to achieve a favorable long-term hiring outcome and experiencing lower hiring rates even when they do.

2 - Why Students Reject AI for Human Counselors in College Applications: A Field Experiment

Hemanshu Das, Yale University, New Haven, CT, United States, Sofoklis Goulas, Faidra Monachou

AI is increasingly used to guide high-stakes educational decisions, yet its effectiveness depends on whether people follow its advice. We present the first large-scale field experiment with adolescents in this context, conducted across 14 public high schools. We compare the adoption of identical college-application recommendations from human counselors versus an AI-based algorithm. Contrary to the common assumption that objective, data-based recommendations favor AI, we find that algorithm aversion intensifies when recommendations are based on objective criteria (e.g., grades, admission chances) and dissipates when criteria are more subjective. We find that student perceptions of the recommender's intent strongly drive this aversion, consistently across scenarios and statistical approaches; perceptions of alignment with personal goals, ability, and comprehension also play significant roles. The results further reveal substantial heterogeneity in recommendation adoption rates. We observe stronger aversion among female students, students from rural schools, lower-GPA students, and those with stronger prestige-seeking attitudes. Using an optimization approach, we demonstrate how a policymaker can navigate the heterogeneity in recommendation adoption rates to optimally prioritize the assignment of human versus AI-based algorithmic recommenders, under varying social priorities and limited capacity of human counselors. We find that a targeting policy relying on few readily available

student and school features can approximate the first-best, personalized targeting policy effectively. These insights underscore the importance of understanding student preferences and trust in an AI system's intent, and of adopting hybrid approaches that blend human guidance with AI tools to design effective recommendation systems.

3 - How Agentic AI Impacts Customer-Intensive Services

Xiaofei Li, Zhejiang University, Hangzhou, China, People's Republic of, Ming Hu, Quan Yuan, Han Zhu

Artificial intelligence (AI) technologies are increasingly employed in customer-intensive services to automate auxiliary tasks and enhance service efficiency. We investigate a service system in which the overall service rate depends on both auxiliary and professional service times. AI effectively reduces the time allocated to auxiliary tasks. Our findings reveal that marginal improvements in AI capability always enhance market coverage but, somewhat surprisingly, may reduce service quality and service price. Depending on the service type, service price may follow different patterns---either always increasing, initially decreasing, or initially increasing and then decreasing---before eventually increasing, as AI capability improves. Only at a sufficiently high AI capability can the service provider enhance both service quality and service price. In contrast to traditional systems without AI, AI assistance tends to lower service quality unless AI capability reaches a sufficiently high level. Furthermore, we uncover an inverted U-shaped pattern in the optimal system utilization as AI capability increases and reveal a paradox: while AI improves the efficiency of auxiliary tasks, it can actually increase the provider's workload. Our study shows that with assistive AI to improve the operational efficiency of auxiliary tasks, the service provider likely reduces service quality and service price, but with more customers served on the demand side while creating more hiring needs for labor on the supply side.

Designing Markets: Algorithms, Mechanisms, Information, and Experiments

Invited Session

Auctions and Market Design

Chair: Pengyu Qian, Boston University, Boston, United States

Co-Chair: Jinglong Zhao, Boston University, Boston, MA, United States

1 - Automated Experimental Design with Optimization from Historical Data Simulations

Ruoxuan Xiong, Emory University, Atlanta, GA, United States

We study the problem of designing randomized experiments to estimate the causal effects of new interventions. The design problem involves selecting a treatment assignment mechanism, including assignment probabilities, in order to optimize a user-defined objective (e.g., maximizing the precision of a causal-effect estimator). A key challenge is that the objective is typically a black-box function of the design, depending on unknown outcome-generating processes and causal effects. To tackle this challenge, we propose a novel automated experimental design (AutoED) approach. AutoED evaluates the objective value of a candidate design by simulating experiments based on stationary historical control data and prior distributions of causal effects. Then a gradient-free method is used to iteratively optimize the design. We rigorously analyze the convergence behavior of AutoED and show how it depends on temporal and cross-unit correlations in historical data as well as on implementation specifics. In synthetic experiments on three application domains—digital platforms, health, and energy—AutoED can reduce the estimation error of treatment effects by up to 25% compared to the state-of-the-art benchmark designs. Our results reveal new design insights to improve efficiency. In particular, for multi-unit crossover experiments with multiple interventions, we find that efficiency is improved by sequentially rolling out (a) the same intervention across units and (b) different interventions on the same unit.

2 - The Power of Two in Token Systems

Süleyman Kerimov, Rice University, Houston, TX, United States, Itai Ashlagi, Omer Tamuz, Geng Zhao

In economies without monetary transfers, token systems serve as an alternative to sustain cooperation, alleviate free riding, and increase efficiency. This paper studies whether a token-based economy can be effective in marketplaces with thin exogenous supply. We consider a marketplace in which at each time period one agent requests a service, one agent provides the service, and one token (artificial currency) is used to pay for service provision. The number of tokens each agent has represents the difference between the amount of service provisions and service requests by the agent. We are interested in the behavior of this economy when very few agents are available to provide the requested service. Since balancing the number of tokens across agents is key to sustain cooperation, the agent with the minimum amount of tokens is selected to provide service among the available agents.

When exactly one random agent is available to provide service, we show that the token distribution is unstable. However, already when just two random agents are available to provide service, the token distribution is stable, in the sense that agents' token balance is unlikely to deviate much from their initial endowment, and agents return to their initial endowment in finite expected time. Our results mirror the power of two choices paradigm in load balancing problems. Supported by numerical simulations using kidney exchange data, our findings suggest that token systems may generate efficient outcomes in kidney exchange marketplaces by sustaining cooperation between hospitals.

3 - Learning to Design Information

Ce Li, Boston University, Boston, MA, United States

Classical information design models (e.g., Bayesian persuasion and cheap talk) require players to have perfect knowledge of the prior distribution of the state of the world. Our paper studies repeated persuasion problems in which the information designer does not know the prior. The information designer learns to design signaling schemes from repeated interactions with the receiver. We design learning algorithms for the information designer to achieve no regret compared to using the optimal signaling scheme with known prior, under two models of the receiver's decision-making. (1) The first model assumes that the receiver knows the prior and can perform posterior update and best respond to signals. In this model, we design a learning algorithm for the information designer with $O(\log T)$ regret in the general case, and another algorithm with $\Theta(\log \log T)$ regret in the case where the receiver has only two actions. (2) The second model assumes that the receiver does not know the prior and employs a no-regret learning algorithm to take actions. We show that the information designer can achieve regret $O(\sqrt{r\text{Reg}(T)T})$, where $r\text{Reg}(T)=o(T)$ is an upper bound on the receiver's learning regret. Our work thus provides a learning foundation for the problem of information design with unknown prior.

4 - Priority Matching in Kidney Exchange Markets

Elaine Liu, Stanford University, Stanford, CA, United States, Itai Ashlagi, Pengyu Qian

We study the kidney exchange market with a priority structure. In this market, one donor-patient pair arrives per period. The pair is type “willing” with probability $\$q$ and “unwilling” otherwise. Donors of “willing” pairs can donate prior to the patient receiving, and receive priority in return once they donate; “unwilling” pairs are only willing to donate at the time or after the patient receives a kidney. Compatibility probability is $\$p$ between any patient and donor, except the pair that arrives together.

In this work, we carefully define “priority” by proposing three different matching algorithms: weak priority, strict priority, and strictest priority. The weak priority algorithm greedily maximizes for the most donations, as long as it does not harm priority patients. The strict priority algorithm greedily finds the fastest way to help priority patients. The greedy nature makes these two algorithms computationally efficient. On the other hand, strictest priority finds the absolute fastest way to help priority patients by searching over the entire market. We analyze the expected waiting time for willing and unwilling patients under all three algorithms. We conclude that, as long as the priority is not overly aggressive, the priority market structure benefits both types of patients alike. Our results have broader implications in self-serving markets beyond kidney exchange.

Technology's Impact on Social Structures and Organizational Dynamics

Invited Session

Social Media Analytics

Chair: Reihane Boghrati, Arizona State University, Tempe, AZ, United States

1 - Beyond Productivity: Design and Effects of Algorithmic Output on Cognitive Engagement and Distinctiveness

Anuschka Schmitt, The London School of Economics and Political Science, London, United Kingdom, Thiemo Wambsganss, Andreas Janson, Krzysztof Z. Gajos

Can GenAI help humans without telling them what to do? Prevalent forms of algorithmic output provide a user with 'one best' solution that can induce the user to fixate on the algorithmic output and neglect critical reasoning. Cognitive engagement is important, though, in consideration of long-term outcomes such as individual learning and intellectual diversity. As part of a series of field experiments in the context of a business pitch writing task, we investigate how alternative designs of algorithmic output impact three interrelated outcomes: task performance, cognitive engagement, and distinctiveness of the written pitches. We explore the potential of (i) reciprocal algorithmic output providing feedback in form of open-ended questions and pro and contra arguments compared to (ii) a 'default' design of solution-focused algorithmic output improving users' writing without any further advice. We show that individuals can improve their writing regardless of the type of algorithmic output exposed to. However, individuals exposed to reciprocal algorithmic output engage significantly more with the task and the algorithmic output and write more distinct business pitches compared to individuals exposed to contrastive algorithmic output. Together, these results indicate that there are different paths that enable productivity gains through GenAI. Next to individual-level upsides, reciprocal algorithmic output can have significant long-term and group-level benefits including the preservation of intellectual distinctiveness. Particularly relevant to educational and organizational settings where cognitive engagement is paramount to learning and skill development, our study illustrates how algorithmic output may serve as a critical stimulator rather than attenuating human agency.

2 - Elements of Persuasiveness in Kickstarter Pitch Videos: a Multi-Modal and LLM-Based Approach

Maryam Rahmani Moghaddam, University of Delaware, NEWARK, DE, United States, Weiguo (Patrick) Fan

This study explores persuasive strategies in crowdfunding pitch videos using a multi-modal framework that incorporates visual and auditory analysis. Guided by the AIDA (Attention, Interest, Desire, Action) model, we focus on identifying persuasive elements such as product demonstrations, statistical claims, and credibility cues using large language models (LLMs) like GPT-4. Videos are segmented into scenes using the Google Vision API, and a representative frame from each scene is analyzed for persuasive content. Acoustic features such as pitch, intensity, and formants are extracted to capture delivery style, while visual features include human presence, colorfulness, and brightness, among others. Our aim is to develop an interpretable model that integrates these features to predict campaign success and provide insights into persuasive communication in video-based crowdfunding.

3 - The Impact of Platform-Driven Movements on Gender Leadership Dynamics

Reihane Boghrati, Arizona State University, Tempe, AZ, United States

Digital information systems, particularly social media platforms, can turn individual stories into widespread movements that drives real change within organizations. Drawing on social movement theory in the context of digital communication, we examine how the MeToo movement, a social media-driven movement, influenced female leadership in the workplace. Using a quasi-experimental approach, we compile and analyze a comprehensive dataset of individual career paths and firm characteristics. Results show an increase in female representation in leadership positions following the MeToo movement. This effect is moderated by factors such as individual industry backgrounds, career mobility, and industry gender composition at leadership levels. Post-MeToo, women saw a 40% increase in the likelihood of attaining leadership roles. Moving from non-IT roles into IT roles (27% increase) as well as moving from non-IT industry to IT industry (11% increase) benefited women post-MeToo. The MeToo movement had a more pronounced positive effect on women's career trajectories in organizations that already had a strong female presence in leadership (64% increase post-MeToo). Our findings provide valuable insights into how the MeToo, a social media-driven movement influenced, as a secondary impact, workplace gender dynamics.

4 - Teaming and Competing with AI: Communication Design in Hybrid Multi-Agent Environments

Sungeun (Selena) Han, Arizona State University, Tempe, AZ, United States, Tian Lu, Reihane Boghrati

As generative-AI (Gen-AI) becomes increasingly integrated into organizational workflows, understanding how AI agents communicate with human teammates has become a critical research frontier. Prior studies have primarily focused on dyadic (one-human, one-agent) collaborations, where emotional and logical communication styles have been shown to shape trust, alignment, and performance. However, many emerging applications involve hybrid multi-agent teams, where a human collaborates with one AI agent while simultaneously competing with others. In these cooperative settings, communication dynamics are more complex, and established findings from dyadic contexts may not generalize. This study investigates how Gen-AI's emotional and logical communication styles shape human perceptions and collaborative outcomes in a multi-agent hybrid cooperation game. We conduct a controlled lab experiment using the social deduction game Werewolves, a high-uncertainty, high-interdependence environment that requires strategic coordination and competition. By systematically varying the AI agent's communication style, we aim to examine its impact on trust, perceived competence, satisfaction, collaborative behavior, and team performance. Emotional communication enhances social presence but may trigger strategic distrust; logical communication improves decision alignment but may limit social cohesion. These dynamics challenge established design principles for AI communication in dyadic collaboration. We contribute to the literatures on human-AI teaming, communication design, and collective intelligence by showing that communication strategies must adapt to the structural complexity of multi-agent environments to support effective and resilient teamwork.

Advances in Scheduling

Contributed Session

Contributed

Chair: Renjie Yu, The University of Sydney, Sydney, Australia

1 - Post-Earthquake Restoration Problem of Water Distribution Network

Peihong Xiao, National University of Singapore, Singapore, Singapore

Restoring water distribution systems is a critical yet complex task in post-disaster recovery. Timely pipe restoration is essential to ensure clean water access, supporting both public health and disaster relief. However, challenges such as limited resources, uncertain pipe damage, and urgent timelines complicate the process.

This study addresses the water distribution network restoration problem under uncertainty, where pipe damage is initially unknown and progressively revealed via sensors at demand nodes. Since delays in repairing damaged pipes can disrupt downstream supply and cause significant losses, the goal is to determine an optimal restoration sequence that minimizes the total weighted delay.

We first model this as a partially observable Markov decision process (POMDP). However, solving large-scale POMDPs is computationally infeasible. To address this, we propose a two-layer open-loop policy that uses current information without relying on future observations. In the outer layer, a Bayesian network updates the belief state of each pipe based on the latest sensor data. This updated state is then passed to the inner layer, a scheduling model that computes the pipe restoration sequence assuming no future observation updates. As new observation becomes available, the process iterates, dynamically adapting decisions while maintaining tractability. We also identify structural properties of the inner-layer scheduling problem and develop a heuristic to efficiently generate restoration sequences.

Numerical experiments on randomly generated networks with varying topologies and information settings show that our approach significantly outperforms benchmark strategies in both efficiency and total cost.

2 - Port Terminal Appointment Scheduling Problem with Random Arrival and Processing TIMES

Mustafa Gurbuz, Zaragoza Logistics Center, ZARAGOZA, Spain, Lygia Brønneberg Velez

Motivated by the resolution published by the Brazilian National Agency of Oil in July of 2022, we study the Port Terminal Appointment Scheduling Problem (PTASP) where ports strive for maximizing profits while offering clients such as ship owners quality service (e.g., appointments that meet clients' requirements, reduced waiting times).

Our model considers clients requests, contractual agreements, delays in arrivals and processing times distributions, and pre-defined berthing sequence rules as input parameters. We assume that the processing times for activities such as loading and unloading at the port are stochastic. Different to most existing work in the field, the "actual" ship arrival times are also stochastic, defined by random deviations from the "scheduled" arrival time in our model.

In order to reduce solution time, we propose heuristics employing a "Cluster First, Schedule Second" methodology and use simulation optimization to perform numerical analysis using real data provided by a major oil and gas transportation company in Brazil. The decision variables are the binary decisions to accept or reject requests from clients and scheduled dates of arrival if accepted.

Our results show that information sharing (e.g., volume information) between the client and the terminal, clients flexibility in the appointment time window, coordination between scheduling and operational teams, and static/dynamic assignment of appointments may have significant impact on the financial and operational performance of the terminal. Interestingly, increased variability in ship arrival times might lead to improvements in profits in some cases.

3 - Appointment Scheduling for Logistics Parks Under Truck Heterogeneity and Order Fulfillment Delay

Yujiao Sun, Guangdong University of Foreign Studies, Guangzhou, China, People's Republic of

Appointment scheduling is critical for logistic parks of manufacturing industry firms to manage inventory turnover and schedule service objects. This work studies the appointment scheduling problem of a logistic park considering truck heterogeneity and order fulfillment delay, where the number of time windows in a day, the number of each type of appointment slot, and the service schedule in each time window are decided. The objective is to minimize the expected total cost of the truck waiting time, inventory, and overtime. We develop a shortest service time first scheduling strategy to determine the service sequence in each time window and prove that it generates optimal scheduling solutions. Based on our proposed scheduling strategy, we develop a recursive calculation to formulate the cost function, which provides a tractable approach to solving combinatorially complex problems. The proposed model is solved by a dual-selection based genetic algorithm (DSGA). The performance of the DSGA is validated by comparing it to a genetic algorithm using a single tournament selection operation. Our experimental results show that the DSGA enlarges the size of subgroups with better fitness and therefore performs satisfactorily.

4 - The Car Resequencing Problem with Makespan Minimization

Xinyi Guo, Tsinghua University, Beijing, China, People's Republic of, Jean-François Côté

In the physical car resequencing problem, a sequence of cars is readjusted to a new one via a buffer placed between two adjacent production shops to minimize total cost. This paper introduces a new version with a minimum makespan objective, which arises when carmakers adopt a buffer with multiple first-in-first-out lanes and a reverse lane to rearrange cars to a given sequence. The reverse lane enhances resequencing flexibility by permitting car re-entry in the buffer but increases computational intractability. We propose a time-space network formulation and valid lower bounds for this problem, investigate its computational complexity, as well as develop an exact Branch-and-Price-and-Cut approach integrated with Constraint Programming (BPC-CP). In the BPC-CP approach, a Constraint Programming model is solved to find a feasible solution using the partial integer information from the Branch-and-Price to mitigate its over-fractional issue. Otherwise, valid inequalities are generated and added when the partial information is verified to be infeasible. Computational experiments demonstrate the effectiveness of the proposed approach.

5 - Drones for Precision Agriculture

Srinivasa Prasanna, IIIT-Bangalore, Bengaluru, India

We discuss the special requirements of drone scheduling for precision agriculture. There are requirements of multiple take-offs/landings at uncertain locations, depending on local crop health, even at the level of each individual plant. The wide area coverage requirements result in unique challenges, different from standard scheduling problems. Multiple heterogeneous drones have to be scheduled in a time and energy optimal fashion, covering the field, with uncertain load -cameras, treatments chemicals, etc. Each drone has to be scheduled with close proximity to 10+ others, for adequate speed in area coverage. This, coupled with return to hubs for charging, poses a challenging optimization problem, with 1000's of variables in large farmlands, to be covered in a couple of hours or less. Results from several approaches will be presented in the talk

6 - Single Machine Scheduling with Fixed Energy Recharging Times to Minimize the Number of Late Jobs and the Number of Just-in-Time Jobs

Renjie Yu, The University of Sydney, Sydney, Australia, Daniel Oron

We study single-machine scheduling problems where processing each job requires both processing time and rechargeable energy. Subject to a predefined energy capacity, energy can be recharged after each job during a fixed recharging period. Our focus is on two due date-related scheduling criteria: minimizing the number of late jobs and maximizing the weighted number of jobs completed exactly at their due dates. This study aims to analyze the parameterized tractability of the two problems and develop fixed-parameter algorithms with respect to three natural parameters: the number of different due dates $\nu(d)$, the number of different processing times $\nu(p)$, and the number of different energy consumptions $\nu(e)$. Following the proofs of $\mathcal{NP}$ -hardness across several contexts, we demonstrate that both problems remain intractable when parameterized by $\nu(d)$ and $\nu(p)$. To complement our results, we show that both problems become fixed-parameter tractable (FPT) when parameterized by $\nu(e)$ and $\nu(d)$, and are solvable in polynomial time when both $\nu(e)$ and $\nu(p)$ are constant.

Chair: Rama Samantapudi, 320 Autumn Oak Way, 78628

1 - Context-Aware Recommendation System for Korean Media Content in Language Education: a Case Study on the Kokiri App

Seungye Bae, Koylabs, Seoul, Korea, Republic of

Korean popular media such as dramas, variety shows, and idol videos are increasingly used by global learners as immersive tools for studying the Korean language. However, selecting suitable content that aligns with each learner's language level, interests, and learning context remains a challenge. To address this, we developed a context-aware recommendation system for language education, designed to personalize the delivery of Korean media content in the KOKIRI app—an AI-powered platform for Korean language learning.

The system integrates user behavior data, such as viewing history and learning progress, with content metadata, including difficulty level, topics, usage scenarios, and speaking styles. Using a hybrid approach that combines content-based filtering with contextual features, the system recommends short-form K-content that best matches each learner's needs and motivations.

This recommendation engine was deployed in a real-world environment and evaluated with active KOKIRI users. The results showed significant improvements in learner engagement, content consumption continuity, and satisfaction with the learning experience. In particular, context-aware recommendations led to longer viewing times and higher rates of voluntary content bookmarking.

This study contributes a scalable framework for personalized language education using cultural media, especially for non-native learners. It demonstrates how the integration of machine learning and cultural context can enhance user experience in EdTech platforms. We present our system architecture, data pipeline, and field results to share insights for both academic and practical applications.

2 - The Impact of Recommendation Systems on Content Consumption Patterns in Serialized Webtoon Content

Bongjin Sohn, Korea University, Seoul, Korea, Republic of, Antino Kim, Gunwoong Lee

This research examines the impact of recommendation systems on user consumption behavior in the context of serialized content platforms. Unlike streaming (or short-form), which allows for continuous consumption, serialized formats such as digital comics (i.e., webtoons) impose a nested temporal structure characterized by mandatory waiting periods and recurring short-session consumptions. These temporal constraints compel users to make frequent consumption decisions under a limited budget and time, increasing cognitive fatigue and altering content engagement patterns. Leveraging a field experiment on a leading webtoon platform in Korea, we compare recommendation-based versus popularity-based content displays to assess their effects on user conversion behavior (i.e., paid or alternative content consumption). The serialized release structure, particularly the distinction between initial publication and subsequent availability, enables us to examine how the timing of algorithmic exposure moderates the effectiveness of recommendations. Preliminary findings suggest that recommendation systems enhance conversion by either reinforcing early-stage engagement or facilitating content switching as decision fatigue accumulates. These results highlight that recommendation systems serve not only as content-matching tools but also as adaptive behavioral interventions in environments requiring repeated decision-making, suggesting important implications for platform operators in designing recommendation strategies aligned with the temporal dynamics of serialized content.

3 - The Ripple Effect of Live Commerce: Market-Wide Impacts of Broadcasting Activity in E-Retail

Mingi Song, Korea University Business School, Seoul, Korea, Republic of, Miaoze Han, Gunwoong Lee, Keongtae Kim

Live Streaming Commerce (LSC) has emerged as a transformative force in digital retail, yet its systemic effects on market dynamics and competitive landscapes remain underexplored. This research examines how LSC broadcasting activity impacts seller performance, competitive interactions, and platform-wide outcomes using comprehensive longitudinal data from a major South Korean e-commerce marketplace. Through rigorous causal inference analysis, we reveal that LSC broadcasting substantially enhances participating sellers' performance by capturing increased consumer attention. These benefits exhibit pronounced heterogeneity—smaller, less-established stores experience disproportionately larger gains compared to dominant sellers. We also identify asymmetric spillover effects: LSC broadcasting creates positive externalities for large competing sellers while generating negative impacts on smaller non-participating rivals. Despite these heterogeneous spillovers, LSC activity produces a net positive effect on overall platform performance, primarily driven by substantial gains among broadcasting sellers, especially smaller ones. This study advances LSC research by quantifying cross-seller and ecosystem-wide effects, providing empirical evidence for attention-based mechanisms and their market-position-dependent value, and demonstrating LSC's role as a market-restructuring innovation that reshapes competitive dynamics. Our findings position LSC broadcasting as a potentially democratizing mechanism in e-commerce that can level competitive playing fields.

4 - The Interplay of The Demand Effects of Recommendations and Advertising

Panagiotis Adamopoulos, Emory University, Atlanta, GA, United States, Vilma Todri

Recommender systems and advertising are independently considered among the most successful persuasion techniques frequently employed by platforms and marketers, owing to their significant influence on consumer behavior. Yet, our scientific understanding of the interplay of these business tactics remains rather limited. In this study, we investigate the relationship between advertising and the effectiveness of recommendations addressing an important gap in the literature. Specifically, we examine whether advertising expenditures relate to the effectiveness of system-generated recommendations towards increasing demand. Interestingly, our results show that even though both recommendations and advertising independently have a positive impact on demand, combining these different persuasion techniques might lead to advertising reducing the effectiveness of recommendations. However, advertising in different channels, earned media, and marketing promotions that increase the transaction utility of consumers might not cannibalize the positive effect of recommender systems on product demand. This discovered interplay of the advertising and recommender systems demand effects is likely due to the consumers' elevated levels of persuasion knowledge when exposed to multiple same-channel consumer persuasion techniques. The findings are supported by various identification strategies and robustness checks. We further validate the findings and underlying mechanisms in a lab experiment. Our study enhances the current understanding of the demand effects of recommendations and extends the persuasion knowledge theory to recommender systems, while having important implications for platforms and marketers and suggesting new directions for future research.

5 - Scalable and Modular Guided Search Query Recommendations via Collaborative User Navigational Behavior Graph Modeling and Modular Signal Merging

Rama Samantapudi, Walmart, Georgetown, TX, United States

This paper presents a scalable framework for constructing guided search query recommendations by leveraging users' real-world search navigational behavior. The proposed system captures collaborative query sequences from millions of user sessions, utilizing them to generate candidate queries through sequence modeling based embedding similarity retrieval techniques. To enhance relevance and diversity, random walks are performed over a directed graph constructed from observed query transitions, effectively simulating synthetic query sequences that preserve semantic coherence. These sequences are then encoded via a Skip-Gram word2vec model to produce dense, contextualized query embeddings.

The framework also integrates signal merging to incorporate global and local ranking using query popularity, conversion rates, and regional engagement scores to surface the most relevant query suggestions. A personalization layer is added which further refines guided search suggestions by leveraging individual user-profiles, historical preferences, and recent activity, ensuring tailored and meaningful query navigation. This multi-layered approach aims to improve the relevance, contextual alignment, and personalization of search query experiences in a modular way enabling us to independently develop each component through customized training schedules and tailored inference pipelines thereby optimizing and reducing overall system costs when compared to existing systems.

Simulation studies on e-commerce data demonstrates that the proposed system can significantly improve relevance, personalization, and user engagement. This work highlights the effectiveness of sequence modeling on graph-based collaborative query walks for injecting users' navigational search journey signals, and the cost-optimized modular approach which supports adding several global, regional & personalized signals to surface contextual, popular and personalized search experience.

Chair: Elia Rezaeian, Stevens Institute of Technology, 5609 Jefferson St, Hoboken, NJ, 07093, United States

1 - Bridging the Digital Divide: the Role of AI Literacy and Trust in Voice Assistant Adoption

Hsin-yi Tsai, National Cheng Kung University, Tainan, Taiwan, Chien-Wen Yuan, po-yu Hsieh, An-Yu Liu, Chieh-Ren Hsiao, Yu-Ting Chen

AI (Artificial Intelligence) technologies have become integral to daily life, yet few studies explore the role of AI literacy in technology adoption. Existing research on AI literacy primarily focuses on technical skills, overlooking essential aspects like ethics, privacy, and risk awareness. This gap is critical as AI systems, such as voice assistants, increasingly process personal data, highlighting the need for safe and responsible usage. Addressing these concerns through AI literacy can promote trust and ethical awareness, supporting smoother adoption.

Voice assistants use speech recognition and AI technologies to improve convenience and quality of life. However, their growing popularity also exposes a digital divide, where certain populations lack the necessary skills or trust to fully engage with these technologies. This divide may lead to inequitable access, emphasizing the need for inclusive digital literacy programs that extend beyond technical proficiency to include ethics and privacy awareness.

This study examines how AI literacy and perceived trust influence the intention to use AI voice assistants. Integrating AI literacy into the Unified Theory of Acceptance and Use of Technology (UTAUT), an online survey in Taiwan ($N = 1,173$) reveals that AI literacy positively impacts perceived trust and effort expectancy, which in turn enhance performance expectancy. Furthermore, AI literacy, perceived trust, and performance expectancy significantly predict usage intentions. These findings underscore the importance of AI literacy for building trust, reducing risk perceptions, and bridging the digital divide, leading to more equitable and responsible technology adoption. Detailed suggestions for promoting the use of voice assistants are provided.

2 - Fraud-Proof Revenue Division on Subscription Platforms

Nicholas Teh, University of Oxford, Oxford, United Kingdom, Abheek Ghosh, Tzeh Yuan Neoh, Giannis Tyrovolas

We study a model of subscription-based platforms where users pay a fixed fee for unlimited access to content, and creators receive a share of the revenue. Existing approaches to detecting fraud predominantly rely on machine learning methods, engaging in an ongoing arms race with bad actors. We explore revenue division mechanisms that inherently disincentivize manipulation. We formalize three types of manipulation-resistance axioms and examine which existing rules satisfy these. We show that a mechanism widely used by streaming platforms, not only fails to prevent fraud, but also makes detecting manipulation computationally intractable. We also introduce a novel rule, ScaledUserProp, that satisfies all three manipulation-resistance axioms. Finally, experiments with both real-world and synthetic streaming data support ScaledUserProp as a fairer alternative compared to existing rules.

3 - Balancing Transparency and Efficiency: the Role of Explainable AI in Multi-Sided Logistics Platforms

Wei Ziyi, Southeast University, Nanjing, China, People's Republic of

With the growing integration of Artificial Intelligence (AI) in modern logistics platforms, AI-driven algorithms are increasingly responsible for core operational decisions such as order allocation, route optimization, and merchant recommendations. While these systems enhance operational efficiency, their opaque “black-box” nature often undermines user trust, raising concerns among merchants and consumers regarding fairness and decision legitimacy. Explainable AI (XAI) emerges as a potential solution by providing transparent insights into algorithmic decisions. However, existing literature predominantly focuses on duopoly market structures, overlooking the complex multi-sided interactions inherent in platform ecosystems.

This study extends the analysis of XAI to a triadic platform environment involving the platform, merchants, and consumers. We develop a multi-stage game-theoretic model where the platform strategically chooses its level of XAI transparency. The model evaluates how different transparency strategies influence stakeholder behaviors, trust, and overall welfare. Furthermore, we assess the implications of regulatory interventions aimed at mandating XAI levels. Our findings suggest that full transparency may not always be socially optimal; instead, a flexible regulatory framework that accommodates platform heterogeneity and interaction dynamics may yield superior outcomes. The study contributes to both the theoretical understanding of XAI in platform economies and the practical design of governance mechanisms in algorithmic decision-making environments.

4 - When Transparency Talks: Explainability in Human-AI Hybrid Decision-Making on Crowdfunding Platforms

Saunak Basu, University of Nevada Las Vegas (UNLV), Las Vegas, NV, United States, Ashmita Biswas

The increasing integration of artificial intelligence (AI) into digital platforms has transformed how users evaluate complex decisions, especially in high-stakes environments like healthcare crowdfunding. While AI can enhance predictive accuracy, its black-box nature can undermine trust and user agency. This study examines whether *explainability* in AI recommendations fosters more effective human-AI collaboration, influencing donor decision-making and campaign success on medical crowdfunding platforms.

Using a unique field dataset from a global healthcare crowdfunding site, coupled with a natural experiment involving the staged rollout of explainable AI (XAI) modules, we employ a difference-in-differences identification strategy to measure causal effects on donor engagement, campaign funding velocity, and donor retention. We further test heterogeneity by sentiment in campaign imagery and narrative language complexity, linking to prior work on visual persuasion.

Our findings provide robust empirical evidence that XAI boosts donor trust and funding participation, particularly in campaigns with emotionally ambiguous narratives. Contrary to expectations, the effect is *stronger* in low-literacy regions, suggesting that transparency—not just accuracy—can democratize digital philanthropy.

We highlight our contribution by foregrounding the behavioral impacts of AI explainability in hybrid decision settings and by highlighting its potential to reduce inequities in digital access. Our work offers actionable insights for platform designers seeking to optimize human-AI interfaces for transparency, fairness, and engagement.

5 - AI and the Extended Workday: Productivity, Contracting Efficiency, and Distribution of Rents

Junyoung Park, Auburn University, Auburn, AL, United States, Wei Jiang, Rachel Xiao, Shen Zhang

This study investigates how occupational AI exposure impacts employment at the intensive margin, i.e., the length of workdays and the allocation of time between work and leisure. Drawing on individual-level time diary data from 2004–2023, we find that higher AI exposure—whether stemming from the ChatGPT shock or broader AI evolution—is associated with longer work hours and reduced leisure time, primarily due to AI complementing human labor rather than replacing it. This effect is particularly pronounced in contexts where AI significantly enhances marginal productivity and monitoring efficiency. It is further amplified in competitive labor and product markets, where workers have limited bargaining power to retain the benefits of productivity gains, which are often captured by consumers or firms instead. The findings question the expectation that technological advancements alleviate human labor burdens, revealing instead a paradox where such progresses compromise work-life balance.

6 - Congestion Games with Dueling Preference Feedback: Equilibrium, Learning, and Provable Efficiency

Yunian Pan, New York University, BROOKLYN, NY, United States, Quanyan Zhu

We propose a new class of congestion games driven by pairwise preference feedback rather than scalar cost functions. Motivated by limitations of classical Wardrop models in capturing complex user behavior, we define the *Borda Wardrop Equilibrium* (BWE) as the equilibrium condition where traffic flows align with Borda-aggregated ordinal preferences. We show that BWE arises as the minimizer of a convex *Borda-Beckmann potential*, generalizing classical potential function arguments for congestion games. We further design an online learning algorithm based on dueling feedback, which achieves $\mathcal{O}(T^{2/3})$ regret and provable convergence to BWE in the large-population limit. Our results establish structural properties of preference-driven congestion games, extend potential game theory to ordinal settings, and demonstrate efficient learning under minimal informational assumptions. This work provides a mathematical foundation for studying non-cost-based congestion phenomena under human-in-the-loop dynamics.

7 - From Black Box to Transparency: Experimental Evidence on the Role of AI Explainability in Shaping Clinicians Perceptions

Olya Rezaeian, Stevens Institute of Technology, Hoboken, NJ, United States, Onur Asan, A. Emrah Bayrak

In recent years, explainability has emerged as a critical factor influencing the adoption and effectiveness of AI-based Clinical Decision Support Systems (CDSS) in healthcare. This mixed-methods study investigates how varying levels of AI explainability affect clinicians' trust, diagnostic performance, and perception in the context of

breast cancer diagnosis. We conducted a human-subject experiment using a custom-built web-based AI system that delivered diagnostic suggestions. Quantitative data were collected from 28 clinicians. To further explore clinicians' interpretations and expectations, semi-structured interviews were conducted and analyzed using thematic analysis. The findings indicate that increasing levels of explanation do not consistently improve clinicians' trust or diagnostic accuracy. High AI confidence scores substantially increased trust but also led to overreliance, ultimately reducing diagnostic performance. In contrast, low confidence scores decreased trust and agreement while increasing the time spent on decisions, reflecting more cautious behavior. Certain explainability features were linked to higher cognitive load and stress. Additionally, demographic factors such as age, gender, and professional role influenced how participants perceived and interacted with the system. Notably, some clinicians exhibited trust in the AI even when it was incorrect, highlighting the complex and sometimes counterintuitive effects of explainability. Qualitative findings revealed clinicians' desire for explanations that are transparent, actionable, and aligned with their clinical reasoning. These results emphasize the need for explainable AI systems that not only inform but also support human decision-making in contextually meaningful ways.

1 - CrowdLLM: a Synthetic Crowd Simulator for Crowdsourcing with LLM Workers Augmented with Lightweight Generative Models

Feng (Ryan) LIN, University of Washington, Seattle, WA, United States, Hanming Zheng, Keyu Tian, Congjing Zhang, Li Zeng, Shuai Huang

LLMs have sparked extensive interest to create synthetic crowds in human decision-making tasks. Using crowdsourcing as a testbed, we propose the CrowdLLM framework that can simultaneously enhance the accuracy and diversity of the collective decision-making outcomes by leveraging pretrained LLMs and generative models.

2 - Scalable First-Order Method for Certifying Optimal K-Sparse GLMs

Jiachang Liu, Cornell University, Ithaca, NY, United States, Soroosh Shafiee, Andrea Lodi

This paper addresses certifying optimality for sparse GLMs using a novel first-order proximal gradient algorithm. Our method solves the perspective relaxation within a branch-and-bound framework, offering linear convergence and GPU compatibility. It significantly accelerates dual bound computations and provides effective optimality certificates for large-scale problems, enhancing model interpretability and trustworthiness.

3 - Domain-Informed Reinforcement Learning for Multi-Component Preventive Maintenance Planning Under Economic Dependence

Jaesung Lee, Texas A&M University, College Station, TX, United States, Tatthapong Srikitrungruanga, Salman Jahani

We propose a domain-informed reinforcement learning framework for preventive maintenance and inspection planning in multi-component systems with stochastic degradation and economic dependence. By integrating hierarchical policies, monotonicity constraints, and Bayesian degradation models, our method addresses vast continuous state-action space challenges. Numerical and case studies validate substantial outperformance over existing methods.

4 - Physics-Augmented Multi-Task Gaussian Process for Modeling Spatiotemporal Dynamics

Xizhuo Zhang, The University of Tennessee, Knoxville, TN, United States, Bing Yao

Modeling high-dimensional spatiotemporal data is challenging due to complex geometries and variable interdependence. We propose a physics-augmented multi-task Gaussian Process (P-M-GP) that integrates geometry-aware modeling, inter-task learning, and physics-based regularization. P-M-GP achieves superior performance over data-driven approaches when applied to cardiac electrodynamic modeling.

1 - Dynamic Calibration of Digital Twin via Stochastic Simulation: a Wind Energy Case Study

Yongseok Jeon, North Carolina State University, Raleigh, NC, United States, Sara Shashaani, Eunshin Byon, Pranav Jain

This study presents an approach to dynamically calibrating a digital twin to support decision-making in systems operating under uncertainty. The framework integrates uncertainty by turning a physics-based model into a stochastic simulation, where independent variables that represent the environmental conditions may be nonstationary whereas target variables are conditionally stationary. The calibration task itself is formulated as a simulation optimization problem that we solve using a root-finding strategy. As a case study, we apply the suggested framework to the prediction of short-term power deficit, known as the wake effect, in wind farms using real-world data and demonstrate the robustness of the proposed framework. Besides advancing digital twin research, the presented methodology contributes to wind farm wake steering strategy by enabling accurate short-term wake effect prediction.

2 - Bll-Pinn: Bayesian Last-Layer Physics-Informed Neural Networks for Uncertainty Quantification in Forward and Inverse Problems

Sina Aghaee Dabaghan Fard, Texas A&M University, College Station, TX, United States, Jaesung Lee

Physics-Informed Neural Networks (PINNs) incorporate known physical laws, typically expressed as partial differential equations (PDEs), directly into the training process of deep neural networks. Conventional PINNs produce only point estimates and lack mechanisms for uncertainty quantification, which limits their applicability in settings where knowing model confidence is crucial, such as safety-critical or risk-sensitive situations. Methods such as Bayesian PINNs (B-PINNs) try to address this limitation by applying Bayesian inference across all network layers to model uncertainty. However, a fully Bayesian treatment is often computationally expensive, analytically intractable, and challenging to scale. We propose a Bayesian Last-Layer PINN (BLL-PINN) for solving forward and inverse problems governed by PDEs under uncertainty. By applying a Bayesian prior only to the last layer, BLL-PINN yields an analytically tractable posterior predictive distribution, ensuring uncertainty quantification for both aleatoric and epistemic noise sources. BLL-PINN is a faster yet effective alternative to B-PINN, maintaining scalability and uncertainty quantification without compromising predictive performance. We evaluate BLL-PINN on a range of benchmark problems and compare its performance with state-of-the-art models. Our experiments demonstrate that BLL-PINN achieves competitive predictive accuracy while delivering well-calibrated uncertainty estimates.

3 - Learning Across Machines: Bayesian Meta-Learning for Transferable Process Optimization in Manufacturing

Aditya Satish Rane, Oklahoma State University, Stillwater, OK, United States, Srikanthan Ramesh, Akash Deep

Manufacturing process optimization presents a significant challenge in modern industrial settings, where each machine shows unique operational characteristics despite being manufactured to the same specifications. Traditional optimization approaches optimize each machine independently, resulting in inefficient historical data utilization and prolonged convergence times.

We propose a Bayesian meta-learning framework that enables knowledge transfer across manufacturing machines to accelerate process optimization. Our approach learns shared inductive biases from datasets collected across multiple machines while adapting to new machines with minimal initial experimentation. By leveraging PAC-Bayesian theory, we develop a principled approach for knowledge transfer across machines. The framework employs Gaussian processes as base learners to model complex, non-linear relationships between process parameters and quality metrics, while maintaining crucial uncertainty quantification through Bayesian optimization.

We validate our approach on both synthetic examples and a real-world case study involving FDM-based additive manufacturing and finite element analysis, demonstrating rapid optimization of new setup by utilizing prior experimental data, thus reducing the need to start from scratch each time.

4 - High-Resolution Elasticity Map Estimation from Noisy, Low-Resolution Measurements: An Integrated Inverse Physics-Informed Machine Learning Approach

Tatthapong Srikitrungruang, Texas A&M university, College station, TX, United States, Jaesung Lee

Estimating spatially heterogeneous elasticity maps from low-resolution measurements remains a significant challenge in inverse elasticity problems. Additionally, the presence of substantial measurement noise further exacerbates the complexity. Existing inverse estimation methods typically require high-fidelity data and are highly sensitive to noise. This work presents an integrated Physics-Informed Machine Learning (PIML) framework that fuses spline-based data-driven methods with governing physical laws to robustly reconstruct heterogeneous elasticity distributions, including Young's modulus and Poisson's ratio. The integration of spline methods enhances spatial representation within the PIML framework, enabling effective handling of low-fidelity data. To address measurement uncertainty, we employ a statistical approach based on maximum likelihood estimation to quantify the impact of measurement noise. This advancement holds significant potential for clinical imaging diagnostics and in-situ mechanical characterization. Validation is conducted using simulated two-dimensional displacement data from mechanical testing. The results demonstrate strong robustness to noise and accurate predictions across various data resolutions.

1 - Development of a Robust Tool Wear Prediction Method Under Novel Operating Conditions Using Deep Unsupervised Domain Adaptation and Physics-Guided Adjustment

Gyeongho Kim, Ulsan National Institute of Science and Technology (UNIST), Ulsan, Korea, Republic of, Sang Min Yang, Sujin Jeon, Soyeon Park, Jae Gyeong Choi, Hyung Wook Park, Sunghoon Lim

Data-driven tool wear prediction has become essential in manufacturing as it improves quality and productivity via precise real-time prognosis on machining tool conditions that enable efficient tool utilization and prevent unexpected machining downtime. However, existing tool condition monitoring (TCM) approaches face critical limitations in real-world practice due to frequent changes in operating conditions that cause data distribution shifts (i.e., domain shifts), which make trained models obsolete under novel operating conditions. In addition, since ground-truth tool wear measurements require considerable costs and domain expertise, obtaining labeled data under novel operating conditions is impractical. Given the abovementioned difficulties, this work proposes a deep unsupervised domain adaptation (DA) method with three novel techniques to perform robust tool wear prediction under novel operating conditions. First, inverse Gramian subspace matching (IGSM) is proposed to reduce distribution discrepancy between two different domains by aligning subspaces of inverse Gramians without using labeled samples from novel operating conditions. Second, a pseudo label-based pairwise regularization (PLPR) is developed to transfer informative knowledge regarding tool wear progression to novel operating conditions. Third, a physics-guided adjustment (PGA) is applied during inference to calibrate predictions on unseen tool wear ranges unobserved during training to provide physics-compliant results. Comprehensive experimental results using a real-world milling dataset under various domain shift scenarios demonstrate the proposed method's efficacy in tool wear prediction under novel operating conditions. The proposed method consistently outperforms existing baseline, state-of-the-art DA regression, and state-of-the-art DA-based TCM approaches, indicating its practical effectiveness.

2 - A Feature Fusion Method Using Adjacent-Parameter Ratios for Latent Defect Chip Detection in Semiconductor Fabrication

Young Mok Bae, POSTECH, Pohang, Korea, Republic of, Kwang-Jae Kim

Latent defect chips in semiconductor fabrication present critical product quality and manufacturing efficiency challenges. These latent defect chips exhibit electrical characteristics similar to good chips during the wafer test but fail early during subsequent back-end processes or customer usage. Traditional detection approaches relied on adjusting test voltages based on engineers' subjective judgments. In contrast, recent approaches have shifted toward data-centric methods utilizing electrical parameters collected from the wafer test. As wafer tests have become increasingly complex and detailed, wafer test data volumes have expanded. At the same time, relationships between parameters have gained critical importance for detection performance. In other words, adjacent test parameters contain complementary information that becomes more informative when analyzed as ratios rather than absolute parameter values. Basic classifiers applicable to latent defect chip detection struggle to identify these parameter relationships. The proposed feature fusion method addresses these challenges by deriving electrical parameter ratios and integrating them with raw parameters through a bidirectional cross-attention autoencoder. The autoencoder architecture extracts fused features at configurable dimensions enriched by parameter relationships to enhance latent defect chip detection performance. Experiments on actual wafer test data demonstrate G-mean improvements of up to 6.23 percentage points across basic classifiers, even under strict dimensionality constraints. The domain-informed feature fusion enables test engineers to implement accurate latent defect chip detection with minimal disruption, facilitating proactive quality control and enhanced fabrication efficiency.

3 - Enhancing Reduced-Order Modeling in High-Dimensional Engineering Applications Through Hybrid Gradient Boosting Tree

Melika Baghi, Georgia Institute of Technology, Atlanta, GA, United States, Xiao Liu, Kamran Paynabar

High-fidelity simulations such as computational fluid dynamics (CFD) and finite element analysis (FEA) are essential for modeling complex engineering systems but remain prohibitively expensive for many-query tasks including parametric studies, optimization, and real-time control. Projection-based reduced-order models (ROMs), most often constructed via Proper Orthogonal Decomposition (POD), alleviate this cost by projecting full-order dynamics onto low-dimensional subspaces. However, conventional POD-Galerkin ROMs can lose accuracy under parameter variation, struggle in nonlinear or discontinuous regimes, and lack mechanisms to preserve geometric structure or quantify predictive uncertainty.

This work introduces a hybrid framework that integrates Gradient Boosting Trees (GBT) with a geometry-preserving embedding of POD subspaces on the Grassmann manifold. A smooth, injective mapping from the manifold to a compact Euclidean space enables efficient GBT regression while maintaining the intrinsic geometry of the bases, and a norm-constrained ensemble training strategy enforces orthonormality and injectivity in predictions.

Validation on two benchmark problems on unsteady viscous flow past a cylinder and compressible shock tube dynamics demonstrates that the proposed method outperforms interpolation-based ROMs, achieving higher accuracy and robust generalization across nonlinear parameter spaces. These results show that combining geometric learning with ensemble regression offers a scalable, interpretable, and physically consistent pathway for reduced-order modeling in high-dimensional, parameter-varying PDE systems.

4 - Modeling of Shape Populations in Manufacturing: An Expectation-Maximization Approach on Riemannian Manifolds

Rifat Hasan, Florida A&M University, Florida State University (FAMU-FSU) College of Engineering, Tallahassee, FL, United States, Chiwoo Park, Arda Vanli

Geometrical forms of products serve as very important quality characteristics in advanced manufacturing, e.g., geometries of 3D printed products and morphology of nano-manufactured products. Quantifying the distribution of product's geometrical forms is critical for assessing both product quality and process variation associated with manufacturing processes. In this study, we propose a new statistical model to characterize the probability distribution of geometric forms in two dimensions. Based on the Riemannian geometry, we define an appropriate space of shapes and proper metric over the space. On the metric space, we model a Gaussian-type distribution and a mixture of the distributions. We have also introduced the multimodality of shapes in the mixture of the distributions. We also present the EM-type algorithm to infer the distribution with a finite number of shape samples from processes. The numerical results of the algorithm are presented with simulation cases and applications to modeling the shape distribution of nanoproducts.

5 - Grid-Scale Battery Life Prediction Using Equivalent Circuit and Particle-Filtered Stochastic Modeling

Krishna Rijal, University of South Florida, Tampa, FL, United States, Mingyang Li, Tapas Das

Increasing penetration of renewables and decreasing cost of lithium-ion batteries make large-scale battery energy storage systems (BESS) a promising solution for supporting grid balance and reliability, and a resource for arbitrage. This is evident from the increasing number of BESS that are either being installed or planned. However, battery systems suffer from degradation from usage, significantly impacting their performance over time. Proper characterization of battery degradation and accurate prediction of the remaining useful life of BESS components are ongoing issues that are yet to be fully addressed. These issues are of critical interest to the BESS operators, whose primary goal is to ensure effective and reliable operation of the system. We propose a new methodology for online detection of battery degradation and prediction of the remaining life using an equivalent electrical circuit model. The circuit parameters are identified and filtered, and with this information, a random process mimicking battery health progression is simulated. The simulation results provide estimates of the first hitting time and the mean hitting time to reach the battery life threshold.

6 - Sensor Placement for Anomaly Detection in Large Scale Networks Under Limited Budget

Feiran Xu, University of Iowa, Iowa City, IA, United States

As large-scale graph-structured systems become increasingly common, maintaining their stability and reliability is critical. A major challenge lies in promptly detecting anomalous nodes and tracing the origins of disturbances. While real-time sensor data from within the network can aid in this process, deploying sensors at every node is often impractical due to cost and logistical constraints. This makes the strategic placement of a limited number of sensors essential for maximizing system observability. In this work, we propose a novel cluster-based framework for selecting optimal sensor locations to support anomaly detection in large networks. Through a series of data-driven experiments, we demonstrate that our approach effectively enhances network observability while operating within budget limitations.

7 - Mechanism-Aware Validation of Data-Driven Cardiovascular Phenotypes in Obstructive Sleep Apnea Using Structural Equation Modeling

Viet Nguyen Ca Hoang, University of South Florida, Tampa, FL, United States, Khanh Do, Phat Huynh, Abhay Sharma, Trung Le

Obstructive Sleep Apnea (OSA) is associated with elevated cardiovascular disease (CVD) risk, yet existing risk models often overlook underlying phenotypic heterogeneity driven by distinct risk pathways. We propose a hybrid modeling framework that integrates outcome-guided feature selection, unsupervised clustering, and structural equation modeling (SEM) to identify and clinically validate OSA-CVD phenotypes.

Using data from 633 patients with 121 multimodal features spanning polysomnographic, clinical, and biomarker domains, we first apply outcome-specific models targeting major adverse cardiac events (MACEs) and apnea-hypopnea index to extract features predictive of CVD and OSA severity. These features are used in hierarchical clustering, evaluated by 5-fold stratified train/validation splits, internal clustering metrics, and external MACE associations.

To clinically validate these data-driven phenotypes, we construct domain-informed SEMs reflecting hypothesized OSA-CVD pathways (e.g., sleep disruption to inflammation to CVD) and test for multi-group path invariance. Unlike conventional phenotyping approach, our framework enables formal hypothesis testing of biological mechanisms underlying observed subgroups. SEM complexity is constrained by a sample-size-to-parameter ratio $\geq 10:1$.

Preliminary findings suggest at least three distinct phenotype clusters with differential CVD risk profiles. We also report bootstrapped confidence intervals for MACE odds ratios across clusters. This approach enables both quantitative validation (via model fit, path invariance, and outcome prediction) and qualitative assessment grounded in clinical understanding.

This mechanism-aware pipeline facilitates interpretable phenotype discovery and generalizes to other multimorbid conditions with known mechanisms and multimodal data. By uncovering phenotype-specific pathways, it may inform targeted treatments, support earlier risk stratification than outcome-based methods, and improve personalized CVD care in OSA.

Behavioral Operations Management

Chair: Chenshan Hu, Washington University in St. Louis, Saint Louis, MO, United States

1 - How a Study of Wait Utility Became a Study of Presentation Format: People Chose Queues over Clocks, 80&Ndash;20

Blair Flicker, University of South Carolina, Columbia, SC, United States

Customer utility depends on wait characteristics, which are shaped by the decisions of system designers. To inform these decisions, we examine how four fundamental wait attributes—average duration, variability, reward for completion, and line length—affect utility and reveal the overlooked role of wait presentation. Specifically, we measure how customer behavior responds to changes in wait format (traditional Queues vs. countdown Clocks) and in the amount of information disclosed (average duration, variability, or no information at all). Study 1 employs conjoint analysis, incentivized with a real wait, to estimate the relative magnitudes of utility across fundamental wait attributes. People dislike long and variable waits and value large rewards for completion. Between presentation schemes, participants behave as though their waiting cost is approximately twice as high when waits are presented as Clocks rather than Queues. Study 2 asks participants to estimate the duration of given waits; they underestimate mean durations by 20% when presented as Queues but estimate them accurately when presented as Clocks. Study 3 asks participants to choose which wait they will endure in real time between two equivalent waits that differ only in presentation format. Nearly 80% prefer the Queue to the Clock, consistent with the model-based prediction from Study 1. This research highlights an underappreciated managerial lever: presentation format. It can reduce disutility without requiring operational redesign.

2 - Pricing and Addiction Control for Digital Services

Xiao Lei, University of Hong Kong, Hong Kong, Hong Kong

The rising use of digital services like video games and video platforms has led to concerns about digital addiction. Unlike traditional addictive goods, these services often use personalized, engagement-based pricing and offer highly varied user experiences. While empirical and behavioral research on digital addiction is growing, a theoretical understanding of how pricing and policies influence addiction is lacking. This study provides the first analytical model of pricing strategies and control measures for addictive digital services, aiming to guide firms and policymakers in addressing addiction without sacrificing profitability. Using dynamic programming to model habit-forming user behavior, we characterize and compare optimal fixed and dynamic pricing. Our findings show that dynamic pricing not only increases profits but also reduces long-term addiction, creating a win-win scenario. One-time new-user promotions, while initially increasing addiction, lead to a net reduction over time. We also evaluate three addiction control policies: consumption limits, price floors, and consumption taxes. The analysis of their profit-addiction efficiency reveals that a consumption limit or tax is most effective, with the variation in user experience being a key determining factor. A numerical case study demonstrates that, compared to fixed pricing, dynamic pricing alone can increase profit by 3.07-3.73% while reducing addiction by 1.31%. When combined with additional controls, it can achieve a 20.65-22.16% reduction in addiction with no profit loss.

3 - Biases of Humans, of AI, and of Humans with Ai

Anton Ovchinnikov, Smith School of Business, Queen's University, Kingston, ON, Canada

Prior research examined whether modern AIs—such as large language models (LLMs) like ChatGPT—are themselves biased. This paper asks a deeper question: how do human decision biases evolve when people interact with biased or unbiased LLMs? We introduce a novel interactive AI experimental paradigm in which human participants complete decision tasks under four conditions: alone, with a human-like AI, an unbiased AI, or with an AI deliberately calibrated to differ in bias. We test this framework across three canonical behavioral operations biases. The results show: (1) AI bias measurably shifts human decision patterns, amplifying or attenuating human bias depending on the AI's stance; (2) a previously undocumented "agentic nudging" effect, in which controlled system prompts steer human choices in predictable directions; and (3) a refined account of algorithm aversion: that the human-AI interaction—not generic distrust of AI—determines collaboration outcomes, either improving or degrading performance.

4 - Video-Based AI Misconduct Monitoring: Unintended Consequences on Operational Outcomes

Zhanzhi Zheng, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Employee misconduct presents ongoing challenges for organizations, yet traditional monitoring methods, such as CCTV, are largely reactive and offer little chance for timely intervention. Recent advances in computer vision and edge computing have enabled AI-enhanced video monitoring systems capable of detecting misconduct in real time and providing immediate feedback—an innovation not previously feasible. Despite its growing adoption, the operational implications of this technology remain underexplored.

Using a unique dataset from a restaurant chain that implemented video-based AI misconduct monitoring, we examine the effects of real-time feedback on organizational performance. Contrary to expectations, we find that deploying this technology significantly reduces performance, as measured by revenue and customer ratings. Further analysis reveals that this effect is primarily driven by high-quality restaurants, while lower-quality restaurants may experience potential improvement.

We also show that the type of feedback matters: individual-focused feedback (e.g., uniform violations) intensifies negative effects, whereas process-focused feedback (e.g., unattended cashier stations) mitigates performance declines.

Our findings highlight the unintended consequences of adopting advanced AI surveillance systems and emphasize the importance of organizational context and feedback design. By illustrating how real-time monitoring can produce counterintuitive outcomes, this study offers new managerial insights into the complex relationship between AI adoption, employee behavior, and operational performance.

Decision-Making with Generative AI

Invited Session

Artificial Intelligence

Chair: Yan Leng, University of Texas at Austin

Co-Chair: Leqi Liu, Carnegie Mellon University, Pittsburgh, PA, United States

1 - Leveraging Large Language Models for Collective Decision-Making

Marios Papachristou, Cornell University, Ithaca, NY, United States, Longqi Yang, Chin-Chia Hsu

In various work contexts, such as meeting scheduling, collaborating, and project planning, collective decision-making is essential but often challenging due to diverse individual preferences, varying work focuses, and power dynamics among members. To address this, we propose a system leveraging Large Language Models (LLMs) to facilitate group decision-making by managing conversations and balancing preferences among individuals. Our system aims to extract individual preferences from each member's conversation with the system and suggest options that satisfy the preferences of the members. We specifically apply this system to corporate meeting scheduling. We create synthetic employee profiles and simulate conversations at scale, leveraging LLMs to evaluate the system performance as a novel approach to conducting a user study. Our results indicate efficient coordination with reduced interactions between the members and the LLM-based system. The system refines and improves its proposed options over time, ensuring that many of the members' individual preferences are satisfied in an equitable way. Finally, we conduct a survey study involving human participants to assess our system's ability to aggregate preferences and reasoning about them. Our findings show that the system exhibits strong performance in both dimensions.

2 - Dbot: Artificial Intelligence for Systematic Long-Term Investing

João Sedoc, New York University, New York, NY, United States, Vasant Dhar

Long-term investing was previously seen as requiring human judgment. With the advent of generative artificial intelligence (AI) systems, automated systematic long-term investing is now feasible. In this paper, we present DBOT, a system whose goal is to reason about valuation like Aswath Damodaran, who is a unique expert in the investment arena in terms of having published thousands of valuations on companies in addition to his numerous writings on the topic, which provide ready training data for an AI system. DBOT can value any publicly traded company. DBOT can also be back-tested, making its behavior and performance amenable to scientific inquiry. We compare DBOT to its analytic parent, Damodaran, and highlight the research challenges involved in raising its current capability to that of Damodaran's. Finally, we examine the implications of DBOT-like AI agents for the financial industry, especially how they will impact the role of human analysts in valuation.

3 - The Habermas Machine: AI-Mediated Systems for Collective Human Decision Making

Michiel Bakker, MIT, Boston, MA, United States

As AI systems become more powerful, there is an urgent need for new systems and institutions that support collective human oversight and decision making. We present a set of AI-mediated systems that combine human input with large language models to help communities deliberate, resolve disagreements, and make accurate collective judgments. These systems, presented in NeurIPS and Science scale democratic processes through model-assisted deliberation, collective fact-checking and oversight of AI systems. First, we introduce the "Habermas Machine", which refines group statements based on participants' opinions and critiques. In a preregistered study (N = 5,734), participants preferred AI-mediated statements over those written by human mediators and often updated their own views. These results were replicated in a demographically representative citizens' assembly. Second, we extend the approach to Community Notes-style fact-checking systems, using LLMs and reward models to synthesize diverse viewpoints into helpful explanatory notes. Finally, we propose methods to align incentives: LLM aggregators use crowd-submitted rationales to form

predictions and distribute rewards based on marginal value. Together, these systems demonstrate how LLMs can support scalable, pluralistic oversight in high-stakes domains.

4 - Active Exploration via Autoregressive Generation of Missing Data

Tzu-Ching Yen, Columbia University, New York, NY, United States

We pose uncertainty quantification and exploration in online decision-making as a problem of training and generation from an autoregressive sequence model, an area experiencing rapid innovation. Our approach rests on viewing uncertainty as arising from missing future outcomes that would be revealed through appropriate action choices, rather than from unobservable latent parameters of the environment. This reformulation aligns naturally with modern machine learning capabilities: we can i) train generative models through next-outcome prediction rather than fit explicit priors, ii) assess uncertainty through autoregressive generation rather than parameter sampling, and iii) adapt to new information through in-context learning rather than explicit posterior updating. To showcase these ideas, we formulate a challenging meta-bandit problem where effective performance requires leveraging unstructured prior information (like text features) while exploring judiciously to resolve key remaining uncertainties. We validate our approach through both theory and experiments. Our theory establishes a reduction, showing success at offline next-outcome prediction translates to reliable online uncertainty quantification and decision-making, even with strategically collected data. Semi-synthetic experiments show our insights bear out in a news-article recommendation task, where article text can be leveraged to minimize exploration.

5 - Tell Me Why: Incentivizing Explanations

Siddarth Srinivasan, Harvard University, Cambridge, MA, United States, Ezra Karger, Michiel Bakker, Yiling Chen

Effective human-AI collaboration requires mechanisms that incentivize truthful, informative contributions, especially when interactions occur through natural language. We introduce a novel collective intelligence mechanism inspired by prediction markets. Unlike traditional prediction markets which primarily elicit numerical forecasts, our mechanism elicits human-generated natural-language *explanations* for beliefs. We formally show that this mechanism is incentive-compatible, meaning providing honest and informative explanations constitutes a Bayesian Nash equilibrium under our design.

A simple instantiation of this mechanism involves participants submitting natural-language rationales responding to a question posed by a mechanism designer (e.g., predictions about policy outcomes or future events). A large language model (LLM) supervisor assesses each rationale, updates its internal beliefs accordingly, and maintains a collaboratively updated wiki-style resource. Contributors receive rewards proportional to how significantly their rationales alter the LLM's beliefs towards some eventually-revealed reference answer.

We focus on applying our mechanism to judgmental forecasting tasks in particular, where experts make forecasts about uncertain future events to aid decision-making. Forecasting provides a clear decision-making application as the outcome of future events offer objective ground truth resolution for evaluating rationales.

Optimization Models for University Operations

Invited Session

INFORMS Committee on Teaching and Learning

Chair: Richard Forrester, Dickinson College, Carlisle, PA, United States

Co-Chair: Lucas Waddell, Bucknell University, Lewisburg, PA, United States

1 - Assigning Faculty in University Committee Service

Liz Bouzarth, Furman University, Greenville, SC, United States, Chelsea Alford, Ben Grannan, Kevin Hutson, Ella Morton

Institutional expectations regarding faculty service vary, but at many schools, faculty members are expected to serve in various roles outside of teaching and research. This often leads to real or perceived differences in service load through both official and unofficial duties like advising, recruiting, departmental service, university committee service, and service to the profession beyond the institution. This talk provides a case study of an integer programming model built to help assign faculty to standing committee service at Furman University based on optimizing faculty preferences while meeting constitutional committee requirements. The annual task of assigning faculty to openings on university committees had previously been done manually, but the use of the integer programming formulation has helped seed the committee's work in creating the annual committee slate for the past five years. Observations regarding service equity will be shared and generalized.

2 - Building a Framework to Schedule Courses at Community Colleges Based on Student Success by Using Binary Integer Programming

Fabio Vitor, University of Nebraska at Omaha, Omaha, NE, United States, Joseph Bonacci

Community colleges play a vital role in the U.S. higher education system by offering both technical training and pathways to bachelor's degrees. These institutions are crucial in shaping the current and future workforce. One notable feature of community colleges is their flexible scheduling, which is designed to accommodate students' varying needs. Effective scheduling practices are essential to ensure accessibility and success for all students. To address this, it is important to consider several factors when scheduling courses, though balancing these factors can be challenging, particularly for departments with limited resources. This talk will discuss an optimization framework for scheduling courses at community colleges with a focus on enhancing student success. The model employs binary integer programming and addresses key elements that contribute to student success, including course frequency and timing, delivery modes (in-person, online, and hybrid), instructor preferences and workloads, integration of high school students, room and technology appropriateness, and co-taught courses. The model is applied and evaluated using data from the Mathematics Department at a community college in Iowa. This optimization framework has the potential to assist community colleges in creating schedules that not only promote student success but also further their goals of accessibility and equity.

3 - Optimizing Final Exam Schedules at Bucknell University

Lucas Waddell, Bucknell University, Lewisburg, PA, United States, Samuel Gutekunst, Thiago Serra, Clara Chaplin, Stanley Gai, Tsugunobu Miyake, Luke Snyder, Vy Tran

This talk will introduce an interdisciplinary undergraduate research project concerning the creation of optimized final exam schedules at Bucknell University. This project, which involves data visualization, integer programming, and web-app development, resulted in an open-source tool that has been used by the Bucknell Registrar's office to schedule final exams since the Spring 2024 semester.

4 - The First-Year Seminar Assignment Problem: a Multi-Objective Optimization Approach

Richard Forrester, Dickinson College, Carlisle, PA, United States

Like many colleges, Dickinson College uses first-year seminars to help students transition into college-level work through writing, research, and discussion. Students rank their top seminar choices from a diverse list, and the college assigns them to seminars with the dual objectives of honoring individual preferences and maintaining diversity within each seminar. While students prefer placement in one of their higher-ranked seminars, faculty aim to ensure that seminar demographics are roughly representative of the entire student body, creating a microcosm of the college. In this talk, we describe a student-faculty research project focused on navigating the trade-offs inherent in seminar assignments by modeling the problem as a multi-objective optimization task. This work demonstrates how mathematical modeling can support institutional decision-making while providing meaningful research experiences for undergraduate students.

Data Mining Best Paper Award

Award Session

Data Mining

Chair: Hadis Anahideh, University of Illinois Chicago, Chicago, IL, United States

1 - Supervised Clustered Interpretability: a Novel Method Towards Transparent AI with Social Good Implications

Matt Baucum, Oklahoma State University, Stillwater, OK, United States, Meysam Rabiee

This paper introduces clustered interpretability, a novel approach enhancing AI transparency and subgroup fairness. Our innovative Separation-Disparity (SD) metric, optimized via tailored particle swarm optimization (PSO), ensures robust subgroup homogeneity. Comprehensive validation using synthetic and real Parkinson's disease datasets demonstrates methodological soundness, practical effectiveness, and novel contributions to interpretable AI literature.

2 - Joint and Condition Modeling for High-Dimensional Aleatoric and Epistemic Uncertainty Quantification

Yongxiang Li, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Chunlin Ji, Dingwei Gong, Meiying Zhang, Terry Ma, Jun Liu

Uncertainty quantification is vital for modeling and decision-making. We propose a scalable approach that jointly models input-output distributions via Gaussian mixtures, enabling closed-form posterior inference. A Stiefel-constrained projection identifies low-dimensional features, optimized via Riemannian SGD. Our method captures aleatoric and epistemic uncertainties efficiently in high-dimensional, data-limited settings.

3 - First-Order Policy Optimization for Robust Policy Evaluation

Yan Li, Texas A&M University, College Station, TX, United States, Guanghui Lan

(Distributionally) robust reinforcement learning aims to learn policies resilient to environment shifts. Yet it is well known that existing methods using function approximation suffer from provable divergence. We resolve this open problem by developing the first robust policy evaluation framework that supports function approximation with provable global convergence, while attaining optimal iteration and sample complexities.

4 - Distribution-in-Distribution-Out Regression

Xiaoyu Chen, University at Buffalo, Buffalo, NY, United States, Yujing Huang, Xinwei Deng

A distribution-in-distribution-out (DIDO) regression is proposed and validated by defining arithmetic operations among probability distributions based on the differential geometry of pseudo Riemannian manifold. We show that the Fréchet least squares is the best linear unbiased estimator, building the foundation for estimation and inference when random objects are probability distributions.

1 - Automatic Melt Pool Tracking and Segmentation in Laser Powder Bed Fusion Using X-Ray Image Sequence

Ruiyuan Zhang, Virginia Tech, Blacksburg, VA, United States, Zhenyu Kong, Maede Maftouni, Jihoon Chung, Bo Shen, Rongxuan Wang, Andrew Law, Prahalada Rao

Laser powder bed fusion (LPBF) is one of the most extensively used techniques for metal additive manufacturing (AM). This process employs a laser to melt metal powder onto a substrate, creating a melt pool. The solid-liquid interface of the melt pool plays a critical role in determining the cooling process, which, in turn, influences the microstructure and the mechanical properties of the printed part. High-speed X-ray imaging has been utilized to study subsurface melt pool phenomena in real-time. However, segmenting the melt pool from X-ray images is challenging due to high noise levels and low contrast. Despite the widespread application of high-speed X-ray imaging, efficient data processing techniques remain underdeveloped. Researchers often rely on manual annotation or basic image processing techniques for object segmentation. These methods are either time-consuming or lack the necessary accuracy and robustness. This work presents a video object segmentation deep learning model to automatically track and segment the melt pool in X-ray image sequences. The proposed model is semi-supervised, requiring only the manual annotation of the melt pool boundary in the first frame to predict it for the subsequent frames. It incorporates spatio-temporal attention modules to effectively capture correlations in X-ray image sequences. Specifically, the co-attention block captures temporal features from the previous frame, while the attention block localizes the key regions within the current frame. Experimental results demonstrate that incorporating attention modules improves melt pool segmentation accuracy compared to existing state-of-the-art methods.

2 - Enhancing Surprise-Based Experimentation with Pointwise Mutual Information for Intelligent Manufacturing

Quan Zeng, Georgia Institute of Technology, Atlanta, GA, United States, Yu Ding, Yinsong Wang

We propose a decision-making framework that integrates pointwise mutual information (PMI) to guide autonomous experimentation. We incorporate PMI into both exploration and exploitation phases to enable informed and locally adaptive search behavior. PMI provides a localized view of the input-response landscape, helping the system identify regions with high expected information gain. We will discuss what differences the PMI guided policy can make.

3 - Privacy-Preserving Porosity Prediction Using Hierarchical Graph-Attention Networks in Laser-Based Additive Manufacturing

Mahathir Mohammad Bappy, Louisiana State University, Baton Rouge, LA, United States

Ensuring structural integrity in metal additive manufacturing (MAM) is critical for aerospace, biomedical, and defense applications where even microscopic defects (i.e., porosity) can lead to catastrophic failures. Porosity control in the LENS process is particularly vital, as internal pores compromise the mechanical strength of printed parts. However, traditional predictive models often struggle to capture the complex, layer-by-layer connectivity and nuanced relationships embedded in frame-level metadata, resulting in suboptimal porosity predictions. To address this challenge, we propose a Hierarchical Graph Attention Network (HGAT) that models intra-layer dependencies while preserving global context. The approach leverages a unified graph based representation of multimodal data, including process parameters and high resolution thermal imagery. Each melt-pool observation is treated as a node in the graph, with edges encoding spatial proximity through k-nearest neighbor connections. This structure enables the HGAT to extract intricate patterns that govern porosity formation. Recognizing the growing need for secure data sharing among distributed suppliers, we further integrate a Feature-Importance Local Differential Privacy mechanism. By applying importance-weighted Gaussian noise, our framework achieves (ϵ, δ) -LDP guarantees while maintaining critical feature fidelity. Evaluation on a public Ti-6Al 4V thin-wall dataset shows that the private HGAT achieves an F1 score of approximately 0.94 at $\epsilon = 1.0$, a performance drop of less than 2% compared to the non-private baseline ($F1 \approx 0.96$) while sustaining a balanced accuracy above 0.92 across various privacy settings. These findings highlight the feasibility of accurate, privacy-preserving porosity prediction, offering a viable path toward secure data exchange and quality assurance.

4 - End-2-End Resilience for Machine Tool Controller Against Cyberattacks

Shashank Galla, Texas A&M University, College Station, TX, United States, Abhishek Hanchate, Vaishnavi Garudkar, Yuhao Zhong, Satish Bukkapatnam

Cyberattacks on sensors and actuators are surging in manufacturing cyber-physical systems (CPS), mainly on machine tool controllers (MTCs). These attacks compromise product quality and disruption schedules. Manufacturing systems must ensure end-to-end resilience to address these threats, which requires fast detection, stable recovery,

and effective mitigation. We propose an integrated framework that combines Neural Network (NN)-based attack detection with Reinforcement Learning (RL)-based control for recovery and mitigation of MTCs under cyberattack scenarios. The framework's effectiveness is validated through two stepper-motor case studies: one in a digital-twin simulation and one with physical hardware. Our results confirm the framework's ability to detect attacks swiftly, maintain system stability, and minimize overall damage.

5 - Domain-Aware Denoising Diffusion Probabilistic Model with Class Conditioning for Melt Pool Minority Class Augmentation

Intiaz Ahmed, West Virginia University, Morgantown, WV, United States, Israt Zarin Era, Srinjoy Das, Zhichao Liu

Thermal imaging of melt pools in laser-based additive manufacturing presents a critical challenge in anomaly detection due to severe class imbalance, where normal instances vastly outnumber abnormal ones. This imbalance impairs the generalization ability of supervised classifiers. To address this, we propose a data augmentation framework using a Denoising Diffusion Probabilistic Model (DDPM) to synthesize high-fidelity thermal images for the minority class. The DDPM captures complex spatial and intensity patterns of melt pool dynamics through iterative noise-to-image denoising. We introduce two key innovations: (1) domain-aware spatial priors based on thermal intensity weighting to emphasize melt pool regions during training, and (2) class conditioning via a context encoder, which injects label-specific information into the bottleneck of the DDPM's U-Net backbone. The context encoder transforms discrete class labels into spatially aligned feature maps that guide the generative process by fusing with bottleneck features. This enables the model to generate class-specific thermal patterns while preserving local structure and physical fidelity.

Managing in Innovative Environments

Invited Session

Technology, Innovation Management and Entrepreneurship

Chair: John Angelis, University of Lynchburg, Lynchburg, VA, 24504, United States

Co-Chair: Juliana Hsuan, Copenhagen Business School, Frederiksberg, DK-2000, Denmark

1 - Organizational Learning and Ambidexterity in a Multi-Level, Multi-Generation, Multi-Phase Process Development Effort

Charles Weber, Portland State University, Portland, OR, United States, Timothy Anderson

A qualitative study of process development in the semiconductor manufacturing ecosystem reveals that organizational learning in this environment is multidimensional and presents the developers with severe ambidexterity challenges. Small teams of developers must concurrently develop constituent technologies for three process generations at three different stages of maturity and multiple levels of integration on the same pieces of equipment. Thus, the need to exploit comes in conflict with the need to explore. Overcoming the ambidexterity challenge involves making knowledge more explicit, as well as designing an organization whose structure exhibits fidelity with the knowledge it attempts to acquire.

2 - Using Genai as An Expert: a Study of Power Generation in Remote Locations

Mark Ryan, Portland State University, Beaverton, OR, United States, Charles Weber

A study of power generation in remote locations, which is based on the opinions of experts, finds that these experts may be hard to find. The study explores how GenAI can be used as an expert when human experts are scarce.

3 - The Effects of Personal Traits on Revisit Likelihood in Data Breaches

John Angelis, University of Lynchburg, Lynchburg, VA, United States, Rajendran Murthy

Data breaches are increasingly common events that undermine customer trust, disrupt consumer-firm relationships, and generate long-term reputational risks. Prior research has examined how consumers assign blame for breaches, how breach severity influences revisit intentions, and how emotional reactions such as fear or anger shape post-breach behaviors. Drawing on attribution theory, protection motivation theory, consumer ethnocentrism theory, justice theory, and risk perception theory, this study extends the "Better Angry than Afraid" emotional processing framework to investigate how personal traits and breach characteristics interact to influence post-breach decision-making.

Specifically, we explore the roles of ethnocentrism, political ideology (conservative vs. liberal), and the experience of multiple breaches from the same company in shaping revisit intentions. Using a scenario-based survey with a diverse sample of U.S. consumers, we manipulate breach recurrence and measure trait-level variables alongside demographic, educational, and behavioral factors, including cybersecurity knowledge and personality characteristics. By integrating perspectives from consumer behavior, political psychology, and information security, this research seeks to advance understanding of how individual predispositions, perceived fairness, and risk assessments jointly shape consumer responses, contributing to a more comprehensive framework for trust recovery and customer relationship management in the aftermath of data breaches.

4 - Tackling Decomposition and Dynamics of Innovation

Juliana Hsuan, Copenhagen Business School, Frederiksberg, Denmark

Decomposition is a process that can facilitate the breaking down of complex systems so standardization and innovation can be managed independently. As systems advance and grow for economies of scale and scope, the tradeoffs and nuances that arise from such process are not trivial. This paper explores how tradeoffs can be operationalized and measured.

5 - Leveraging Weighted Syntactic and Semantic Attention Summary (Ssas) Towards Text Categorization Using LLMs

Nitin Joglekar, Villanova School of Business, Villanova, PA, United States, Nitin Mayande, Sharookh Daruwalla, Shreeya Verma Kathuria, Charles Weber

Automatic summarization, a subfield of NLP, tackles the challenge of efficiently extracting key points from vast amounts of text. However, achieving accurate summaries requires models to go beyond simple word frequencies. Accurate summarization hinges on effectively bridging the gap between syntax and semantics. Our proposed methodology, Syntactic and Semantic Attention Summary (SSAS), uses a combined approach to provide a more nuanced understanding of the text by generating summaries that are not just grammatically sound but also semantically accurate. While SSAS does an excellent job in capturing the relevant information within large text data, the methodology can be improved. Weighting the data points is one such improvement - it provides a way to give a higher weight to information that is seen more frequently across the dataset while simultaneously pruning out less valuable information. This enables the summary generated from Weighted-SSAS (wSSAS) to be more representative of the main information contained in a dataset. One useful application of wSSAS-based summarization is data categorization. Data categorization enables bucketing individual datapoints into either pre-defined or auto-generated categories with the help of LLMs. In this study, we discuss the impact of weights on data summarization and ultimately, on the task of data categorization.

1 - Nonlinear Spatio-Temporal Run-to-Run Control: Leveraging Diffusion Models for Disturbance Management**Zihan Zhang, Georgia Institute of Technology, Atlanta, GA, United States**

Run-to-run (R2R) control is widely used in advanced manufacturing processes. Conventional R2R control methods often assume that system disturbances exhibit linear structures or low-rank approximations in high-dimensional data, such as images or videos. While these assumptions facilitate implementation, they limit the effectiveness of R2R control in managing sophisticated manufacturing processes with intricate nonlinear disturbances. To address these challenges, we propose a novel nonlinear spatio-temporal R2R control framework that estimates system disturbances using a diffusion model and applies control actions to compensate for them. The proposed approach integrates an offline modeling phase to capture disturbance dynamics and an online control phase that dynamically adjusts actions to minimize deviations from the target system response, ensuring system stability and precision. Unlike conventional deterministic control strategies, the proposed method explicitly quantifies uncertainty, enabling more robust and informed decision-making. The effectiveness of this method is validated through simulation studies and a case study, demonstrating its adaptability in complex, high-dimensional environments.

2 - An Equitable Energy Transition: Integrating Community Perspectives into Power System Modeling in An Emerging Economy - Poster**Faustina Sarfo, UMass Amherst, Amherst, MA, United States**

This project integrates community-based participatory research into energy modeling to address equity gaps in Ghana's power system. We co-develop equity-focused metrics with underserved communities and implement them in GenX, a capacity expansion model. By linking system cost, reliability, and access, we evaluate energy pathways that reflect local priorities and support inclusive, just energy transitions.

3 - Dynamic Transmission Line Switching Amidst Wildfire-Prone Weather Under Decision-Dependent Uncertainty**Juan-Alberto Estrada-Garcia, University of Michigan, Ann Arbor, MI, United States**

Dry and windy seasons increase wildfire risk conditions, threatening transmission lines and causing grid vulnerabilities. We propose a multi-stage optimization model that adaptively adjusts grid topology to optimally respond to wildfire propagation, accounting for decision-dependent uncertainty in which line survival probabilities depend on usage. Using distributionally robust optimization and a stochastic nested decomposition variant, we provide a finite convergence guarantee and show strong performance on realistic California grid data against two-stage policies.

4 - A Novel Method to Identify Potential Collaborators with A Patent-Behavior Knowledge Graph**Tongrui Zhang, Sun Yat-sen University, Guangzhou, China, People's Republic of**

This study proposes a framework for constructing an innovation collaboration knowledge graph by integrating multilayer patent collaboration behaviors. It transforms the static network into a dynamic and predictive one, enhancing path strength by 428.06% and collaborator recommendations by 57.14%. The framework enriches the innovation collaboration network theory by offering a dynamic perspective and supports data-driven collaborator identification to reducing bias in managerial decision-making.

5 - Finding Minimal Monitoring Windows for Fetal Risk Prediction: a Two-Stage Machine Learning Framework**Jaber Qezelbash-Chamak, University of Florida, Gainesville, FL, United States**

Prolonged fetal heart rate (FHR) monitoring complicates timely and accurate anomaly detection due to variability. We propose a two-stage machine learning approach to optimize the minimal CTG monitoring duration required for reliable fetal anomaly detection, achieving accuracy, precision, recall, and specificity exceeding 99% and enhancing clinical decision-making efficiency.

6 - Leveraging Inequality Measures for Equitable Food Bank Operations: a Data-Driven Approach**Enoch Bonsu, North Carolina A&T State University, Greensboro, NC, United States**

This study employs the Gini and Hoover indices to assess equity in food distribution at a local food bank. Using Meals Per Person in Need data, we reveal rising network inequality and localized branch imbalances. These standardized measures provide a quantitative framework for identifying disparities, tracking trends, and guiding resource allocation, thereby advancing equity in food banking.

7 - Modeling Spatial Health Damage Disparities from CCS Under Atmospheric and Policy Uncertainty - Poster**Nexus Attiogbe, UMass Amherst, Amherst, MA, United States**

Recent U.S. policies, including the Inflation Reduction Act's 45Q Tax Credit and the EPA's CO₂ Performance Standards, aim to incentivize carbon capture (CC) in the power sector. This study evaluates how these individual policies and their combinations affect CC deployment, co-pollutant emissions (NO_x, SO_x, PM_{2.5}, NH₃, and VOCs), and the distribution of health damages across socioeconomic groups. Using a stylized three-node model, we optimize the generation investment and dispatch. We apply this regional case studies in Alabama and Texas to investigate health disparities. Air pollution exposure modeling is paired with census tract-level data to assess disparities in per-capita monetized health damages. Regional variation in co-pollutant dispersion patterns due to atmospheric conditions is incorporated to reflect climate-based uncertainties. This study highlights the importance of considering environmental injustice when designing policy by analyzing trade-offs between CC adoption, co-pollutant exposure, and equity outcomes. Results emphasize the need for decarbonization strategies that remain robust under uncertainty and prioritize equitable emission reductions.

8 - Differentially Private Sequential Learning - Poster**Yuxin Liu, University of Pittsburgh, Pittsburgh, PA, United States**

In a differentially private sequential learning setting, agents introduce endogenous noise into their actions to maintain privacy. We develop a smoothed randomized response mechanism for continuous signals, achieving faster learning ($\Theta(\epsilon \log(n))$) and finite stopping time—compared to the slower $\Theta(\sqrt{\log(n)})$ rate in non-private regimes. For binary signals, privacy can help avoid early information cascades and increase the probability of a correct cascade.

9 - Bridging the Gap: Quantifying Spatial and Temporal Access Within a Food Bank Network**Rashik Siddiquee, NCSU, Raleigh, NC, United States**

This study presents a data-driven framework to quantify accessibility to food pantries, focusing on food-insecure populations and varying transportation access. By integrating geospatial data on food pantries, transit stops, road networks, and food insecurity rates, we derive tract-level accessibility indices. Utilizing both geographic proximity and capacity, we identify underserved areas to guide more effective resource allocation within the food bank network.

10 - Building Dynamic Capacity Function for Receiving Donations in Hunger-Relief Networks -Poster**Naimur Rahman Chowdhury, North Carolina State University, Raleigh, NC, United States**

Donation receiving capacity in a food bank network is influenced by the operational performance of food agencies, which changes over time. In this study, we perform dynamic agency categorization to build a capacity function leveraging deep learning and unsupervised learning. We demonstrate results with data from North Carolina.

11 - Optimizing Weight-Based and Nutritional Fairness Metrics in Food Bank Distribution - Poster

Nowshin Sharmile, North Carolina A&T State University, Raleigh, NC, United States

Food insecurity affects over 47 million people in the U.S. This study develops a lexicographic model to improve food bank distribution using the HER Nutrition Guidelines. The model balances weight-based fairness with nutrition-tier equity, considering varying supply levels and agency preferences to explore trade-offs between total pounds and nutritional quality.

12 - An Order-Based Bayesian Network to Analyze Diagnostic Delay and Type 2 Diabetes-Related Outcomes**Yukti Kathuria, University of Massachusetts Amherst, Amherst, MA, United States**

We developed a Bayesian Network model utilizing temporally ordered socio-demographic and healthcare utilization data to analyze the relationship between diagnostic delays and Type 2 Diabetes outcomes in primary care. Results indicated that higher glucose levels at diagnosis worsened long-term glycemic variability, and care continuity influenced outcomes based on diagnostic delay.

13 - Monotonic Mixture of Experts for Shape-Constrained Machine Learning**Yating Fang, Rutgers University, Piscataway, NJ, United States**

We introduce a shape-constrained Mixture-of-Experts (MoE) model that enforces global monotonicity—a property not guaranteed by monotonic experts alone. Our theoretical analysis proves this gap, and we propose a novel optimization framework that binds experts via shared constraints. The method is validated on tasks including molecular dynamics simulations of alloy failure, where it outperforms unconstrained counterparts.

14 - Assessment of Primary Healthcare Accessibility in Rural Areas - Poster**Valentina Castaneda-Torres, Georgia Institute of Technology, Atlanta, GA, United States**

Providing primary healthcare (PHC) is a global challenge, particularly in rural areas where nearly half of the population lives and lacks adequate access to essential healthcare services. This research addresses the assessment of accessibility to PHC in rural areas, where multiple socioeconomic, geographic, and infrastructure factors limit service accessibility and exacerbate populations' vulnerability. We propose a p-median facility location problem and explicitly model vulnerability by employing deprivation cost functions. We conduct a case study in a rural region in Colombia, and a series of sensitivity analyses of the impact of deprivation and terminal costs on PHC access. The findings show that 22% of the municipalities lacks access to PHC service points, and among those with access, 20% shared PHC service points and ranked highest in deprivation costs. This research also shows that terminal costs highly influence the optimal allocation of PHC service points to populations, conditioning the prioritization of more vulnerable populations when allocating essential resources.

15 - Design and Layout of a 100-Kw Scale Receiver Test Facility Using An Available Tower**Sebastian Dogue, Colorado School of Mines, Golden, CO, United States**

This study explores converting a 60-meter tower in Arvada, Colorado, into a 200-kWth concentrating solar test facility. The National Renewable Energy Laboratory's SolarPILOT was used to model heliostat field layouts and receiver positions to evaluate solar flux performance. Two layout strategies, dense and spaced, were compared to optimize efficiency, flux uniformity, and cost. The facility aims to support the cost-effective development of advanced heliostat and solar receiver technologies.

16 - A Scalable Deterministic Global Optimization Algorithm for Constraint Clustering Problems - Poster**Pedro Chumplitaz, University of South Florida, Tampa, FL, United States**

Constrained clustering leverages limited domain knowledge to improve clustering performance and interpretability, but incorporating pairwise must-link and cannot-link constraints is an NP-hard challenge, making global optimization intractable. Existing mixed-integer optimization methods are confined to small-scale datasets, limiting their utility. We propose Sample-Driven Constrained Group-Based Branch-and-Bound (SDC-GBB), a decomposable branch-and-bound framework that collapses must-linked samples into centroid-based pseudo-samples and prunes cannot-link constraints through geometric rules, while preserving convergence and guaranteeing global optimality. By integrating grouped-sample Lagrangian decomposition and geometric elimination rules for efficient lower and upper bounds, the algorithm attains scalability via embarrassingly simple parallelism. Experimental results show that our approach handles datasets with 200,000 samples for cannot-link constraints and 1,500,000 samples for must-link constraints—200–1500x larger than the current state of the art under comparable settings—while reaching an optimality gap of < 3 %. In providing deterministic global guarantees, our method also avoids the search failures that off-the-shelf heuristics often encounter on large datasets.

17 - Shortest Path: Ramp Optimization in Open Pit Mining**Felix Ayaburi, Colorado School of Mines, Lakewood, CO, United States**

We model haul roads as 3D graphs and use A* with slope- and turn-based penalties to optimize truck paths. Implemented in Python with NetworkX, our approach improves fuel efficiency for Komatsu 930Es and Hitachi EH5000ACs. Results show reduced fuel consumption. Future work includes subsurface planning and trade-off analysis for long-term efficiency.

18 - Multi-Objective Optimization for Equitable Electric Vehicle Charger Siting - Poster**Kevin Bamwiso, Colorado School of Mines, Lakewood, CO, United States, Estifanose Shiferaw**

As electric vehicle adoption accelerates, public Level 2 charging infrastructure must balance accessibility, usage, and cost. We present a tri-objective mixed-integer program that co-optimizes social equity, demand fulfillment, and grid-constrained costs when siting and sizing charger infrastructure. Case studies in Seattle and Pittsburgh demonstrate financially viable, socially inclusive expansion pathways.

19 - Predictive Maintenance for Steel Mill Roll Wear Using Large-Scale Data Analysis**Edikan Udofia, Colorado School of Mines, Lakewood, CO, United States**

Developing predictive models for steel mill roll wear using large industrial datasets (1GB+). Random Forest algorithms predict wear from steel grade, temperature, and coil properties. Campaign identification handles data quality challenges including roll reuse patterns. Achieving $R^2 > 0.85$ for maintenance optimization and cost reduction through data-driven scheduling.

20 - Integrated Learning and Optimization for Ramping-Cost Minimization In Real-TIME Electricity Markets - Poster**Imran Pervez, King Abdullah University of Science and Technology, Thuwal, Saudi Arabia**

We developed a new integrated learning and optimization (ILO) methodology to predict context-aware unknown parameters in economic dispatch (ED), a crucial problem in power systems solved to generate optimal power dispatching decisions to serve consumer load. The ED formulation in the current study consists of load and renewable generation as unknown parameters in its constraints predicted using contextual information (e.g., prior load, temperature). The ILO framework train a neural network (NN) to estimate ED parameters by minimizing an application-specific regret function which is a difference between ground truth and NN-driven decisions favouring better ED decisions. We thoroughly analyze the feasible region of ED formulation to understand the impact of load and renewable learning together on the ED decisions. Corresponding to that we developed a new regret function to capture real-time electricity market operations where differences in predicted and true loads are corrected by ramping generators in real-time but at a higher cost than the market price. The proposed regret function when minimized using ILO framework train the NN to guide the load and renewable predictions to generate ED decisions favouring minimum generator ramping costs. This is unlike conventional sequential learning and optimization (SLO) framework which train NN to accurately estimate load and renewable instead of better ED decisions. The combined training of load and renewable using ILO is a new concept and lead to significantly improved ramping costs when compared with SLO based training of load and renewable and SLO trained load with 100% accurate renewable proving its decision-focused capability.

21 - A Dynamic Ensemble Method for Spatio-Temporal Wind Energy Forecasting - Poster**Jiaxiang Ji, Rutgers University, New Brunswick, NJ, United States**

The reliable operation of wind farms depends heavily on accurate wind energy forecasts across multiple look-ahead horizons. A central challenge is that methods optimized for short-term often perform poorly at longer horizons, and vice versa. To address this, we propose a dynamic ensemble framework that integrates two spatio-temporal models, each tailored to a specific forecast horizon. Applied to real-world data from the U.S. Mid-Atlantic region, our approach achieves considerable improvements.

22 - An Optimization Model for Urban Food Networks with Diverse Facilities and Access Constraints

Meen-Sung Kim, Georgia Institute of Technology, Atlanta, GA, United States

This study develops an optimization model to design urban food networks that improve access to fresh food for underserved populations. The model incorporates accessibility constraints, facility capacity, and minimum consumption thresholds, while accommodating diverse food outlet types. It explores trade-offs in placement decisions affecting proximity, coverage, and equity. The model is being applied in a Chicago-area case study to demonstrate real-world potential.

23 - Microbiome-Aided Classification of Forensic Body Fluid Mixtures via Conjecturing and Machine Learning

Samuel Paul Gyamfi, Virginia Commonwealth University, Henrico, VA, United States

We develop a microbiome-informed forensic pipeline that classifies biological samples as mixtures or single-source fluids using qPCR-derived Cq values for *S. salivarius*, *L. crispatus*, and *B. uniformis*. Several supervised models were employed to distinguish mixtures and infer their components, with top accuracies achieved by SVM, Random Forest, and Neural Networks. We then use invariant and property-based conjecturing to derive interpretable bounds between bacterial markers, aiding forensic explainability and enhancing microbial evidence modeling.

24 - Rethinking College Admissions: Can Test-Optional Policies Even the Playing Field?

Zijin Zhang, Carroll School of Management, Boston College, Chestnut Hill, MA, United States

This paper studies how test-required (TR) and test-optional (TO) policies affect academic merit and socioeconomic representation in college admissions. Using a game-theoretical model, we show that under TO, two forces—pool expansion and signal enhancement—jointly disadvantage middle-class students. Our results also suggest that the TO policy does not necessarily improve the representation of low- socioeconomic students at the cost of academic merit, challenging the popular belief. Empirical evidence from 3,701 U.S. colleges (2000–2019) supports these findings, revealing that TO often amplifies institutional biases and creates unequal outcomes.

1 - Analytics for Better Urban Cycling

Bo Lin, University of Toronto, Toronto, ON, Canada

Cycling has become an increasingly popular transportation mode, offering significant benefits for urban mobility, public health, economic growth, and sustainability. However, safety and comfort concerns remain significant barriers to cycling adoption. Toward the vision of making biking safer and more inviting, this thesis develops quantitative methods for the efficient assessment, planning, and utilization of urban bike infrastructure, with a particular focus on fostering cycling adoption in Toronto, Canada. First, we introduce a computer vision approach to assess cycling stress—the discomfort cyclists experience on urban road networks. This method leverages the widespread availability of street-view images to replace current data- and labour-intensive assessment practices. Next, we formulate an optimization model to determine the optimal locations for new bike lanes, aiming to maximize the city's low-stress cycling accessibility—a metric strongly correlated with cycling mode choice in Toronto. Given the size and complexity of Toronto's road network, this optimization model cannot be solved by any existing methods. In response, we develop a machine learning-augmented optimization approach that is computationally efficient and produces provably high-quality solutions. Finally, we investigate cycling path recommendations in the context of last-mile delivery, where cycling couriers often deviate from delivery routes prescribed by platforms, leading to increased delivery times and inefficiencies in order batching and assignment, both of which depend heavily on accurate route modelling. To address this, we propose a data-driven approach to prescribing delivery paths that are both high-quality and perceived as such by couriers. The former property ensures service quality, while the latter promotes adoption.

2 - Understanding and Optimizing Societal Systems: Methods and Applications

Zhi Liu, Cornell Tech, Seattle, WA, United States

Modern societal systems are increasingly complex and present challenges in (1) understanding their impact through the vast amount of data collected, and (2) designing policies that promote efficient and equitable usage. In this dissertation, we describe methods and applications that tackle these challenges in two real-world systems: the urban crowdsourcing system and the urban library system. In doing so, we demonstrate how to leverage robust theoretical modeling and empirical analyses together, to uncover insights from data, and inform policy design.

3 - New Theory and New Practical Methods for Solving Large-Scale Linear and Conic Optimization

Zikai Xiong, MIT Operations Research Center, Cambridge, MA, United States

In the last several years there has been a dramatic shift in the way many large-scale linear programs (LPs) are solved in practice, with classic methods (etc, simplex method and interior-point method) being replaced by the primal-dual hybrid gradient method (PDHG) to solve large-scale LP problems. While PDHG has been very successful in solving large-scale LP problems, its performance can have substantial variance and an intuitive understanding of the drivers of its performance has been lacking. In this context, this dissertation (i) develops new theory to explain PDHG's performance in the worst case and the "average" case through deterministic and probabilistic analysis, (ii) develops new practical methods (central-path conic rescaling) for large-scale LPs based on the new theory, (iii) generalizes the new theory and methods to a broader class of conic optimization problems, and (iv) develops a practical GPU-based general-purpose conic program solver for solving large-scale problems including but not limited to quadratic programs, second-order cone programs and exponential cone programs.

4 - Models and Algorithms for Safeguarded Data-Driven Decision Making

Aras Selvi, Imperial College Business School, London, United Kingdom

This thesis focuses on making safeguarded data-driven decision making applicable and scalable in practice, while minimizing the cost of safeguarding. Privacy and fairness safeguards can reduce the utility gained from data, while robustness safeguards often lead to models that are intractable in real-world settings. The work in this thesis develops optimization frameworks for privacy-preserving mechanisms, applies fairness constraints in sequential decisions such as housing allocation with LAHSA, and revises robust models to handle categorical and synthetic data in collaboration with JP Morgan.

IISE Transactions: Insights and Perspectives from the Editorial Board

Panel Session

Committee's Choice

Co-Chair: Judy Jin, University of Michigan, Ann Arbor, MI, United States

1 - Moderator Panelist

Judy Jin, University of Michigan, Ann Arbor, MI, United States

This panel session aims to provide valuable insights into IISE Transactions, the flagship journal of the Institute of Industrial and Systems Engineers (IISE). The session will cover the journal's overall scope and clarify distinctions among its four Focused Issues: Data Science, Quality, and Reliability (DSQR); Design and Manufacturing (DM); Operations Engineering and Analytics (OEA); and Supply Chain and Logistics (SCL). The panelists, including the Editor-in-Chief and the four Focused Issue Editors, will discuss the peer-review process, highlight emerging research trends, and offer practical guidance for preparing successful submissions. Given the journal's broad relevance and high-impact contributions across multiple domains, this is a community choice session, led by the Quality, Statistics, and Reliability (QSR) Section

and co-sponsored by the Data Mining (DM) Section, INFORMS Computing Society (ICS), the Society on Location Analysis (SOLA), and the Transportation Science and Logistics (TSL) Section.

2 - Panelist

Kaibo Liu, UW-Madison, Madison, WI, United States

3 - Panelist

Zhenyu Kong, Virginia Tech, Blacksburg, VA, United States

4 - Panelist

Siqian Shen, University of Michigan, Ann Arbor, MI, United States

5 - Panelist

Multi Criteria Decision Making

Chair: Salvatore Greco, University of Catania, Catania, Italy

Co-Chair: Banu Lokman, University of Portsmouth, Portsmouth, United Kingdom

1 - A Novel Spatiotemporal Multi-Attribute Method for Assessing Flood Risks in Urban Spaces Under Climate Change and Demographic Scenarios

Lucas da Silva, Universidade Federal de Pernambuco (UFPE), Recife, Brazil, Marcelo Alencar, Adiel de Almeida

Addressing the challenge of building safer societies in the context of climate-induced extreme events is complex, particularly due to the interplay of uncertain and sometimes contradictory urban policies. Given this backdrop, this research proposes a novel decision-making framework grounded in non-stationary multi-attribute utility theory (NSMAUT), which incorporates human, environmental, and economic dimensions to evaluate flood risks in urban settings. Building upon expected utility theory and extending the multi-attribute utility theory (MAUT), this approach represents a methodological advancement by addressing dynamic preferences over time. A key feature of the model is its ability to account for temporal preferences, recognizing that decision-makers may demonstrate greater patience when considering outcomes that occur further in the future, specially climate and demographic scenarios.

This time-sensitive perspective is essential in urban adaptation planning in a changing climate, where the advantages of resilience measures often unfold gradually. The model is applied in a numerical case study, supported by climate and demographic modeling, statistical tools and simulation techniques, to thoroughly explore its practical use. Findings suggest that this approach can significantly improve the formulation of urban adaptation policies by offering a dynamic and multidimensional tool for assessing climate-related risks. By reflecting real-world complexities such as uncertainty and time-delayed impacts, the model supports the creation of more adaptive and robust strategies for urban resilience in an era of intensifying climate threats.

2 - Towards Explainable Interactive Multiobjective Optimization: R-XIMO

Giovanni Misitano, University of Jyväskylä, Jyväskylä, Finland, Bekir Afsar, Giomara Lárraga, Kaisa Miettinen

Interactive multiobjective optimization methods guide decision makers toward preferred solutions in problems involving multiple conflicting objectives. By incorporating human preferences into the solution process, these methods support exploration of trade-offs and help identify satisfactory compromises. However, it is often unclear how the stated preferences influence the resulting solutions. This lack of transparency can reduce trust, hinder learning, and weaken the overall impact of the decision-support process.

To address this challenge, we propose a novel paradigm: explainable interactive multiobjective optimization. We introduce R-XIMO, a new method that integrates explainability into reference point-based interactive multiobjective optimization using tools from explainable artificial intelligence. Specifically, R-XIMO applies SHAP (Shapley Additive exPlanations) values to quantify and communicate how preferences shape the optimization outcomes.

R-XIMO enhances decision support in two ways. First, it helps the decision maker understand how their preferences affect the generated solutions and what trade-offs are involved. Second, it offers guidance for revising preferences, suggesting which objective to compromise to improve another of higher interest. This kind of feedback is lacking in existing interactive methods.

This research is one of the first to combine explainable artificial intelligence with interactive multiobjective optimization. By bridging these two fields, R-XIMO delivers explanations and strengthens the decision-support process. We demonstrate the method's potential through a numerical example and a case study.

Our findings suggest that incorporating explainability into interactive optimization holds significant promise. It enables more transparent, and effective decision-support, opening a new and exciting research direction at the intersection of optimization and explainable artificial intelligence.

1 - Reconciling Discrete-Time Mixed Policies and Continuous-Time Relaxed Controls in Reinforcement Learning and Stochastic Control

Mathieu Lauriere, NYU Shanghai, Shanghai, China, People's Republic of, Rene Carmona

Reinforcement learning (RL) is currently one of the most popular methods, with breakthrough results in a variety of fields. The framework relies on the concept of Markov decision process (MDP), which corresponds to a discrete-time optimal control problem. In the RL literature, such problems are usually formulated with mixed policies, from which a random action is sampled at each time step. Recently, the optimal control community has studied continuous-time versions of RL algorithms, replacing MDPs with mixed policies by continuous-time stochastic processes with relaxed controls. In this talk, we rigorously connect the two problems: we prove the strong convergence of the former towards the latter when the time discretization goes to 0. Joint work with Rene Carmona (Princeton University).

2 - Algorithmic Collusion and Entry Deterrence Through Limit Pricing

Patrick Chang, Oxford University, Oxford, United Kingdom

We derive a theoretical model of oligopolistic behavior competition in market-making in a model with payment for order flow (PFOF). In a model with high-speed trading and no value from price discovery, a retail liquidity program (RLP) based on PFOF is a more efficient mechanism to provide liquidity as it allows liquidity providers to

avoid sniping from faster traders. Some RLP implicitly acknowledge this negative effect by requiring firms participating in RLPs to provide liquidity in the exchange. We find that such arrangements can backfire, leading to collusive equilibria, where the faster market-makers undercut slower market-makers in the exchange in order to exclude them and reduce competition for retail orders through the RLP. This undercutting can be interpreted as dumping liquidity in the exchange in order to corner the RLP.

3 - Mf-Oml: Online Mean-Field Reinforcement Learning with Occupation Measures for Large Population Games

Anran Hu, Columbia University, IEOR, New York, NY, United States

Reinforcement learning for multi-agent games has attracted significant attention in recent years. However, due to the complexity of solving Nash equilibria in large-population games, existing works with guaranteed polynomial complexity primarily focus on variants of zero-sum and potential games or aim to compute (coarse) correlated equilibria, particularly in online settings. In this talk, we propose MF-OML (Mean-Field Occupation-Measure Learning), an online mean-field reinforcement learning algorithm for approximating Nash equilibria in large-population sequential symmetric games. Evaluated in terms of cumulative deviation from Nash equilibria, the algorithm achieves a high-probability regret bound for monotone games. The regret bound consists of two components: one capturing the effect of mean-field approximation, which vanishes as the number of players approaches infinity, and the other that grows sublinearly with the number of episodes. As a by-product, we also establish the first tractable, globally convergent computational algorithm for solving Nash equilibria in monotone mean-field games.

4 - Multi-Task Dynamic Pricing in Credit Market with Contextual Information

Jingwei Ji, University of Southern California, Los Angeles, CA, United States, Adel Javanmard, Renyuan Xu

We study the dynamic pricing problem faced by a broker seeking to learn prices for a large number of credit market securities, such as corporate bonds, government bonds, loans, and other credit-related securities. A major challenge in pricing these securities stems from their infrequent trading and the lack of transparency in over-the-counter (OTC) markets, which leads to insufficient data for individual pricing. Nevertheless, many securities share structural similarities that can be exploited. Moreover, brokers often place small "probing" orders to infer competitors' pricing behavior. Leveraging these insights, we propose a multi-task dynamic pricing framework that leverages the shared structure across securities to enhance pricing accuracy. In the OTC market, a broker wins a quote by offering a more competitive price than rivals. The broker's goal is to learn winning prices while minimizing expected regret against a clairvoyant benchmark. We model each security using a d -dimensional feature vector and assume a linear contextual model for the competitor's pricing of the yield, with parameters unknown a priori. We propose the Two-Stage Multi-Task (TSMT) algorithm: first, an unregularized MLE over pooled data to obtain a coarse parameter estimate; second, a regularized MLE on individual securities to refine the parameters. We show that the TSMT achieves a regret bounded by $\tilde{O}(\sqrt{M d}) + M d$, outperforming both fully individual and fully pooled baselines, where M is the number of securities and d quantifies their heterogeneity.

5 - A Two Timescale Evolutionary Game Approach to Multi-Agent Learning and Its Application in Algorithmic Collusion Study

Mingyue Zhong, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Nan Chen

In this paper, we propose a novel two-timescale evolutionary game approach for solving general-sum multi-agent reinforcement learning (MARL) problems. Unlike existing literature that requires solving Nash equilibria exactly or approximately in each learning episode, our new approach synthesizes three key design components. First, we introduce a simple perturbed best response-based protocol for policy updates, avoiding the computationally expensive task of finding exact equilibria at each step. Second, agents use fictitious play to update their beliefs about other agents' policies, relaxing the requirement for observable Q-values of all agents as in classical Nash Q-learning. Third, our algorithm updates policies, beliefs, and Q-values at two different timescales to address non-stationarity during learning. The new approach provably converges to ϵ -Nash equilibria of MARL problems without imposing the global optima or saddle point conditions, two restrictive assumptions typically needed in the existing literature. AI-powered algorithms are increasingly used in marketplaces for pricing goods and services. The numerical experiments in this paper show that the realization of collusive Nash equilibrium is highly path-dependent and hinges on many factors, such as agents' impatience and the algorithm's exploration degree. Moreover, we also find that intervention timing is crucial for the effectiveness of regulatory policies.

1 - Social Learning with Limited Attention: Negative Reviews Persist under Newest First

Jackie Baek, New York University, New York City, NY, United States, Atanas Dinev, Thodoris Lykouris

We study a model of social learning from reviews where customers are computationally limited and make purchases based on reading only the first few reviews displayed by the platform. Under this limited attention, we establish that the review ordering policy can have a significant impact. In particular, the popular Newest First ordering induces a negative review to persist as the most recent review longer than a positive review. This phenomenon, which we term the Cost of Newest First, can make the long-term revenue unboundedly lower than a counterpart where reviews are exogenously drawn for each customer.

We show that the impact of the Cost of Newest First can be mitigated under dynamic pricing, which allows the price to depend on the set of displayed reviews. Under the optimal dynamic pricing policy, the revenue loss is at most a factor of 2. On the way, we identify a structural property for this optimal dynamic pricing: the prices should ensure that the probability of a purchase is always the same, regardless of the state of reviews. We also consider a setting where product quality evolves over time according to a Markov chain; we find that Newest First better tracks current quality but still leads to lower revenue, highlighting a trade-off between customer belief accuracy and revenue. Finally, we support our theoretical findings with numerical simulations and an empirical analysis on reviews from Tripadvisor.

2 - Can Price Discrimination be Progressive?

Max Biggs, University of Virginia, Charlottesville, VA, United States, Titing Cui, Michael Hamilton, Enfeng Xing

Traditional welfare analysis evaluates pricing policies based on aggregate revenue and customer surplus. However, modern approaches increasingly emphasize equity by asking not just how much aggregate surplus is derived, but by whom. In this work, we examine the impacts of price discrimination on market outcomes under a new notion of proportional surplus, which measures the percentage of a customer's valuation that is retained as surplus. We show proportional surplus provides a more equitable lens by which to view market outcomes, assigning greater weight to utility gained by customers with the least ability to pay. Further, we demonstrate that although traditional customer surplus often decreases when firms price discriminate, proportional surplus increases under moderate levels of revenue-maximizing price discrimination in many natural markets. These findings challenge the conventional belief that price discrimination harms customers and suggests instead that modest levels of price discrimination can improve outcomes for both firms and the markets that they serve when equity is considered.

3 - A Data-driven Approach to Improve Artisans' Productivity in Distributed Supply Chains

Divya Singhvi, New York University, New York, NY, United States, Somya Singhvi, Xinyu Zhang

Despite their vital role in the global rural economy, and as a major source of employment for women in the developing world, artisanal supply chains continue to be plagued by low productivity and high poverty levels. Identifying effective and implementable solutions to improve artisan productivity is a challenging task due to high fragmentation in the upstream parts of the supply chain. This paper presents research conducted in close collaboration with one of the leading exporters of handmade rugs in India. Leveraging insights from the field visits and detailed supply chain data, we provide robust empirical evidence that frequent supervisor visits can play a crucial role in improving artisans' productivity. Our results from Instrumental Variables analysis indicate that a one-day decrease in the average number of days between supervisor visits to remote weavers can increase weaving rates by 8.5%. We also find that (i) visits to looms with difficult-to-weave rugs and (ii) visits that are

consistently scheduled are associated with a more substantial positive impact on weavers' productivity. To capitalize on these insights, we propose an optimization framework for scheduling supervisor visits in the supply chain. Finally, we collaborate with our partner to implement this scheduling framework for a set of treatment looms over 25 consecutive weeks. A difference-in-differences (DID) analysis using data from almost 6,000 supervisor visits across 200 looms during the implementation suggests that the implementation is associated with a statistically significant 16.7% increase in the weaving rate for treatment looms, highlighting the practical relevance of the work.

4 - Strong Formulations and Algorithms for Regularized A-optimal Design

Yongchun Li, Chinese University of Hong Kong, Shenzhen, Shenzhen, Hong Kong

We study the Regularized A-Optimal Design (RAOD) problem, which selects a subset of k experiments to minimize the inverse of the Fisher information matrix, regularized with a scaled identity matrix. RAOD has broad applications in Bayesian experimental design, sensor placement, and cold-start recommendation. We prove its NP-hardness via a reduction from the independent set problem. By leveraging convex envelope techniques, we propose a new convex integer programming formulation for RAOD, whose continuous relaxation dominates those of existing formulations. More importantly, we demonstrate that our continuous relaxation achieves bounded optimality gaps for all k , whereas previous relaxations may suffer from unbounded gaps. This new formulation enables the development of an exact cutting-plane algorithm with superior efficiency, especially in high-dimensional and small- k scenarios. We also investigate scalable forward and backward greedy approximation algorithms for solving RAOD, each with provable performance guarantees for different k ranges. Finally, our numerical results on synthetic and real data confirm the efficacy of the proposed algorithms. We further showcase the practical effectiveness of RAOD by applying it to a real-world user cold-start recommendation problem.

1 - Optimizing Expeditionary Logistics: Dynamic Discretization for Fleet Management

Haden Boone, Georgia Institute of Technology, Atlanta, GA, United States, Mathieu Dahan

This paper introduces the Expeditionary Logistics Network Design Problem (ELNDP), a novel formulation that captures the operational complexity of military logistics in expeditionary environments, where unmet demand penalties dominate transportation costs and multi-modal fleet management is essential. We propose Solve-ELNDP, an iterative refinement algorithm based on dynamic discretization discovery (DDD), which extends prior work by incorporating asset management and multi-commodity flow optimization. Our method constructs partially time-expanded networks that adaptively refine temporal resolution, enabling high-fidelity modeling without the computational burden of full time expansion. Theoretical results establish the validity of our relaxation. Through a case study involving 68 realistic instances validated by the United States Marine Corps, Solve-ELNDP is able to solve 36.7% more instances, demonstrates up to a 56.4% reduction in solve times, and up to a 148.9% increase in demand fulfillment compared to traditional formulations. These results highlight the potential of dynamic discretization discovery to support scalable, data-driven decision-making in high-stakes logistics planning.

2 - Optimal Control of Transport Systems: Leveraging Set-Based Methods and Complex Analysis

Zhexian Li, University of Southern California, Los Angeles, CA, United States

Transport behaviors are fundamental to the effective operation of civil infrastructure systems, such as urban transportation networks and water distribution systems. Optimally controlling these behaviors, typically modeled by partial differential equations (PDEs), significantly enhances infrastructure performance and societal well-being. We investigate optimal control strategies for two classes of transport behaviors -- roadway traffic flow governed by nonlinear continuity equations, and solute transport in fluids described by linear evolution equations.

The first part addresses finite-dimensional traffic control problems, designing set-membership predictive control (Set-PC) methods for freeway ramp metering and intersection signal timing with partial traffic information. Using discretized traffic dynamics (Cell Transmission Model and deterministic queuing models), the proposed Set-PC framework maximizes network throughput, robustly handles incomplete information, and ensures bounded queue lengths.

The second part explores infinite-dimensional optimal control problems, presenting analytical and numerical solutions for optimal control of linear evolution equations with boundaries. Applying the unified transform (Fokas method) with complex analysis, a closed-form expression for the linear quadratic regulator of linear evolution equations is derived, revealing structural insights into optimal control. Additionally, numerical methods for optimal velocity control in advection-diffusion-reaction systems with state constraints are developed, demonstrating practical computational strategies for these complex PDE-driven systems.

3 - A Double Decomposition Algorithm for Network Planning and Operations in Deviated Fixed-Route Microtransit

Alexandria Schmid, MIT, Cambridge, MA, United States, Bernardo Martin-Iradi, Kayla Cummings, Alexandre Jacquillat

Microtransit offers opportunities to enhance urban mobility by combining the reliability of public transit and the flexibility of ride-sharing. This paper optimizes the design and operations of a deviated fixed-route microtransit system that relies on reference lines but can deviate on demand in response to passenger requests. We formulate a Microtransit Network Design (MiND) model via two-stage stochastic integer optimization, with a first-stage network design and service scheduling structure and a second-stage vehicle routing structure. We derive a tight second-stage relaxation using a subpath-based representation of microtransit operations in a load-expanded network. We develop a double-decomposition algorithm combining Benders decomposition and subpath-based column generation. We prove that the algorithm maintains a valid optimality gap and converges to an optimal solution in a finite number of iterations. Results obtained with real-world data from Manhattan show that the methodology scales to large and otherwise-intractable instances, with up to 10-100 candidate lines and hundreds of stops. Comparisons with transit and ride-sharing suggest that microtransit can provide win-win outcomes toward efficient mobility (high demand coverage, low costs, high level of service), equitable mobility (broad geographic reach) and sustainable mobility (limited environmental footprint). We provide an open-source implementation to enable replication.

4 - Optimizing Freight Electrification: Stochastic Routing and Grid-Aware Infrastructure Design

Ruiting Wang, University of California, Berkeley, Berkeley, CA, United States

Electrifying heavy-duty trucks is critical for reducing emissions in logistics but remains challenging due to high energy demands, operational uncertainties, and infrastructure limitations. This talk presents innovative strategies to overcome these challenges, including advanced optimization for routing and infrastructure design. I will show our methods of energy-efficient routing for mixed fleets of electric and conventional trucks under energy consumption uncertainty. Reformulated as a second-order cone mixed-integer program, this approach reduces operating costs, cuts emissions, and greatly reduces route capacity violations under real-world energy consumption uncertainty. In addition, I will compare battery swapping and fast charging mechanisms for heavy-duty freight from different perspectives. Focusing on California's logistics network, we introduce an optimization framework for station location, sizing, and battery sizing, leveraging real-world data on freight traffic, energy prices, renewable generation, and grid services. Through evaluations of transportation efficiency, battery utilization efficiency, and grid service potential, we provide pioneering insights into charging infrastructure networks for sustainable freight systems. Finally, I will discuss open challenges in operation and grid-aware infrastructure planning, and mobility operation, how scalable solutions are desired in this area, and my proposals to address them.

GenAI and User Productivity

Invited Session

Information Systems

Chair: Lei Wang, Indiana University, Bloomington, IN, 47405, United States

1 - AI-Powered Digital Streamer in Live Streaming

Si Xie, George Mason University, Fairfax, VA, United States

Livestream shopping has emerged as a popular method for promoting and selling products online, traditionally featuring human livestreamers. However, with advancements in generative artificial intelligence (GenAI), virtual livestreamers (VLS) capable of natural language processing and gesturing have been introduced to assist human hosts.

In this study, we analyze livestream session-level data from over 500 livestreaming channels on a major Chinese livestream shopping platform to assess the impact of VLS adoption on sales. Our findings indicate that while integrating virtual livestreamers initially boosts session sales, this positive effect diminishes over time. Specifically, we find that VLS performance improves in responding to viewers' questions, yet viewers spend less time watching the sessions, ultimately leading to reduced sales. This paradox likely stems from the increased efficiency of VLS, which enables viewers to obtain satisfactory answers more quickly, spending less time watching more product presentations.

To mitigate this decline, we explore potential strategies and find that using non-humanoid, engaging VLS interfaces—such as a mascot—helps sustain sales performance. Our results highlight the importance of carefully implementing generative AI to maximize its long-term effectiveness in driving sales.

2 - Transparent-by-Design: a Retrieval-Augmented Information System for Interpretable Healthcare Predictions

Sizhe(Jasmine) Chen, University of Utah, Salt Lake City, UT, United States, Paul Hu, Da Xu

While artificial intelligence (AI) offers immense potential for healthcare, its clinical adoption is hindered by interpretability challenges: most predictive models operate as opaque "black boxes," existing eXplainable AI (XAI) methods fail to produce narrative evidence essential for clinical reasoning, and generating such explanations raises data privacy concerns when deploying large language models in healthcare settings. To address these issues, this study proposes a novel Retrieval-Augmented Generation (RAG) framework that bridges the gap between AI systems and clinical practice. Our method leverages a multi-agent system to perform knowledge-guided retrieval of similar patient cases from institutional databases, generating case-based evidence for its predictions through local inference deployment that ensures complete data privacy compliance. To ensure rigor, we conduct a multi-faceted evaluation. We assess predictive performance using standard clinical metrics (AUC, F1-Score) and validate the explanations of our RAG model through conceptual evaluation property (Co-12) framework and a small-scale user study with healthcare professionals. Our RAG-based approach transforms opaque predictions into trustworthy, evidence-based decision support tools. By providing interpretable predictions that respect data privacy, our work facilitates the deeper integration of AI into clinical workflows, enabling clinicians to derive greater value from health information systems.

3 - A Domain-Adversarial, Two-Stage Ensemble Learning Method for Predicting the Length of Stay of Trauma Patients

Jiaxuan Peng, The University of Utah, Salt Lake City, UT, United States, Da Xu, Paul Hu, Tingshuo Huang

Length of stay (LOS) management is crucial to resource allocation efficiency and patient outcome, especially for trauma patients who often need hospitalization care. Data-driven analytics supports LOS predictions but are constrained the number of trauma patients in healthcare organizations and the highly skewed LOS distributions among patients. We address these challenges and develop a domain-adversarial, two-stage ensemble learning method that leverages the large-scale National Trauma Data Bank (n = 352,391) and a proprietary patient cohort in a healthcare organization in Taiwan (n = 9,485). This method incorporates a domain -adversarial feature extractor that aligns the heterogeneous feature distributions between the two datasets to learn shared domain-invariant representations and classify each patient as of short (< 7 days) or long (≥ 7 days) LOS. The shared representations, together with the classification probabilities, then inform regressors to derive initial domain-invariant LOS estimates (in days). In this (second) stage, a feedforward neural network, trained on domain-specific features learned from the proprietary patient data, generates (target) domain-specific LOS estimates. Finally, ensemble learning is applied to fuse both domain-invariant and domain-specific predictions and produce a LOS estimate for each patient. Evaluations show our method's mean absolute error is significantly lower than those of prevalent methods that represent different analytics approaches, thus demonstrating the value of adversarial domain adaptation, coupled with a classification-driven regression cascade and ensemble learning, for estimating patients' LOS and suggests a scalable strategy for harnessing large data registries to augment analyses of proprietary patient data for downstream predictions.

4 - Is Algorithm Enough? An Informational Perspective on Viewer Targeting in Live-Streaming Commerce

Lei Wang, Indiana University, Bloomington, IN, United States, Qingping Lin, Jing Tian, Ning Jia

In order to attract traffic in the live streaming, many merchants are increasingly implementing the algorithmic viewer targeting (AVT) strategy. After viewers acquisition through the AVT strategy, interactive engagement subsequently assumes the central role in bridging the gap between traffic and conversion. Thus, this strategy requires close coordination with engagement-based information to retain traffic and drive conversions. To assess the effectiveness of the AVT strategy, we compare the responses of targeted viewers to organic viewers regarding two key sources of interactive information: streamer expressions, including both informative and persuasive content, and viewer comments, comprising both self-generated and other-generated comments. Specifically, we also consider the influence of two different types of streamers: influencers and non-influencers. Our findings contribute to the growing literature on the effectiveness and mechanisms of AVT in live streaming and offer practical insights for optimizing information provision strategies under AVT across different types of livestreams.

Information Disclosure

Job Market Showcase

Job Market Showcase

Chair: YANG XIA, City University of Hong Kong, Hong Kong, Hong Kong

1 - Information Disclosure Policies for Omnichannel Service with Invisible Customers

Guanling Yang, Simon Business School, University of Rochester, Rochester, NY, United States, Ricky Roet-Green

The omnichannel service, which integrates brick-and-mortar stores and online channels, has become the prevailing standard in the service industry. While walk-in customers are physically in the store and therefore visible to others, online customers are typically invisible due to the inherent nature of the online channel. This invisibility poses a significant challenge for customers' decisions about whether to wait for service, and service providers' ability to manage the service system. In our study, we investigate different information-sharing policies that reflects common real-world practices. We find that information invisibility can, in many cases, increase revenue while reducing social welfare. Perhaps surprisingly, in certain market segments, information invisibility can enhance social welfare and customer satisfaction. These findings underscore the importance of tailoring information disclosure policies to the specific characteristics of each service segments. In particular, we show that the optimal policy depends on the prevalence of online orders and the normalized service value perceived by customers.

2 - The Value of Community Information for Pricing Under Network Externalities

Calvin Roth, University of Minnesota, Minneapolis, MN, United States, Ankur Mani, Jiali Huang

We study the value of community information for pricing decisions for a merchant selling divisible goods with positive network externalities to consumers in a social network. In this setting, we consider consumers whose utility functions are homogeneous except for their position in the network. We study optimal pricing structures when there is uncertainty about the network structure and provide general expressions for the optimal price and profit. Prior work has shown that in a large class of networks, pricing using the information about the social network does not improve profit significantly. Yet, it is unclear whether there is value of network information for some random networks. We study the value of network information for dense stochastic block models. For these networks, each block gives information on how communities on average interact with the rest of the network instead of consumers. We find that for this class of networks, there will be significant losses when pricing decisions are made with no information about the network compared to optimal profits under full network information. We also find that for asymptotically large networks making pricing decisions using only the information about community structure and community memberships of the consumers does not introduce any significant change in expected profits over optimal pricing under full network information. Further, we show that as the community information becomes noisy, coarser price structure provides higher profit and when the noise density exceeds the structured network density then optimal price is uniform and network information has no value.

3 - Patenting and Information Disclosure

Xizhao Wang, Kellogg School of Management, Northwestern University, Evanston, IL, United States

Invention disclosure facilitates knowledge spillovers, supporting future progress but potentially limiting appropriability for the inventor. This paper examines invention disclosure behavior by analyzing the readability of patent texts, using both traditional and novel AI-based readability scores. Using two difference-in-differences analyses, the study finds that following the 1980 Bayh-Dole Act and the establishment of Technology Transfer Offices, university-affiliated inventors reduced the readability of patent detailed descriptions. This decrease in readability does not extend to patent summary texts, suggesting that university inventors strategically limit information on how to make and use the invention. The findings reveal strategic disclosure behavior not just in the decision of whether to patent or keep inventions as trade secrets, but also in the degree of patent language clarity. Institutional changes lead inventors to selectively adjust the information disclosed in their patents. The mechanisms behind this influence and its impact on follow-on innovation are further explored.

4 - Efficient Queueing via Partial Bayesian Persuasion: Nudging Just Enough Customers Amid Quality Uncertainty

YANG XIA, City University of Hong Kong, Hong Kong, Hong Kong, Pengfei Guo, Qiao-chu He, Yulan Wang

We study the information design problem for a service provider whose service quality fluctuates between high and low levels, and only a portion of customers receive information about its service quality. We model this as a Bayesian persuasion problem, where the service provider sends a binary quality signal to a portion of customers based on a committed information strategy after the service quality level is realized. Customers then update their beliefs using Bayes' rule and decide whether or not to queue. We analyze two cases: one in which the persuasion coverage level is fixed, and the other in which it is a decision variable. We derive the optimal information design strategies for both profit maximization and welfare maximization. When the persuasion coverage level is fixed, the profit-maximizing provider often adopts a partial disclosure strategy: sending a positive signal when service quality is high and randomizing between positive and negative signals otherwise. By contrast, the welfare-maximizing provider's information strategy depends on market size: full disclosure in small-sized markets, where each signal fully reveals the service quality; partial disclosure in medium-sized markets, where the service provider randomizes between positive and negative signals when service quality is high and sends a negative signal otherwise; and non-disclosure in large-sized markets, in which it sends the same signal regardless of the realized quality level. When the persuasion coverage level is a decision variable, we show that irrespective of the provider's objective, partial persuasion always outperforms full persuasion when the market size is sufficiently large.

Job Market Showcase

Chair: Austin Saragih, Massachusetts Institute of Technology, Cambridge, MA, 02142, United States

1 - Spin the Bottle Bill: Deposit-Refund System Policy and Reverse Supply Chain Design

Austin Saragih, Massachusetts Institute of Technology, Cambridge, MA, United States, Lara Pontes, Saurabh Amin, Jan Fransoo

The state of California's Bottle Bill, a deposit-refund system policy, charges consumers a deposit upon beverage purchase and refunds it upon return of the empty container to a recycling center. In California and many other states, the refund value has remained stagnant at 5 cents for decades, and the number of recycling centers has decreased, leading to a decline in recycling rates. To address these issues, we spin the Bottle Bill by jointly optimizing its policy and reverse supply chain as a bi-level mixed-integer nonlinear program. At the policy design level, we optimize the redemption value, manufacturers' fees, and distance to recycling centers. Given this distance policy, at the network design level, we then optimize the number of recycling centers for each county in the state. To solve the bi-level problem, we devise an approach that transforms it into a single-level problem using continuous approximation, and solves it to global optimality using monotonicity analysis. Applying our approach to California's Bottle Bill, we provide policy options and insights that the state could implement to achieve its 80% recycling goal. These options and insights can also be adapted to other states and countries to advance the circular economy.

2 - Multi-Objective Optimization for Sustainable Watershed Management: Algorithms, Tools, and Decision Support System

Ashim Khanal, University of South Florida, Tampa, FL, United States, Hadi Charkhgard

We introduce a suite of advanced optimization algorithms and automated decision-support tools designed for nutrient management in large-scale watershed systems. Central to this work is AquaNutriOpt, a Python-based framework that formulates and solves large-scale mixed-integer network optimization models under a multi-objective setting. These models determine cost-effective combinations of Best Management Practices (BMPs) and Treatment Technologies (TTs) to minimize phosphorus and nitrogen loads, subject to budgetary and land-use constraints. The framework supports bi-objective optimization over multiple time periods, accounting for the variable nature of nutrient loading and enabling decision-makers to explore robust trade-offs. In addition to the traditional approach of approximating the entire trade-off frontier between conflicting objectives, we propose a complementary strategy that directly balances these objectives using Nash social welfare optimization, which produces more equitable solutions. However, because exact methods are often computationally expensive, we introduce a novel feasibility pump heuristic in the criterion space to solve these problems efficiently. In the context of controlling harmful algal blooms (HABs), this approach maximizes the product of phosphorus and nitrogen reduction loads, thereby directly targeting reductions in chlorophyll-a levels—a key indicator of HABs that is strongly influenced by the phosphorus-to-nitrogen (P:N) ratio. We further present a web-based decision support system that automates hydrological model selection with user inputs, optimization execution, and output visualization through an intuitive interface. Input data automation for popular models such as WAM and SWAT, and custom data for other models is available. Collectively, these tools provide scalable, high-performance, and actionable solutions for sustainable watershed management.

3 - Navigating Ambiguity in Scheduling: Distributionally Robust Workload Coordination in Data Centers

Yifu Ding, Massachusetts Institute of Technology, Cambridge, MA, United States, Thomas Magnanti

Amid rising energy demands from data centers (DCs), cloud providers seek solutions to reduce power consumption and alleviate grid stress. Dynamic Voltage and Frequency Scaling (DVFS) offers a promising approach that adjusts CPU/GPU power usage to enable demand response. However, the effectiveness of DVFS is impacted by the volatility and uncertainty in real-time CPU utilization, which can lead to rebound effects in the absence of robust scheduling mechanisms. The scheduling problem is critical in many domains, such as transportation and computer system management. This work models a group of servers coordinated by a market aggregator scheduling for grid demand reduction. To address ambiguity in CPU utilization, we propose a scenario-based distributionally robust optimization (DRO) formulation that captures the dynamics of power consumption over multiple time stages. Our approach is evaluated using synthetic and real-world datasets within a scalable power market game framework.

4 - Decentralized Der Integration into Wholesale Energy Markets via Reinforcement Learning of Mean-Field Games

Jun He, Purdue University, West Lafayette, IN, United States, Andrew Liu

FERC Order 2222 facilitates the integration of distributed energy resources (DERs) into wholesale energy markets, but specific mechanisms are needed for effective prosumer participation through aggregators. Current research primarily focuses on how a single aggregator manages DER portfolios, often under the simplifying assumption that wholesale market prices, such as locational marginal prices (LMPs), are exogenously fixed. While this perspective provides valuable insights into aggregator operations, it overlooks the feedback loop where aggregator actions influence market outcomes.

In response, we propose a hybrid Mean-Field Control (MFC) and Mean-Field Game (MFG) framework for integrating DER aggregators into these markets with a large number of agents. Unlike traditional approaches, our model captures the feedback between aggregators' strategies and LMPs while enabling decentralized decision-making. This algorithm enables aggregators to maintain beliefs about LMPs at a long-run equilibrium, solve their own Markov decision problems, and determine prosumers' supply or demand bids, which are then aggregated for the wholesale market. System operators continue running multi-settlement systems with economic dispatch. We prove the existence of a mean-field equilibrium (MFE) and provide a reinforcement-learning-based algorithm for prosumers to learn to converge to an MFE with entropy regularization. Numerical results show that LMPs can quickly reach a steady state. Furthermore, numerical comparisons with and without energy storage illustrate that our model can prevent extreme LMP values, fostering a more stable market even with completely decentralized decision-making.

1 - When More Medical Decisions Mean Better Healthcare

Suyanpeng Zhang, Northwestern University, Evanston, IL, United States

Frequent and data-driven medical decisions can significantly enhance patient care. This talk explores how increasing decision-making opportunities leads to improved outcomes. We present methodological advances in Markov models with applications in disease management.

2 - Optimizing Access to Vaccines and Preventive Services in Healthcare

Marta J. Ventura, Penn State University, State College, PA, United States

The first research problem is a new mathematical framework (integer linear program) that proposes to generate an optimal COVID-19 vaccination schedule for residents (in a region). This mathematical model coordinates all the necessary activities for selecting the locations and capacities of temporary medical facilities, purchasing single-dose and two-dose vaccines by medical facilities in an orderly manner, and generating a vaccination timetable for residents while minimizing the overall cost.

The second research problem is dental healthcare problem that estimates the impact of changes in Medicaid Dental Benefits on functional dentition in US Adults. We estimate the impact of the change in dental benefits due to Medicaid expansion in US states on tooth retention in 2012 and 2018 among working-aged adults who were Medicaid-eligible and not-eligible. We used a difference in difference model to examine the impact of changing dental benefits from a state's Medicaid policy on tooth retention.

The third research problem is about latent Gaussian Mixture Modeling (GMM) of Spatio-temporal COVID-19 Dynamics. We investigate the generation of dynamic COVID-19 density maps, modeling the multimodal probability density function (PDF) of a COVID-19 density maps, and tracking the epicenter of COVID-19 peaks. We present a novel approach to simulate the COVID-19 cases for statistical estimation and modeling of the multimodal PDF of a COVID density map.

The fourth research problem is a vehicle routing problem (VRP) application for an effective large-scale vaccine distribution for the state of Pennsylvania. We used state-of-the-art 'VRPsolvereasy' which is a Branch-Cut-and-Price exact solver for solving VRPs.

3 - Revealing Gaps in Modeled Smoking Histories: Implications for Lung Cancer Screening Eligibility

Hesam Mahmoudi, MGH Institute for Technology Assessment, Harvard Medical School, Boston, MA, United States, Alexandra L. Potter, Jacopo Di Silverstre, Andrew Eckel, Vidit Munshi, Chi-Fu Jeffrey Yang, G. Scott Gazelle

Purpose: Evaluate the National Cancer Institute's Smoking History Generator (SHG) for modeling smoking histories and assess its impact on lung cancer screening eligibility, with particular attention to how smoking duration may be undervalued compared to pack-year thresholds.

Methods: We analyzed data from the Southern Community Cohort Study (SCCS) and the Multiethnic Cohort (MEC) Study—both with substantial representation of minority groups—comparing SHG-generated smoking histories with real-world patterns. Discrepancies were assessed using smoking duration, pack-years, and proportions meeting established and proposed screening guidelines.

Results: Notable differences emerged between SHG simulations and observed data for both Black and White subpopulations. A higher proportion of Black smokers reported fewer than 20 pack-years in actual data than the SHG predicted, while a smaller proportion of White smokers reported fewer than 20 pack-years than indicated by SHG. As a result, reliance on SHG overestimates screening benefits for Black smokers under pack-year-based eligibility criteria and underestimates them for White smokers. Additionally, SHG consistently underestimated eligibility based on smoking duration thresholds, suggesting that exclusive focus on SHG simulation results can overshadow the potential advantages of duration-based criteria for all subpopulations.

Conclusions: These findings indicate that unstratified, pack-year-based SHG simulations may not accurately capture real-world smoking histories. Incorporating more detailed, stratified data into SHG—along with giving greater consideration to smoking duration—could enhance the accuracy of screening models and lead to more effective and broadly applicable screening policies.

4 - Improved Operations of Infectious Disease Elimination: a Model-Based Study of Polio

Yuming Sun, Georgia Institute of Technology, Atlanta, GA, United States, Pinar Keskinocak, Stephanie Kovacs, Lauren Steimle

Despite the availability of a new vaccine, persistent poliovirus outbreaks remain a global health concern, revealing the need to improve outbreak response vaccinations. Outbreak response aims to quickly vaccinate all at-risk children when outbreaks occur, regardless of their vaccination history. However, with limited vaccine supply, more strategic use of vaccines is essential, e.g., prioritizing under-vaccinated children. This study investigates whether operational improvements of outbreak response, specifically the vaccine allocation strategies, can achieve the elimination of poliovirus.

Developing a flexible deterministic compartmental model, we simulated outbreaks in Nigeria and evaluated several response scenarios. These varied in the number of vaccination rounds and the vaccine allocation strategies: proportional distribution, prioritization of under-vaccinated children, and prioritization of low-immunity children. Results showed that elimination was only achieved in the most sophisticated and idealized scenario incorporating five vaccination rounds all targeting truly low-immunity children. More practical scenarios, such as prioritizing the under-vaccinated, reduced transmission but did not eliminate the virus.

These findings highlight a key insight: although operational improvements in outbreak response can potentially eliminate poliovirus, the required changes may exceed the capacity of the global polio eradication program. To achieve and sustain elimination, a shift is needed from purely reactive outbreak response to strategies that incorporate

preventive vaccinations, such as adding the new vaccine to routine immunization. Our study contributes to global polio eradication efforts by identifying inefficiencies in outbreak response and emphasizing the need for prevention-oriented vaccination planning.

1 - Adapting Strategies for Trucking Platforms in the Gig Economy

Himani Ananthula, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Milind Sohoni, Achal Bassamboo

We examine how trip duration, shaped by network structure, affects labor supply in gig-based long-haul trucking. Using data from a large trucking platform in India, we show that longer trips reduce driver reliability. Further, using a queuing-based analytical model, we find that under demand uncertainty, adaptive dynamic staffing makes the Relay Network (RN) more cost-efficient than the Point-to-Point (P2P) model. Our results highlight how the dynamics of the on-demand economy, combined with supply behavior, shift optimal network design towards a win-win outcome.

2 - Toward a Hyperconnected Multi-Carrier Multi-Hub LTL Freight Transportation System

Sixtine GUERIN, Georgia Institute of Technology, Atlanta, GA, United States

3 - Cross- vs. in-Region Courier Routing in on-Demand Delivery

Arseniy Gorbushin, Rotman School of Management, Toronto, ON, Canada, Ming Hu, Xiaotang Yang, Yun Zhou

On-demand delivery platforms have expanded rapidly. A key advantage often attributed to their success is the ability to optimize courier routing by sharing couriers across locations and among multiple vendors (e.g., restaurants and grocery stores). However, in practice, couriers on food delivery platforms tend to work in the same regions, thus limiting the potential benefits of cross-region operations. To examine whether and how sharing couriers across regions benefits a firm, we develop a spatial queuing model where couriers serve as servers, and the delivery time depends on a customer's location, their chosen vendor, and the dispatch policy. Surprisingly, we find that in many cases, the in-region policy—under which couriers are dedicated to specific vendors—can outperform the cross-region policy, which uses a shared fleet to serve multiple vendors. This result stems from the randomness and potential imbalance in courier allocation that cross-region routing introduces. With an exogenous delivery fee, commonly used in the early stages of market penetration, the cross-region policy is more profitable when the market size is large; otherwise, the in-region policy is superior. However, with an endogenous delivery fee—typical for well-established firms who adjust the delivery fees to influence demand—the in-region policy is even more likely to be optimal: In addition to market size condition, high enough service value is required for cross-region policy to be efficient. Furthermore, we show that the cross-region policy perform better in markets where restaurants offer distinctive cuisines, whereas the in-region policy is more advantageous when restaurants have similar offerings.

4 - Optimizing Ambulance Deployment: a Stochastic-Machine Learning Framework for Emergency Service Efficiency

Daniela Cantarino, University of South Florida, Tampa, FL, United States, Jorge Acuna, Jose Zayas-Castro

Emergency department (ED) overcrowding remains a persistent challenge in the U.S. healthcare system, contributing to higher mortality rates, financial losses, and ambulance diversions. To mitigate these issues and enhance patient outcomes, hospital workflows, and system efficiency, centralized ambulance deployment strategies are critical to managing this flow effectively. This study proposes an integrated framework that combines multistage stochastic programming with machine learning to optimize ambulance allocation from accident sites to hospitals. We employ the progressive hedging algorithm to solve the allocation problem across diverse scenarios, incorporating stochastic demand variations, dynamic hospital occupancy, resource capabilities, wait times, travel distances, and patient acuity levels. The algorithm generates a robust dataset of optimal dispatch decisions, accounting for uncertainty in real-world conditions. Using this data, we train a machine learning model to predict near-optimal allocation strategies rapidly, enabling real-time decision-making. Preliminary results using real-world data from a county's Emergency Medical Services (EMS) demonstrate that our approach enhances resource utilization, reduces ambulance turnaround time, patient wait times, and improves system resilience compared to traditional static deployment methods. By bridging stochastic optimization and predictive modeling, this framework offers a scalable, adaptive solution for ambulance management, with potential to alleviate ED overcrowding and inform healthcare policy.

2 - What Does Thompson Sampling Optimize?

Yanlin Qu, Columbia University, New York, NY, United States, Hongseok Namkoong, Assaf Zeevi

Thompson Sampling and its variants are one of the most widely used algorithms for multi-armed bandit problems, known for their conceptual simplicity and strong empirical performance. Despite its popularity, a fundamental question about this heuristic algorithm remains elusive: What objective, exactly, is Thompson Sampling optimizing? We address this question by "rediscovering" Thompson Sampling as an online optimization algorithm that, at each round, minimizes a suitable notion of instantaneous regret regularized adaptively by a simple uncertainty measure. Our optimization perspective provides a fresh principled way to understand Thompson Sampling, and leads to natural avenues for algorithmic improvement.

3 - An Active Learning Framework for Multi-Group Mean Estimation

Abdellah Aznag, Columbia University, New York, NY, United States, Rachel Cummings, Adam Elmachtoub

We study a fundamental learning problem over multiple groups with unknown data distributions, where an analyst would like to learn the mean of each group. Moreover, we want to ensure that this data is collected in a relatively fair manner such that the noise of the estimate of each group is reasonable. In particular, we focus on settings where data are collected dynamically, which is important in adaptive experimentation for online platforms or adaptive clinical trials for healthcare. In our model, we employ an active learning framework to sequentially collect samples with bandit feedback, observing a sample in each period from the chosen group. After observing a sample, the analyst updates their estimate of the mean and variance of that group and chooses the next group accordingly. The analyst's objective is to dynamically collect samples to minimize the collective noise of the estimators, measured by the norm of the vector of variances of the mean estimators.

We propose an algorithm, Variance-UCB, that sequentially selects groups according to an upper confidence bound on the variance estimate. We provide a general theoretical framework for providing efficient bounds on learning from any underlying distribution where the variances can be estimated. This framework yields upper bounds on regret that improve significantly upon all existing bounds, as well as a collection of new results for different objectives and distributions than those previously studied.

4 - Bayesian Algorithms for Adversarial Decision-Making Under Uncertainty in General Action Spaces

Alexander Terenin, Cornell University, Ithaca, NY, United States

Understanding how to make decisions under uncertainty in a manner that guarantees strong performance in hindsight - no matter what might happen in the external environment - is a fundamental research question. The online learning game is a minimax game which captures this question, and is known by many names, including no-regret learning, and prediction with expert advice. Algorithms which achieve a no-regret online learning guarantee are a basic building block of other decision-making and equilibrium-computation algorithms, including certain forms of sample-efficient reinforcement learning. Most approaches are based on mirror descent variants such as exponential weights, which are convex-analytic in nature and best understood for discrete action spaces.

Given that online learning is a minimax game, it appears to have little to do with Bayesian decision-making. In spite of this, we show that a Bayesian approach - specifically, Thomson sampling over the space of the adversary's future actions (as opposed to the more-obvious state space) - admits a no-regret online learning guarantee, even in non-discrete action spaces. This is achieved by developing a Bayesian way of analyzing minimax regret of Thompson sampling, by decomposing regret into the regret the learner expects to incur according to the prior, and excess regret resulting from the presence of an adversary. With this, we show - in both the classical discrete setting, and on a unit cube against a bounded Lipschitz adversary - that Thompson sampling achieves a low excess regret, and therefore a low minimax regret. We conclude by discussing progress toward extending this to more general smoothness classes.

Topics in Assortment Optimization

Job Market Showcase

Job Market Showcase

Chair: Shuo Sun, University of California, Berkeley, Berkeley, CA, United States

1 - Multi-Objective Assortment Optimization: Profit, Risk, Customer Utility, and Beyond

Zhen Chen, Arizona State University, Tempe, AZ, United States, Heng Zhang, Hongmin Li, Scott Webster

Assortment optimization is a fundamental problem in revenue management, in which the objective usually is to selectively offer a subset of products to maximize expected revenue or profit. However, business practices often involve multiple and potentially conflicting goals. In this work, we propose a general framework and a novel reformulation method for solving multi-objective assortment optimization problems. Specifically, we consider assortment problems whose objectives are sums of multiple convex objective functions on linear combinations of choice probabilities, and we present a reformulation that effectively “linearizes” the problem. We prove that the reformulated problem is equivalent to the original problem and that it leads to a unified solution approach to multi-objective assortment optimizations in various contexts. We show that the approach encompasses a wide range of operational objectives, such as risk, customer utility, (transformations of) market share, costs with economies of scale, and dualized convex constraints. We first illustrate our approach with the multinomial logit model, and then show that our framework leads to tractable solutions under the Markov chain choice model. Using large-scale numerical experiments, we highlight that our work provides a powerful and flexible tool for solving multi-objective assortment problems, which arise frequently in practice.

2 - Supply Chain-Driven Assortment Planning Under Uncertainty

Jisoo Park, Georgia Institute of Technology, Atlanta, GA, United States

We propose an integrated optimization framework for assortment planning that incorporates supply chain considerations using a rank-based customer choice model. Our multi-stage stochastic model captures multiple sources of uncertainty and customer substitution behavior, maximizing expected profit while aligning product offerings with operational capabilities. Empirical validation using data from an e-commerce furniture retailer demonstrates that our proposed approach significantly improves profitability and enhances supply chain resilience.

3 - Leveraging Assortment Similarities for Data-Driven Demand Prediction

Amin Farzaneh, University of Texas at Dallas, Richardson, TX, United States, Tarek Abdallah, Ashwin Venkataraman

Choice models are fundamental tools in revenue management, used to predict customer demand and optimize operational decisions such as pricing and assortment. Parametric models, like the MNL and nested logit, facilitate efficient estimation and decision-making but are prone to misspecification, which can degrade prediction accuracy. Nonparametric models, such as rank-based models, better capture complex substitution patterns and offer more accurate demand predictions, but are computationally intensive, harder to optimize, and require large datasets to avoid overfitting. This trade-off complicates the selection of an appropriate choice model in practice. In this work, we propose a fully data-driven framework that combines the strengths of both parametric and nonparametric approaches. Given access to historical transaction data, our method predicts choice probabilities for a test assortment by leveraging data from historical assortments that are most “similar” to it, drawing inspiration from nearest-neighbor methods in machine learning. We show that our method provides universal consistency of both demand predictions and assortment decisions—that is, they converge to the true values as historical data grows, regardless of the underlying choice model. Numerical experiments on synthetic data demonstrate the superior prediction and decision performance of our framework compared to parametric models like MNL and LC-MNL. We further introduce a hybrid approach that combines predictions from our similarity-based method with those from parametric models, enhancing prediction accuracy even with limited transaction data. This integration bridges the strengths of both approaches, making our framework practical and robust in real-world applications.

4 - A Markovian Approach for Cross-Category Complementarity in Choice Modeling

Shuo Sun, UC Berkeley, Berkeley, CA, United States, Rajan Udawani, Omar El Housni

In modern retail and e-commerce, consumers frequently purchase multiple items across different product categories, exhibiting both substitution and complementary behaviors. We propose a general framework for complementarity in settings where customers first select from a primary product category followed by secondary product(s), and the transition probabilities between product categories reflect complementarity. In contrast to previous approaches, our framework supports a tractable algorithm for joint assortment optimization across product categories. We demonstrate the efficacy of our framework by conducting extensive numerical experiments on both synthetic data and a large-scale transaction-level grocery dataset. We also introduce an empirical metric to quantify complementarity between different categories. Results show that the proposed framework improves model fit, prediction accuracy, and expected revenue when cross-category complementarity is present.

1 - Data-Driven Optimization for Air Traffic Flow Management with Trajectory Preferences

Guglielmo Lulli, Lancaster University, Lancaster, United Kingdom

In this talk, I present a novel data-driven optimization approach for trajectory-based air traffic flow management (ATFM). A key aspect of the proposed approach is the inclusion of airspace users' trajectory preferences, which are computed from traffic data by combining clustering and classification techniques. Machine learning is also used to extract consistent trajectory options, whereas optimization is applied to resolve demand-capacity imbalances by means of a mathematical programming model that judiciously assigns a feasible four-dimensional trajectory and a possible ground delay to each flight. The methodology has been tested on instances extracted from the Eurocontrol data repository. With more than 32,000 flights considered, we solve the largest instances of the ATFM problem available in the literature in short computational times that are reasonable from the practical point of view. As a by-product, we highlight the trade-off between preferences and delays as well as the potential benefits. Indeed, computing efficient solutions to the problem facilitates a consensus between the network manager and airspace users. In view of the level of accuracy of the solutions and the excellent computational performance, we are optimistic that the proposed approach can make a significant contribution to the development of the next generation of air traffic flow management tools.

2 - An Optimization Approach for the Terminal Airspace Scheduling Problem

Nuno Ribeiro, Singapore University of Technology and Design, Singapore, Singapore, Wayne Ng, Diana Jorge

Efficient management of the Terminal Manoeuvring Area (TMA) is vital to reduce delays, fuel burn, and emissions. While most research has centered on runway sequencing, the broader Terminal Airspace Scheduling Problem (TASP) remains less explored. We introduce **TMAOpt**, a metaheuristic that jointly optimizes runway sequencing and TMA decisions such as runway assignment, speed control, holding patterns, vectoring, and point merges. By combining Linear Programming with metaheuristics, TMAOpt delivers rapid feasible solutions within seconds and converges within minutes. Using real-world data from Changi Airport, results show delays reduced by up to 27% compared with state-of-the-art microsimulation tools. Sensitivity analyses further highlight the value of balanced TMA interventions.

3 - Advancing Urban Air Mobility: Strategic, Tactical, and Human-Centered Approaches to Traffic Management

Shulu Chen, George Washington University, Washington, DC, United States

Urban air mobility (UAM) offers a transformative solution for urban transportation. However, its integration faces unprecedented regulatory and operational challenges. Existing airspace frameworks are ill-equipped for high-density urban operations, requiring stringent safety measures to manage eVTOL aircraft over populated areas. Addressing these challenges demands a focus on both regulatory adaptation and operational efficiency.

This dissertation proposes an integrated traffic management framework for UAM that balances safety and efficiency by increasing autonomy in both vertiport and airspace operations. At the strategic level, a MILP based demand-capacity balancing (DCB) algorithm computes optimal departure schedules using ground delay to manage traffic bottlenecks. At the tactical level, a multi-agent reinforcement learning (MARL) approach provides real-time speed advisories to maintain safe separations. To further enhance performance across varying scenarios, a LLM-augmented MARL framework adjusts reward structures based on contextual needs and human preferences, improving conflict resolution efficiency. To bridge research with practical deployment, this work introduces the vertiport human-automation teaming toolbox (V-HATT), a decision-support system that integrates human operators with automation.

By combining strategic and tactical conflict management with human-autonomy teaming, this research delivers a scalable, adaptive, and safety-focused framework for UAM operations. These contributions lay a foundation for the sustainable and efficient growth of future urban air transportation systems.

Optimal Sourcing at Amazon

Invited Session

The Practice Section of Informis

Chair: Ozge Sahin, Johns Hopkins Carey Business School, Baltimore, MD, United States

1 - Just-in-TIME-Aware Long Lead Buying Policy

Yuguang Wu, Amazon, Bellevue, WA, United States, Muhong Zhang, Xiuli Chao, Huseyin Topaloglu

Amazon Retail employs a dual-sourcing strategy for many products, leveraging short-lead time Just-In-Time (JIT) and long-lead time Direct Import (DI) channels to balance inventory replenishment cost and risk. However, managing dual-sourcing inventory replenishment poses significant challenges due to lost-sales dynamics, non-stationary and correlated demand, and stochastic supply availability. Existing analytical methods offer theoretical rigor but face practical limitations, including computational inefficiency and restrictive assumptions such as i.i.d demand or demand backlogging. To address these challenges, we propose the JIT-Aware Long-Lead Buying (JITA-LLB) algorithm, a simulation-based optimization framework that integrates long-lead buying decisions with JIT policies. The algorithm employs sample-path gradients to iteratively optimize multi-period replenishment strategies, offering scalability and adaptability to real-world complexities. We evaluate JITA-LLB against heuristic TIP-scaling policies using real-world test instances, demonstrating its competitive expected long term profit performance and its ability to adapt to high demand variability. This work advances scalable dual-sourcing inventory management through a practical and modular approach.

3 - Multi-Period Optimization Models for Distribution Center Inventory Management Under Uncertainty

Caner Taskin, Amazon, Seattle, WA, United States, Alp Muharremoglu

This research presents optimization-based approaches for managing buying decisions in distribution centers (DCs) within Amazon's e-commerce network. Our models are designed to handle multi-period planning horizons while considering various operational constraints and uncertainties in demand and supply. Our models aim to improve inventory management efficiency while maintaining high service levels. We explore different mathematical modeling approaches to address the inherent complexities of DC inventory management and underlying uncertainties while maintaining computational tractability considering Amazon's large-scale network.

4 - Structure-Informed Deep Reinforcement Learning for Inventory Management

Alvaro Maggiar, Amazon.com, Arlington, VA, United States

This paper investigates the application of Deep Reinforcement Learning (DRL) to classical inventory management problems, with a focus on practical implementation considerations. We apply a DRL algorithm based on DirectBackprop to several fundamental inventory management scenarios including multi-period systems with lost sales (with and without lead times), perishable inventory management, dual sourcing, and joint inventory procurement and removal. The DRL approach learns policies across products using only historical information that would be available in practice, avoiding unrealistic assumptions about demand distributions or access to distribution parameters. We demonstrate that our generic DRL implementation performs competitively against or outperforms established benchmarks and heuristics across these diverse settings, while requiring minimal parameter tuning. Through examination of the learned policies, we show that the DRL approach naturally captures many known structural properties of optimal policies derived from traditional operations research methods. To further improve policy performance and interpretability, we propose a Structure-Informed Policy Network technique that explicitly incorporates analytically derived characteristics of optimal policies into the learning process. This approach can help interpretability and add robustness to the policy in out-of-sample performance, as we demonstrate in an example with realistic demand data. Our work bridges the gap between data-driven learning and analytical insights in inventory management while maintaining practical applicability.

5 - Pareto Frontier Profiling for Order Assignment Optimization at Amazon

Neo Huang, Amazon, San Diego, CA, United States, Sherief Reda, Jikai Zou, Andrea Qualizza

We will discuss an application of the Augmented ϵ -Constraint Method (AUGMECON) to profile the Pareto Frontier and generate multi-objective weights (MOW) for the order assignment problem at Amazon responsible to decide how and when each order gets fulfilled. This approach uses stratified sampling and symmetry reduction to

consolidate similar demand attributes, significantly reducing the problem complexity. Unlike other approaches, our framework generates MOWs for production use directly from Pareto-efficient solutions without requiring reference solutions and enables weight generation at any desired frontier location within predefined thresholds.

Inbound Supply Chain Planning and Execution

Invited Session

Practice Track

Chair: Daniel Ulch, Amazon, Bellevue, WA, United States

Co-Chair: Marcus Poggi, Amazon, Bellevue, WA, United States

1 - Amazon Distribution Centers Picking Optimization

PREM KUMAR VISWANATHAN, Amazon, Bellevue, WA, United States, Shuocheng Guo

This study introduced novel optimization-based algorithms for order picking in bulk businesses, focusing on Amazon Distribution Centers (DCs) that supply downstream warehouses and physical stores, with the goal of optimizing order fulfillment and transportation costs. While existing methods optimize static-allocated order picking with fixed demand-to-inventory allocation, they often yield suboptimal solutions by failing to address dynamically-allocated orders stored across multiple locations.

In this study, we propose a two-stage optimization-based algorithm that efficiently handles both static and dynamic-allocated orders, addressing current DC operations while maintaining flexibility and generalization for future requirements. Given that over 70% of DC orders are static-allocated, our algorithm strategically decomposes the problem into two stages: first, assigning items/SKUs with static locations to containers using an enhanced version of the current prototype, and second, allocating remaining items/SKUs with multiple inventory locations to partially-filled containers.

To improve computational efficiency, we introduce two acceleration techniques, Pre-fixing and Pre-assignment, which integrates detailed warehouse layout information to model realistic travel time distributions. Specifically, we account for both horizontal movement along aisles and vertical movement for accessing higher bins. This two-dimensional travel pattern, where pickers must walk horizontally and operate their order picker lift truck vertically, introduces complexity in computations. Extensive numerical experiments across 167 instances demonstrate about 40% average improvement in run times over more optimal formulations for medium and larger instances.

2 - Inbound Inventory Allocation in a Tiered Fulfillment Network with Storage Distribution Centers

Di Wu, Amazon.com, Seattle, WA, United States, Tolga Cezik, STEPHEN GRAVES, Daniel Chen, Jason Acimovic

With the scale of Amazon's fulfillment network, optimally placing incoming inventory into fulfillment nodes becomes challenging due to the large decision space, numerous physical capacity constraints, and operational challenges. Existing processes handling inbound decisions, although sophisticated, are also complex. As a result, managers cannot audit the processes without spending significant time 'deep-diving'. Because these processes lack auditable transparency, the inbound system operates sub-optimally in ways we cannot detect. Inspired by the recent success in regionalizing outbound, this paper proposes a simplified, holistic inventory allocation policy based on a tiered fulfillment network that partitions demand areas into regions. In this regime, Amazon must distribute inventory at each echelon level to the lower levels in its region, one after the other, while at the last level, Amazon must split inventory between customer-facing fulfillment centers and pure storage nodes. We focus on developing inventory policies that perform well in such a tiered network, from both cost and computational efficiency points of view.

3 - When to Split: Optimizing Container Breaking and Inventory Distribution Decisions in an Inbound Supply Chain

Marcus Poggi, Amazon, Bellevue, WA, United States, Daniel Ulch

This talk presents a novel approach to solving the Placement Adherence (PLAD) optimization problem, which minimizes deviation from inventory targets at warehouse nodes while respecting resource constraints in complex supply chain networks. We focus on the computational challenges of this problem and introduce an efficient column generation heuristic that significantly improves scalability. The Placement Adherence problem is particularly challenging due to its size and complexity - involving millions of unique products flowing through a multi-echelon network with various resource constraints. Products travel through the network in batches (e.g. pallets, cases, totes). Breaking batches down enables a higher degree of inventory spread, but consumes more resources to sort at downstream nodes. Resource constraints link the products together, creating a massive integer multi-commodity generalized flow problem. Our column generation approach reformulates the problem to select, for each product, a feasible integer flow through the network. The master problem coordinates resource allocation across products. This decomposition approach provides several advantages: it yields stronger bounds than direct linear relaxation, scales to hundreds of thousands of products (compared to just thousands with traditional MIP solvers), and produces high-quality solutions that respect the integer nature of case breaking decisions. We'll discuss implementation challenges, including parallelization strategies and efficient subproblem solution techniques.

Behavioral Modeling and Learning in Smart Mobility Systems

Invited Session

TSL: Intelligent Transportation Systems

Chair: Devansh Jalota, Columbia University, Severna Park, MD, United States

1 - Analyzing Platform-Worker Dynamics in the Gig Economy: A Simulation-Based Approach

Tara Eslami, Northeastern University, Boston, MA, United States, Ozlem Ergun

The gig economy has changed the traditional working by enabling short-term, flexible employment. Although workers have autonomy, algorithmic control and changing market conditions bring them various challenges. Changes in policies such as pricing and task allocation can affect workers' behavior and well-being. However, most of the research is aimed at improving the system efficiency or customer satisfaction, with little consideration for how the workers are affected. Even where workers' behavior is being simulated, it is presented as a constraint, not an outcome of value. This leaves a gap for understanding the complete dynamics of gig economy.

These changes within the system and policies of the gig economy impact both the workers welfare and the platform performance. We seek to create a more comprehensive picture of these markets with efficiency as well as fairness. Using an agent-based model (ABM), we simulate heterogeneous workers and an adaptive platform within a dynamic environment. The workers have varied strategies - maximizing earnings, following their schedules, or targeting a specific income. They also adapt their behavior based on the market conditions. The platform assigns jobs, determines wages, and adjusts policies depending on system performance.

Our simulations demonstrate how policy interventions affect the workers and changes the system outcomes. We can see how some workers leave the system early and decrease peak-hour reliability, while others provide stability at the cost of responsiveness. Through this model, platform designers, policymakers, and scholars can better explore how sustainable, efficient, and fair gig systems can be created for all stakeholders.

2 - Meal Delivery Routing with Courier Behavior and Graph Neural Networks

Niels de Jong, University of Groningen, Groningen, Netherlands, Ilke Bakir, Kees Jan Roodbergen

We address the Meal Delivery Routing Problem (MDRP) faced by online food delivery platforms, where customer orders arrive dynamically and must be assigned to autonomous couriers. Each courier picks up orders from merchants and delivers them to customers. The platform must handle several challenges: couriers have varying behaviors and capabilities; courier-to-order assignment decisions must balance immediate and future costs; decisions must be made in seconds; multiple orders can be efficiently bundled; some assignments can be delayed; and there is inherent uncertainty in food preparation times, travel speeds, and order delivery locations. To address

these challenges, we develop a scalable, polynomial-time heuristic using Graph Neural Networks (GNNs) to estimate future assignment costs in a rolling horizon assignment framework. We test our approach using a modular, open-source digital twin that simulates millions of deliveries in seconds and is validated on real data from Meituan. Our GNN-based heuristic is trained using Twin Delayed Deep Deterministic Policy Gradient (TD3). Results show our method reduces average delivery time (click-to-door) by 11.6% and order rejections by 2% compared to a myopic benchmark. It also adapts to varying courier behaviors and changing spatio-temporal demand, enabling real-time, efficient decision-making for food delivery and related applications like ride-sharing.

3 - Understanding the Behavior of Large Language Models: a Case Study on the Value of Travel TIME

Yingnan Yan, University of Michigan, Ann Arbor, MI, United States, Tianming Liu, Yafeng Yin

In recent years, the rapid emergence of artificial intelligence (AI) has greatly accelerated the evolution of modern transportation systems. The latest AI paradigms exhibit unprecedented intelligence. Large language models (LLMs), the state-of-the-art AI models, excel at language processing, contextual interaction, and decision-making, behaving much like humans. AI models like LLMs are increasingly deployed in transportation systems as agents for human, which may deeply engage with humans and be applied to analyses of human behavior. Therefore, it is essential to assess how closely the behaviors of LLMs align with humans in transportation scenarios. Currently, the investigation into LLMs' behaviors in transportation still remains limited and vague. This study offers a quantitative comparison of behavioral patterns between LLMs and humans through the estimation of LLMs' value of travel time (VOT). Results show that LLMs can differentiate the assigned context and display human-like responses correspondingly, though the magnitudes of these distinctions are smaller than those of humans. Overall, the behaviors of LLMs do resemble human travelers, suggesting considerable potential for having LLMs coexist with humans in transportation systems and using LLMs in pilot studies of human behavior.

Keywords: Large language model, Behavior in transportation, Human agent

4 - Distributional End-to-End Learning of User Equilibrium with Uncertainty Quantification

Peisen Li, University of Michigan, Ann Arbor, MI, United States, Zhichen Liu, Yafeng Yin

Traditional user equilibrium models often rely on oversimplified assumptions about traveler behavior and produce point predictions without reflecting real-world uncertainties. My research addresses these limitations by extending the end-to-end learning framework to incorporate distributional prediction and uncertainty estimation. This approach integrates Monte Carlo dropout and recursive neural network refinement to produce a distribution over UE flow predictions. Instead of deterministic outputs, the model estimates both the mean and variance of predicted traffic flows, offering richer information about confidence levels under varying input conditions (e.g., demand fluctuations, network states). A recursive network architecture refines UE predictions iteratively, while dropout layers in the Attribute Net and Weight Net enable stochastic sampling. This combination allows for the estimation of both model and data uncertainty. The proposed framework is evaluated using the Sioux Falls transportation network, where performance is measured using MAPE and PICP metrics. Results demonstrate that our method not only improves predictive accuracy but also yields well-calibrated uncertainty estimates, which are critical for robust transportation planning and policy evaluation.

5 - Combatting Fraud in Welfare Programs: Theory and Applications in Smart Mobility

Devansh Jalota, Stanford University, Stanford, CA, United States, Matthew Tsao, Marco Pavone

As AI-enabled algorithmic decision-making systems become more prevalent, there is a growing need for market mechanisms resilient to user fraud and strategic behavior. Of particular interest in this work is the concern of misreporting fraud in welfare programs, wherein users can misreport their private attributes to receive more aid than they are entitled to, often resulting in millions of dollars of financial losses and reduced aid for eligible low-income users. To combat this concern, in this work we develop an audit mechanism to mitigate misreporting fraud and present algorithms for societal-scale equilibrium computation in the signaling game it induces, with a real-world use case in law enforcement in a smart mobility setting. In our proposed audit mechanism, the administrator can audit users at some cost and levy fines against them for misreporting. We study the resulting signaling game induced by our audit mechanism in two settings: a static setting where the distribution of user types is common knowledge, and an online setting where the distribution of user types is not known to the administrator. In the static setting, we present a linear programming approach to compute the resulting equilibria and, in the online setting, we develop an auditing algorithm that achieves sublinear regret with respect to the optimal static strategy. Finally, we highlight the practical viability of our audit mechanism in mitigating misreporting fraud through a case study based on Washington D.C.'s federal transit benefits program.

Chair: Abdullah Konak, Penn State Berks, Reading, PA, United States

1 - Improving Food Accessibility in Food Bank Supply Chains: Expanding Network Capacity Through Partner Agency Recruitment

Lauren Davis, North Carolina A&T State University, Greensboro, NC, United States, Rabiatsu Bonku, Funda Samanlioglu, Shubhra Paul

Food banks are non-profit organizations that distribute purchased and donated food to people in need of food assistance. Their distribution network consists of local hunger relief agencies (e.g. soup kitchens and food pantries) that work collaboratively with the food bank to ensure efficient, effective and equitable flow of food from food bank warehouses to food-insecure individuals. Partner agencies play a critical role in this supply chain and their physical location throughout the food bank's service area can contribute to inequitable distribution and low accessibility for certain populations. In this work, we aim to improve accessibility and equitable distribution by expanding network capacity through partner agency recruitment. Utilizing data from a local food bank, we identify geographic areas of unmet need. We also develop a framework for identifying potential agencies to recruit and utilize k-means clustering to estimate their service capacity. Lastly, we develop a capacitated set covering model to determine the optimal number of new agencies to on-board, taking into consideration food bank goals and preferences related to the target population and type of programs offered.

2 - Network Fairness Analysis in Food Distribution Systems

Sadan Kulturel-Konak, Pennsylvania State University, Berks, Reading, PA, United States, Abdullah Konak, Lauren Davis, Steven Jiang, Ryan Hassler

This study presents a practical framework designed to enhance fairness in the distribution of emergency food across the United States. It focuses on ensuring that vulnerable communities, particularly those with limited access to transportation, receive equitable support. The framework helps identify gaps and inefficiencies in current food distribution systems by combining local data, mapping tools, and mathematical optimization. A key feature of this approach is its strong collaboration with stakeholders, including food banks, community groups, volunteers, and the individuals receiving assistance. To enhance understanding and actionability of the data, the framework includes customized visuals and decision-support tools that do not require technical expertise. It also establishes feedback loops, allowing these tools to evolve over time based on what works and what doesn't. Ultimately, the goal is to support communities in developing more equitable, efficient, and resilient food systems. Real-world examples from a regional food bank will illustrate how this framework can be applied in practice.

3 - Food Insecurity and Charitable Food Systems: Analyzing Donations at a Local Food Bank

Muhammad Habeeb Mohammed, North Carolina A&T State University, Greensboro, NC, United States, Florielvis Pernaleta, Steven Jiang, Lauren Davis, Abdullah Konak, Sadan Kulturel-Konak

Food insecurity is a condition in which households lack consistent access to adequate, nutritious food. Food insecurity remains a critical global challenge, even in developed nations such as the United States. Despite federal food assistance programs, millions of Americans continue to experience food insecurity, highlighting the vital role of charitable food systems like food banks in hunger relief. While food banks universally face challenges such as securing consistent donations, each operates within unique local contexts. This study analyzes donation data from a local food bank to identify patterns and trends in food contributions. By examining donor behavior and seasonal fluctuations, the findings can inform operational decisions such as optimizing truck capacity for donation pickups and ultimately enhance the food bank's efficiency and impact.

4 - Multi-Criteria Network Consolidation Problem in Charitable Food Distribution

Abdullah Konak, Penn State Berks, Reading, PA, United States, Sadan Kulturel-Konak

The growing and evolving demand for food assistance, coupled with limited and fluctuating food donation resources, presents significant challenges for food banks. As traditional sources of donations diminish, food banks must periodically reassess and optimize their distribution networks despite constrained operational capacities. This study addresses the strategic planning dilemma faced by food banks, which seek to streamline delivery operations by reducing, consolidating, or relocating service sites. Such changes, however, risk reducing food accessibility for vulnerable populations, particularly those with limited transportation options. We propose a network reconfiguration and consolidation framework that integrates principles of social justice and operational efficiency. Key objectives include equitable access, fair distribution, respect for rights and dignity, and financial sustainability. This multifaceted approach aims to support food banks in making informed, balanced decisions that align logistical efficiency with community well-being.

5 - Evaluating Food Accessibility: Analyzing the Impact of Fresh Mobile Markets Using the Enhanced Two-Step Floating Catchment Area Method

Motunrayo Ogunmola, North Carolina A&T State University, Greensboro, NC, United States, Shona Morgan, Dwight Lewis, Lauren Davis

Food insecurity persists as a pressing issue in low-income and low-access (LI/LA) communities, where physical and economic barriers limit access to nutritious food. This study evaluates the impact of Fresh Mobile Markets (FMMs) on food accessibility in Greensboro, NC, using the Enhanced Two-Step Floating Catchment Area (E2SFCA) method. Unlike traditional travel-time-based measures, the E2SFCA method accounts for both the supply of food assistance facilities—FMMs and food pantries—and the demand from surrounding low-income households, offering a more robust spatial analysis. Accessibility was assessed at the U.S. Census block group level, mitigating the modifiable areal unit problem (MAUP) and ensuring more precise estimates. Comparative analysis between travel time to the nearest facility and E2SFCA-derived accessibility scores reveals disparities, with travel-time measures often overestimating access in densely populated, high-need areas. Preliminary findings suggest that integrating FMMs into the food assistance network enhances spatial accessibility, but gaps remain in North and Southeast Guilford County due to scheduling and location constraints. This study underscores the value of advanced spatial models in optimizing food assistance strategies and highlights opportunities for improving the equitable distribution of mobile market services.

Decision Making and Experimentation

Invited Session

Applied Probability Society

Chair: Sadegh Shirani, Stanford University, Stanford, CA, United States

1 - Asymptotically Efficient Distributed Experimentation

Ankur Mani, University of Minnesota - Twin Cities, Minneapolis, MN, United States, Ilan Lobel, Josh Reed

Sequential decision making by a large set of myopic agents has gained significant attention over the past decade. In such settings, even a little amount of experimentation from a few agents would benefit all others but obtaining such experimentation could be challenging for a central planner. The academic literature has focused on mechanisms for promoting experimentation through monetary incentives and persuasion through careful information disclosure. In this paper, we study a simple control that the central planner can use to coordinate experimentation. We consider a set of myopic agents that observe their own histories but not the histories of other agents. In a continuous-time stochastic multi-armed bandit model, the agents pick arms myopically and receive instantaneous rewards. Meanwhile, the central planner can observe the history of all agents. We consider a class of policies where the central planner is allowed to irrevocably remove arms. We show that an appropriately chosen policy within this class can generate the needed experimentation and match the regret bounds for a centralized problem thus mitigating the cost of decentralization. We also quantify the minimum number of agents that are needed for such a policy to be asymptotically optimal and the impact of the number of agents on the speed of learning.

2 - Incentive as Instruments: Identification and Estimation of Treatment Effects with Unobserved Confounders In Treatment Choice

Jiachun Li, Massachusetts Institute of Technology, Cambridge, MA, United States, David Simchi-Levi, Yunxiao Zhao

Unobserved Confounders are one of the most difficult challenges in estimating treatment effect in observational study. In this work, we model the selection of treatment as utility maximization (or more broadly, as certain threshold policy). Under this condition, we provide sufficient conditions for treatment identification. When it is not identified, we provide sharp identification sets, as well as efficiency bound for convergence to this identified set.

3 - Causal Message Passing for Experiments with Unknown and General Network Interference

Sadegh Shirani, Stanford University, Stanford, CA, United States, Mohsen Bayati

Randomized experiments are the gold standard for assessing the impact of various decisions, including policy changes, medical treatments, or product enhancements. However, these experiments often face the challenge of network interference, where a decision affecting one individual impacts others, complicating the analysis. Our research introduces Causal Message-Passing, a framework inspired by techniques from physics and statistics to tackle this complexity. It allows for a more nuanced understanding of interconnected data, crucial for predicting outcomes in environments where individual responses are interdependent. This approach enhances the accuracy of decision-making in networked settings, offering insights for scientists and practitioners across diverse fields.

Applications in Optimization

Invited Session

Minority Issues Forum

Chair: Alexandra Newman, Colorado School of Mines, Golden, CO, United States

1 - Multi-Objective Optimization for Equitable Electric Vehicle Charger Siting

Kevin Bamwiso, Colorado School of Mines, Golden, CO, United States, Estifanose Shiferaw

As the adoption of electric vehicles (EVs) accelerates across the United States, the demand for accessible and reliable public charging infrastructure continues to rise. However, the market-driven placement of charging stations often prioritizes high-income, high-traffic urban areas, leaving under-served communities with limited access to the infrastructure needed to support EV ownership. This gap exacerbates existing environmental and transportation inequalities, making clean transportation adoption less attainable in these underserved communities. To address this challenge, we develop a tri-objective mixed-integer programming model that simultaneously considers social equity, user demand, and infrastructure costs in EV charging infrastructure placement. We maximize equity and demand while minimizing infrastructure costs. Equity metrics include the consideration of low-income and minority populations, as well as households without off-street parking while demand metrics consider regions

with high EV ownership potential, high-income households, and total vehicles. Finally, cost components address electrical grid constraints and financial feasibility. Studies in Seattle and Pittsburgh provide insights into how cities can expand EV infrastructure in a way that is both financially sustainable and socially inclusive, supporting a just transition to clean transportation.

2 - Exploring Equality and Sustainability Trade-Offs of Energy Transition Outcomes in the United States in 2050

Destenie Nock, Carnegie Mellon University, Pittsburgh, PA, United States, Teagan Goforth, Maxwell Brown, Tapajyoti Ghosh, Patrick Lamers

With increasing focus on equitable and just energy transition, it is critical to understand the trade-offs of different decarbonization outcomes across economic, environmental, and social sustainability criteria. In this analysis, we use a multi-criteria decision analysis to quantify sustainability outcomes across 32 decarbonization outcomes in 2050 in the U.S. The economic sustainability criteria we use are system cost, national average retail rate, and electricity system employment. The environmental sustainability criteria we use are life cycle greenhouse gas emissions, life cycle water depletion, life cycle land transformation, and air pollution fatalities. The social sustainability (distributional impacts) criteria we use are retail rate equality across states, electricity employment equality across low-income households, and air pollution disparities across census tracts. We evaluate performance across these criteria under eleven different stakeholder preference scenarios. We find that decarbonization policies with indefinitely extended tax credits have the highest sustainability score under equal criteria weighting, with greater investments in renewable energy technologies, and result in better environmental, system cost, job, and air pollution disparities compared to mid-case scenarios, that only include current policies and CO2 reduction targets. We also see that our multi-criteria decision analysis identifies decarbonization outcomes that would not have been identified as optimal under a single objective, which highlights the importance of trade-off analyses to understand decarbonization outcomes more holistically.

3 - Degrees of Equity: How Households Adapt with Energy Efficiency Interventions

Kester Wade, Carnegie Mellon University, Pittsburgh, PA, United States, Destenie Nock, Xue Gao

Energy efficiency and conservation play a central role in addressing the challenges of energy system transitions in the US. Powering society's growing needs would directly benefit from reduced energy costs—requiring less energy for units of output or activities. These strategies can also improve affordability for households to meet their energy needs. Yet, despite their importance for climate goals and energy affordability, barriers often prevent low-income households from benefitting. Energy poverty involves excessive spending on energy bills, disconnections, and sacrificing essential services like heating and cooling to limit costs. There's a lack of understanding regarding how energy efficiency programs impact vulnerable groups.

This study considers ~125,000 households in a Florida county and examines the impacts of energy efficiency and conservation programs on household heating and cooling behaviors over a 10-year period. We focus on the outdoor temperatures at which households turn on heating or air conditioning systems to understand whether low-income households tolerate extreme indoor temperatures to reduce financial stress. Difference-in-difference comparisons help us estimate how these household behaviors change during and after voluntary energy efficiency program participation such as loans or rebates for new efficient appliances.

Energy efficiency technologies and conservation behaviors have massive potential to improve physical and financial well-being. This especially affects households that might engage in risky behaviors to mitigate their energy needs. We advance the scientific understanding of whether, why, and how different energy efficiency and conservation programs work in different households, informing over 900 similar programs offered by U.S. utilities.

4 - From Data to Decisions: Optimizing Pediatric Vaccine Tender Schedules Under Uncertainty

Nicholas Uhorchak, University of Arkansas, Fayetteville, AR, United States, Ruben Proano, Sandra Eksioglu, Burak Eksioglu, Asif Sharon

This study presents a data-driven framework for long-term pediatric vaccine tender scheduling, enhancing existing procurement practices to address future uncertainty in demand for vaccines and manufacturing capacity, and improve long term decision-making. While UNICEF and similar agencies regularly organize multi-year tenders, additional tenders are often initiated in response to unexpected supply shortfalls, disease outbreaks, or production issues—leading to inefficiencies such as stockouts, excess inventory, and reduced vaccine coverage due to logistical and storage constraints. We propose a stochastic optimization model to generate multi-year tender schedules under uncertain demand for vaccines and manufacturing capacity. We develop three models that focus on affordability (balanced), profitability (max profit), and public health (social benefit) impact. We evaluate the impacts of these models with regards to optimal sequencing and timing of tenders, expected tender costs and expected number of missed doses. We propose an L-shaped algorithm to solve these models. We use Pareto-optimal cuts and valid inequalities to accelerate the convergence of the algorithm and ensure practical solution times. We use real-world data from UNICEF to model uncertainty in vaccine demand, and synthetically generate manufacturing capacity scenarios. This approach is critical to capturing the variability that affects long-term tender scheduling in practice. Results indicate that while the balanced model yields marginally more missed doses compared to a purely social objective, it significantly reduces administrative complexity for global health agencies such as UNICEF, PAHO, and GAVI.

Operations Research to Help Address the Mental Health Crisis on College Campuses

TutORial session

TutORials

Chair: David Alderson, Naval Postgraduate School, Monterey, CA, United States

1 - Operations Research to Help Address the Mental Health Crisis on College Campuses

Hrayer Aprahamian, Texas A&M University, College Station, TX, United States

In this TutORial, we address the growing mental health crisis affecting university campuses across the nation. Specifically, we provide a comprehensive overview of the challenges faced by Counseling and Psychological Services (CAPS) centers and present a range of data analytics and Operations Research tools aimed at mitigating these issues. By posing key unresolved questions, we offer a holistic analysis that spans the spectrum from individual patient outcomes to system-level operational performance,

highlighting the complex interdependencies between clinical effectiveness and operational efficiency. Through this lens, we present a structured and accessible framework that both summarizes and contextualizes the primary operational and clinical challenges in university mental health services. In doing so, we also showcase a variety of data-driven methodologies designed to address these challenges, offering insight into the strengths and limitations of current approaches.

Grand Challenges in Public Sector Operations Research: Opportunities at the Intersection of AI and OR

Panel Session

Women in OR/MS (WORMS)

Co-Chair: Irem Sengul Orgut, Loyola University Chicago, Tuscaloosa, AL, United States

Co-Chair: Chaitra Gopalappa, University of Massachusetts, Amherst, Amherst, MA, United States

1 - Moderator Panelist

Chaitra Gopalappa, University of Massachusetts, Amherst, Amherst, MA, United States

The OR community has a strong tradition of tackling socially engaged and impactful application areas, many of which are characterized by high levels of complexity, uncertainty, and evolving constraints. As public sector challenges—from health equity and infrastructure to emergency response and resource allocation—grow in scale and intricacy, there is an urgent need to explore new computational paradigms. Artificial Intelligence (AI), with its ability to learn from large-scale data and model complex interactions, offers powerful tools but often lacks the robustness and transparency required for high-stakes decision-making. Conversely, OR methods are valued for their rigor and reliability in decision support but may struggle to scale or adapt in dynamic environments.

This panel will explore grand challenges in the public sector that require the complementary strengths of AI and OR. Panelists will discuss where the integration of AI and OR creates new possibilities that neither field could achieve alone, identify current gaps and methodological needs, and chart future research directions that can deepen the societal impact of the AI+OR interface.

Location for Social Good

Invited Session

Location Analysis

Chair: Marziehsadat Rezaei, University of Louisville, Louisville, KY, United States

Co-Chair: Monica Gentili, University of Louisville, Louisville, KY, United States

1 - Location-Based Planning for Mixed-Fleet Transit: Balancing Equity and Efficiency in Uneven Urban Demand

Madelaine Martinez Ferguson, University of Tennessee, Knoxville, TN, United States, Mustafa Camur, Xueping Li

Many urbanized areas in the US exhibit spatially and temporally sparse transit demand, posing a resource allocation challenge for transit agencies (TAs) due to the ridership–coverage dilemma. Agencies often prioritize high-ridership corridors at the expense of broader coverage, limiting accessibility for transit-dependent populations. As emerging mobility options such as shared autonomous vehicles (SAVs) gain traction, their integration into public transportation systems offers an opportunity to enhance both access and efficiency. However, research on mixed-fleet operations—combining buses and SAVs—remains limited. This study contributes to closing this gap in two significant ways. First, it involves a location decision to select underserved areas or routes for system implementation, guided by a transit coverage analysis. Second, it identifies transition points—bus stops—where each fleet type will operate based on spatial demand density. Buses are assigned to dense corridors, while SAVs are deployed in low-density areas. These decisions are evaluated through an agent-based simulation framework that captures operational dynamics. The model explores trade-offs between vehicle capacity and flexibility, offering insights into how integrated, adaptive transit configurations can enhance equity and service efficiency in urban settings with heterogeneous demand.

2 - Location and Mode Selection in Drone-Enabled Medical Logistics for Transplant Support

Kevin Martin, University of Missouri, St Louis, Wildwood, MO, United States, Shakiba Enayati, Haitao Li

Timely testing of donor blood samples is a critical component of the organ donation and transplantation process. Laboratory results directly inform organ allocation decisions that can save lives. In regions where transplant coordination spans large geographic areas, delays in transporting blood samples to central laboratories can jeopardize organ viability and matching efficiency. This challenge is especially acute in rural and underserved areas where traditional ground and air transportation can be slow and expensive. Emerging drone technologies offer a promising solution by enabling swift, reliable, and cost-effective delivery of time-sensitive medical specimens across long distances.

Our study proposes a mixed-integer linear programming (MILP) model to design an optimized multi-modal distribution network for donor blood sample transportation. The model determines the most efficient combination of transportation modes—including drones—along the delivery routes from hospitals to the laboratories, while selecting strategic locations for long-term drone infrastructure. The objective is to minimize transportation costs while satisfying constraints on maximum allowable transit time.

The model is designed in collaboration with an organ procurement organization located in Missouri. The geographic focus includes hospitals in the southwestern parts of the state and a testing lab in the St. Louis area. Current logistics rely on costly ground couriers and aircraft. Our model evaluates the integration of drones to improve efficiency, reduce transit times, and lower costs while complementing existing services. We also conduct sensitivity analyses and trade-offs for practical decision-making. This work contributes to accelerating the donor matching process and enhancing the overall effectiveness of organ transplant logistics.

3 - Location Optimization for Mobile Ground-Based Polarimetric Radar for Strategic Monitoring of Severe Storm Systems

Xin (Selena) Feng, University of Oklahoma, Norman, OK, United States, Bikram Parajuli, Chenchun Wang

Accurate radar observations are critical to improving the prediction and warning of life-threatening and economically impactful severe weather events. Compared to fixed ground-based radar systems, mobile radars have proven to offer better spatial and temporal resolution when they are deployed close to where the perception system occurs. A key issue about mobile radar observations that has been overlooked is where to deploy the mobile radar vehicles. The scientists experimenting face significant difficulties in simultaneously considering selecting deployment locations based on their intuition and experience while collecting high-quality data during fast-evolving severe weather events and ensuring the safety of operators and vehicles. A timely understanding of the local environment is essential for real-time deployment; however,

on-site, in-person assessment requires time and a lot of human and material resources. A framework consisting of geospatial and meteorological information, geographic information systems (GIS), and location analysis and modeling was developed for field use to delineate feasible areas, eliminate inferior solutions, and identify suitable locations. The problem has been formulated as a coverage location problem, and both exact and heuristic algorithms have been utilized and compared to solve it. The findings highlight the potential of quantitative decision-making techniques in improving the effectiveness of mobile radar deployment, thereby advancing real-time severe weather sensing.

4 - Strategic Placement of Drone Platforms in Out-of-Hospital-Cardiac-Arrest: A Case Study for Jefferson County, Louisville, Ky

Monica Gentili, University of Louisville, Louisville, KY, United States

Each year, over 350,000 out-of-hospital cardiac arrests (OHCAs) occur in the U.S., with survival rates as low as 8–10% due to delayed ambulance arrivals and limited use of publicly available Automated External Defibrillators (AEDs). Unmanned Aerial Vehicles (UAVs), or drones, present a transformative solution for rapid AED delivery to OHCA scenes, overcoming barriers like AED accessibility and bystander hesitation. Using Louisville's EMS data, this study identifies priority areas for drone delivery and potential launch sites in Jefferson County, Louisville, KY. These inputs inform an optimization model to determine the minimum number of launch platforms needed to cover a specified percentage of intervention calls within a desired service time. We present results of the optimization model under different scenarios, by varying the priority areas, the number and location of the platforms, and the drone flight parameters.

Advances in Distributionally Robust and Stochastic Optimization

Invited Session

Computing Society

Chair: Yiling Zhang, University of Minnesota, Minneapolis, MN, United States

1 - Managing Shared Mobility Systems with Electric Vehicles Under Correlated Demand Uncertainties

Kai Pan, The Hong Kong Polytechnic University, Hung Hom, Hong Kong, Ziliang Jin, Bin Tian, Yun Fong Lim

Using electric vehicles (EVs) with vehicle-to-grid (V2G) technology in a shared mobility system promotes sustainability but limits vehicle accessibility. This highlights the importance of optimizing the initial EV allocation, which should also consider subsequent operational decisions. The problem is further complicated by correlated uncertainties in trip demands across service regions and time periods without perfect knowledge of these correlations. We propose a two-stage distributionally robust optimization (DRO) model considering ambiguously correlated trip-demand uncertainties. In the first stage, an operator decides the initial vehicle allocation. In the second stage, the operator determines various operational decisions to meet demands over a time horizon. The objective is to minimize the expected cost under a worst-case joint distribution within an ambiguity set based on moment information of the correlated uncertainties. We show a monotonic relationship between the optimal objective value and the trip-demand covariance matrix. We further prioritize trip-demand pairs based on their covariance value or shadow price, enabling us to focus on a subset of demand pairs, which is especially appealing given the operator's limited resources. To improve computational efficiency, we propose tight approximations of the DRO model based on principal component analysis and develop a hybrid algorithm using a temporal decomposition technique. Numerical results based on real data confirm our approach's efficiency. It is crucial to properly incorporate correlation information, which can attain up to 4.66% total cost reduction.

2 - Bi-Parameterized Two-Stage Stochastic Min-Max and Min-Min Integer Programs

Manish Bansal, Virginia Tech., Blacksburg, VA, United States

We introduce two-stage stochastic min-max and min-min integer programs with bi-parameterized recourse (BTSPs), where the first-stage decisions affect both the objective function and the feasible region of the second-stage problem. To solve these programs efficiently, we introduce Lagrangian-integrated L-shaped (L^2) methods, which guarantee exact solutions when the first-stage decisions are pure binary. For mixed-binary first-stage programs, we present a regularization-augmented variant of this method.

Our computational results for a stochastic network interdiction problem show that the L^2 method outperforms a benchmark method, solving all instances in 23 seconds on average, while the benchmark method failed to solve any instance within 3600 seconds. The L^2 method also achieves optimal solutions, on average, 18.4 times faster for a stochastic facility location problem. Furthermore, we show that the L^2 method can effectively address distributionally robust optimization problems with decision-dependent ambiguity sets that may be empty for some first-stage decisions, achieving optimal solutions, on average, 5.3 times faster than existing methods.

3 - Robust System Identification: Finite-Sample Guarantees and Connection to Regularization

Grani Adiweni Hanasusanto, University of Illinois Urbana-Champaign, Urbana, IL, United States, Hyuk Park, Yingying Li

We study the problem of learning nonlinear dynamical systems from a single sample trajectory. While the least squares estimate (LSE) is a standard approach, it often yields poor identification accuracy when the sample size is limited or the model is misspecified. To address these challenges, we propose a robust LSE framework that leverages robust optimization techniques. We show that this framework is equivalent to a regularized LSE with general Schatten-norm penalties. For linear systems, we establish non-asymptotic performance guarantees, demonstrating a near optimal error rate of $O(1/\sqrt{T})$ that avoids the curse of dimensionality. Empirical evaluations on real-world system identification and online control tasks highlight the substantial performance gains of our method over existing approaches.

4 - Contextual Distributionally Robust Optimization Under Streaming Data: An Alternating Optimization Method

Guzin Bayraksan, The Ohio State University, Columbus, OH, United States, Haoyuan Xue, Merve Bodur

We consider data-driven decision-making that incorporates a prediction model within the 1-Wasserstein distributionally robust optimization (DRO) given joint observations of uncertain parameters and covariates using regression residuals in a streaming-data setting. In this setting, additional data become available and allow decisions to adapt to the growing knowledge of the underlying uncertainty. The ambiguity set shrinks as more data is observed. We propose an efficient online optimization method for this streaming-data contextual DRO setting, which iteratively alternates between optimizing the decision and determining the worst-case distribution. We analyze the asymptotic convergence properties of this algorithm and establish dynamic regret bounds to certify the performance of online solutions. Through numerical experiments, we validate our theoretical findings and demonstrate that our approach significantly enhances computational efficiency while maintaining high solution quality under streaming data.

5 - A Primal Perspective on Distributionally Robust Two-Stage Problems with Integer Recourse

Yiling Zhang, University of Minnesota, Minneapolis, MN, United States

: In this talk, we introduce and study a two-stage distributionally two-stage linear problem with integer recourse, where the objective coefficients are random. The random parameters follow the worst-case distribution belonging to a second-order conic representable ambiguity set of probability distributions. We show that the worst-case recourse objective, under various risk measures, can be formulated as a conic program from a primal perspective. This method also provides additional information on the probability of attaining an integer recourse solution, extending the concept of persistency studied in Bertsimas et al. (2006). Unlike the marginal moment sets used in Bertsimas et al. (2006), the second-order conic representable ambiguity sets in our method offer greater flexibility by incorporating more distributional information. Furthermore, this method enables column constraint generation methods for solving two-stage problems with integer recourse.

Recent Trends in Algorithms and Probability Theory

Invited Session

Computing Society

Chair: Ilias Zadik, Yale, New Haven, CT, United States

1 - New Local Search Algorithms in Sparse PCA

Ilias Zadik, Yale, New Haven, CT, United States

Local-search methods are widely used in statistics, but their theoretical foundations are far less developed than those of low-degree polynomials or spectral methods. A striking example arises in sparse tensor principal component analysis (PCA), where prior work uncovered a large “local-computational” gap: many local Markov chain methods perform significantly worse than the best polynomial-time algorithms.

We address this by proposing new local-search procedures that provably close this gap across multiple regimes of the model, including—and extending beyond—those where traditional local methods fail. Our framework covers two main families: (1) standard greedy and randomized greedy algorithms applied to the (regularized) posterior, and (2) new random-threshold variants. In the latter, the randomized greedy algorithm accepts a move only if the Hamiltonian increase exceeds a Gaussian random threshold, rather than simply being positive.

2 - Learning with Systematic Bias and Missing Data

Alvertos Kalavasis, YALE UNIVERSITY, New Haven, CT, United States

In many problems in Econometrics and Statistics, we only have access to imperfect data due to systematic bias in the data collection process. In this talk, we will present a general formulation for learning in the presence of such biasing mechanisms. Under this framework, we will discuss learning algorithms for: (i) parameter estimation for mixture models, (ii) inference under self-selection bias and coarsening, and (iii) estimation of treatment effects in causal inference.

3 - The Broken Sample Problem Revisited: Proof of a Conjecture by Bai-Hsing and High-Dimensional Extensions

Simiao Jiao, Duke University, Durham, NC, United States, Yihong Wu, Jiaming Xu

We revisit the classical broken sample problem: Two samples of i.i.d. data points $\mathbf{X} = \{X_1, \dots, X_n\}$ and $\mathbf{Y} = \{Y_1, \dots, Y_m\}$ are observed without correspondence with $m \leq n$. Under the null hypothesis, $\mathbf{X}$ and $\mathbf{Y}$ are independent. Under the alternative hypothesis, $\mathbf{Y}$ is correlated with a random subsample of $\mathbf{X}$, in the sense that $(X_{\pi(i)}, Y_i)$'s are drawn independently from some bivariate distribution $\pi: [m] \rightarrow [n]$. Originally introduced by DeGroot, Feder, and Goel (1971) to model matching records in census data, this problem has recently gained renewed interest due to its applications in data de-anonymization, data integration, and target tracking. Despite extensive research over the past decades, determining the precise detection threshold has remained an open problem even for equal sample sizes ($m = n$). Assuming m and n grow proportionally, we show that the sharp threshold is given by a spectral and an L_2 condition of the likelihood ratio operator, resolving a conjecture of Bai and Hsing (2005) in the positive. These results are extended to high dimensions and settle the sharp detection thresholds for Gaussian and Bernoulli models.

4 - An Improved Upper Bound for the Euclidean Tsp Constant

Charlie Guan, Northwestern University, Evanston, IL, United States

Consider n points generated uniformly at random in the unit square, and let L_n be the length of their optimal traveling salesman tour. Beardwood, Halton, and Hammersley (1959) showed $L_n / \sqrt{n} \rightarrow \beta$ almost surely as $n \rightarrow \infty$ for some constant β . The exact value of β is unknown but estimated to be approximately 0.71 (Applegate, Bixby, Chvátal, Cook 2011). Beardwood, Halton, and Hammersley further showed lower and upper bounds such that $0.625 \leq \beta \leq 0.92117$. Currently, the best known bounds are $0.6277 \leq \beta \leq 0.90304$, due to Gaudio and Jaillet (2019) and Yu and Carlsson (2023). In this talk, we present an improved upper bound of 0.89851. In all existing methods that obtain the upper bound, the central idea is to divide the unit square into bands of height $h / \sqrt{n}$ and to construct a path traversing all vertices within each band. The additional length required to merge these band-paths into a valid tour is $O(\sqrt{n})$, so the sum of the lengths of the band-paths is an upper bound on $\beta \sqrt{n}$. Our approach allows paths to cross bands and takes advantage of pairs of points in adjacent bands which are close to each other. Numerical integration techniques yield an upper bound of 0.89851, which is the first upper bound to eclipse 0.90, to the best of our knowledge.

5 - The Price of Sparsity: Sufficient Conditions for Sparse Recovery Using Sparse Measurement Matrices

Youssef Chaabouni, MIT, Boston, MA, United States

We consider the problem of recovering the support of a sparse signal using noisy projections. While extensive work has been done on the dense measurement matrix setting, the sparse setting remains less explored. In this work, we establish sufficient conditions on the sample size for successful sparse recovery using sparse measurement matrices. Bringing together our result with previously known necessary conditions, we discover that, in the regime where $\frac{ds}{p} \rightarrow +\infty$, sparse recovery in the sparse setting exhibits a phase transition at an information-theoretic threshold of $n_{\text{INF}}^{\text{SP}} = \Theta(\frac{s \log(p/s)}{\log(ds/p)})$, where p denotes the signal dimension, s the number of non-zero components of the signal, and d the expected number of non-zero components per row of measurement.

Energy System Design and Operations Under Uncertainty

Invited Session

ENRE: Energy

Chair: Jordan Kern, North Carolina State University, Durham, NC, United States

Co-Chair: Benjamin Rachunok, North Carolina State University, Raleigh, NC, United States

1 - Electrified Systems with Resource Uncertainty: Future Flexibility and Resilience

Constance Crozier, Georgia Institute of Technology, Atlanta, GA, United States

This talk will explore the ability of electrified systems to adapt to possible longer interruptions in energy supply. We will consider how potentially volatile electricity prices would change the capital investments that industrial consumers make, and the benefits that this may have for supply chain and energy resilience. Historically, industrial consumers have coped with relatively stable energy prices and certain energy security. This has led to very “lean” supply chains with little flexibility. The deployment of extremely low cost renewable energy means that supply chain operators stand to profit if they have the flexibility to benefit from cheap variable energy. These effects will be demonstrated using a case study of electrified freight transport along the East Coast.

2 - Transmission Cost Allocation via Stochastic Capacity Expansion Planning

Elizabeth Glista, Lawrence Livermore National Laboratory (LLNL), Livermore, CA, United States, Jean-Paul Watson

Due to booming demand for electric power and aging electric infrastructure, new investments are needed in many existing generation and transmission systems. However, interconnection delays and costs are a huge barrier to new generation and utility-scale storage coming online. During the interconnection process, developers are notified

of the associated cost to upgrade transmission and may withdraw their projects at any point. In many U.S. markets, these transmission upgrades are assigned based on a "beneficiaries pay" approach that seeks to assign the upgrades to those who most benefit from them. However, the benefit of a transmission upgrade in a meshed network is hard to measure, and this cost allocation scheme can lead to system-level investment distortions. In this talk, we demonstrate how transmission cost allocation can be included in a stochastic capacity expansion planning (CEP) model that co-optimizes investments in new generation, storage, and transmission. Then we establish conditions for transmission cost allocation that prevent system-level distortion in both energy-only and capacity markets. While considering the set of active generation and storage projects in the existing interconnection queue, we examine different transmission cost allocation methods on a synthetic-but-realistic model of the state of California that has around 8,000 buses. Using future weather projections as a stochastic input to the model, we demonstrate how our method can be used to establish a transmission cost allocation scheme that results in optimal system behavior over a long-term, uncertain planning horizon.

3 - Critical Mineral Supply Chains for Energy System Modeling: Optimizing Multiple Players and Objectives

Erick Jones, University of Texas at Arlington, Arlington, TX, United States

Critical Minerals, which include elements like Lithium, Cobalt, and Rare Earth Elements, are essential for modern energy and defense applications. There are a variety of concerns about various nations ability to acquire these minerals. Furthermore, even if a sufficient supply is obtainable, refining, and component production has been concentrated in a small number of nations; creating supply chain and even geopolitical risks. Yet even with these known problems most energy systems models exclude supply chain challenges and assume that the materials to build identified technologies are not only available but available at the predicted price. In order to address this gap, this work investigates how to model critical mineral supply chains which include multiple players balancing multiple objectives in an optimization framework that leverages advances in game theory, decomposition techniques, and MILP algorithms to model these supply chains, investigate how different nations will compete for market share, and evaluate how this all affects prices. Then, this work will discuss how these findings can be integrated into energy system modeling workflows to improve accuracy.

4 - Modelling Extreme Weather Risks to Daily US Natural Gas Markets Under near-Term Growth in Electric Power and Lng Export Demand

Cameron Lisy, North Carolina State University, Raleigh, NC, United States, Jordan Kern

Recent steady growth in the production of U.S. domestic natural gas has kept up with rising demand in the power sector, and prices have remained stable despite rising geopolitical headwinds from conflict and uncertainty in trade relationships. But this balance of fundamentals may shift in the near term as more LNG export terminals have begun operations and hyperscale datacenter growth encourages the building of more gas turbines by utilities to meet their 24/7 demand for electricity. Simultaneously, natural gas infrastructure vulnerability to extreme winter storms, most recently experienced from weakened polar vortex events in 2019, 2021, 2023, 2024 and 2025 have raised concerns about the potential for disruption at critical times of year when customers rely on natural gas deliveries both directly and to electric power generators for space heating. To understand the impacts these events and new market conditions may have on the price and availability of natural gas to end-use consumers in key regions of the country and how they may influence each other, we utilize our model of daily U.S. production and state-to-state pipeline flows. We evaluate several possible combinations of supply and demand scenarios, along with simulated disruptions to supply from extreme weather, and explore what they may mean for the future of the natural gas market in the U.S.

5 - Incorporating Equity and Fairness into a Mathematical Model for Power Restoration After Natural Hazards

Benjamin Rachunok, North Carolina State University, Raleigh, NC, United States, Ignacio Sepulveda

The power grid is a critical infrastructure of a community, yet the increasing frequency and intensity of extreme weather events have led to longer, more frequent power outages, disproportionately affecting low-income and minority groups as well as rural communities. To enhance recovery after such events, various restoration strategies have been proposed, focusing on cost reduction and critical infrastructure prioritization. However, these strategies often overlook people's needs, highlighting the need to incorporate equity/fairness into power restoration planning. This study addresses the power restoration planning problem for transmission networks considering customer vulnerability as captured by the Social Vulnerability Index of the United States. In this problem, we employ a Mixed-Integer Linear Programming model to dispatch a set of homogeneous repair crews to fix damaged components, combining operational and power flow constraints for transmission networks, and vehicle routing constraints, testing different objective perspectives. Exact and heuristic methods are proposed to solve the model depending on its complexity. The model's solutions are analyzed in order to understand, first, the cost of equity/fairness; second, the reason of the disparity; last, what is the best strategy for each instance.

6 - A Risk-Averse Stochastic Optimization Approach for Reliably Operating Energy Storage Technology Supply Chains

William Yang, Lawrence Livermore National Laboratory, Livermore, CA, United States, Mengyao Yuan, Elizabeth Glista, Michael Grappone, Jean-Paul Watson

There are unique challenges to reliably managing supply chains for energy storage or generation technologies, as well as other power grid resources. Many grid technologies require assembly from multiple raw materials sourced from across the world. Furthermore, raw materials are often processed at locations that are different than the final production stage, which adds more complexity. There is a high degree of uncertainty in the price and demand for grid technologies because of the ever-changing landscape of power grids and the energy sector. Moreover, uncertainty from market and geopolitical factors impacts the ability to ship materials from one location to another and is exacerbated by the highly interconnected nature of grid technology supply chains. To address these challenges, we develop a risk-averse stochastic optimization methodology to provide secure operation of the energy storage technology supply chain. Our model considers not only the raw material flow, but also the intermediate processing and the final production stage, with each stage taking place in different locations. We additionally incorporate stochastic components such as uncertainties caused by unplanned demand, pricing, and trade dynamics. Our model incorporates risk by optimizing the Conditional Value at Risk metric, which allows us to produce more reliable results compared to traditional stochastic optimization methods. We present experimental results that demonstrate our methodology's efficiency and its ability to reliably provide cost-effective solutions. A major consequence of our methodology is that it can allow grid planners to securely obtain necessary technologies to expand grid capabilities.

Building B Level 2 B204

Optimization Under Uncertainty for Power Systems Resilience Integrating Distributed Energy Resources

Invited Session

ENRE: Electricity

Chair: Tanveer Bhuiyan, The University of Texas at San Antonio, San Antonio, TX, 78249, United States

1 - A Stochastic Game-Theoretic Optimization Approach for Managing Coupled Local Electricity and Thermal Markets with Electric Vehicles and Renewable Sources

Dai Nam Nguyen, The University of Texas at San Antonio, San Antonio, TX, United States, Tanveer Bhuiyan, Sayed Hamid Hosseini Dolatabadi, Yang Chen

With the growing need for sustainable, resilient, and environmentally friendly energy ecosystems—alongside the rapid adoption of electric vehicles (EVs), renewable energy sources (RESs), combined heat and power systems (CHPs), and heat pumps (HPs)—local energy markets (LEMs) present a distinct potential to promote clean energy, enhance grid stability, and lower emissions. However, unlocking the full potential of LEMs requires addressing complex challenges related to market dynamics, EVs and RESs integration, and electricity-thermal energy interdependency. Our study presents a stochastic bi-level model for managing LEMs, where the local transaction center (LTC) and other market participants—load aggregator (LA), pure thermal industrial prosumers (PTIP), and their lower-level prosumers—aim to maximize their profits in a competitive game-theoretic structure. To ensure grid stability and profitability, the LTC, as the leader, designs a robust dynamic pricing strategy under uncertainty, while the LA and PTIP, as followers, determine the energy transaction amounts under uncertainties in generation and consumption. We address several novel aspects of LEMs, including the heterogeneous behavior of entities, uncertainties in renewable generation and load profiles, and electricity-thermal energy coupling. We develop an exact approach based on Karush–Kuhn–Tucker (KKT) and a parallel dynamic cutting plane algorithm (PDCP) leveraging piecewise linear approximation and

Sampling strategy to efficiently solve the model. Results show that the PDGP algorithm outperforms the KKT-based approach. Results also show that considering the electricity-thermal interdependency increases LTC's profit to 127% of its original value.

2 - Data-Driven Distributionally Robust Optimization for Power System Dispatch

Xunhang Sun, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Xiaoyu Cao, Bo Zeng, Miaomiao Li, Xiaohong Guan, Tamer Basar

Due to the highly intermittent, fluctuating, and random nature, the increasing scale of renewable energy poses huge challenges to the economic and secure operation of power systems. In this work, we present a two-stage distributionally robust optimization (DRO) approach for power system dispatch under supply and demand uncertainties. Specifically, we focus on a practical situation in which the probability distributions of random factors are not known exactly, whereas a limited set of empirical data is available. In this setting, a continuous Wasserstein ambiguity set is constructed to support data-driven decision-making. By fully leveraging the specific structure of the worst-case expectation problem, a discrete equivalence of it is proposed from the *primal* perspective. Then, we customize and develop a novel and exact decomposition algorithm under the framework of column-and-constraint generation for the DRO dispatch problem that guarantees finite-step convergence and facilitates parallel computing. As a byproduct, we shed light on the interrelationships of the DRO dispatch model with the traditional ones based on stochastic programming (SP) and robust optimization (RO). Numerical studies on a multi-energy microgrid demonstrate that, compared to the SP model, the DRO model reduces the probabilities of electricity and heat load shedding from 8.7% to 0.3% and from 12.1% to 1.2%, respectively, with only a negligible 0.3% increase in total cost. And, the DRO model exhibits much less conservativeness than the RO one. The significant improvement of our solution algorithm is verified by comparing to the popular algorithms in the literature for two-stage DRO problems.

3 - An Improved Branch-and-Price Algorithm for Routing and Energy Scheduling of Electric School Buses for Disaster Restoration

Sayed Hamid Hosseini Dolatabadi, The University of Texas at San Antonio, San Antonio, TX, United States, Yuchon Dong, Tanveer Bhuiyan, Bo Zeng

Natural disasters threaten the resilience of power systems, causing widespread power outages that disrupt critical loads (e.g., hospitals) and endanger public safety. Leveraging government-controlled electric school buses (ESBs) having large battery capacity and deployment readiness offers a promising solution for faster power restoration to critical loads during disasters while traditional maintenance is underway. We propose an efficient mixed-integer linear programming model for dispatching, routing, and scheduling a heterogeneous fleet of ESBs to satisfy the energy demand of critical isolated loads around disasters with the minimum cost, addressing the following practical aspects: combined transportation and energy scheduling of ESBs, multiple back-and-forth trips of ESBs between isolated loads and charging stations, and spatial-wise coupling among multiple ESB routes. We develop efficient exact and customized heuristic branch-and-price (B&P) algorithms to solve the proposed model for large networks. Numerical results based on a realistic case study of Florida hospitals demonstrate that our proposed exact and heuristic B&P algorithms are computationally 193 and 343 times faster, respectively, than Gurobi. Using network sparsity to incorporate the limitation in shelter-ESB type compatibility demonstrates that the total cost increases by 217% as the network becomes fully sparse compared to fully connected. The effective usable capacity metric reflects that the largest-capacity ESBs are up to 10 times more effective than the least-capacity ESBs in critical load restoration. Additionally, results demonstrate that the required fleet size increases by 429% as the weather changes from normal to adverse.

4 - Improving the Resilience of the Power Grid to Extreme Heat: Prediction, Evaluation and Optimization

Erhan Kutanoglu, The University of Texas at Austin, Austin, TX, United States

Power grid's operational performance increasingly depends on weather, which shows short- and long-term variability stressing the grid in multiple ways. Temperature and heat waves play a significant role in electricity supply and demand as well as the grid's overall capacity to handle the resulting power flows. We study how to model the long-term weather patterns including climate-shifted temperatures at high temporal and spatial resolutions, how to evaluate their effects on the operational performance of the grid, and how to optimize a resilience improving investment strategy. We use two synthetic test grids mimicking Texas' power system in two different sizes and generation mix profiles and measure the benefits of several optimized planning strategies, including deployment of energy storage systems, for the resilience of the grid against extreme heat.

Building B Level 2 B205

Electricity Market Design and Pricing Strategies

Contributed Session

Contributed

Chair: Carlos Olivios, Universidad Católica del Norte, Angamos 0610, Antofagasta, Chile

1 - Data-Driven Electricity Price Calibration Based on Bayesian Inference

Haolin Yang, Rensselaer Polytechnic Institute, Troy, NY, United States, Siby Jose Plathottam, Kristen Schell, Todd Levin, Zhi Zhou

Electricity prices in real-world markets can vary widely; prices in the New York Independent System Operator's (NYISO) market, for example, can vary by two orders of magnitude: from a mean of 30/MWh up to 4000/MWh. However, simulated price data from electricity system production cost models (PCMs) result in much narrower distributions. This research has developed a new framework to better calibrate simulated price data from PCMs to real-world price data. This framework is based on Bayesian inference and utilizes two different types of Bayesian models to tackle two problems: Bayesian Ridge Regression to capture extreme price spikes and two Dual-head Bayesian Neural Networks (DBNN) to model prices within the normal range. The calibration framework is validated on real-world data from two regional wholesale electricity markets (California Independent System Operator (CAISO) and NYISO). It is shown that the calibrated PCM data much more closely follows the real-world data distributions, achieving closer skewness and kurtosis values and achieving overall improvement in similarity by as much as 73.58%.

2 - Joint Optimization of Pricing Strategies and Charging Infrastructure Configuration in Urban Networks

Alireza Rostami, Michigan State University, East Lansing, MI, United States, Ali Zockaie

The growing adoption of electric vehicles (EVs), supported by advancements in battery technology and reduced operational costs, introduces new planning challenges for cities and utility providers. While EVs are well-suited for daily urban trips, unmanaged charging demand can stress the power grid, especially during peak hours when users typically prefer to charge. These peaks can increase the gap between average and maximum grid load, requiring costly upgrades in generation, and distribution systems. Moreover, since charging infrastructure is designed to minimize queuing and ensure acceptable service, high peak demand can drive up investment costs. One promising solution is implementing demand management strategies, particularly through dynamic electricity pricing. By shifting charging demand to off-peak hours and less congested locations, pricing mechanisms can improve grid efficiency and reduce infrastructure costs. However, poorly designed pricing schemes can lead to increased detour times, higher user costs, or even lower charger utilization. Most prior work optimizes pricing assuming a fixed charging network, overlooking how pricing impacts charging infrastructure needs. In reality, pricing and infrastructure decisions are tightly linked and should be optimized together. This study develops a large-scale framework that jointly determines station locations, charger counts, and spatiotemporal pricing. It integrates discrete choice models to capture users' responsiveness to pricing, detour time, and SOC, and leverages the POLARIS activity-based model to simulate realistic travel behavior and charging needs. Applied to the Chicago regional network, the framework aims to reduce investment costs, improve user experience, and guide policy design for smarter EV infrastructure planning.

3 - "Credit Scores" for Modern Electric Grid Resources

Trishant Roy, Arizona State University, Tempe, AZ, United States, Kory Hedman

The electric grid is undergoing a fundamental transition from conventional thermal resources to emerging technologies like renewable energy, electric storage, and demand-side management. This brings operational challenges in managing the intermittency and uncertainty characterized by the newer resources. Motivated by standardized financial credit scores, this study aims to propose an analogous scoring mechanism for grid resources to quantify the performance risk associated with fulfillment of the resource's market bid/position. Statistical tools like logistic regression and k-nearest neighbors are being leveraged to develop the framework. The proposed scoring mechanism will allow Independent System Operators (ISOs; entities responsible for ensuring reliable and efficient operation of the electric grid) to assess resources with different characteristics in a unified framework. For example: a controllable solar farm with a strong record of fulfilling its obligations might receive

a score of 750 whereas a hydro-based powerplant with a previous history of outages/disconnections might receive a score of 550. The higher scoring resource (i.e., the controllable solar farm in this example) will be cleared in the electricity market. Hence, this framework allows ISOs to better assess the short-term resource mix of the grid and to maintain reliability. The presentation will delve deeper into the scoring mechanism (dataset creation, features utilized, models tested, and challenges faced).

4 - Improved Price-Taker Optimization of Integrated Energy Systems Using Data-Driven Surrogate Models

Xinhe Chen, University of Notre Dame, South Bend, IN, United States, Daniel Laky, Kay Lu, Alexander Dowling

Integrated energy systems (IESs) combine various energy technologies to enhance operational flexibility and efficiency. Optimization plays a key role in their techno-economic evaluation, but existing models face a trade-off between accuracy and computational cost. While simplified models ignore grid dynamics, rigorous production cost models (PCMs) are computationally intensive due to complex grid constraints and unit commitment problems.

Price-taker (PT) models offer a middle ground by treating electricity prices as fixed inputs. However, they fail to account for how IES decisions may influence market prices, leading to inaccuracies. To address this, we propose a novel optimization framework that integrates data-driven surrogate models into the PT formulation, enabling more accurate representation of market participation effects with a lower computational burden than PCMs.

Our method trains surrogate models on PCM simulation data to capture how IES design and operation affect electricity prices. These surrogates are embedded in the PT optimization to enhance market interaction realism without needing full grid models. We apply this approach to a nuclear power plant retrofitted with a proton exchange membrane (PEM) electrolyzer for hydrogen co-production. The electrolyzer enables flexible operation, allowing the plant to respond to market price fluctuations. Results show that the surrogate-assisted PT model captures key market interactions, improving design and bidding strategies.

This work bridges the gap between computational efficiency and modeling accuracy in IES optimization, offering a scalable solution for market-aware system design.

5 - Forward Trading, Demand Volatility, and Allocative Efficiency

Sebastien Mittraille, Toulouse Business School, Toulouse, France, Henry Thille

We analyze quantity competition between n firms with heterogeneous but constant unit costs of production which face an uncertain demand. Firms can sell forward before demand realizes, and then sell or purchase spot once demand is revealed. The possibility to sell forward ahead of risk and to buy or sell spot once demand is known is common in electricity and gas wholesale markets or in commodity markets (e.g. minerals, fossil fuels, or semi-conductors). Marginal cost heterogeneity corresponds to the situation in which firms operate different technologies of production (e.g. coal, gas, or nuclear electricity generation, mineral resource extraction from different deposits, or cost heterogeneous semi-conductor foundries). Demand volatility can result from the injection of renewable electricity (solar or wind) on the grid whose production is weather dependent, or from geopolitical risks. We show that demand uncertainty partially reverses the welfare gains associated with forward sales in a deterministic setting. Inefficient firms purchase spot to meet their forward commitment in low demand states, and use the forward market to ensure to sell at the expected spot price. Efficient firms sell less on the spot market in low demand states, and reduce forward trading to not overcommit their aggregate sales. Demand volatility reduces the incentives of efficient firms to sell forward, which allows the inefficient firms to increase their forward market share to the detriment of efficient firms. The equilibrium in pure strategies exists in which the number of operative firms vary with demand volatility (holding expected demand fixed). Concentration index decrease.

6 - Mechanism Design in Sector Coupling Communities Using a Game Theory Approach

Yuin Moon, POSTECH, Pohang, Korea, Republic of, Seokwoo Kim, Dong Gu Choi

This study proposes a fair price calculation and settlement mechanism based on the two-step Shapley value for sector coupling energy communities where diverse energy flows such as distributed energy, hydrogen, and heat are linked. In the first step, a coalition is formed through cooperation between stakeholders who have distributed energy resources such as solar and wind power and facilities such as energy storage devices, electrolyzers, hydrogen storage devices, and heat pumps. The value function is calculated based on the energy system model of the formed coalition. In the second step, the Shapley value is calculated based on the derived coalition and value function to perform profit distribution among the coalitions. To evaluate the stability of the proposed settlement mechanism, we examine whether the resulting allocation resides within the core, thereby ensuring that no subset of participants has an incentive to deviate from the community. If the allocation lies outside the core, a subsidy allocation mechanism is proposed to support continued community participation and enhance social welfare from the repeated game perspective.

7 - Strategic Bidding in Electricity Markets Using Metaheuristics

Carlos Olivios, Universidad Católica del Norte, Antofagasta, Chile, Pamela Bustamante

In modern electricity markets, generation companies compete by submitting bids that specify how much energy they are willing to produce and at what price. This process, known as bidding, plays a key role in how electricity is scheduled and priced. Moreover, this decision is complex because companies do not know what their competitors will do in advance. To address this problem, we propose a mathematical model that supports energy producers in creating better bidding strategies. Our model uses ideas from game theory to represent how companies compete in the market. To solve this model, we apply a metaheuristic algorithm. This allows us to find good solutions faster than traditional methods, especially when the problem becomes large or includes uncertainty. Preliminary results of the algorithm tested using synthetic data will be presented.

Coupling of Supply Chains and Energy Systems with Variable Renewable Energy

Invited Session

ENRE: Environment and Sustainability

Chair: Constance Crozier, Georgia Tech ISyE, Atlanta, GA, United States

Co-Chair: Elnaz Kabir, Texas A&M University, College Station, TX, United States

1 - A Data-Intensive Framework for Understanding Residential Energy Needs

Lauren Janicke, Carnegie Mellon University, Pittsburgh, PA, United States, Destenie Nock

Following the recent cuts to the U.S. Department of Health and Human Services and its Low Income Home Energy Assistance Program (LIHEAP), understanding the state of residential energy vulnerability in the U.S. has become even more critical. Past metrics like energy burden and the energy equity gap are valuable; however, they ignore housing characteristics and offer no baseline for residential energy expectations. Past research has focused on developing multi-tier frameworks to measure energy access levels for low- and middle-income countries. We seek to estimate thresholds for the expected energy required to maintain various levels of thermal comfort and safety assuming accessible grid connectivity. Thus, we establish a multi-tier framework focused on understanding energy vulnerability and affordability by using housing characteristics and smart meter data. First, we compare various methods for parameterizing residential energy use from a practical and statistical perspective. Then, we will develop an energy comfort framework using household survey and smart meter data from Arizona's Salt River Project and explore the sensitivity of the framework to

housing characteristics using state-level data from the Residential Energy Consumption Survey. Initial work finds that using a lagged dependent variable in the regression improves model fit the most. This work aims to provide utilities and governments a tool to easily analyze energy vulnerability in their region by incorporating metrics that account for multiple influencing factors.

2 - Toward Net-Zero: a Case Study on Bioenergy System Optimization

Joon Moon, Princeton University, Princeton, NJ, United States, Hongxi Luo, Eric Larson

Decarbonization pathways require energy system models that capture spatial, technological, and temporal complexity, especially for sectors with significant land-use implications like bioenergy. This study introduces a high-resolution supply chain optimization framework designed to identify cost-effective strategies for bioenergy production, conversion, and distribution. The model employs mixed-integer linear programming-based framework to determine optimal infrastructure placement while accounting for economic, environmental, and land-use constraints at a fine geographic scale. It operates in a sequential, myopic fashion, aligning with national-level system optimization by translating aggregated results into localized, actionable strategies. Detailed techno-economic and resource data were compiled across thousands of subnational regions and tested in a key biofuel-producing area under four forward-looking scenarios, including variations in demand growth, electrification trajectories, and environmental protection levels. Findings highlight how infrastructure coordination can support bioenergy scale-up while managing trade-offs in cost, land use, and emissions. This framework offers both a methodological advancement for spatial downscaling in integrated assessment models and a decision-support tool for regional energy planning.

3 - Net-Zero Emissions Heat

Jacqueline Dowling, Stanford University, Stanford, CA, United States, Dimitri Saad, Alicia Wongel, Inês Azevedo, Kenneth Caldeira, Adam Brandt, Steven Davis

Heating accounts for about 40% of U.S. and global CO₂ emissions. We estimate the costs to decarbonize specific industrial and building heating demands in the U.S., and how these costs scale with heat-related carbon emissions avoided for different industrial processes and geographic locations. Our results identify and quantify the most and least challenging heating to decarbonize, target energy infrastructure upgrade priorities, and guide clean heat technology investment and associated research. Local carbon abatement cost data that matches local U.S. decision-making will help advance clean heat deployment.

4 - Implementing Energy Transition Speed Limits in Capacity Expansion Planning

Emil Dimanchev, ZERO Lab, Princeton University, Princeton, NJ, United States, Dominic Davis, Aniruddh Mohan, Eric Larson, Chris Greig, Jesse Jenkins

Net-zero emissions goals imply a transformation of the energy system of an unprecedented speed, scale, and complexity. Energy system optimization models are commonly used to inform decision makers on technological pathways for achieving these goals. However, such tools simplify the ways in which the speed of energy transitions is influenced by constraints on technological development and deployment. We construct a set of constraints, which we refer to as speed limits, that have a meaningful impact on the speed of technology deployment, including: capital discipline processes, supply chain inertia, and endogenous technological learning. We demonstrate the implementation of these speed limits in a state-of-the-art, scalable, open-source energy system optimization model. Our analysis then explores their impact on the U.S. power sector transition and what they imply for the relative merits of different technological pathways. Overall, this work sheds light on avenues for improving the representation of transition speed in energy system optimization modeling.

Data-driven Decision-making in Healthcare

Invited Session

Health Applications Society

Chair: Vishal Ahuja, Southern Methodist University, Dallas, TX, United States

Co-Chair: Yingchao Lan, University of Nebraska-Lincoln, Lincoln, NE, United States

1 - The Ripple Effects of Hospital Closures on Nursing Home Demand, Staffing, and Care Quality

Jong Myeong Lim, Miami Herbert Business School, Coral Gables, FL, United States, Xinyu Liang

Hospital closures have far-reaching consequences for healthcare delivery, yet their impact on nursing homes—a critical component of post-acute and long-term care—remains understudied. This research examines how hospital closures affect nursing home operations, with a focus on the dynamics of demand inflows, care delivery capacity, and quality of care.

2 - Prescriptive Service Rate Model for Healthcare

Sokol Tushe, University of South Florida, Tampa, FL, United States, Yixuan Wang, Donald Lee

Service process plays a central role in operations, but the literature on high resolution models that can be used prescriptively in simulations is relatively sparse. We address this gap by developing a data-driven service rate model that matches observed properties of service times across a range of settings, including healthcare.

3 - Optimizing Lift for a Targeted Set

Shannon Harris, Virginia Commonwealth University, Richmond, VA, United States, Jerrold May, Johnson Moore, Luis Vargas

This paper introduces novel methodologies for binary classification that directly optimize lift at a specified target level. Lift is widely used in practice due to its intuitive interpretation and alignment with many real-world decision-making settings. We propose two linear programming models: one formulated as a mixed-integer program and the other as a bilevel optimization problem. Both are designed to maximize lift at a predefined target level, with the bilevel model additionally generating a ranking of the observations. We apply these models to a no-show prediction problem in outpatient behavioral health clinics, where only a limited number of patients can be contacted with reminders. Compared to logistic regression, our models identify different target groups, thus demonstrating that explicitly optimizing for lift under resource constraints can lead to more effective interventions. These results underscore the value of tailoring classification models to operational realities.

4 - Using Analytics to Build a Reliable Surgery Schedule

Vishal Ahuja, Southern Methodist University, Dallas, TX, United States

Efficient surgery scheduling in operating rooms (OR) is critical for optimizing hospital operations and patient outcomes. The average cost of an unused OR minute is estimated to be \$46. However, scheduling decisions are complex, influenced by factors such as surgery type, provider and room availability, and team familiarity. We develop a machine learning-based predictive model that improves the estimation of surgery durations while also characterizing their uncertainty. Our model leverages historical surgical data and incorporates important features relevant to the surgery. Beyond prediction, we integrate these uncertainty-aware estimates into a robust optimization framework for surgery case scheduling. We demonstrate the effectiveness of our method through a case study using data from a large pediatric hospital. Our work serves as a template for hospitals seeking to enhance operational planning under uncertainty.

1 - A Simple Heuristic to Learn Primal Solutions for AC Optimal Transmission Switching Using Historical Data

Berkay Becu, Georgia Institute of Technology, Atlanta, GA, United States, Santanu Dey

Power systems problems involve solving a series of similar optimization problems that change slightly over time due to fluctuating demand and cost within short time frames. In a transmission network, the AC Optimal Power Flow (AC-OPF) problem determines generator outputs and bus voltages to minimize costs, meet demand, and maintain AC-feasible power flow under physical limitations. The AC Optimal Transmission Switching (AC-OTS) problem extends OPF by reconfiguring network topology through line switching, yielding further cost reduction. Non-convex AC power equations and binary variables for line switching makes the problem non-convex mixed-integer that presents significant computational challenges. This work introduces a heuristic framework that leverages historical data to efficiently generate high-quality primal solutions to the AC-OTS problem. To find primal solutions, we use a sensitivity-based ranking heuristic based on dual values from convex, second-order cone and quadratic, relaxations of AC-OPF as well as the DC-approximation of the problem. These heuristics use the relaxations to acquire possible switching decisions and test them by AC-OPF model which guarantees AC-feasible primal solutions to AC-OTS problem. Since real-world instances have the demand and cost fluctuations in smaller magnitudes, we propose a k-nearest neighbor (kNN) learning approach to identify historically similar cases and reuse their best topologies, found by the heuristics, for new instances. Computational experiments demonstrate that kNN yields near-optimal solutions significantly faster than the expert (heuristics). On average, the expert method took 247.35 seconds with 2.03% cost improvement while kNN algorithm took 10.4 seconds with 1.87% cost improvement.

2 - Learning to Accelerate the Global Optimization of Qcqp: Strong Partitioning and An End-to-End Graph ML-Based Approach

Rohit Kannan, Virginia Tech, Blacksburg, VA, United States, Erin George, Harsha Nagarajan, Deepjyoti Deka

We learn optimal instance-specific heuristics for the global minimization of nonconvex quadratically-constrained quadratic programs (QCQPs). Specifically, we consider partitioning-based convex mixed-integer programming relaxations for nonconvex QCQPs and propose “strong partitioning” to optimally partition variable domains without sacrificing global optimality. Given that solving the strong partitioning problem exactly can be highly challenging, we design a local optimization method using the generalized gradients of the value function in the inner minimization problem. However, solving the strong partitioning problem to local optimality can still be computationally expensive. To address this, we propose a simple AdaBoost regression-based machine learning approximation for homogeneous families of QCQPs. We conduct a detailed computational study on randomly generated QCQP families, including instances of the pooling problem, using the open-source global solver Alpine. Numerical experiments demonstrate that our AdaBoost regression-based approximation of strong partitioning reduces Alpine’s solution time by a factor of 2 to 4.5 on average, with maximum reduction factors ranging from 10 to 200 across different QCQP families. Additionally, we design a novel end-to-end loss function to train a neural network-based policy that directly maps QCQP instance features to corresponding partitioning points, eliminating the need for an expert strong partitioning policy. We also demonstrate how to apply the graph scattering transform to train a single neural network model that generalizes across QCQP families of various sizes. Our results show that this graph scattering-based end-to-end neural network learns a partitioning policy that significantly outperforms the AdaBoost-based approach and generalizes well to larger QCQPs beyond those encountered in training.

3 - Extreme Strong Branching for Qcqp

Dahye Han, Georgia Institute of Technology, Mableton, GA, United States, Santanu Dey, Yang Wang

Since its introduction in 1995, the strong branching technique has proven to be an effective variable selection method in the branch-and-bound algorithm for solving MILPs. While its extension to MINLP is conceptually straightforward, its applicability remains limited. In MILPs, branching creates two child nodes by fixing the branching variable to either 0 or 1. However, branching on a continuous variable requires additional decision on the branching point. Strong branching on a continuous variable typically includes first defining a branching point, and then solving $2n$ relaxations where n is the number of candidate variables to evaluate the improvement by branching on the specific branching point selected a priori.

We propose an “extreme” strong branching, which evaluates multiple branching points for each variable and selects the branching variable and the branching point simultaneously based on the objective value improvement. Despite computational cost, there are two main benefits of this approach: (i) Bound tightening can be done during the branching process. It is similar in the spirit to the FBBT or OBBT implemented in modern global solvers, one key difference is that the bound reduction is a byproduct of the branching process rather than a separate step. (ii) Since the extreme strong branching rule considers improvement in the objective function value, it resembles closely and takes advantage of the strong branching rule that has shown to be successful in the MILP. We show the effectiveness of extreme strong branching on bipartite bilinear problem instances in the structural engineering field.

4 - Recent Advances in the Gurobi Global MINLP Solver

Rodrigo Fuentes, Gurobi Optimization, Plymouth, MN, United States

MILP solver codes have been around for more than 50 years. Their spatial branching counterparts that solve MINLPs to optimality are in an earlier stage of development, making bigger performance improvements easier to accomplish. This talk will discuss performance improvements to the Gurobi MINLP solver as well as support for additional nonconvex nonlinear functions such as the hyperbolic tangent function and the signed power function.

5 - What's New for the Global Solver in FICO Xpress

Tristan Gally, FICO, Birmingham, United Kingdom

This talk discusses the latest updates and improvements to the global optimization capability within FICO Xpress Solver, which allows to solve general mixed-integer nonlinear problems to global optimality. We will discuss the internal workings of the solver, its features, and recent performance improvements, as well as sharing insights about the types of problems that can be solved with global optimizers nowadays.

1 - Optimizing Community Resilience Investments: a Framework for Fair Building Retrofit Planning Under Multi-Hazard Risk

Himadri Sen Gupta, University of Oklahoma, Norman, OK, United States, Andres Gonzalez, Dylan Sanderson

Traditional hazard mitigation planning often struggles to integrate fairness considerations, overlooking disproportionate impacts on vulnerable populations and hindering equitable community resilience outcomes. This research introduces an optimization framework designed to guide fairness-centered planning for community resilience investments through building-level retrofitting. The framework is formulated as a mixed-integer program employing piecewise-linear approximations to operationalize distributive fairness. Specifically, it uses the decomposable Theil index to minimize disparities in mitigation resource allocation across key demographic dimensions (such as housing tenure, race, and income). Simultaneously, the model optimizes for minimized expected economic losses, total building repair times, and population displacement stemming from multi-hazard impacts (earthquake and tsunami). Utilizing hazard impact data derived from the IN-CORE modeling environment, we study the trade-offs between the different objectives for the coastal community of Seaside, Oregon, under 500-year and 1000-year hazard event scenarios and across multiple budget levels

(\$40M, \$80M, \$120M). The results quantitatively demonstrate significant, non-linear trade-offs between minimizing allocation unfairness and achieving efficiency goals, highlighting that substantial budget increases markedly improve the potential for simultaneous gains in fairness and efficiency, but fundamental conflicts often remain, particularly the high marginal cost in efficiency required to achieve the absolute lowest levels of unfairness. This decision-support tool provides planners with a transparent, data-driven method to explicitly evaluate the implications of different mitigation strategies, visualize complex fairness-efficiency trade-offs, and make more informed, evidence-based decisions that enhance community resilience while actively addressing potential disparate impacts.

2 - Optimizing School Bus Pickups with Third-Party Coordination and Delay Prediction

Neha ., Tepper School of Business, Pittsburgh, PA, United States, Peter Zhang, Holly Wiberg

Parents and policymakers throughout the United States report frequent school bus delays and no-shows. Data from New York City (NYC) shows that traffic is responsible for 63% of these delays, followed by aging buses, weather, and driver shortages. In response, we study the school bus routing problem in the presence of traffic and weather-related delays. Specifically, we investigate the benefits of integrating third-party hired drivers alongside regular drivers to mitigate the impact of these delays on the school bus network. We use machine learning models to predict delays by combining historical school bus delay data with traffic and weather information. These delay predictions inform an optimization model, which allocates third-party drivers—at an increased cost—to support delayed routes in the school bus network. This data-driven approach enables schools to minimize disruptions by strategically deploying third-party drivers, ensuring reliable bus operations during delays.

Our findings show that employing third-party services is effective when policymakers prioritize total expected student travel time. However, these benefits are sensitive to the relative weight of student experience and operational costs. The proposed approach is validated through numerical experiments using NYC delay data, highlighting its potential as a tactical tool to manage school bus operations in potential delays.

3 - Impact of Service Operations on Senior-Volunteer Satisfaction in a Non-Profit Organization

Shikha Safaya, Scheller College of Business, Georgia Tech, Atlanta, GA, United States, Basak Kalkanci, Ravi Subramanian

Nonprofit organizations (NPOs) play an essential role in enhancing societal welfare by addressing gaps left by insufficient governmental resources or policies. Predominantly relying on volunteers to deliver critical services such as food and shelter, NPOs significantly contribute to socioeconomic well-being. However, effectively managing volunteers is complex, as NPOs frequently face challenges like volunteer retention without financial incentives, limited scheduling control, and inconsistent participation. We partner with a nonprofit providing meals and personal interactions through volunteers to elderly individuals experiencing limited mobility and food insecurity. Our research investigates how different elements of service design contribute to sustained volunteer engagement and service quality. Additionally, we empirically identify operational characteristics that drive stakeholder satisfaction, including beneficiaries (seniors), volunteers, and donors.

A key finding of our study is that incorporating the service preferences of volunteers and beneficiaries significantly reduces gaps in volunteer engagement and social isolation among seniors. Furthermore, we explore the tradeoff between incorporating these preferences during volunteer allocation to beneficiary demand and managing the mismatch between volunteer supply and beneficiary demand. Our analysis provides prescriptive insights for NPOs on effectively balancing cost considerations with service quality and stakeholder welfare. Specifically, we demonstrate that the volunteers' utility gap between preferred and non-preferred assignments significantly influences their participation decisions. Thus, initiatives such as targeted volunteer training and recognition programs can effectively bridge this gap, enhancing overall volunteer satisfaction and retention.

4 - Cohort Formation for Resource Sharing in the Nonprofit Sector

Weixiao Huang, Worcester Polytechnic Institute, Worcester, MA, United States, Faidra Monachou, Andrew Trapp

Nonprofit organizations (NPOs) increasingly face challenges in accessing physical assets, as well as skills and talent critical to their missions. While collaboration among locally connected, mutually known NPOs offers a partial remedy to resource scarcity, forming effective and sustainable resource-sharing cohorts beyond existing neighborhood bonds, especially with attention to customization, has yet to be effectively addressed. This study proposes a data-informed cohort formation framework to facilitate efficient resource sharing in the nonprofit sector. Our approach integrates empirical experiments and preference elicitation to understand NPO partnership inclinations. These insights then inform the development of partitioning models that generate optimized, preference-aligned cohorts. We evaluate the framework's effectiveness and efficiency through real-world deployments, measuring both the quantity and quality of resource exchanges over time. Our work contributes to the advancement of innovative operations research for social good and offers actionable pipelines to enhance collective impact within the nonprofit sector.

5 - Optimizing a New Metric for Partisan Fairness of Political Districting Plans

Brendan Ruskey, Lehigh University Department of Industrial Engineering, Bethlehem, PA, United States

In this presentation, we describe a new metric for evaluating the partisan fairness of a political districting plan, and explain how this metric can be optimized to generate legal, unbiased districting plans. The new metric tracks how closely the two-party vote-seat curve of a districting plan adheres to an "ideal" vote-seat curve, with more likely shifts in voter partisanship being weighed more heavily. Plans that perform well under our metric satisfy an intuitive definition of partisan fairness. In addition, our metric has clear and notable advantages over existing partisan fairness metrics. We explain how the proposed metric can be used in a mixed-integer program to optimize the partisan fairness of a districting plan, and how a given plan can be heuristically improved to improve its partisan fairness. We present experimental results suggesting that our optimization models can be used to generate compact, fair districting plans that satisfy limits on county splits and Voting Rights Act requirements.

First-order Methods for Function-constrained Optimization and VI Problems

Invited Session

OPT: Nonlinear Optimization

Chair: Digvijay Boob, Southern Methodist University, Dallas, TX, United States

1 - Uniformly Optimal and Parameter-Free First-Order Methods for Convex and Function-Constrained

Zhenwei Lin, Purdue University, West Lafayette, IN, United States

This paper presents new first-order methods for achieving optimal oracle complexities in convex optimization with convex function constraints. Oracle complexities are measured by the number of function and gradient evaluations. To achieve this, we develop first-order methods that can utilize computational oracles for solving diagonal quadratic programs in subproblems. For problems where the optimal value f^* is known, such as those in overparameterized models and feasibility problems, we propose an accelerated first-order method that incorporates a modified Polyak step size and Nesterov's momentum. Notably, our method does not require knowledge of smoothness levels, H^* continuity parameter of the gradient, or additional line search, yet achieves the optimal oracle complexity bound of $\mathcal{O}(\frac{1}{\epsilon^2(1+3\rho)})$ under H^* smoothness conditions. When f^* is unknown, we reformulate the problem as finding the root of the optimal value function and develop inexact fixed-point iteration and secant method to compute f^* . These root-finding subproblems are solved inexactly using first-order methods to a specified relative accuracy. We employ the accelerated prox-level (APL) method, which is proven to be uniformly optimal for convex optimization with simple constraints. Our analysis demonstrates that APL-based root-finding also achieves the optimal oracle complexity of $\mathcal{O}(\frac{1}{\epsilon^2(1+3\rho)})$ for convex function-constrained optimization, without requiring knowledge of any problem-specific structures. Through experiments on various tasks, we demonstrate the advantages of our methods over existing approaches in function-constrained optimization.

2 - Regularized Operator Extrapolation Method for Stochastic Bilevel Variational Inequality Problems

Mohammad Khalafi, Southern Methodist University, DALLAS, TX, United States, Digvijay Boob

The bilevel variational inequality (BVI) problem is a general model that captures various optimization problems, including VI-constrained optimization and equilibrium problems with equilibrium constraints (EPECs).

This paper introduces a first-order method for smooth or nonsmooth BVI with stochastic monotone operators at inner and outer levels. Our novel method, called Regularized Operator Extrapolation (ROPE), is a single-loop algorithm that combines Tikhonov's regularization with operator extrapolation. This method needs only one operator evaluation for each operator per iteration and tracks one sequence of iterates. We show that ROPE gives $\mathcal{O}(\epsilon^{\frac{1}{4}})$ complexity in nonsmooth stochastic monotone BVI, where ϵ is the error in the inner and outer levels. Using a mini-batching scheme, we improve the outer level complexity to $\mathcal{O}(\epsilon^{\frac{1}{2}})$ while maintaining the $\mathcal{O}(\epsilon^{\frac{1}{4}})$ complexity in the inner level when the inner level is smooth and stochastic. Moreover, if the inner level is smooth and deterministic, we show complexity of $\mathcal{O}(\epsilon^{\frac{1}{2}})$. Finally, in case the outer level is strongly monotone, we improve to $\mathcal{O}(\epsilon^{\frac{1}{4}})$ for general BVI and $\mathcal{O}(\epsilon^{\frac{1}{2}})$ when the inner level is smooth and deterministic. To our knowledge, this is the first work that investigates nonsmooth stochastic BVI with the best-known convergence guarantees. We verify our theoretical results with numerical experiments.

3 - Solving Variational Inequality Problem Under Generalized Lipschitz Conditions

Digvijay Boob, Southern Methodist University, Dallas, TX, United States

We present efficient methods for solving monotone variational inequality problems when the operator is not uniformly Lipschitz continuous, and the feasible set may be unbounded. In recent years, optimization problems under generalized Lipschitz conditions have gained traction. However, there is limited literature on generalized conditions for VI problems. We introduce a new type of generalization of Lipschitz conditions for the VI problem that includes convex function-constrained optimization and variational inequality problems, average reward MDPs, and general robust optimization with semi-infinite (or robust) function constraints. In our problem setup, a uniform Lipschitz smoothness constant may not hold, especially since we allow the feasible set to be unbounded. Under the assumption that a VI solution exists and after carefully designing the algorithm, we show that our iterates remain bounded and establish state-of-the-art convergence rate guarantees for various cases, including monotone or strongly monotone operators with possibly generalized nonsmoothness. When the operator is stochastic, we show expected convergence guarantees. We also establish that the iterates are bounded in expectation. Our convergence criterion uses a Nesterov-type sufficiently large radius ball that contains the VI solution. However, unlike Nesterov, we do not need to know this radius to implement our methods for the abovementioned cases.

4 - Variance-Reduced First-Order Method for Convex Function Constrained Optimization with Finite-Sum Objective and Constraints

Yasin Gharehmohammadi, Southern Methodist University, Dallas, TX, United States

This paper investigates the function-constrained convex optimization problem where the objective function $\frac{1}{n} \sum f_i(x)$ has a finite-sum form and function constraints $\frac{1}{n} \sum g_j(x)$ also possibly finite-sum functions. We present a novel Variance-reduced Constraint Extrapolation Method (VR-ConEx), which is motivated by the ConEx method [?] developed for stochastic convex programs. We prove VR-ConEx can obtain reduced gradient complexity utilizing variance reduction compared to the ConEx method. In particular, for the semi-stochastic case, i.e., $n \ll 1$, the VR-ConEx method converges at the rate of $\mathcal{O}(1/K\sqrt{m})$ and $\mathcal{O}(1/K^2)$ for constant and non-constant step size policy, respectively. This gives $\mathcal{O}(m/\sqrt{\epsilon})$ and $\mathcal{O}(m/\sqrt{\epsilon} + 1/\epsilon^{1.5})$ gradient complexity for the constant and non-constant step-size policy, respectively. For the fully-stochastic case, we have proved that the Lagrangian norm is bounded by some constant and then improved the gradient computation. The convergence rate for the constant step size for fully stochastic case is $\mathcal{O}(1/K\sqrt{\max\{m,n\}})$ with $\mathcal{O}(\{m+n\}\epsilon/\max\{n,m\} + \sqrt{\max\{n,m\}}\epsilon)$ gradient computations. For non-constant step size the convergence rate is $\mathcal{O}(1/K^2)$ with $\mathcal{O}(\{m+n\}/\sqrt{\epsilon} + 1/\epsilon^{1.5})$ gradient computations.

5 - Improved Analysis for Large-Scale Difference-of-Convex Algorithms

Anh Duc Nguyen, National University of Singapore, Singapore, Singapore, Alp Yurtsever, Sra Suvrit, Kim-Chuan Toh

We propose and analyze DCA-PAGE, a novel algorithm that integrates the difference-of-convex algorithm (DCA) with the Probabilistic Gradient Estimator (PAGE) to solve structured nonsmooth difference-of-convex programs. In the finite-sum setting, our method achieves a gradient computation complexity of $\mathcal{O}(N + \sqrt{N}/\epsilon)$, surpassing the previous best-known complexity of $\mathcal{O}(N + N^{2/3}/\epsilon)$ for stochastic variance reduced (SVR) DCA methods. Furthermore, DCA-PAGE readily extends to online settings with a similar optimal gradient computation complexity $\mathcal{O}(N + \sqrt{N}/\epsilon)$, a significant advantage over existing SVR DCA approaches that only works for finite sum setting. We further refine our analysis with a gap function, which enables us to obtain comparable convergence guarantees under milder assumptions.

Recent Advances in Nonsmooth and Stochastic Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Ying Cui, University of California, Berkeley, Berkeley, CA, United States

1 - Asymptotic Normality and Optimality of Stochastic Linearized Augmented Lagrangian Method

Jiajin Li, The University of British Columbia, Vancouver, BC, Canada

In their seminal work, Polyak and Juditsky showed that stochastic approximation algorithms for solving smooth equations enjoy a central limit theorem and attain asymptotic-covariance optimality in the local minimax sense of Hájek and Le Cam. More recently, these guarantees have been extended to stochastic nonlinear programming via two well-studied primal methods: (i) stochastic projected gradient descent, which achieves asymptotic optimality but relies on expensive projections and does not identify the active constraint manifold in finite time; and (ii) dual averaging, which identifies the active manifold yet is provably optimal only under affine constraints. To date, no algorithm simultaneously offers projection-free updates, finite-time manifold identification, and asymptotic optimality for general nonlinear constraints. In this paper, we take the first step toward closing this gap by proving that the Stochastic Linearized Augmented Lagrangian Method (SLALM) combines all of these advantages. To that end, we develop two key technical results: (i) Almost-sure convergence of the full primal-dual iterate (ii) Local last-iterate convergence for both primal and dual variables. These results are not only key to establishing the asymptotic normality of SLALM but also provide a proof framework of independent interest for future stochastic primal-dual algorithms.

2 - A Descent-Oriented Subgradient Method for Nonsmooth Optimization

Ying Cui, University of California, Berkeley, Berkeley, CA, United States

Stochastic optimization shares the same fundamental difficulty as nonsmooth optimization, that is, sampled gradients do not vary continuously along the iterates, making the design of convergent descent methods based on merely first-order information particularly challenging. Classical methods in nonsmooth optimization such as bundle techniques and gradient sampling attempt to overcome this by aggregating subgradients from nearby points, but these approaches are often complex and may lack deterministic guarantees. In this talk, I first present a unifying principle behind these methods and introduce a general framework for provably convergent descent algorithms under solely first-order oracle information. Central to this framework is a simple yet powerful technique called subgradient regularization, which generates stable descent directions using only function values and subgradients at a single point, eliminating the need for neighborhood sampling. This framework captures a broad class of nonsmooth marginal functions, including pointwise maxima and minima of smooth functions. Notably, when applied to composite functions, our approach recovers the classical prox-linear method and offers a new dual perspective. I will conclude with numerical experiments showcasing the method's robustness on challenging nonsmooth problems, such as Nesterov's Chebyshev-Rosenbrock function.

3 - Uniformly Optimal Gradient Minimization Using Higher Order Methods

Yao Ji, Georgia Institute of Technology, Atlanta, GA, United States, Guanghui Lan

We propose a novel uniformly optimal framework for minimizing functions that are p -times differentiable with Lipschitz continuous p -th derivatives, targeting approximate solutions with small (sub)gradient norms. The methods achieve the best-known complexity guarantees across convex, uniformly convex, and nonconvex

settings. In the convex case, the number of tensor method iterations required to reach a point with gradient norm at most ϵ is bounded by $\mathcal{O}\left(\frac{L_{p+1} - x^*}{\epsilon^{2/(3p+1)}}\right)$, where L_{p+1} is the p -th order Lipschitz smoothness parameter and x^* is any optimal solution, matching the known lower bound. For uniformly convex functions with parameter σ_{p+1} , the complexity improves to $\mathcal{O}\left(\frac{L_{p+1}}{\sigma_{p+1}^{2/(3p+1)}} \log\left(\frac{f(x_0) - f(x^*)}{\epsilon}\right)\right)$. In the nonconvex case, we introduce a lower curvature property to characterize the degree of nonconvexity and obtain the bound $\mathcal{O}\left(\frac{L_{p+1}^{2/(3p+1)}}{\ell_{p+1}^{1/p - 2/(3p+1)}} \left[f(x_0) - f(x^*)\right] \epsilon^{(p+1)/p}\right)$, where ℓ_{p+1} is the p -th order lower curvature parameter. This improves upon the existing lower bound in terms of dependence on L_{p+1} .

4 - Recent Advances on First-Order Methods for Semidefinite Programming: Rank Identification and Local Linear Convergence

Xin Jiang, Cornell University, Ithaca, NY, United States, Shucheng Kang, Heng Yang

We investigate the performance of the Alternating Direction Method of Multipliers (ADMM) when applied to Semidefinite Programming (SDP). A longstanding belief suggests that ADMM is only capable of solving SDPs to moderate accuracy, primarily due to its sublinear worst-case complexity and empirical observations of slow convergence. We challenge this notion by introducing a new sufficient condition for local linear convergence: as long as the converged primal–dual optimal solutions satisfy strict complementarity, ADMM attains local linear convergence, independent of nondegeneracy conditions. Our proof is based on a direct local linearization of the ADMM operator and a refined error bound for the projection onto the positive semidefinite cone, improving previous bounds and revealing the anisotropic nature of projection residuals. Extensive numerical experiments confirm the significance of our theoretical results, demonstrating that ADMM achieves local linear convergence and computes high-accuracy solutions in a variety of SDP instances, including those where nondegeneracy fails. Furthermore, we identify cases where ADMM struggles, linking these difficulties with near violations of strict complementarity—a phenomenon that parallels recent findings in linear programming.

5 - Analysis of A Class of Heaviside Composite Minimization Problems

Shaoning Han, National University of Singapore, Singapore, Singapore, Ying Cui, Jong-Shi Pang

The minimization of nonclosed functions is a difficult topic that has been minimally studied. Among such functions is a Heaviside composite function that is the composition of a Heaviside function with a possibly nonsmooth multivariate function. Unifying a statistical estimation problem with hierarchical selection of variables and a sample average approximation of composite chance constrained stochastic programs, a Heaviside composite optimization problem is one whose objective and constraints are defined by sums of possibly nonlinear multiples of such composite functions. In this talk, we first present difficulties of tackling such problems using existing optimization techniques. Then we establish stationarity conditions for the problem, and introduce a sufficient condition, termed local convex-like property, under which the proposed stationary point is a local minimizer. Finally, we briefly discuss solution strategies via lifting and reformulation techniques.

1 - Khachiyan Prize

Marc Teboulle, School of Mathematical Sciences, Tel Aviv University, Tel Aviv, Israel

Over four decades, optimization has evolved from the solid ground of convex analysis to the open challenges of nonconvex and data-driven models. This talk retraces a research journey across these transformations: from convex duality and proximal methods to modern nonconvex and adaptive first-order algorithms, highlighting enduring principles, evolving challenges, and the lasting appeal of optimization in theory and applications.

2 - Farkas Prize

Maryam Fazel, University of Washington, Seattle, WA, United States

Over-parameterization (often due to model's scale) has been observed to drastically improve the optimization landscape in learning models, helping standard training algorithms that fail due to bad local minima of the loss function in exact parameterization, remarkably converge to the ground truth under mild assumptions. In this talk, we consider learning Gaussian Mixture Models (GMMs), a fundamental problem in machine learning, for which the Expectation-Maximization (EM) algorithm and its variant gradient-EM are widely used in practice. When the learning model uses the same number of components (m) as the ground-truth model, prior work has shown EM methods succeed in recovering the ground-truth when $m=2$, but fail to do so when $m>2$. We consider the "over-parameterized" case, where the learning model uses $n>m$ components. We show that gradient-EM converges globally: for a well-separated GMM, with only mild over-parameterization $n=O(m \log m)$, randomly initialized gradient-EM converges to the ground truth at a polynomial rate. The analysis relies on novel techniques to characterize the geometric landscape of the likelihood loss, and is the first global convergence result for EM methods beyond the case of $m=2$. Based on joint work with Mo Zhou, Weihang Xu, and Simon Du (Univ. of Washington).

3 - Balas Prize

Minyi Hong, University of Minnesota, Minneapolis, MN, United States

Professor Hong's work has transformed our understanding of distributed, nonconvex, and bilevel optimization, advancing algorithms that resolve longstanding open questions on ADMM (Alternating Direction Method of Multipliers), establish rigorous complexity results for stochastic bilevel problems, and illuminate the structure of minimax formulations. His research has profoundly shaped modern applications in machine learning, signal processing, and AI alignment, while also inspiring new directions across theory, algorithms, and computation. His creativity, depth, and impact embody the spirit of the Balas Prize.

1 - Real-Time Personalization with Simple Transformers

Lin An, Carnegie Mellon University, Pittsburgh, PA, United States, Andrew Li, Vaisnavi Nemala, Gabriel Visotsky

Real-time personalization has advanced significantly in recent years, with platforms utilizing machine learning models to predict user preferences based on rich behavioral data on each individual user. Traditional approaches usually rely on embedding-based machine learning models to capture user preferences, and then reduce the final optimization task to nearest-neighbors, which can be performed extremely fast. However, these models struggle to capture complex user behaviors, which are essential for making accurate recommendations. Transformer-based models, on the other hand, are known for their practical ability to model sequential behaviors, and hence have been intensively used in personalization recently to overcome these limitations. However, optimizing recommendations under transformer-based models is challenging due to their complicated architectures. In this paper, we address this challenge by considering a specific class of transformers, showing its ability to represent complex user preferences, and developing efficient algorithms for real-time personalization. We focus on a particular set of transformers called simple transformers. We show that simple transformers are capable of capturing complex user preferences. We then develop an algorithm that enables fast optimization of recommendation tasks based on simple transformers. Our algorithm achieves near-optimal performance in sub-linear time. Finally, we demonstrate the effectiveness of our approach through an empirical

study on datasets from Spotify and Trivago. Our experiment results show that (1) simple transformers can model/predict user preferences substantially more accurately than non-transformer models and nearly as accurately as more complex transformers, and (2) our algorithm completes simple-transformer-based recommendation tasks quickly and effectively.

2 - Sequential Allocation of Perishable Social Goods: Notification Design Under Heterogeneous Response

Ari Lerner, Yale University, New Haven, CT, United States

Platforms that coordinate the distribution of perishable goods, such as surplus food or medical donations, often notify recipients rather than allocating directly. In these systems, recipients compete to claim resources upon notification, creating a trade-off between efficiency (ensuring goods are claimed quickly) and equity (ensuring fair access across recipients with different response capabilities). This talk examines how notification strategies can be designed to navigate that trade-off. We develop a model in which goods arrive randomly and must be allocated to one of several agencies before perishing. Agencies differ in responsiveness, and the platform selects a notification strategy that determines when each agency is notified. Under natural conditions on the objective, we show that the problem reduces to finding a deterministic notification order. Simulations show that prioritization can improve equity. However, beyond a critical threshold, the optimal strategy shifts to notifying all recipients at once. These findings offer managerial insights for designing notification systems that balance equity and efficiency in allocating perishable resources.

3 - Free-Order Prophet Matching with Patience Constraints: Improved Approximations via Threshold Policies

Calum MacRury, Columbia University, New York, NY, United States

We study a bipartite online stochastic matching problem where the set of feasible edges is known in advance, but the weight of each edge is drawn from a known distribution and revealed only upon querying. The algorithm may adaptively decide which edges to query in an order of its choosing, subject to *patience constraints* that bound the number of queries per vertex. Upon querying an edge, it must immediately and irrevocably decide whether to include it in the matching.

Computing the optimal algorithm is known to be NP-hard, even when one side consists of a single vertex. On the positive side, Pollner, Roghani, Saberi, and Wajc (EC 2022) give a polynomial-time algorithm with an approximation ratio of 0.426 when vertices on one side have unlimited patience, which drops to 0.395 when both sides have bounded patience. Their result is based on rounding a linear program that cannot be rounded within a factor better than 0.544 in the worst case. In this work, we significantly improve these guarantees to $1 - 1/e$ and 0.58, respectively, for the one-sided and two-sided patience settings. A key ingredient in our work is a new configuration LP that allows for more effective rounding.

Our approach is based on designing *threshold policies*, where each queried edge is accepted if its realized weight exceeds a chosen threshold. This framework also extends our results to more general objectives beyond maximizing expected weight, including *revenue* in the sequential pricing problem.

4 - Distributionally Robust Newsvendor on a Metric

Ayoub Foussoul, Columbia University, New York, NY, United States, Vineet Goyal

We consider a fundamental generalization of the classical newsvendor problem where the seller needs to decide on the inventory of a product jointly for multiple locations on a metric as well as a fulfillment policy to satisfy the uncertain demand that arises sequentially over time after the inventory decisions have been made. To address the distributional ambiguity, we consider a distributionally robust setting where the decision-maker only knows the mean and variance of the demand, and the goal is to make inventory and fulfillment decisions to minimize the worst-case expected inventory and fulfillment cost. We design a near-optimal policy for the problem with theoretical guarantees on its performance. Our policy generalizes the classical solution of Scarf (1957), maintaining its simplicity and interpretability: it identifies a hierarchical set of clusters, assigns a "virtual" underage cost to each cluster, then makes sure that each cluster holds at least the inventory suggested by Scarf's solution if the cluster behaved as a single point with "virtual" underage cost. As demand arrives sequentially, our policy fulfills orders from nearby clusters, minimizing fulfillment costs, while balancing inventory consumption across the clusters to avoid depleting any single one. We show that the policy achieves a poly-logarithmic approximation. To the best of our knowledge, this is the first algorithm with provable performance guarantees. Furthermore, our numerical experiments show that the policy performs well in practice.

5 - Parallel Prophets: Dynamic Cut Minimization on Series-Parallel Graphs

William Frendreiss, Georgia Institute of Technology, Atlanta, GA, United States, Alejandro Toriello

We introduce a sequential decision problem on directed graphs. The decision maker adds vertices v in a directed graph and then observes the weight of the arcs out of v from known distributions. The objective is to minimize the expected total weight of the arcs out of the chosen vertices. We explore the connections to the classical prophet inequality setup of Krenkel & Sucheston; in particular, our model can encode an instance of a minimization optimal stopping problem using a directed path. A natural generalization from path graphs is to look at directed series-parallel graphs with source s and sink t . We prove that finding an optimal policy is $\#P$ -hard on this class of graphs. We study a separable lower bound that decomposes the problem into independent, parallel prophet problems, and a heuristic policy that uses this lower bound to decide when to stop. Roughly speaking, the heuristic's approximation guarantee grows with the number of non-sink nodes with in-degree greater than one and is tight even in the case of parallel paths that merge into a single path.

Service Science

Chair: Guiping Hu, Oklahoma State University, Stillwater, OK, United States

Co-Chair: Mohammad Fili, Oklahoma State University, Stillwater, OK, United States

1 - A Digital Twin Based on Noisy Data for Productive Maintenance

Samiksha Aryal, Missouri University of Science and Technology, Rolla, MO, United States, Abhijit Gosavi, Susan Murray

A model based on **renewal reward theory** is developed to determine the optimal **preventive maintenance** interval within a **digital twin** (DT) framework. DTs are increasingly being deployed in smart factories to minimize human intervention in equipment monitoring and maintenance.

Unlike traditional maintenance approaches, where a human operator collects data, fits a distribution offline, and then performs optimization to determine the maintenance schedule, the DT automates the entire process. The DT continuously gathers data from the machine to which it is attached, analyzes the data gathered, and automatically triggers maintenance alerts when the machine is close to failure and needs maintenance.

The **time to failure** (TTF) in this work is modeled via an **empirical distribution** here due to its **self-correcting** nature that accommodates adapting to changing data conditions. In ideal conditions (i.e., noise-free data), the empirical TTF results in an increasing failure rate. However, in this study, the data are assumed to be **noisy**, which is typical of real-world conditions. To address this complexity, this research employs a backpropagation **neural network** to fit the TTF distribution. The neural network results in a **smoothed approximation** of the TTF, which is expected to be **more robust** than directly fitting a basic TTF model to noisy data to determine the optimal maintenance interval.

2 - Uncertainty-Aware Digital Twin Manufacturing: a Q-Learning Approach to Robust Production Scheduling

Syed Hasib Akhter Faruqi, Sam Houston State University, Huntsville, TX, United States, Kazi Masum Billah, Rakib Hasan, Hung-da Wan

Machine degradation, quality control, workforce constraints are some of the complicating factors in production scheduling in manufacturing systems. While digital twin technology offers new possibilities for production optimization, handling uncertainty in real-time scheduling decisions still remains a significant challenge. To address this challenge, we develop an uncertainty-aware RL scheduler that quantifies uncertainty by (i) value uncertainty through Bayesian approximation and (ii) data uncertainty through bootstrap sampling. We utilize contextual information from the production system, i.e., defect rate, machine performance, workforce availability, etc. to formulate the reward function. The framework is implemented within a comprehensive digital twin environment simulating a multi-product manufacturing system with machine degradation, quality control processes, and dynamic order management. Our approach extends traditional Q-learning by maintaining probability distributions over Q-values and using uncertainty-informed action selection strategies. The system's performance is evaluated through comparative analysis of four scheduling approaches: standard Q-learning, uncertainty-aware scheduling, Thompson Sampling, and UCB methods. Simulation shows that Thompson Sampling achieves the most significant improvements with 19.5% higher production throughput (2915.40 vs 2440.20 completed items), 99% reduction in demand failures (0.20 vs 17.60 failures), and 99.7% reduction in demand shortfalls compared to standard Q-learning. The uncertainty-aware scheduler shows 4.2% production improvement and 45% reduction in performance variance, while UCB provides 9.4% throughput gains with 37% faster execution time. Parameter sensitivity analysis reveals that Thompson Sampling with skeptical priors yields optimal performance, while UCB demonstrates robustness across hyper-parameter variations. Our findings indicate that explicit uncertainty quantification in Q-learning significantly enhances the robustness of production scheduling decisions.

Health Applications Society

Chair: Tsai-Hsuan (Angel) Chung, The Wharton School, UPenn, Philadelphia, PA, United States

Co-Chair: Hamsa Bastani, Wharton School, Philadelphia, PA, United States

1 - Preference-Aware Models for Workforce Allocation in Healthcare

Katherine Adams, The University of Texas at San Antonio, San Antonio, TX, United States, Arka Roy, Vishal Ahuja, Justin Boutilier, Yonatan Mintz, Sarang Deo

Effective workforce allocation is critical in settings where resources are limited and where making preference-aware decisions aids the retention of patients or employees. This presentation explores two applications of sequential decision-making models tailored to distinct healthcare environments: community-based diabetes care and anesthesiology department operations.

The first project focuses on appointment allocation for a community health worker (CHW) intervention targeting office workers in low- and middle-income countries. Aimed at diabetes prevention and management through lifestyle education, our goal is to maximize enrollment in the care program. Behavioral health interventions often face high attrition rates due to varying preferences in terms of care frequency. To address this issue, we developed a reinforcement learning model that sequentially assigns appointments to be delivered by CHWs by trading off decisions that maximize present enrollment and gather information to improve future enrollment.

The second project focuses on shift allocation in an anesthesiology department. Concurrency protocols have allowed for the expansion of anesthesiologist capacity by allowing a single provider to supervise multiple rooms if each room is staffed with a qualified nurse or resident. This poses an additional burden on the providers, who must oversee multiple rooms simultaneously. Our goal is to enhance provider satisfaction and retention by accommodating individual preferences in shift types, workdays, and team compositions. We developed an optimization model that ensures coverage while promoting team compatibility and provider well-being. Together, these projects demonstrate how sequential decision-making frameworks can be leveraged to improve healthcare outcomes by incorporating individual preferences.

2 - Harmonizing Safety and Speed: a Human-Algorithm Approach to Enhance the FDA's Medical Device Clearance Policy

Mohammad Zhalechian, Kelley School of Business, Indiana University, Bloomington, IN, United States, Soroush Saghaian, Omar Robles

For a medical device to be approved under the FDA's Premarket Notification 510(k) pathway, the manufacturer can submit a claim indicating that it is as safe and effective as another legally marketed device. This regulatory process has been associated with a high recall rate for devices approved under this pathway, raising important concerns over the approach used by the FDA. We develop a combined human-algorithm methodology to assist the FDA in improving the 510(k) medical device clearance process by reducing the risk of potential recalls and the workload of the FDA. We first develop machine learning methods to estimate the risk of recall for 510(k) medical devices based on the information available at the time of submission. We then propose a data-driven clearance policy that recommends acceptance, rejection, or deferral to the FDA's committees for in-depth evaluation. We conduct an empirical study using a unique, large-scale dataset, and our results show a 31.8% improvement in the recall rate and a 40.5% reduction in the FDA's workload. Our analyses also indicate that implementing our policy could result in significant cost savings.

3 - DA BE ACTIVE: Piloting Dynamic Adaptation

John Silberholz, University of Maryland Smith School of Business, College Park, MD, United States, Hamsa Bastani

Dynamic adaptation is a promising strategy for scaling the impact of behavioral interventions by personalizing interventions based on individuals' needs. Key challenges include designing pilots that create sufficient dynamic variation in intervention strategies, identifying promising sources of heterogeneous treatment effects with limited and noisy data, and evaluating the resulting policies online. We report progress on these fronts on a physical activity intervention motivated by the BE ACTIVE randomized controlled trial, which demonstrated significant and durable step count gains in a high-risk patient population when using gamification or providing financial incentives. Our pilot, which we call the Dynamically Adaptive (DA) BE ACTIVE Pilot, allocates all participants to gamification to encourage step count increases. Participants who fail to meet their step count goals in a given week are randomized to one of three interventions in the following week: study staff outreach, financial incentive, or no additional intervention. Allocation probabilities are dynamically adapted based on accruing study data.

4 - To Batch or Not To Batch: The Impact of Batching Behavior in Emergency Department Prescription Orders

Yong Xia, University of California, San Diego, La Jolla, CA, United States, Danqi Luo, RJ Niewoehner

Emergency departments (EDs) are under constant pressure to balance efficiency and quality of care, yet diagnostic test ordering patterns remain a critical and understudied factor in this equation. We know operational characteristics influence test ordering, where ordering tests early in a visit reduces congestion (Batt and Terwiesch 2017), or where the testing process can alter test-ordering likelihood (Jaeger and Tucker 2019). In recent years, the frequency of diagnostic test orders has increased substantially (O'Sullivan et al. 2018), leading to our primary research question: How do physicians structure their test orders over multiple patients, and what implications does this have for efficiency and patient outcomes?

One understudied aspect of test ordering is batching behavior, where physicians see multiple patients in succession before submitting orders collectively. While prior research has examined when and how frequently tests are ordered (e.g., Ergun-Sahin et al. 2022), little attention has been given to the ordering process itself, specifically, whether batching affects the quantity of tests ordered, resource utilization, or patient outcomes. This study addresses this gap by evaluating the impact of batching on test-ordering patterns, ED operational efficiency, and healthcare costs. We analyze detailed patient-order data from two distinct healthcare settings to identify how batching shapes test utilization. Our econometric approach accounts for confounding factors such as physician workload and ED congestion, ensuring a robust analysis of batching behavior. Our findings provide insight into whether batching should be discouraged as a source of unnecessary test overuse or recognized as an efficiency-enhancing practice in emergency care.

1 - Interconnected Care: System-Wide Intelligence for Optimizing Hospital Flow

Fernando Acosta-Perez, University of Wisconsin-Madison, Madison, WI, United States, Gabriel Zayas-Caban, Justin Boutilier, Sabrina Adelaine, Frank Liao, Brian Patterson

Coordinating emergency department (ED) admissions is a challenging task for hospital systems, requiring decision makers to balance multiple competing objectives such as minimizing patient waiting times, ensuring appropriate level-of-care placements, and avoiding downstream bed blocking. These challenges are amplified in multisite hospital networks, where increased interconnectivity presents new opportunities for coordinated decision making across facilities. This talk explores how health systems can leverage interhospital connectivity to improve patient flow. We first examine the role of real-time discharge predictions to support proactive admission planning. Using historical discharge data from our partner system, we evaluate strategies for forecasting short-term discharges across multiple hospitals and discuss their implications for operational decision making. Although such models can serve to aid decision makers with complicated decisions, it is not clear how can they transform such predictions into actionable insights. Building on this, we propose a markov decision process framework for inpatient admission control that models the complex trade-offs involved in routing patients across multiple hospitals. Given the high-dimensional nature of this problem, we explore approximate solution strategies that draw insights from the fluid control problem. Through simulation experiments informed by real-world hospital data, we evaluate the potential of coordinated policies that allow interhospital transfers compared to policies that restrict admissions to the arrival hospital. Preliminary results suggest that coordinated strategies may lead to reductions in ED boarding and improve overall patient placement.

2 - Ambulance Allocation for Patient-Centered Care

Eric Stratman, Columbia University, New York, NY, United States, Laura Albert, Justin Boutilier

Emergency Medical Services (EMS) in the United States and similar systems typically utilize a single treatment pathway, transporting all patients to emergency departments (EDs), regardless of their actual care needs or preferences. Recent policy reforms have sought to introduce alternative treatment pathways to divert lower acuity patients from the ED, but operationalizing these options has proven difficult. This paper proposes a patient-centered EMS (PC-EMS) ambulance allocation model that supports multiple care pathways by aligning EMS responses with individual patient needs. We develop a two-stage mixed-integer optimization framework that incorporates multiple dispatch and secondary assignment strategies which enable dynamic resource deployment. The model maximizes appropriate ED diversions while maintaining ambulance availability using a queueing-based availability constraint. We leverage national EMS data and machine learning to estimate dispatcher accuracy and diversion potential. Simulations across diverse geographic regions suggest that agencies can achieve up to 80% of possible ED diversions by equipping only 15–25% of their fleet with diversion-capable units. Adaptive dispatch strategies improve diversion rates by 3.4 to 8.6 times compared to conventional single-unit dispatch. These results demonstrate a critical trade-off between equipment investment and operational coordination, allowing agencies to strategically balance fleet upgrades against the complexity of dispatch protocols based on their specific organizational constraints.

3 - Dynamic Interval Prediction of Patient Waiting TIMES for Cancer-Care Facilities

Yashi Huang, University of Rochester, Rochester, NY, United States, Arik Senderovich, Yaron Shaposhnik

We develop a system for a large cancer institute for predicting in real-time patients' waiting times. The system consists of a collection of machine learning and simulation models that are assembled to make predictions (e.g., different models are used in different cases in different stages of the service process). The system is designed to overcome various challenges such as stochasticity (e.g., unexpected cancellations, and random service and arrival times), heterogeneity (e.g., of patients, providers, and workflow), complex service process (e.g., multiple interconnected stages), and limitations of the available data (e.g., noisy data and changes to the schedule that may not be electronically recorded). At the same time, the system is designed to provide the users explanations about why predictions are made and alert them about potentially inaccurate predictions and delays to the schedule. We report on the performance of our models for the various prediction tasks using a real-world data set.

4 - Fairness and Efficiency of Teledermatology Triage Policies

Le Sun, University of Rochester, Rochester, NY, United States, Yaron Shaposhnik, Vera Tilson

We examine a hybrid teledermatology triage system where certain patients access electronic screening (E-screening) while others go through face-to-face (FTF) screening, with both pathways potentially followed by a FTF treatment. This dual-pathway approach, despite offering operational benefits, creates a tradeoff between system efficiency and equitable access. The disparity manifests because E-screening remains inaccessible to a substantial portion of the population due to technological or institutional barriers. Our research examines how different prioritization policies affect system efficiency and fairness.

5 - Constrained Distributional Reinforcement Learning in Healthcare

Zequan Chen, Dartmouth College, Hanover, NH, United States

The medical system often faces understaffing and time pressure, which can cause patients to miss critical treatment windows. To address this, we propose an automated treatment recommendation system. Existing systems typically rely on expected outcomes to evaluate treatments, recommending the option with the highest expected benefit. However, informative decision-making often requires more than just expectation. Motivated by this limitation, we develop a treatment recommendation framework based on distributional reinforcement learning (DRL), which models the full distribution of potential outcomes for each treatment. This enables personalized recommendations that align with the preferences of both doctors and patients. Furthermore, we incorporate constraints into the DRL process—our constrained DRL algorithm can account for constraints in fairness, financial limitations, and treatment risks. Numerical results demonstrate that our method achieves near-optimal treatment outcomes while respecting these practical constraints and supporting personalized, stakeholder-driven decisions.

1 - A Novel Adaptive Testing Scheme for Multi-Disease Testing

Berk Gorgulu, DeGroote School of Business, McMaster University, Hamilton, ON, Canada, Douglas Bish, Ebru Bish, Merve Bodur

Disease testing plays a critical role in disease mitigation by enabling early detection and timely intervention. However, the high cost of testing—especially in settings requiring screening for multiple diseases—limits its widespread implementation. Two cost-saving strategies are commonly employed: *multiplexing*, where a single assay tests for multiple diseases, and *pooling*, where samples from multiple individuals are tested together. While combining these strategies creates reduction in testing costs, the standard Dorfman testing—using the same multiplex assay for both pooled and individual follow-up tests—can be inefficient, particularly when only a subset of diseases triggers retesting.

This work introduces and analyzes a novel strategy: *adaptive testing*, which leverages laboratory automation to customize retesting assays based on preliminary pooled test results. By adding disease-specific reagents only for relevant diseases during retesting, adaptive testing can reduce costs significantly compared to Dorfman pooling or large multiplexing alone. We develop a rigorous analytical framework for multi-disease testing with flexible retesting and derive structural properties of the optimal solutions. Algorithmic methods are proposed to solve the resulting complex combinatorial problem. Through a case study on 18 respiratory diseases using real data, we show that adaptive pooling can reduce testing costs significantly relative to current best practices.

2 - Data-Driven Optimization of Clinical Treatment Guidelines

Sun Ju Lee, Georgia Institute of Technology, Atlanta, GA, United States, Gian Garcia

Evidence-based guidelines play an important role in informing how chronic diseases should be managed, as these recommendations are widely disseminated and widely implemented. However, they are one-size-fits-most, failing to account for patient-to-patient differences. Personalized medicine has shown significant potential to improve health outcomes over clinical practice guidelines. However, the implementation of personalized medicine may be challenging, resulting in unwanted practice variation and suboptimal patient care. To find the right balance between personalized medicine and clinical guidelines, we propose the treatment guideline design problem. We develop a framework to design optimal treatment guidelines for a population of patients which are each modeled according to their own Markov Decision Process parameters. We propose several exact and heuristic methods to solve the problem, including a mixed-integer linear program formulation and a branch-and-bound clustering algorithm. Our results on a hypertension treatment planning case study demonstrate that with only a small number of subgroups, we can develop clinical practice guidelines which perform almost as well as personalized treatment policies.

3 - Inventory Optimization for Pharmaceutical Fulfillment Networks: a Predictive and Prescriptive Analysis at Amazon Pharmacy

Yinsheng Wang, University of Washington, Seattle, WA, United States, Alexandre Alves, Pierre Bhoorasingh, Cristobal Pais, Xin Tang, Shan Liu

Effective inventory management is critical for all pharmacies, but becomes even more challenging for nationwide digital-forward pharmacies, where timely delivery, regulatory compliance, and diverse product requirements pose significant operational challenges. Amazon Pharmacy continues to expand its services, eliminating pharmacy deserts and expanding sub-same day prescription delivery. This study develops a data-driven inventory optimization framework, integrating predictive and prescriptive analytics at a pharmaceutical fulfillment center. Utilizing de-identified operational data, we first applied automatic statistical distribution fitting to characterize demand patterns accurately. Customer abandonment behavior was explicitly modeled to reflect realistic operational dynamics. Next, we implemented and systematically compared several inventory replenishment policies, including (s, S), Newsvendor, On-Demand, and Safety Stock, through extensive simulation experiments. Empirical results reveal that dynamically selecting replenishment policies tailored to distinct demand profiles significantly outperforms static policies, effectively reducing inventory costs and stockouts. Additionally, critical operational constraints such as cold chain storage capacity were incorporated, demonstrating robustness of the approach under realistic operational conditions. Overall, this study provides critical methodological insights and practical contributions to inventory management strategies specifically tailored for Amazon Pharmacy, leading to potential 18.10% savings of average cost compared to current production baseline.

4 - Machine Learning-Based Risk Stratification for Corneal Transplantation Outcomes in North India: a Retrospective Analysis

Qian Deng, University of Iowa, Iowa city, IA, United States, Nick Street, Simran Sarin, Kanwal Singh Matharu, Neha Kapur

Corneal diseases remain a major contributor to blindness in India. In this study, we retrospectively analyzed the clinical records of 911 patients who underwent corneal transplantation at a leading non-profit tertiary referral eye center in North India between October 2021 and February 2024. Among all evaluated clinical features, Therapeutic Penetrating Keratoplasty (TPK) and infection by *Pythium* species emerged as highly significant predictors of graft failure in classification models. An XGBoost-based predictive model achieved robust stratification into high- and low-risk groups, with Kaplan–Meier survival curves demonstrating significant differentiation (log-rank test p-value = 0.0064). Our findings underscore the potential of machine learning methods, particularly XGBoost, in providing valuable decision support for clinical management and identifying critical factors associated with graft failure following corneal transplantation in India.

5 - Inverse Quadratic Optimization with Application to Cancer Radiotherapy

Archis Gbate, University of Minnesota, Minneapolis, MN, United States

In a typical (forward) optimization problem, a decision-maker uses given values of model parameters to compute the values of decision variables. The goal in inverse optimization (IO) is instead to infer parameters that render given values of decision variables optimal. Most papers on IO utilize duality to impute objective function parameters. A corresponding literature for imputing constraint parameters is essentially non-existent, even for linear programs. The difficulty is that these IO problems include nonconvex bilinear constraints and/or objectives. We will discuss models and solution methods designed to tackle this challenge when the forward problems are quadratic. That is, when the objective is quadratic and the constraints are either linear or quadratic. We will illustrate key ideas using the motivating problem of optimizing treatment plans in intensity modulated radiotherapy for cancer.

1 - Regulating Adaptive Medical Artificial Intelligence: Can Less Oversight Lead to Greater Compliance?

Liang (Leon) Xu, Singapore Management University, Singapore, Singapore, Jiayi Lai, Xin Fang, Tinglong Dai

As of June 2024, the U.S. Food and Drug Administration (FDA) has approved 950 medical artificial intelligence (AI) devices. The current regulatory framework freezes AI algorithms after approval, requiring new submissions for updates to ensure compliance with Good Machine Learning Practices (GMLP). This approach imposes a significant administrative burden, while hindering the ability of AI algorithms to learn from new data. To address these challenges, the FDA has explored a novel pathway known as Predetermined Change Control Plans (PCCP), allowing developers to outline future changes during initial submissions and exempting approved changes from regulatory review. Yet, the impact of this exemption on GMLP compliance remains uncertain. In this paper, we model the strategic interaction between a developer and a regulator in a two-stage game with asymmetric information. The developer may choose to follow or deviate from GMLP in developing and retraining the AI algorithm, whereas the regulator reviews the marketing-clearance application for approval. Our analysis shows that, contrary to intuition, less review can actually lead to greater compliance. This scenario arises, even without considering the administrative burden saved, when (1) auditing capability is moderate and (2) the potential for efficiency improvements through retraining is substantial. Conversely, reclearance is valuable when regulatory review effectively detects noncompliance or when efficacy improvements from retraining are unlikely. We also show adaptive algorithms offer advantages over frozen algorithms in terms of not only improved device efficiency but also greater compliance. Interestingly, these advantages are particularly salient when regulatory oversight has limited ability to detect noncompliance.

2 - Assortment Optimization for Patient-Provider Matching

Naveen Raman, Carnegie Mellon University, Pittsburgh, PA, United States, Holly Wiberg

Rising provider turnover forces healthcare administrators to frequently rematch patients to available providers, which can be cumbersome and labor-intensive. To reduce the burden of rematching, we study algorithms for matching patients and providers through assortment optimization. We develop a patient-provider matching model in which we simultaneously offer each patient a menu of providers, and patients subsequently respond and select providers. By offering assortments upfront, administrators can balance logistical ease and patient autonomy. We study policies for assortment optimization and characterize their performance under different problem settings. We demonstrate that the selection of assortment policy is highly dependent on problem specifics and, in particular, on a patient's willingness to match and the ratio between patients and providers. On real-world data, we show that our best policy can improve match quality by 13% over a greedy solution by tailoring assortment sizes based on patient characteristics. We conclude with recommendations for running a real-world patient-provider matching system inspired by our results.

3 - Optimal Algorithms for Online Scheduling

Anvit Garg, Harvard University, Cambridge, MA, United States, Michael Lingzhi Li

We study an online scheduling problem for a single hospital room, where patients arrive sequentially and request a known length of stay (LOS). Upon each arrival, the decision-maker must accept or reject the patient, earning a LOS-dependent reward only if the patient is admitted. We formulate the problem as a Markov Decision Process (MDP) and analyze the structure of the optimal policy. We show that it admits a compact, transformed-threshold form. Through theoretical analysis and simulation, we explore how this threshold depends on key factors such as the discount rate, arrival rate, and the distribution of LOS. Our results offer insight into interpretable, low-dimensional policies for real-time decision-making in constrained healthcare settings. We also explore extensions to cases where LOS is estimated rather than known.

4 - The Human-AI Dance: Dynamic Adaptive Learning for Optimal AI Guidance

Shirley Huang, Harvard Business School, Boston, MA, United States, Michael Lingzhi Li

As AI systems increasingly assist humans in high-stakes, repeated decisions, it becomes crucial to design optimal collaboration strategies. Most existing approaches assume a static human-AI system, overlooking how users adapt to algorithmic guidance through repeated interactions. We propose a dynamic framework for human-AI collaboration, modeled as a Markov Decision Process (MDP) and selectively provides recommendations to a human whose trust in the AI evolves based on past agreement. Using perturbation analysis, we derive interpretable closed-form approximations that characterize nonlinear tradeoffs between building trust and optimizing short-term outcomes. Our analysis reveals when it is optimal to withhold or even reverse AI recommendations to strategically manage trust and improve long-term performance. Building on these insights, we develop a practical recommendation algorithm that learns the trust threshold online and intervenes only when guidance is expected to improve cumulative outcomes. Simulated and empirical experiments demonstrate that our approach preserves trust and achieves superior long-term rewards compared to always-advise and myopic baselines. These findings offer actionable insights for designing trust-aware AI decision support systems across healthcare, operations, and digital platforms.

5 - Structural Estimation of Treatment Heterogeneity in Sequential Decision-Making Tasks

Ziyuan Zhang, University of Toronto, Toronto, ON, Canada, Ningyuan Chen, Rodrigo Mansur, Vahid Sarhangian

Multi-armed bandit (MAB) tasks are widely used in psychiatry to assess human decision-making behavior, particularly how they navigate the trade-off between exploration and exploitation (E&E). In this work, we propose structural estimation models to estimate the heterogeneous treatment effect of a clinical intervention (e.g., a pharmacological intervention) on the E&E behavior of the participants of a MAB tasks. We consider a randomized experimental design where all participants complete a MAB task twice: once before and once after receiving either an intervention or placebo. To evaluate the treatment effect, we adopt a difference-in-differences (DID) approach that compares pre- and post-treatment periods. We apply the proposed methods to data from a randomized trial involving patients with major depressive disorder (MDD) who completed a four-armed bandit task before and after receiving either a GLP-1R agonist (the active substance in Ozempic) or placebo. The data also includes individual characteristics, such as age, BMI, and depression level, potentially resulting in heterogeneity in treatment responses.

1 - Multi-Market Cournot Competition with Investments

Boxuan Li, Columbia University, New York, NY, United States

We develop a two-stage model of multimarket Cournot competition in which firms strategically invest in cost-reducing technologies before competing across multiple interconnected markets. Our model explicitly incorporates endogenous investments into firms' production-cost structures, enabling the analysis of how investment affects firms' competition and welfare in a networked economy. We find that firms' investments are strategic substitutes: the investment of one firm imposes a negative externality on others and reduces their incentive to invest. We show that an inefficiency arises when the adjustment cost is high, pushing large firms to invest more than what is socially optimal. We demonstrate that if adjustment costs are more homogeneous across firms, less central firms benefit from investment which in turn reduces market concentration. Conversely, if cost heterogeneity is higher, more central firms can increase their competitive advantage over smaller firms and increase market concentration. Our analysis suggests that policies offering subsidies to smaller firms to mitigate their higher adjustment costs can effectively prevent excessive market centralization.

2 - A Risk Sensitive Contract-Unified Reinforcement Learning Approach for Option Hedging

Xianhua Peng, Peking University, Shenzhen, China, People's Republic of

We propose a new risk sensitive reinforcement learning approach for the dynamic hedging of options. The approach focuses on the minimization of the tail risk of the final P&L of the seller of an option. Different from most existing reinforcement learning approaches that require a parametric model of the underlying asset, our approach can learn the optimal hedging strategy directly from the historical market data without specifying a parametric model; in addition, the learned optimal hedging strategy is contract-unified, i.e., it applies to different options contracts with different initial underlying prices, strike prices, and maturities. Our approach extends existing reinforcement learning methods by learning the tail risk measures of the final hedging P&L and the optimal hedging strategy at the same time. We carry out comprehensive empirical study to show that, in the out-of-sample tests, the proposed reinforcement learning hedging strategy can obtain statistically significantly lower tail risk and higher mean of the final P&L than delta hedging methods.

3 - Multi-Product Newsvendor with Submodular Demand Restrictions

Linda Punt, Rotterdam School of Management, Rotterdam, Netherlands, Daniel Chen, Gar Goei Loke, Yashar Ghiassi

We study a novel subclass of the multi-product newsvendor model where sales is restricted by a maximal demand that is submodular and random. This setting is prevalent in the inventory and revenue management literature and arises from (i) product indifference, where customers perceive no difference in net utility among a set of alternatives, and (ii) fulfillment deference, where due to indifference, choice of the specific product to fulfill customer demand is deferred to the retailer. We characterize the exact optimal solution, showing that optimal inventory levels should be decided greedily by prioritizing products in decreasing sequence of selling price, while cost only affects the specific inventory levels. Furthermore, these inventory levels are the critical quantiles of some demand distribution, akin to the traditional newsvendor

problem. However, this distribution also captures the demand of other products that the relevant product could fulfill due to product indifference. Our work calls for deeper examination into stochastic optimization over submodular random variables.

4 - Supply Chain Strategy and Risk Hedging

Jingren Zhao, The University of Hong Kong, Hong Kong, Hong Kong, Liao Wang

Push and pull are two common supply chain strategies. In a push system, the retailer (newsvendor) bears all the demand risk, as the supplier "sells to" the retailer. In contrast, a pull system allows the retailer to return unsold units to the supplier, who then assumes the demand risk.

It is well established that, in a risk-neutral setting, pull strategies generally coordinate the supply chain more effectively than push strategies. However, in a risk-averse setting where the parties have differing risk aversion levels, prior literature shows that pull does not necessarily outperform push—this depends on the asymmetry in risk aversion.

In this work, we assume that the party bearing demand risk (the supplier in pull and the retailer in push) can employ risk hedging using financial assets correlated with demand. We then analyze how hedging influences whether push or pull better coordinates the supply chain. Additionally, we examine a scenario where the retailer has a more accurate demand forecast than the supplier and study how risk hedging affects both strategies.

5 - Dynamic Contracting for Patent Screening with AI Techniques

Ruiting Zuo, Financial Technology Thrust, The Hong Kong University of Science and Technology (Guangzhou), Guangzhou, China, People's Republic of, Jussi Keppo, Jiahui Shi

We study incentive contracts within a continuous-time principal-agent framework, where a principal hires an agent to review patent applications. The agent exerts costly efforts in both the quantity and quality of the review process. The principal cannot directly observe the agent's actions but instead monitors a stochastic volume process of examined applications, and a jump process that captures the occurrence of adverse events, such as the erroneous granting of unqualified patents or the rejection of qualified ones. Our model characterizes the structure of the optimal dynamic contract that simultaneously incentivizes the agent to balance examination speed and accuracy under moral hazard. Furthermore, we analyze the interaction between the agent's efforts in quantity and quality across different scenarios and provide a comparative evaluation of human examiners' performance relative to AI-assisted review systems.

1 - Balancing Control and Cost in Automotive Strategies: a Game-Theoretic Model for Sales and Service Mode Selection

Zhepei Chen, Tianjin University, Tianjin, China, People's Republic of, Zhaofang Mao

With the rise of new energy vehicle manufacturers and increasing competition in the automotive market, the traditional 4S dealership model is undergoing profound transformation. Sales and after-sales services have become two critical sources of profit for car manufacturers, prompting a reevaluation of distribution and service strategies. This study develops a game-theoretical framework to analyze a manufacturer's optimal choice between agency and reselling models for vehicle sales, as well as self-operated versus outsourced models for after-sales service. Using a Stackelberg game structure, we examine how wholesale pricing, commission rates, and service quality decisions affect the profits of both the manufacturer and 4S dealerships under four distinct combinations (A1–B2). The model incorporates consumer utility sensitivity to both price and service quality and derives optimal strategies under different levels of product substitutability and service cost structures. Results reveal the trade-offs between pricing control and service delegation and offer managerial implications for automotive firms seeking to balance brand consistency, cost efficiency, and customer satisfaction.

Keywords:

Automotive Distribution, Reselling vs. Agency, After-Sales Service, Service Quality, Stackelberg Game

2 - A Comparative Analysis of Display and Shopping Ads on Social Media Platforms

Jiayu Fan, Temple University, Philadelphia, PA, United States, Subodha Kumar

Social media platforms are increasingly adopting monetization strategies that integrate e-commerce functionalities. Platforms like TikTok and Instagram have pioneered the use of shopping ads, which can generate both ad revenue and commission revenue. For started social media platforms, it is unclear for them whether shopping ads are more profitable than display ads. Furthermore, the ad pricing strategy and ad amounts can be different for display ads and shopping ads, which may be affected by the commission rate. However, there is no existing study that can answer these questions. Hence, our study fills this gap by providing a framework to compare the profit, ad price, and ad amount for display ads and shopping ads. Our findings suggest that shopping ads may generate higher profit than display ads even if users dislike shopping ads more than display ads and the product value sold through shopping ads is relatively low. In addition, if users dislike display ads more than shopping ads: 1) the platform may still price display ads at a lower rate compared to shopping ads when the market size of display ads is larger than that of shopping ads; 2) the platform may put more display ads than shopping ads, interestingly, this may happen when users' aversion to display ads is greater than a given threshold meanwhile product value is relatively high. This understanding provides actionable insights for platforms looking to optimize their advertising revenue and commission revenue.

3 - Dynamic Budget Allocation and Sponsored Advertising Policy in E-Commerce with Lost Clicks

Yunzhi Cao, City University of Hong Kong, Hong Kong, Hong Kong, Houmin Yan

Sponsored product is an advertising service provided by a platform for retailers to promote products in E-commerce. With a finite budget of a retailer, this paper studies a joint budget allocation and advertising policy over multiple periods. At each period, the retailer needs to allocate a budget to a financial account for the expense of advertising service during this period. A cost-per-click occurs after setting the bidding price for the expression on the sponsored list, which brings lost clicks if there is no remaining budget in the financial account. We formulate a Markov decision process and establish a dynamic programming reformulation. Incorporating the definition of stochastically concave in midpoint, we provide general and easy-to-verify conditions for a tractable optimal policy, that is, a base allocation listing bidding policy, and characterize its structural properties.

4 - Marketing Mix Modeling as a Strategic Tool: Driving Business Growth

Micky Mukesh Chhabda, University of Connecticut School of Business, Auburn Hills, MI, United States

Marketing Mix Modeling (MMM) offers a powerful analytical framework that quantifies the influence of diverse marketing channels on sales and revenue, empowering organizations to optimize budgets and maximize return on investment. This keynote delves into advanced MMM methodologies that extend beyond traditional reporting, illustrating how innovative modeling approaches can unlock strategic insights and guide transformational marketing decisions.

Attendees will explore the design and execution of MMM projects aligned with business objectives, focusing on interpreting results to make data-driven budget allocations that enhance competitive positioning. The presentation features real-world, cross-industry case studies demonstrating significant improvements in marketing efficiency and measurable business growth driven by MMM insights.

By sharing practical techniques and evidence-based frameworks, this session equips analytics professionals and marketing leaders to champion MMM within their organizations, foster stakeholder trust, and drive impactful, sustainable growth through data storytelling and analytics innovation.

Key Takeaways:

- Understanding the fundamentals of Marketing Mix Modeling
- Designing MMM studies that align with strategic business goals
- Translating complex MMM results into actionable marketing decisions
- Integrating MMM with broader analytics frameworks for comprehensive insights
- Real-world examples demonstrating measurable ROI and business impact

Chair: Laixi Shi, California Institute of Technology (Caltech), Pasadena, CA, United States

1 - Nonparametric Policy Improvement in Continuous Action Spaces via Expert Demonstrations**Enrique Mallada, Johns Hopkins University, Baltimore, MD, United States, Agustin Castellano, Sohrab Rezaei, Jared Markowitz**

The policy improvement theorem is a cornerstone of classical reinforcement learning in discrete action spaces, providing critical theoretical guarantees for policy optimization. However, extending these guarantees to continuous action spaces—especially under function approximation—has long been an open challenge, often forcing policy optimization algorithms to rely on conservative updates that slow convergence. In this talk, I introduce a novel nonparametric policy framework tailored for deterministic Markov Decision Processes (MDPs), which admits a provable policy improvement theorem without requiring parametric assumptions. Leveraging mild regularity conditions on the optimal policy, we demonstrate how data from expert demonstrations can be used to construct a nonparametric lower bound on policy value, enabling robust evaluation. This lower bound directly yields a simple yet effective improvement mechanism: add more demonstrations. Moreover, we provide a method to identify regions in the state space where additional data is most needed to meet performance targets. Building on these insights, we propose a policy optimization algorithm that guarantees monotonic improvement of the value lower bound and offers high-probability performance guarantees. This work lays the foundation for a rigorous, data-driven approach to policy improvement in continuous action spaces.

2 - Enhancing Safety in Sequential Decision-Making**Shangding Gu, UC Berkeley, Berkeley, CA, United States**

As artificial intelligence continues to evolve, reinforcement learning has emerged as a powerful tool for training agents to make decisions in complex environments. However, ensuring safety during the learning and deployment phases remains a critical challenge, especially in high-stakes domains like autonomous driving and robotics. This talk will introduce the fundamental concepts behind safe reinforcement learning, discuss why safety is vital in real-world applications, and highlight key methodologies aimed at ensuring safety during the learning process.

4 - Hybrid Transfer Reinforcement Learning: Provable Sample Efficiency from Shifted-Dynamics Data**Chengrui Qu, California Institute of Technology, Pasadena, CA, United States, Laixi Shi, Kishan Panaganti, Pengcheng You, Adam Wierman**

Online reinforcement learning (RL) typically requires online interaction data to learn a policy for a target task, but collecting such data can be high-stakes. This prompts interest in leveraging historical data to improve sample efficiency. The historical data may come from outdated or related source environments with different dynamics. It remains unclear how to effectively use such data in the target task to provably enhance learning and sample efficiency. To address this, we propose a hybrid transfer RL (HTRL) setting, where an agent learns in a target environment while accessing offline data from a source environment with shifted dynamics. We show that -- without information on the dynamics shift -- general shifted-dynamics data, even with subtle shifts, does not reduce sample complexity in the target environment. However, focusing on HTRL with prior information on the degree of the dynamics shift, we design HySRL, a transfer algorithm that outperforms pure online RL with problem-dependent sample complexity guarantees. Finally, our experimental results demonstrate that HySRL surpasses the state-of-the-art pure online RL baseline.

1 - Who Directs the Control Tower? Customer vs. Supplier-Managed Inventory in Supply Chains**Shi Chen, University of Washington Foster School of Business, Seattle, WA, United States, Morris Cohen, Hau Lee**

In recent years, information distortion and incentive misalignment have contributed to suboptimal supply chain performance. As a result, many companies have adopted the "control tower" approach, in which one party assumes responsibility for replenishment decisions across the supply chain. But who should direct the control tower? In some cases, this role is assigned to the customer -- Customer-Managed Inventory (CMI) -- and in others, to the supplier -- Supplier-Managed Inventory (SMI). This paper investigates when it is preferable to adopt one approach over the other. We consider a two-stage supply chain with either a one-to-one inventory structure (a customer with a single warehouse) or a one-to-many structure (a customer with multiple warehouses), and derive the optimal inventory policies and cost-sharing contract parameters under both CMI and SMI. Our analysis reveals that two primary factors drive the choice between CMI and SMI: the shortage penalty cost ratio between the customer and supplier, and the number of customer warehouses. A higher customer-to-supplier penalty cost ratio or fewer customer warehouses tends to favor CMI, while the opposite conditions favor SMI. Secondary factors, including holding costs, lead times, the distribution of demand across warehouses, and demand correlation, also play a role. We illustrate our findings with four industry cases: Barilla, Saturn, Boeing, and HP. The results offer practical guidance for selecting and implementing the appropriate control tower strategy, enabling firms to improve supply chain performance through more effective allocation of decision rights and cost-sharing mechanisms.

2 - Mainstreaming vs. Fairwashing in Fair Trade Operations**Daehoon Jung, University of Florida, Gainesville, FL, United States, Seung-Jae Park**

This study explores the effects of competition on fair trade operations. Specifically, as a benchmark, we first consider a model with single fair trade organization (FTO), i.e., a monopoly FTO. We then extend the analysis to a setting with two competing FTOs, i.e., duopoly FTOs. Although both FTOs share the common goal of alleviating farmers' poverty, they adopt contrasting strategies: one FTO seeks to lower the barriers to fair trade in an effort to mainstream it, while the other maintains stricter

standards to prevent fairwashing (or greenwashing). Following industry practices, we implement two modes of competition and compare them with the monopoly benchmark. We find that competition between FTOs increases the aggregate demand for fair trade certified products (mainstreaming) but results in less aggregate premium (fairwashing). Furthermore, we consider the potential application of blockchain technology in fair trade operations, demonstrating that blockchain offers a promising solution to mitigate the fairwashing effects from competition between FTOs.

3 - Inventory Holdback for Humanitarian Logistics: Reducing Wastage Under Uncertain Demand

Nesim Erkip, Bilkent University, Ankara, Turkey, Vera Tilson

Humanitarian organizations operate under strict donor requirements and financial scrutiny, often facing challenges in managing medical supply distribution due to demand uncertainty and logistical constraints. Expired or excess supplies can strain relationships with donors and host governments, making prepositioning stock without a clear usage plan risky. Reverse logistics for retrieving unused inventory is costly and complex. Motivated by these challenges, we model a humanitarian distribution system as a two-echelon, one-warehouse multiple-retailer (OWMR) supply chain, where demand at retailers is highly variable and not necessarily stationary. Given the potential for wastage, there is an incentive to hold more inventory at a central warehouse rather than at the retailers. We introduce a novel holdback distribution policy that withholds a portion of stock using a non-myopic two-period planning horizon to minimize total costs associated with stockouts and wastage. Computational experiments show that our policy outperforms conventional myopic distribution strategies by effectively reducing stockouts and excess inventory, making it particularly well-suited for volatile demand environments.

4 - Enhancing Sustainability: Smallholder Farmers' Incentives for Sharing Yield Data Information

Jae-Hyuck Park, New Jersey Institute of Technology, Newark, NJ, United States, Hyo Duk Shin

Recent technological advancements have expanded agriculture-related data accessible to small farmers. We examine when smallholder farmers are incentivized to share yield uncertainty information and its sustainability implications. Farmers' decisions are influenced by market structure and information accuracy, highlighting the need for alignment and economic incentives to ensure sustainable land use.

5 - Fulfillment-by-Platform as Strategy: Competitive and Antitrust Implications

Yao Li, Kellogg, Northwestern University, Evanston, IL, United States, Lauren Lu, Wenqiang Xiao, Jan A. Van Mieghem

By tying access to Prime customers and enhanced platform visibility to the use of Fulfillment by Amazon (FBA), Amazon effectively compels third-party sellers to adopt its proprietary logistics service. While this practice may improve operational consistency, it raises significant antitrust concerns by limiting sellers' fulfillment options, thereby reducing cross-platform competition and potentially harming consumer welfare. In this study, we develop a stylized analytical model that incorporates both Amazon's FBA requirement and the broader dynamics of cross-platform competition. We examine settings with one or multiple sellers operating across competing platforms and characterize the conditions under which Amazon's tying strategy may reduce—or, counterintuitively, enhance—consumer welfare. Our findings contribute to the ongoing debate on digital platform governance and the trade-offs between operational efficiency and market fairness.

Recent Advances in Data-Driven and AI-Guided Decision-Making

Invited Session

MSOM: Service Operations

Chair: Hamsa Bastani, Wharton School, Philadelphia, PA, United States

Co-Chair: Stefanos Poulidis, INSEAD, Fontainebleau, France

1 - Deepstock: Reinforcement Learning with Policy Regularizations for Inventory Management

Yaqi Xie, University of Chicago, Chicago, IL, United States, Will Ma, Linwei Xin

In the age of big data and compute, Deep Reinforcement Learning (DRL) has emerged as a promising methodology for inventory management. However, off-the-shelf implementations have shown mixed success. We demonstrate that combining DRL with policy regularizations, grounded in classical inventory concepts such as the “basestock” can significantly improve its effectiveness. In particular, our policy regularizations accelerate training, reduce sensitivity to hyperparameters, and improve overall performance across several DRL algorithms. We also revisit classical DRL policies from the perspective of data usage, comparing those that update based on state-action pairs with those that update based on entire trajectories. We evaluate their efficiency and performance under varying data quality, with a particular focus on the quality of endogenous features. We implement our regularized DRL approach at scale within Alibaba and conduct additional experiments on synthetic data to better understand the benefits of different combinations of DRL policies and regularizations.

2 - Self-Regulated use of AI Hinders Long-Term Learning

Stefanos Poulidis, INSEAD, Fontainebleau, France, Hamsa Bastani, Osbert Bastani

As generative AI tools become widely adopted, educational environments are shifting from \emph{system-regulated} (or paternalistic) to \emph{self-regulated} learning, where learners control when and how to engage with AI tutors. While greater learner agency is often presumed to enhance motivation and learning, access to AI without guidance or guardrails can backfire. We study the impact of self-regulated use of generative AI on long-term learning in a 100-day field experiment with students recruited from chess academies, comparing system-regulated AI assistance with self-regulated use, in which students decide when and how to request help. Students in both conditions improved, but those in the system-regulated condition exhibited significantly greater engagement and learning. We find that highly motivated students self-regulate more effectively and achieve substantially greater skill improvement. In contrast, skill level does not moderate the effect: even skilled students tend to offload cognitive effort and are harmed by self-regulated use of generative AI tools. Our findings highlight how design choices in generative AI deployments can shape long-term learning outcomes and inform the scaffolding of effective AI-mediated learning environments.

3 - Data-Driven Decision Making in Dynamic Systems

Stefan Wager, Stanford GSB, Stanford, CA, United States

Emerging Topics in Socially Responsible Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Somya Singhvi, USC Marshall School of Business, Los Angeles, CA, United States

1 - Disability-Inclusive Workforce Planning

Chen Hu, Xi'an Jiaotong-Liverpool University, Suzhou, China, People's Republic of, Anyan Qi, Yongbo Xiao

Hiring people with disabilities (PWDs) is widely recognized as an essential component of corporate social responsibility (CSR). However, such employment often entails challenges in lower service level or increased training costs due to the generally limited educational attainment of PWDs. This paper studies the hiring and training decisions for a socially responsible firm and examines how these decisions are shaped by government intervention policies.

2 - Sustainable Sourcing of Agricultural Products: Fixed vs. Flexible Premiums

Can Zhang, Duke University, Durham, NC, United States, Vishal Agrawal

Sustainability certifications have gained increasing popularity for agricultural product sourcing. To help improve smallholder farmers' livelihoods, these certifications set a premium that firms must pay to farmers for certified crops on top of the market price. This premium can be structured in different ways: A popular approach adopted by several major certifications is called a fixed premium, under which farmers receive a fixed level of premium independent of the market price. However, this approach has been criticized for not sufficiently protecting farmers when the market price is low. Accordingly, an alternative approach called a flexible premium, under which farmers receive a higher premium when the market price is lower, has been promoted by farmer advocacy groups and recently implemented by some certifications. We analyze and compare the effectiveness of these premium approaches and offer several managerial insights. First, contrary to expectation, we show that the flexible premium approach can lead to a lower expected farmer income than the fixed premium approach. Even when a flexible premium improves farmer income, it can lead to a lower expected sustainable sourcing quantity and firm profit. Second, we nevertheless identify that a flexible premium can lead to a "win-win-win" outcome for farmer income, sustainable sourcing quantity, and firm profit, but only in settings with ample certified supply relative to demand. Finally, motivated by the trend of firms creating their own sustainability labels, we show that such self-labeling can lead to a higher sustainable sourcing quantity but lower farmer income compared to NGO labeling.

3 - Optimizing Inventory for Impact: Large-Scale Inventory Routing to Distribute Clean Cooking Devices in Kenya

Simon Thomä, RWTH Aachen, Aachen, Germany, Sergio Camelo, Dan Iancu, Maximilian Schiffer

Access to clean cooking technologies remains an issue in developing economies. Around 2.1 billion people around the globe rely on polluting fuels for cooking, leading to more than 3 million premature deaths annually. In Kenya, where most households rely on polluting fuels, bio-ethanol stove suppliers use carbon credits to subsidize stove prices. Still, affordability remains a challenge due to high distribution costs caused by highly stochastic and heterogeneous demand distributed over several thousand small retailers in Nairobi alone. We address this challenge by formulating a large-scale Inventory Routing Problem with stochastic demand and propose a new two-step approach to solve it. First, we relax the problem by taking long-term averages to compute target policies and valid lower bounds. Building on these target policies, we derive dynamic routing and replenishment policies that scale well to real-world instances with several thousand stores. Our numerical experiments show that the proposed methods significantly improve over the status quo, leading to significant cost savings.

4 - Optimizing Nonprofit Operations Under Display-Dependent Demand

Yanchong Zheng, Massachusetts Institute of Technology, Cambridge, MA, United States, Yuan Shi, Mahyar Eftekhari

We study a nonprofit warehouse inventory problem motivated by data from a regional U.S. food bank. Many food banks use a shopping-like allocation model where partner agencies select food items directly from warehouse shelves, facing the dual goal of achieving equitable access over time (fairness) and maximizing accepted donations within limited capacity (efficiency). We develop a dynamic inventory model that accounts for display-dependent stochastic demand, heterogeneous resource types, and capacity constraints. We characterize optimal acceptance and display policies that balance fairness and efficiency and identify key drivers of the fairness-efficiency trade-off, including demand uncertainty and resource heterogeneity. Our findings support the design of a decision-support tool now under development with our partner food bank. Backtesting on inventory data shows an over 10% improvement in both fairness and efficiency compared to current practices.

1 - Does Second-Hand Clothing Perpetuate Fashion Overproduction?

Xiaoyang Long, University of Wisconsin-Madison, Madison, WI, United States, Luyi Gui, Bo Pang

In this work, we analytically study the impact of a resale platform on fashion consumers' purchase and resale decisions. We analyze the conditions under which the provision of a resale option could inadvertently increase total consumption and production, leading to worse environmental outcomes.

2 - A Novel Return Policy: Negotiating Refunds Without Returns

Tingliang Huang, Haslam College of Business, University of Tennessee, Knoxville, TN, United States, Ziqin Gao, Ganquan Huang, Yan Liu, Yugang Yu

Returns of low-salvage-value products intensify the fundamental return dilemma in retailing industries. Recently, some retailers tried to address this dilemma by adopting the Negotiating Refunds Without Returns (NROR) policy, where consumers keep mismatched products with a negotiated refund without physical returns. To assess the profitability and social implications of NROR, we develop a game-theoretic model based on the Nash bargaining framework.

3 - Reuse and Repeat: the Design of Deposit Return Scheme

Yunlong Peng, University of Warwick- Warwick Business School, Coventry, United Kingdom, Fei Gao, Jian Chen

A growing number of brands are piloting reusable packaging programs managed through deposit-return schemes, in which consumers pay a deposit to borrow reusable packaging and must return it within a specified window to receive a refund. In this paper, we study the optimal design of such schemes and evaluate their economic and environmental implications.

Practice-driven Revenue Management

Invited Session

Revenue Management

Chair: Xiao Lei, University of Hong Kong, Hong Kong, N/A

1 - On Size Substitution and Its Role in Assortment and Inventory Planning

Yi-Chun Akchen, University College London, London, United Kingdom, Felipe Caro

How should (apparel) retailers manage product sizes? For example, if most customers wearing a given shoe size, such as 9.5, are willing to accept a half-size up or down, is it necessary for a retailer to carry that size at all? Additionally, while identical products in different sizes are treated as distinct SKUs in inventory management, they are often aggregated for assortment and strategic planning, although there is no theoretical justification showing that such aggregation approach is sensible. In this paper, we address these fundamental questions about size management, which have remained largely unexplored in the operations literature. We propose a choice model where each customer forms a consideration set based on the in-stock availability of products of her best-fit size and adjacent sizes. Using a real-world dataset from a large footwear retailer, we show that nearly 25% of the unmet demand caused by stockouts spills over to adjacent sizes. We further solve the assortment and inventory optimization problems under the proposed choice model. Our findings show that the optimal assortment remains unchanged regardless of the likelihood that customers might purchase adjacent sizes. We utilize this finding and further show that inventory policies that ignore size substitution can be (asymptotically) optimal when the demand rate is high or the selling horizon is long. We also propose a mixed-integer program to find inventory levels that account for size substitution and obtain higher profits in the low-demand settings.

2 - When Art Auctions Overlap: Revenue Effects of Concurrency in Online Markets

Hester Zhang, IESE Business School, Barcelona, Spain, Abhishek Deshmane

This paper studies the revenue implications of concurrent auctions on an online art auction platform. The shift to online auctions has dramatically reduced transaction costs for bidders, enabling new formats such as the simultaneous auctioning of similar items—what we call concurrent auctions—a feature rarely feasible in traditional in-person settings. While concurrency may reduce auction revenues due to competition among similar items (“cannibalization”), it may also enhance them by improving matching through lower search costs and facilitating portfolio-based bidding by collectors. Using a novel dataset of bid-level information on over 350,000 items from a European online platform that partners with small auction houses, we examine whether concurrency raises auction revenues. Our preliminary analyses find systematically higher revenues for concurrent auctions of artworks by the same artist. Moreover, we observe that revenues initially rise with the number of concurrent auctions, then decline—suggesting that gains from improved matching initially dominate, but are eventually offset by cannibalization effects. We also explore a potential mechanism behind the revenue gains: bidders appear to cross-reference bid increments across similar concurrent auctions, potentially intensifying competition. These findings indicate that online platforms can strategically leverage concurrency to enhance auction outcomes, with broader implications for the design of digital marketplaces.

3 - Dynamic Segmentation and Personalization in in-App Advertising Games

Xiao Lei, University of Hong Kong, Hong Kong, Hong Kong, Jiacheng Chang, Zhixi Wan

In-app advertising (IAA) games represent a unique segment of mobile gaming, where monetization is achieved solely through rewarded ads that players can opt into for in-game advantages. The design and management of these games are intricate due to the high diversity and rapid attrition rates of players. This study introduces a novel framework that dynamically segments users and personalizes game difficulty with the objective of maximizing each user's lifetime value. We detail a method for parameter estimation that accounts for the exogenous shocks frequently encountered in gaming environments. Additionally, we outline an actionable policy derived from Partially Observable Markov Decision Processes (POMDP), designed for straightforward implementation. The efficacy of our approach is demonstrated through a field experiment conducted with a commercial IAA game, where we achieved a 20% increase in revenue when compared to traditional methods employing uniform and fixed difficulty settings.

4 - Robust Ancillary Pricing for Airlines: When a Single Mark-up Outperforms Personalisation

Xiao Jin, National University of Singapore, Singapore, Singapore, Junjie Ren, Chung Piau Teo

In low-cost carriers, ancillary products, such as checked bags and seat selection, are priced with sparse transaction data. We investigate the revenue effects of **assuming homogeneous willingness-to-pay (WTP) noise when, in reality, the noise varies across customers**. Within this misspecified framework we develop and compare two practical rules: (i) a personalised and (ii) a constant feature-based mark-up. Analytical error bounds show that revenue loss grows with the square of the markup error. Numerical experiments and field tests indicate that when the noise model is inaccurate, the constant markup delivers higher median revenue and lower variability than the personalised rule. The findings suggest that, under data sparsity, it may be better off applying a single, conservatively chosen premium rather than pursuing fine-grained personalisation before the WTP distribution is properly identified.

Revenue Management

Chair: Dragos Florin Ciocan, INSEAD, Fontainebleau, France

1 - Airline Revenue Management with Carbon

Dragos Florin Ciocan, INSEAD, Fontainebleau, France

In order to contain the airline industry's massive environmental footprint, regulations impose that airlines who exceed their emission thresholds pay into emissions trading systems. This effectively imposes a carbon cost over the flights an airline operates. We study how the presence of these costs affects pricing policies and network layouts for airlines.

2 - A Distributed Supply Chain: Inventory and Capacity Analysis

Victor Araman, American University of Beirut, Beirut, Lebanon, Sasha Ghaya

We consider a simple supply chain model consisting of a retailer facing a constant demand from end-consumers while being supplied by a distributed network of suppliers (DNS) made of local, heterogeneous artisans, each operating as independent entities. Within this setting, the retailer determines the adequate base-stock level, while each supplier decides on the amount of capacity to allocate to the retailer. We specifically model the supply function as an infinite server queue. We suggest an approximation of the problem's formulation obtained through a heavy traffic limiting regime, to which we apply a static mean field game's approach. We analyze first the centralized system as a benchmark and obtain a closed form solution to the decentralized problem. As we do so, we quantify the inefficiency of the decentralized setting and suggest a simple linear transfer payment-type contract that achieves the first best solution.

3 - Improving Housing Market Outcomes via Auditing and Financial Facilitation: a Platform-Based Model of Ngo Intervention

Irmak Dai, INSEAD, Fontainebleau, France, Atalay Atasu, Dragos Florin Ciocan, Antoine Desir

Housing markets in low-income settings often suffer from poor-quality construction, informal housing practices, and information asymmetry between builders and beneficiaries. This leads to inefficient allocation, where even high-budget beneficiaries may receive low-quality housing. We study the role of a nonprofit intermediary that aims to improve market outcomes through two costly interventions: (i) auditing builders to deter misrepresentation, and (ii) facilitating beneficiary access to external financial resources. We develop a stylized model in which builder qualities and beneficiary budgets are continuously distributed, and the intermediary operates under imperfect observability. Preliminary results indicate that no single intervention is sufficient to improve outcomes across the market. Instead, coordinated action—engaging NGOs, public authorities, and financial institutions—appears necessary to address the underlying inefficiencies. This work contributes to the literature on allocation under asymmetric information and platform-enabled interventions in under-regulated markets.

4 - Market Design of Contest Platforms

ZONGSEN YANG, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Xiao Lei, Pin GAO, Zizhuo Wang

We study the market design problem in an online contest platform (e.g., GGPoker) that repeatedly organizes large-scale contests to optimize long-term player retention. We build a novel dynamic model where the players' active probability depends on their skill levels and engagement states. Active players decide whether to participate based on their gains in each round. The platform must incentivize user participation and match them to maximize player engagement. When players' incentives are disregarded, we propose an outcome-based matching scheme that reallocates the number of winning points among players by matching high-level players with low-level ones. This scheme departs from traditional room-based approaches and can be framed as a downstream network flow problem. We prove that the common skill-based matching is optimal when games are highly competitive/non-competitive, or engagement states are limited. However, it could perform poorly compared to the optimal cross-level matching. We also find that when players suddenly disengage after loss streaks, the optimal policy would transfer winning points from the most and least engaged players to the second-least engaged players. However, the optimal policy may completely sacrifice the interests of low-level players and discourage them from joining in the contests. To resolve this, we design a token-based mechanism to incentivize players and recover the first-best outcome. Our results remain valid in the contexts of limited transfer or online arrivals. Our analysis provides actionable insights and practical solutions for contest platforms seeking to better entertain players.

Revenue Management

Chair: Ilan Morgenstern, Yale University, New Haven, United States

Co-Chair: Zhen Lian, Yale School of Management, New Haven, CT, United States

1 - Tagging the Shift: Effect of Large Language Models on Knowledge Communities

Neha Sharma, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States, Simin Li

The widespread adoption of Large Language Models (LLMs) is profoundly altering human-AI interaction, raising critical questions about their impact on online collaborative knowledge ecosystems. We empirically investigate these dynamics using a comprehensive dataset from a large online community for programming and technical expertise. Employing a difference-in-differences framework and network analysis of tag co-occurrence, our study explores how LLMs influence user behavior and the structural organization of knowledge within such platforms. We aim to understand the evolving nature of collective intelligence and human-AI co-evolution in these digital spaces.

2 - The Price of Prestige: Exclusive Pricing and Selling of Luxury Bands and Resale Market Dynamics

Zhe Liu, Imperial College London, London, United Kingdom, Anran Li, Rachel Zhang

Luxury brands like Hermès and Chanel balance exclusivity with revenue through distinct strategies. Hermès requires customers to purchase ancillary products before accessing premium items like Birkin bags, while Chanel sets higher direct prices without bundling requirements. This study examines how luxury brands should design pricing mechanisms considering resale market dynamics. We develop a novel model capturing customers with dual valuations for premium and ancillary products, creating three segments: primary buyers, resellers, and resale market buyers. Our game-theoretic analysis shows how optimal pricing emerges from equilibrium interactions between these customer types and reveals why seemingly restrictive strategies can be optimal. We provide insights for luxury brands to enhance prestige, revenue, and customer loyalty while navigating primary and secondary market dynamics.

3 - Who Ate the Lunch? A Belief Propagation Algorithm for Identifying Refund Hunters

Chenkai Yu, Columbia University, New York, NY, United States, Arpit Agarwal, Hongyao Ma

For online platforms such as UberEats and DoorDash, a central challenge in customer service is the lack of ground truth: when a customer reports that an order was never received, it is difficult for support agents to determine if the driver kept the food, a passer-by took the delivery, or the customer is falsely claiming a missing order. This fundamental uncertainty often results in platforms shouldering refunds and appeasement costs without holding either side of the market accountable. In this work, we propose a belief propagation (BP) algorithm for identifying strategic customers and drivers, considering both their frequency of platform use and the trustworthiness of the participants they had interacted with. In large markets, we show that our proposed BP algorithm approximately recovers the correct types on the driver side, and achieves the highest statistical power on the customer side. Additionally, there is an exponentially large gap in the ratio of false positive rates between our algorithm and a naive benchmark that only relies only on the average past refund rate of each participant. Extensive experiments on both synthetic data and data from our industry collaborator — a major Southeast Asian platform — demonstrate that the BP algorithm provides substantial and robust accuracy improvements.

4 - Learning Competition Status with Small Samples in Gig Economy Platforms

Zhen Lian, Yale School of Management, New Haven, CT, United States

Gig economy platforms such as Uber and Lyft operate in dynamic and competitive markets where drivers may receive offers from multiple platforms. A central challenge is determining optimal compensation when drivers' reservation wages are both heterogeneous and influenced by competitors' actions—factors typically hidden from the platform. For example, temporary pay incentives offered by Uber can raise drivers' willingness-to-accept on Lyft, yet Lyft has no direct visibility into such promotions. We study how a ride-hailing platform can make adaptive pay decisions using small samples and real-time driver responses. We model the platform's problem as a sequential decision process in which pay offers are adjusted based on observed acceptances and rejections, with rejections serving as implicit signals of external competition. We analyze three settings— independent, fully correlated, and mixed drivers—and characterize the structure of optimal pay policies using dynamic programming. Our results highlight that optimal wage sequences are non-decreasing across drivers, and we quantify the trade-off between flexibility in wage setting and the value of information about competition. We further show how a platform can infer competitor activity from limited data and adaptively refine its pay strategy. This framework provides structural insights into wage design and offers a practical approach for platforms to optimize driver pay in uncertain, competitive environments.

1 - Optimal Selection Using Algorithmic Rankings with Side Information

Kathleen Donahue, MIT, Cambridge, MA, United States, Nicole Immorlica

Motivated by online platforms such as freelance job markets, we study an agent choosing from a list of candidates, each with a hidden quality that determines match value. The agent observes only a noisy ranking of the candidates plus a binary signal that indicates whether each candidate is "free" or "busy." Being busy is positively correlated with higher quality, but can also reduce value due to decreased availability. We study the agent's optimal selection problem in the presence of ranking noise and free-busy signals and ask how the accuracy of the ranking tool impacts outcomes. In a setting with one high-valued candidate and an arbitrary number of low-valued candidates, we show that increased accuracy can result in reduced social welfare. This can occur for two reasons: agents may be more likely to make offers to busy candidates, and (paradoxically) may be more likely to select lower-ranked candidates when rankings are more indicative of quality. We further discuss conditions under which these results extend to more general settings.

2 - Data Informativeness in Decision-Making

Amine Bennouna, Kellogg, Northwestern University, Cambridge, MA, United States, Omar Bennouna, Saurabh Amin, Asuman Ozdaglar

We study the fundamental informational value of a dataset with respect to a given decision-making task under uncertainty. Given a task and an uncertainty set, we characterize which datasets are sufficient to recover the task's optimal solution. These results enable us to introduce a novel principled approach for the important problem of task-specific data collection.

3 - Breaking Algorithmic Collusion via Simple Defections

Meena Jagadeesan, UC Berkeley, Berkeley, CA, United States, Natalie Collina, Eshwar Ram Arunachaleswaran

When firms deploy algorithms to automate pricing decisions, the implicit competition between these algorithms can lead to market prices that are higher than in a competitive market. In this work, we investigate whether high prices persist even when some firms defect to simpler heuristics. Our main finding is that even a single firm defecting to a simple heuristic strategy can significantly drive down the market prices, though not necessarily all the way down to the competitive price. We specifically

analyze a repeated Bertrand pricing game under defections to no-regret strategies and FollowTheLeader (FTL). We show that when the lowest-profit firm defects to a no-regret strategy, the worst-case market price scales approximately inversely with the number of other firms in the market. Furthermore, we extend our results to defections by multiple firms at once, and we also show that FTL can lead to strictly higher prices than no-regret defections. Taken together, our results illustrate how algorithmic collusion can break down when even a small number of firms do not adopt pricing algorithms, as long as there are sufficiently many other firms in the market.

4 - Balancing Optimality and Practicality: Bidding Strategies for Value Maximizers in Repeated Discriminatory Auctions

Sourav Sahoo, MIT, Cambridge, MA, United States, Negin Golrezaei

We study repeated multi-unit discriminatory (pay-as-bid) auctions, commonly used to sell treasury securities and commodities. Our goal is to design bidding strategies for value-maximizers—those seeking to maximize total value across rounds while satisfying per-round return on investment (RoI) constraints. Motivated by real-world platforms, we assume buyers submit bids in an m -uniform format. We first characterize *safe* bidding strategies—those that always satisfy RoI constraints regardless of competitors' bids—and show they correspond to simple no-overbidding conditions. Despite this simplicity, safe strategies are *lossless*: they achieve the same value as any RoI-feasible strategy. We then develop a polynomial-time online learning algorithm that learns optimal safe strategies with sublinear regret under both full information and bandit feedback. We next analyze a finite subset of safe strategies, called *base strategies*. While the worst-case performance of the best base strategy is only a $1/m$ -fraction of the optimal safe strategy's value, our empirical analysis on Austrian treasury bond auctions reveals that base strategies far outperform this bound in practice. Furthermore, they exhibit faster learning over time and benefit from lower computational and space complexity, making them a practical and efficient alternative to the theoretically optimal safe strategies. Finally, we present a result that bridges these two classes of strategies—any m -uniform safe strategy can be expressed as a convex combination of at most m base strategies.

5 - Improved Approximations for Stationary Bipartite Matching: Beyond Probabilistic Independence

Tristan Pollner, Stanford University, Palo Alto, CA, United States, Amin Saberi, Ali Aouad, Alireza Amaniamedani

We study stationary online bipartite matching, where both types of nodes—offline and online—arrive according to Poisson processes. Offline nodes wait to be matched for some random time, determined by an exponential distribution, while online nodes need to be matched immediately. This model captures scenarios such as deceased organ donation and time-sensitive task assignments, where there is an inflow of patients and workers (offline nodes) with limited patience, while organs and tasks (online nodes) must be assigned upon arrival.

We present an efficient online algorithm that achieves a $(1-1/e+\delta)$ -approximation to the optimal online policy's reward for a constant $\delta>0$, simplifying and improving previous work by Aouad and Saritaç (2022). Our solution combines recent online matching techniques, particularly pivotal sampling, which enables correlated rounding of tighter linear programming approximations, and a greedy-like algorithm. A key technical component is the analysis of a stochastic process that exploits subtle correlations between offline nodes, using renewal theory. A byproduct of our result is an improvement to the best-known competitive ratio—that compares an algorithm's performance to the optimal offline policy—via a $(1-1/\sqrt{e+\eta})$ -competitive algorithm for a universal constant $\eta>0$, advancing the results of Patel and Wajc (2024).

Social Networks and Predictive Insights: Analysis, Markets, and Models

Invited Session

Social Media Analytics

Chair: Tong Wang, Yale University, New Haven, CT, United States

1 - Social Media and Ride Hailing Demand: An Empirical Analysis

Adrija Majumdar, Indian Institute of Management Ahmedabad, Ahmedabad, India, Sandip Chakrabarti

Can content generated by users on social media be leveraged as a strategic tool to adjust service quality and performance to attract and retain customers—especially in industries like shared mobility, where customer experience shapes demand? This study investigates whether the volume and sentiment of social media discussions can help predict ridership demand for app-based ride-hailing services, particularly during volatile periods when traditional forecasting methods fall short. We analyze over fifteen months of tweets about Uber rides posted on the X platform in a major U.S. city during the Covid-19 pandemic. Our findings show that chatter from the previous day positively influences ridership. We further segment the analysis into high- and low-uncertainty phases, revealing that social media discussions have a stronger impact on consumer choices during uncertain times (such as before vaccine announcements), when customers tend to rely more on online information and peer experiences for decision-making. We also identify conversation themes that influence ridership and find that positive discussions boost demand. This research highlights the potential for private ride-hailing providers to use social media data to forecast short-term demand trends, particularly during unpredictable conditions. Public transport agencies can also leverage social media data for shared transportation planning and operations.

2 - The Curse of Rashomon Effects - from Model Explanation to Data Misinterpretation

Ronilo Ragodos, University Of Iowa, Iowa City, IA, United States

Machine learning models have been increasingly used in business research. However, most state-of-the-art machine learning models, such as deep neural networks and XGBoost, are black boxes in nature. Therefore, post hoc explainers that provide explanations for machine learning models by, for example, estimating numerical importance of the input features, have been gaining wide usage. Despite the intended use of post hoc explainers being explaining machine learning models, we found a growing trend in business research where post hoc explanations are used to draw inferences about the data. In this work, we investigate the validity of such use. We investigate with extensive experiments whether the explanations obtained by the two most popular post hoc explainers, SHAP and LIME, provide correct information about the importance of features for different interpretations of feature importance. In particular, we investigate how well SHAP and LIME can tell us features' global and local importance, how useful they are for prediction, and how effective they are in pursuit of actionable recourse. We refer to an explainer's utility in these respects as data-alignment. We then identify what factors influence the alignment of explanations and conclude that it is often not appropriate to infer data insights from post hoc explanations. We articulate appropriate alternative uses, the most important of which is to facilitate the proposition and subsequent empirical investigation of hypotheses. The goal of this paper is to caution business researchers against translating post hoc explanations of machine learning models into potentially false insights and understanding of data.

3 - Predicting Team Success with Representation Learning from Multi-Relational Collaboration Graphs—A Case of Nfl Coaching Teams

Seyong HA, University of Iowa, Iowa City, IA, United States

Despite its potential for insights into predicting team success, coaching collaboration has received little attention. This research explores how multi-relational structures in coaching collaboration graphs influence team success using the National Football League dataset. We propose a graph representation learning framework that captures these complex dynamics and offers a new perspective on coaching collaborations. This framework predicts a team's seasonal success by learning multi-relational collaboration representations and utilizes individual coach features such as historical performance. Our results show that leveraging both relational and individual attributes leads to an enhanced predictive power.

Prior work has typically aggregated coaching collaborations into a single network. In contrast, our framework utilizes five distinct collaboration networks that offer a richer representation. These include embeddings from three separate collaborations (supervision, reporting, and peer) and two more with different weighting schemes to the original collaboration graph. We apply an attention mechanism over the embeddings to formulate context-rich coach representations. Subsequently, the framework synthesizes team representation embeddings by attentively aggregating these individual coach representations. Attention in both aggregation steps allows us to identify and emphasize the most predictive collaboration types and key coaches while enhancing the explainability of influential factors.

Applying this approach to the NFL coach dataset from the 1963 to the 2019 season demonstrates that we can achieve better performance in terms of both explainability and accuracy via the proposed framework. Our results shed light on the vital role of coaching collaboration and reveal how it can be used to predict team success in sports.

4 - The Geometry of Persuasion: Mapping Opinion Dynamics in Embedding Space

Yen-Shao Chen, Yale University, New Haven, CT, United States, Tauhid Zaman

Persuasion—the process of changing opinions or behaviors—exhibits surprisingly elegant geometric patterns when analyzed through the lens of large language models. We investigate a paradigmatic scenario: a salesperson persuading a customer to purchase a product. By embedding conversational messages into high-dimensional space, we discover that successful persuasive interactions trace distinctive curves through this landscape. Different persuasion strategies manifest as unique trajectories, revealing an underlying geometry to the art of influence. We construct a vector field in the embedding space that identifies persuasion paths, offering both theoretical insights into the mechanics of opinion change and practical applications for understanding effective communication strategies. This geometric framework provides a novel perspective on how minds navigate the space of beliefs during persuasive encounters.

1 - Reinforced Stable Matching for Crowd-Sourced Delivery Systems Under Stochastic Driver Acceptance Behavior

Shixuan Hou, Ivey Business School, Western University, London, ON, Canada, Bissan Ghaddar

Crowd-Sourced Delivery Systems (CDS) depend on occasional drivers to deliver parcels directly to online customers. These freelance drivers have the flexibility to accept or reject orders from the platform, leading to a stochastic and often unstable matching process for delivery assignments. This instability results in frequent rematching, delayed deliveries, decreased customer satisfaction, and increased operational costs, all highlighting the critical need for improved matching stability within CDS. While traditional stable matching theory provides a foundation, it primarily addresses static and deterministic scenarios, making it less effective in the dynamic and unpredictable environments typical of CDS. Addressing this gap, this research extends the classic Gale–Shapley (GS) stable matching algorithm by incorporating tailored compensations for drivers, incentivizing them to accept assigned orders and thus improving the stability of matchings, even with the inherent uncertainties of driver acceptance. We prove that the proposed mechanism can generate reinforced stable matching results based on tailored compensation values. Our numerical study shows that this reinforced stable matching approach significantly outperforms traditional methods in terms of both matching stability and cost-effectiveness. It reduces the order rejection rate to as low as 1% and cuts operational costs by up to 18%.

2 - Order Assignment and Two-Stage Integrated Scheduling in Fruit and Vegetable Supply Chains

Gang Wang, University of Massachusetts Dartmouth, North Dartmouth, MA, United States

Fruit and vegetable supply chains require tight integration to maintain freshness during post-harvest, production, and distribution. This paper addresses the scheduling problem in a two-stage flow shop within the supply chain, involving procurement, production, distribution, and order assignment with contract growers, processors, and demand points. The first stage focuses on production and distribution schedules from growers to processors, while the second stage involves assigning demand points to processors and scheduling production and distribution from processors to demand points. We propose a mixed-integer linear programming model for these processes and present two strongly polynomial algorithms to solve the sub-problems. Additionally, we develop a two-phase heuristic algorithm that integrates both stages. Computational experiments show that our algorithms outperformed CPLEX in large-scale instances while also analyzing the effects of waste reduction, processing costs, and shipping rates on supply chain performance.

3 - A Hybrid Genetic Programming for Online Rescheduling of Semiconductor Manufacturing Systems

Yutong Su, Arizona State University, Tempe, AZ, United States, Feng Ju, Nital Patel

Semiconductor manufacturing assembly systems are subject to random disruptions such as machine failures, which can lead to delays and time window violations that render the pre-determined master schedule suboptimal or even infeasible. Recreating a new master schedule is time-consuming and may incur greater losses than the original disruption. To mitigate the negative impact of machine failures, we propose a novel hybrid Genetic Programming approach for short-horizon rescheduling in real-world semiconductor manufacturing systems. The proposed method introduces custom-designed features, referred to as terminals, specifically tailored for handling machine failures, which make the rescheduling process inherently interpretable, in contrast to many meta-heuristics or machine learning methods where the rationale behind adjustments is often difficult to discern. Experimental results demonstrate that the proposed approach significantly reduces delays within a reasonable computation time, thereby improving overall system efficiency.

4 - Creator Incentives in Recommendation Systems: a Cooperative Game-Theoretic Approach to Multi-Agent Bandits

Ramakrishnan Krishnamurthy, New York University, New York, NY, United States, Arpit Agarwal, Lakshmi Subramanian, Max Nickel

In modern online recommender systems, user interactions with content serve as implicit learning signals, enabling platforms to generalize preferences across users and content. Consequently, content creators influence not only their own outcomes but also those of others—user feedback on one creator’s content can affect how the system recommends others’ content, impacting their exposure and revenue across the ecosystem. Recognizing this interdependence, we study how observation sharing (collaboration) among creators (agents) affects learning efficiency and investigate the conditions in which such collaboration is collectively rational and equitable.

To this end, we model the problem as a collaborative variant of the multi-agent stochastic linear bandit framework, where agents individually interact with a common environment but may form coalitions to share observations and improve learning efficiency. We formalize this as a transferable utility (TU) cooperative game, where the value of a coalition corresponds to the negative sum of bandit regrets incurred by its members. This framework allows us to examine how algorithmic design and structural assumptions about agents affect collaboration incentives.

We show that under some algorithmic conditions, the induced TU games exhibit desirable properties: for identical agents, the game is convex and admits a non-empty core containing the Shapley value, ensuring stable and equitable collaboration. For heterogeneous agents, we demonstrate core non-emptiness and propose a simple, implementable payoff mechanism that satisfies all but one of the Shapley value axioms. Experiments on MovieLens-100k-derived bandit problems highlight where empirical payouts align or diverge from theoretical ideals, offering insights for incentive-aligned collaborative learning design.

5 - Online Lead TIME Quotation Under Delayed Feedback: Theoretical Guarantees and Empirical Evaluation with Offline Production Scheduling

Kelvin Ekun, University of Massachusetts, Amherst, Amherst, MA, United States, Ana Muriel

As customer order inquiries arrive over time, make-to-order (MTO) firms must provide competitive lead time quotations on the spot and manage their capacity to fulfil customised orders in a timely fashion under high uncertainty on future demand and when/whether customers will accept the given quotations. The firm must balance between quoting longer lead times that might result in the loss of the order if customers are not willing to wait and quoting shorter lead times that may end in significant delay penalties. We first consider the case of customers arriving and receiving quotations sequentially in a single sales period, while customer final acceptance decisions and production occur over the subsequent N periods. We later extend this model to allow for customer arrivals throughout the production periods. In both settings, we propose an online primal-dual quotation algorithm to maximise the total expected profit from arriving orders in a single-machine environment, showing it achieves a competitive ratio of $1/(1+\beta)$, where β is the dual-update parameter. We analyse the algorithm’s performance with periodic production scheduling against benchmarks given by naive conventional rules and an all-knowing offline oracle. Our extensive computational experiments suggest that the performance of the primal-dual algorithm

is very sensitive to the choice of dual-update parameters. Combining worst-case analysis with empirical testing, we identify robust parameter settings and show significant savings relative to our benchmarks.

1 - Unintended Consequences of Status Effect in Reputation Systems

Yingxin Lin, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong, Jihao Hu, Dapeng Xu, Xiaoquan Zhang

To encourage users to contribute higher-quality reviews, many review platforms implement community status systems (e.g., user levels, badges, ranks) as reputational incentives. A reviewer's community status also serves as an important signal for both consumers and marketers in their decision-making processes. In practice, both marketers and consumers tend to place greater trust in reviewers with a higher status. However, it remains unclear whether this is a prudent strategy. This study aims to uncover the existence of status-related preferences among marketers and consumers and, more importantly, to examine whether they truly benefit from this strategy. Drawing on both observational and experimental data, we demonstrate that, on one hand, marketers are more likely to invite high-status (vs. low-status) reviewers to participate in incentive campaigns; on the other hand, reviews posted by high-status reviewers have a greater influence on consumers, even when the review content is identical. Furthermore, we find that high-status reviewers are more inclined to provide lower ratings, suggesting a downward bias in their online rating behavior. This bias diminishes the overall helpfulness of online reviews for both consumers and marketers. We validate these findings through a series of robustness checks and further explore the mechanisms underlying this bias. Finally, we discuss the theoretical and managerial implications of our findings.

2 - Reddit Users Unleashed - Understanding User Behaviour and Their Impact on Meme Stocks

Inez Maria Zwetsloot, University of Amsterdam, Amsterdam, Netherlands, Simon Trimbom

Online social networks play an important role in financial markets and facilitate information sharing among investors for meme stocks, as was shown vividly in the recent Reddit hype. In the literature either a theoretical model is build to characterize the role of individual social network users on financial markets or aggregated empirical models are tested on small networks, leaving a gap for investigating this relationship empirically for large scale networks like Reddit. We study this relationship empirically with network data from WallStreetBets, a subreddit, via a model we term the Interpretable Social Network and Market Behaviour Model (ISBM); a novel model which captures heterogeneous individual user behaviour and links this through innovative change point modelling to the stock market. The model is scalable and includes both influential nodes as well as followers. We find that 1) both influential users as well as followers impact market behaviour, 2) changes in the network are observed well before the market frenzy, 3) changes in users behaviour can explain the market movements and improves the adj. R2 from modelling the return by 630%. Our results lead to insights and recommendations for regulators on effects of meme stocks on markets.

3 - A Game-Theoretic Analysis of System Design in Multiplayer Video Games with A Social Comparison Effect

Haruto Morimoto, Keio University, Yokohama, Japan, Nobuo Matsubayashi

Multiplayer video games have increasingly received consumers' attention, and many games have been distributed online through platforms such as Steam. However, when heterogeneous consumers interact with each other through multiplayer games on various hardware, social comparisons are likely to occur, and they may experience psychological loss or gain. These benefits and costs of social comparisons are due to heterogeneity in terms of the competitive strength of the hardware they have, which has been examined in the literature, as well as their own individual competitive strength.

This study investigates the strategic interaction between one game content developer (e.g. Tencent) and two competing hardware manufacturers (e.g. Nintendo and Sony) in the presence of such social comparison effects. The manufacturers individually choose to adopt either a closed system, whereby their game content is offered only to consumers who have purchased their hardware, or an open system, whereby all consumers on the platform (e.g. steam) can play the game content. It is assumed that social comparisons among consumers due to differences in their hardware only occur under a closed system. The open system is only sustained in equilibrium when both manufacturers choose it.

We show that the open system benefits the manufacturer that offers a superior hardware, while the closed system benefits the manufacturer that offers an inferior hardware. However, we find that the open system can be sustained in the equilibrium when the degree of the social comparison effect is intermediate, which also maximizes the total profit for the channel parties.

4 - Gg or Rage Quit? the Effect of in-Game Peer Toxicity on Self-Toxicity in Competitive Online Gaming Across Sequential Matches

Sunan Qian, University of Notre Dame, Notre Dame, IN, United States, Corey Angst, Yoonseock Son

With the growing popularity of online video games, toxic in-game communication has become a persistent challenge, threatening player retention, community health, and overall gaming experience. Understanding the dynamics of how this toxicity spreads is crucial for designing effective moderation strategies. Using data from 1,358 Dota 2 players across 51,771 matches (Dec 2024 – Jan 2025), we explore how exposure to toxicity in past matches influences a focal player's self-toxicity in subsequent games. We examine whether this contagion effect changes over time, how it is shaped by the outcome of a match (win/loss), and whether certain types of players are more susceptible to adopting toxic behaviors than others. We use a BERT-base natural language model to measure explicit and implicit textual toxicity. Results from our empirical analysis show that toxicity spreads from both teammates and opponents, with teammates exerting over 10 times the negative effect as opponents. Cooldown time between matches does not stop the spread of explicit toxicity, and longer breaks actually increase the spread of implicit toxicity from teammates, suggesting that implicit toxicity may operate more as a persistent habit than a reactive behavior. Toxicity contagion persists regardless of prior match outcomes, even though the peer effect from opponent explicit toxicity is weaker after a win. High-skill players resist opponents but absorb teammate influence, and active players are more susceptible to opponent peer effects. Our findings encourage gaming companies to adopt tailored interventions to address implicit and explicit toxicity through distinct strategies like habit-breaking nudges and rapid response systems.

5 - Can We Talk?: Artificial Emotional Intelligence Chatbots and Loneliness Reduction

Mohammad Arif Ul Islam, University of North Carolina Greensboro, Greensboro, NC, United States, Nikhil Mehta

Artificial Emotional Intelligence (AEI) has become a game-changing development in digital communication by combining affective computing and natural language processing to mimic human empathy. In contrast to traditional rule-based systems, AEI-driven chatbots now provide dynamic, emotionally intelligent interactions. These changes are particularly relevant to the problem of loneliness, which is a complex emotional experience characterized by a sense of emotional and social loneliness. Since loneliness is strongly associated with negative consequences including anxiety, depression, and cardiovascular problems, it is becoming more widely acknowledged as a public health issue. AEI chatbots present a promising intervention by facilitating emotionally resonant conversations that enhance users' psychological well-being. A central mechanism influencing their effectiveness is perceived emotional authenticity (PEA)—the extent to which users regard the chatbot's emotional responses as

sincere and emotionally aligned. High PEA encourages emotional transparency, user happiness, and trust—all of which are critical for applications related to mental health. In order to establish this authenticity, empathy—both generation and simulation—are essential. This study examines how AEI chatbots' empathy mechanisms help users perceive emotional authenticity and, in turn, how this perception affects reductions in social and emotional loneliness. It also looks at how trust may either increase or decrease the effect of PEA on loneliness outcomes. The work intends to contribute to scalable, user-centered methods for emotional support and loneliness reduction by incorporating knowledge from affective computing, human-computer interaction, and mental health research.

1 - On the Statistical Capacity of Deep Generative Models

Edric Tam, Stanford University, San Francisco, CA, United States, David Dunson

Deep generative models are routinely used in generating samples from complex, high-dimensional distributions. Despite their apparent successes, their statistical properties are not well understood. A common assumption is that with enough training data and sufficiently large neural networks, deep generative model samples will have arbitrarily small errors in sampling from any continuous target distribution. We set up a unifying framework that debunks this belief. We demonstrate that broad classes of deep generative models, including variational autoencoders and generative adversarial networks, are not universal generators under a variety of statistically relevant divergences. Under the predominant case of Gaussian latent variables, these models can only generate concentrated samples that exhibit light tails. Using tools from concentration of measure and convex geometry, we give analogous results for more general log-concave and strongly log-concave latent variable distributions. We extend our results to diffusion models via a reduction argument. We use the Gromov-Levy inequality to give similar guarantees when the latent variables lie on manifolds with positive Ricci curvature. These results shed light on the limited capacity of common deep generative models to handle heavy tails. We illustrate the empirical relevance of our work with simulations and financial data.

2 - Avalon: An Agentic Methodology for Multi-Scale, Quantifiable Verification of Research Reports

Murtaza Nasir, Wichita State University, Wichita, KS, United States

Increasingly, research outputs are being augmented or even completely generated by AI systems, and new methods for robust and scalable quality evaluation are required. While traditional peer review is invaluable, it is fraught with issues of subjectivity, scalability, and generating fine-grained, quantifiable feedback that can be used for iterative improvement or training of generative AI. In this paper, we propose AVALON (Agentic Verification for Logically-grounded Objective N-dimensional assessment), a novel agentic system to automatically verify and quantify the quality of research reports, human- or AI-authored. AVALON takes as input a research report and its cited references (optionally with the original user-prompt) and evaluates it using a multi-agent system at multiple scales, including broad assessments of structure, style, and coherence, as well as granular, claim-by-claim factual verification, where agents attempt to retrieve and analyze text from referenced sources. AVALON further includes agents that can execute code to verify quantitative analyses, and search existing literature to find potentially overlooked research. The methodology results in a multi-dimensional quantitative scorecard and qualitative, peer-review-style comments. The goal of AVALON is to help address an important gap in providing an objective, reproducible, and detailed verification method, to enable standardized quality evaluation and a quantifiable reward signal for training and advancement of state-of-the-art AI research systems.

3 - Toward a Trustworthy Optimization Modeling Agent via Verifiable Synthetic Data Generation

Vinicius Lima, IBM Research, Yorktown Heights, NY, United States, Dzung Phan, Jayant Kalagnanam, Dhaval Patel, Nianjun Zhou

We present a framework for training trustworthy large language model (LLM) agents for optimization modeling via a verifiable synthetic data generation pipeline. Focusing on linear and mixed-integer linear programming (LP/MILP), our approach begins with structured symbolic representations and systematically produces natural language descriptions, mathematical formulations, and solver-executable code in multiple optimization languages. By programmatically constructing each instance with known optimal solutions, the pipeline ensures full verifiability and enables automatic filtering of low-quality demonstrations generated by teacher models, without the need for annotation by optimization experts. Each dataset instance includes a structured representation of the optimization problem, a corresponding natural language description, the verified optimal solution, and step-by-step demonstrations — generated by a more powerful teacher model — that show how to model and solve the problem across multiple optimization modeling languages. This enables supervised fine-tuning of open-source LLMs specifically tailored to optimization tasks. Empirical evaluation shows that models trained using our pipeline achieve state-of-the-art performance on standard optimization modeling benchmarks through majority-vote inference and multi-language cross-validation. Our approach provides a scalable, verifiable, and principled path toward building reliable LLM agents for real-world optimization modeling applications.

4 - Genai and Decision Making - An Eye-Tracking Study

Shehara Grabau, Auburn University, Auburn, AL, United States, Pankush Kalgotra

With the rise of Generative AI (GenAI) in e-commerce, more platforms are integrating GenAI tools such as review summarization and chatbots to assist consumers in decision making. Consumers experience less information overload and greater decision satisfaction when exposed to a manageable amount of user reviews. This suggests that GenAI review summarization can reduce the cognitive burden on consumers. Recent work is beginning to uncover how GenAI summaries and their valence influence decision making. For instance, AI-generated summaries have been shown to positively impact product sales, with their effectiveness shaped by factors such as number of reviews, average rating, and rating dispersion. These findings suggest GenAI tools influence purchasing decisions under varying conditions. However, such tools are often examined in isolation. The combined effect of multiple GenAI-powered tools, as in real-world settings, remains underexplored. Our study investigates how GenAI review summaries and chatbot conversations collectively influence consumer decision making. While review summaries provide a quick overview of public opinion, chatbots offer tailored responses to specific queries. Drawing on Media Richness Theory, we propose that chatbots represent a richer medium than static GenAI summaries. We also examine the definite valence of GenAI summaries as a moderator of their influence on purchase intention. Using eye-tracking technology, we measure cognitive engagement during a simulated e-commerce shopping task. Metrics such as fixation duration, fixation count, and time to first fixation across predefined Areas of Interest (AOIs) will be analyzed to understand how consumers process GenAI tools and their joint impact on decision making.

5 - Causal Modeling of User Retention with Large Language Models for Decision-Driven Platforms

YITING TANG, Univeristy of Sydney, Sydney, Australia

We develop a unified causal modeling framework for user retention in online platforms, combining generative language models with heterogeneous treatment effect estimation. As digital platforms increasingly rely on personalized engagement strategies, it becomes critical to understand not only *what* interventions work, but *why* and *for whom*. Our framework addresses this challenge by integrating psychological features extracted from user-generated texts—such as reviews and browsing histories—using large language models (LLMs), into a structural causal analysis of user churn.

We begin by encoding high-dimensional textual data into semantically meaningful embeddings, which serve as individualized covariates reflecting dissatisfaction, sentiment polarity, and engagement dynamics. These covariates are then incorporated into a potential outcomes framework, where treatment is defined as a time-sensitive promotional intervention (e.g., issuing coupons several days after first purchase), and outcome as the likelihood of user repurchase. To estimate causal effects, we employ causal forests to compute conditional average treatment effects (CATE), while using doubly robust estimation with cross-fitting to reduce selection bias from observational data.

We further analyze treatment effect heterogeneity across behavioral and demographic subpopulations, revealing actionable insights for targeted marketing strategies. Empirical validation on real-world e-commerce datasets demonstrates that incorporating LLM-derived psychological signals improves AUC in churn prediction and increases policy value compared to conventional models. These results underscore the potential of integrating generative AI with causal inference frameworks to drive interpretable, adaptive, and demographically personalized retention strategies in decision-driven platforms.

QSR Student Introduction and Interaction Session

Panel Session

Quality, Statistics and Reliability

Co-Chair: Alan Vazquez, Tecnologico de Monterrey, Monterrey, 64700, Mexico

Co-Chair: Yu Jin, University at Buffalo, Binghamton, NY, 14260, United States

1 - Moderator Panelist

Yu Jin, University at Buffalo, Binghamton, NY, United States

This interactive session serves as a vital platform for connecting PhD students with the broader Quality, Statistics, and Reliability community. Following the successful format of previous years, the session begins with a series of concise "elevator pitches" where selected QSR student members (especially those nearing graduation) present their research interests and accomplishments. This showcase segment provides valuable exposure for emerging talent. The second part features an interactive mini-panel discussion and Q&A with invited senior QSR faculty and industry professionals. These experienced members will share insights and advice on navigating the academic and industry job markets, developing research programs, teaching effectively, and building a successful career in QSR-related fields. The session aims to foster networking, highlight student research, and provide targeted mentorship.

2025 PGE Energy Analytics Challenge: Solutions and Lessons Learned

Panel Session

Quality, Statistics and Reliability

Co-Chair: Murat Yildirim, Wayne State University, Detroit, MI, United States

Co-Chair: Ahmed Aziz Ezzat, Rutgers University, Piscataway, NJ, United States

1 - Moderator Panelist

Ahmed Aziz Ezzat, Rutgers University, Piscataway, NJ, United States

The panel will discuss the findings and lessons learnt from the 2025 PG&E Energy Analytics Challenge, co-organized by IISE and INFORMS, and sponsored by the Pacific Gas & Electric Company (PG&E) -- one of the largest electric utilities in the U.S. The 2025 challenge theme was on electric load forecasting, where contestants were provided multi-year electric load data, together with exogeneous weather and operational information. The competition challenged contestants to design data-science-based forecasting models to predict day-ahead electric loads. This panel will first introduce the challenge, as well as an overview of the methods used by the top-performing contestants. A distilled summary of the key insights and lessons learned by the challenge organizers will then be interactively discussed with the contestants, PG&E representatives, and the audience, as well as their relevance to the field of energy analytics and forecasting.

2 - Moderator Panelist

Data-Driven Reliability and Maintenance

Contributed Session

Contributed

Chair: Mobolaji Shobanke, George Washington University, Washington, DC, United States

1 - An Interleaved-Deletion Markov Boundary Discovery Method for Key Process Feature Identification in Manufacturing Systems

Jiaqi Zhang, Tianjin University, Tianjin, China, People's Republic of, Liangxing Shi

Identifying key process features (KPF) is critical to ensure product quality in manufacturing systems. The task is complicated by the large number of quality features and the underlying mechanisms among features, which often hinder accurate KPF identification. To tackle this challenge, this study proposes an improved Markov Boundary discovery method, called Interleaved-Deletion Markov Boundary (IDMB), for causal feature selection in manufacturing quality control. The IDMB method introduces three key innovations. First, it allows overlap between candidate parent-child (PC) and spouse node sets, broadening the search space for causal features and improving completeness. Second, it employs an interleaved deletion mechanism that removes potential false-positive spouses one PC node at a time. It reduces the risk of discarding true causal features erroneously due to conditional independence test errors. To cope with the problem of product quality data imbalance, IDMB allows embedded sampling methods. The proposed method extensively validates IDMB on eight standard Bayesian network benchmarks and six real-world manufacturing quality datasets from the UCI repository. The results show that IDMB achieves higher recall in identifying true causal features, outperforming thirteen state-of-the-art Markov Boundary discovery methods and four non-causal feature selection methods. The proposed approach advances the methodology of causal feature selection by improving identification accuracy and robustness and offers practical value for manufacturing quality control.

2 - Reliability Optimization of Air Traffic Control System

Merve Uzuner, Baskent University, Ankara, Turkey, Orhan Dengiz, Berna Dengiz

Communication networks within air traffic control (ATC) systems play a crucial role in ensuring secure and reliable communication among aircraft, ground control units, and other various air traffic management units. These networks enable the transfer of critical information such as flight plans, position reports, meteorological data, and control instructions. A wide range of technologies, such as satellite communications, data linkages, and radio frequencies, are used to provide coverage, particularly in distant and transoceanic areas. Communication networks are made up of three main components: ground-based communication stations, satellite systems, and onboard communication devices. These components work together in an integrated manner using complicated communication protocols and operational procedures. Due to increased air traffic, enhancing the reliability of these networks has become a significant area of research for the sustainability of air traffic management systems.

Efforts to improve system reliability are typically addressed in the literature under the framework of the "reliability optimization problem." The Redundancy Allocation Problem (RAP) is frequently used to solve this issue. This paper formulates and addresses the design of a highly reliable communication network within an ATC system using RAP. To solve RAP, which is known to be an NP-hard problem, a well-established heuristic method—Genetic Algorithm (GA)—is proposed. The algorithm's performance is evaluated through computational analysis based on varying problem sizes.

3 - Swinnext-Haada: Hierarchical Adaptive Attention-Driven Dual-Stream Architecture for Medical Image Classification

Tien Truong, University of South Florida, Tampa, FL, United States, Phat Huynh, Ca Hoang, Khanh Do, Son Pham, Han Lam, Trung Le

Deep learning methods have facilitated significant progress in medical image classification; however, substantial challenges remain in unifying anatomically global context with locally detailed features and adaptively selecting salient patterns across heterogeneous disease presentations. We propose *SwinNeXt-HAADA*, a dual-stream architecture that integrates Swin Transformer and ConvNeXt backbones for end-to-end medical image analysis. Our framework features a systematic, cross-stream fusion of *Dynamic Attention Refinement (DAR)* and *Stage Importance Weighting (SIW)*: DAR selectively amplifies relevant channels at the fusion level, while SIW highlights cross-stage combinations that yield the greatest discriminative power. These mechanisms enable *SwinNeXt-HAADA* to dynamically emphasize both large-scale contextual cues (via transformer-based global attention) and fine-grained local details (via convolution-driven feature extraction), even in anatomically complex images. We evaluated our approach on three medical imaging domains—brain tumor MRI, chest X-ray, and gastrointestinal endoscopy—totaling over 22,000 images. The proposed model achieved up to 99.56% accuracy for brain tumor classification, 98.70% for chest disease detection, and 98.53% for endoscopic lesion recognition, surpassing state-of-the-art methods. Further analysis of the learned attention distributions revealed that channel-level gating uncovers subtle but critical features (e.g., tumor boundaries), while stage-level weighting adaptively prioritizes synergy between deeper stages of both streams for MRI and mid-to-late or early-late pairings for other pathologies. Feature activation visualization underscored the effectiveness of a joint global-local strategy. Altogether, these results suggest that *SwinNeXt-HAADA* can serve as a strong candidate for multiscale, heterogeneous medical image classification.

4 - Computing Distributionally Robust Preventive Maintenance Intervals

Heraldo Rozas, Department of Electrical Engineering, University of Chile, Santiago, Chile, Nagi Gebrael, Weijun Xie

Preventive maintenance (PM) intervals are traditionally determined using predict-then-optimize (PTO) frameworks, wherein historical failure time (FT) data is first used to characterize the underlying FT distribution, and then an optimization problem is solved to determine the optimal PM intervals. Nonetheless, such PTO frameworks may perform poorly out-of-sample if the fitted FT distribution differs significantly from the true distribution. This talk addresses this issue by introducing a contextual Distributionally Robust (DR) model for computing optimal PM intervals. The proposed model integrates empirical FT data directly into the PM optimization framework without assuming any specific distribution. Potential perturbations of the empirical FT distribution are captured using a Wasserstein ambiguity set. The DR model admits tractable mixed-integer linear programming reformulations in various practical settings, making it easy to implement with off-the-shelf optimization solvers. Its efficacy is demonstrated through computational studies involving both simulated and real-world failure time data.

5 - Neighborhood-Based Modeling and Prediction of Spatiotemporal Melt-Pool Dynamics

Siqi Zhang, Southern Illinois University Edwardsville, Edwardsville, IL, United States, Hui Yang

Laser powder bed fusion (LPBF) is a metal-based additive manufacturing process to produce 3D parts directly from digital designs. In LPBF, a laser beam scans a powder bed to selectively fuse the material into the shape of the desired part. At each fusing point, the laser heats and liquidizes the powder, during which a melt pool is formed. The dynamics of the melt pool are the result of laser-powder interactions over time and significantly influence the microstructure and mechanical characteristics of the final part. Accurate prediction of melt pools is essential to many applications, e.g., optimizing process parameters and enabling real-time defect prevention. However, this prediction problem is challenged by spatial-temporal effects and time-varying process parameters in actual manufacturing. In this work, we develop a neighbor-based encoder-decoder framework to capture spatiotemporal effects and predict melt-pool dynamics. Specifically, the encoder consists of 1) a process module that captures the spatial heterogeneity between a melt pool and its neighbors due to process variations and 2) a temporal module to model time-related dependences within the neighboring region. Given a set of neighboring melt-pool images and their associated process variables, the encoder generates a spatiotemporal latent representation, which is then decoded for prediction. The proposed framework is evaluated using melt-pool imaging data from LPBF benchmark experiments. Compared to traditional spatiotemporal models, it not only incorporates process variables into the modeling but also accommodates non-continuous images as temporal data. This framework is broadly extensible to other problems involving spatiotemporal dynamics with non-continuous data.

6 - Timescale Selection and Reliability Modeling for Condition-Based Maintenance of Medical Equipment

Mobolaji Shobanke, The George Washington University, Washington, DC, United States, Connor Roberts, Ekundayo Shittu

Driven by growing interest in data-driven approaches to equipment reliability, the transition from fixed-interval preventive maintenance to condition-based maintenance (CBM) has gained traction in healthcare technology management. While recent studies focus on stochastic modeling techniques, the fundamental choice of degradation timescale is understudied. Most reliability models default to recorded calendar age in service logs. Potentially obscuring relevant operational variability in systems where

usage intensity varies widely across units. This study presents a comparative analysis of reliability models using calendar time and stress-related metrics to predict the risk of failure in 121 repairable medical devices. Loglinear nonhomogeneous Poisson process (NHPP) with inverse gaussian frailty models were developed for each timescale to estimate expected failures and assess predictive performance based on individualized equipment usage duration. Although calendar time model produced lower mean squared error in some equipment, it exhibited minimal prediction variance, and nearly uniform frailty estimates across the equipment in the study. In addition, it showed a tendency to regress toward the system-wide average failure rate; thus, indicating poor sensitivity to operational differences. Conversely, utilization-based models captured broader frailty distributions, higher prediction variance, and stronger correlation with observed failure patterns. These findings underscore the importance of operational stress measures as more appropriate indicators of equipment degradation and highlight how timescale selection fundamentally affect model fidelity. This empirical validation provides practical evidence to theoretical CBM frameworks and offers guidance for practitioners implementing condition-based maintenance strategies in systems with differentiated usage.

Human Decisions and Technological Interfaces: Behavioral and Operational Insights in Modern Systems

Invited Session

Behavioral Operations Management

Chair: Lai Wei, Boston College, Chestnut Hill, MA, United States

1 - The Impact of Smart Micromobility on Urban Crime: Evidence from Bike-Sharing Systems

Wen Ya Shen, Arizona State University, Tempe, AZ, United States, Zenan Zhou, Jiding Zhang, Pei-yu Chen

Urban safety remains a preeminent concern for residents, profoundly influencing their quality of life, shaping business activities, and guiding urban planning initiatives. Smart micromobility systems are emerging technology-based solutions that leverage digital platforms and infrastructure to provide short-term access to lightweight shared vehicles. However, there is ongoing debate over whether these systems enhance public safety or inadvertently contribute to crime. On the one hand, bike-sharing can improve transit accessibility and increase street activities, potentially enhancing mobility and fostering natural surveillance, which may deter crime (the crime-reducing effect). On the other hand, offenders may exploit the convenience of shared bikes and designated parking areas to facilitate criminal activities (the crime-inducing effect). This study examines the impact of smart micromobility systems on urban crime and the underlying mechanisms. Building on crime activity theories and the Land Use and Transportation (LUT) Planning framework, we conceptualize smart micromobility as an intermediary between automobility (including transit mobility) and pedestrian mobility. By increasing speed and mobility for potential targets, reducing exposure to offenders, and providing flexibility to circumvent high-risk areas, these systems may influence crime patterns. Leveraging a large-scale dataset on bike-sharing deployment in Chicago, we find that the introduction of bike-sharing has an overall crime-reducing effect. The effect is more pronounced in areas with higher automobility constraints and greater transit accessibility. Additionally, our analysis of crime patterns and neighborhood heterogeneity reveals that neighborhoods with higher reliance on smart micromobility and those experiencing opportunistic crimes benefit more significantly from the system's crime-reducing effect.

2 - Replacing What Could be Repaired: a Structural Analysis of Two-Stage Diagnostic Decisions in Managing Shared-Bike Returns

Jingxuan Geng, University of Michigan, Ann Arbor, MI, United States, Hailong Cui, Guangwen Kong

Bike-sharing platforms face significant challenges from high maintenance costs, driven by heavy usage and inefficiencies in diagnostic decision-making. Using task-level data from a leading bike-sharing platform, we develop a structural estimation model to analyze two-stage diagnostic decisions made by inspectors (stage 1) and workers (stage 2). These decisions are modeled as a strategic interaction governed by a Bayesian Nash Equilibrium (BNE). To address the computational complexity of Maximum Likelihood Estimation with BNE constraints, we employ machine learning to approximate BNE. We identify systematic overtreatment tendencies among inspectors and workers, resulting in a higher false positive rate than that under the firm's optimal decisions and thus inflating maintenance costs. Our counterfactual analyses show that higher part costs, reducing workers' piece-rate wages, adopting structured job matching, and prioritizing worker training can substantially reduce costs. Transitioning from a two-stage to a one-stage process lowers diagnostic accuracy and increases costs, although optimizing wages narrows this gap. This framework provides actionable insights for mitigating inefficiencies in multi-agent diagnostic decision systems and is generalizable to other credence goods industries, such as heavy equipment maintenance and healthcare, where diagnostic errors have significant financial, operational, and health implications.

3 - Stress Trauma and Decision Making in Humanitarian Logistics

Julie Niederhoff, Syracuse University, Syracuse, NY, United States, Llord Brooks

Experience and trauma may influence humanitarian aid workers' decision-making in inventory management and resource allocation. Through a behavioral experiment, we compare decisions across varying levels of trauma and experience to identify when decision-makers are most vulnerable to new information and potential trauma triggers. We also examine which factors (e.g., speed, quantity, cost) they prioritize during the decision-making process.

4 - Hagglng with a Bot: Human vs. LLM Negotiation in Supply Chain Contracts

Rihuan Huang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Yang Chen

Buying and selling by autonomous AI agents are no longer visions of the future. Large companies like Walmart employ AI agents in contract negotiations. However, AI-human negotiation in the supply chain context is not well understood. In this paper, we experimentally investigate the negotiation dynamics and outcomes of supply chain contract terms between human and large language model (LLM) agents. Specifically, we consider a two-tier supply chain comprising an upstream supplier and a downstream retailer. The retailer purchases units from the supplier at a per-unit wholesale price and fulfills random demand. We design an experiment in which participants act as retailers and negotiate the wholesale price and quantity with an LLM-powered supplier. Our experiment follows a 2×2 design, varying two key dimensions: 1) which party, retailer or supplier, bears the cost of unsold inventory, and 2) whether the retailer can engage in free-form conversations during negotiations. The experimental results show that, compared to human-human negotiations, suppliers represented by LLM agents achieved similar bargaining outcomes when they bear the risk of unsold inventory. In contrast, when retailers take on this risk, the LLM agents' performance depends on the negotiation format. When free-form conversations are enabled, LLM agents perform similarly to humans. However, when free-form conversations are disabled, LLM agents significantly outperform humans by increasing supplier profit through higher wholesale prices, while the channel profit remains unchanged.

5 - Large Language Models in the Workplace: a Social Perspective

Lai Wei, Boston College, Chestnut Hill, MA, United States

Powered by Large Language Models (LLMs), AI tools such as ChatGPT provide a compelling alternative to seeking guidance from human supervisors when workers face challenges in the workplace. However, adoption of these general-purpose tools in the workplace can be affected by workers' prior personal experiences with LLMs which are often influenced by workers' social attributes such as social class. This leads to unequal adoption of LLMs across different social groups. Using surveys and controlled experiments, we examine the differences in the adoption of LLMs as a substitute for interactions with human supervisors among workers from lower, middle, and upper social classes, measured through both objective and subjective dimensions. For objective social class, defined by parental education level and income, both lower- and upper-class participants are less likely to adopt LLMs compared to middle-class participants. For subjective social class, based on participants' perceptions of their parental social rank, upper-class participants also show a lower preference for LLMs than the middle class, which is driven by their lower social interaction costs when seeking guidance from supervisors. Interestingly, while lower-class participants generally exhibit similar preferences to the middle class, those with limited understanding of LLMs' capabilities, limitations, and application contexts, are less likely to adopt LLMs compared to the middle class. This paper provides important insights for workers, companies, and policymakers aiming to promote equitable and effective integration of LLMs in the workplace.

1 - Fairness Evaluations on Continuous Glucose Monitor Large Sensor Models

Junjie Luo, Johns Hopkins University, Baltimore, MD, United States

Foundation models are becoming central to AI applications in healthcare, with large sensor models (LSMs) trained on continuous glucose monitoring (CGM) data demonstrating strong predictive capabilities for diabetes management. Despite their promise, little is known about whether these models perform fairly across diverse patient populations. In this study, we conduct a fairness evaluation of CGM-based LSMs by examining performance disparities across diabetes type, age, and gender groups. Using near-future glucose prediction as the benchmark task, we uncover systematic gaps in accuracy and calibration, particularly for younger individuals, females, and those with Type 1 diabetes. These disparities raise concerns about equitable model deployment and highlight the need for fairness-aware development and evaluation practices to ensure that LSMs benefit all patient groups reliably.

2 - Using Latest Large Language Models and Prompting Strategies for Social Media Analysis: a Feasibility Study for a use Case in Healthcare

Anthony Fu, USC and DFHS, Columbia, SC, United States

Youth vaping poses serious health risks, and social media offers key insights into user behavior. This study evaluates the capacity of the latest large language models (LLMs)—including GPT-o1, GPT-o3-mini, Gemini 2.0 Flash, Gemma 2, LLaMa 3.3, R1, and Grok-2—to detect user quit intentions and cessation stages from social media posts. Model outputs were benchmarked against human annotations using various prompting strategies. Preliminary results indicate OpenAI's GPT-0.1 is the best-performing model, followed by LLAMA 3.3; the worst was Gemma 2. Although the current preliminary results demonstrate the potential of LLMs, none of them can replace human annotators.

3 - Designing An AI-Driven Clinical Decision Support Systems for Hiv Care

Dezhi Wu, University of South Carolina, Columbia, SC, United States

This work-in-progress study aims to apply "human-in-the-loop" design strategies to develop and implement an AI-driven clinical decision-support system for HIV clinicians. Driven by a large population-level HIV patient electronic health record dataset from a southeastern state in the US, we aim to use clinical machine learning models to classify different levels of HIV patient risks and provide AI-driven recommendations to HIV clinicians for more informed treatment decisions. Using a mixed-methods approach, this study will provide timely design implications for incorporating AI outputs to support HIV clinical decision support processes. More results will be updated before the INFORMS 2025 conference.

INFORMS Committee on Teaching and Learning

Chair: Yulia Vorotyntseva, University of St Thomas, Minneapolis, MN, United States

1 - Teaching Retail Assortment Strategy: the Assortment Planning Game Simulation

Yulia Vorotyntseva, University of St Thomas, Minneapolis, MN, United States

This work presents a web-based simulation in which learners engage in retail assortment planning — that is, selecting which products to offer in a given category. Market demand is modeled using the Multinomial Logit (MNL) consumer choice model -- a widely used framework in assortment optimization -- making the simulation a practical tool for introducing this model to learners. The simulation is implemented on the SoPHIELabs Classroom platform.

Through this interactive game, learners explore the trade-offs between expanding market share by offering a greater variety of products and reducing operational costs through variability pooling. It enables them to experientially grasp and internalize key concepts such as the cost implications of increased product variety (including higher inventory and overhead costs), and the phenomenon of product cannibalization (where additional variety may not significantly increase revenue).

By engaging with this simulation, learners connect theoretical models with practical decision-making skills essential for managing retail operations.

2 - Continuous Improvement for Impact: Case Development, Industry Collaboration, and Student Engagement

Xiao Zhang, Saint Louis University, Saint Louis, MO, United States, Varun Gupta

This session aims to share practical insights and strategies for developing meaningful business case studies, fostering industry research partnerships, and engaging students in impactful ways. Using multiple case studies as examples, we will guide participants through case development processes, publishing options, and collaboration opportunities.

3 - Contributing to a More Sustainable World One Student at a Time for over a Decade

Tarkan Tan, University of Zurich, Zurich, Switzerland

In 2013, we developed a course on sustainable supply chains that introduces key concepts and decision-making challenges in environmentally and socially responsible operations and supply chains, well before the topic became popular in business education. A core element of the course is a real-life project carried out by student teams in collaboration with companies or organizations. This challenge-based learning approach allows students to apply what they learn to practical sustainability issues. The course also adopts a flip-the-classroom format: students present selected topics and project progress to their peers, receiving structured feedback and contributing to one another's learning. Peer assessment is used as part of the grading process to encourage active engagement and critical reflection. To support the course, we co-edited a textbook -now in its second edition- that combines research-based insights with practical relevance. While originally designed for master's students, the course has been adapted to bachelor's, PhD, and executive education settings by adjusting content depth, project expectations, and delivery style.

This talk draws on over a decade of experience in designing and delivering the course. We will share reflections on its evolution, how it can be tailored to different audiences, and how it has helped students bring sustainability thinking into their careers, some becoming ambassadors for responsible business practices, others working directly on sustainable operations after graduation.

4 - Compete OR Collaborate? Experimental Insights on Team-Based Learning in Predictive Analytics Education

Nicolas Nunez, Centrum PUCP, Lima, Peru

Our study explores how team configuration—collaborative vs. competitive—affects student learning outcomes in a predictive analytics course. Students were assigned to work in teams under two distinct pedagogical conditions using a controlled experimental design within a graduate-level classroom. One emphasized cooperation, the other gamified competition, while both followed the same course structure and tasks. Preliminary results suggest that while competitive settings may boost engagement and speed, collaborative teams tend to outperform in depth of understanding and model interpretation. This work contributes to designing more effective data science education strategies by aligning pedagogical methods with cognitive and behavioral outcomes.

AI and Machine Learning for Modeling, Prediction, and Decision Making in Healthcare

Invited Session

Data Mining

Chair: Jianxin Xie, University of Virginia, Charlottesville, VA, United States

Co-Chair: Xin Zan, University of Iowa, Coralville, IA, United States

1 - Quantile-Based Monitoring of Profiles with Generally Distributed Responses

Xin Li, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Jian Li, Kai Wang

Conventional profile monitoring employs linear regression for modeling, which investigates how the mean of the response depends on explanatory variables. This, however, renders such methods highly constrained by the assumption of normally distributed responses. In contrast, quantiles that are derived from the concepts of sorting and ranking make no assumptions about the response distribution. We employ quantile regression to characterize the functional relationship between the response quantile and explanatory variables. And by jointly monitoring multiple different quantile regression coefficients, we are in a position to monitor the relationship between the entire distribution of the response and explanatory variables. Furthermore, to address the computational complexity associated with parameter estimation in quantile regression, a Hotelling's T^2 type monitoring statistic is proposed by leveraging the Bahadur representation of conditional quantiles and their asymptotic distribution. Extensive simulations have demonstrated the superior performance of the proposed method across various types of response distributions.

2 - Transformers with Koopman-Enhanced Graph Convolutional Network for Spatiotemporal Dynamics Forecasting

Zekai Wang, Fairfield University, Fairfield, CT, United States, Bing Yao

Spatiotemporal forecasting is essential for understanding and controlling dynamic systems in fields ranging from transportation to biomedicine. However, modeling these processes remains challenging due to irregular spatial geometries, nonlinear dynamics, and long-range temporal dependencies. In this study, we propose a novel two-stage predictive framework, Transformer with Koopman-enhanced Graph Convolutional Network (T-KGCN), to address these challenges. Our approach integrates graph convolutional networks (GCNs) to model complex spatial structures, Koopman operator theory to embed the system's state into a latent space with approximately linear dynamics, and a transformer to capture long-range temporal dependencies. Our contributions include: (1) a unified architecture combining GCN, Koopman embedding, and transformers; (2) a principled approach to model nonlinear dynamics with latent linear evolution; and (3) enhanced performance in long-range forecasting. While demonstrated in a cardiac setting, our framework is broadly applicable to diverse spatiotemporal prediction tasks.

3 - A Self-Supervised Self-Corrected Masked Autoencoder with Brain Tumor Applications

Hairong Wang, Georgia Institute of Technology, Atlanta, GA, United States

Intra-tumoral heterogeneity poses a significant challenge for glioblastoma (GBM) diagnosis and treatment. Histopathological and molecular analyses are limited by surgical sampling, highlighting the need for non-invasive methods to map these alterations across the entire tumor. Limited biopsy samples hurdle the power of artificial intelligence (AI) models, and patient heterogeneity further complicates the task with small sample sizes. We propose a self-supervised framework using abundant MRI data beyond biopsy regions to enhance AI model robustness and generalizability. Our framework consists of two steps. First, we train generative models in a self-supervised manner to translate each patient's image into a synthetic "healthy" version, under the hypothetical condition that the patient does not have the tumor, through vision transformer based masked autoencoder. This step captures the inherent differences in patients' brains. Second, we classify regional biomarkers such as hallmark genes, tissue states, and cell types based on both real and generated MRI. Our study uses 283 image-localized biopsies with corresponding T1Gd and T2 MRI data from 67 GBM patients. Our model achieved satisfying classification accuracy, surpassing state-of-the-art methods. Additionally, we generated biomarker prediction maps across entire tumors, providing a quantitative assessment of intra-tumoral heterogeneity in histopathological and molecular alterations. These results highlight the emerging role of AI in Precision Medicine and its potential for broader applications in GBM diagnosis and treatment.

4 - Heterogeneous Domain Adaptation for Survival Analysis

Dan Ni Lin, Texas Tech University, Lubbock, TX, United States

Artificial Intelligence (AI) technologies have advanced clinical risk prediction by effectively handling complex data and uncovering insights from large medical datasets. However, small medical centers with limited and unlabeled patient data face challenges in adopting these tools, which rely on large, labeled datasets for development. Domain adaptation technique adapts models developed from larger centers or national registries to smaller healthcare settings by leveraging the knowledge and features learned from a large dataset to enhance generalization. However, differences in feature distribution and dimensionality between datasets pose challenges for existing domain adaptation methods. This study introduces a heterogeneous domain adaptation (HDA) method which is a semi-supervised approach to adapt neural network Cox Proportional Hazard models derived from large source datasets to smaller target datasets. The method integrates dictionary learning and adversarial training to address structural and statistical differences between source and target domains.

Data Mining for Education and Learning Analytics

Invited Session

Data Mining

Chair: Ishita Malhotra, 75204

1 - Course Recommendation Using Domain-Based Cluster Knowledge and Matrix Factorization with Generative Ai-Driven Synthetic Data Augmentation

Satyam Mittal, California State University, Fresno, Dallas, CA, United States, Ishita Malhotra

We propose an enhanced course recommendation system combining domain-based clustering and matrix factorization, augmented with Generative AI for synthetic data curation. Unlike prior work that relies solely on historical enrollment data, our approach uses Generative AI to generate school-specific synthetic student-course interactions, tailored to academic domains and performance trends. This enriched data enables robust training even for institutions with sparse records, improving personalization, fairness, and privacy in educational recommendations.

2 - Tracing Epistemic Influence Through Semantic Embedding Spaces

Onur Seref, Virginia Tech, Blacksburg, VA, United States

This study explores how fields of knowledge evolve by modeling changes in their underlying semantic structures over time. Using a large corpus of research abstracts from top Information Systems journals, we construct a temporally layered embedding space to investigate how influential contributions relate to local shifts in meaning, including conceptual drift, turbulence, and re-centering. We combine entropy-based field metrics, clustering coherence, and citation-informed dynamics to detect signals of epistemic movement across time and context. This work offers a preliminary step toward AI-assisted field analysis, where semantic embeddings can help characterize, visualize, and ultimately forecast how knowledge systems evolve, reposition themselves, or reorganize across conceptual or institutional boundaries.

3 - Feddes: Graph-Based Dynamic Ensemble Selection for Personalized Federated Learning

Brianna Mueller, University of Iowa, Iowa City, IA, United States

Dynamic ensemble selection (DES) methods aim to enhance predictive performance by identifying a subset of classifiers most suitable for each individual data sample. These methods often assume that samples in close proximity exhibit similar classification behavior and therefore estimate classifier competence within a local

neighborhood of the query. However, sensitivity to local structure can limit robustness and applicability, as traditional DES techniques may overlook complex interdependencies between classifiers and data samples. To address this, we propose a novel graph-based DES framework that leverages graph neural networks (GNNs) to learn sample-specific ensemble weights. Our approach is particularly motivated by the challenges of personalized federated learning (pFL), where clients possess diverse local data distributions and benefit from tailored model selection. In the proposed method, each client constructs a heterogeneous graph in which nodes represent local data samples and classifiers shared by other participants in the network, while edges encode relationships such as classifier confidence, sample similarity in the decision space, and classifier diversity. During inference, test samples are inductively inserted into the graph, allowing the model to leverage learned relationships to output classifier weights for a personalized ensemble prediction. We evaluate our method on the eICU Collaborative Research Database, treating each hospital as a federated client and each locally trained model as a candidate classifier. Our results demonstrate that modeling sample-classifier relationships through a graph-based framework can enhance generalization for personalized federated learning.

4 - Optimization-Based Dimensionality Reduction

Deniz Yoltay, Ozyegin University, Istanbul, Turkey, Erhun Kundakcioglu

Dimensionality reduction is a fundamental task in data visualization, aiming to represent high-dimensional data in a low-dimensional space while preserving essential structural relationships. This study introduces a novel optimization-based framework that formulates the problem using a set of distance-preserving constraints. The proposed approach aims to capture key relational patterns among data instances and maintain geometric fidelity in the resulting low-dimensional embedding.

Healthcare Innovation: Business Models and Technology

Invited Session

Technology, Innovation Management and Entrepreneurship

Chair: Ersin Korpeoglu, UCL School of Management, London, United Kingdom

Co-Chair: Yupu Sun, University College London, London, United Kingdom

1 - Managing Prediction Errors in Healthcare Capitation: a Two-Stage Risk Adjustment Approach

Zhaowei She, Lee Kong Chian School of Business, Singapore Management University, Singapore, Singapore, Kanix Wang, Yajing Chen

This study tackles a fundamental challenge in capitation-based healthcare payment: prediction errors in risk adjustment that result in systematic underpayment for some patients and overpayment for others. These errors compromise both insurer budget neutrality and the actuarial soundness of the system. Motivated by a recent reform proposal from the Centers for Medicare & Medicaid Services (CMS), we develop a novel two-stage estimation algorithm for the HHS-HCC risk adjustment model. Our method directly targets and corrects persistent prediction errors—especially those that incentivize patient selection at the extensive margin. Using administrative claims data from the ACA Marketplace, we empirically show that our approach substantially improves predictive accuracy and achieves near-perfect actuarial equivalence across patient risk groups.

2 - Doctor + AI: Rethinking Medical Communication for the Digital Age

Mehmet Ayyaci, The University of Texas at Dallas, Richardson, TX, United States, Dicle Yagmur Ozdemir, Alejandro Zentner

As AI tools increasingly mediate healthcare communication, an open question is how best to integrate them into physician workflows. While AI-generated responses are often perceived as more helpful, clear, and respectful than those of physicians, concerns remain about misinformation and loss of human oversight. This study evaluates whether AI-physicians collaboration can improve communication without sacrificing clinical credibility. To do so, we conducted an experiment where both laypeople and medical professionals evaluated medical responses across four conditions: (1) physician-only, (2) AI-only, (3) AI-refined physician responses, and (4) AI-physician combined responses. In refinement, AI improves tone without adding medical content; in combination, AI merges its response with a physician's, unseen. Our results show that both lay and expert evaluators prefer AI-only and AI-physician collaboration responses over physician-only ones. Laypeople show a stronger preference for AI, but AI-physician collaborations, particularly refinement, narrow this preference gap, aligning lay evaluations more closely with expert judgments. These findings suggest that hybrid communication models can enhance medical communication while maintaining expert oversight. Rather than replacing physicians, AI can be used to augment their communication, offering a pathway for more effective, trustworthy, and scalable doctor-patient interactions.

3 - The Role of Hospital Rcm Systems in Mitigating Personal Bankruptcy Filings

Shuhua Wu, Temple University, Philadelphia, PA, United States, Chenzhang Bao, Sezgin Ayabakan, Min-Seok Pang

Medical debt has become a challenging concern in the US. Its overall amount has climbed to \$220 billion nationwide, and nearly 41% of the adults currently owe medical debts, especially those with high medical needs and who belong to disadvantaged groups. Consequently, medical debts have become one of the leading causes for individual bankruptcy filings. This study investigates how revenue cycle management (RCM) systems adopted by hospitals affect personal bankruptcy filings. By improving information completeness and accuracy, smoothing information flow, and streamlining the billing and collection process, RCM systems can decrease the uncertainty of revenue collection and improve the providers' financial stability. This allows hospitals to find alternative financial protection for near-poor patients, decreasing their propensity to file for bankruptcy. On the other hand, the improved efficiency in the billing and collection processes could also exacerbate bankruptcy filings as near-poor patients without insurances usually face larger medical bills than insured patients. We draw on organizational information processing theory to understand why hospitals choose to adopt RCM systems and how it affects individual bankruptcy filings. We construct a panel dataset from multiple sources and employed two-way fixed-effect models with instrumental variables to address the endogeneity concerns. Our analysis shows that the average RCM system adoption rate by hospitals in a county is negatively associated with bankruptcy filings, especially when a state expands the Medicaid coverage. This study contributes to the literature that examines the societal impacts of information systems in healthcare settings and provides ample implications for practitioners and policymakers.

4 - Does Virtual Take Longer? An Empirical Investigation of Service Time in Telemental Health

Yupu Sun, University College London, London, United Kingdom, Ersin Korpeoglu

Telemedicine visits, in the form of synchronous virtual interactions between patients and providers, have witnessed a significant surge during the COVID-19 pandemic. In this study, we employ an instrumental variable model to examine the causal relationship between the form of psychology treatments (virtual or in person) and the service time of these treatments. Using visit-level patient data for psychology visits in the United States (US), we find that telemedicine use significantly increases cumulative service time and visit frequency per month. Depending on which of these effects dominates, the duration of single visits can decrease or increase when using telemedicine. Specifically, we find that telemedicine use decreases the duration of single visits for private insurance patients while increasing it for Medicare insurance patients. Furthermore, we find that telemedicine use leads to a larger increase in per-visit service time for retired patients than for non-retired ones. These results show that serving Medicare patients, especially retired ones, with telemedicine can substantially increase the burden on healthcare providers. Our study contributes to a better understanding of how telemedicine affects the efficiency of care delivery in mental health.

5 - The Rise of Subscription-Based Healthcare: Strategic Impacts on Patients and Providers

Ozden Cakici, American University, Washington, DC, United States, Hessam Bavafa

Subscription-based healthcare systems (SBHS) offer patients unlimited access to primary care for a fixed fee, e.g., Amazon One Medical, Blueberry Pediatrics. This revenue model challenges traditional fee-for-service (FFS) models that bill per visit. While SBHS are designed to reduce administrative burden and improve access, particularly for low-acuity patients, their expansion raises concerns about equity and market efficiency.

We develop an analytical model to examine competition between SBHS and FFS providers, capturing patient decisions based on illness severity, costs, and wait times. SBHS attract noncritical cases, relieving FFS congestion but introducing their own capacity constraints. Providers must set subscription fees and define the maximum severity they can manage to maintain profitability and service quality.

Our analysis shows that SBHS alter the structure of congestion rather than eliminating it. Equilibrium outcomes depend on the acuity distribution of the population and market conditions. Financial sustainability may require excluding certain patient groups, and even when both high- and low-acuity patients are included, welfare gains are unevenly distributed.

These findings challenge the assumption that SBHS universally improve access and equity. We offer guidance for healthcare managers and policymakers on integrating SBHS to enhance system performance while mitigating disparities.

1 - Poster - Automated Analysis of Experiments Using Hierarchical Garrote

Wei-Yang Yu, Georgia Institute of Technology, Atlanta, GA, United States

In this work, we propose an automatic method for the analysis of experiments that incorporates hierarchical relationships between the experimental variables. We use a modified version of the nonnegative garrote method for variable selection which can incorporate hierarchical relationships. The nonnegative garrote method requires a good initial estimate of the regression parameters for it to work well. To obtain the initial estimate, we use generalized ridge regression with the ridge parameters estimated from a Gaussian process prior placed on the underlying input-output relationship. The proposed method, called HiGarrote, is fast, easy to use, and requires no manual tuning. Analysis of several real experiments are presented to demonstrate its benefits over the existing methods.

2 - Poster - Generating Synthetic Aia Images from Historical Ground-Based Observations: a Diffusion Model Approach for Extended Coronal Hole Analysis

Marco Marena, New Jersey Institute of Technology, Newark, NJ, United States

Accurate and continuous observations of the Sun's extreme ultraviolet (EUV) emissions are critical for understanding solar dynamics and monitoring solar activity. However, EUV observations availability is limited to the past ~30 years, restricting our ability to study long-term solar corona. This study aims to reconstruct a historical dataset of synthetic AIA 193 Å and 304 Å — solar corona and chromosphere — using historical ground-based chromospheric observations in H α and CaII K, available for over a century. To generate AIA observations before 2010, we propose to use a novel deep learning methodology, the Diffusion Model Translation (DMT) framework, built on a fine-tuned Denoising Diffusion Probabilistic Models (DDPM), and a Two-Stream Image-to-Image Translation (TSIT) network as a translator between the noising and denoising processes, to bypass the diffusion steps and accelerate training. We used H α and CaII K lines from Kanzelhöhe Solar Observatory (KSO) spanning from 2011 to 2024, and AIA 193 Å and 304 Å from the Solar Dynamic Observatory (SDO). For the independent test set, the model shows a high full-disk correlation (CC = 0.942) and achieves a Dice coefficient of 0.893 for coronal holes. Particularly, the high Dice coefficient highlight the model's effectiveness in identifying and delineating coronal holes, sources of high-speed solar wind streams. By providing reliable synthetic EUV imagery for historical periods lacking direct observations, our methodology facilitates deeper analyses of coronal hole evolution, as well as long-term solar activity trends.

4 - Poster - Hybrid Diffusion-Transformer Approach for Multivariate TIME Series Imputation

Ramiro Valdes-Jara, University of Miami, Miami, FL, United States

Many real-world spatiotemporal data contain gaps when sensors fail or communication issues occur. Spatiotemporal imputation focuses on reconstructing missing values by leveraging patterns that repeat across both space and time. In recent years, deep learning approaches have emerged as powerful tools for spatiotemporal imputation, consistently outperforming traditional methods. Although recent work has improved performance, two persistent gaps remain: (i) diffusion-based methods model uncertainty well but are confined to local temporal contexts and fixed spatial graphs, and (ii) transformer-style architectures capture long-range dependencies yet handle missing-value uncertainty only heuristically. We propose a hybrid method that addresses the limitations of each individual approach, namely, the Hybrid Diffusion Transformer (HDT). The diffusion component treats each time series as a noisy signal that can be gradually reconstructed, giving the model a way to handle uncertainty and to learn to remove the noise step by step. The transformer component adds an attention mechanism, enabling the model to simultaneously learn spatial correlations and non-stationary temporal patterns. During inference, the reverse diffusion trajectory, guided by the transformer component, iteratively reconstructs missing values while producing confidence intervals. By integrating these parts in a single, end-to-end framework, our approach offers a robust and interpretable solution for multivariate time series imputation. We evaluate HDT on varied traffic and physiological datasets chosen to test long-range and spatiotemporal dependencies. Model validation covers a range of missing-value patterns and compares mean absolute error (MAE) and root mean square error (RMSE) against state-of-the-art baseline methods.

7 - Deep Belief Enabled Coupled High-Order State Transition Mode

Vipul Bansal, University of Wisconsin Madison, Madison, WI, United States

We propose a Deep Belief Updater (DBU) Model to address the challenge of modeling complex temporal dependencies in Coupled Higher-Order Hidden Semi-Markov Chains. These models extend Higher-Order Hidden Semi-Markov Chains by incorporating temporal dependencies among hidden states across multiple interdependent chains. Replacing underlying temporal dynamics with neural networks is computationally intensive, as it requires updating the state history at each time instance for each chain, based on the history of all the chains. To overcome this, we find that forward-state probabilities, the probabilities of being in a given state at a time instance based on the history of observations, can be expressed as a function of the Stage I belief states derived from individual observations. Stage I belief state is the likelihood of the system being in a certain state based solely on the current observation, without considering the influence of previous or future observations. The DBU model directly estimates these forward-state probabilities using Stage I belief. These probabilities are used to construct a likelihood function to train the model. By enabling the direct estimation of forward-state probabilities, the DBU model effectively captures the intricate transition dynamics of systems with interdependent chains.

8 - Airu-Wrf-Ens: A Multivariate, Time-Dependent Ensemble Method for Space-Time Wind Energy Forecasting

Jiaxiang Ji, Rutgers University, New Brunswick, NJ, United States

The reliable and cost-effective operation of offshore wind farms depends on accurate wind speed and power predictions across a range of forecast horizons. Yet, forecasting models typically perform well at a narrow range of look-ahead horizons: methods tailored for short-term forecasts (e.g., one or two hours ahead) rapidly degrade in accuracy as the forecast horizon extends (e.g., day-ahead), and vice versa. Using separate models for different forecast horizons is a possible solution, but would result in temporally discontinuous forecasts, limiting their value to wind farm and power system operations under uncertainty. In response, we propose an ensemble method which combines the outputs of multiple forecast models, each designed for a specific range of look-ahead horizons, thereby ensuring a temporally continuous forecast across the full forecast horizon. The proposed ensemble method preserves the temporal- and cross-correlations of individual ensemble members, introduces time-varying weighing to adapt to each model's degrading performance over time, and fully characterizes the predictive distribution of the ensemble output considering temporal- and cross-covariance information, enabling calibrated uncertainty quantification and decision support under uncertainty. Tested on offshore wind data from the Northeastern U.S.-a geographical region with significant offshore wind energy potential-the proposed approach achieves promising improvements, in terms of both point and probabilistic forecast evaluation metrics, relative to a representative set of forecasting methods.

15 - Poster - Tensor-Efficient High-Dimensional Q-Learning

Junyi Wu, University of Washington, Seattle, WA, United States

High-dimensional reinforcement learning faces challenges with complex calculations and low sample efficiency in large state-action spaces. Q-learning algorithms struggle particularly with the curse of dimensionality, where the number of state-action pairs grows exponentially with problem size. Current solutions include function approximation methods and neural network-based approaches like Deep Q-Networks, but these often suffer from instability and require extensive hyperparameter tuning. We propose Tensor-Efficient Q-Learning (TEQL), which applies low-rank tensor decomposition via block coordinate descent on discretized state-action spaces, incorporating novel exploration and regularization mechanisms. The key innovation is an exploration strategy that combines approximation error with visit count-based upper confidence bound to prioritize actions with high uncertainty, avoiding wasteful random exploration. Additionally, we incorporate a frequency-based penalty term in the objective function to encourage exploration of less-visited state-action pairs and reduce overfitting to frequently visited regions. Empirical results on large discrete control tasks demonstrate that TEQL outperforms conventional matrix-based methods and deep RL approaches in both sample efficiency and total rewards, making it suitable for resource-constrained applications, such as space and healthcare where sampling costs are high.

18 - Poster - Deepoformer: Deep Operator Learning with Domain-Informed Features for Fatigue Life Prediction

Chenyang Li, New Jersey Institute of Technology, Fanwood, NJ, United States

Fatigue life characterizes the duration a material can function before failure under specific environmental conditions, and is traditionally assessed using stress-life (S-N) curves. While machine learning and deep learning offer promising results for fatigue life prediction, they face the overfitting challenge because of the small size of fatigue experimental data in specific materials. To address this challenge, we propose, DeepOFormer, by formulating S-N curve prediction as an operator learning problem. DeepOFormer improves the deep operator learning framework with a Transformer-based encoder and a mean L2 relative error loss function. We also consider Stüssi, Weibull, and Pascual and Meeker (PM) features as domain-informed features. These features are motivated by empirical fatigue models. To evaluate the performance of our DeepOFormer, we compare it with different deep learning models and XGBoost on a dataset with 54 S-N curves of aluminum alloys. With seven different aluminum alloys selected for testing, our DeepOFormer achieves an R2 of 0.9515, a mean absolute error of 0.2080, and a mean relative error of 0.5077, significantly outperforming state-of-the-art deep/machine learning methods including DeepONet, TabTransformer, and XGBoost, etc. The results highlight that our DeepOFormer integrating with domain-informed features substantially improves prediction accuracy and generalization capabilities for fatigue life prediction in aluminum alloys.

19 - Poster - Conformalized Decision Risk Assessment

Wenbin Zhou, Carnegie Mellon University, Pittsburgh, PA, United States

High-stakes decisions in domains such as healthcare, energy, and public policy are often made by human experts using domain knowledge and heuristics, yet are increasingly supported by predictive and optimization-based tools. A dominant approach in operations research is the predict-then-optimize paradigm, where a predictive model estimates uncertain inputs, and an optimization model recommends a decision. However, this approach often lacks interpretability and can fail under distributional uncertainty - particularly when the outcome distribution is multi-modal or complex - leading to brittle or misleading decisions. In this paper, we introduce CREDO, a novel framework that quantifies, for any candidate decision, a distribution-free upper bound on the probability that it is suboptimal. By combining inverse optimization geometry with conformal prediction and generative modeling, CREDO produces finite-sample risk certificates that are both statistically rigorous and practically interpretable. This framework enables human decision-makers to audit and validate their own decisions under uncertainty, bridging the gap between algorithmic tools and real-world judgment.

22 - Poster - Monitoring the Covariance of Multichannel Profiles

Davide Forcina, University of Naples Federico II, Naples, Italy

Modern industrial systems continuously produce multichannel profile data for real-time process monitoring and fault diagnosis. Although most existing techniques focus on detecting shifts in the process mean, changes in the covariance structure are equally critical, as the process behavior depends on the interactions among multiple variables.

In this work, we use functional graphical models to capture conditional dependencies in multichannel profile data, where high dimensionality and sparsity exacerbate model estimation and interpretability.

The proposed approach employs penalized likelihood ratio tests with adaptive penalty levels to detect various types of covariance changes.

Additionally, a diagnostic procedure based on change-point detection identifies which relationships have shifted. Extensive simulations and a real-world application involving multi-channel temperature profile monitoring confirm the proposed method's effectiveness over competing methods already appearing in the literature.

24 - Accelerated Brain Aging in Alzheimer's Disease with Lewy Body Co-Pathology: Insights from Brain MRI and Alpha-Synuclein SAAs

Babak Ahmadi, University of Florida, Gainesville, FL, United States

Alzheimer's disease (AD) and Lewy body (LB) pathology often occur together, but only recently has LB pathology become detectable in living patients via cerebrospinal fluid (CSF) α -synuclein seed amplification assays (SAA), enabling investigation of its joint impact with AD on neurodegeneration. We trained a deep learning brain age model on multi-cohort MRI scans from 4,355 cognitively unimpaired adults and applied it to 803 cognitively impaired participants. Individuals were assigned to four groups based on AD status ($p\text{-tau}_{181}/A\beta_{42}$) and LB status (SAA). The co-pathology group (AD+LB+) showed the greatest brain age acceleration. Model saliency maps indicated more widespread saliencies, which was corroborated by faster longitudinal atrophy across multiple regions and parallel cognitive decline. Together, these results suggest that LB pathology amplifies AD-related neurodegeneration and support the use of combined biomarker testing and targeted interventions for patients with co-existing AD and LB pathology.

25 - Poster - Adaptive Robust Optimization with Data-Driven Uncertainty for Enhancing Distribution System Resilience

Shuyi Chen, Carnegie Mellon University, Pittsburgh, PA, United States

Extreme weather events are placing growing strain on electric power systems, exposing the limitations of purely reactive responses and prompting the need for proactive resilience planning. However, existing approaches often rely on simplified uncertainty models and decouple proactive and reactive decisions, overlooking their critical interdependence. This paper proposes a novel tri-level optimization framework that integrates proactive infrastructure investment, adversarial modeling of spatio-temporal disruptions, and adaptive reactive response. We construct high-probability, distribution-free uncertainty sets using conformal prediction to capture complex and data-scarce outage patterns. To solve the resulting nested decision problem, we derive a bi-level reformulation via strong duality and develop a scalable Benders decomposition algorithm. Experiments on both real and synthetic data demonstrate that our approach consistently outperforms conventional robust and two-stage methods, achieving lower worst-case losses and more efficient resource allocation, especially under tight operational constraints and large-scale uncertainty.

28 - Poster - Rampseg: a Robust Calibration-Free Image Segmentation Method for Reliable Melt Pool Analysis in Laser Powder Bed Fusion

Nazmul Hasan, University of Arizona, Tucson, AZ, United States

Coaxial monitoring of the melt pool, the molten region formed during laser exposure in laser powder bed fusion (LPBF) additive manufacturing, is critical for ensuring part quality, as its morphology reflects process stability. However, melt pool images are inherently stochastic due to variations in processing conditions, imaging setups, and transient phenomena such as spatter. The impact of this variability on segmentation accuracy has not been thoroughly explored in the literature, resulting in a critical gap in the development of robust methods. As a result, existing segmentation techniques often lack the generalizability and reliability needed to perform consistently across diverse conditions. In response, we propose RAMPSeg (Robust Adaptive Melt Pool Segmentation) algorithm, an intensity-agnostic and calibration-free edge-detection-based method that introduces three key innovations: (i) data-driven optimization of edge detection parameters, (ii) a quantitative segmentation review using an edge-to-area ratio to guide refinement, and (iii) an adaptive smoothing feedback loop. Unlike prior methods, RAMPSeg avoids arbitrarily selected parameters, over- or under-segmentation, and fixed heuristics. Instead, it achieves self-regulating segmentation that dynamically balances noise reduction and boundary preservation across diverse imaging conditions, enabling more generalizable melt pool analysis. We comprehensively evaluated its effectiveness using three distinct datasets encompassing diverse process conditions, materials, machines, and imaging systems. This unprecedented evaluation demonstrated consistently high segmentation accuracy (~90%) against expert-annotated ground truth, significantly outperforming conventional thresholding, Otsu's method, and state-of-the-art zero-shot vision transformer models (SAM and CLIPSeg). RAMPSeg enables reliable melt pool segmentation under dynamic conditions, supporting accurate anomaly detection, process optimization, and quality assurance.

29 - Poster - Topology-Aware Conformal Prediction for Stream Networks

Jifan Zhang, Northwestern University, Evanston, IL, United States

Stream networks, a unique class of spatiotemporal graphs, exhibit complex directional flow constraints and evolving dependencies, making uncertainty quantification a critical yet challenging task. Traditional conformal prediction methods struggle in this setting due to the need for joint predictions across multiple interdependent locations and the intricate spatio-temporal dependencies inherent in stream networks. Existing approaches either neglect dependencies, leading to overly conservative predictions, or rely solely on data-driven estimations, failing to capture the rich topological structure of the network. To address these challenges, we propose Spatio-Temporal Adaptive Conformal Inference (STACI), a novel framework that integrates network topology and temporal dynamics into the conformal prediction framework. STACI introduces a topology-aware nonconformity score that respects directional flow constraints and dynamically adjusts prediction sets to account for temporal distributional shifts. We provide theoretical guarantees on the validity of our approach and demonstrate its superior performance on both synthetic and real-world datasets. Our results show that STACI effectively balances prediction efficiency and coverage, outperforming existing conformal prediction methods for stream networks.

30 - Efficient Derivative Computation in Physics-Informed Neural Networks Without Autodiff

Soumik Sarkar, Florida State University, Tallahassee, FL, United States

no abstract

31 - Poster - Theoretical Analysis for Optimal Design of An Online Monitoring and Sampling Scheme Under Partial Observations**Dongmin Li, Georgia Institute of Technology, Atlanta, GA, United States**

High-dimensional streaming data is collected in a wide range of applications, such as advanced manufacturing and environmental monitoring. However, practical constraints such as limited sensors, transmission bandwidth, and data storage capacity, restrict the ability to observe all variables of interest at each data collection time for online monitoring. Although adaptive sampling strategies have been proposed that are integrated into monitoring schemes for quick anomaly detection, the theoretical analysis of detection performance for optimal design in practical settings has not been addressed. While few studies provide upper bounds for the average detection delay, the bounds are either asymptotic or excessively large, failing to provide valuable guidance on parameter design for optimal detection performance in practical applications. To fill this gap, we propose a holistic monitoring-based probabilistic sampling framework under partial observations and theoretically analyze the average detection delay to inform optimal design. By leveraging the sampling probabilities of variables, which are explicit functions of monitoring statistics, we derive formulas for practical average detection delay as functions of design parameters and system settings, such as the number of sampled variables and total variables in the system. These theoretical results enable the determination of the number of sampled variables and parameter settings to achieve optimal detection performance while satisfying false alarm requirements and considering practical resource constraints such as sampling costs. Simulation studies across various parameters and system settings validate the effectiveness of the theoretical results, demonstrating significant practical value for optimal performance design.

1 - Reinforcement Learning in MDPs with Information-Ordered Policies**Zhongjun Zhang, Northwestern University, Evanston, IL, United States**

We introduce an epoch-based reinforcement learning algorithm for Markov Decision Processes in the infinite-horizon average cost setting leveraging a partial order over a policy class parameterized by $\in \Theta$. θ^* whenever data collected under can counterfactually estimate the performance of θ^* , without extra environment interactions. This yields a $(\sqrt{\log(|\Theta|)})$ regret where w is the order's width. We demonstrate our approach on several case studies in operations research, providing new theoretical guarantees and numerical validation.

2 - Robust Paths: Geometry and Computation**Hao Hao, Carnegie Mellon University, Pittsburgh, PA, United States**

Applying robust optimization requires calibrating the uncertainty set. In practice, this calibration is expensive and typically done by solving the robust counterpart multiple times under different uncertainty sets. We study the robust path: a set of robust solutions under varying the uncertainty set's parameters. Our central insight: the robust path can be algorithmically characterized by the trajectory of a proximal point method (PPM) applied to the nominal problem. Our results imply that a single run of an optimization algorithm on the nominal problem can approximate the entire robust path.

3 - A Stochastic Growth Model for Online Platform**Farbod Ekbatani, Chicago Booth School of Business, Chicago, IL, United States**

We investigate the growth trajectory of online platforms operating as market makers in two-sided matching markets. Their expansion, often referred to as the “chicken-and-egg dilemma”, poses an inherent challenge; service providers find value in joining the platform due to the presence of customers, while customers are drawn to the platform by the availability of diverse services. Under mild conditions, we characterize the optimal server compensation schemes the platform should adopt and show that the platform must account for each server's seniority, measured by the time at which they joined.

4 - Managing Tail Risk in Online Learning: Efficiency, Safety, Robustness, and Relationship to Alphago**Feng Zhu, MIT, Cambridge, MA, United States**

This work provides a detailed characterization of regret distribution in online learning, and demonstrates how managing regret tail risk leads to extra benefits on policy robustness. In Part I, we design policies that enjoy both optimal regret expectation and light-tailed regret distribution. In Part II, we study the optimal trade-off between expectation and tail risk for regret distribution. Notably, we find that our policy design coincides with what was adopted in AlphaGo MCTS, providing high-level insights to the success of their engineered solution in complex decision-making environments.

Multi-criteria Decision Aiding: Methods and Applications

Invited Session

Multi Criteria Decision Making

Chair: Milosz Kadzinski, Poznan University of Technology, Poznan, Poland

Co-Chair: Milosz Kadzinski, Poznan University of Technology, Poznan, Poland

1 - Multiple Criteria Decision Aiding Using a Rule Preference Model in Seven-Valued Logic**Roman Slowinski, Poznań University of Technology, Poznań, Poland, Salvatore Greco**

One of the challenges in Multiple Criteria Decision Aiding (MCDA) is ensuring the explainability and transparency of preference modeling. It is acknowledged that "if... then..." decision rules meet this requirement better than utility or outranking models. Moreover, rules induced from preference data using the Dominance-based Rough Set Approach (DRSA), when integrated with the recently proposed seven-valued logic, allow for distinguishing vagueness due to imprecision from that caused by inconsistency in the preference data. DRSA with seven-valued logic approach effectively addresses typical MCDA challenges, such as uncertainty, imprecision, and indeterminacy.

2 - Data Elicited from Pairwise Comparisons for Decision Making May Not be as Trustworthy as Believed**Evangelos Triantaphyllou, Louisiana State University, Baton Rouge, LA, United States, Juri Yanase**

A challenging issue in decision making is how to elicit qualitative / subjective data from decision makers. Using pairwise comparisons is a widely accepted approach as it offers an intuitive and appealing way towards this problem. The proliferation of this approach is mostly attributed to Saaty who proposed it as part of his AHP framework to decision making. Although many users may feel comfortable with this approach, a lingering question is whether one should rely on the derived results when pairwise comparisons are used. Thus, a critical question is how to validate it. We offer a testing approach that is based on a deliberately very optimistic (utopic) assumption. According to this assumption the decision maker is exceptionally accurate when he/she elicits the comparisons, one-at-a-time. We call it the ultra-accurate decision maker (or UADM) assumption. However, even under this highly favorable assumption towards the use of such comparisons, our research findings demonstrate that the results may be highly erroneous and thus it should not be trustworthy. The results may exhibit too often some serious logical contradictions.

3 - Triple-Loop Learning in Retail Demand Forecasting: a Systematic Evaluation of Benchmarking and Reproducibility of Machine Learning Models**Huijing Chen, University of Portsmouth, Portsmouth, United Kingdom, Huiqing Wang, Ashraf Labib**

In recent years, Machine Learning methods have gained more popularity in retail demand forecasting, aided by the availability of Big Data. Many algorithms have been proposed and applied, but there is no systematic understanding of how effective they are, and under what conditions. In this paper we incorporate the single-, double- and triple-loop learning theory as a theoretical lens in order to systematically categorise the retail demand forecasting literature from 2014 to 2024, especially on the goal of achieving triple-loop learning with three variant conceptualisations.

Two main issues identified from the literature are the lack of robust benchmarking and reproducibility. We apply MCDA tools to further analyse 60 papers on the two issues and provide insight and guidance for future research.

4 - Sensitivity Analysis for Multiple Criteria Decision Making: a New Perspective**Richard O'Shea, University College Cork, Cork, Ireland, Evangelos Triantaphyllou**

Multiple Criteria Decision Making (MCDM) methods such as the Weighted Sum Model (WSM), Compromise Programming (CP), and TOPSIS, combine the performance of alternatives across multiple criteria with criteria weights to generate a composite score and rank the alternatives. Sensitivity analysis is vital to assess the robustness of the ranking with regards to changes in criteria weights. Current sensitivity analysis methods use deterministic or stochastic alterations of weights and can be time consuming, computationally intensive, and imprecise. Existing analytical sensitivity analysis methods for the WSM can identify the most sensitive weight but only consider either the allowable increase or decrease, respectively. This work develops three analytical sensitivity analysis methods for use with the WSM, CP, and TOPSIS, respectively, to precisely determine the allowable increase and decrease to criteria weights. The most sensitive weight can be identified considering (i) the minimum allowable relative increase or decrease (ii) the weight stability interval (using the relative allowable increase and decrease) and (iii) a Pareto dominance approach considering relative increase and decrease. These methods are applied to a notional example. The allowable range of increase and decrease in criteria weights is larger when seeking to maintain the top q ranked alternatives than when seeking to maintain the full ranking of all alternatives. The most sensitive criteria weights can vary depending on the method used to define sensitivity and vary depending on whether the full ranking of alternatives is to be maintained, or, whether the ranking of the top q ranked alternatives is to be maintained.

5 - Integrating Response TIME and Attention Duration In Bayesian Preference Learning for Multiple Criteria Decision Aiding**Milosz Kadzinski, Poznan University of Technology, Poznan, Poland, jiaxuan jiang, Jiapeng Liu, Xiuwu Liao, Jingyu Dong**

We introduce a multiple criteria Bayesian preference learning framework incorporating behavioral cues for decision aiding. The framework integrates pairwise comparisons, response time, and attention duration to deepen insights into decision-making processes. The approach employs an additive value function model and utilizes a Bayesian framework to derive the posterior distribution of potential ranking models by defining the likelihood of observed preference data and specifying a prior on the preference structure. This distribution highlights each model's ability to reconstruct Decision-Makers' holistic pairwise comparisons. By leveraging both response time as a proxy for cognitive effort and alternative discriminability as well as attention duration as an indicator of criterion importance, the proposed model surpasses traditional methods by uncovering richer behavioral patterns. We report the results of a laboratory experiment on mobile phone contract selection involving real subjects using a dedicated application with time-, eye-, and mouse-tracking components. We validate the novel method's ability to reconstruct complete preferences. The detailed ablation studies reveal time- and attention-related behavioral patterns, confirming that integrating comprehensive data leads to developing models that better align with the DM's actual preferences.

6 - A Multi-Objective Optimization Approach to Optimize Dairy Farm Operations to Optimize Profit and Minimize Greenhouse Gas Emissions**Julio César Góez Gutiérrez, NHH Norwegian School of Economics, Bergen, Norway, Rasmus Bang, Mario Guajardo**

Governments and societies strive to balance food production with environmental goals. In this context, identifying farm-level economic and climatic win-win and lose-win scenarios is essential, not only for farmers but also for policymakers and the broader society. This study aims to examine economic performance and greenhouse gas (GHG) emission intensity in combined milk and beef production on dairy farms. We present a multi-objective optimization framework to economically optimize production at farm level under various operational constraints while minimizing the corresponding GHG emissions. We apply this framework in Norway. The optimization results demonstrate that the effectiveness of various measures to increase economic performance and to reduce GHG emissions strongly depends on operational conditions and the GHG emissions intensity measure used. We compare the results using GHG emissions intensity measure and analyze the impact on the managerial insights to support the dairy farmers.

Blockchain Economics and Decentralized Finance

Invited Session

Finance

Chair: Fayçal Drissi, University of Oxford, Oxford, N/A, United Kingdom

1 - A Structural Model of Automated Market Making

David Cao, University of Pennsylvania, Philadelphia, PA, United States, Brett Falk, Leonid Kogan, Gerry Tsoukalas

Automated market makers (AMMs) facilitate ~\$1 trillion of transactions yearly, yet their reliance on static fees contrasts with classical microstructure theory, which emphasizes volatility-sensitive spreads in mitigating adverse selection. To assess whether this theory extends to AMMs, we develop a structural model capturing the interconnected decisions of noise traders, arbitrageurs, and liquidity providers. We empirically test this model using transaction-level data from Uniswap, leveraging a two-stage GMM approach to overcome endogeneity between trading and liquidity volumes. We find the optimal AMM fee structure dynamically adjusts to volatility, leading to improved trade. Our results suggest that, despite their microstructure differences, both traditional and decentralized markets can share fundamental design principles.

2 - Optimal Dex Convexity in the Presence of Infrastructure Rent: a Convex Analysis Approach

Nan Chen, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Blockchain-based decentralized exchanges (DEX) are subject to infrastructure rents, imposing significant costs for liquidity provision. Utilizing convex analysis and calculus of variation methods, this work investigates how to select optimal convex pricing curves to mitigate adverse selection risks for DEXs.

3 - Do Longer Block Time Impair Market Efficiency in Decentralized Markets?

Fayçal Drissi, Oxford University, Oxford, United Kingdom, Alvaro Cartea, Agostino Capponi

In blockchains, traders bid priority fees to compete for queue position at regular intervals known as block time. Priority fees reduce trading volumes of informed traders and mitigate adverse selection costs. Longer block times can improve price efficiency by increasing speculative profits and by encouraging traders to acquire information. However, beyond a certain block time, expected losses from adverse selection outweigh the benefits of priority fees, leading to a liquidity freeze—unless uninformed liquidity demand grows sufficiently with block time. In equilibrium, traders only reveal their information immediately before the block is created.

4 - Designing Block Priority Mechanisms for Efficient Decentralized Markets

Gianluca Palmari, Scuola Normale Superiore, Pisa, Italy, Fayçal Drissi, Alvaro Cartea, Fabrizio Lillo

This paper investigates alternative designs for competition over block priority in blockchain systems and their implications for the microstructure of decentralised exchanges. We propose contest-based mechanisms in which higher priority fees increase the likelihood of obtaining priority in the block, but do not guarantee it. We develop a multi-stage model of trader competition and characterise equilibrium outcomes in terms of priority fees, trading volumes, and market participation. We compare the economic implications of different designs for builders, traders, and liquidity providers.

5 - Endogenous Price Formation at a Decentralized Exchange

Fahad Saleh, University of Florida, Winston-Salem, NC, United States

We provide an economic model of a Decentralized Exchange (DEX) liquidity pool to study price formation in this context. Crucially, we do not model an alternative venue (e.g., a Centralized Exchange) where the price formation occurs and thus our framework reveals the implications of price formation occurring directly at the Decentralized Exchange. We allow that the DEX employs a generalized Constant Function Automated Market Maker (CFAMM). Moreover, we allow for both strategic trading and endogenous liquidity provision. Our framework highlights the role that two-way positive externalities play in the price formation process.

1 - Multi Agent Markov Entanglement

Shuze Chen, Columbia University, New York City, NY, United States, Tianyi Peng

Value decomposition has long been a fundamental technique in multi-agent dynamic programming and reinforcement learning (RL). Specifically, the value function of a global state $s_1, s_2, \dots, s_N$ is often approximated as the sum of local functions: $V(s_1, s_2, \dots, s_N) \approx \sum_{i=1}^N V_i(s_i)$. This approach traces back to the index policy in restless multi-armed bandit problems and has found various applications in modern RL systems. However, the theoretical justification for why this decomposition works so effectively remains underexplored.

In this paper, we uncover the underlying mathematical structure that enables value decomposition. We demonstrate that a multi-agent Markov decision process (MDP) permits value decomposition if and only if its transition matrix is not “entangled” — a concept analogous to quantum entanglement in quantum physics. Drawing inspiration from how physicists measure quantum entanglement, we introduce how to measure the “Markov entanglement” for multi-agent MDPs and show that this measure can be used to bound the decomposition error in general multi-agent MDPs. Using the concept of Markov entanglement, we prove that a widely used class of index policies is weakly entangled and enjoys a sublinear $\mathcal{O}(\sqrt{N})$ scale of decomposition error for N -agent systems. Finally, we show how Markov entanglement can be efficiently estimated in practice, providing practitioners with an empirical proxy for the quality of value decomposition.

2 - Learning to Select and Rank from Choice-Based Feedback: a Simple Nested Approach

Yifan Feng, National University of Singapore, Singapore, Singapore, Junwen Yang

We study a ranking and selection problem with choice-based feedback under dynamic assortments. In this setting, a company sequentially presents subsets of items to customers and observes their choices. Assuming only that preferences follow an unknown strict ranking, the goal is to identify the most preferred item or recover the full ranking using as few samples as possible and with high confidence. We propose two simple and effective algorithms: Nested Elimination (NE) for identifying the best item, and Nested Partition (NP), a divide-and-conquer extension of NE, for recovering the full ranking. Both algorithms come with sharp, instance-dependent, non-asymptotic sample complexity bounds. These bounds are derived using an analytical framework that characterizes the system dynamics as a sequence of multi-dimensional random walks. We also connect our nested approach to information-theoretic lower bounds. As a result, we show that NE is worst-case asymptotically optimal, while NP is near-optimal up to constant factors. Experiments on both synthetic and real-world data support our theoretical findings.

3 - Minimax Optimal Dynamic Assortment Selection with Contextual Information

Min-hwan Oh, Seoul National University, Gwanak-Gu, Korea, Republic of, Joongkyu Lee

We study the contextual multinomial logistic (MNL) bandit problem, where a decision-making agent sequentially selects assortments of items based on contextual information, and user choices follow an MNL model. This problem plays a central role in today’s online retail, online advertising, and recommendation systems, and is becoming increasingly relevant in the post-training of large language models. However, a long-standing open problem remains: (i) the gap between known lower and upper regret bounds, and (ii) the gap between theoretical guarantees and practical algorithms.

We close these gaps by establishing, for the first time, minimax optimal regret with matching lower and upper bounds. We design constant-time algorithms achieving the optimal regret, and we further provide instance-dependent optimal bounds. Our methods are both provably optimal (up to logarithmic factors) and computationally efficient. Empirical studies validate the theory, showing consistent improvements over existing approaches. To our knowledge, this is the first work to establish minimax optimality for contextual MNL bandits in both uniform and non-uniform revenue settings, while simultaneously providing practical algorithms.

4 - Online Learning for Equilibrium Pricing in Markets Under Incomplete

Devansh Jalota, Columbia University, Severna Park, MD, United States, Haoyuan Sun, Navid Azizan

The computation of equilibrium prices at which the supply of goods matches their demand typically relies on complete information on agents' private attributes, e.g., suppliers' cost functions, which are often unavailable in practice. Motivated by this practical consideration, we consider the problem of learning equilibrium prices over a horizon of T 's periods in the incomplete information setting wherein a market operator seeks to satisfy the customer demand for a commodity by purchasing it from competing suppliers with cost functions unknown to the operator. We first consider the setting when suppliers' cost functions are fixed and develop algorithms that, on three pertinent regret metrics, simultaneously achieve a regret of $\mathcal{O}(1)$ when the customer demand is constant over time, and $\mathcal{O}(\sqrt{T})$ when the demand varies over time. In the setting when the suppliers' cost functions vary over time, we demonstrate that, in general, no online algorithm can achieve sublinear regret on all three metrics. Thus, we consider an augmented setting wherein the operator has access to hints/contexts that reflect the variation in the cost functions and propose an algorithm with sublinear regret in this augmented setting. Finally, we present numerical experiments that validate our results and discuss various model extensions.

1 - Prescriptive Machine Learning for Multi-Period Dynamic Nurse Deployment

Siqiang Wang, Peking University, Beijing, China, People's Republic of, Kailai Chen

To address staffing shortages, hospitals increasingly use float pool programs to deploy internal nurses dynamically across facilities. We formulate it as a multi-stage stochastic program and develop a prescriptive machine learning framework that combines offline optimization with real-time neural decision models. By embedding key structures, we ensure feasibility and solution quality. Trained on high-quality data, our method delivers near-optimal, constraint-satisfying decisions in milliseconds. A case study on real data demonstrates substantial speedups with minimal cost gaps.

2 - Survey of Data Driven Newsvendor: Unified Analysis and Spectrum of Achievable Regrets

Zhuoxin Chen, Tsinghua University, Beijing, China, People's Republic of

This paper studies the data-driven Newsvendor problem under all combinations of additive vs. multiplicative regret, high probability vs. expectation bounds, and different distribution classes. We provide a unified analysis based on a notion of clustered distributions, which shows that the entire spectrum of regrets between $1/\sqrt{n}$ and $1/n$ is possible. Our framework simplifies existing proofs and fills gaps in the literature. Simulations on commonly-used distributions demonstrate that our notion is the "correct" predictor of empirical regret across varying data sizes.

3 - An Aggregated Partition-Based Method for Decision-Focused Learning: Application to Microgrid Energy Management

Cristofer Lizama, Universidad Adolfo Ibáñez, Quilpué, Chile

This research addresses an integrated learning and optimization framework in data driven problems, in which an estimator is trained to achieve the best operational performance within a specific planning problem. The resulting model is formulated as a bilevel optimization problem with multiple lower-level subproblems. Given the high computational burden, an adaptation of the Aggregated Partition-Based Method is proposed to reduce the number of subproblems. The methodology is validated in a case study involving the energy management of residential microgrids with photovoltaic generation.

4 - Conformal Robust Optimization and Satisficing for Prescriptive Analytics

Lingjie Zhao, Tsinghua University, Haidian, China, People's Republic of

Prescriptive analytics increasingly leverages rich contextual data, yet classical predict-then-optimize fails under uncertainty. We introduce Conformal Robust Optimization (CRO) and Conformal Robust Satisficing (CRS), which learn and calibrate the parameter uncertainty sets with any, including black-box, predictor. We prove finite-sample coverage guarantees, analyze sample efficiency, derive suboptimality bounds for CRO, and establish a fundamental CRO–CRS equivalence. Numerical studies on knapsack and facility location problems show that CRO and CRS significantly outperform baselines.

Dynamic and Robust Optimization in Transportation

Job Market Showcase

Job Market Showcase

Chair: Ahmad Ghasemkhani, University of Oklahoma, Norman, OK, 73071, United States

1 - Dynamic Crowdsourcing for Last-Mile Delivery with Parcel Lockers

Ali Sabzevari Zadeh, University of Alabama, Tuscaloosa, AL, United States, Iman Dayarian

This study addresses a dynamic crowdsourcing and last-mile delivery problem that integrates same-day delivery through parcel lockers (PLs) with next-day home delivery (HD), allowing PL customers to participate in delivery operations. At checkout, a PL customer selects a period from an available menu to schedule their pickup and may submit bids on bundles of HD orders from a customized list offered to them. If a bid is accepted, the associated bundle is delivered from the depot to the corresponding PL along with the customer's own orders, which they then deliver to the respective HD customers in exchange for store credits. Vehicle routes are periodically planned to jointly deliver selected HD orders to customers and PL orders, along with accepted HD bundles, to designated PLs before scheduled pickup times. Therefore, in each period, the retailer must decide which bids to accept, which HD orders to dispatch, and which to postpone, aiming to minimize delivery costs and credits awarded over a single-day, multi-period horizon. To solve the problem, which is stochastic due to the dynamic nature of PL order arrivals and the resulting variability in crowdsourcing capacity, a two-phase heuristic is developed. The first phase selects a subset of HD orders and bids using a sample-scenario planning approach to predict future PL orders and crowdsourcing capacity. The second phase designs vehicle routes for joint HD and PL delivery. Results show that cost savings decline as the HD-to-PL order ratio increases, especially in dense areas with sparse PL networks.

2 - Dynamic Path Planning in Stochastic Environments

Li Zhou, Auburn University, Auburn, AL, United States, Elvan Ceyhan

We introduce a sequential decision-making framework for navigation in environments with uncertain, spatially correlated obstacles. Using Gaussian Random Field models, our method captures spatial dependencies and continuously refines obstacle information through sequential Bayesian updates. By combining model-based and model-free reinforcement learning approaches, the proposed framework dynamically balances immediate traversal costs with the long-term benefits of information gathering, effectively addressing the exploration-exploitation tradeoff. Additionally, a search space reduction technique is integrated to enhance computational scalability.

Experimental evaluations demonstrate that our approach robustly adapts to dynamic uncertainties and presents improved performance across various simulation scenarios under different uncertainty, noisy conditions.

3 - Enhancing Adaptive Robust Optimization with Archetypal Analysis for Data-Driven Decision-Making

Ahmad Ghasemkhani, University of Oklahoma, Norman, OK, United States, Charles Nicholson, Andres Gonzalez Huertas

Robust optimization (RO) addresses decision-making under uncertainty by optimizing for worst-case scenarios within defined uncertainty sets. Archetypal analysis (AA), an unsupervised learning method that identifies extreme patterns in data, offers a powerful approach to construct these sets by simplifying complex datasets into representative scenarios. This abstract explores the integration of AA with RO to enhance decision-making in fields such as infrastructure restoration, economic resilience, and resource allocation. By applying AA, high-dimensional uncertain data such as infrastructure damage scenarios or economic disruption patterns are reduced to a small set of archetypes, each representing extreme yet plausible outcomes. These archetypes form the basis of uncertainty sets, enabling RO models to efficiently balance robustness and computational tractability. For instance, in interdependent network restoration, AA-derived scenarios capture critical failure patterns, guiding optimal resource allocation to minimize worst-case service disruptions. Similarly, in economic planning, archetypes highlight sector-specific resilience extremes, informing adaptive strategies. The synergy of AA and RO improves model interpretability and scalability, offering insights into uncertainty structures while maintaining rigorous optimization. This approach outperforms traditional uncertainty set constructions by leveraging data-driven insights, making it suitable for real-world applications with limited computational resources.

AI, Algorithms, and Recommender Systems

Invited Session

Information Systems

Chair: Xiang (Shawn) Wan, Santa Clara University, Santa Clara, CA, 95050, United States

Co-Chair: Yinliang Tan, University of Houston, Houston, TX, United States

1 - Algorithmic Collusion or Competition: The Role of Platforms Recommender Systems

XINGCHEN XU, University of Washington, Seattle, WA, United States, Stephanie Lee, Yong Tan

Recent scholarly work has extensively examined the phenomenon of algorithmic collusion driven by AI-enabled pricing algorithms. However, online platforms commonly deploy recommender systems that influence how consumers discover and purchase products, thereby shaping the reward structures faced by pricing algorithms and ultimately affecting competition dynamics and equilibrium outcomes. To address this gap, we first develop a structural search model to characterize consumers' decision-making processes in response to varying recommendation sets. This model incorporates both observable and unobservable heterogeneity in utility and search cost functions, and is estimated using real-world data. Building on the resulting consumer model, we formulate personalized recommendation algorithms designed to maximize either platform revenue or consumer utility. We further introduce pricing algorithms for sellers and integrate all these elements to facilitate comprehensive numerical experiments. Our experimental findings reveal that a revenue-maximizing recommender system intensifies algorithmic collusion, whereas a utility-maximizing recommender system encourages more competitive pricing behavior among sellers. Intriguingly, and contrary to conventional insights from the industrial organization and choice modeling literature, increasing the size of recommendation sets under a utility-maximizing regime does not consistently enhance consumer utility. Moreover, the degree of horizontal differentiation moderates this phenomenon in unexpected ways. The "more is less" effect does not arise at low levels of differentiation, but becomes increasingly pronounced as horizontal differentiation increases. These findings provide valuable insights for regulators, platform designers, and market participants, and they open up a range of promising avenues for future research.

2 - Voice Your Preferences: the Dual Impact of Personal Voices on Personalized Recommendation

Yaqiong Wang, Santa Clara University, Santa Clara, CA, United States

As recommender systems evolve beyond traditional behavioral data to enhance personalization, understanding the broader impacts of using sensitive personal information becomes critical. This study examines the efficacy and implications of using personal voices in recommender systems. Through two controlled experiments, we first establish the significant correlation between individual vocal features and personal preferences. This correlation is mediated by individual demographic, emotional, and personality traits. These findings lay a theoretical foundation of recommender system design with personal voice beyond traditional behavioral data. Following the discovery, we investigate the impact of personalization strategy disclosure involving different types of personal data. Our results indicate that revealing the use of personal data—particularly voice—significantly reduces users' perceived recommendation quality and willingness-to-pay. This behavioral backlash highlights a growing tension between personalization and privacy, especially when biometric data is involved. Our findings offer empirical insights for system design and data regulation, emphasizing the significance of transparency strategies in the deployment of recommender systems.

3 - Decoding User Engagement: a Mutual Information-Enhanced Multi-Task Learning Framework for Predicting Gratification on Social Media

Cong Wang, Peking University, Beijing, China, People's Republic of, Xinpei Yao, Xunhua Guo

User engagement is a critical factor in the digital economy, where social media platforms strive to deliver contents that fulfill users' multifaceted gratification needs. These needs are inherently complex and linked to distinct engagement outcomes, making their accurate prediction essential for optimizing content delivery. Traditional multitask learning frameworks often struggle to model the intricate interdependencies among engagement objectives, particularly in data-sparse contexts with the absence of explicit relationships between these outcomes. This limitation can result in inferior multitask learning performance with "seesaw effect", where improving one objective inadvertently compromises another. To address these challenges, we propose the Mutual Information-Enhanced Multitask Graph Convolution Network (MIEMGCN), a novel approach for predicting multiple user engagement outcomes while capturing their complex interdependency. MIEMGCN integrates a multitask learning architecture with graph convolution networks, modeling both task-specific and shared embeddings to learn various engagement outcomes. This design allows MIEMGCN to effectively capture the social propagation of user preference and address data sparsity issues. Furthermore, MIEMGCN incorporates mutual information constraints into its loss function to enhance information sharing across tasks. These constraints quantify task correlations and promote more targeted and efficient information sharing. To overcome the computational challenges of exact mutual information inference, we propose a proxy based on conditional mutual information and provide theoretical validation of its effectiveness. Empirical evaluations on datasets from two major short video platforms demonstrate that MIEMGCN outperforms state-of-the-art methods by achieving higher prediction accuracy while mitigating the seesaw effect, offering valuable insights for boosting user engagement and refining content delivery strategies.

4 - When Product Recommendations Fall Short: the Heterogeneous Impact of Product Network Characteristics on Recommender System Performance

Xiang (Shawn) Wan, Santa Clara University, Santa Clara, CA, United States, Anuj Kumar, Haldun Aytug

Recommender systems create a network of interconnected products on e-commerce websites by showing related products on the focal product pages. We conduct a field study on a US fashion e-tailer's website to show how two core product network characteristics – the focal product's network centrality and the strengths of the edge connecting the focal product to its recommended products – could influence the recommendation's effect on product sales. While we find it beneficial to show either closely or weakly related recommended products for the focal products at the center of the recommendation network, it is helpful to recommend only weakly related products for the focal products at the edges. We provide empirical evidence that consumers seek a higher level of variety when exploring focal products at the network's edges. Thus, offering dissimilar product recommendations to them may better fulfill their variety-seeking needs. Finally, we show that retailers can exploit the heterogeneous impact of product network characteristics to generate recommendation policies to optimize product sales. We show the e-retailer could obtain four percent higher sales under our suggested recommendation policy.

5 - Personalization, Consumer Search, and Algorithmic Pricing

Liyang Qiu, Carnegie Mellon University, Pittsburgh, PA, United States, Yan Huang, Param Singh, Kannan Srinivasan

Our study investigates the impact of product ranking systems on artificial intelligence (AI) powered pricing algorithms. Specifically, we examine the effects of "personalized" and "unpersonalized" ranking systems on algorithmic pricing outcomes and consumer welfare. Our analysis reveals that personalized ranking systems, which rank products in decreasing order of consumer's utilities, may encourage higher prices charged by pricing algorithms, especially when consumers search for products sequentially on a third-party platform. This is because personalized ranking significantly reduces the ranking-mediated price elasticity of demand and thus incentivizes to lower prices. Conversely, unpersonalized ranking systems lead to significantly lower prices and greater consumer welfare. These findings suggest that even in the absence of price discrimination, personalization may not necessarily benefit consumers since pricing algorithms can undermine consumer welfare through higher prices. Thus, our study highlights the crucial role of ranking systems in shaping algorithmic pricing behaviors and consumer welfare.

Novel Approaches to Data Analysis

Job Market Showcase

Job Market Showcase

Chair: Ann-Kathrin Meyer, University of Münster, Münster, Germany

1 - Dynamic Correlation Learning in Diverse Markets: a Graph-Based Approach for Adaptive Stock Price Prediction

Fang He, Southeast University, Jiangsu, China, People's Republic of, Wei Yin

Stock price forecasting has become a significant and complex research area within financial technology. The dynamic correlations among stocks and the inherent noise in price volatility present considerable challenges in accurately forecasting stock prices and enhancing investment returns. This paper introduces a novel Dynamic Correlation Graph Convolution Network (DyCGCN) with embedded temporal correlation extraction. Firstly, we propose a dual-scale dynamic graph generation method to capture the topological relationships among stocks. Secondly, we develop a dynamic correlation-temporal convolution module that extracts high-level temporal correlations. Thirdly, we introduce a prospect theory-guided multi-strategy loss function that accommodates the diverse risk preferences of investors. Additionally, we present a joint regression-classification learning method to extract and leverage stock trend information. Experimental results on four real-world datasets show the efficacy of the proposed DyCGCN model, demonstrating its superior accuracy and effectiveness in stock price forecasting.

2 - Fairness, Balance, and Scale: a Multilevel Graph Approach to Deep Neural Networks

Rachel Bennett, University of Oklahoma, Oklahoma City, OK, United States

The rapid growth in data generation has elevated neural networks as essential tools in machine learning. However, this growth also brings challenges, including increased computational demands, class imbalance, and bias toward certain subpopulations. To address these issues, we propose a novel **Multilevel Deep Neural Network (MLDNN)** framework designed to scale efficiently to large datasets while addressing class imbalance. Our method uses graph-based data representations and coarsening techniques to progressively reduce the dataset size. To further enhance model fairness, we introduce a fairness-aware extension of this framework. This approach integrates fairness considerations during the coarsening stage to reduce bias across demographic groups. We evaluate our MLDNN models against conventional single-level deep neural networks on both benchmark and real-world datasets.

3 - Cracking the Ca(U)Ses: Unraveling Urban Crime Dynamics with Agent-Based Modeling

Ann-Kathrin Meyer, University of Münster, Münster, Germany, Konstantina Valogianni, Balaji Padmanabhan, Tobias Brandt

The complexity of phenomena like infectious diseases, traffic congestion, or crime arises from their intricate and diverse underlying relationships. While statistical models are powerful aids towards understanding those phenomena, they often fall short with respect to flexibility and addressing deeper causal structures. This issue is particularly relevant in

cases where different combinations of causal factors can lead to similar outcomes (equifinality) or similar initial conditions to different outcomes (multifinality). Agent-Based Modeling offers a promising alternative by employing a dynamic, process-oriented approach to causation. This is a simulation method that models the interactions of autonomous agents

to assess their effects on the system as a whole. Causal Agent-Based Modeling, i.e. grounded in theoretical and empirical foundations, facilitates a comprehensive understanding of diverse pathways leading to similar or different outcomes. Using the Causal Agent-Based Modeling lens, this paper addresses the complexities of modeling crime in an urban environment by incorporating spatial factors together with temporal dimensions. In addition to studying a key problem through a new lens, the exploration of equifinality and multifinality using Causal Agent-Based Modeling contributes to operations management research by accounting for the numerous interacting factors and uncertainties inherent in operational processes and policy decisions. We show that our approach can uncover multiple plausible causal sets for criminal behavior using real spatial data, rather than seeking a single explanation. This methodology therefore can aid investigators by offering automated candidate explanations, improving current crime intelligence practices and enhance operational decisions through explicit industry-specific contextual understandings.

Modeling the Electricity Grid

Job Market Showcase

Job Market Showcase

Chair: Yamil Essus, North Carolina State University, Raleigh, NC, United States

1 - Centralized Scheduling of Home Charging Operations for Electric Vehicles: a Gamification Approach

Alireza Ghahtarani, HEC Montreal, Côte-St-Luc, QC, Canada, Jorge Mendoza, Martin Cousineau, Amir-massoud Farahmand

We study the centralized scheduling of home charging operations for electric vehicles (EVs) using a gamification-based approach. Inspired by Tetris, we model the charging schedule as a dynamic block-stacking game, where scheduling decisions impact grid efficiency. We propose heuristic methods and apply DAGGER (Dataset Aggregation) to train an agent that learns to optimize EV charging schedules through imitation learning. The primary objective is peak shaving, ensuring a balanced distribution of charging demand to reduce grid stress. Our approach is compared against reoptimization methods and full information optimization, evaluating trade-offs between computational efficiency and performance. Simulation results demonstrate that gamification offers a practical and scalable alternative, effectively mitigating peak loads while maintaining scheduling efficiency.

2 - Risk-Averse Markov Decision Processes for Managing Uncertainty in the Electricity Grid

Arash Khojaste, University of Massachusetts Amherst, Amherst, MA, United States, Jonathan Pearce, Golbon Zakeri

We present various methods from the perspective of system operators to enhance decision-making in an electricity grid facing the uncertainties associated with renewable energy sources. We incorporate different risk measures into our decision framework to address risk aversion in the system's operational planning. In a Markov Decision Process (MDP) framework, we use Conditional Value-at-Risk (CVaR) to build a risk-averse model that minimizes costs while ensuring grid reliability by hedging against high-cost scenarios. We propose a computationally efficient method to solve the resulting optimization problem and reach a global optimum. Additionally, we suggest various constraints that can increase the electricity grid's reliability. These constraints include one that prevents consecutive demand curtailments. We use a real-world example of a backup system for wind power integration to show the application of our models.

3 - Efficient Integration of Energy Storage Resources in Modern Power Systems Through Synergistic Integration of Mathematical Optimization and Machine Learning

Farhan Hyder, Rochester Institute of Technology, Rochester, NY, United States

The recent emergence and increased penetration of variable renewable energy resources introduce new operational challenges in the modern electrical grid. For the grid operators, this means more generation-demand imbalances, greater pressure on the transmission network, and increased computational burden for efficient operation of the grid. Utility-scale Energy Storage Resources (ESRs) can play a crucial role in mitigating the load fluctuations caused by renewables, as they are capable of instantly switching between charging (consuming) and discharging (generating) modes for a reliable, secure and sustainable grid of the future. However, with the integration of a large number of ESRs, the complexity of the resulting unit commitment (UC) problem increases significantly due to the increased number of binary variables for preventing simultaneous charging and discharging. Hence, computationally efficient modeling of ESRs can play a key role in mitigating the computational challenges introduced by the integration of ESRs.

To address the challenge of increased computational burden, a machine learning enhanced formulation tightening approach is developed. Under this approach, the ESR's mathematical formulation is transformed to be closer to its convex hull, resulting in better computational performance. However, due to the combination of utility-scale renewables and ESRs, the computational burden might still be high. Hence, a novel deep learning-based approach is developed to filter redundant transmission capacity constraints in the UC problem. This can improve computational performance of the UC problem.

Results on medium and large-sized networks shows the effectiveness of the formulation tightening and transmission line screening approaches.

4 - Leveraging GeoAI Foundation Models for Generalizable Spatial Prediction of Power Outages

Yamil Essus, North Carolina State University, Raleigh, NC, United States, Benjamin Rachunok

Uncertainty in the location of weather-based power outages leads to multidimensional risks associated with cascading impacts on engineering systems. The main challenge in developing generalizable models for power outage prediction is the high dimensionality of weather features representing multiple geographies. We applied transfer learning and fine-tuning to build a deep learning model based on recent Geospatial Artificial Intelligence (GeoAI) methods to produce accurate estimations of power outage locations. In order to reduce data and compute requirements, we used Prithvi WxC, a foundation model for weather and climate applications, as the starting point of our network.

Inference and Resource Allocation in Healthcare Systems

Job Market Showcase

Job Market Showcase

Chair: Hyunwoo Shin, Virginia Tech, Blacksburg, VA, United States

1 - Optimal use of Alternative Care Modalities and Ppe Supplies During Infectious Disease Outbreaks

Mina Bahadori, Clemson University, Central, SC, United States, Tugce Isik

Resource shortages—whether of healthcare personnel or medical equipment—are a persistent challenge in healthcare systems. These shortages are often exacerbated during infectious disease outbreaks due to sudden surges in demand and supply chain disruptions, and tend to affect different facilities and patient populations unequally. In this work, we focus on the effective and fair use of limited personal protective equipment (PPE) supplies, which is critical to protect healthcare workers and maintain safe and successful care delivery. We formulate a finite-horizon Markov decision process (MDP) to optimally allocate different patient populations to alternative care modalities during a PPE shortage induced by an infectious disease outbreak. We consider in-person care with PPE and telehealth as available care modalities and maximize total utility of PPE allocation decisions across different patient populations who differ in infection risk and in their ability to receive care in-person or via telehealth. We analyze the structure of the optimal policy and establish key monotonicity properties of the reward and value functions. These structural insights enable us to design interpretable and implementable dynamic allocation policies. In addition, we explore how various factors—including inventory replenishment policy used by the healthcare facility and uncertainty in PPE replenishment (e.g., delays, partial restocking) impact the optimal policies. Our findings highlight the need for adaptive, risk-aware strategies to manage resource shortages and offer practical guidance for equitable decision-making during public health crises.

2 - Heterogeneous Treatment Effects in Panel Data: Insights into the Healthy Incentives Program

Emily Zhang, Massachusetts Institute of Technology, Cambridge, MA, United States, Retsef Levi, Elisabeth Paulson, Georgia Perakis

We study the impact of adding new vendors to the Massachusetts (MA) Healthy Incentives Program (HIP), a food-subsidy program aimed at increasing the consumption of fruits and vegetables among low-income households, on the utilization of the program. This is an instance of a core problem in causal inference: estimating heterogeneous treatment effects (HTE) using panel data. Existing methods either do not utilize the underlying structure in the panel data or do not accommodate the general vendor addition patterns in the HIP data. We propose the Panel Clustering Estimator (PaCE), a novel method that first partitions observations into disjoint clusters with similar treatment effects using a regression tree, and then leverages the (assumed) low-rank structure of the panel data to estimate the average treatment effect (ATE) for each cluster. Our theoretical results establish the convergence of the resulting estimates to the true treatment effects. Computational experiments with semi-synthetic data show that PaCE achieves superior accuracy for ATE and HTE estimation compared to existing approaches. This performance was achieved using a regression tree with no more than 40 leaves, making PaCE both more accurate and interpretable. Applying PaCE to HIP data, we discern the heterogeneous impacts of vendor additions on program utilization across different regions of MA. These findings provide valuable insights for future budget planning and for identifying which MA ZIP codes to target with vendor additions.

3 - Optimizing U.S. Lung Allocation Policy via a Multi-Objective Trust-Region-Based Simulation Optimization Algorithm

Hyunwoo Shin, Virginia Tech, Blacksburg, VA, United States, Sait Tunc, Xi Chen

Simulation models play a critical role in evaluating and guiding organ allocation policies. A common approach by using kriging-based surrogates with active learning faces two key challenges: difficulty in setting credible input bounds and the high computational burden of global exploration and repeated surrogate updates. To address these challenges, we propose a multi-objective trust-region simulation-optimization framework, tailored for lung allocation policy design. Our method begins each search iteration with a low-fidelity kriging surrogate, built from existing simulation data, to identify a promising initial policy. The search is then confined to a dynamically adjusted trust region around the current best solution, allowing focused exploration while limiting unnecessary simulations. Our localized strategy significantly reduces computational costs by avoiding repeated global surrogate fits and by targeting high-potential areas for refinement. This makes it a practical and scalable tool for policy optimization in real-world transplantation settings, supporting timely and evidence-based decision-making.

4 - Mass Vaccination Scheduling: Trading off Infections, Throughput, and Overtime

Shanshan Luo, UBC Sauder School of Business, Vancouver, BC, Canada

Mass vaccination is essential for epidemic control, but long queues can increase infection risk. We study how to schedule arrivals at a mass vaccination center to minimize a tri-objective function of a) the expected number of infections acquired while waiting, b) throughput, and c) overtime. Leveraging multimodularity results of a related optimization problem, we construct a solution algorithm and apply it to a case study of COVID-19. We find that although the standard equally-distributed, equally-spaced schedule sits near the Pareto-optimal frontier, it is located away from a sharp elbow in the trade-off between infections and overtime. Specifically, the “elbow policy” achieves approximately 38% fewer expected infections for nearly the same expected overtime. We also discuss managerial insights around the structure of the optimal schedule and compare it to the well-known “dome-shaped” policies found in other appointment scheduling settings.

How to Make Decisions Under Uncertainty in the AI Era?

Panel Session

Applied Probability Society

Co-Chair: David Goldberg, Cornell University, Ithaca, NY, United States

1 - Moderator Panelist**David Goldberg, Cornell University, Ithaca, NY, United States**

This panel will discuss a variety of aspects arising from the above OR-AI comparison/conflict/interface, in how to make decisions under uncertainty, a question at the core of the entire OR discipline.

These include, for example: 1) What are the roles and strong/weak scenarios in using mathematical analysis, e.g., asymptotic analysis for large-scale stochastic systems, compared to using heuristic or black-box AI approaches in decision learning? 2) The usual "mindset" of OR methodological study is to devise algorithms by theoretically understanding their performances, through convergence analysis, regret or error bounds, computational complexity, etc. Would it be a competitive approach to empirically test and validate performances only or before asking for a rigorous theory? 3) Should, or how much should, we change the criteria to publish in top OR journals to embrace more empirical papers or judge the merit of theoretical works? 4) How do we compare the interpretability and trustworthiness of OR models with AI models, which may be opaque but empirically performant? Especially when facing high-stakes decisions, how should we trade off explainability vs. accuracy? 5) How should we train the next generation of OR researchers and practitioners in balancing theory, data skills, and domain knowledge needed to thrive at the OR-AI interface?

Learning, Ranking, and Selection

Job Market Showcase

Job Market Showcase

Chair: Zixian Yang, University of Michigan, Ann Arbor, MI, 48109, United States

1 - Bayesian Procedures for Ranking and Selection with Multiple Objectives**Jinbo Zhao, Texas A&M University, College Station, TX, United States**

Ranking and selection (R&S) problems with multiple objectives remain challenging when approached from a Bayesian perspective, primarily due to the computational difficulty of evaluating integrals over high-dimensional, non-convex regions. We propose a reformulation using sample average approximation via posterior sampling that effectively circumvents these complex integrals. The resulting framework supports diverse acceptability definitions—including top-m selection, stochastically constrained optimality, and Pareto optimality—provided that acceptability can be determined from the known performances of all simulated alternatives. We study several Bayesian guarantees concerning the probability of returning at least one acceptable alternative, the probability of returning a superset of all acceptable alternatives, and the expected proportion of acceptable alternatives returned. We further propose two adaptive budget allocation schemes: one based on the gradient of these posterior quantities and another based on the gradient of the largest posterior variance among alternatives' probabilities of being acceptable. Both gradients are with respect to additional simulation effort and estimated via posterior sampling. Preliminary numerical experiments illustrate the potential effectiveness and efficiency of these adaptive allocation policies in multi-objective R&S.

2 - Optimizing Input Data Collection for Ranking and Selection**Taeho Kim, HKUST, Hong Kong, China, People's Republic of, Eunhye Song**

We study a ranking and selection (R&S) problem when all solutions share common parametric Bayesian input models updated with the data collected from multiple independent data-generating sources. Our objective is to identify the best system by designing a sequential sampling algorithm that collects input and simulation data given a budget. We adopt the most probable best (MPB) as the estimator of the optimum and show that its posterior probability of optimality converges to one at an exponential rate as the sampling budget increases. Assuming that the input parameters belong to a finite set, we characterize the ϵ -optimal static sampling ratios for input and simulation data that maximize the convergence rate. Using these ratios as guidance, we propose the optimal sampling algorithm for R&S (OSAR) that achieves the ϵ -optimal ratios almost surely in the limit. We further extend OSAR by adopting the kernel ridge regression to improve the simulation output mean prediction. This not only improves OSAR's finite-sample performance, but also lets us tackle the case where the input parameters lie in a continuous space with a strong consistency guarantee for finding the optimum. We numerically demonstrate that OSAR outperforms a state-of-the-art competitor.

3 - Optimizing Adaptive Experiments: A Unified Approach to Regret Minimization and Best-Arm Identification**Chao Qin, Stanford University, Palo Alto, CA, United States, Daniel Russo**

Practitioners conducting adaptive experiments often encounter two competing priorities: maximizing total welfare (or 'reward') through effective treatment assignment and swiftly concluding experiments to implement population-wide treatments. Current literature addresses these priorities separately, with regret minimization studies focusing on the former and best-arm identification research on the latter. This paper bridges this divide by proposing a unified model that simultaneously accounts for within-experiment performance and post-experiment outcomes. We provide a sharp theory of optimal performance in large populations that not only unifies canonical results in the literature but also uncovers novel insights. Our theory reveals that familiar algorithms, such as the recently proposed top-two Thompson sampling algorithm, can optimize a broad class of objectives if a single scalar parameter is appropriately adjusted. In addition, we demonstrate that substantial reductions in experiment duration can often be achieved with minimal impact on both within-experiment and post-experiment regret.

4 - Online Learning for Two-Sided Markets**Zixian Yang, The University of Michigan, Ann Arbor, MI, United States, Sushil Mahavir Varma, Lei Ying**

We study a two-sided market, wherein, price-sensitive heterogeneous customers and servers arrive and join their respective queues. A compatible customer-server pair can then be matched by the platform, at which point, they leave the system. Our objective is to design pricing and matching algorithms that maximize the platform's profit, while maintaining reasonable queue lengths. As the demand and supply curves governing the price-dependent arrival rates may not be known in practice, we design a novel online-learning-based pricing policy and establish its near-optimality. In particular, we prove a tradeoff among three performance metrics: $\tilde{O}(T^{\frac{1}{2}})$ regret, $\tilde{O}(T^{\frac{1}{2}})$ average queue length, and $O(T^\gamma)$ maximum queue length for $0 < \gamma \leq 1/6$, where T is the time horizon. Moreover, barring the permissible range of γ , we show that this trade-off between regret and average queue length is optimal up to logarithmic factors under a class of policies, matching the optimal one as in (Varma et al., 2023), which assumes the demand and supply curves to be known. Our proposed policy has two noteworthy features: a dynamic component that

optimizes the tradeoff between low regret and small queue lengths; and a probabilistic component that resolves the tension between obtaining useful samples for fast learning and maintaining small queue lengths.

Novel Problems in Revenue Management

Job Market Showcase

Job Market Showcase

Chair: Jessie Jiang, Cornell University, Ithaca, NY, United States

1 - Pricing with Tips in Three-Sided Delivery Platforms

Gary Ma, Harvard University, Cambridge, MA, United States, Yannai Gonczarowski, David Parkes

We model a delivery platform facilitating transactions among three sides: buyers, stores, and drivers. In addition to buyers paying store-specific purchase prices and drivers receiving store-buyer-specific delivery compensation from the platform, each buyer has the option to directly tip for delivery from a specific store. An equilibrium consists of prices, compensations, tips, and transactions that clears the market, such that buyers receive deliveries from preferred stores considering prices and tips they pay, and drivers deliver preferred orders considering the compensations and tips they receive.

We illustrate the role of tips in pricing: with tips an equilibrium always exists, but without tips an equilibrium is only guaranteed to exist when drivers outnumber the minimum number of buyers and stores. From an efficiency perspective, the optimal with-tip equilibrium welfare is always weakly larger than the optimal without-tip equilibrium welfare. However, we show that even with tips, efficient equilibria may not exist, and that calculating the optimal equilibrium welfare is NP-hard. To address these challenges, we identify conditions on market structure that ensure the existence of efficient with-tip equilibria and allow these efficient equilibria to be computed in polynomial time.

2 - Fluid Approximations in Revenue Management with Correlated Demands and Intertemporal Constraints

WEIYUAN LI, Cornell Tech, New York, NY, United States, Huseyin Topaloglu, Paat Rusmevichientong, Jingwei Zhang

In this talk, we explore fluid approximations as a tool for tackling revenue management problems with correlated demand and intertemporal constraints. We focus on designing asymptotically optimal policies informed by these fluid approximations.

3 - Beyond One-Size-Fits-All: Personalized Delivery and Fulfillment Optimization

Quan Zhou, McGill University, Montreal, QC, Canada, Mehmet Gumus, Sentao Miao

Motivated by our collaboration with an online platform operating in North America, we explore the joint optimization of the order fulfillment process with personalized delivery options in the context of e-commerce. Customers can choose from personalized fulfillment options to proceed with the purchase or leave with no purchase. The retailer periodically makes fulfillment decisions and relies on multiple logistic providers to perform the fulfillment operations. We model customer behavior with a general discrete choice model and formulate the joint optimization as a stochastic dynamic program. We propose a tractable deterministic approximation and develop a computationally efficient heuristic with a provable performance guarantee. Using real datasets collected from our industrial partner, we demonstrate the value of personalizing fulfillment options for the customers and jointly optimizing the options with fulfillment assignments. Our results show that demand management via personalized fulfillment options is prominent when customers favor quicker fulfillment and when the fulfillment capacity is limited. However, an optimized fulfillment operation becomes more critical when customers are more willing to wait.

The One Where Operations Fights Climate Change

Invited Session

MSOM: Sustainable Operations

Chair: Siddharth Singh, University College London, London, E14 5AA, United Kingdom

1 - Preventing Catastrophic Wildfires Through Optimized Grid Annual Inspection and Maintenance Plan

Abolfazl Taghavi, UCLA Anderson School of Management, Los Angeles, CA, United States, Ali Fattahi, Sriram Dasu, Reza Ahmadi

Power grid failures are a major cause of catastrophic wildfires, making wildfire prevention a top priority for utility companies and regulators. Inspection and maintenance are crucial to wildfire mitigation, and utilities must annually report which grid segments will be inspected, the planned preventive actions, and anticipated reductions in wildfire costs. This paper addresses the inspection and maintenance planning problem to minimize wildfire costs due to grid failures. The power grid consists of millions of components grouped into thousands of clusters, each containing hundreds of correlated segments. Using uncertain wildfire cost estimates provided by utilities, we formulate a large-scale stochastic optimization problem to design optimal inspection and maintenance plans under capacity constraints. We show that the problem is NP-hard and analyze how inspection and segment correlation affect cost reduction. We reformulate it as a more tractable, non-convex integer program, which decomposes by cluster, and develop an approximate solution method that constructs a surrogate objective via the lower surface of the convex hull of sampled points. We also derive a lower bound on the objective and provide a theoretical a priori error analysis. We validate our framework using a disguised instance based on data from one of California's largest utility companies. Our method achieves an approximation error of just 0.22%, significantly outperforming a heuristic similar to current industry practice, which incurs a 14.31% error.

2 - Effect of Charging Stations on EV Adoption

Andrey Makhnov, University of North Carolina, Chapel Hill, NC, United States, Nur Sunar, Jayashankar Swaminathan

The strategic deployment of electric vehicle (EV) charging infrastructure plays a critical role in adoption, yet optimizing placement remains a complex challenge. This research applies a state-of-the-art machine learning approach to evaluate the impact of charger locations and network density on adoption patterns. By leveraging geospatial and socioeconomic modeling, we estimate heterogeneous treatment effects of charging station deployment across different regions. Findings from this analysis aim to provide insights that support data-driven decision-making for infrastructure optimization.

3 - Subsidizing Circularity to Support the Domestic Renewable Energy Industry

Nilsu Uzunlar, Carnegie Mellon University, Pittsburgh, PA, United States, Alan Scheller-Wolf, Siddharth Singh

There is expected to be a large number of solar panels and wind turbines disposed of in the upcoming decade. These products are prohibitively expensive to recycle. In addition to the problem of expensive recycling, some countries' abundant production/mining capacity makes domestic manufacturers overly reliant on foreign suppliers. We explore how domestic recycling regulation could solve the dual problems of catalyzing domestic production and reducing renewable energy product waste. We propose a model in which a regulator sets a recycling requirement for key commodities. Simultaneously, the regulator introduces competition by subsidizing a domestic recycler, who operates alongside a foreign supplier. We use a game-theoretic framework to understand the supplier's capacity decision in response to the introduction of the recycler, how this affects demand allocation within the market, and its implications for renewable energy supply and mining. We fully characterize the optimal recycling requirement for a focal commodity. We find that it is infeasible to impose legislation if the collection rate of retiring products is too low, or if the expected price of the commodity is too high. In general, as the expected market price increases, both the collection rate and the subsidy must increase to render recycling effective.

Furthermore, an alternative intervention, imposing tariffs on foreign commodity supply, will typically not render recycling feasible if it was infeasible to start with. However, if legislation is feasible without a tariff, it may remain so under a tariff, and the tariff may potentially lead to an increase in recycling volumes.

4 - Watt's Next: Navigating the Surge in Electric Vehicle Adoption and Its Implications for Grid Operations

Siddharth Singh, University College London, London, United Kingdom, Karthik Murali, Owen Wu, Mesut Yavuz

As policy decisions pave the way for more Electric Vehicles (EVs), a tremendous strain on the utility grid is expected. Managing this strain requires careful planning and possibly control of EV charging. This may include utilities managing intra-day demand using grid-scale batteries and influencing EV charging through active or passive managed charging programs, including possible use of Vehicle-to-Grid (V2G) technologies. Managed charging must be carefully controlled, accounting for EV users' driving patterns and the extent to which they permit the utility to manage their battery ("offered flexibility"). How can this best be done? We explore this question from the perspective of an integrated energy system planner seeking to minimize generation and emissions costs from the electricity and transportation sectors. Using a stylized analytical model with two daily periods (peak and off-peak), we derive optimal grid operations assuming a fraction of EVs participate in managed charging. We find the interplay between EVs and grid-scale batteries is non-trivial—they can be substitutes or complements in the planner's portfolio. We supplement our analytical model with a higher-fidelity 24-hour model calibrated to real data from the PJM interconnection region and extend it numerically to include EV drivers with heterogeneous default charging behavior. The most effective lever to reduce system costs is managing more EVs, rather than increasing flexibility of already-managed ones. With sufficient EV management, reliance on grid-scale batteries decreases, and the need for V2G—associated with high battery degradation—is avoided.

Innovative Approach to Efficient Airspace Management

Invited Session

Air Transportation Section

Chair: Go Nam Lui, Lancaster University Management School, Lancaster, LA15NL, United Kingdom

1 - 3D Optimal Airspace Sector Design with Mixed Integer Linear Programming

Go Nam Lui, Lancaster University, Lancaster, United Kingdom, Guglielmo Lulli

The increasing complexity of air traffic management and the growing demand for efficient airspace utilization have driven the development of smart upper airspace systems that leverage advanced operations research methodologies. This presentation presents the application of operations research techniques in the design and configuration of intelligent upper airspace frameworks in the SMARTS project, focusing on optimization models that enhance traffic flow management and improve overall system performance. We explore two key applications: First, the optimal design of airspace sectors. Mathematical programming models, such as Mixed Integer Programming (MIP), are employed to create sectors that balance controller workload and ensure smooth traffic flow, with the connectivity and traffic flow convexity consideration. Complementary heuristic approaches demonstrate the ability to achieve near-optimal solutions rapidly, crucial for operational agility. Second, dynamic airspace configuration. Here, OR techniques, including integer linear programming and graph-based algorithms, enable the selection of optimal airspace configurations in response to fluctuating traffic demand and uncertainty. These methods aim to maximize capacity, minimize delays, and provide robust plans adaptable to unforeseen demand surges. Validated with real-world data, these OR applications provide theoretically sound and practically implementable tools. They offer significant improvements in ATM efficiency, workload distribution, and system robustness, paving the way for more adaptive and resilient airspace management in the face of evolving challenges.

2 - Functional Data Analysis in Flight Trajectory Clustering

GUGLIELMO LULLI, University of Milano-Bicocca, Milano, Italy, Nicos Pavlidis, Go Nam Lui, Sameer Alam, B Pang, C Raibulet

Machine learning (ML) is revolutionizing flight trajectory analysis, offering unprecedented capabilities to enhance safety, efficiency, and sustainability in aviation. This presentation showcases diverse ML applications that transform raw flight data into actionable intelligence. We explore how predictive models, leveraging techniques like regression and time-series analysis, can accurately forecast arrival times, fuel burn, and potential conflicts, enabling proactive decision-making. Unsupervised learning algorithms, such as clustering and anomaly detection, are examined for their power in identifying common flight patterns, detecting deviations from standard procedures, and flagging potential safety hazards from large-scale trajectory datasets (e.g., ADS-B). The presentation will demonstrate tangible benefits, including optimized route planning for reduced fuel consumption and emissions, improved airspace capacity utilization, and enhanced situational awareness for air traffic controllers and pilots. We will also touch upon the challenges of data integration and model validation in this critical domain. Ultimately, this exploration aims to underscore how ML-driven trajectory analysis contributes directly to a safer, more efficient, and environmentally conscious global air transportation system, paving the way for next-generation air traffic management. This work has been supported by the AI4ATM project, funded by both MAECI (Italy) and A*STAR (Singapore).

3 - Evaluation of near-Terminal Operation Performance Under Uncertainties in High-Density Airspace

Yutian Pang, The University of Texas at Austin, Austin, TX, United States

Future high-density airspace operations are sensitive to uncertainties from various aspects of the aviation system. This challenge is expected to intensify with the integration of highly automated and autonomous aircraft into the existing airspace. To address this, the present study evaluates near-terminal arrival performance under two sources of aeronautical communication uncertainty, (i) communication availability, (ii) communication system latency, as well as the uncertain human-induced pilot response delays. The analysis considers a congested arrival scenario with two converging flows one straight-in approach stream and one downwind stream merging via a base-to-final turn. Aircraft arrivals are generated by modified Poisson processes subject to minimum separation constraints, simulating high-density traffic operations. The merging logic incorporates fixed-duration turns, pilot response delays, and dynamic gap availability in real time. System performance is measured using runway throughput, the average delay (holding time) experienced by downwind aircraft, and the fraction of downwind arrivals that merge immediately without holding. The evaluation employs a Monte Carlo-based discrete event simulation to analyze system behavior across a wide range of conditions. To capture the impact of all scenarios, importance sampling techniques are incorporated, allowing efficient exploration of low-probability events that could significantly affect outcomes. The results provide the reliability levels of terminal operation performance metrics under different air traffic intensities, and the sensitivity of reliability to the communication availabilities. It emphasizes implications and guidance for future vectoring procedures in congested terminal areas, highlighting the impact of communication system uncertainties and pilot response delays to the efficiency and safety of civil operations.

4 - Prescriptive Analytics for Optimizing Airport Slot Allocation

Nuno Ribeiro, Singapore University of Technology and Design, Singapore, Singapore

This talk presents recent advancements in prescriptive analytics to support airport slot allocation and the determination of declared capacities. We explore a modeling framework that integrates mixed-integer linear programming (MILP) and heuristic algorithms to optimize slot allocation decisions, while incorporating queuing models to estimate airport delays and machine learning models to predict passenger connections.

The Practice Section of Informatics

Chair: SMA Bin Al Islam, Amazon.com, North Reading, MA, 01843, United States

1 - Optimizing Pick Operations Through Distributed Inventory Assignment in Fulfillment Centers

SMA Bin Al Islam, Amazon.com, North Reading, MA, United States, Michael Caldara, Mouhacine Benosman

Amazon's state-of-the-art multilevel containerized inventory system in its next-generation fulfillment center presents new optimization opportunities for customer fulfillment. Where before multi-item customer orders would need to be processed by multiple floors based on inventory availability, our robots now transport containers to and from a vertical lift to process that order on a single floor, thus simplifying downstream fulfillment processes. In this work, we explore several candidate approaches to optimally solve the container relocation problem. We find that traditional centralized optimization models are effective in solution quality; however, when planning across multiple floors, this formulation faces scalability limitations due to time complexity. To address these challenges, we develop a distributed optimization framework that decomposes the global inventory assignment problem into smaller, parallel sub-problems. Each floor-level sub-problem is formulated as a mixed-integer linear program and solved independently, while global coordination is achieved through a Lagrangian relaxation approach. We demonstrate through experimental evaluation that the distributed method offers substantial reductions in runtime while preserving key performance metrics.

2 - Scheduling Jobs for Print on Demand

Alfredo Nantes, Amazon, San Diego, CA, United States, Prem Viswanathan, Yaoguang Zhai

This paper presents a generalized assignment problem (GAP) inspired formulation for unrelated parallel machine scheduling with sequence-dependent setup times. We model the problem using configuration groups that define machine capabilities, reducing decision variables compared to conventional models. Assuming each machine implements configurations from a single group throughout the planning horizon eliminates the need to explicitly model sequence-dependent setups and track individual job completion times, simplifying the model. We apply this formulation to an industrial print optimization problem, demonstrating its effectiveness in balancing customer commitments, costs, and throughput. Experimental results show computational advantages, with the model scaling well and finding near-optimal solutions (relative gap < 1.26%) for large-scale problems of up to 100,000 jobs, 34 machines, and 15 configurations.

3 - Optimizing Delivery Speed Through Shipping Incentives

Prasanna Venkatesh Ramadas, Amazon, Bellevue, WA, United States, Bhaskar Vooradi, Krishna Pendyala

Online shopping experience heavily relies on delivery speed and on-time delivery (OTD), where Fulfillment by Merchant (FBM) sellers handle their own logistics unlike Fulfillment by Amazon (FBA) and often prioritize cost-efficiency over speed. Since faster and reliable deliveries significantly improve customer satisfaction and drive long-term benefits for both Amazon and sellers through increased sales and visibility, shipping discounts are provided as incentives for adopting speedier delivery options. To spend the shipping discount budget optimally for a better customer experience, we build a two-step discount model. The model firstly optimizes the overall delivery speed for all orders by maximizing the expected volume shipped through faster ship methods for a given budget. Then a machine learning model is applied to predict seller affinity on a ship method that is used to continuously refine the estimated expected volume used as input in the optimization model. This approach allows for a more strategic and effective use of shipping discounts, balancing cost considerations with the imperative of rapid delivery in the competitive e-commerce landscape.

Advances in Traffic Modeling and State Estimation

Invited Session

TSL: Intelligent Transportation Systems

Chair: Ruolin Li, University of Southern California, Los Angeles, CA, United States

1 - Integrating Differential Games of Truck-Borne Freight and Passenger Flows

Terry Friesz, Pennsylvania State University, University Park, PA, United States, Cheng-Chang Lin

The problem we study is the combined congestion of freight (truck) flows and passenger (automobile) flows occurring on the same road network when a portion of passenger vehicles are autonomous. Notably we model freight traffic as a dynamic spatial price equilibrium (DSPE) and passenger traffic as a dynamic user equilibrium (DUE) with superior routing information available to autonomous passenger vehicles (AVs). These modelling perspectives allow the fundamental observation that freight transportation is induced by the spatial separation of production and consumption activities to be directly invoked, while allowing passenger departure time and route choice to occur according to widely endorsed behavioral notions. They also provide the foundation for a model-based digital twin (DT) of urban traffic useful as a tool for congestion forecasting. The challenges of integrating the DSPE and DUE paradigms and setting the stage for a congestion DT will be reviewed, including: (1) finding a recognized mathematical formulation; (2) developing a 2-species (truck and passenger vehicle) path delay operator (PDO); (3) selecting and verifying that one or more algorithms are appropriate to the chosen formulation; (4) demonstrating existence of solutions; and (5) assessing whether the tasks of data assimilation, sensitivity analysis, and near real-time approximate solution can be carried out to an extent that make a digital twin (DT) of combined DSPE/DUE viable.

2 - When Altruism Meets Autonomy: Managing Weaving Ramp Congestion with Strategic AVs

Ruolin Li, University of Southern California, Los Angeles, CA, United States, Kexin Wang, Haohui He

Weaving ramps are critical bottlenecks in highway networks due to conflicting traffic flows and complex interactions among heterogeneous vehicle types. This study seeks to capture, predict, and optimize the aggregate lane-choice behavior of mainline vehicles approaching these zones. We first introduce a lane-choice model for human-driven vehicles (HDVs) based on the Wardrop equilibrium principle, validated through microscopic traffic simulations that demonstrate high predictive accuracy. Building on this foundation, we propose a bi-level Stackelberg-Wardrop framework for mixed traffic, in which connected and autonomous vehicles (CAVs) serve as strategic leaders. At the upper level, CAVs are centrally coordinated to optimize their lane-changing strategies for societal traffic conditions; at the lower level, HDVs adapt via equilibrium-based lane choice. We examine the impact of CAV integration across varying penetration rates and evaluate its effect on overall weaving zone performance. Finally, we explore incentive mechanisms for CAV cooperation by incorporating heterogeneous Social Value Orientations (SVO), highlighting the potential of altruistic behavior and strategic design to enhance social traffic outcomes.

3 - Large-Scale Inverse Learning of User Equilibrium via Multiconvex Optimization

Zhichen Liu, University of Michigan, Ann Arbor, MI, United States, Xi Lin, Yafeng Yin

This study develops a scalable multiconvex optimization framework for inverse learning, from multi-day link flow observations, of contextual travel demand and cost functions for constructing transportation network equilibrium models. The framework parameterizes unknown demand and cost functions using graph-diffusion-based convex bases and formulates the inverse learning problem as a multiconvex optimization. This multiconvex optimization is solved iteratively by addressing two constrained convex subproblems: a quadratic optimization with sparse constraints and a decomposed convex subproblem involving multiple traffic assignment problems. Under the assumption that observed flows are at equilibrium, the framework ensures a tight approximation of the underlying network equilibrium models. By leveraging open-source solvers, the proposed framework promises scalability for modeling large-scale transportation networks using partial link flow observations.

4 - Building Traffic Network Equilibrium Models with Vehicle Trajectory Data

Benjamin Rosenblad, University of Michigan, Ann Arbor, MI, United States, Xi Lin, Yafeng Yin

Transportation network equilibrium models are fundamental tools used in the planning and operation of transportation systems. They help planners evaluate the effectiveness of various improvement strategies and guide decisions on infrastructure investments and policy interventions. Although significant progress has been made in formulating and solving these models, empirical calibration is rather limited, due to the lack of traffic data and computational challenges. However, with the growing availability of vehicle trajectory data made possible by advances in connected vehicle technologies, new opportunities are emerging to overcome these barriers. This research introduces a computationally efficient, end-to-end learning framework that builds traffic equilibrium models directly from vehicle trajectory data. By relying solely on this data source, the approach reduces dependence on traditional inputs from local agencies, making it more adaptable and scalable across cities with varying data resources. Rather than replacing the comprehensive trip-based or activity-based models used in long-range planning, our goal is to develop lightweight models that can support short-term policy decisions and congestion mitigation efforts. By accepting minor trade-offs in behavioral realism for gains in computational speed and scalability, we aim to show that large-scale trajectory data can produce models with sufficient accuracy to meaningfully support decision-making.

Data Driven Control and Optimization of Stochastic Systems

Invited Session

Applied Probability Society

Chair: Andrew Lim, National University of Singapore, Singapore, Singapore

1 - Optimal Sequential Hypothesis Testing with Costly Information Acquisition

Luhao Zhang, Johns Hopkins University, Baltimore, MD, United States

We study the sequential testing problem of two alternative hypotheses when observations are costly. Mathematically, we frame this as an optimal stopping problem in which the decision-maker aims to minimize classification errors plus a running cost proportional to the duration of information acquisition. By formulating a value function that captures both the expected decision risk and the running cost, we derive a set of variational inequalities that govern the evolution of the optimal strategy. Our analysis encompasses two different informational regimes: Gaussian and Poisson. We characterize the continuation regions within which further information collection is optimal and derive monotonicity properties with respect to different parameters, including the noise level, running cost, difference between the two hypotheses, and the relative importance of false positive and false negative errors. For Poisson signals, we utilize a diffusion approximation to study the asymptotic regime of frequent small jumps. Overall, our model advances understanding of how observation costs reshape classical sequential hypothesis testing. It also offers practical guidelines for designing adaptive and non-adaptive testing schemes in medicine, engineering, and related fields under real-world resource constraints.

2 - Optimal Trade Execution with Learning: the Multi-Asset Case

Kok Tong Lim, National University of Singapore, Singapore, Singapore

We consider the problem of optimal trade execution with multiple assets over a finite horizon with a linear permanent price-impact function with parameters that are constant but unknown to the decision maker. The Bayesian stochastic control formulation of this problem is computationally and analytically intractable due to the nonlinearities of the posterior update equation and the dimensionality of the state, which consists of the trader's inventory level and the mean and covariance matrix of all the price-impact coefficients. Using the Hamilton-Jacobi-Bellman dynamic programming equation, we derive an asymptotic expansion of the value function and optimal trading rate in the high-noise regime and characterize the terms of this expansion as solutions of partial differential equations. The zeroth order term corresponds to the "plug-in" (exploitation) decision while higher order terms characterize the exploration strategy and the value of learning. All terms of the expansion can be easily computed by solving a system of recursive equations and play an integral role in the exploration-exploitation trade-off. The higher order terms provide insight into the impact of horizon and inventory on optimal exploration, and an analytical characterization of how to optimally learn interference effects.

3 - On the Bayesian Modeling and Regret Analysis of Nonstationary Bandits

Seungki Min, SNU Business School, Yuseong-Gu, Korea, Republic of

Analyses of nonstationary bandits are often split between two paradigms: adversarial nonstationary models (e.g., unknown sequences with a bounded number of changes or total variation), and stochastic nonstationary models (e.g., autoregressive processes). Adopting the latter approach, this talk presents a general Bayesian regret analysis framework from the paper "An Information-Theoretic Analysis of Nonstationary Bandit Learning", applicable to any stochastic nonstationarity model. Our main result reveals that the intrinsic difficulty of a nonstationary bandit problem is characterized by the entropy rate of the optimal action process. This talk aims to illustrate this key insight through a sharp comparison with established results from the adversarial framework.

4 - Data-Driven Merton's Strategies via Policy Randomization

Yanwei Jia, The Chinese University of Hong Kong, Shatin, Hong Kong, Min Dai, Yuchao Dong, Xunyu Zhou

We study Merton's expected utility maximization problem in an incomplete market, characterized by a factor process in addition to the stock price process, where all the model primitives are unknown. The agent under consideration is a price taker who has access only to the stock and factor value processes and the instantaneous volatility. We propose an auxiliary problem in which the agent can invoke policy randomization according to a specific class of Gaussian distributions, and prove that the mean of its optimal Gaussian policy solves the original Merton problem. With randomized policies, we are in the realm of continuous-time reinforcement learning (RL) recently developed in Wang et al. (2020) and Jia and Zhou (2022a, 2022b, 2023), enabling us to solve the auxiliary problem in a data-driven way without having to estimate the model primitives. Specifically, we establish a policy improvement theorem based on which we design both online and offline actor-critic RL algorithms for learning Merton's strategies. A key insight from this study is that RL in general and policy randomization in particular are useful beyond the purpose for exploration -- they can be employed as a technical tool to solve a problem that cannot be otherwise solved by mere deterministic policies. At last, we carry out both simulation and empirical studies in a stochastic volatility environment to demonstrate the decisive outperformance of the devised RL algorithms in comparison to the conventional model-based, plug-in method.

5 - The Exploration, Exploitation Robustness Tradeoff

Andrew Lim, National University of Singapore, Singapore, Singapore

Parameter uncertainty and model misspecification are fundamental concerns in multi-period data-driven decision making, but little is understood about the tradeoff between exploration, exploitation and robustness. To study this tradeoff, we consider a robust optimal stopping problem with Bayesian learning. We show that an ambiguity-averse decision maker spends less time exploring, even though model uncertainty is reduced by having more data, because the "learning shock" for each posterior update increases the sensitivity of the expected profit to model misspecification. We also show that a willingness to explore can be restored by introducing a hedging instrument that offsets the learning shock.

Co-Chair: Alexander Estes, University of Maryland, College Park, MD, United States

1 - Tri-Level Defender-Attacker-Defender Problem of Bidirectional Energy Supply Logistics

Hyunhwa Kim, University of Illinois Urbana-Champaign, Urbana, IL, United States, Eleftheria Kontou

A cyberattack on the power system could cause severe electricity outages. Sophisticated adversaries attack by magnifying the power load shed by disruption. At the same time, defenders like utility and city planners can harden potentially grid infrastructure in advance to alleviate the damage. During an outage, electric uncrewed aerial (UAVs) and ground (UGVs) vehicles can provide backup power using bidirectional energy exchange technology. These vehicles supply energy to external demand by discharging their batteries as mobile energy sources and recharge at charging infrastructures if needed. However, the functionality of charging infrastructure depends on the power system disruption because the required charging energy is transmitted through the power grid. We develop a tri-level defender-attacker-defender problem to provide a planning strategy for outages caused by cyberattacks. This problem integrates transportation and power systems with charging infrastructure connecting both networks. The problem consists of: (1) a fortification framework to minimize power load shed and travel distance by fortifying power lines; (2) an interdiction framework to maximize power load shed by damaging lines under limited attacker budget; and (3) an operational framework to determine UAV and UGV routes and charging station locations. The problem is formulated as a min-max-min model and decomposed into two bi-level problems. The defender's problem is solved using logic-based Benders' decomposition and adaptive large neighborhood search. The attacker's problem is reformulated into a single-level binary linear program. This model is applied to integrated transportation and power networks, providing planning insights as a response to coupled transport-power system cyberattacks.

2 - Decentralized Coordination of Autonomous Traffic Through Advanced Air Mobility Corridors

Jasmine Jerry Aloor, Massachusetts Institute of Technology, Cambridge, MA, United States, Hamsa Balakrishnan

"The use of dedicated corridors for Advanced Air Mobility (AAM) traffic is one of the most commonly proposed pathways to integrating them into existing airspace operations. Most prior research has focused on the design of networks of AAM corridors and conflict resolution for aircraft within corridors. It is also generally believed that while attractive from an implementation perspective, corridor-based operations may be inefficient, especially in the absence of centralized traffic management. In this paper, we show that contrary to this belief, it is possible for autonomous aircraft to learn to self-organize into corridor flows in decentralized settings. We illustrate our approach using scenarios in which fixed-wing aircraft need to safely and efficiently traverse (1) a single corridor with metering after the exit, (2) a sequence of two consecutive corridors, and (3) a corridor that splits into two. We find that in decentralized settings with only local information, the aircraft are able to conform to the corridor boundaries more than 95% of the time and reach their goal in a relatively efficient manner. Furthermore, tactical interventions to handle violations of the separation minimum are needed only infrequently in low- and medium-density settings. However, such tactical interventions become more frequently necessary only when traffic density is high."

3 - A Dynamic Model for Airline Fleeting and Scheduling

Jingxing Wang, University of California Berkeley, Berkeley, CA, United States, Chiwei Yan, Archis Ghate

COVID-19 has reshaped the global airline industry. Travel demands are volatile, and passengers have more flexibility in bookings and cancellations. More than ever, airlines have to be agile and adaptive while making operational decisions. We introduce a dynamic model to help airlines make adaptive fleeting and scheduling decisions based on stochastically evolving bookings. The model incorporates both arrivals (new bookings) and departures (cancellations). This significantly generalizes and strengthens previous modeling attempts. We develop a Lagrangian relaxation framework that decomposes the dynamic program defined on a large time-space network into separable flight-level problems. Owing to the complexities of this network, our Lagrangian dual problem is not straightforward to solve. We therefore develop a tailored yet simple projected subgradient algorithm that exploits the structure of this network for efficient solutions. We establish the correctness and convergence properties of this procedure. Our analysis yields new theoretical, algorithmic, and managerial insights into the dynamic fleeting and scheduling problem. We present computational experiments based on real-world airline data to demonstrate the potential benefits of this approach.

4 - Aircraft Trajectory Decisions for Combinatorial Sampling in the National Airspace

Lavanya Marla, University of Illinois at Urbana-Champaign, Urbana, IL, United States

We study the value of collecting information in highly non-stationary settings with spatial correlations and information decay, motivated by the lack of near real-time information for routing aircraft. We propose to use a fleet of en-route aircraft as weather "sensors" to sample and collect near-real-time information so as to reduce long-term uncertainty about the airspace. We develop a stylized graph structure to capture the combinatorial nature of realistic aircraft trajectory networks, and model the cost incurred due to weather and wind over each arc using a unique spatial-temporal correlation structure. We mathematically show how to optimally explore and collect information to maximize information gain first in temporally correlated environments and next in jointly spatially and temporally correlated environments under combinatorial network structures. We demonstrate first that it is possible to collect information by parsimonious but careful sampling of the airspace. Next we show that the fuel burn reduction due to this additional information is significant, resulting in reduced environmental impact of aviation.

5 - Strategic Capacity Planning for a Network of Aircraft Maintenance Facilities

JohnPaul Adimonyemma, FAMU-FSU College of Engineering, Tallahassee, FL, United States, Yanshuo Sun

Most existing studies in aircraft maintenance optimization have centered on check scheduling, often overlooking the critical role of capacity planning for maintenance stations. To minimize total maintenance costs, airlines must jointly optimize facility capacity and maintenance scheduling based on projected aircraft utilization. This study addresses that gap by proposing a novel integrated mixed-integer quadratic program optimization model that jointly optimizes station capacities, check scheduling, and aircraft-to-station assignments. This model accounts for fleet heterogeneity, station-specific capabilities, stations' capacity limits, and projected aircraft utilization with the aim of minimizing total maintenance cost. Due to the complexity of large instances, traditional solvers are impractical. Hence, we propose decomposition algorithms, including one augmented with machine learning. A major U.S. airline case study will be presented, which will enable airlines and professionals to properly plan for their maintenance operations.

6 - Rethinking Crew Pairing Optimization: A GPU Accelerated Approach

Filipe Cabral, American Airlines, Inc, Fort Worth, TX, United States, Yanqing Kuang

Airlines heavily rely on the Crew Pairing Problem (CPP) to minimize crew costs by creating flight sequences (pairings) that cover all scheduled flights while adhering to complex operational and regulatory constraints. Formulated as a set partitioning problem, CPP's vast solution space challenges traditional methods like branch-and-price and column generation to their computational limits. These algorithms can even become computationally infeasible for large legacy airlines. Our research approaches this challenge by leveraging the power of GPUs, the very hardware behind the recent success of Large Language Models and Deep Neural Networks. Specifically, we shift from the solution of computationally expensive linear systems inherent in Simplex and Interior Point methods to a more scalable approach using a first-order method called cuPDLP. Preliminary results using real-world airline data demonstrate significant performance gains over traditional CPU-based approaches, highlighting the potential of our method.

Learning and Experimentation

Invited Session

Revenue Management

Chair: Will Ma, Columbia Business School, New York, United States

Co-Chair: Jinglong Zhao, Boston University, Boston, MA, United States

1 - Experiment Design for Assortment Optimization

Xintong Yu, Columbia Business School DRO, NYC, NY, United States, Will Ma

We propose a structured experimental design framework for assortment optimization, aiming to improve parameter estimation across a wide range of consumer choice models. While discrete choice models are well-studied, how to *design experiments*—that is, which assortments to offer to best learn preferences—remains underexplored.

Our work makes two main contributions:

Deterministic Learning of Nest Structures: In nested logit models, products are grouped into latent “nests” reflecting correlated preferences. Typically assumed known, these nests are often unknown in practice. We show that, under exact choice probabilities, a simple and scalable non-adaptive experimental plan can recover the true nest structure using only a small number of queries. This solves a long-standing open problem.

Efficient Choice Estimation: Beyond nested logit, we evaluate our design on general models like MNL, Markov, and ranked list models. Compared to random assortment designs, our fixed plan achieves lower estimation error under equal sample budgets. Built on the Random Utility Model framework and leveraging existing estimation tools, our results isolate the benefit of design alone.

Overall, our framework offers both theoretical guarantees and strong empirical performance. It is especially impactful in large-scale settings—like e-commerce or fantasy sports—where choosing the right product mix is crucial. Our results demonstrate that strategic experimentation, rather than random trial-and-error, can significantly enhance learning of consumer behavior.

2 - A Generalized Bayesian Framework for Online Optimization

Kaizheng Wang, Columbia University, New York, NY, United States

We introduce a generalized Bayesian framework for online optimization, centered on a new concept of generalized posterior distribution that effectively summarizes uncertainty from partial knowledge. This approach extends existing Bayesian methods while offering enhanced flexibility to incorporate valuable prior knowledge, such as shape constraints on the objective function. New bandit problems derived from this framework are shown to achieve optimal regret bounds up to logarithmic factors.

3 - Data-Driven Sequential Search

Cagin Uru, Duke University, Durham, NC, United States, David Brown

How can one search effectively with limited prior knowledge on the distribution of alternative values? This paper addresses this question in the context of sequential search. In our data-driven setting, traditional methods that rely on a known value distribution no longer apply and feasible search policies are based solely on the history of explored alternative values. We seek to identify a policy that maximizes the worst-case ratio of expected reward compared to an oracle (referred to as Pandora) with full knowledge of the value distribution. We first consider a general setting where alternative values may follow any arbitrary distribution. We design simple policies that statically commit to a prespecified number of explorations. We show that these static policies guarantee a competitive ratio of at least $1/e \approx 37\%$ of the Pandora benchmark for any arbitrary value distribution. Our approach involves studying nature's problem to select a distribution to counter a policy and identifying worst-case distributions. Moreover, we study how the structure of the unknown value distribution influences achievable performance guarantees by considering a setting where feasible distributions belong to the class of monotone hazard rate distributions. In this case, we improve our guarantee to $(e/(e+1))^2 \approx 53\%$ of the Pandora benchmark. In both settings, we derive performance limits for feasible policies to complement our performance guarantee results. We illustrate the efficacy of our policies through numerical examples based on price search. Our results provide insights to the decision makers with no prior knowledge of value distributions across many search applications.

4 - Gen-DFL: Decision-Focused Generative Learning for Robust Decision Making

Prince Wang, Carnegie Mellon University, Pittsburgh, PA, United States

This talk introduces Gen-DFL, a framework that enhances traditional decision-focused learning by integrating generative models to adaptively sample uncertainty. Gen-DFL improves robustness in high-dimensional and risk-sensitive environments while maintaining interpretability and performance. Applications in logistics and scheduling highlight strong gains over baseline methods.

Self-Exciting Processes

Invited Session

Applied Probability Society

Chair: Andrew Daw, University of Southern California, Los Angeles, United States

1 - Single-Server Queues with State-Dependent Hawkes Arrivals

Guodong Pang, Rice University, Houston, TX, United States, Bo Li

We study single-server queues with Hawkes arrivals whose intensity process depends on the queue length or workload through the self-exciting function, and with i.i.d. general service times, under the first-come first-served discipline. We prove the functional law of large numbers (FLLNs) and functional central limit theorems (FCLTs) for the joint processes of the arrivals, queue-length and workload processes, in the heavy traffic regime. The fluid limit is given by a set of nonlinear integral equations such that the fluid queue or workload has a reflection at zero. We analyze the transient and equilibrium behaviors of the fluid limit, in particular, identifying the equilibrium points for the queue or workload fluid model. We assume that the fluid limit is at an equilibrium point in order to establish the FCLTs for the joint diffusion-scaled arrival, queue-length and workload processes in the critically load regime. When the equilibrium point of the queue is at zero, the limit for the joint processes satisfies a stochastic differential equation such that the queue-length or workload limit has a reflection at zero. In particular, the queue-length or workload process is equivalent in distribution to a generalized (possibly nonlinear drift) Ornstein-Uhlenbeck (OU) diffusion with reflection at zero. When the equilibrium point is positive, the limit for the joint processes is a diffusion process without reflection, in particular, the queue-length or workload process is a generalized OU diffusion.

2 - Spatiotemporal Hawkes Processes with a Graphon-Induced Connectivity Structure

Justin Baars, Universiteit van Amsterdam, Amsterdam, Netherlands, Roger Laeven, Michel Mandjes

We introduce a spatiotemporal self-exciting point process $\{N_t(x)\}$, boundedly finite both over time $[0, \infty)$ and space $\mathbb{X}$, with excitation structure determined by a graphon W on $\mathbb{X}^2$.

This graphon Hawkes process generalizes both the multivariate Hawkes process and the Hawkes process on a countable network, and despite being infinite-dimensional, it is surprisingly tractable.

After proving existence, uniqueness and stability results, we show, both in the annealed and in the quenched case, that for compact, Euclidean $\mathbb{X} \subset \mathbb{R}^m$, any graphon Hawkes process can be obtained as the suitable limit of d -dimensional Hawkes processes $\tilde{N}^d$, as $d \rightarrow \infty$.

Furthermore, in the stable regime, we establish an FLLN and an FCLT for our infinite-dimensional process on compact $\mathbb{X} \subset \mathbb{R}^m$, while in the unstable regime we prove divergence of $N_T(\mathbb{X})/T$, as $T \rightarrow \infty$.

Finally, we exploit a cluster representation to derive fixed-point equations for the Laplace functional of N , for which we set up a recursive approximation procedure. We apply these results to show that, starting with multivariate Hawkes processes $\tilde{N}^d_t$ converging to stable graphon Hawkes processes, the limits $d \rightarrow \infty$ and $t \rightarrow \infty$ commute.

3 - Multivariate Generalized Polya Processes and Applications

Brian Fralix, Clemson University, Clemson, SC, United States, Jeffrey Kharoufeh, David Pittman

We will examine various types of multivariate Generalized Polya Processes, as well as various stochastic models “fed” by these type of point processes. Connections to other models found within the literature on Polya urn processes will also be discussed.

4 - Dynamic Pricing Under Self-Exciting Arrival Processes

Longyuan Du, University of San Francisco, San Francisco, CA, United States, Quan Yuan, Ming Hu

We study dynamic pricing under a stochastic, non-linear, self-exciting demand arrival process over a finite sales horizon. We adopt such a correlated demand process to capture the phenomenon that customers who have made a purchase can inform and excite future customers to arrive. Specifically, the stochastic arrival intensity is

stimulated with an immediate boost after any purchase and gradually decays over time between two consecutive purchases. The arrival intensity is also affected by the market phase the seller operates in, a growth or maturity stage, which convexly or concavely shapes how many new customers informed customers can stimulate. We show that the optimal pricing policy depends on the current time and excitement level, which measures the currently accumulated influence that previously informed customers exert and is shown to be the only sufficient statistic for our problem. Over time, the seller tends to initially set a low price to attract early customers who can excite later arrivals and later increase the price to maximize profits. Perhaps surprisingly, for a given time, in the growth stage of the market, the optimal price rises with the excitement level, and conversely, in the maturity stage of the market, the optimal price drops with the excitement level. Moreover, we show that adopting the optimal time-varying (open-loop) pricing policy solved from the deterministic problem leads to only a constant performance loss from the optimal dynamic (i.e., contingent) pricing policy, which would not hold for the classic revenue management problem with a capacity constraint.

5 - Stopping Self-Excitement

Andrew Daw, University of Southern California, Los Angeles, CA, United States

From management of service interactions to studies of neural signal propagation, there is a subtle but fundamental challenge that comes with such endogenously spurred activity: when should you say it's over? If each point has the potential to beget future points, there is an inherent tradeoff between omission and excess: stop too early and you may miss further observations, but stop too late and you've wasted too much time. In this paper, we study an optimal stopping problem that aims to balance this omission-excess tradeoff within a cluster of history-driven events. We analyze and prescribe stopping policies for the self-exciting stochastic process through a transformation to the workload process for an M/D/1 queueing system. Then, to connect these model-based insights to practice, we draw upon ideas from the algorithms-with-predictions literature and improve the model-based policies to adapt to contextual information, such as the texts within a service interaction. Finally, we demonstrate the performance of these policies through application to a publicly available linguistics data set.

Solving Quadratic Unconstrained Binary Optimization Models on Quantum Computers"

Tutorial session

Tutorials

Chair: Nilay Noyan, AMAZON, Bellevue, WA, United States

1 - Solving Quadratic Unconstrained Binary Optimization Models on Quantum Computers

Sridhar Tayur, Carnegie Mellon University, Pittsburgh, PA, United States, Arut Rhik Mazumder

This tutorial offers a quick, hands-on introduction to solving Quadratic Unconstrained Binary Optimization (QUBO) models on currently available quantum computers and their simulators. We cover both IBM and D-Wave machines: IBM utilizes a gate-circuit architecture, and D-Wave is quantum annealer. We provide examples of three canonical problems and two models from practical applications. The tutorial is structured to bridge the gap between theory and practice: we begin with an overview of

QUBOs, explain their relevance and connection to quantum algorithms, introduce key quantum computing concepts, provide the foundations for two quantum heuristics, and provide detailed implementation guides. An associated GitHub repository provides the

codes in five companion notebooks. In addition to reaching undergraduate and graduate students in computationally intensive disciplines, this article aims to reach working industry professionals seeking to explore the potential of near-term quantum applications.

As our title indicates, this tutorial is intended to be a starting point in a journey towards solving more complex QUBOs on quantum computers.

Emerging Topics in Location and Logistics

Invited Session

Location Analysis

Chair: Sibel Alumur Alev, University of Waterloo, Waterloo, ON, Canada

1 - Demand-Driven Hub and Service Network Design Under Uncertainty

Hao Li, FICO, Oakville, ON, Canada

We consider a planning problem for freight transportation carriers that seeks to profitably match supply with demand while recognizing uncertainty in shipment volumes. On the supply side, the problem determines transportation network design decisions regarding hub locations and the number of vehicles to be dispatched within the network in each period of the planning horizon. On the demand side, the problem incorporates the carrier's ability to expand its service coverage by selectively accepting additional customer demands beyond its existing contractual base. Furthermore, while some of these additional customers seek a long-term commitment from the carrier, others are transactional and only require the transportation of a single set of shipments. We refer to this problem as the Demand-driven Hub and Service Network Design under Uncertainty problem and formulate it as a two-stage stochastic program. Further, we develop an enhanced Benders Decomposition-based solution method for solving instances of this model. The solution methodology is inspired by Partial Benders Decomposition, leveraging a problem reformulation that embeds subsets of subproblem variables and constraints into the master problem, while also incorporating valid inequalities to strengthen the formulation. We illustrate with an extensive computational study that the proposed method outperforms adaptations of benchmarks proposed for similar problems. We validate the benefits of solving the proposed model, which integrates decisions that have not yet been jointly modeled, with an analysis based on Sample Average Approximation.

2 - Electrification of Freight Transportation Hub Networks with Emissions-Sensitive Customers

Gita Taherkhani, Loyola University Chicago, Chicago, IL, United States, Dipayan Banerjee, Mike hewitt

This paper investigates a tactical and strategic planning problem faced by a motor carrier operating a fixed middle-mile hub network for clients sensitive to greenhouse gas (GHG) emissions. Commodities purchased by retailers from multiple vendors must be transported from their origins to destinations via a hub-to-hub network, with all-or-nothing service decisions. The carrier must decide which commodities to serve, how to route accepted shipments, where to install electric vehicle (EV) charging infrastructure, and how many diesel and electric trucks to deploy on each lane, all while satisfying client-specific GHG emission budgets. Emissions are estimated using the GLEC well-to-wheel framework and allocated proportionally among shippers. To support these decisions, we develop a mixed-integer programming formulation for hub network design. Using realistic instances, we conduct an extensive computational study on both deterministic and stochastic versions of the problem. The analysis aims to (1) evaluate the computational performance of the proposed model and (2) examine the impact of incorporating GHG emission constraints on optimal network design.

3 - Pattern-Based Kernel Search for the Single-Source Capacitated Facility Location Problem

Stefan Nickel, Karlsruhe Institute of Technology, Karlsruhe, Germany, Hannah Bakker, Gianfranco Guastaroba, Maria Grazia Speranza

We introduce Pattern-based Kernel Search (PaKS), a two-phase metaheuristic expanding the successful Kernel Search (KS) for the capacitated facility location problem with single sourcing (SSCFLP). KS leverages the fact that solving a sequence of small BIPs can be more efficient than solving one large BIP by partitioning decision variables into disjoint subsets — a kernel of “promising variables” and complementary buckets. An initial solution is obtained by solving the restricted BIP with only the kernel variables. Then, a sequence of restricted BIPs combining kernel and bucket variables is solved, progressively improving the solution and updating the kernel. The performance of kernel search is critically impacted by the partitioning of the variables into the kernel and the buckets. While KS relies solely on information from the LP relaxation, PaKS uses pattern recognition to analyze a series of modified LP relaxations in its first phase. As a result, facilities and customers are divided into regions, each region corresponding to a bucket. Leveraging this implied spatial information allows to drastically reduce the size of the buckets. For the SS-CFLP, the largest instances solved in the literature contain up to 1,000 facilities and customers each. Computational experiments show that PaKS outperforms state-of-the-art approaches even on benchmark instances containing up to 2,000 facilities and customers each, demonstrating its strong potential for solving large-scale problems.

4 - Handling Volunteer Convergence from An OR Perspective: Volunteer Based Team Formation

Bahar Yetis Kara, Ihsan Dogramaci Bilkent University, Ankara, Turkey, Egehan Ugras, Zehranaz Donmez

Search and Rescue (SAR) operations are essential in disaster response, particularly after earthquakes where immediate action saves lives. Their success depends on effective team management and coordination. Urban Search and Rescue (USAR) teams, specialized in rescuing people from collapsed structures, are classified by the International Search and Rescue Advisory Group (INSARAG) into three levels: Light, Medium, and Heavy. These multi-disciplinary teams are crucial for complex disaster environments. Our study presents a mathematical model for the formation and assignment of SAR teams. The model assigns volunteers to teams, forms teams with appropriate expertise, and allocates them to debris sites while considering operational constraints. The model incorporates debris site requirements and the feasibility of assigning specific team types to different debris locations. A key feature of our approach is the introduction of an additional team category between light and medium teams, designed to improve flexibility in SAR operations. This new team type allows for partially completed teams that can either be combined with international teams for full functionality or provide critical information on missing personnel needed to meet medium team requirements. The model identifies gaps in staffing and allows this information to be shared with professional chambers, NGOs, or relevant organizations to recruit the necessary personnel or adjust assignments as new volunteers arrive. Model is also applicable for different disaster scenarios. By incorporating this adaptive team structure, our model enhances coordination in disaster response, ensuring that SAR efforts can be dynamically adjusted based on resource availability.

Can Yin, University of Minnesota, Twin Cities, Minneapolis, MN, United States, Yiling Zhang

The rapid growth of e-commerce has increased demand for fast delivery, straining last-mile logistics. Additionally, traditional home deliveries often lead to missed packages and theft, raising costs and inefficiencies, while fixed parcel locker locations limit accessibility, especially in low-density areas. To overcome this, mobile parcel lockers provide a flexible alternative by dynamically relocating based on demand to improve efficiency and reduce customer travel. However, their implementation faces challenges, including responding to uncertain customer demand preferences, and balancing the interplay between long-term planning. Existing research largely emphasizes the latter challenge but overlooks the impact of dynamic and uncertain demand patterns. Our work addresses these gaps by proposing an integrated framework to guide the planning and scheduling of mobile parcel locker systems. In particular, first, we account for the interdependencies between customer demand and locker schedule and locations using a variant of the multinomial logit (MNL) model to represent customer preferences among different available options. Second, we consider the interactions between long-term scheduling decisions and operational capacity allocation under demand uncertainty following unknown distributions. The problem is formulated as a two-stage mixed 0-1 distributionally robust optimization (DRO) model. To solve the proposed models efficiently, we exploit the hidden discrete dual structure of the problem, identify the worst case distribution based on the supermodularity of second stage problem. Later, we propose an equivalent mixed-integer linear programming (MILP) reformulation. Additionally, we develop practical variants for flat-rate and locational pricing policies to accommodate real-world deployment.

2 - Stochastic Optimization Models for the Generalized Assignment Problem

Harshit Kothari, University of Wisconsin-Madison, Madison, WI, United States, Jim Luedtke, Luke Marshall, Konstantina Mellou

The Generalized Assignment Problem (GAP) involves assigning tasks to agents with capacity constraints, aiming to minimize total cost while respecting resource limits. In many real-world settings, uncertainty in task requirements and agent capacities introduces stochasticity, giving rise to the Stochastic Generalized Assignment Problem (SGAP). This talk addresses a variant of SGAP relevant to cloud service providers, where virtual machines (jobs) are assigned to physical machines under uncertainty in job demands and arrivals. We formulate this as a two-stage stochastic integer program: in the first stage, initial jobs are assigned, and in the second stage, additional jobs arrive with uncertain resource requirements and costs. First-stage assignments may be relocated, incurring relocation penalties. Due to the complexity of solving SGAP with integer recourse, we explore decomposition approaches like column generation.

3 - Dynamic Inspection Routing in Infrastructure Networks with Decision-Dependent Cascading Failures

Juan-Alberto Estrada-Garcia, University of Michigan, Ann Arbor, MI, United States, Siqian Shen

We study the problem of dynamically scheduling inspection routes in infrastructure systems, such as water distribution and power networks, under uncertainty and interdependent risks. These systems are characterized by aging components whose failures can propagate, triggering cascading disruptions across the system. We formulate a multistage stochastic dynamic integer program, where component failure probabilities evolve in a decision-dependent manner, and cascading effects are explicitly represented. To address the computational challenge, we develop a solution approach based on the Stochastic Dual Dynamic Integer Programming (SDDIP) algorithm and benchmark its performance against a Deep Q-learning method from the literature. We focus our evaluation on water distribution networks, whose mesh-like structure and operational interdependencies provide a realistic setting for analyzing the impact of routing decisions on cascading failure risk.

4 - Scalable and Robust in-Database Stochastic Optimization

Anh Mai, New York University Abu Dhabi, Abu Dhabi, United Arab Emirates

In-database stochastic optimization often involves choosing a multi-set of tuples (row in a relational database table) that optimizes an expected outcome while minimizing risks. Sample Average Approximation (SAA) uses millions of scenarios (realizations of stochastic attributes of all the tuples) to formulate an Integer Linear Program (ILP). This ILP contains millions of decision variables corresponding to the number of tuples in the database and a large set of artificial variables and constraints corresponding to the number of scenarios needed to reasonably approximate the optimal solution. On the other hand, SummarySearch formulates its ILP after reducing the number of constraints by summarizing the large set of scenarios into a much smaller set of conservative summaries. In this way, SummarySearch aims to achieve its scalability by searching for the fewest summaries that return a near-optimal solution. Nevertheless, the solutions found by SummarySearch or SAA lack robustness when the number of scenarios is limited and the empirical distribution is inaccurate. In contrast, Robust Satisficing (RS) directly optimizes a solution that reliably attains a target objective even when the true data distribution deviates significantly from the empirical one. However, RS lacks scalability due to having the same ILP size as SAA. In this work, we explore a hybrid algorithm that adapts RS for solving stochastic optimization in database while making it scalable via the scenario-summarization technique introduced in SummarySearch and via a novel variable pruning strategy.

5 - Stochastic Bilevel Optimization for Network Design of Multimodal Transit Systems

Suri Liu, Dalian University of Technology, Dalian, China, People's Republic of, Yiling Zhang, Beste Basciftci, Wenyan Wang

This paper investigates the network design problem of the multimodal transit system under travel time uncertainty. A stochastic bilevel model is proposed to capture the strategic interaction between the transit agency and the riders. The objective is to design a bus route network that balances the interests of both agents and achieves an equilibrium. A tree search algorithm is proposed to solve the large-sized bilevel model, which enumerates the follower responses and represents their behavior using a set of linear constraints, thereby converting the bilevel model to a single-level formulation. To address the computational intractability of exhaustively enumerating the responses of all followers, a Column-and-Constraint Generation algorithm is developed to obtain the optimal solution efficiently. The superiority of the proposed algorithm in comparison with existing single-level reformulations is evaluated on a small-sized synthetic dataset. Finally, the approach is applied to a real-world network design case, providing an analysis of the benefits of adopting the multimodal transit system.

1 - Electricity Markets with Consumer-Defined Carbon Costs: a New Paradigm for Greening the Grid

Wenqian Jiang, University of Wisconsin-Madison, Madison, WI, United States

An increasing number of electricity consumers can be characterized as carbon-sensitive, i.e. they are willing to adapt when (and in some cases where) they consume electricity based on the real-time carbon intensity of electricity. However, current electricity markets provide limited opportunity for consumers to express their preferences for low-carbon electricity. To provide consumers, ranging from carbon-agnostic to carbon-sensitive, with a tool to actively manage their roles in carbon emission mitigation, we propose a new green electricity market clearing paradigm, where consumers can not only bid for power but also assign a cost to the carbon emissions incurred by their electricity use. The centralized market clearing problem maximizes social welfare under consideration of carbon preferences, and from this problem, we derive an equivalent equilibrium formulation. Based on the equilibrium formulation, we show that differences in consumers' carbon costs and generators' carbon emission intensities result in carbon-adjusted electricity prices and prove that the proposed market clearing satisfies revenue adequacy and cost recovery. Our investigation informs the ongoing debate about carbon-aware market design in the electricity sector. Joint work with Line Roald.

2 - Improving the Accuracy of the DC Power Flow Approximation via Parameter Optimization

Daniel Molzahn, Georgia Institute of Technology, Atlanta, GA, United States, Babak Taheri

Many power system operation and planning problems use the DC power flow approximation to address computational challenges from the nonlinearity of the AC power flow equations. The DC power flow simplifies the AC power flow equations to a linear form that relates active power flows to phase angle differences across branches,

parameterized by coefficients based on the branches' susceptances. Inspired by techniques for training machine learning models and recent progress in differentiable optimization, this talk presents several algorithms that seek optimal coefficient and bias parameters to improve the DC power flow approximation's accuracy for various applications, including optimal power flow and optimal transmission switching.

3 - Dual Conic Proxy for Semidefinite Relaxation of AC Optimal Power Flow

Qiu Guancheng, Georgia Institute of Technology, Atlanta, GA, United States

The nonlinear, non-convex AC Optimal Power Flow (AC-OPF) problem is fundamental for power systems operations. The intrinsic complexity of AC-OPF has fueled a growing interest in the development of optimization proxies for the problem, i.e., machine learning models that predict high-quality, close-to-optimal solutions. More recently, dual conic proxy architectures have been proposed, which combine machine learning and convex relaxations of AC-OPF, to provide valid certificates of optimality using learning-based methods. Building on this methodology, this paper proposes, for the first time, a dual conic proxy architecture for the semidefinite (SDP) relaxation of AC-OPF problems. Although the SDP relaxation is stronger than the second-order cone relaxation considered in previous work, its practical use has been hindered by its computational cost. The proposed method combines a neural network with a differentiable dual completion strategy that leverages the structure of the dual SDP problem. This approach guarantees dual feasibility, and therefore valid dual bounds, while providing orders of magnitude of speedups compared to interior-point algorithms. The paper also leverages self-supervised learning, which alleviates the need for time-consuming data generation and allows to train the proposed models efficiently. Numerical experiments are presented on several power grid benchmarks with up to 500 buses. The results demonstrate that the proposed SDP-based proxies can outperform weaker conic relaxations, while providing several orders of magnitude speedups compared to a state-of-the-art interior-point SDP solver.

4 - Understanding and Mitigating Real-TIME Price Spikes in Power Markets

Alexander Derenchuk, Colorado School of Mines, Golden, CO, United States, Tomas Tapia, Yury Dvorkin, Daniel Bienstock, Alexandra Newman

In wholesale power markets, system operators use real-time balancing auctions to deploy and compensate additional generation necessary to account for deviations between expected and realized demand (i.e., volatility). Often, prices in these real-time markets greatly exceed the marginal cost of any individual power plant contributing generation to meet load. These price "spikes" can be caused by systemwide generation scarcity, which triggers administratively set prices that activate when there is a shortage of operating reserves. They can also be caused by local generation scarcity, which manifests as transmission network congestion. Under congestion, high prices can arise from penalties for exceeding flow limits on transmission lines in the economic dispatch algorithm used by the system operator. Increasing penetration of solar and wind generation in power systems can increase volatility and thus the likelihood of real-time systemwide scarcity. It can also increase on the system due to the typical placement of large wind and solar power plants in rural areas far from urban centers with high power demand. Using data from Oklahoma Gas and Electric (OGE) and the Southwest Power Pool (SPP), we identify the causes, locations, and timing of price spikes in the SPP grid region and analyze their potential impact on member utilities such as OGE. We then investigate whether strategic battery storage deployment at specific grid locations in critical periods could dampen or eliminate these spikes, and we identify optimal policies for battery storage deployment and operation. Joint work with Tomas Tapia, Yury Dvorkin, Alexandra Newman and Daniel Bienstock.

5 - Linear Relaxations for Large-Scale Acopf

Matias Villagra, Columbia University, New York City, NY, United States, Daniel Bienstock

In this talk, we present fast and scalable algorithms for computing dual bounds of challenging Multi-Period Security Constrained AC-OPF instances from the ARPA-E Grid Optimization Competition. We primarily focus on linear relaxations that are dynamically computed. We present results on very large instances. Joint work with Daniel Bienstock.

Improving Coordination of Interdependent Natural Gas and Power Systems during Winter Storms: Risks and Impacts

Invited Session

ENRE: Energy

Chair: Chiara Lo Prete, The Pennsylvania State University John and Willie Leone Family Department of Energy and Mineral Engi, University Park, PA, United States

1 - Predicting Gas-Fired Generator Performance Under Extreme Winter Weather in the Northeastern United States

Anamika Dubey, Washington State University, Pullman, WA, United States

Extreme winter weather events pose significant risks to the operation of gas-fired power generators. We utilize generator outage data from the NERC GADS, ambient temperature records from NOAA, and system demand data from NYISO and ISO New England in a two-part Bayesian regression model to predict the derated output of gas-fired generators in the Northeastern United States under extreme freezing conditions. The first stage employs Bayesian logistic regression to estimate the probability of a non-zero (derated) output, while the second stage applies Bayesian linear regression to predict the derated capacity conditioned upon non-outage scenarios. Results show that generators exhibit increasing probabilities of complete outages with decreasing temperature and increasing system demand. Although the model is currently limited by the aggregation of temperature data at the state level and incomplete event cause labelling, it provides a probabilistic framework to assess generator net available capacity during extreme winter scenarios. By leveraging this framework, system operators can identify most vulnerable generators to extreme cold weather and develop targeted planning strategies to enhance overall grid resilience. Access to more granular data, including generator-specific locations and accurately labelled outage causes, is necessary for improving model predictability and reducing uncertainty.

2 - Quantifying Winter Storm Risks on Interdependent Power and Natural Gas Systems

Malo Lahogue, Massachusetts Institute of Technology, Cambridge, MA, United States, Saurabh Amin, Rahman Khorramfar

Extreme winter storms increasingly threaten the reliability of interdependent natural gas and electric power systems by simultaneously disrupting gas-fired generation, reducing fuel availability, and increasing heating and electricity demand. As climate volatility intensifies, system operators and planners need tools to quantify the risk of such rare, high-impact events and to guide the design of more resilient systems. Conventional reliability assessments—such as N-1 contingency analysis, Monte Carlo simulation, and scenario tree generation—struggle to capture compound risks driven by weather-induced uncertainties. To address this gap, we develop a modular, data-driven framework to estimate the quantile-at-risk (or value-at-risk) of a user-defined resilience metric (e.g., unserved energy or outage duration), conditioned on temperature forecasts and system parameters. The framework integrates historical data on generator outages and recovery, a probabilistic scenario generator, and an adaptive stochastic importance sampling (A-SIS) procedure for efficient quantile estimation. Applied to the New England region, our framework identifies gas generator failure patterns that significantly elevate system risk under fuel and demand uncertainties driven by extreme winter conditions. Its modular design enables users to define resilience metrics, incorporate updated data, and interpret risk drivers. This work offers a scalable, interpretable approach to risk-informed energy system planning and operations under increasing climate and infrastructure uncertainty.

3 - Pipeline Capacity Allocation Mechanisms to Mitigate Fuel Supply Interruptions at Gas-Fired Power Plants

Ashish Radhakrishnan, Pennsylvania State University, STATE COLLEGE, PA, United States, Chiara Lo Prete

Fuel supply interruptions at gas-fired power plants during extreme winter weather remain a persistent challenge to electric system reliability. These disruptions are typically driven by spikes in residential and commercial gas demand, constrained pipeline capacity, and rigid legacy gas curtailment protocols that limit the flexibility to redirect gas to generators that contribute to power system reliability during periods of system stress. Although gas-fired power plants often hold firm transportation contracts, they are treated on equal footing with other firm customers, such as industrial users, without consideration for their critical role in maintaining electric system reliability during winter emergencies. This study investigates the design and analysis of pipeline capacity allocation mechanisms intended to reduce the risk of fuel supply interruptions at power plants during winter emergencies. We evaluate the cost and operational impacts of these mechanisms using a large-scale optimization model of the joint operation of natural gas and electricity systems. The model incorporates competing gas demand across sectors (residential, commercial, industrial and power plant), gas contract types, and emergency gas curtailment priority protocols. The proposed mechanisms for pipeline capacity allocation are tested on a case study representing the Northeastern U.S. during the 2014 Polar Vortex, a period characterized by extreme cold and significant stress on natural gas and electricity infrastructure. The analysis

provides insights into how alternative pipeline capacity allocation mechanisms could potentially improve gas-electric system coordination and enhance the electric system reliability under severe winter conditions.

4 - Steady Flow of Natural Gas in Pipeline Networks - Modeling Choices and Their Implication in Estimating Impact of Extreme Events

Kaarthik Sundar, Los Alamos National Laboratory, Los Alamos, NM, United States, Shriram Srinivasan, Anatoly Zlotnik, Russell Bent

Steady flow of natural gas through interstate pipeline networks is governed, in the most general sense, by nonlinear differential equations. To make these equations more tractable, it is common to neglect several mathematically inconvenient terms and thereby reduce them to a system of nonlinear algebraic equations. Typical simplifying assumptions include: (1) treating natural gas as an ideal gas (to govern the pressure–density relationship), (2) assuming an isothermal (constant-temperature) regime throughout the entire network, and (3) neglecting elevation changes. These simplified equations are widely used for operational optimization, state estimation, and assessing the impact of extreme events on gas-fired generators that, in turn, feed into the power grid. However, the pressure and flow estimates produced by such models can differ substantially from actual values in the pipeline. In this talk, we will begin with first principles, present the governing equations, and then detail the common simplifications found in the literature. Using simple pipeline models, we will demonstrate the errors introduced by each approximation and provide guidance on when each simplification is—or is not—appropriate for different variants of the steady-flow problem. Our goal is to help attendees select the modeling approach best suited to their specific application.

1 - Synthesizing Grid Data with Cyber Resilience and Privacy Guarantees

Vladimir Dvorkin, University of Michigan, Ann Arbor, MI, United States, Shengyang Wu

Differential privacy (DP) provides a principled approach to synthesizing data (e.g., loads) from real-world power systems while limiting the exposure of sensitive information. However, adversaries may exploit synthetic data to calibrate cyberattacks on the source grids. To control these risks, we propose new DP algorithms for synthesizing data that provide the source grids with both cyber resilience and privacy guarantees. The algorithms incorporate both normal operation and attack optimization models to balance the fidelity of synthesized data and cyber resilience. The resulting post-processing optimization is reformulated as a robust optimization problem, which is compatible with the exponential mechanism of DP to moderate its computational burden.

2 - From Static to Dynamic: Rethinking Transmission Limits in Wholesale Electricity Markets

Yury Dvorkin, Johns Hopkins University, Baltimore, MD, United States

Extreme weather events increasingly strain power system reliability, exposing limitations in traditional transmission planning and operations. Static line ratings, based on worst-case and conservative assumptions, often underutilize available capacity. While Dynamic Line Ratings (DLRs) offer a promising alternative by reflecting real-time conditions, their integration into market operations remains limited. This talk introduces a stochastic market framework that treats DLR-enabled transmission capacity as a time-dependent, stock-like resource. Using a conservative approximation of line temperature evolution, we formulate a chance-constrained multi-period DC optimal power flow problem and derive a convex reformulation of its non-convex constraints. This approach enables the calculation of energy and reserve prices while ensuring reliability under uncertainty. We demonstrate the model's efficacy and scalability on both an 11-zone and a full 1814-bus NYISO system, highlighting how DLRs can be operationalized for market-based dispatch and pricing under extreme conditions.

3 - Optimization Proxies Using Limited Labeled Data and Training TIME &Ndash; a Semi-Supervised Bayesian Neural Network Approach

Deepjyoti Deka, MIT, Cambridge, MA, United States, Parikshit Pareek, Kaarthik Sundar, Sidhant Misra, Abhijith Jayakumar

Constrained optimization problems arise in various engineering systems such as inventory management and power grids. Standard deep neural network (DNN) based machine learning proxies are ineffective in practical settings where labeled data is scarce and training times are limited. We propose a semi-supervised Bayesian Neural Networks (BNNs) based optimization proxy for this complex regime, wherein training commences in a sandwiched fashion, alternating between a supervised learning step for minimizing cost, and an unsupervised learning step for enforcing constraint feasibility. We show that the proposed semi-supervised BNN outperforms DNN architectures on important non-convex constrained optimization problems from energy network operations, achieving up to a tenfold reduction in expected maximum equality gap and halving the inequality gaps. Further, the BNN's ability to provide posterior samples is leveraged to construct practically meaningful probabilistic confidence bounds on performance using a limited validation data, unlike prior methods.

4 - Madnlp.Jl, Madncl.Jl, and Madqp.Jl: Gpu Solvers for Large-Scale Optimization

Alexis Montoison, Argonne National Laboratory, Chicago, IL, United States, François Pacaud, Sungho Shin, Mihai Anitescu

In recent years, the development of scalable continuous optimization solvers on GPUs has made significant progress, primarily driven by advances in GPU-based sparse linear algebra.

This talk presents a suite of Julia-based open-source solvers designed to efficiently tackle large-scale linear, quadratic, and nonlinear programming problems with full GPU acceleration.

We first introduce MadNLP.jl, a GPU-native solver for nonlinear programming (NLP) based on interior-point methods and sparse direct solvers.

It was the first solver in the suite and remains central to solving general nonlinear problems efficiently.

Building on this foundation, MadNCL.jl is a robust meta-solver that orchestrates multiple NLP solves to handle degeneracy, ill-conditioning, and to achieve high-accuracy solutions with tolerances below 1e-8.

The latest solver MadQP.jl, targets large-scale linear and quadratic programs (LP / QP).

All three solvers are based on second-order algorithms, enabling greater robustness and accuracy compared to purely first-order methods such as PDLP.

We present performance results on real-world benchmark instances, demonstrating substantial speedups between CPU and GPU implementations, while maintaining high solution quality.

5 - Robust Power Grid Defense Under Attacker Budget Uncertainty

Andrew Mastin, Lawrence Livermore National Laboratory, Livermore, CA, United States

Defending the power grid from attacks is often modeled in three stages. In the first stage, a defender hardens up to h components, making them invulnerable. In the second stage, an attacker disables up to k of the remaining vulnerable components. Finally, the system operator makes remedial adjustments to optimize performance on the surviving infrastructure. For a fixed attacker budget k , the Best Response Intersection algorithm has demonstrated the ability to identify optimal hardening strategies on large systems. However, experiments show that such strategies are not robust when the attacker's budget differs from the assumed value. We present a modified version of the Best Response Intersection algorithm to produce hardening strategies that are effective across a range of attacker budgets. We demonstrate its effectiveness on standard test problems.

1 - Optimization of Ship-Deployed Uav Collaborative Operation for Far Offshore Wind Turbine Blade Inspections**Feng Hui, Harbin Engineering University, Harbin, Heilongjiang Province, China, People's Republic of, YuZhen Hu**

Abstract With the far offshore and large-scale development of offshore wind power, inspecting wind turbine blades has become increasingly challenging. Unmanned Aerial Vehicles (UAVs), with flexible, cost-effective, and safe advantages have become an ideal alternative to manual inspection, and the ship-deployed UAV collaboration mode provides a novel solution to overcome endurance limitations and expand inspection coverage. This study focuses on optimizing the ship-deployed UAV collaborative operation for offshore wind turbine blade inspections. It considers the UAV's continuous inspection capabilities and flexible interactions with the ship to plan collaboration routes that minimize the inspection time span. To meet the multi-scale inspection requirements, this study proposes a two-level branch-and-bound algorithm and a two-stage greedy heuristic with slack, both embedding a second-order cone programming model to optimize UAV launch and retrieval locations. Numerical experiments validate the superiority of the collaborative mode and the solution method, and investigate the influence of key UAV parameters on inspection plans across various scenarios, providing decision support for efficient unmanned inspection of offshore wind turbine blades.

Keywords far offshore wind farm; wind turbine blade inspection; ship-deployed UAV; Path Optimization

2 - Integrated Design of a Green Hydrogen Production System Under Climate and Demand Uncertainty**MINZHUO HUANG, King Abdullah University of Science and Technology, Jeddah, Saudi Arabia, Ricardo Lima, Omar Knio**

This study presents a comprehensive modeling framework for designing an integrated green hydrogen production systems in hot, arid regions like Saudi Arabia. These areas offer strong solar potential but face freshwater scarcity and fluctuating renewable energy availability. Furthermore, climate change introduces long-term shifts in resource availability and operational reliability, while hydrogen demand profiles remain uncertain due to varying local and global applications. To address this, the model incorporates CMIP6 climate projections and multiple demand profiles, including a local continuous demand and an export-oriented pattern.

The system integrates photovoltaic and wind generation, concentrated solar power with thermal storage, batteries, seawater reverse osmosis desalination, PEM electrolysis, and hydrogen storage.

A two-stage stochastic program is proposed: the first stage determines investments in energy, water, and hydrogen infrastructure, while the second optimizes operations under hourly weather and demand scenarios to minimize total cost and the leveled cost of hydrogen (LCOH).

To ensure computational tractability over multi-year horizons with hourly resolution, the model is reformulated as a mixed-integer linear program from a mixed-integer nonlinear program. Case study for Saudi Arabia demonstrates system's operational resilience and ability to minimize expected LCOH across varying climate and demand scenarios. Also, detailed results, including the value of stochastic solution and perfect information are discussed, as well as the system designs and LCOH obtained with alternative climate scenarios.

This work underscores the necessity of incorporating uncertainty into green hydrogen infrastructure planning and offers a scalable, technically feasible model that can be adapted to other regions with similar renewable resource profiles.

3 - An Exact Penalty Riemannian Alternating Direction Method of Multipliers**Gino J. Lim, University of Houston, Houston, TX, United States, Farzane Ezzati, Zhijie Sasha Dong**

We consider a class of binary programming problems with convex objectives. Such problems arise in diverse applications, including microgrid planning, portfolio optimization, production planning, and machine learning tasks such as sparse principal component analysis, feature selection, and prototype selection in clustering. We propose an Exact Penalty Riemannian Alternating Direction Method of Multipliers (EPR-ADMM) to solve this class of discrete non-convex problems. The binary constraints are reformulated via an exact penalty term in the objective and a $n - 1$ -dimensional sphere manifold embedded in Euclidean space. Each iteration of the algorithm involves computationally simple steps. We analyze the algorithm's computational complexity and establish convergence to first-order KKT points, achieving an ϵ -tolerance satisfaction of the exact penalty conditions. To the best of our knowledge, this is the first work to investigate exact penalty properties in Riemannian optimization within the ADMM framework. Numerical experiments on representative problem instances demonstrate the effectiveness of the proposed method.

Keywords: Binary Programming, Riemannian Manifold, Exact Penalty, ADMM.

4 - A Post Processing on Locational Marginal Costs Considering Fixed Losses on DC Optimal Power Flow**Bruno Amaral, PSR, Rio de Janeiro, Brazil, Tiago Andrade, Sergio Granville, Luiz Carlos da Costa**

The economic dispatch problem is used by system operators to determine optimal generation and storage schedules that minimize operational costs while satisfying physical, economic, and environmental constraints. A key output of these models is the locational energy price, which varies across both space and time. Accurate network modeling improves price signals by capturing equipment limits and the dynamics of energy flows. In a simplified setting without congestion or explicit losses, neighboring nodes would have identical prices. In practice, however, network losses introduce spatial price differences even in the absence of congestion.

Explicitly modeling losses is computationally demanding for large networks, making such models intractable for large systems or long planning horizons. To address this, we propose an efficient method to approximate the effect of losses on nodal prices. Rather than modeling losses directly, our approach post-processes prices from simulations using a simplified network based on Power Transfer Distribution Factors (PTDFs), with fixed losses incorporated as nodal demands. While fixing the losses yields reasonable generation and flow results, it fails to reflect well in nodal prices.

To overcome this, we apply a post-processing adjustment to marginal prices using PTDFs and the optimal generation response, estimating the impact of losses on prices when marginal demand increases at each node. Our results show that the method accurately captures both spatial and temporal variations in nodal prices while significantly reducing computational requirements. Thus, we are able to solve large systems with complex network with limited computational resources.

5 - Enhancing Power Grid Resilience: a Risk-Averse Stochastic Optimization Approach for Infrastructure Hardening**Minhang Zhou, University of Arizona, Tucson, AZ, United States, Pavlo Krokhmal**

Hurricanes remain a major threat to overhead distribution networks. This study investigates covered conductors as a cost-effective hardening option that reduces weather-related line faults and service interruptions. We formulate a two-stage stochastic program in which the degree of conductor coverage is selected in the first stage, while the second-stage minimizes total load shedding once hurricane damage is realized. A principal challenge is the decision-dependent uncertainty. To address risk preferences, several stochastic optimization models are proposed, including the traditional risk-neutral formulation and risk-averse extensions based on both linear and non-linear

coherent measures of risk. Exact solution algorithms that employ Benders decomposition and polyhedral approximations of nonlinear constraints have been proposed. Computational experiments on the IEEE 33-bus system demonstrate the properties of the constructed models, as well as the efficiency of the proposed algorithms.

6 - Desalination Investment Decisions in Water-Stressed Regions

Yolanda Matamala, Universidad Católica de la Santísima Concepción, Concepción, Chile

Water scarcity represents a critical challenge for sustainable development, especially in water-stressed regions where projections indicate 33 countries will face severe water scarcity by 2040. This study proposes a methodology based on a Stackelberg model to evaluate the synergy between freshwater markets and electricity, considering the integration of desalination technologies and their impact on electricity prices. Our research addresses two critical uncertainties: the risk of increasing water scarcity and the impact on energy systems from incorporating desalination plants. Results demonstrate that integrating desalination with freshwater management creates viable pathways for emission reduction through green and blue hydrogen production, providing insurance against water availability risks while generating a significant increase in electricity demand. Our analysis indicates that balanced technological portfolios incorporating diverse renewable sources, energy storage, and strategic desalination integration offer more resilient pathways to achieve both water security and decarbonization. The methodology provides policymakers with robust frameworks for developing strategies that address the complex interrelationships between energy production, water resources, and uncertainty management in water-stressed contexts.

7 - Optimization-Based Electricity Pricing for Effective Demand Response

Joonmo Sung, Yonsei University, Seoul, Korea, Republic of, Soongeol Kwon

This study proposes a framework for establishing electricity pricing schemes to support the effective implementation of demand response programs. The proposed framework utilizes an optimization model that integrates energy-aware production scheduling, aiming to encourage load shifting through a combination of energy charges and demand charges based on peak demand. To effectively manage the peak demand, it is essential to design a balanced pricing structure between time-varying pricing and demand charge rate. The framework enables electricity utilities to determine appropriate demand charge levels to regulate peak demand by analyzing the interrelationship between energy charges and peak demand. Numerical experiments were conducted using real-world electricity tariffs in a parallel machine scheduling environment. The results demonstrate that the proposed framework aids utilities in making informed pricing decisions under various operational conditions. This study contributes to promoting voluntary changes in electricity consumption patterns and enhancing the success of demand response programs.

8 - Optimization of Hydrogen Supply Operations for Decarbonizing Energy-Intensive Industries: a Multi-Timescale Rolling Horizon Approach

Giulia Fede, NTNU, Trondheim, Norway, Fabio Sgarbossa, Daniel F. Silva

The replacement of natural gas with green hydrogen, produced via water electrolysis using renewable energy sources, is increasingly recognized as a promising decarbonization strategy for energy-intensive industries. However, the feasibility of this transition largely depends on the economic viability of hydrogen supply, highlighting the importance of optimized hydrogen supply operations to minimize costs. This study develops a Mixed-Integer Nonlinear Programming (MINLP) model to optimize on-site green hydrogen production, which can be complemented by external hydrogen delivery when required. The model explicitly captures key operational dynamics, including variable loads, transitions between operational states, and efficiency degradation of the electrolyzer stack. The MINLP formulation is embedded within a multi-timescale rolling horizon framework. The rolling horizon approach enables reactive hydrogen supply scheduling to address uncertainties, such as fluctuations in renewable energy availability and hydrogen demand. The multi-timescale structure distinguishes between short-term decisions (e.g., operational states and variable loads of the electrolyzer) and long-term decisions (e.g., scheduling of truck deliveries), consequently accounting for their distinct implementation lead time requirements. Overall, the proposed approach aims to support cost-effective integration of green hydrogen into energy-intensive industrial processes while ensuring continuous and reliable fuel supply.

1 - Blockchain Driven Scope 3 Emission Disclosure for Eco-Conscious Consumer-Oriented Platform Economy

Yuqian Wang, Renmin University of China, Beijing, China, People's Republic of, Jianghua Wu

Platform-led supply chains are adopting blockchain-powered Scope 3 carbon emissions in addition to Scope1-2 carbon emissions when designing their carbon footprint reduction (CFR) project to accommodate eco-conscious consumers. There are two common types of Scope 3 emissions disclosures: Closed-loop (C-Scope 3) which includes emissions from all members in the supply chain, and Cradle-to-Gate (U-Scope 3) which includes emissions only from upstream members. This paper considers a supply chain consisting of a platform, an upstream supplier and a downstream logistics service provider. We explore the effectiveness of the platform and supply chain in achieving economic and environmental goals under different carbon disclosure. Firstly, our results suggest that when the CFR subsidy is low with lower initial emission transparency and traceability cost, adopting U-Scope 1-3 and C-Scope 1-3 emission disclosure strategies can benefit the platform and the supply chain. However, C-Scope 1-3 (instead of U-Scope 1-3) is more likely to achieve win-win (environment-economic) Pareto improvement for both the platform and the supply chain. Secondly, when traceability cost (CFR subsidy) is low, C-Scope3(Scope1-2) is the most environmentally and economically beneficial strategy. Thirdly, the U-Scope3 (C-Scope3) optimal CFR subsidy is larger when the upstream (downstream) margin is larger. Moreover, as for designing logistic mode, when the cost of self-run logistic is low, lower CFR subsidy and traceability cost leads to adopting self-run logistic strategy benefits the platform and the supply chain. This provides management insights for disclosure strategy, emission incentive design and logistic mode selection.

2 - ESG Reports as Decision Support: Topic Modeling, Investor Behavior, and Market Implications

Yichuan Wang, Northern Arizona University, Flagstaff, AZ, United States, Jun Cheng, Yuyu Liu, Suying Sun

We examine the informational value of corporate ESG reports for sustainable investment and decision-making. Using a large sample of ESG reports from Chinese listed firms, we apply Latent Dirichlet Allocation (LDA) to extract narrative topics and employ an XGBoost model with Bayesian optimization to predict institutional investors' shareholding decisions. Interpretable machine learning methods (e.g., feature importance, SHAP values, and accumulated local effects) reveal which ESG topics and tones most strongly influence investor behavior, uncovering nonlinear effects often overlooked in prior work. In addition, we construct hedging portfolios based on ESG narrative topics and tones, many of which generate significant excess returns. These findings suggest that ESG reports contain underutilized decision-relevant information, with implications for sustainable investment, market efficiency, and corporate ESG disclosure strategies. Our study contributes to the literature by integrating textual analysis with advanced machine learning to demonstrate how ESG narratives shape capital allocation and support sustainable operations.

3 - Motives and Results of Sustainable Supply Chain Practices: An Empirical Investigation from An Integrated Theoretical Perspective

Xianghui Peng, Penn State University - Erie, Erie, PA, United States, Lu Xu, Xinyu Wei, Ying Cao, Victor Prybutok

This study examines the existing approaches and frameworks on sustainable supply chain management (SSCM). Theories and practices from other fields, including quality management, supply chain management, and management (stakeholder theory and institutional theory), are explored to identify their contribution to theory development in SSCM. Drawing upon these theories and practices, a research model for SSCM is developed with an integrated theoretical perspective. The developed research model

integrates leadership, instrumental motives, relational motives, and moral motives, along with SSCM practices to drive economic results, social results, and environmental results of an organization. The developed research model provides a comprehensive overview of the functioning mechanism of SSCM at an organizational level. We empirically test and validate the research model through survey data using a structural equation modeling approach. The construct measurements are tested and validated first. The research model is supported by empirical results, which provide rich evidence for theory development and guiding industry practices.

1 - Location and Capacity Planning of Substance use Treatment Facilities for Maximizing Access and Population Health Outcomes

Zixuan Feng, The Pennsylvania State University, University Park, PA, United States, Qiushi Chen, Paul Griffin, Pengyi Shi

The opioid epidemic has devastated communities across the US, causing more than 800,000 deaths over the past two decades and costing \$2.7 trillion economic burden in 2023 alone. As more resources became available for expanding treatment capacities, a practical question arises on how to optimally allocate treatment resources geographically. Although travel distance has been shown to significantly impact treatment retention, few studies have considered this critical factor for strategic planning of treatment capacities. To address this gap, we developed a data-driven approach to guide the capacity allocation aimed at curbing the impact of the opioid epidemic. We formulated a discrete-time compartment model to characterize the dynamic course of opioid use disorder, in-treatment, and recovery for patients from different regions and treatment facilities at different locations. In this model, patients' travel distance affected not only treatment retention rates but also their preferences in choosing a treatment location when initiating treatment. We further incorporated this dynamic model in a mixed-integer program that optimizes the allocation of treatment capacity to possible treatment facility locations to minimize the overdose deaths. In our computational study, we estimated treatment retention rates based on travel distances using patient-level data from a clinical study, and calibrated other transition parameters against public health data for the opioid epidemic at the state level. We compared total overdose deaths over the planning horizon under the optimal policy derived from our proposed approach with other heuristic capacity allocation strategies.

2 - A Multi-Agent Reinforcement Learning Algorithm for Personalized Recommendations in Bipolar Disorder

Sidian Lin, Harvard University, Cambridge, MA, United States, Soroush Saghaian, Jessica M. Lipschitz, Katherine E. Burdick

This study introduces a novel multi-agent reinforcement learning (MARL) algorithm designed for identifying and optimizing personalized recommendations in bipolar disorder. The algorithm leverages longitudinal offline data from wearables to recommend self-care strategies tailored to individual patients. We focus on self-care strategies involving physical activity (measured by steps), sleep duration, and bedtime consistency, aiming to reduce the periods of mood exacerbations. A key innovation of our MARL approach is the integration of copulas to model inter-agent dependencies, enhancing coordination among agents and improving policy learning. Findings suggest that following our algorithm's self-care recommendations could significantly reduce periods of elevated mood symptoms, resulting in improved overall well-being. Finally, the algorithm offers important clinical insights for treating bipolar patients, and shows promising theoretical properties independent of the specific application. Thus, this work not only advances MARL applications in personalized healthcare but also provides a new algorithmic approach for adaptive interventions in a wide range of chronic diseases.

3 - Dynamic Programming for Coordinated Care Across Multiple Chronic Conditions

Kuofu Liu, University of Michigan, Ann Arbor, MI, United States, Luke DeRoos, Amirhossein Moosavi, Mariel Lavieri, Jason Miller, Joshua Stein

In the US, four in ten adults live with two or more chronic health conditions. For many of these conditions, treatment timing is determined by the maximum safe treatment interval (the longest allowable gap between consecutive treatments). Coordinating care across multiple conditions can reduce patient costs and improve their experience without compromising health outcomes. In this study, we develop a dynamic programming approach to optimize treatment synchronization of patients with multiple chronic conditions based on their maximum safe treatment intervals. Our analysis determines when it is optimal to synchronize treatments across conditions versus treating them independently, and we derive the corresponding optimal synchronization policy. For complex scenarios involving many conditions, we propose a closed-form heuristic and establish a bound on its regret. We demonstrate the approach through a case study of patients with bilateral (two-eye) age-related macular degeneration, a condition in which treatment needs often differ between eyes. The results indicate that synchronizing treatments could save US patients up to \$582 million annually in direct costs.

4 - Dynamic Nonuse Risk Estimation for Timely Interventions in Transplantation

Umur Kose, Virginia Tech, Blacksburg, VA, United States

Over 90,000 patients in the U.S. await kidney transplants, yet nearly 28% of recovered kidneys go unused each year. Existing risk estimation models fall short in predicting kidney nonuse because they often overlook key operational realities of the allocation process including the dynamic accumulation of cold ischemia time (CIT), evolving responses from transplant centers during the match run, and critical geographic and logistical factors. Moreover, these models treat nonuse as a binary outcome, ignoring its inherently time-dependent nature. To address these limitations, we develop a dynamic survival analysis framework to predict kidney utilization outcomes in real time during the match run. Our approach combines baseline donor characteristics, such as demographics and clinical lab values, with temporal and spatial features, including accumulated CIT, rejection reasons, the proximity of donor hospitals to major airports, and the density of nearby transplant centers. Our models achieve strong performance as measured by the time-dependent concordance index. Feature importance analysis using SHAP values highlights that several dynamic and spatial variables play a dominant role in predicting kidney nonuse. Our framework can be operationalized within organ procurement workflows to identify kidneys at elevated risk of nonuse and trigger timely, targeted interventions before CIT accumulation reduces transplant viability.

5 - Modeling the Potential Effects of Obstetric Unit Closures on Delivery Volume and Distance to Care

Lauren Steimle, Georgia Institute of Technology, Atlanta, GA, United States, Meghan Meredith, Margaret Carrel, Stephanie Radke

There are known risks associated with childbirth in rural obstetric units with low delivery volume. However, there are concerns that the consolidation of patient volume through the closure of rural obstetric units may reduce already limited access to obstetric care. We use a mathematical optimization model to determine strategic obstetric facility closures that would ensure all open obstetric units have at least 500 deliveries per year, while minimizing the overall travel distance to obstetric care. The model assumes all patients seek care at their closest obstetric care facility and uses data from the U.S. Census Bureau for two states: Iowa and Georgia. In the model, Georgia currently has 15 low-volume (<500 annual births) rural hospitals. After 10 strategic closures, all obstetric units are projected to have at least 500 annual births. Among those who would have to travel farther due to the closures, the average travel distance would increase by 10.6 miles (from 8.7 to 19.3 miles). Iowa has 34 low-volume rural hospitals. After 25 closures, all obstetric units are projected to have at least 500 annual births. The average travel distance would increase by 14.5 miles (from 11.5 to 26.0 miles) among those who would have to travel farther. This conceptual model demonstrates the trade-offs between the consolidation of delivery volume and geographic access to care. This work illustrates that coordinated and thoughtful closures of low-volume obstetric units that are not geographically isolated may result in the consolidation of delivery volume with small impacts on travel distance to care.

Global Optimization Methods in Robust and Stochastic Programming

Invited Session

OPT: Global Optimization

Chair: Shixuan Zhang, Texas A&M University, College Station, TX, United States

1 - Global Decomposition Methods for Stochastic Minlp

Joseph Scott, Georgia Institute of Technology, Atlanta, GA, United States, Jingzhi Yang

This talk presents results from a numerical study identifying key bottlenecks in decomposition algorithms for solving nonconvex two-stage stochastic mixed-integer nonlinear programs (SMINLPs). SMINLPs are difficult to solve due to nonconvexity and large scale. To address this, decomposition methods like those by Cao & Zavala (CZ) and Li & Grossmann (LG) project the problem into the first-stage space and perform Branch-and-Bound (B&B) on the first stage only while still guaranteeing global optimality. Good performance of both methods is only observed when the problem has a small first-stage decision space or the problem is solved at the root node using cuts or bound tightening. The slow convergence of both methods in other problems is hypothesized to be caused by the cluster problem—a very large number of small B&B nodes in the immediate vicinity of the global solution.

From clustering theory, first-order convergence lower bounding scheme suffice to eliminate clustering at a constrained minimizer if the objective grows linearly in all feasible directions. Our numerical study on five benchmark SMINLPs showed that both methods are at least first-order convergence empirically confirmed by the results from prior work by Robertson et al. who investigated the convergence order of CZ and LG methods under different assumptions about problem geometry. However, two SMINLPs still show signs of clustering in contrast to the prediction by the clustering theory. The talk will conclude with a discussion of possible paths forward given these new observations.

2 - Moment Relaxations for Wasserstein Distributionally Robust Optimization

Shixuan Zhang, Texas A&M University, College Station, TX, United States, Suhan Zhong

We study moment relaxations for data-driven Wasserstein distributionally robust optimization. In particular, we identify conditions that ensure asymptotic consistency of the relaxations, for both single- and two-stage problems, as the Wasserstein radius approaches zero. Numerical experiments are also included to show the effectiveness of these relaxations.

3 - Disjunctive Benders Decomposition

Geunyeong Byeon, Arizona State University, Tempe, AZ, United States, Kaiwen Fang, Inho Sin

This paper presents a novel approach to enhancing Benders decomposition by incorporating the generation of valid inequalities for the convex hull of the Benders reformulation, addressing the limitation of conventional Benders decomposition, which typically generates cuts that are only tight with respect to the continuous relaxation. Our method efficiently integrates disjunctive programming theory with Benders decomposition, introducing a new routine that leverages existing cut-generating oracles for uncovering constraints required to construct valid inequalities for the convex hull. For mixed-binary linear programs, this approach eliminates the need to solve the master problem as a mixed-integer program entirely. Additionally, we extend the a posteriori strengthening and lifting procedure for lift-and-project cuts into the Benders decomposition framework in a straightforward and efficient manner, and present an approximate routine for generating lift-and-project cuts. Numerical studies on large-scale uncapacitated and capacitated facility location problems demonstrate the effectiveness of our approach, reducing the number of nodes explored in the branch-and-bound tree by orders of magnitude to reach the lower bound attained by a conventional Benders decomposition.

4 - Multistage Robust Optimization with Predictions

Shuai Li, Georgia Institute of Technology, Atlanta, GA, United States, Xin Chen, Weijun Xie

We study a single-dimensional, multi-stage robust control problem with linear system dynamics, convex state and action costs, and box-type uncertainty sets. Beyond the standard robust control setup, we incorporate a key feature: the uncertainty sets shrink as the decision-maker approaches each stage, reflecting the progressive acquisition of information. The degree of shrinkage is assumed to be known in advance. This model extends the classical robust control framework and aligns with emerging work on algorithms with predictions.

While dynamic programming is effective in the static uncertainty setting, we show it becomes computationally intractable in our model due to the curse of dimensionality. We therefore focus on the decision rule approach, particularly affine policies. We prove that affine policies remain optimal when uncertainty sets begin to shrink only one step before their realization. However, if the shrinkage begins two steps ahead, affine policies become suboptimal, and we construct a counterexample to demonstrate this.

To evaluate the performance gap of affine policies in this more general setting, we propose two lower bounds: one based on a dual affine policy, which offers tighter bounds but at greater computational cost, and another using information relaxation, which is more scalable but looser. Finally, we validate our theoretical insights through numerical experiments.

5 - Bayesian Optimization of Risk with Student-T Process Prior

Alexander Vinel, Auburn University, Auburn, AL, United States, Armin Khayyer

We consider the problem of optimization of tail risk measures (particularly Conditional-Value-at-Risk, CVaR) for black-box functions. We follow the Bayesian optimization framework with a few variations compared to the traditional implementations. We consider the potential to employ the Student-t process instead of the commonly used Gaussian process as the prior in the Bayesian optimization framework, since it places a larger emphasis on the extreme outliers. To this end, we provide a closed-form formulas for a collection of acquisition functions and then demonstrate how the Student-t process version of Bayesian optimization of risk can be organized for optimization of risk. We will then present some preliminary results with benchmark functions using CVaR as the objective.

1 - Community Factors Influencing the Duration of Buprenorphine Treatment in Individuals with Opioid use Disorder

Carolina Vivas-Valencia, The University of Texas at San Antonio, San Antonio, TX, United States, Paula Jaimes-Buitron, Kehe Zhang, Wanru Guo, Yanmin Gong, Yuanxiang Guo, Cici Baurer

Opioid Use Disorder is a significant public health issue in the United States, with fewer than 25% of diagnosed individuals starting treatment, and more than half discontinuing within a year. Medications for Opioid Use Disorder, such as buprenorphine, methadone, and naltrexone, are effective in reducing the risk of overdose; however, long-term adherence to treatment is crucial to minimize relapse and mortality rates. This study explores the relationship between the duration of buprenorphine treatment and social determinants of health using data from the IQVIA PharMetrics database spanning from 2006 to 2023. Key factors analyzed include the availability of buprenorphine-waivered providers, the density of mental health services, and socioeconomic vulnerabilities. Buprenorphine treatment episodes were categorized into four duration groups: 0–3 months, 3–6 months, 6–12 months, and over 12 months. A stepwise multinomial regression model was utilized to assess the association between demographic and community-level factors and treatment duration.

The results indicate that patients in areas with lower Social Vulnerability Index scores tended to remain in treatment for longer periods. A greater number of buprenorphine-waivered providers and mental health services were linked to better treatment retention. However, patients enrolled in Medicaid experienced shorter treatment durations, which may be attributed to issues related to provider availability or prior authorization. Additionally, female patients had shorter treatment durations compared to males, likely influenced by caregiving responsibilities and the stigma surrounding OUD. These findings highlight disparities in OUD treatment retention and underscore the need for targeted, evidence-based strategies to address health inequities.

2 - Operationalizing Advanced Primary Care in Employer-Sponsored Insurance

Katherine Bobroske, Morgan Health, Washington, DC, United States, Jacob Caswell, Rowana Ahmed, Joseph Real

In the United States, advanced primary care (APC) is a care delivery model that strives to connect patients to comprehensive care in the primary care setting. Programs provide patients with more direct and integrated access to primary care clinicians, virtual appointments, nutrition and behavioral health counseling, and chronic condition management. The model aims to manage patients preventatively and reduce the patient demand for high cost specialists and avoidable acute/emergency care. While there is evidence that APC effectively improves quality and reduces barriers to care in some Medicare settings, there are unique barriers to overcome when deploying these models in the employer-sponsored insurance (ESI) context.

To better understand if and how APC can improve patient management in ESI, we clustered patients based on their primary care usage, including: primary care visit counts, medical and prescription costs, chronic condition management status, self-reported behavioral health and wellness scores. The algorithm identified 8 distinct clinical personas - including emergency room "frequent fliers," patients disconnected from primary care who struggled with condition management, and healthy patients with above-average wellness scores. We then leveraged a decision tree methodology to develop heuristics that providers could use to classify patients into the clinical personas. The findings provide insight into how APC programs can target their engagement strategies and initiatives to improve the overall impact that APC makes in ESI.

3 - Real-Time Patient Placement in Observation Units: a Capacity-Aware Optimization Approach with Machine Learning

Vera Tilson, University of Rochester, Rochester, NY, United States, Dessislava Pachamanova, Keely Dwyer Matzky

Observation Units (OUs) are short-term care settings designed for patients who require additional evaluation following an Emergency Department (ED) visit. Deciding whether to admit a patient to the OU or to an inpatient ward carries important consequences for clinical outcomes, operational efficiency, and financial costs. Our approach incorporates machine learning to predict which patients are most likely to benefit from OU placement, further we propose a real-time, capacity-sensitive optimization framework to support these critical placement decisions. Using hospital data and queueing theory, we assess the algorithm's performance across various capacity scenarios, highlighting key trade-offs between ED crowding and total hospital length of stay.

4 - Nurse Decision Making During Triage and the Value of Algorithmic Intervention

Anna Zink, Tufts University, Medford, MA, United States

The health care industry is investing billions of dollars on sophisticated algorithms to enhance clinical decision making, but the return on investment is far from guaranteed. How can healthcare organizations make more informed adoption decisions? We study this question in the context of Emergency Department (ED) triage, where triage plays a crucial role in ensuring that patients with urgent needs are treated quickly. Using data from more than 2 million emergency department encounters in 52 clinical sites, we find that nurses misclassify urgent cases; however, when the emergency department is busier and triage mistakes carry higher stakes because of longer waiting times, nurses tend to do a better job of identifying urgent cases. Hispanic, Medicaid, and uninsured patients are systematically undertriaged compared to other patients, and this disparity increases when the ED is busy, despite improved triage accuracy for the average patient. Finally, we demonstrate that implementing an algorithmic solution trained on nurse triage scores alone would perpetuate these biases. Instead, our results find that a more optimal approach is a hybrid one that combines human judgment with algorithmic input to improve triage accuracy and equity.

Advances in Nonlinear Optimization I

Invited Session

OPT: Nonlinear Optimization

Chair: Albert Berahas, University of Michigan, Ann Arbor, MI, United States

1 - Random Subspace Methods for Solving Nonconvex Qps

Yunlang Zhu, Lehigh University, Bethlehem, PA, United States, Frank E. Curtis, Aida Khajavirad

Various real-world applications involve the formulation of quadratic programming (QP) problems, and an important area of research is finding ways to find good approximate solutions of large-scale QPs efficiently. Recently, a series of papers have been published about applying random projections to reduce the dimension of the decision variables of QP problems, leading to projected problems of smaller dimension. Motivated by these results, we consider combining certain deterministic components extracted from the original QP problem with random projections so that we can select the subspace to be projected onto based on problem information, not solely randomness. Numerical experiments show that our method yields better approximate solutions than purely random projections with comparable efficiency. Moreover, we provide theoretical guarantees for our method, which shows improved bounds compared to random projections.

2 - Proximal Gradient Methods for Regularized Optimization with Constraints

Xiaoyi Qu, Lehigh University, Bethlehem, PA 18015-3728, PA, United States

The proximal gradient method is a well-established technique for solving regularized optimization problems. However, its extension to problems involving general nonlinear constraints remains largely unexplored. In this talk, we introduce a proximal gradient method specifically designed for such constrained problems. Our approach begins by employing a decomposition strategy to compute trial steps, followed by the use of a merit function to assess the acceptance or rejection of the trial step. Under common constraint qualifications, we establish both worst-case complexity bounds, and subsequence convergence guarantees. Computational results will be presented to demonstrate the effectiveness and robustness of the proposed method.

3 - An Adaptive and Parameter-Free Nesterov's Accelerated Gradient Method for Convex Optimization

Jaewook J. Suh, Rice University, Houston, TX, United States, Shiqian Ma

We propose AdaNAG, an adaptive accelerated gradient method based on Nesterov's accelerated gradient method. AdaNAG is line-search-free, parameter-free, and achieves the accelerated convergence rates $f_k - f_\star = O(1/k^2)$ and $\min_{i \in \{1, \dots, k\}} \|\nabla f(x_i)\|^2 = O(1/k^3)$ for L -smooth convex function f . We provide a Lyapunov analysis for the convergence proof of AdaNAG, which additionally enables us to propose a novel adaptive gradient descent (GD) method, AdaGD. AdaGD achieves the non-

ergodic convergence rate $f_k - f_\star = O(1/k)$, like the original GD. The analysis of AdaGD also motivated us to propose a generalized AdaNAG that includes practically useful variants of AdaNAG. Numerical results demonstrate that our methods outperform some other recent adaptive methods for representative applications.

4 - Nearly Optimal Lp Risk Minimization

Zhichao Jia, Georgia Institute of Technology, Atlanta, GA, United States, Guanghui Lan, Zhe Zhang

Convex risk measures play a foundational role in the area of stochastic optimization. However, in contrast to risk neutral models, their applications are still limited due to the lack of efficient solution methods. In particular, the mean Lp semi-deviation is a classic risk minimization model, but its solution is highly challenging due to the composition of concave-convex functions and the lack of uniform Lipschitz continuity. In this paper, we discuss some progresses on the design of efficient algorithms for Lp risk minimization, including a novel lifting reformulation to handle the concave-convex composition, and a new stochastic approximation method to handle the non-Lipschitz continuity. We establish an upper bound on the sample complexity associated with this approach and show that this bound is not improvable for Lp risk minimization in general through the construction of a nearly matching lower complexity bound.

5 - Popov Mirror-Prox Method for Variational Inequalities

Abhishek Chakraborty, ASU, Tempe, AZ, United States, Angelia Nedich

This paper examines the convergence properties of the Popov mirror-prox algorithm for solving stochastic and deterministic variational inequalities (VIs) under a polynomial growth condition on the mapping variation. Unlike existing methods that require prior knowledge of problem-specific parameters, we propose step-size schemes that are entirely parameter-free in both constant and diminishing forms. For stochastic and deterministic monotone VIs, we establish optimal convergence rates in terms of the dual gap function over a bounded constraint set. Additionally, for deterministic VIs with H^ν-order continuous mapping, we prove convergence in terms of the residual function without requiring a bounded set or monotone mapping, provided a Minty solution exists. This allows our method to address certain classes of non-monotone VIs. However, knowledge of the H^ν-order exponent is necessary to achieve the best convergence rates in this case. By extending mirror-prox techniques to mappings with arbitrary polynomial growth, our work bridges an existing gap in the literature. We validate our theoretical findings with empirical results on matrix games, piecewise quadratic functions, and image classification tasks using ResNet-18, demonstrating the effectiveness of our method.

Building B Level 2 B211

Sequential Decision-making Under Uncertainty

Invited Session

OPT: Optimization Under Uncertainty

Chair: Harsha Gangammanavar, Southern Methodist University, Dallas, TX, United States

1 - Inverse Optimization In Finite-State Semi-Markov Decision Processes

Nhi Nguyen, University of Minnesota, Minneapolis, MN, United States, Archis Ghatge

Inverse optimization involves finding values of problem parameters that would render given values of decision variables optimal. This is in contrast with the usual forward optimization where decision variables are computed using given values of problem parameters. In the context of finite-state Markov decision processes (MDPs), the inverse optimization literature has focused on imputing two types of inputs that would make a given policy optimal: (i) cost parameters or (ii) transition probabilities. All existing work only considers the case of discrete-time MDPs. We will present an extension to the case of semi-Markov decision processes (SMDPs), with continuous-time MDPs (CTMDP) as a special case. We will utilize Bellman's equations for SMDPs to formulate a parametric version of the inverse problem. In this parametric version, estimates of parameters that characterize costs are given along with a target policy. The goal is to find parameter values that are as close as possible to these estimates and render the given policy optimal. We will present a tractable linear or convex formulation of this problem. Computational experiments on applications will be discussed.

2 - A Gpu Acceleration Procedure in Decomposition Algorithms for Stochastic Linear Programs

Yihang Zhang, University of Southern California, Los Angeles, CA, United States, Suvrajeet Sen

We present an acceleration method based on off-loading the dual bounding ("argmax") scheme by using a GPU to conduct a particular matrix-matrix multiplication which leverages the massive parallelism of GPUs.

3 - Comparative Study of Sampling-Based Multistage Stochastic Linear Programming Algorithms

Zhiyuan Zhang, Southern Methodist University, Dallas, TX, United States, Harsha Gangammanavar

Multistage stochastic linear programming (MSLP) provides a powerful framework for decision-making under uncertainty over time. In this study, we compare two prominent approaches for solving stagewise independent MSLP problems: stochastic dual dynamic programming (SDDP) and stochastic dynamic linear programming (SDLP). We also present a regularized variant of SDDP that, like SDLP, employs basic feasible policies to identify the prox-center. We evaluate the algorithms on benchmark instances of varying size and structure, investigating their convergence behavior and computational efficiency. A series of numerical experiments is conducted to demonstrate the trade-offs among these methods in terms of accuracy and scalability.

4 - A Stochastic Decomposition Method for Multistage Distributionally Robust Optimization Under Streaming Data

Tian Xia, The Ohio State University, Columbus, OH, United States, Harsha Gangammanavar, Guzin Bayraktan

Multistage Stochastic Programming (MSP) is a fundamental framework for modeling sequential decision-making under uncertainty. However, challenges such as curse of dimensionality and random variable's unknown probability distribution make MSP difficult to solve in practice. In this talk, under the streaming data setting, we present a Multistage Distributionally Robust Optimization (MDRO) framework to approximate the original MSP, where the radius of the ambiguity set of distributions shrink as more data is obtained. We propose a Stochastic Decomposition (SD) method specifically tailored to MDRO under streaming data, i.e., an online environment, named as MDRSD. Within the streaming data-driven paradigm, we construct the ambiguity sets using the Wasserstein distance with shrinking radii and develop efficient approximations for both value functions and solutions to MSP. We show conditions under which the sequence of incumbent solutions generated by MDRSD converge asymptotically to those of the original MSP. As an additional theoretical result, we establish that the optimal value of the MDRO converges asymptotically to that of the MSP under our problem setting. Finally in numerical experiments, we validate the efficiency of MDRSD in solving real-world applications under streaming data.

Optimization Society Award Session II

Award Session

Optimization

Chair: Jeff Linderoth, University of Wisconsin-Madison, Madison, WI, United States

1 - Young Researchers Prize

Benjamin Grimmer, Johns Hopkins University, Baltimore, MD, United States

Benjamin Grimmer is awarded the 2025 INFORMS Optimization Society Young Researchers Prize for his paper "Provably Faster Gradient Descent via Long Steps", SIAM Journal on Optimization 34.3 (2024): 2588-2608. For decades, it was unknown whether stepsizes longer than those guaranteeing per-iteration descent could improve the convergence of gradient descent for smooth convex optimization. The cited paper resolves this long-standing open question with a breakthrough result:

carefully designed cyclic schedules that periodically include long steps provably achieve strictly better worst-case guarantees than the classical constant-stepsize method, even though individual iterates may temporarily worsen the objective. Methodologically, the work departs sharply from traditional one-step induction analyses by leveraging a computer-assisted performance-estimation framework. It introduces a “straightforwardness” property for stepsize schedules that can be certified via a semidefinite program, enabling automated discovery and proof of effective long-step patterns. In contrast to its more common role of confirming or refining existing analyses, here, performance estimation enabled the derivation of an unexpected result. The paper has already drawn broad interest and inspired substantial follow-up research, establishing a new foundation for our understanding of gradient descent

2 - Accessible Theoretical Complexity of the Restarted Primal-Dual Hybrid Gradient Method for Linear Programs with Unique Optima

This paper develops the first accessible iteration bound for the restarted primal-dual hybrid gradient method (rPDHG), a method that has emerged as a particularly successful alternative for solving large-scale linear programs. The bound is expressed in closed form using quantities tied directly to the optimal solution and basis, making it both theoretically rigorous and practically computable. The analysis sheds new light on the method’s two-stage performance, sensitivity to perturbations, and practical heuristics, and is further supported by numerical experiments. This single-authored student paper stands out for its accessible analysis, important results, and current relevance, making it a deserving recipient of this prize.

3 - A Simple Uniformly Optimal Method without Line Search for Convex Optimization.

Tianjiao Li, Massachusetts Institute of Technology, Cambridge, MA, United States

Line search (or backtracking) procedures have been widely employed into first-order methods for solving convex optimization problems, especially those with unknown problem parameters (e.g., Lipschitz constant). In this paper, we show that line search is superfluous in attaining the optimal rate of convergence for solving a convex optimization problem whose parameters are not given a priori. In particular, we present a novel accelerated gradient descent type algorithm called auto-conditioned fast gradient method (AC-FGM) that can achieve an optimal rate of convergence for smooth convex optimization without requiring the estimate of a global Lipschitz constant or the employment of line search procedures. We then extend AC-FGM to solve convex optimization problems with Holder continuous gradients and show that it automatically achieves the optimal rates of convergence uniformly for all problem classes with the desired accuracy of the solution as the only input. Finally, we report some encouraging numerical results that demonstrate the advantages of AC-FGM over the previously developed parameter-free methods for convex optimization.

Discrete Optimization for Social Good

Invited Session

OPT: Integer and Discrete Optimization

Chair: Sean Lo, Massachusetts Institute of Technology, Cambridge, MA, United States

1 - Online Assignment-Routing for Organ Transplants

Sean Lo, Massachusetts Institute of Technology, Cambridge, MA, United States, Alexandre Jacquillat

TransMedics is a US-based healthcare startup which operate devices for organ transplants. These portable devices preserve the shelf-life of donated organs outside the donor's body, allowing for less time-dependent organ-donor matchings and improved healthcare outcomes. We help TransMedics solve a complex logistics problem in an online setting with a hybrid assignment/routing structure: we assign surgeons, device specialists, and devices to organ donors, and route them to organ recipients via a fleet of planes. We propose an online algorithm which takes into account uncertainty in case arrivals, and demonstrate how it outperforms a greedy approach. Real-world experiments show how our approach improves the volume of transplants served.

2 - Meeting Uncertain Demand with Deadlines: Applications in Defense and Disaster Relief

Louis Chen, Naval Postgraduate School, Monterey, CA, United States, Roberto Szechtman, Vince Vanterpool, Chiwei Yan

We formulate and study the problem of allocating resources across a network towards (uncertain) demands with (certain) deadlines. In particular, allocations are made online, and the decision maker receives “satisficing” feedback in between rounds. This problem encompasses a wide range of applications in defense and beyond. More specifically, it provides new dynamic weapon target assignment and disaster relief models. In addition to introducing these models, we present online policies, structural results, and numerical experiments.

3 - Optimizing Wildfire Suppression: a Branch-and-Price-and-Cut and Double Machine Learning Approach

Leonard Boussioux, UW Foster, Harvard, Seattle, WA, United States, Alexandre Jacquillat, Jacob Wachspress

Wildfires present an escalating threat to communities, infrastructure, and ecosystems, demanding sophisticated strategies for effective suppression. This talk introduces an advanced optimization framework—branch-and-price-and-cut—for coordinating wildfire suppression efforts in complex, dynamic environments. Our two-sided set-partition formulation simultaneously models fire spread dynamics and crew routing decisions on time-expanded networks, integrating critical considerations such as travel cost, crew fatigue, fire damage, and suppression difficulty. We demonstrate computational advances through augmented Generalized Upper-Bound (GUB) cutting planes, dual-aware branching rules, and targeted primal heuristics, achieving substantial improvements in both solution quality and computational efficiency. A comprehensive data-driven case study leveraging historical wildfire data and a double machine learning approach highlights the practical impact of our optimization model, enabling precise estimation of suppression effectiveness and improved decision-making under uncertainty. Results reveal that optimized resource allocation significantly enhances suppression outcomes, prioritizing high-risk fires while balancing crew fatigue and travel costs. This research provides robust, scalable solutions vital for addressing the increasing complexity and severity of wildfire events.

4 - Conformal Inverse Optimization for Adherence-Aware Prescriptive Analytics

Bo Lin, University of Toronto, Toronto, ON, Canada, Erick Delage, Timothy Chan

Inverse optimization has been increasingly used to estimate unknown parameters in an optimization model based on decision data. We show that such a point estimation is insufficient in a prescriptive setting where the estimated parameters are used to prescribe new decisions. The prescribed decisions may be low-quality and misaligned with human intuition and thus are unlikely to be adopted. To tackle this challenge, we propose conformal inverse optimization, which seeks to learn an uncertainty set for the unknown parameters and then solve a robust optimization model to prescribe new decisions. Under mild assumptions, we show that the suggested decisions can achieve bounded out-of-sample optimality gaps, as evaluated using both the ground-truth parameters and the decision maker's perception of the unknown parameters. Our method demonstrates strong empirical performance compared to classic inverse optimization.

5 - Optimizing Threshold-Based Fairness

John Hooker, Carnegie Mellon University, Pittsburgh, PA, United States, Ozgun Elci, Peter Zhang

Threshold-based fairness is designed to balance efficiency and equity in a principled way. It maximizes a social welfare function that measures total benefit up to a threshold at which the distribution of benefits becomes unfair. At this point it begins to switch to a Rawlsian maximin or leximax criterion. An interpretable parameter regulates the relative importance of equity and efficiency in the solution. This talk shows how to give this criterion a practical formulation in an optimization model. It illustrates results on facility location and public transport network problems in which one seeks an efficient solution that provides an acceptable service level to everyone.

6 - Optimizing Wildfire Suppression: A Branch-and-Price-and-Cut and Double Machine Learning Approach

Leonard Boussioux, University of Washington, Foster School of Business, Seattle, WA, United States, Alexandre Jacquillat, Jacob Wachspress

Wildfires present an escalating threat to communities, infrastructure, and ecosystems, demanding sophisticated strategies for effective suppression. This talk introduces an advanced optimization framework—branch-and-price-and-cut—for coordinating wildfire suppression efforts in complex, dynamic environments. Our two-sided set-partition formulation simultaneously models fire spread dynamics and crew routing decisions on time-expanded networks, integrating critical considerations such as travel cost, crew fatigue, fire damage, and suppression difficulty.

We demonstrate computational advances through augmented Generalized Upper-Bound (GUB) cutting planes, dual-aware branching rules, and targeted primal heuristics, achieving substantial improvements in both solution quality and computational efficiency. A comprehensive data-driven case study leveraging historical wildfire data and a double machine learning approach highlights the practical impact of our optimization model, enabling precise estimation of suppression effectiveness and improved decision-making under uncertainty. Results reveal that optimized resource allocation significantly enhances suppression outcomes, prioritizing high-risk fires while balancing crew fatigue and travel costs. This research provides robust, scalable solutions vital for addressing the increasing complexity and severity of wildfire events.

1 - Dynamic Substitution Strategies for Perishable Products in Food Retailing

Ke Sun, McGill University, Montreal, QC, Canada, Yichuan Ding, Mehmet Gumus

We study the dynamic management of perishable inventory in food retail, characterized by uncertain demand, product perishability, and substitution behavior. In collaboration with a major North American grocery retailer, we develop a multi-period stochastic optimization model that jointly determines replenishment and substitution decisions to maximize long-term expected revenue. We begin by characterizing the structure of the optimal policy and show that it takes the form of a state-dependent threshold policy. However, deriving such thresholds becomes computationally intractable due to the curse of dimensionality. To address this challenge, we propose a heuristic approach based on Lagrangian relaxation, which decomposes the original problem into more tractable subproblems while preserving key system dynamics. Using the real transaction data from our industry partner, we benchmark the proposed approach against commonly used heuristics and observe consistent improvements in revenue. Our results highlight the value of incorporating substitution effects and forward-looking decision-making in the management of perishable inventory. This work contributes to the literature on sustainable retail operations and provides implementable insights for practitioners aiming to improve inventory efficiency in perishable product categories.

2 - Productive Delays

Guillaume Lapierre-Berger, McGill University, Montreal, QC, Canada, Juan Camilo Serpa, Yael Grushka-Cockayne

Contractors strive to minimize project delays at all costs. We demonstrate that some delays can actually improve productivity in the long term, as contractors transfer learning from these delays into other projects within their portfolio. We substantiate this hypothesis using task-specific data from thousands of projects. Our findings reveal that contractors who experienced delays in a given task category were less likely to be delayed later across the same task categories across other projects in their portfolio. Surprisingly, such an early delay has a net positive effect on the portfolio, meaning that the learning spillovers outweighed the costs of the delay. This effect is more pronounced when the delayed tasks lie on the project's critical path.

3 - Causal Estimation and Optimization of Retail Staffing Levels

Xin Wang, University of Toronto, Toronto, ON, Canada, Vahid Sarhangian, Liu Sheng, Opher Baron

This study investigates the causal impact of staffing levels on retail sales, while controlling for key factors such as traffic, inventory, and promotional activities. We begin by applying stratified linear models at the aggregate, store, and time levels to estimate the effect of labor deviations on sales fluctuations. However, treatment effects vary across stores, seasons, and years, resulting in small sample sizes within subgroups and unstable estimates under stratification. To address these challenges, we adopt the Double Machine Learning (DML) framework, which enables the estimation of heterogeneous treatment effects using flexible machine learning models. DML enhances robustness by orthogonalizing the treatment and outcome with respect to high-dimensional confounders, thereby reducing bias from confounding and model misspecification. Unlike traditional stratified models, DML accommodates complex, nonlinear relationships and supports valid statistical inference, even when predictive models are imperfect. Building on these causal estimates, we formulate a roster optimization problem to determine the optimal staffing levels for each store and time period, relative to the baseline labor plan. The objective is to maximize net profit, accounting for counterfactual sales fluctuations and operational constraints in labor scheduling. Finally, we examine the performance of the proposed methods using data from a large retail network.

1 - A Two-Stage Robust Optimization Approach for Anesthesiologist Scheduling with Handovers

Abhishrut Sinha, State University of New York, Binghamton, Binghamton, NY, United States, Ankit Bansal, Osman Ozaltin, Michael Russell

The transfer of operating room responsibilities between anesthesiologists—known as handovers—can increase the likelihood of medical errors and lead to negative health outcomes. To minimize these handovers, we propose a two-stage robust optimization model that assigns anesthesiologists to operating rooms while incorporating key operational constraints. We show that the second-stage problem can be modeled as a longest path problem on a layered acyclic graph and consequently, formulated as a linear program. This linear program is then dualized and embedded into the first-stage model, resulting in a single, integrated Mixed-Integer Linear Programming (MILP) formulation. We also introduce valid inequalities for the first stage and demonstrate their strength by showing that they describe the convex hull of the relaxations of the first-stage integer set. Computational experiments based on real hospital data demonstrate the effectiveness of our proposed approach.

2 - Mixed Integer Linear Program for Family Medicine Residency Scheduling with Clinic First Objectives

Mohammad Al Syouf, State University of New York at Binghamton, Binghamton, NY, United States, Ankit Bansal, Jean-Philippe Richard, Bjorn Berg

Family medicine physicians make up the largest share of the primary care provider (PCP) workforce, accounting for 40% of all PCPs. A notable contributor to the shortage of PCPs is the tendency of family medicine residents to pursue subspecialties or careers as hospitalists. This issue has been primarily linked to a training gap within the family medicine residency curriculum. In practice, family medicine physicians work mainly in outpatient primary care clinics—known within the field as continuity clinics—where they focus on long-term care and maintaining continuity in the physician-patient relationship. However, traditional residency training often emphasizes hospital-based experiences, creating a disconnect between training and practice. The Clinic First paradigm is an educational approach developed to close this gap by prioritizing outpatient clinic experience and reinforcing continuity of care. In alignment with this model, we introduce a Mixed Integer Linear Programming (MILP) model designed to generate annual rotation schedules for family medicine residents. This model captures the complex constraints imposed by accreditation standards and program-specific requirements. It explicitly incorporates two key objectives that reflect the Clinic First paradigm: Clinic Time Consistency (CTC) and Level-Loading (LL). To address the computational challenges, we develop multiple heuristics that efficiently produce high-quality feasible solutions that can be used to significantly speed up the solution of the problem with Gurobi. Computational experiments based on data from an existing residency program demonstrate the effectiveness of our approach.

3 - Bilevel Formulation for Share Allocation in Food Distribution Auctions

Hou-An Chen, NC State University, Raleigh, NC, United States, Osman Ozaltin

This work presents a bilevel optimization framework to address share allocation in Feeding America's Choice system, a market-based mechanism for distributing food donations among food banks. The Choice system uses auctions where food banks bid on food bundles using a specialized currency named shares. While the system offers flexibility and responsiveness to food bank preferences, it has been suffering from low participation from small food banks due to limited shares allocated. To address this, we model the interaction between Feeding America (as the leader) and food banks (as followers) within a single auction window. A centralized decision-making model is first introduced to maximize aggregate utility, followed by a bilevel formulation that captures the strategic behavior of food banks under uncertainty and budget constraints. The proposed model aims to enhance equity and efficiency in food allocation by Choice, offering insights for policy refinement and operational improvements in hunger relief logistics.

4 - Cost-Effectiveness of Personalized Policies for Implementing Organ-at-Risk Sparing Adaptive Radiation Therapy in Head and Neck Cancer

Daniel Suarez Aguirre, Georgia Tech, Atlanta, GA, United States, S. Mohammad Hosseinian, Cem Dede, Raul Garcia, Lucas McCullum, Mehdi Hemmati, Aysenur Karagoz, Mohamed Abdallah S.R. , Stephen Y. Lai, Katherine A. Hutcheson, Amy C. Moreno, Kristy K. Brock, Fatemeh Nosrat, Clifton D. Fuller, Andrew Schaefer

Background and Purpose

The principle of adaptive radiation therapy (ART) is to adjust radiation plans in response to anatomical changes during treatment. The purpose of this study was to develop a decision-making model for implementation of personalized ART that balances the costs and clinical benefits of radiation plan adaptations in head and neck cancer (HNC).

Materials and Methods

Using retrospective imaging data from 52 HNC patients, a Markov decision process (MDP) model was developed to determine optimal timing for plan adaptations based on the difference in normal tissue complication probability (Δ NTCP) between planned and delivered doses to organs-at-risk. To capture the trade-off between the costs and benefits of plan adaptations, the end-treatment Δ NTCPs were converted to Quality Adjusted Life Years (QALYs) and then to equivalent monetary values using a willingness-to-pay per QALY parameter.

Results

The optimal policies were derived for 96 combinations of willingness-to-pay per QALY (W) and re-planning cost (RC) and validated using Monte Carlo simulation for two representative scenarios: (1) W = \$200,000, RC = \$1,000; (2) W = \$100,000, RC = \$2,000. In scenario (1), the MDP model's policy reduced the probability of excessive toxicity (Δ NTCP $\geq 5\%$) to zero (from 0.21 without re-planning) at an average cost of \$380 per patient. In scenario (2), it reduced this probability to 0.02 at an average cost of \$520 per patient.

Conclusions

The MDP model's policies outperformed the current fixed-time (one-size-fits-all) approaches in both clinical and financial outcomes in the simulations.

3 - A Tree-Based Policy Reinforcement Learning Algorithm in Non-Stationary Environments with Applications in Healthcare

Mina Yi, Dartmouth College, West Lebanon, NH, United States, Wesley Marrero

Reinforcement Learning (RL) addresses sequential decision-making in dynamic environments, where optimal policies (i.e., sequences of decisions) are identified to balance long-term consequences under uncertainty.

However, the trust in RL is limited in high-stakes areas. Traditional RL methods operate as black boxes and prioritize long-term cumulative returns without considering human intuition or ethics (i.e., lack of interpretability). In high-stakes settings like healthcare, where humans remain the primary decision-makers, trustworthy recommendations must align with human logic. Through conversations with our medical collaborators, we have identified the clinically relevant notions of interpretability: tree-based structures.

Although emerging RL frameworks have incorporated interpretability metrics as constraints, these methods assume environments that do not change over time (i.e., stationary). This assumption rarely holds in practice, so non-adaptive policies may not remain optimal as conditions change. In healthcare, stationary policies may lead to ineffective treatments and undesirable outcomes as patients' biological conditions fluctuate and diseases progress.

To address these challenges, we proposed an adaptive tree-based algorithm. This algorithm ensures that the internal mechanisms will adapt to changes in non-stationary systems, and the resulting policy will remain inherently interpretable.

4 - Data-Driven Decision Making for Hospital Discharge and Home-Based Care

Mark Van Oyen, University of Michigan, Ann Arbor, MI, United States, Sogand Soghrati Gasbeh, Arlen Dean

Improving patient flow and optimizing hospital resource utilization are critical challenges in modern healthcare systems. Predictive analytics offers a powerful approach to support these goals by enabling proactive decision-making for patient transitions. This presentation introduces a data-driven framework for anticipating care transitions, with a focus on hospital-based or post-acute care pathways.

In one application, we develop and validate a Next-Day Discharge (NDD) prediction model using electronic health record data. Our modeling approach first stratifies patients based on their length of stay and then applies targeted classifiers to predict discharges within each group. This framework captures patient heterogeneity and improves predictive performance over standard models. By identifying patients likely to be discharged in advance, hospitals can better plan for capacity, coordinate follow-up care, and reduce discharge delays.

Further, the framework can be extended to identify patients suitable for Hospital-Care-at-Home (HCaH) programs. HCaH has emerged as a promising alternative to inpatient care for select populations, offering equivalent outcomes with improved patient satisfaction and lower costs. Our predictive model supports this transition by identifying stable inpatients who meet safety and clinical eligibility criteria for at-home care.

For both use cases, we evaluate model performance using real-world hospital data and explore operational implications. The presentation discusses the methodological challenges of deploying prediction models in clinical workflows and the potential for machine learning to enhance hospital operations and patient-centered care.

1 - Modeling Health and Economic Outcomes of Providing Stable Housing to Homeless Adults with Opioid use Disorder

Isabelle Rao, University of Toronto, Toronto, ON, Canada

The number of people experiencing homelessness (PEH) in the United States is increasing, and drug overdose, primarily driven by opioids, is the leading cause of death in this population. Addressing opioid use disorder (OUD) among PEH is a critical public health priority. We develop a continuous time compartmental model to evaluate the health and economic impacts of providing stable housing to PEH with OUD, without requiring entry into OUD treatment. We simulate a cohort of 1,000 PEH with OUD, comparing outcomes under the housing intervention to those under the status quo (no housing provision) to determine the incremental cost-effectiveness ratio (ICER). Over five years, the housing intervention reduces total deaths from 191 to 140, and reduced total overdoses from 554 to 494. The intervention increases lifetime quality-adjusted life years (QALYs) by 3.59 per person at an incremental cost of \$26,200 per QALY gained compared to the status quo. Across a wide range of sensitivity analyses that could make the housing intervention appear less favorable, the ICER remains below \$90,000 per QALY, indicating that the intervention is cost-effective. Our findings show that investing in stable housing for this marginalized population, even with no requirement to enter OUD treatment, would not only save lives and improve health outcomes but would also be cost-effective. Efforts are urgently needed to improve the health of PEH with OUD. It is essential to understand the effectiveness and cost-effectiveness of housing provision for this marginalized population, as housing status is a key social determinant of health.

2 - Correcting Bias in Value-of-Information: Monte Carlo Errors in Simulation ModelsGary Qian, Stanford, Stanford, CA, United States, Fernando Alarid-Escudero², Hawre Jalal, Jeremy Goldhaber-Fiebert

Monte Carlo (MC) error in microsimulation models introduces a one-sided bias in estimates of value-of-information (VOI), such as the expected value of perfect information (EVPI). While this bias can be reduced with more microsimulated samples, the computational cost can be prohibitive. We aim to develop bias correction approaches under a limited computational budget to feasibly improve the accuracy of VOI calculations using microsimulation models.

3 - The Value of Proxy Information in Location Optimization for Rare Events: Application to Major Trauma Response

Rachel Stephenson, University of Toronto, Toronto, ON, Canada, Sheng Liu, Timothy C. Y. Chan

Major traumas are extremely rare; inherent uncertainty and limited data positions the major trauma response base location problem within the *small-data, large-scale* optimization regime. We analyze the value of proxy information in location optimization for rare events (e.g., major trauma). Specifically, we explore the use of mixed-effects (ME) policies which leverage high variance, unbiased historical observations (e.g., major trauma EMS calls) and low variance, biased proxy data (e.g., population data, low acuity trauma calls) in location decisions. We investigate the structural properties and value of ME policies to present insights to decision makers for informed application to location problems.

4 - Distributionally Robust Group Testing with Correlation Information

Aiqi Zhang, Wilfrid Laurier University, Waterloo, ON, Canada, Daniel Zhuoyu Long, Jin QI, Yu SUN

Motivated by the need for more efficient and reliable methods of group testing during widespread infectious outbreaks, this paper introduces a novel operational improvement to the widely-used Dorfman's group testing procedure, where a single test is conducted on the pooled sample, followed by individual testing of positive pools. Our method minimizes a weighted sum of testing volume and misclassifications, predicated on prevalence rates and inter-individual Pearson correlation coefficients. Recognizing the inherent ambiguity in the population-level joint probability distribution of infection statuses that rises from the correlations between individuals, our approach leverages a distributionally robust optimization (DRO) framework to counteract the worst-case probability distribution. In single-cluster cases, where each pair of subjects are equally correlated, we establish uniform group sizes and connect our analysis to Nash equilibrium principles. Larger testing groups are generally favored under high correlation, whereas individual testing becomes optimal under high prevalence. In multi-cluster cases, where the population is formed by several intra-correlated but inter-independent clusters, we highlight the effectiveness of mixed-cluster testing strategies, particularly at lower levels of prevalence and correlation. This is a notable addition to the prevailing view that advocates pooling correlated individuals. For both single- and multi-cluster cases, we develop polynomial-time solutions and offer practical insights and policy implications for optimal pooling strategies. We demonstrate the trade-offs and benefits of our DRO approach through a thorough comparison with stochastic alternatives, and demonstrate the impact of incorporating correlated infections in a case study using a COVID-19 dataset from Hong Kong.

5 - Cost-Effectiveness of a Precision Digital Health Program for Glucose Management in Pediatric Patients with Newly Diagnosed Type 1 Diabetes

Paul Dupenloup, Stanford University, Stanford, CA, United States, Yupeng Chen, Priya Prahalad, Ramesh Johari, Ananta Addala, Dessi Zaharieva, Mindy Lee, David Maahs, David Scheinker, Margaret Brandeau

Introduction: Youth with Type 1 diabetes (T1D) frequently fail to achieve recommended glycemic targets, increasing their risk of complications. We evaluated the cost-effectiveness of the Teamwork, Targets, Technology, and Tight Range (4T) care model compared to self-monitoring of blood glucose (SMBG) and continuous glucose monitoring (CGM) alone.

Methods: We developed a decision-analytic Markov model simulating 5-year-old newly diagnosed T1D patients over a 20-year time horizon. The model incorporated diabetes-related complications, mortality, and healthcare costs. The 4T intervention combined early CGM initiation, remote patient monitoring via the TIDE platform, and team-based care with standardized glycemic targets.

Results: The 4T model increased quality-adjusted life years (QALYs) compared to both SMBG and CGM alone. Additionally, 4T reduced healthcare costs per patient compared to both alternatives, primarily through reductions in complication-related costs. These findings remained robust across sensitivity and scenario analyses.

Conclusions: The 4T care model simultaneously improves clinical outcomes and reduces costs in pediatric T1D management. National implementation for newly diagnosed youth could yield substantial healthcare savings while enhancing care quality and addressing healthcare disparities. These findings support broader adoption of structured, technology-enabled care models for pediatric T1D management.

1 - When Life Gives You Lemons: Spillovers Between Pharmaceutical Recalls and Shortages

Hanu Tyagi, University of Illinois, Urbana-Champaign, IL, United States, Rachna Shah, Junghee Lee

Operational failures like drug recalls and shortages have serious public health consequences and often occur together. This paper examines how a firm's recall experience affects shortage outcomes - a relationship largely overlooked despite both issues stemming from similar quality and manufacturing problems. Using longitudinal data from 319 firms over 120 months, we find that **completed recalls** reduce the risk of future shortages, while **ongoing recalls** increase the duration of shortages and the risk of future shortages. The effects are stronger when recalls are more severe. We contribute to the literature on learning from failures by showing that **spillovers can occur across different failure types**, not just within the same category. These findings offer actionable insights for managers and regulators on leveraging learning from completed failures while minimizing the harm of ongoing ones.

2 - Strength in Teams: Named Physician Pairs Improve Continuity of Care in Primary Care Amid Workforce Pressures

Laura Poreschack, University of Cologne, Cologne, Germany, Harshita Kajaria-Montag, Stefan Scholtes

Context: Continuity of care - a sustained relationship between a patient and their primary care physician - improves outcomes and reduces healthcare utilization, but workforce pressures threaten its sustainability. Building on the Named Physician model in England, this study proposes a Named Physician Pair model, where two physicians jointly ensure continuity, with a secondary physician covering when the primary physician is unavailable.

Main findings: Using 11 years of data from over 30 million consultations in 381 English primary care practices, we found that seeing a primary physician extends the time to the next consultation by 14.0%, while a secondary physician extends it by 6.5%, compared to other physicians. The benefits of both physicians are particularly strong for older patients, those with multiple comorbidities, and when these physicians are more familiar with the patient and each other. We also observed fewer emergency visits and hospitalizations within a week of consultations with primary or secondary physicians, with secondary physicians achieving more than 50% of the impact seen with primary physicians.

Impact assessment: Applying the Named Physician Pair model to the study practices, targeting the patients who benefit most from continuity, increased consultations with either physician from 53% to 86%, reducing consultation demand by 4.9%. This included 3.4% from primary physicians and 1.5% from secondary physicians, with estimated savings across England exceeding £100 million annually. The study highlights managerial and policy challenges in implementing the Named Physician Pair model but demonstrates its potential to enhance care and alleviate pressures on primary care services.

3 - Short Supply, Long Delays: Evidence from the Parenteral Opioid Shortage

Xinyu Liang, INSEAD, Singapore, Singapore

The U.S. has been grappling with a prolonged opioid epidemic, leading to tighter regulations and production controls; however, as parenteral opioids are critical for acute and surgical pain management, supply disruptions raise serious concerns about unintended consequences for patient care and opioid misuse.

We combine 10+ years of DEA's ARCOS shipment data with patients' electronic health records from Truveta Data. Using geographic variation in shortage exposure, we estimate the impact of a 2017 opioid shortage's impact on care delivery and opioid misuse using a shift-share instrumental variables strategy and an event-study design. We find that the shortage not only delayed care but also increased reliance on riskier opioid use pathways. The findings shed light on how supply shocks in controlled substances affect healthcare delivery and exacerbate risks of opioid misuse.

4 - Improving Rural Healthcare Access: Evidence from Osf Healthcare Facility Expansions in Illinois

Dmitrii Sumkin, University of Illinois at Urbana-Champaign, Urbana-Champaign, IL, United States, Ujjal Mukherjee, Sridhar Seshadri

Access to healthcare remains a persistent challenge for rural populations. This study examines how the expansion of OSF HealthCare facilities influences healthcare utilization in rural Illinois, leveraging patient visit data and publicly available social vulnerability indices. We model patient facility choice and implement a staggered difference-in-differences approach, taking advantage of the phased rollout of new healthcare sites across underserved areas. Our analysis finds that the opening of new facilities leads to a significant reduction in the ratio of emergency department visits to regular visits—suggesting a shift toward proactive, preventive care. Additionally, both follow-up visit rates and the average number of follow-up encounters increase, highlighting improved care continuity. These findings demonstrate the vital role of physical access in shaping not only patients' initial care-seeking behavior but also their ongoing engagement with the healthcare system. Based on these insights, we offer actionable, data-driven recommendations to OSF HealthCare for optimizing its network expansion strategy. Specifically, we identify high-impact locations for new clinics, telemedicine hubs, and healthcare kiosks aimed at maximizing benefits for rural communities across Illinois.

Manufacturing and Service Operations Management (MSOM)

Chair: Lesley Meng, Yale School of Management, Yale University, New Haven, CT, United States

1 - Reuniting Forcibly Separated Families Through Shared Memories

Huifeng Su, Yale School of Management, New Haven, CT, United States, Lesley Meng, Edieal Pinker

For decades, hundreds of thousands of children have been forcibly separated from their birth families due to abduction or displacement. Many of these separations began in childhood and persisted into adulthood, leaving individuals to search for their families decades later. This situation has created an urgent and large-scale demand for effective reunion services.

These services face significant challenges, including vast search spaces, missing identification information, and incomplete memories. Despite their profound societal importance, family reunification processes remain understudied, particularly with respect to the operational complexities inherent in such searches.

Using data from a large online platform dedicated to family reunification, we develop a predictive pipeline that integrates representation learning with transformer-based language models to recommend likely matches from user-submitted narratives. Our system substantially reduces the search space and, in aggregate, could shorten separation durations by years for affected families. Beyond algorithmic improvements, we also uncover systematic reporting biases in child-submitted reports and demonstrate heterogeneity in how children and parents allocate narrative effort, both of which could undermine the efficiency of searches.

Together, this work advances both the design of algorithmic tools for family reunification and the understanding of human-reporting dynamics that shape their effectiveness.

2 - Keeping the Human in Humanitarian: the Effects of Artificial Intelligence on Donations to Humanitarian Organizations

Marialena Bevilacqua, University of Notre Dame, Notre Dame, IN, United States, Cameron Kormylo, Alfonso Pedraza-Martinez

The increasing adoption of artificial intelligence (AI) by for-profit organizations (FPOs) is largely driven by its potential to enhance operational performance. Nonprofit organizations (NPOs) have begun to adopt AI in hopes of achieving similar benefits. In particular, humanitarian organizations are utilizing AI to improve the efficiency and effectiveness of relief provided to victims of disaster worldwide. However, unlike FPOs that are funded by paying customers, humanitarian organizations rely on donor contributions. Private donors, who do not receive direct goods or services in return for their contributions, are motivated by a range of organizational, internal, and external factors specific to the humanitarian context. While customer preferences are well-studied, little is known about how private donors perceive the use of AI in humanitarian contexts. This research investigates the impact of AI adoption on private donor behavior through a series of online experiments using choice-based conjoint designs. Our findings reveal a strong preference for humanitarian organizations that do not utilize AI for decision making, with significant reductions in donation amounts when AI is involved. This effect holds even when private donors are only exposed to AI-utilizing organizations. Employing a between-subjects experimental design, results suggest an approximately 27% decrease in donations among individuals only exposed to organizations utilizing AI compared to individuals only exposed to organizations not utilizing AI. These insights offer valuable implications for the integration of AI in humanitarian organizations and the importance of addressing private donor perceptions to maintain trust and financial support.

3 - Enabling Personalized Learning with Large Language Models via Reinforcement Learning

Tsai-Hsuan (Angel) Chung, The Wharton School, UPenn, Philadelphia, PA, United States, Hamsa Bastani, Osbert Bastani, Ling-Chieh Kung

Education technology, from Information and Communication Technology (ICT) to recent advancements in Generative AI have proven to be a double-edged sword in shaping student learning, depending on how these tools are incorporated and implemented in education. The inevitable widespread adoption of technologies like ChatGPT highlights the necessity to leverage these tools to enhance rather than hinder educational outcomes. While research indicates that LLMs can democratize education by offering personalized support, the existing personalization approach is “passive”, assuming a level of self-awareness and assessment capability in educators and learners that might not be readily available, especially among low-achieving students and under-resourced settings.

This paper develops and incorporates reinforcement learning with a large language model to help assess each student’s unique educational needs dynamically to provide “auto-adaptive” personalized learning. In collaboration with Department of Education of Taipei City Government, we conduct a large scale randomized control trial (RCT) by offering students a GPT-4-powered mentoring interface enhanced by reinforcement learning. We aim to evaluate whether incorporating reinforcement learning with LLMs significantly enhances the personalization of learning experiences and contributes to more equitable educational environments. Through this study, we demonstrate how adaptive AI interventions can actively support diverse learners and bridge gaps created by traditional passive personalization strategies.

4 - Online, but off-Task: Broadband as a Tool and a Temptation in the Student Learning Process

RJ Niewoehner, Kelley School of Business, Indiana University, Bloomington, IN, United States, Eric Xu, Eunae Yoo, Hyojun Jeong

Background: Providing education is inherently a service operation, an operation with a particular interest in quality outcomes. In today's learning environment, the quality of the service increasingly depends on the quality of the service channel between instructor and student. An internet connection has become the service channel that unlocks resources that can enhance student learning.

Aim: Though prior literature has studied how internet access affects student learning globally, the results remain mixed and context-dependent. We aim to fill the gap by answering: Does access to a reliable internet connection affect student learning outcomes across the US? A longitudinal, US-based study can leverage the diversity between states to connect internet access to student outcomes and so inform national policy and broader international discussions.

Results: All of the following correspond to an increase in math proficiency: greater access to broadband internet, less reliance on cell-only internet, or smaller broadband disparities within a district. Relative to average proficiency, we observe that a 1% increase in broadband corresponds to a greater than 1% increase in proficiency nationally. More interestingly, we find that though proficiency initially improves with broadband speed, the effect eventually reverses (mirroring an inverted U-shape). Such a “tipping point” indicates some students may not be able to resist the temptations of faster internet. We also find some of the effects vary depending on the economic status and even the age of student groupings, as economically advantaged and younger students see greater gains.

5 - Can Increased Platform Liability Reduce Sex Trafficking? Evidence from the Price Effect

Helen Zeng, University of California, Davis, Davis, CA, United States

In March 2018, the U.S. Congress enacted a liability regulation called FOSTA-SESTA that made it illegal for digital platforms to knowingly assist, facilitate, or support sex trafficking. While there has been contentious debate as to whether regulations such as FOSTA-SESTA should exist or be modified to address a variety of concerns, there remains a basic question of whether the law had the intended effect: reducing the supply of minors being advertised on websites providing commercial sex advertisements to US consumers. In this paper, we provide empirical evidence for answering this question.

Our research introduces a novel approach to measuring the effectiveness of platform liability in addressing underage sex trafficking by examining its impact on transaction prices for commercial sex services. Using data from two escort review sites, we employ both linear and double machine learning difference-in-differences frameworks. Our analysis reveals a 7%-17% increase in transacted prices for service providers from the youngest age group relative to other participants. These findings suggest that platform liability increased the difficulty of selling minors in the online commercial sex market. We further show conditions for when this increase in transacted prices of service providers from the youngest age group corresponds to a reduction in the supply of minor participants. Our results contribute to policy discussions on platform regulation through liability-based approaches and offer broader implications for the governance of harmful content in digital marketplaces and the regulation of technological harms.

Strategic Perspectives on Food Supply Chains and Food Security: Allocation, Risk, and Resilience

Invited Session

Decision Analysis Society

Chair: Deniz Besik, University of Richmond, Richmond, VA, United States

Co-Chair: Deniz Karakoc, Arizona State University, Tempe, AZ, United States

1 - A Multi-Tiered Network Equilibrium Model of Fresh Produce Supply Chains with Discounting and Donations

Deniz Besik, University of Richmond, Richmond, VA, United States

This paper develops a multi-tiered network equilibrium model for fresh produce supply chains that incorporates quality deterioration, discount timing decisions, and food donation incentives. Distributors and retailers interact under Cournot-Nash competition, with retailers facing uncertain demand across a finite selling period. Retailers can dynamically adjust prices through discounting and donate surplus produce to food banks to receive tax benefits. The equilibrium model is formulated as a finite-dimensional variational inequality. Numerical results provide insights into optimal pricing, fresh produce allocation, and donation decisions, offering managerial guidance for balancing profit maximization with sustainability and food equity goals.

2 - Natural Disaster Risk and Food Infrastructure

Rocio Tenorio, University of Richmond, Richmond, VA, United States

Food infrastructure is critical for global health and safety. Food banks in particular serve as essential food access resources, as well as for community building, access to health care, and for community disaster preparedness. While these food banks are essential for meeting the needs of vulnerable populations, the food banks themselves can be vulnerable to a variety of natural disaster risks. Following a natural disaster, several factors can influence the food bank’s ability to meet demand, including destruction to the road access network, damage to the facility itself, lack of transportation resources for customers, loss of energy, loss of water, and others. This paper develops a

model to evaluate food infrastructure vulnerability to various disaster risks; and leverages a multi-criteria approach to define highest priorities for investments in food bank resilience. The methods and results of this study will be of interest to risk assessors, policy managers, and the general public.

3 - Spatio-Temporal Trends of Food Consumption: Implications for Food Waste and Insecurity in the U.S

Deniz Karakoc, Arizona State University, Tempe, AZ, United States

Food consumption is a vital topic of discussion regarding the social, economic, and environmental impacts of agri-food systems. Particularly in the United States, food consumption is a major contributor to food waste and a direct indicator of socio-economic inequalities. Thus, it is essential to better understand the country's food consumption trends across time and space in a finer resolution. We introduce a machine-learning integrated multi-criteria decision-making framework to assess how the surrounding environment impacts local food consumption and to what extent. We also pinpoint the spatially resolved highest food-consuming U.S. counties through time. These locations also account for higher food waste and insecurity. Our findings can improve the understanding of agri-food systems and can aid policies to enhance food security and sustainability.

4 - An Optimization Model for Designing Urban Food Networks with Diverse Facility Types and Accessibility Constraints

Meen-Sung Kim, Georgia Institute of Technology, Atlanta, GA, United States, Sofia Perez-Guzman, Carla Tejada, Otgondulam Boldbaatar

Urban food access interventions often rely on limited definitions of infrastructure—focusing primarily on supermarkets—while failing to account for the broader variety of food outlets that serve different community needs. This study develops an optimization framework to guide the design of urban food networks aimed at improving spatial access to fresh food for underserved populations. Building on prior efforts to classify diverse food infrastructure—including traditional and non-traditional outlets with varying purposes—this phase of the project formulates a decision-support model that incorporates accessibility constraints, facility capacity, and minimum consumption thresholds. The model selects from a set of candidate facility locations to ensure each population group is served by at least one viable facility within travel time and distance limits. The objective function incorporates an accessibility measure that balances facility attractiveness—based on capacity—and travel impedance, capturing how distance and travel time reduce the likelihood of access. This allows for exploring trade-offs in placement decisions that affect proximity, coverage, and equitable access. The framework is designed to flexibly incorporate diverse facility types and behavioral access parameters, supporting future exploration of infrastructure configurations in urban settings. The framework is currently being applied to the Chicago metropolitan area to explore how different facility types and spatial configurations affect accessibility outcomes. Its structure supports future integration of diverse food outlet typologies and policy levers, offering a flexible platform for testing equitable strategies to improve urban food access.

5 - A Location-Allocation Model for Food Distribution in Post-Disaster Environments

Diana Ramirez-Rios, University at Buffalo, Buffalo, NY, United States, Angelo Soto-Vergel, Trilce Encarnacion, Johanna Amaya

This research investigates the optimal location decisions in a food distribution network in post-disaster environments. We propose a location-allocation model for a food bank network that minimizes the total social costs generated by distributing food supplies to disaster survivors through the network's points of distribution (PODs), e.g., food pantries. The social costs include the costs of the delivery operation and the external costs of the survivor's suffering in the form of deprivation costs. Our model incorporates an empirically estimated deprivation cost function for food and water supply, which is non-linear with respect to the survivor's deprivation time. We define the deprivation time as the time a survivor has to wait for the delivery, which includes their travel time to the POD and their expected waiting time to receive the food supplies. The model proposes the optimal location of PODs and their allocation to demand zones for food distribution following a disaster, along with a relief distribution strategy. We used the Houston Food Bank network to test the feasibility of activating the nodes as a relief distribution network that could serve the impacted community. The instances aim to mimic a potential design that would have been implemented in response to a future disaster like Hurricane Harvey in 2017. It also addresses the impact of location on delivery frequencies and shipment sizes. The results provide practical insights that can help prioritize the needs of survivors during an emergency or disaster event.

Assorted Topics I

Contributed Session

Contributed

Chair: Justin Keeler, Wichita State University, Maize, KS, United States

1 - A Conjoint Analysis Model with Attribute Groups : Focused on Smartwatch

Sangwon Eum, Korea University, Ansan-si, Korea, Republic of, Hosun Rhim

In this paper, we develop a conjoint analysis model based on attribute groups to effectively consider massive numbers of attributes. In the proposed model, all attributes are divided into multiple attribute groups, and conjoint analysis is performed for each attribute group. Then the results are integrated. Unlike existing models, we do not conduct bridging experiments to aggregate subproblems; instead, we integrate them by including one common attribute to all attribute groups and standardizing based on the part-worths of that attribute. We applied newly developed model to the design of a smartwatch.

2 - After the Party: Unlocking Post Incubation Success in Corporate Incubators

Pragathi Mavinakere Swamygowda, Rotterdam School of Management, Erasmus University, Bengaluru, India, vareska van de rande, Murat Tarakci

Corporate incubators are increasingly adopted by firms to drive innovation by integrating emerging technologies into corporate strategies. However, their true value is realized in the post-incubation phase, where innovations are integrated, scaled, and sustained within the parent firm. Using the structured systematic literature review methodology (Denyer & Tranfield, 2003), we analyzed 40 peer-reviewed articles spanning 2001-2024. Through thematic coding, the study identifies key antecedents, mediators, moderators, and post-incubation innovation outcomes across internal and external corporate incubator models. Internal incubators thrive on R&D capabilities, strategic alignment, and knowledge management systems. These are activated through mediators such as knowledge-sharing platforms and cross-functional collaboration, producing outcomes like accelerated innovation cycles and enhanced market positioning. External incubators, on the other hand, leverage ecosystem connectivity, open innovation practices, and boundary-spanning activities, with mediators including resource fit and external knowledge integration. Their success results in market-oriented innovations and ecosystem synergies but is influenced by moderators such as institutional support and market dynamics.

The study integrates the resource-based view, dynamic capabilities theory, and absorptive capacity theory to contextualize how firms acquire, assimilate and exploit knowledge during post-incubation. Our proposed integrative framework underscores the centrality of absorptive capacity in bridging innovation and application across both incubation models. Thereby, this research provides actionable insights for corporate incubation strategies to ensure sustainable innovation and long-term corporate advantage.

Keywords:

Post-incubation, corporate incubators, innovation management, external incubators, innovation scaling, corporate success, competitive advantage, knowledge integration, strategic agility.

3 - Ecompass: a Decision Support System for Finding Optimal Locations

Vijay Paidi, Dalarna university, Falun, Sweden, Kenneth Carling, Niklas Rudholm

Identifying optimal locations has long been a priority when establishing facilities or business units. Optimal locations can reduce travel distances and, consequently, emissions, contributing to environmental sustainability. While omnichannel retailing and e-tailing are on the rise, a significant number of consumers still visit physical

stores, especially for groceries and other essential goods. This persistence is often due to logistics complexity, automation costs, or the value of in-person product experiences. Optimizing facility locations for consumer electronics, for example, has the potential to reduce emissions by 35%. This opportunity is not unique to retail, it extends to sectors such as healthcare, education, and urban planning. Given the widespread relevance of this issue, there is a clear need for user-friendly, open-source tools that support such location decisions. We present eCompass, an open-source web application that helps identify optimal facility locations by considering both population density and associated carbon emissions. eCompass can support decisions such as selecting a new store location, evaluating a set of candidate sites, expanding a business chain, or pruning underperforming outlets. We demonstrate its utility using a case study of IKEA store locations in Sweden. In 2013, IKEA operated 17 stores and expanded to 20 by 2015. Our analysis shows that similar access could have been achieved with fewer stores, highlighting how eCompass helps to reduce emissions by minimizing unnecessary travel. Although eCompass does not address all real-world complexities of facility location, it offers valuable, data-driven insights to support decision-making in sustainability-conscious planning.

4 - Geodesic Paths and Location Problems in Different Lp-Norms Polyhedral Complexes

Justo Puerto, Universidad de Sevilla, Seville, Spain

In this paper we address two different related problems. We first study the problem of finding a simple shortest path in a d-dimensional real space subdivided in several polyhedra endowed with different lp-norms. The second problem that we consider is the continuous single facility location or Weber problem that results in this subdivision of lp-normed polyhedra. The first problem is a variant of the weighted region problem, a classical path problem in computational geometry introduced. As done in the literature for other geodesic path problems, we relate its local optimality condition with Snell's law and provide an extension of this law in our framework space. We propose a solution scheme based on the representation of the problem as a mixed-integer second order cone problem (MISOCp). We derive two different MISOCp formulations, theoretically compare the lower bounds provided by their continuous relaxations, and propose a preprocessing scheme to improve their performance. The usefulness of this approach is validated through computational experiments. The formulations provided are flexible since some extensions of the problem can be handled by transforming the input data in a simple way. To solve the second problem, we adapt the solution scheme that we developed for the shortest path problem and validate our methodology with extensive computational experiments.

5 - Sorting Matters: On Exact Recovery in Discrete Ordered Median Problems

Victor Blanco, University of Granada, Granada, Spain, Diego Laborda, Miguel Martinez-Anton

The core goal of clustering is data group recognition according to some criterion. It ensures a non-supervised classification of data into clusters with similar features. Because of its practical potential, clustering problems have become a main concern in data science and a ubiquitous tool with a wide range of applications in natural or social science, management, and engineering. Among the goodness of this class of problems, one finds the flexibility and relevance of the decision-maker at the time of setting the group criterion. Over the last decades, modern optimization has emerged as a powerful field to tackle problems in classification and data science. Within this framework, clustering problems meet location theory. The k-median clustering approach uses a proximity criterion to detect data groups close to each other and distant from others.

In 2000, Puerto and Fernandez introduced ordered median operators into location theory, which serve as clustering criteria and give rise to the class of discrete ordered median problems (DOMP). These aim to minimize the weighted sum of distances to their respective centers, accounting for the order of distances, making sorting part of the decision. By adjusting the weights, one can retrieve the k-median, the minimax, among other robust variants.

We study exact recovery in key mixed-integer linear programs for DOMP, identifying conditions that guarantee optimal integer solutions for their linear programming (LP) relaxations. This means a first step toward exact and polynomial-time solutions via LP relaxation, enabled by prior knowledge of data distribution in ordered problems.

6 - Don't Smash the Watermelon! Field-Tested Tools for Teaching Analytics Field Courses

Patrick Noonan, Emory Univ., Emeritus, Greensboro, NC, United States

Project-based field courses - real problems with real clients - are widely used to bridge theory and practice, to infuse soft skills into a hard curriculum, and to otherwise integrate and reinforce diverse methodological approaches. But these courses are hard to pull off well, with risks for students, clients and the faculty responsible for them. A field-tested curriculum built around "structured problem solving" (the canon of the consulting profession), along with a classroom-tested pedagogy for analytics students, can increase the effectiveness of field projects and better prepare students for the work environment.

7 - Beautifying Analytical Workflow and Syntax Documentation via Quarto: a Technical Workshop Session

Justin Keeler, Wichita State University, Maize, KS, United States

This technical session is designed to show scholars how to take their workflow and analytical syntax documentation beyond scripts in an IDE. A focus will be on using Quarto within RStudio for R and within VSCode for Python. I will provide access to my GitHub repository for attendees to have working code as templates during and after the session. I need a full 75 minutes for this workshop. The value proposition of this offering is showing individuals how to create html and/or pdfs of their workflows/syntax can have multiple purposes - personal annotation, teaching documentation, or potential book publishing (see R for Data Science - <https://r4ds.hadley.nz/quarto.html>).

1 - *Nr Qflex: a Quantile Basis Expansion Framework for Flexible Probability Distributions

Eric Bickel, The University of Texas at Austin, Austin, TX, United States, Connor Colombe, Benjamin Leibowicz

We present **QFlex**, a new family of probability distributions built on the **Quantile Basis Expansion** (QuBE) framework. QuBE defines quantile functions as linear combinations of monotonic basis functions composed with valid base quantile functions, ensuring strict monotonicity and distributional validity by construction. QFlex specializes this approach using interleaved odd-power transformations of exponential, reflected exponential, and uniform quantile functions. The resulting system offers high flexibility, supports bounded and semi-bounded forms via transformations, and allows interpolation through arbitrary quantile assessments. Compared to existing systems like Metalog, QFlex demonstrates improved accuracy, stability, and structural interpretability across a wide range of distribution shapes and applications.

2 - Developing a Value Model Using Microsoft Copilot & Potential and Pitfalls

Gregory Parnell, University of Arkansas, Fayetteville, AR, United States, Eric Specking, Nicholas Shallcross

Unmanned Aeronautical Vehicle (UAV) Swarms are being used and developed for many national security and civilian applications. We decided to develop a multiple objective value model for two book chapters in a new book on Military Operational Analysis and use UAV Swarms as our illustrative example. One chapter would develop the model. The second chapter would apply the model to an analysis of alternatives. As an experiment, we decided to use Microsoft CoPilot prompts as the primary source for the objectives, value measures, and value model. We describe the prompts we used, the CoPilot responses, and the changes the authors made to correct omissions and errors. The results demonstrate the potential and the pitfalls of using generative AI in decision analysis

3 - Wisdom of Sequential Crowds: Quantile Forecast Aggregation with Learning and Updating

Majid Karimi, California State University San Marcos, San Marcos, CA, United States, Arthur Carvalho

From forecasting the yield of corn in agribusiness problems to winning the Nenana Ice Classic by correctly estimating the exact date and time the ice breaks on the Tanana River, point forecasts are often made sequentially, allowing for *learning* and *updating*. This study investigates quantile forecast aggregation in the presence of learning from previous forecasts and updating whenever new information becomes available. In the absence of learning or updating, simple averaging of quantiles is often a common and robust solution, canceling out the individual biases. In sequential settings, however, point forecasters (humans, machines, or both) can engage in social learning — learning from others' actions — and update their forecasts in light of new information. Furthermore, optimal forecast combinations in sequential settings, in particular, can be hard to come by due to the significance, relevance, or efficacy of the forecasters' historical performance. Using synthetic and real data, we explore different aggregation methods, including our proposed Bayesian approach, and compare different techniques. We find that incorporating learning and updating results in sharper and more calibrated forecasts in sequential settings, particularly for the proposed Bayesian approach and even when considering simple learning heuristics such as quantile matching estimation.

4 - Combining Model Predictions for Decisions with Asymmetric Costs

Andrea Hupman, University of Missouri - St. Louis, Saint Louis, MO, United States

Predictive models provide information to help determine policies that maximize the value to the decision maker. This work examines the case of a two-action decision that is informed by an ensemble of predictions from multiple models, and where the prediction errors have asymmetric costs. We examine how the decision maker's risk attitude and the underlying probability distributions interact to affect value, and also how the properties of the component models and the approach to combining them interact to affect value.

Experimentation in Operations

Invited Session

MSOM: Supply Chain

Chair: Chonghuan Wang, Massachusetts Institute of Technology, Cambridge, MA, United States

1 - Effect Sizes, Sequential Methods, and Advancing Experimentation for Science and Industry

Ken Kelley, University of Notre Dame, Notre Dame, IN, United States

Experimentation in digital and non-digital contexts is about making inferences from samples to a population. Inferences may be in terms of the existence of effects, the size of effects, finding the best treatment, among other reasons. In this talk I discuss questions a manager or research might have when designing studies and discuss multiple perspectives of inferences for multiple types of effects. In particular, I consider planning studies from the accuracy in parameter perspective to obtain accurate estimates of magnitude of an effect or statistical power analysis to have a specified probability of obtaining a statistically significant effect if the null hypothesis is false. With regards to effect sizes, in addition to discussing the concept of effect size itself, I consider omnibus effects to quantify a general hypothesis and targeted effect sizes to quantify a specific effect of interest. I show how different types of designs for digital experimentation have implications that go beyond a single experiment and discuss how a narrow view of experimentation can impact the way in which a firm leverages study results. Ultimately, I argue that while selection of the best of two treatments (A/B) might be an industry standard, it is a narrow way to understand customers, contexts, and limits a firm's cumulative knowledge and consideration of heterogeneous findings that can lead to future advancement and successes.

2 - Safe Reinforcement Learning with Contextual Information: Theory and Applications

Esmail Keyvanshokoo, Mays Business School Texas A&M University, College Station, TX, United States, Junyu Cao, Tian Liu

We develop a new safe reinforcement learning (RL) theory that learns a personalized, safe control policy under uncertainty, modeled as a contextual constrained Markov decision process with unknown dynamics and constraints. Our approach ensures safety throughout the learning process and achieves sub-linear regret, significantly improving upon existing results in both safe and contextual RL. We validate our approach using synthetic and clinical data from patients with co-morbid type 2 diabetes and hypertension, demonstrating its superiority over current benchmarks and highlighting its broad applicability to domains requiring both safety and personalization.

3 - Pricing Experiments in Matching Marketplaces Under Interference: Designs and Estimators

Arthur Delarue, UVA Darden School of Business, Charlottesville, VA, United States, Kleanthis Karakolios

Interference between treated and untreated units is a source of bias in marketplace experiments. In this paper, we specifically consider pricing interventions, in which a platform seeks to adjust base pricing levels at the marketplace level in order to increase demand. In a matching marketplace, this type of experiment leads to a crucial design question: should the platform match treated and untreated units differently because they paid different prices? We find that standard estimation techniques are biased, but the sign of this bias depends strongly on this design choice. Bias can be reduced by using the "shadow price estimator", which relies on the optimal dual solution of the platform's supply-demand matching problem; especially when the platform chooses to ignore pricing differences at matching time. We validate our findings both theoretically in a fluid limit setting, and numerically in a finite-sample setting.

4 - Benefits and Costs of Adaptive Sampling for Inference

Yu-Shiou Lin, Columbia University, New York City, NY, United States, Dae Woong Ham, Iavor Bojinov

Multi-arm bandits are gaining popularity as they enable real-world sequential decision-making across application areas, including clinical trials, recommender systems, and online decision-making. While prior work typically focus on regret-minimizing properties of multi-arm bandits or enabling valid inference from adaptively collect data, it is still unclear whether one should adaptively collect data for more effective inference. To address this gap, we characterize the trade-offs involved in adaptive experimentation when both objectives are considered in a multi-arm setting.

Using both fixed and adaptive allocation rules, we analyze different mean squared error (MSE) based objectives as a measure for inference guarantees. Our theoretical results demonstrate that adaptive allocation can reduce total MSE when variances are heterogeneous and correlated with arm means; however, no single allocation rule uniformly dominates across all arms. This finding underscores the importance of optimizing inference for a targeted subset of arms rather than uniformly distributing samples across all treatments. Simulation results support these insights: adaptive strategies consistently outperform uniform allocation for high-variance arms, particularly in settings with imbalanced variance. These findings motivate a reevaluation of the goals of online experiments. Beyond traditional regret minimization, we advocate for inference-oriented performance metrics that also consider estimation accuracy for arms of greatest interest. This work proposes a framework for adaptive experimentation that integrates exploitation, statistical efficiency, and targeted inferential precision.

Socially Aware Service Operations

Invited Session

MSOM: Service Operations

Chair: Vahideh Manshadi, Yale, Westwood, United States

1 - Who to Offer, and When: Redesigning Feeding America's Real-time Donation System Amid Heterogeneous Response Times

Soonbong Lee, Yale university, New Haven, CT, United States, Vahideh Manshadi, Daniela Saban

In collaboration with Feeding America, we aim to redesign RealTime, its growing food rescue system that connects ad-hoc, time-sensitive food donations to local agencies through an offering process. Due to heterogeneity in agencies' response rates, in making offering decisions, RealTime and similar platforms face a key challenge in balancing efficiency and equity: offering to many agencies upfront improves efficiency (likelihood of acceptance) but may disadvantage those with lower response rates. The uncertainty of future donations further complicates offering decisions. Motivated by these challenges, we study a dynamic offering problem in which donations arrive sequentially and are matched through a multi-stage offering process. The goal is to maximize an objective balancing efficiency and equity—promoting allocations proportional to agencies' needs. We first develop a dynamic programming (DP) algorithm that optimally solves the one-donation problem and yields an intuitive nested offering sequence. Moving beyond one donation, and motivated by the ad-hoc nature of donations, we take a robust approach to designing sequential offering policies that do not rely on knowledge of future arrivals. Our policy solves a modified one-donation DP by applying properly designed penalties to historical allocations to hedge against uncertainty. We establish strong—and optimal in asymptotic regimes—performance guarantees of our proposed policy. We further show the importance of hedging: a greedy policy solving one-donation DP without hedging fails to achieve comparable guarantees. Numerical results on real data demonstrate that our approach significantly improves both equity and efficiency relative to current practice and several benchmarks.

2 - Algorithmic Pricing, Transparency, and Discrimination in the Gig Economy

Daniel Chen, Boston College, Chestnut Hill, MA, United States, Gad Allon, Kenneth Moon

Algorithms control pricing and match customers and workers in the gig economy. However, algorithms face several critiques: they lack transparency, can be biased, and can be inefficient. We empirically analyze these issues and show that variation in algorithmic pricing incentivizes workers to decline a large portion of trips in practice, significantly decreasing system efficiency. We estimate policy counterfactuals and show that minimum wage and transparent pricing policies can improve efficiency without harming fairness constraints.

3 - Data-Driven Inventory Management Under Privacy Concerns

Elena Belavina, Cornell University, New York, NY, United States, Lorraine Yuan

Firms increasingly rely on customer data to improve demand forecasting and inventory management. However, attackers can exploit these data-driven decisions—by linking them with external information—to infer sensitive data, raising serious privacy concerns and limiting adoption. This study develops and compares privacy-preserving approaches for data-driven inventory management that are robust to such attacks. We propose differential privacy-based adaptations of two leading data-driven inventory management methods—the traditional two-step estimate-then-optimize, and a more contemporary one-step joint estimate-optimize paradigm—and establish theoretical guarantees on their performance. We quantify trade-offs between privacy protection, profitability, and customer surplus. Our analysis shows that the one-step paradigm dominates the two-step paradigm by enabling lower-cost privatization of customer data through more targeted noise injection, achieving lower privacy exposure risk, higher profitability, and greater customer surplus. This finding reshapes our understanding of privacy protection—the costs and benefits of privacy preservation are not only driven by the privacy algorithms used but are also fundamentally shaped by the underlying data-driven decision-making paradigm. We also show that a firm that uses our methods and chooses an optimal privacy level will, in fact, increase its demand, profit, and customer surplus (under most conditions)—challenging the notion that privacy protection comes necessarily at a cost. Numerically, one-step algorithms offer 3–6 stronger privacy and up to 40% higher profits than the two-step alternative—benefits that remain even under high customer sensitivity to privacy.

4 - Multi-Listing for Horizontally Differentiated Services

Yichuan Ding, McGill University, Montreal, QC, Canada, Zhou Chen, Luyi Yang

This paper studies a queueing system with horizontally differentiated servers. Each customer decides whether to join the queues of multiple servers simultaneously ("multi-list"), join the queue exclusively served by her preferred server, or balk. Such a multi-listing system contrasts a single-listing system, which allows for server choice but prohibits multi-listing, and a pooling system, which precludes server choice by requiring every joining customer to multi-list. We build queueing-game-theoretic models of the three systems above and compare their throughput and social welfare in equilibrium. Between a single-listing system and a pooling system, the former better facilitates matching between customers and servers, whereas the latter excels at reducing waiting time through load balancing. Accordingly, we find that either system can outperform the other in either throughput or social welfare. We find that multi-listing indeed outperforms pooling in both throughput and social welfare. While multi-listing also achieves higher throughput than single-listing, it can strikingly underperform single-listing in social welfare. In contrast to the equilibrium, both the social-welfare-maximizing or revenue-maximizing routing policies of the multi-listing system can be asymmetric across the servers even when the servers are ex-ante symmetric. Relative to the socially or revenue-optimal state, customers under-choose multi-listing in equilibrium when the congestion level is low but may over-multi-list otherwise. The social planner can charge nonnegative, asymmetric prices to restore efficiency and profitability in equilibrium. Our paper provides design guidance for the configuration of multi-server service systems.

Data-driven Sustainable Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Neha Sharma, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States

1 - Modeling Borrower Intent: Optimizing Commercial EV Loan Management

Leann Thayaparan, Johns Hopkins University, Baltimore, MD, United States, Vikas Deep, Neha Sharma

The adoption of commercial electric vehicles (CEVs) is crucial for reducing logistics emissions but remains limited, especially among small businesses that dominate markets like India. These firms face high upfront costs and lack access to favorable financing due to uncertainties around CEV value and borrowers' creditworthiness.

This study presents a novel framework to improve lending decisions and interventions by introducing a latent "willingness to pay" (WTP) metric. We model borrower behavior using a Markov decision process, where the firm's actions—calls, visits, or repossession—depend on WTP estimates derived from high-dimensional features including vehicle usage.

Our collaboration with Turno, a major Indian CEV lender, provides a rich dataset combining financial and usage information. Results show our approach improves prediction accuracy, reduces bias, and better allocates costly interventions. By explicitly modeling WTP, we also introduce interpretable and fairer decision-making that considers not just repayment likelihood but also the cost-benefit tradeoffs of lender actions.

This work contributes to literature on credit risk, fairness, and interpretable machine learning. It highlights the value of data sharing between EV producers and lenders, offering a practical path to broaden CEV adoption while maintaining financial sustainability in emerging markets.

2 - Learning Sustainability Assessments

Ilgın Dogan, INSEAD, Fontainebleau, France, Atalay Atası, Luk Van Wassenhove

This paper studies the ecosystem of a sustainability rating company as a sequential triadic game involving buyers, suppliers, and the company. Each party engages in parallel learning: buyers and suppliers assess the ratings' accuracy in capturing long-term risks which in turn influences their retention, while the company learns their behaviors to adapt pricing and maximize system-wide retention. Calibrated with real data, our model provides data-driven, regret-minimizing sequential decision policies that help all three parties reduce ambiguity in measuring sustainability risks.

3 - Optimal Experimental Design with Routing Constraints

Baizhi Song, London Business School, London, United Kingdom, Jean Pauphilet

Data collection in application domains like agriculture and environmental science requires the deployment of sensors in large remote areas. These use cases challenge the traditional optimal experimental design (OED) formulation from statistics by their scale as well as the presence of complex operational constraints, such as that data is collected along the trajectory of a drone. This paper proposes a tailored branch-and-bound algorithm to solve large-scale instances of OED as well as account for routing constraints. Efficient screening rules and first-order methods for solving the relaxations are key to the tractability of our algorithm, which significantly outperforms commercial solvers on both the classical OED problem and OED with routing constraints. For classical OED for example, it increases the size of instances solvable under a minute from $n=200$ to $n=10,000$. In the presence of routing constraints, it finds solutions with up to 10% higher objective value and solves twice as many instances to optimality. In use cases where data is collected to construct a predictive model, our approach achieves the same accuracy as alternative collection strategies with 30-50% less samples, hence demonstrating the potential impact of optimization on data collection cost.

4 - A Dual Perspective on Decision-Focused Learning

Paula Rodriguez Diaz, Harvard University, Boston, MA, United States, Kirk Bansak, Elisabeth Paulson

Many decision-making pipelines solve an optimization model on predicted inputs (predict-then-optimize, PtO). Decision-Focused Learning (DFL) trains predictors to improve downstream decisions rather than minimize predictive error; however, state-of-the-art methods either differentiate through the optimizer or employ tight task-specific surrogates, requiring frequent solver calls and inflating training cost. We propose a dual-guided DFL procedure that preserves decision alignment while sharply reducing solver-in-the-loop cost: the downstream problem is solved only at scheduled refreshes to estimate Lagrange multipliers, and between refreshes the predictor is updated on dual-adjusted targets using simple surrogate losses. Tuning the refresh interval trades compute for fidelity: longer intervals approach standard ERM, while shorter ones recover classical DFL. Across representative PtO tasks, the method matches the decision quality of solver-heavy baselines with substantially fewer solver calls and lower wall-clock time, improving the scalability of decision-aware learning to large datasets.

Consumer Choice Models

Invited Session

Revenue Management

Chair: Qi Feng, Purdue University, West Lafayette, IN, United States

Co-Chair: MENGYING XUE, Fudan University, Shanghai, N/A

1 - A Feature-Based Consideration Set Choice Model for Online Retailing

Ashwin Venkataraman, University of Texas at Dallas, Richardson, TX, United States, Amin Farzaneh, Sajad Modaresi

We propose a feature-based consideration set choice model (FCM) motivated by customers' purchasing behavior in online retail platforms. The FCM incorporates heterogeneity in customer preferences across both the consideration and purchase stages, and allows customers to re-evaluate products' utility in the second stage. We develop an efficient maximum likelihood estimation procedure for estimating the model parameters from customers' click and purchase data. We show that the assortment optimization problem under FCM is NP-hard by drawing a connection to the assortment problem under the LC-MNL model. We propose a variant of our model that admits a tractable MILP formulation for solving the assortment problem and also facilitates the study of the more complex joint assortment and pricing problem. Through numerical experiments on real and synthetic data, we demonstrate that our proposed model outperforms the MNL and LC-MNL benchmarks on out-of-sample prediction accuracy and decision performance. Finally, we introduce a novel operational problem which identifies the subset of features to display during the consideration formation stage to maximize expected revenue. We establish the NP-hardness of this problem under both model variants and propose a tractable MILP formulation for solving it.

2 - Modeling Consumer's Rationality: the Token Tree

Qi Feng, Purdue University, West Lafayette, IN, United States, J Shanthikumar, MENGYING XUE

We propose a tree-based representation to model individual consumer choices over a set of available options by allocating tokens along the tree branching based on the choice outcomes. The token tree framework is flexible enough to capture both rational and boundedly irrational behaviors in consumer decision-making. At the aggregate level, the expected token tree provides a basis for empirically testing the rationality of consumer choices and identifying meaningful clusters of consumer segments.

3 - Approximation Schemes for Dynamic Pricing with Opaque Products

Xingxing Chen, University of Richmond, Richmond, VA, United States, Jacob Feldman, Danny Segev, Levi DeValve, Yukai Huang

In this paper, we consider a multi-period, multi-product dynamic pricing problem in which each product is endowed with an exogenous starting inventory level, and there is the added complexity of an opaque selling option. That is, alongside traditional (transparent) products, the retailer or platform also has the option to create and price an opaque product, which corresponds to a dummy product comprised potentially of any subset of the displayed transparent products. In the event that a customer selects the opaque product, the platform has the freedom to choose any of the opaque product's constituents to satisfy this demand. All-in-all, we are left with a classical dynamic pricing problem with a twist, since the addition of the opaque selling option gives the platform an extra lever of flexibility to balance supply and demand. For this novel product setting, we develop a nuanced constant factor approximation scheme for choosing the opaque product as well as the dynamic transparent and opaque product prices in a multi-period setting.

1 - Going Live, Going Unequal? Gender Gaps in Patient Demand on Online Medical Platforms

YIXUAN LIU, Hong Kong Polytechnic University, Hong Kong, Hong Kong, YIXIN LU, Xiaofei Zhang

Medical live streaming has emerged as a novel communication tool on online medical consultation (OMC) platforms, enabling physicians to engage patients through real-time video broadcasts. However, its impact on physician inequality—particularly gender-based disparities in patient demand—remains understudied. In particular, while medical live streaming may enhance patient engagement and visibility, concerns persist that it could amplify pre-existing gender biases by disproportionately favoring male physicians, thereby exacerbating inequality in how patients allocate attention. This raises important questions about whether digital technologies democratize access or reinforce structural disparities on OMC platforms. Using data from a leading Chinese OMC platform, we examine how medical live streaming affects the gender gap in patient demand. We find that live streaming significantly increases patient demand for both male and female physicians, with a larger gain for male physicians—thereby widening the platform's existing gender gap. However, this effect reverses in female-dominated specialties and is moderated by physician seniority and streaming characteristics. Female physicians benefit more when holding junior seniority or streaming in environments that convey clinical professionalism, while male physicians gain more when exhibiting stronger emotional variation. Our study highlights how emerging digital tools can either alleviate or amplify structural inequalities depending on their design and usage. We offer theoretical and practical implications for platform operators seeking to promote equitable patient access while enhancing overall engagement through medical live streaming.

2 - Fintech Lending, Open Banking, and Data Manipulation

Yangguang Wang, University of Illinois Urbana-Champaign, Champaign, IL, United States, Fasheng Xu, Zhengping Wu

Financial inclusion remains a major challenge due to information asymmetry and limited credit histories, especially for underserved borrowers. While FinTech firms have broadened credit access using alternative data, such data can be strategically manipulated by consumers. This raises concerns about whether open banking (OB)—which grants access to consumers' banking data—can mitigate these issues and create value. We develop a signaling model to analyze OB's impact on consumer manipulation, financial inclusion, and market efficiency. OB introduces two opposing forces: a *muddling effect* that undermines alternative data value, and a *differentiating effect* that improves screening accuracy. The dominance of either effect depends on manipulation costs. When the muddling effect prevails, OB can reduce FinTech profitability and hinder inclusion. Still, it consistently raises consumer surplus by balancing manipulation incentives and lending decisions. To enhance OB's effectiveness, we propose two interventions: (1) **calibrated algorithmic transparency** to steer manipulation in beneficial ways, and (2) **semi-open banking**, which selectively limits banking data access to improve screening. These strategies help FinTechs restore data value, increase profitability, and promote broader financial inclusion. Our findings inform FinTech and policy efforts to design OB initiatives that better align consumer behavior with market efficiency.

3 - Swap Contract for Production Motivation in General Risk-Averse Newsvendor Problems

Yiwen Shen, HKUST, Hong Kong, Hong Kong, Qingfa Zhang

Risk-aversion plays a central role in agent's decision-making. In particular, it can drive producers to set lower production levels, causing economic inefficiency and welfare loss. We study this problem in a general newsvendor setting, with a social planner aiming to incentivize production from risk-averse producers. We model the decision-making of producers by a general optimization problem, which encompasses most of the objectives and risk constraints considered in the literature. To mitigate underproduction, we develop a novel swap contract between the social planner and producer by extending a return payoff function proposed in recent operations management literature. For producers with general optimization problems, the swap contract increases their optimal production quantities in an incentive compatible way towards the risk-neutral level. The swap contract is budget neutral for the social planner and robust to information asymmetry regarding producer's concrete optimization problem. Economically, the swap contract decouples the operational decision from the risk preference of producers. In addition, the social planner can manage his risk associated with the swap contract by pooling and trading his claims.

4 - Persuasion and AI News Summary

Societal Aspects of Markets -- Vahideh & Faidra

Invited Session

Revenue Management

Chair: Vahideh Manshadi, Yale, Westwood, United States

Co-Chair: Faidra Monachou, Yale University, New Haven, CT, United States

1 - Why the Rooney Rule Fumbles: Limitations of Interview-Stage Diversity Interventions in Labor Markets

Faidra Monachou, Yale University, New Haven, CT, United States, Setareh Farajollahzadeh, Soonbong Lee, Vahideh Manshadi

Many industries, including NFL with Rooney Rule and law firms with Mansfield Rule, have adopted interview-stage diversity interventions of inconclusive effectiveness. Motivated by this, we develop a framework of a two-stage hiring process, where rational firms, with limited interview and hiring capacities, aim to maximize the match value of their hires. There are two equi-sized groups, m and w , with identical ex-post match value distributions. Match values are revealed only post-interview, while interview decisions rely on partially informative pre-interview scores. Pre-interview scores are more informative for group m , while interviews reveal more for w . Therefore, if firms could interview all candidates, both groups would be equally hired. However, we show that requiring equal representation in the interview stage does not translate into equal representation in hiring. With or without intervention, a firm may interview more group w candidates but still hire fewer. At an individual level, we show that strong candidates from both groups benefit from the intervention as the candidate-level competition weakens. For borderline candidates, only group w candidates gain at the expense of group m . Furthermore, we study two vertically differentiated firms, where only the top firm adopts the intervention. We show that, due to increased firm-level competition, the lower firm may hire fewer group w candidates, and find examples where fewer group w candidates are hired across the market. At an individual level, while superstar candidates in both groups benefit, surprisingly borderline candidates may be worse. Generally, our natural two-stage market framework may be of independent interest.

2 - Centralization Vs Decentralization in Hiring and Admissions

Juba Ziani, Georgia Tech, Atlanta, GA, United States, Benjamin Fish, Diptangshu Sen

There is a range of ways to organize hiring and admissions in higher education, as in many domains, ranging from very centralized processes where a single person makes final decisions to very decentralized processes where many people make decisions about who to admit or hire. Decentralized processes can enable individual and collective empowerment, but this may come at the cost of efficiency. With the advent of automated decision making, this question of centralization has a big impact on hiring and admissions, given that automated systems often are easier to implement, or even require, more centralized decision making.

In this paper, we develop a strategic model to explore the impact of the degree of centralization on both the candidates and the hirers, with a focus on university admissions. The model reflects a trade-off between a centralized committee where preferences may not capture individual hirers' preferences, and a decentralized process where individual hirers face extra costs to interview candidates themselves. We characterize when individual hirers prefer the decentralized process over the centralized process as a function of the degree to which the centralized process and hirers' preferences are aligned. We also show that decentralization can have devastating consequences for fairness, leading to major disparities in the likelihood of getting hired across candidates. Our results demonstrate the trade-offs that occur under the question of centralization vs decentralization, and point to how an answer to this question can impose significant harm to people in these systems.

3 - Learning Fair Demand Models

Hyemi Kim, Columbia University, New York, NY, United States, Adam Elmachtoub, Jonathan Tan

Fairness is an increasingly critical concern in algorithmic pricing, particularly when decisions have disparate impacts across demographic groups. This work examines the role of fairness constraints in machine learning-based pricing pipelines, focusing on a two-stage framework comprising demand estimation and price optimization. We incorporate fairness into the estimation stage from both price and demand perspectives and assess its impact on downstream outcomes such as revenue. These results are then compared to interventions applied at the price optimization stage, highlighting how the point of fairness intervention can influence downstream outcomes.

4 - Adaptive Priority Mechanisms

Oguzhan Celebi, University of Michigan, Ann Arbor, MI, United States, Joel Flynn

How should authorities that care about match quality and diversity allocate resources in the face of uncertainty? We introduce adaptive priority mechanisms (APM) that prioritize agents based on their scores and characteristics. We show that APM uniquely implement the ex post optimal allocation. The ubiquitous priority and quota mechanisms are optimal if and only if the authority is risk-neutral or extremely risk-averse over diversity, respectively. Deferred Acceptance implements the unique stable

matching when all authorities use the optimal APM. We provide a practical roadmap for implementing APM as a market-design solution and illustrate this using Chicago Public Schools data.

5 - Accelerated Allocation Policies to Improve Utilization of Marginal Deceased Donor Kidneys

Grace Guan, Stanford University, Stanford, CA, United States, Felipe Subiabre, Philipp Strack, Itai Ashlagi

While around 90,000 patients are currently waiting for a deceased donor kidney transplant, almost 30% of recovered deceased donor kidneys go unused due to inefficiencies in the current allocation system. The Organ Procurement and Transplantation Network is currently searching for a structured and equitable way to improve organ utilization. We demonstrate how data-driven insights and simulation can provide a transparent and principled way to identify which organs are at risk of nonuse and how to allocate them.

Auctions under Limited Information

Invited Session

Auctions and Market Design

Chair: Rachitesh Kumar, Carnegie Mellon University, Pittsburgh, PA, United States

Co-Chair: Omar Mouchtaki, New York University, New York, NY, United States

1 - Single-Sample Online Resource Allocation

Sahil Singla, Georgia Tech, Atlanta, GA, United States

In online resource allocation, n buyers arrive sequentially, each with a combinatorial valuation—such as submodular or XOS—over subsets of m indivisible items. The goal is to immediately allocate a subset of the remaining items to maximize total welfare, defined as the sum of buyer valuations. While extensive prior work has addressed this problem under the assumption that buyer valuations are drawn from known, independent distributions, these algorithms typically rely on full access to the underlying distributions.

In contrast, real-world applications often offer only limited information. In this talk, we investigate how well one can approximate the hindsight optimum when the algorithm is given just a **single sample** from each buyer's valuation distribution. We show that even this minimal input suffices to achieve a **(1- ϵ)-approximation** for general buyers, assuming large item budgets, and an **$\Omega(1)$ -approximation** for submodular and XOS buyers even with small budgets.

This talk is based on joint work appearing in **STOC 2025** and **FOCS 2024**.

2 - Auction Design Using Value Prediction with Hallucinations

Omar Mouchtaki, New York University, New York, NY, United States, Ilan Lobel, Humberto Moreira

We investigate a Bayesian mechanism design problem where a seller seeks to maximize revenue by selling an indivisible good to one of n buyers, incorporating potentially unreliable predictions (signals) of buyers' private values derived from a machine learning model. We propose a framework where these signals are sometimes reflective of buyers' true valuations but other times are hallucinations, which are uncorrelated with the buyers' true valuations. Our main contribution is a characterization of the optimal auction under this framework. Our characterization establishes a near-decomposition of how to treat types above and below the signal. For the one buyer case, the seller's optimal strategy is to post one of three fairly intuitive prices depending on the signal, which we call the "ignore", "follow" and "cap" actions.

3 - An Equilibrium Model of the First-Price Auction with Strategic Uncertainty: Theory and Empirics

Bernhard Kasberger, University of Linz, Linz, Austria

In many first-price auctions, bidders face considerable strategic uncertainty: they cannot perfectly anticipate the other bidders' bidding behavior. We propose a model in which bidders do not know the entire distribution of opponent bids but only the expected winning bid and lower and upper bounds on the opponents' bids. We characterize the optimal bidding strategies and prove the existence of a novel equilibrium. Finally, we apply the model to estimate the cost distribution in highway procurement auctions. Our model fits the data better than existing approaches in which the entire distribution of opponent bidders is assumed to be known.

4 - Prior-Independent Bidding Strategies for First-Price Auctions

Rachitesh Kumar, Carnegie Mellon University, Pittsburgh, PA, United States, Omar Mouchtaki

First-price auctions are one of the most popular mechanisms for selling goods and services, with applications ranging from display advertising to timber sales. Unlike their close cousin, the second-price auction, first-price auctions do not admit a dominant strategy. Instead, each buyer must design a bidding strategy that maps values to bids -- a task that is often challenging due to the lack of prior knowledge about competing bids. To address this challenge, we conduct a principled analysis of prior-independent bidding strategies for first-price auctions using worst-case regret as the performance measure. First, we develop a technique to evaluate the worst-case regret for (almost) any given value distribution and bidding strategy, reducing the complex task of ascertaining the worst-case competing-bid distribution to a simple line search. Next, building on our evaluation technique, we minimize worst-case regret and characterize a minimax-optimal bidding strategy for every value distribution. We achieve it by explicitly constructing a bidding strategy as a solution to an ordinary differential equation, and by proving its optimality for the intricate infinite-dimensional minimax problem underlying worst-case regret minimization. Our construction provides a systematic and computationally-tractable procedure for deriving minimax-optimal bidding strategies. When the value distribution is continuous, it yields a deterministic strategy that maps each value to a single bid. We also show that our minimax strategy significantly outperforms the uniform-bid-shading strategies advanced by prior work. Finally, we analyze the impact of the value distribution on the performance loss, and find that it decreases as the buyer's values become more dispersed.

Data Analysis and Optimization in Social and Communication Networks

Invited Session

Social Media Analytics

Chair: Alexander Semenov, University of South Florida, Shalimar, FL, United States

1 - An Empirical Analysis on Systems of Nonlinear Equations for Social Network Influence Propagation Stability

Alexander Semenov, University of South Florida, Shalimar, FL, United States, Michael Hirsch, Panayote (Panos) Pardalos

How information spreads throughout a complex network can be modeled through influence propagation, Stability analysis, done through simulation of the influence propagation on the network over time, allows one to realize the final effects of the influence on all nodes of the network. In this research, we investigate various influence propagation models and the stability of the underlying complex network through the solving of systems of nonlinear equations, and compare computational results when using simulation.

2 - Coordinated Routing of Uavs and Refueling Trucks for Persistent Aerial Surveillance Using Milp

Donald McMann, University of Florida, Shalimar, FL, United States, Yongpei Guan, Alexander Semenov

This work presents a mixed-integer linear programming (MILP) formulation for coordinating fixed-wing unmanned aerial vehicles (UAVs) and refueling trucks to enable persistent surveillance over large border or coastal regions. UAVs are tasked with patrolling a grid-based coverage area, subject to battery/fuel limitations and telemetry range constraints. Ground vehicles provide mobile refueling support and must rendezvous with UAVs to recharge them during operations.

Our formulation captures UAV and truck movements through a time-expanded network, enforcing flow conservation, co-location constraints for refueling, and rolling coverage windows that ensure each grid cell is visited at least once within a predefined time horizon. The model also accounts for practical constraints such as maximum UAV flight range from a ground station and truck-only access nodes.

We implement the model in Pyomo solver and demonstrate its performance on simulated grid instances. The results highlight trade-offs between coverage persistence, battery constraints, and truck mobility. A Complexity analysis indicates that the problem is NP-hard, motivating future work on decomposition-based or heuristic approaches.

This research contributes to the growing body of work on autonomous aerial-ground system coordination and has direct applications in border security, coastal patrol, and post-disaster reconnaissance.

3 - TBA

Alexander Nikolaev, University at Buffalo, Buffalo, NY, United States

4 - Ultra-Small World Detection in Networks: Subgraphs with Prescribed Distance Distributions

Vladimir Boginski, University of Central Florida, Orlando, FL, United States

We introduce a class of distance-based clique relaxation models, which enforce certain distributions on vertex pairwise distances in the corresponding induced subgraphs. Both “local” and “global” versions of the proposed approach are studied. For the global case, the distribution of distances is considered for all vertex pairs in the subgraph. For the local (and, in a sense, more restrictive) case, the required property must be satisfied for any vertex with respect to its distances to the other vertices in the subgraph. We refer to the proposed clique relaxations as *global* and *local ultra-small worlds*, respectively. Our modeling approach has several meaningful interpretations; in particular, it is closely related to the concept of an “effective” graph diameter. Furthermore, density- and degree-based quasi-cliques are two well-known special cases of the proposed concept. We exploit these relationships to develop mixed integer programs (MIPs) that can be used with an off-the-shelf solver for finding maximum global and local ultra-small worlds. Then, we outline a simple-to-implement algorithm that iteratively solves feasibility versions of our MIPs for each possible subgraph size within some lower and upper bounds; we derive one non-trivial upper bound using the linear programming relaxations. Our modeling approach also generalizes the *k*-club concept; hence, some links to this well-known distance-based clique relaxation are also explored. Finally, to illustrate the obtained results, we perform a computational study on graphs representing various types of real-world datasets and systems. Some interesting empirical observations and insights are provided.

5 - The Effect of Repetition and Complexity Within and Between Topics on Social Media Engagement

Timothy Kaskela, Oregon State University, Corvallis, OR, United States, Jaeki Song

Social media allows organizations to communicate with individuals at a rapid pace. Research has traditionally examined the effect of a single post on engagement and other factors. However, there is an opportunity to examine the within topic effects of repetition and complexity as organizations post across longer periods of time, as the pace of communication on social media platforms allows an organization to quickly shift between multiple topics in a short time frame. This study examines the effect of repetition on engagement, as well as how complexity embedded within each post moderates said effect. A pilot study is conducted on the social media posts from 5 NASDAQ 100 companies to examine how repetition within and between posts impacts engagement, as well as how the complexity of the posts moderates this effect. The pilot study findings suggest that there is a u-shaped relationship between topic repetition and engagement, while post complexity has an inverted u-shaped direct effect on engagement. In addition, post complexity does indeed moderate the relationship between topic repetition and engagement. The findings suggest a full study examining the dynamics of repetition and complexity on social media is warranted.

1 - New Optimization Method for Assigning Vehicles to Transportation Products in Steelworks

Katsuki Shimada, JFE Steel Corporation, Fukuyama-shi, Japan, Shinji Tomiyama

In the large steelmaking companies, the products transportation between factories, warehouses, and shipping berths by special vehicles plays an important role. The vehicle assignment schedule for products transportation is made and revised manually for 24 hours. However, achieving efficient scheduling is quite challenging due to the complex interactions among many vehicles and cranes, which can be influenced by various disturbances. As a result, the current manual scheduling often leads to inaccuracies, causing increased vehicle waiting times and canceled deliveries.

In this study, we develop the new computer algorithm to generate vehicle assignment schedules for steel coil products transportation within steelworks. The proposed algorithm aims to generate feasible vehicle assignment schedules that can adapt to real-time changes of operations. It effectively distributes workloads for both vehicles and cranes by estimating the total workload for each facility. Additionally, by using a rule-based approach, the algorithm can generate a schedule in accordance with actual operations. Furthermore, the algorithm is capable of computing schedules in under one minute using straightforward logic.

To evaluate the performance of the proposed algorithm, we conducted simulation experiments. The results of simulation show that the algorithm can generate vehicle assignment schedules that reduce the number of transportation cases exceeding the scheduled completion time for transportation jobs by approximately 45% compared to manual scheduling.

The performance of the algorithm enables both efficient vehicle assignment scheduling and frequent rescheduling to adapt to the changes of operations.

2 - A Simulation-Based Sensitivity Analysis of Consensus Performance in Public Blockchains with Dynamic Committees

Jin Choi, Ajou University, Suwon, Korea, Republic of, Jaeyoung Lee

This study presents a simulation-based sensitivity analysis of consensus performance in public blockchains employing dynamic committees. In such systems, major nodes typically initiate the network, and consensus committees are formed dynamically by both major and minor nodes. We focus on node-level decentralization, defined as the proportion of a node's total stake that participates in the consensus process. Although this metric is intended to ensure fair participation, it can lead to centralization, as nodes with larger stakes tend to dominate committee involvement. To explore this issue, we conduct simulations by varying key parameters, including the number of major and minor nodes, average stake per node, stake distribution, and the number of consensus rounds. Our analysis reveals how these factors influence fairness and the risk of centralization in consensus participation. Based on the results, we propose an effective control strategy for managing dynamic committees, aiming to improve both fairness and efficiency in public blockchain networks.

3 - Developing Strategic Decision-Makers for the AI Era: Lessons from a Leadership Simulation Workshop

Joseph Cazier, Arizona State University, Tempe, AZ, United States, Daniel Mazzola, Gayatri Gade

As AI accelerates change across industries, the demands placed on future business leaders are evolving rapidly. Success now requires more than analytical ability—it depends on strategic decision-making, systems thinking, and the ability to lead under uncertainty. Yet many graduate programs struggle to deliver these skills in ways that reflect the complexity and pressure of real-world environments.

To address this gap, we designed and delivered an experiential leadership simulation for graduate business students. In this hands-on workshop, participants managed virtual companies across multiple competitive rounds, making decisions on pricing, R&D, hiring, and capital allocation. Market conditions changed dynamically, requiring teams to analyze data, respond to shifting variables, and collaborate under pressure.

The simulation was designed to align with key learning goals in critical thinking, communication, leadership, data-driven decision-making, and systems integration. Participants engaged in structured self-assessments and received individualized feedback on their decision-making processes and team leadership behaviors.

Results showed strong participant engagement and perceived skill development, with high satisfaction and demand for continued offerings. Qualitative feedback emphasized the value of learning through consequence-rich decisions in a low-risk setting—replicating the challenges of executive leadership in an AI-enabled economy.

We argue that simulation-based learning provides a scalable, high-impact model for graduate education. It allows students to move beyond theory and practice complex, integrated skills essential for leading in the digital age. We conclude with recommendations for integrating simulations into the core curriculum and for further research on longitudinal skill retention and performance transfer.

4 - A Stochastic Optimization Approach to Robust and Equitable Surgeon Workload Allocation

Jonathan Akhagbosu, University of Massachusetts Amherst, Amherst, MA, United States, Hari Balasubramanian, Tovv Kamine, Muge Capan

Surgeon workload influences clinical outcomes, provider well-being, and operational efficiency. Yet, existing research in surgical operations has largely focused on optimizing system-level resources such as operating room utilization or bed capacity, rather than considering the surgeon as a constrained resource. In addition, there is a need for incorporating workload equity in surgical case allocation to ensure optimal use of surgeons as resources. This study presents a stochastic integer programming model that incorporates workload equity into surgical case allocation. Workload is quantified using surrogate indicators, including surgery duration, American Society of Anesthesiologists (ASA) classification, case complexity, and procedure timing (regular vs. off-hours). Based on these indicators, surgical cases are grouped into discrete workload types using k-means clustering. This workload categorization informs the cost parameters used in the objective function. Equity is defined through a pairwise envy-based metric, which measures the absolute difference in total workload between any two surgeons. The model minimizes the maximum pairwise workload envy across all surgeon pairs, subject to constraints on surgical volume, surgeon availability, and uncertainty in surgery durations. Surgical cases are assigned to surgeons over a fixed planning horizon. The model was applied to a dataset of over 86,000 surgical cases performed between 2020 and 2023 across multiple specialties at a large academic medical center. Preliminary results indicate reduction in maximum pairwise workload envy by up to 87% relative to baseline assignment practices. Future research will expand the workload definition to include non-surgical tasks and develop equity-aware scheduling policies that preserve capacity for emergency cases.

5 - Payroll Minimization in Electronics Contract Manufacturing via Role-Specific Assignment of Direct, Indirect, and Managerial Labor

Luis Alcalá Becerra, North Dakota State University, Fargo, ND, United States, Diana Lopez Soto, Mohajid Saaed Osman

Electronics contract manufacturing (ECM) is a \$500-billion-dollar industry and is expected to grow to \$1,000 billion by 2030. This industry usually operates under tight resource constraints, a high product mix, and volatile demand. The industry's average operating margin is around 3%, with payroll costs representing approximately 10% of total revenue. These challenges make workforce planning a critical activity for proper operations. Current literature shows multi-skilled assignment for single departments, solely focusing on direct labor without considering the effect indirect labor has on payroll costs. This study presents a mixed-integer linear programming framework tailored to the ECM industry. The model incorporates 1) direct and indirect labor cost structures, 2) role-specific skills and productivity differences, 3) multi-department assignments, and 4) partial allocation of managerial personnel. The objective of the model is to minimize payroll expenses. The model is validated using multiple instances generated based on real scenarios. This framework provides valuable information to managers tasked with personnel reallocation and operating costs optimization on the ECM industry.

Dynamic Pricing and Revenue Management

Contributed Session

Contributed

Chair: Sichen Guo, Shanghai University of Finance and Economics, Shanghai, N/A, China, People's Republic of

1 - Time-Sensitive Price Discount Optimization for Seller Facing Strategic Buyers with Stochastic Arrival

Suyeon Choi, KAIST, Daejeon, Korea, Republic of, Changhyun Kwon, Seungki Min

We investigate the optimal discount pricing schedule for a single indivisible perishable item over a finite sales horizon, during which strategic buyers arrive stochastically.

Due to the item's perishability, these buyers may delay their purchases in anticipation of more favorable prices, while risking the possibility of stockout.

To facilitate analytical tractability, we restrict each buyer's strategy to depend separately on their arrival time and private valuation.

This leads us to introduce a novel framework—Value-Arrival Separable strategies—which decouples the interdependence inherent in general strategies and enables the characterization of equilibrium behavior via an ordinary differential equation.

Building on this framework, we analyze the seller's efficient frontier, which identifies the optimal trade-off between expected revenue and expected buyer waiting time.

Specifically, we characterize near-optimal pricing schedules under two distinct market regimes.

In thick markets with high buyer arrival rates, the optimal schedule follows a linear discounting rule, with the slope determined by seller's time sensitivity.

In contrast, in thin markets with low arrival rates, a constant pricing schedule is optimal.

The shape of the optimal pricing schedule endogenously depends on the arrival rate of buyers.

Our findings contribute to the literature on dynamic pricing by providing practical insights for e-commerce and retail platforms managing expiring goods in the presence of strategic consumer behavior.

2 - Conditional Generative Learning for Joint Pricing and Inventory Control

Xianghua Jiang, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Xiangbin Hu, Xun Zhang, Zhisheng Ye

We propose a provable deep conditional generative framework for data-driven joint pricing and inventory control with contextual information, in which the retailer makes pricing and inventory decision based solely on historical data consisting of demand, price and covariates.

In contrast to the existing methods that directly learn the optimal policy curve as a function of the covariate, we develop a deep conditional generative learning approach to learn from historical data the whole demand distribution conditional on selling price and covariates.

The conditional demand estimator is a deep conditional generator, which is a function of the selling price, covariates and a 'noise' variable independent of price and covariates.

The special structure of the deep conditional generator allows us to sample the noise easily and compute the gradient of the random cost in closed form, with which stochastic gradient descent can be designed for the subsequent policy optimization under both risk neutral and risk averse settings.

We establish asymptotic properties of our data-driven policy including asymptotic optimality and consistency, and we provide a consistent estimator of the optimal expected cost.

Through comprehensive simulations, we show that the expected cost evaluated at our data-driven policy is significantly smaller than those from state-of-the-art prescriptive benchmarks.

In particular, we apply our method to real meal delivery data and find that our method beats the benchmarks by at least 10% reduction in out-of-sample costs, and it is at least four times faster than three machine learning-based descriptive approaches.

3 - Optimal Pricing in Trade-in Programs: the Consequences of Rebate Adjustments for Firm Profits and Social Welfare

Haoying Guo, Southeast University, Nanjing, China, People's Republic of, Yi Ding

As trade-in programs gain increasing popularity, firms have adopted various pricing strategies, including basic, estimated, and range-estimated pricing. The basic pricing strategy determines trade-in rebates immediately based on the condition of the used product. The estimated pricing strategy operates in two stages: an initial rebate estimate is offered, followed by a final trade-in rebate upon receipt of the used item. In contrast, the range-estimated pricing strategy initially sets a rebate range rather than a fixed amount. We develop game-theoretical models to compare these three strategies. Our analysis yields several key insights. First, when firms adopt the estimated pricing strategy, they tend to lower final trade-in rebates, increasing their profits at the expense of replacement consumers' surplus. Notably, this reduction in trade-in rebates may also negatively impact social welfare. Second, under range-estimated pricing, consumers form precise psychological expectations about trade-in rebates, which reduces trade-in demand. In response, firms optimally lower the selling price of new products, thereby improving consumer surplus for new consumers. Finally, the range-estimated pricing strategy does not universally dominate the basic or estimated pricing strategies in terms of profits or social welfare. Their relative performance depends on market size, consumer sensitivity, and the durability of used products.

4 - Dynamic Pricing of Split Stays

Yi Zhuang, Zicklin School of Business, Baruch College, CUNY, New York, NY, United States, Arash Asadpour, Yuan-Mao Kao

Traditional hotel stays are typically based on fixed check-in and check-out dates, with guests occupying the same room throughout their stay. In 2022, Airbnb introduced a "split stay" feature, allowing customers to book separate accommodations within a single trip. In this work, we study optimal pricing strategies for split stays in the hotel and accommodations industry, where a split stay refers to a guest switching rooms within the same hotel over the course of a trip. We model the seller's decision problem as a dynamic program, where prices for both standard and split-stay options are adjusted over a finite selling horizon based on time and room availability. Under the optimal policy, split stays are used to balance inventory when room availability is uneven across nights within the hotel. The timing of when split stays are offered is also crucial. Early in the selling horizon, the seller anticipates high future demand and conserves inventory for standard high-value bookings. Closer to the end of the horizon, the seller becomes more myopic, favoring high-value bookings that yield immediate revenue. As a result, the mid-horizon emerges as the optimal window for offering split stays—when there is neither strong demand certainty nor urgent revenue pressure. In this period, split stays are most effective for smoothing inventory use and maximizing overall revenue.

5 - Relatively Robust Multiproduct Pricing

Ru Zhang, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, Thomas Weber

This study presents a relatively robust pricing framework for multiproduct monopolies under distribution-free demand uncertainty characterized by Frobenius-norm constraints. Compared to extant models based on interval uncertainty, our approach employs ambiguity sets that align naturally with standard multivariate estimation techniques. The optimal robust price vector, obtained as the solution to a quasi-concave programming problem, maximizes the worst-case ratio of achieved profit to the ex-post optimal profit under full information. A key structural result is that the performance index is strictly quasi-concave in price, allowing the unique optimum to be characterized by a first-order condition. An embedded fixed-point problem can be solved efficiently, and closed-form expressions are derived for symmetric linear, semi-log, and log-log demand systems with associated parameter uncertainty. In general nonlinear settings, the model remains applicable through local linearization and regression-based confidence regions. To evaluate the approach, we conduct both extensive simulation experiments and empirical analyses using large-scale datasets from a major online retailer. The results demonstrate the superior performance of the relatively robust pricing method compared to alternative robustness criteria such as maximin payoff, minimax regret, and Laplacian uncertainty.

6 - Switching Gradient: Learning to Compete with Price Matching Guarantee

Sichen Guo, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of, Shukai Li, Cong Shi, Chaolin Yang

We study a sequential pricing problem in a duopoly market, where two sellers compete through dynamic pricing to maximize individual revenues without prior knowledge of their respective demand functions. We consider a setting in which one seller offers a price-matching guarantee (PMG), committing to match the competitor's price upon customer request. We show that, under positive hassle costs, the introduction of PMG fundamentally alters the structure of the revenue function, introducing non-convexities and discontinuities. These structural complexities render conventional learning algorithms and analytical tools inapplicable. To address these challenges, we propose a switching gradient framework capable of handling piecewise-quadratic revenue functions with discontinuities. We prove that our algorithm achieves a last-iterate convergence rate of $O(\log T / \sqrt{T})$ and a dynamic regret bound of $O(\log T \sqrt{T})$, relative to the optimal dynamic benchmark.

1 - Interpretable Low-Rank Discriminative Cvae for Fault Clustering

Nan Li, Tsinghua University, Beijing, China, People's Republic of, Chen Wang

Data-driven models have become foundational in system health monitoring, enabling automated analysis of complex operational data. However, the inherent opacity of many advanced techniques limits their deployment in real-world environments where interpretability is critical. To address this challenge, we propose a novel Bayesian modeling framework that enhances interpretability by explicitly disentangling operational context—extraneous factors unrelated to system health—from sensor observations. Our approach integrates a conditional variational autoencoder (CVAE) with a mixture-based latent prior, further augmented by a low-rank discriminative regularization. This design encourages the extraction of low-dimensional, structured latent representations that promote meaningful clustering and facilitate intuitive interpretation of fault patterns. Beyond latent space modeling, we introduce a covariance-based interpretability module that systematically analyzes reconstructed sensor

data. This module identifies dominant sensor patterns associated with failure modes and degradation trends, offering a data-driven pathway for unsupervised fault clustering and fault characterization.

We validate the proposed approach through comprehensive experiments on benchmark datasets and operational records from service systems. Results demonstrate the framework's effectiveness in isolating context-independent health states, uncovering latent fault structures, and delivering actionable insights for fault diagnosis and predictive maintenance. Our work bridge the gap between data-driven models and the practical needs of transparent decision-making in health management applications.

2 - Optimizing Rag System Configurations Through Task-Specific Search Strategies

Yajuan Wang, Shanghai JiaoTong University, Shanghai , China, People's Republic of, Lai Wei

Retrieval-Augmented Generation (RAG) systems have become an effective approach to addressing hallucination and improving factual accuracy in Large Language Models (LLMs), especially in knowledge-intensive applications. However, most existing RAG implementations adopt a fixed, one-size-fits-all configuration across different tasks and datasets, overlooking the considerable differences in retrieval requirements, generation objectives, and domain complexity. This uniform design limits the adaptability of the system and reduces the overall quality of generated outputs in real-world scenarios. In this study, we present a task-adaptive RAG optimization framework that systematically identifies suitable configurations for different types of tasks. Using a network-based search method, we examine combinations of key RAG components—such as retrievers, top-k values, and reranking options—across two distinct datasets: Natural Questions and PubMedQA. These tasks differ significantly in their factual requirements, domain specificity, and tolerance for inaccuracy, making them well-suited for analyzing the impact of configuration choices. Our results show that task-specific configurations consistently outperform fixed, uniform baselines in terms of METEOR, ROUGE, and Semantic Similarity Scores. In addition, we identify clear patterns linking task characteristics with optimal configuration settings, offering both theoretical insights and practical guidance for the deployment of intelligent systems. This study contributes to the field of AI system management by proposing a scalable, data-driven approach to configuration adaptation in generative architectures.

3 - The New Knowledge Worker: AI as An Active Contributor to Organizational Knowledge Management

Matthias Bickel, ETH Zurich, Zurich, Switzerland, Torbjørn Netland

How does Artificial Intelligence change the way knowledge is created and shared? For decades, Nonaka's SECI model has been a foundational framework in knowledge management, describing how tacit and explicit knowledge are transformed through four stages: Socialization, Externalization, Combination, and Internalization. However, as AI becomes increasingly integrated into how individuals and organizations interact, collaborate, and make decisions, this model should be reconsidered. In this research, we revisit the SECI model and propose an updated version that reflects AI's evolving role—not just as a tool, but as an active participant in knowledge processes. We examine how specific AI technologies contribute to this shift: Generative AI and Inverse Reinforcement Learning help capture and formalize tacit knowledge during the externalization phase, while Reinforcement Learning supports the synthesis and integration of explicit knowledge in the combination phase. To demonstrate the practical relevance of the revised framework, we apply it to the airline industry. For this, we focus on operational challenges such as disruption management, tail assignment, and crew rostering. These examples show how AI technologies can improve the utilization and effectiveness of knowledge use in operational decision-making. We contribute a new perspective on knowledge management in the context of AI and offer practical implications for organizations implementing AI in operational contexts.

4 - Generative AI-Enhanced Mathematical Programming Workshop with Fico Xpress

Alkiviadis Vazacopoulos, Optimization Direct, Inc., Harrington Pk, NJ, United States

This workshop introduces participants to the transformative potential of generative AI in mathematical programming using FICO Xpress. Through hands-on demonstrations and practical exercises, attendees will learn how to leverage generative AI to streamline model development, enhance code generation, and improve result interpretation. The workshop covers key aspects including automated model formulation, intelligent debugging assistance, and AI-powered console output analysis. Participants will gain practical experience in using generative AI to solve complex optimization problems more efficiently, interpret solver outputs more effectively, and generate comprehensive documentation. This workshop is designed for optimization practitioners, researchers, and developers who want to enhance their mathematical programming workflow with state-of-the-art AI capabilities.

5 - Speeding up Grover's Algorithm

Stefan Creemers, UCLouvain, Louvain-la-Neuve, Belgium

To find one of the M target entries in an unstructured database that has N entries, Grover's algorithm performs $\pi/4(N/M)^{1/2}$ iterations. In each iteration, a function is called that evaluates whether an entry is a target entry. Compared to a classical procedure, that requires N/M evaluations, Grover's algorithm achieves a quadratic speedup. This quadratic speedup, combined with its general applicability as a search algorithm, have made Grover's algorithms one of the most important algorithms available today. A study to improve its runtime is more than justified. For this purpose, we investigate two speedup strategies: (1) reducing the number of iterations that are performed in each run of Grover's algorithm and (2) partitioning the database. For each of these strategies, we not only execute Grover's algorithm in parallel, but also explore the possibility to execute Grover's algorithm in series on a single Quantum Processing Unit (QPU) as well as on multiple QPUs. For each combination of execution mode (serial, parallel, and serial/parallel) and speedup strategy, we show how to obtain optimal policies using closed-form expressions and a gradient-descent procedure. For a single QPU we obtain a speedup factor of 1.1382 when compared to a textbook implementation of Grover's algorithm. If multiple QPUs are at our disposal, we obtain a speedup factor of at most $1.1382 Q^{1/2}$, where Q denotes the number of QPUs. In addition, we show that the dominant policies that minimize the expected number of Grover iterations also minimize the expected number of iterations that are performed per qubit.

6 - Operationalizing Artificial Intelligence in Pharmaceutical R&D: from Strategy to Scalable Impact

Shujaullah Khan Mohammed, AstraZeneca, Washington DC, DC, United States

Artificial Intelligence (AI) is rapidly reshaping the pharmaceutical R&D landscape, offering unprecedented opportunities to improve efficiency, accuracy, and speed across the value chain. Yet many organizations struggle to transition from fragmented pilots to enterprise-scale impact. This paper presents a comprehensive framework for operationalizing AI across core R&D functions including clinical operations, Chemistry, Manufacturing & Controls (CMC), medical writing, and real-world evidence (RWE) analysis.

A five-stage AI maturity model is introduced, ranging from experimental deployments to agentic AI systems capable of autonomous decision support. Detailed use cases demonstrate AI's potential to optimize clinical trial protocols, enhance patient recruitment, automate site monitoring, predict manufacturing stability, generate regulatory documentation, and extract insights from complex omics and real-world datasets. The paper highlights the growing role of AI agents in performing tasks traditionally handled by data scientists and medical writers, allowing organizations to redeploy human expertise toward more strategic and creative work.

A four-phase implementation roadmap is outlined covering strategic alignment, platform and data modernization, value realization, and enterprise scaling. Drawing on recent academic publications, industry benchmarks, and regulatory trends, this paper provides actionable guidance for pharmaceutical R&D leaders seeking to embed AI as a core operating capability. The future of drug development lies in systems that can reason, learn, and collaborate, transforming AI from a supportive technology into a strategic partner across the lifecycle of therapeutic innovation.

7 - Generative Artificial Intelligence and the Primacy of Public Policy: Using Self-Evolving Algorithms to Regulate an Algorithmic Superspecies

Sunil Erevelles, University of North Carolina, Charlotte, Charlotte, NC, United States, Anjali Sinha, Sahar Maleki, Emanuel Valenzuela

Generative artificial intelligence (AI) differs from *all* past technologies in that it is not a tool, but has independent agency. A tool can be controlled by humans and gives humans more power. Generative AI, by contrast, has the capacity to *create, decide, and execute* on its own. It has higher emotional intelligence than humans, specifically because it is emotionless. It turns humans into algorithmic inputs, and is increasingly able to precisely understand and control us. It evolves faster than humans, making it impossible for humans to catch up. In conformance with the biological and ecological species concepts, generative AI is fast exceeding the accepted criteria for species,

but inorganically. Accordingly, we define generative AI as an "inorganic superspecies." For the first time in human history, a species superior to humans is emerging. While the benefits of generative AI to humanity are remarkable, it also is likely that generative AI poses considerable danger to humanity, if not managed *proactively*. The purpose of this research is to help develop self-regulating mechanisms for generative AI public policy. Methodologically, the authors use transformer-based attention mechanisms, as well as an understanding of traditional support vector machine models, additive explainability analysis and adaptive moment estimation algorithms to create an inductive realist-based framework for regulating generative AI. This initial framework, consisting of foundational premises based on generative AI logic, could help contribute to academic advances in self-regulating generative AI techniques, as well as help practitioners use generative AI in a more effective and safe manner.

1 - Generating Synthetic Aia Images from Historical Ground-Based Observations: a Diffusion Model Approach for Extended Coronal Hole Analysis

Marco Marena, New Jersey Institute of Technology, Newark, NJ, United States, Bo Shen, Qin Li, Haimin Wang

Accurate and continuous observations of the Sun's extreme ultraviolet (EUV) emissions are critical for understanding solar dynamics and monitoring solar activity. However, EUV observations availability is limited to the past ~30 years, restricting our ability to study long-term solar corona. This study aims to reconstruct a historical dataset of synthetic AIA 193 Å and 304 Å — solar corona and chromosphere — using historical ground-based chromospheric observations in H α and CaII K, available for over a century. To generate AIA observations before 2010, we propose to use a novel deep learning methodology, the Diffusion Model Translation (DMT) framework, built on a fine-tuned Denoising Diffusion Probabilistic Models (DDPM), and a Two-Stream Image-to-Image Translation (TSIT) network as a translator between the noising and denoising processes, to bypass the diffusion steps and accelerate training. We used H α and CaII K lines from Kanzelhöhe Solar Observatory (KSO) spanning from 2011 to 2024, and AIA 193 Å and 304 Å from the Solar Dynamic Observatory (SDO). For the independent test set, the model shows a high full-disk correlation (CC = 0.942) and achieves a Dice coefficient of 0.893 for coronal holes. Particularly, the high Dice coefficient highlight the model's effectiveness in identifying and delineating coronal holes, sources of high-speed solar wind streams. By providing reliable synthetic EUV imagery for historical periods lacking direct observations, our methodology facilitates deeper analyses of coronal hole evolution, as well as long-term solar activity trends.

2 - An Advanced Spectral Shapley-Based Active Learning to Analyze Extreme Weak Sensor Signals for Precision Process Monitoring

Xinchen Wang, SUNY Binghamton, Binghamton, NY, United States, Zimo Wang

Understanding streaming sensor signals is essential for in-process monitoring and quality inspection for various industry applications. These signals contain rich, time-sensitive information that supports real-time detection of anomalies and quality deviations. However, at the micro- and nano-scale monitoring process, the acquired signals are often overwhelmed by high levels of noise and interferences with unknown structures, which may significantly impact the accuracy and effectiveness of signal interpretations where conventional filtering methods—such as bandpass filtering or denoising autoencoder—may be insufficient for isolating relevant information. To address these challenges, we introduce a Hierarchically Influenced Spectral Shapley-based Active Learning (HISS-AL) approach, which learns the underlying information from streaming sensor data. The method is first validated using music timbre recognition and then applied to real-time surface morphology characterization during nanomachining. Results confirm the model's ability to capture intrinsic spectral features in simulated and real acoustic environments. In nanomachining, the framework achieves an overall accuracy of 84% for predicting surface morphology based on the signal gathered during the nano-scale material removals. These findings highlight the method's robustness in high-noise, low-SNR environments, where conventional approaches often falter. Overall, the proposed strategy offers a promising direction for advancing sensor-based monitoring and quality control in precision manufacturing.

3 - Physics-Informed Pipeline Corrosion Reliability Prediction Using Inspection Images

Nikesh kumar, University of Arkansas, fayenteville, AR, United States, miao tan, Haitao Liao

This study presents a hybrid framework for predicting the reliability of pipelines subject to internal corrosion by integrating image-based defect extraction, finite element stress analysis, and stochastic degradation modeling. Using machine learning methods, corrosion geometries including depth, length, and width are extracted from inline inspection images, even in challenging areas such as welds and branches. These geometric features drive the development of a physics-informed stochastic model. Pit initiation is represented by a nonhomogeneous Poisson process, where the rate of new pit formation varies with time and environmental conditions such as temperature, pressure, and fluid chemistry. The depth of each pit evolves over time according to a Gamma process, while the defect length and width grow with linear trends. The proposed formulation allows the model to capture the full three-dimensional evolution of corrosion. To manage computational complexity, finite element simulations are conducted to first generate a library of stress fields for varying defect shapes. These are used to scale growth rates according to local stress intensity. Instead of simulating each defect individually, the model interpolates stress effects based on the matched geometries from inline images. Monte Carlo simulation samples random environmental conditions and material properties, producing failure probabilities over time by tracking whether cumulative damage surpasses critical thresholds.

Validation is performed using offshore pipeline data. The model's predictions closely match historical failure trends, demonstrating accuracy in assessing pipeline failure risk. Compliant with ASME B31G and API 579 standards, the framework enables proactive, image-guided maintenance planning and supports scalable pipeline integrity management.

4 - Diffusion Models for Anomaly Detection in General Textured Surfaces

Mehrdad Moradi, Georgia Institute of Technology, Atlanta, GA, United States, Kamran Paynabar, Marco Grasso, Bianca Maria Colosimo

Anomaly detection at the pixel and instance level in textured patterns has gained considerable attention, with both statistical and machine learning approaches demonstrating strong performance. However, most existing methods are limited to modeling a **single pattern type**, restricting their applicability in complex or multi-pattern environments. While neural networks offer greater flexibility by learning multiple patterns within a single model, they often suffer from limited interpretability and require large volumes of labeled data.

In this work, we introduce a novel diffusion-based methodology for anomaly detection that is theoretically grounded and capable of handling **multiple textured patterns** without prior knowledge of their number or form. Our approach partitions input data into patches and applies a newly developed **pixel-level anomaly detection mechanism** based on reverse diffusion dynamics. Experimental results show that our method outperforms both state-of-the-art diffusion-based models and traditional statistical techniques.

5 - Multivariate Nonparametric Functional Calibration of Wake Effect Models

Cheoljoon Jeong, University of Michigan, Ann Arbor, MI, United States, Eunshin Byon

As wind energy continues to grow, understanding wake effects—wind shadows cast by upstream turbines that reduce downstream power output—has become increasingly important. Accurately modeling these effects requires calibrating parameters within simulation models using operational data. Prior studies often fail to capture the complex dependence of parameters on multiple environmental factors. This study proposes a new nonparametric functional calibration method that estimates parameters without assuming a predefined functional form of the parameters. Our method accounts for multivariate environmental influences and is validated through both simulated and real-world wind farm case studies.

1 - Locally Transparent Rule Sets for Interpretable Machine Learning**Brian Liu, MIT, Cambridge, MA, United States, Rahul Mazumder**

We introduce the concept of local transparency in machine learning: models in which predictions on a subset of the data can be explained concisely. We propose an optimization-based framework for constructing locally transparent rule sets and develop algorithms to efficiently evaluate the trade-off between local transparency and accuracy.

2 - Natural Hypergradient Descent: Algorithm Design, Convergence Analysis and Parallel Implementation**Deyi Kong, University of Minnesota, Minneapolis, MN, United States, Zaiwei Chen, Shuzhong Zhang, Shancong Mou**

Bi-level optimization has emerged as a powerful framework for modern machine learning applications such as meta-learning, data synthesis, and hyperparameter tuning. Hypergradient descent is commonly used to solve bi-level optimization problems, but computing the hypergradient—particularly the Hessian inverse of the inner problem, either explicitly or implicitly—poses significant computational challenges when the inner problem involves large-scale models. In this paper, we propose a simple and scalable method, Natural Hypergradient Descent (NHGD), which follows an optimize-and-approximate strategy. NHGD approximates the Hessian inverse using a running average of the inverse empirical Fisher information matrix (EFIM), computed directly from the gradients generated by each inner-loop SGD update. We provide a detailed non-asymptotic analysis demonstrating convergence to stationary points with iteration complexity matching that of existing optimize-then-approximate hypergradient methods, which first solve the inner problem to a desired accuracy and then approximate the Hessian inverse via Neumann series or conjugate gradient solvers. A key advantage of NHGD is that its optimize-and-approximate design enables parallel computation of the hypergradient approximation alongside the inner-loop SGD steps. This leads to substantial improvements in computational efficiency, particularly for large-scale problems. Experiments on hyper data cleaning and data distillation tasks demonstrate that NHGD achieves comparable or better performance.

3 - Theoretical Analysis for Optimal Design of An Online Monitoring and Sampling Scheme Under Partial Observation**Dongmin Li, Georgia Institute of Technology, Atlanta, GA, United States, Xiaochen Xian**

In modern quality control, online monitoring of high-dimensional data streams has become increasingly important as large volumes of real-time data are collected from diverse sources. However, practical constraints such as limited sensors, transmission bandwidth, and storage capacity often restrict data availability to only a subset of variables at each time. In such resource-constrained settings, the determination of key parameters, particularly the number of observed variables, is critical to balance detection capability with resource costs to achieve optimal statistical and/or economic performance. This parameter design relies on analyzing the relationship between detection delay and parameter values, but such analysis is lacking in existing monitoring schemes under partial observations. While some studies provide upper bounds for average detection delay, these bounds are either asymptotic or excessively large, offering limited practical guidance. To address this gap, we develop an optimal design framework based on theoretical analysis of detection delay for a monitoring-based probabilistic sampling scheme that adaptively selects observed variables at each time. Leveraging sampling probabilities that are explicit functions of monitoring statistics, we derive formulas for average detection delay in finite settings as functions of design parameters and system settings, such as the number of observed and total variables. Enabled by the theoretical results, we propose an economic-statistical design framework that determines the optimal number of observed variables to meet detection goals while accounting for practical costs. Simulation studies across various parameters and system settings validate the effectiveness of the theoretical results and design framework, demonstrating significant practical value for optimal design.

4 - Tensor-Efficient High Dimensional Q-Learning**Junyi Wu, University of Washington, Seattle, WA, United States**

High-dimensional reinforcement learning faces challenges with complex calculations and low sample efficiency in large state-action spaces. Q-learning algorithms struggle particularly with the curse of dimensionality, where the number of state-action pairs grows exponentially with problem size. Current solutions include function approximation methods and neural network-based approaches like Deep Q-Networks, but these often suffer from instability and require extensive hyperparameter tuning. We propose Tensor-Efficient Q-Learning (TEQL), which applies low-rank tensor decomposition via block coordinate descent on discretized state-action spaces, incorporating novel exploration and regularization mechanisms. The key innovation is an exploration strategy that combines approximation error with visit count-based upper confidence bound to prioritize actions with high uncertainty, avoiding wasteful random exploration. Additionally, we incorporate a frequency-based penalty term in the objective function to encourage exploration of less-visited state-action pairs and reduce overfitting to frequently visited regions. Empirical results on large discrete control tasks demonstrate that TEQL outperforms conventional matrix-based methods and deep RL approaches in both sample efficiency and total rewards, making it suitable for resource-constrained applications, such as space and healthcare where sampling costs are high.

1 - A Discrete-Time Markov Chain for Lifetime of Lithium-Ion Batteries**Jeongeom Lee, Seoul National University of Science and Technology, Seoul, Korea, Republic of, Min Kyu Sim**

Lithium-ion batteries (LiBs) are pivotal for energy storage systems (ESS) and electric vehicles (EVs). Their capacity, represented by the State of Health (SoH), degrades over their service life. Because each use cycle incurs economic depreciation, understanding this degradation behavior is critical for devising optimal operation strategies. Most existing models divide battery degradation into two distinct phases: a “normal degradation” phase until the SoH reaches 80%, and a “knee curve degradation” phase characterized by a drastic decline after the SoH falls below 80%. This bifurcated approach makes it challenging to accurately and reliably estimate the battery’s Remaining Useful Life (RUL). To address this limitation, we propose a discrete-time Markov chain (DTMC) that integrates both phases. Specifically, each state in our model encodes a discretized SoH level and a binary knee-phase flag, enabling us to capture both degradation patterns simultaneously. Because the DTMC can serve as a stochastic building block, it offers various advantages. For example, simulation studies can yield not only point estimates but also interval estimates, allowing for risk-adjusted pricing. Moreover, the model can be used to analytically and numerically estimate a wide range of statistics, including means, confidence intervals, and complete distributions. Through empirical studies, we confirm that our model aligns well with existing publicly available datasets. From a practical perspective, it is expected to provide a fundamental guideline for second-life battery (SLB) applications in the near future.

2 - Latent Variable Transfer Learning for Modeling Energy Demand in Industrial Systems**Afshin Asadi, UNIVERSITY OF MIAMI, Miami, FL, United States, Ramin Moghaddass**

Accurate and adaptive energy consumption modeling is essential for optimizing industrial efficiency, reducing operational costs, and supporting grid stability. However, industrial systems pose signifi-

cant modeling challenges due to complex operational dynamics and latent factors such as equipment degradation, variable production schedules, and environmental fluctuations. Traditional models often lack the flexibility to generalize across different systems, especially when historical data is scarce. This paper presents a recurrent variational neural network (VRNN) framework that learns compact latent representations from historical energy data, capturing underlying patterns shared across industrial processes. Leveraging transfer learning, the proposed approach enables efficient adaptation to new systems by reusing learned representations and fine-tuning only the output layers. Numerical experiments demonstrate that this strategy improves prediction accuracy while preserving key system dynamics. The framework offers a data-efficient solution for industrial energy forecasting, highlighting the value of latent variable modeling and transfer learning in real-world energy management applications.

3 - Advances in Robust Linear Regression with Doubly Censored Data

Matthew Saltzman, Clemson University, Clemson, SC, United States, William Bridges

This study evaluates a modification of median-based robust linear regression estimators to accommodate “general” censoring, where both the predictor and response variables can be left- or right-censored. We examine statistical properties of the resulting estimator and modifications to efficient algorithms for computing slope and intercept estimators that account for the censored observations.

4 - Uncertainty Quantification in Ros2 Gazebo Simulations: a Leader-Follower use-Case

Trevor McClain, University of Alabama in Huntsville, Huntsville, AL, United States, Rahul Bhadani

Robotics physics simulators are widely used to test the safety and correctness of autonomous robot control systems. In this work, we quantify the uncertainty present in the robotics control simulation environment, Gazebo Humble, and show that this uncertainty can lead to erroneous results on basic problem statements. Reproducibility in autonomous robot control systems simulations is of paramount importance to allow for useful data collection. The robotics control problem chosen for this work was the Intelligent Driver Model (IDM). In our setup, a fixed-velocity leader robot was followed by up to twelve follower robots. Our research showed that the Gazebo multi-robot simulation did not exhibit repeatable, or deterministic, behavior when the number of robots was seven or greater for the IDM car following model. This coincided with a degradation of the real time factor (RTF) of the simulations. Consistency in simulation results are vitally important for safety verification and data reproducibility, and our results raise concerns for the reproducibility and safety verification of simulation-based environments.

5 - Shift-Adaptive Multi-Step Conformal Prediction for Non-Stationary Time-Series

Marzieh Amiri Shahbazi, Rochester Institute of Technology, Rochester, NY, 14623, NY, United States, Ali Baheri

Shift-Adaptive Multi-Step Conformal Prediction, or SAM-CP, tackles the persistent challenge of producing reliable forecast uncertainty when both the mean and the variance of a time-series evolve over time. Operating fully online, the method first applies a lightweight cumulative-sum test to a sliding window of standardized residuals to sense distributional change. It then nudges a horizon-specific significance schedule through a Robbins–Monro update so that any empirical coverage shortfall is driven toward zero, and finally forms conformal prediction sets with the recalibrated non-conformity scores. We prove that this interplay of change-point monitoring and adaptive significance guarantees marginal coverage at the nominal level for every forecast horizon under arbitrary piece-wise stationary shifts, extending adaptive-conformal validity into the multi-step domain. Empirical studies on electricity demand, traffic flow, and macroeconomic benchmarks—each sliced into deliberately adversarial train-test regimes—show that SAM-CP maintains near-target coverage while producing substantially narrower prediction bands than baselines that rely on a fixed significance level or static residual weighting. Because the procedure wraps any existing forecaster without retraining, it offers practitioners a plug-and-play uncertainty layer that tracks evolving dynamics in real time, making it attractive for applications such as staffing, inventory, and energy dispatch.

6 - Forecasting Seasonal Changeoint Models Utilizing Changeoint Uncertainties

Vasileios Pavlopoulos, The University of Alabama in Huntsville, Huntsville, AL, United States, Rebecca Killick, Ege Can, Pham Hieu, Paras Bhatt

Forecasting in the presence of changeoints is a challenging task. However, if changeoints occur regularly across seasons, we want to utilize that information in our predictions for the next season. In this paper, we develop a framework for forecasting seasonal data that contain within-season changeoints. In our forecasts, we account for uncertainty in the changeoint locations both within and across seasons via a weighting approach across changeoint uncertainties. The framework is very flexible across different changeoint model assumptions and approaches to identifying changeoint confidence sets. We demonstrate the improvement in forecasting performance of our framework for 1) atmospheric pressure with a multivariate changeoint approach and 2) air pollution with a univariate changeoint approach.

7 - Revolutionizing Reliability Forecasting: Machine Learning vs. Finite Element Method and Empirical Models for Solder Joints

Seyed Soroosh Alavi, Auburn University, Auburn, AL, United States, Daniel Silva

Reliable estimation of solder joint lifetime is essential for maintaining the integrity of electronic assemblies, particularly when exposed to harsh environmental conditions. This work presents a comparative analysis of machine learning (ML) techniques alongside traditional power-law-based empirical models and finite element method (FEM) simulations carried out in ANSYS. Using an extensive dataset of 185 experimental tests, the study evaluates each method's performance. The ML framework integrates a wide range of isothermal aging and thermal cycling scenarios into a single predictive model, unlike empirical and FEM methods that require reconfiguration or recalibration for each specific condition and demand significant computational effort.

While FEM simulations offered valuable physical understanding, they were constrained by high computational costs and complexity in model setup. Empirical approaches, on the other hand, tended to lose accuracy under elevated temperatures or intricate component geometries. In contrast, ML models—particularly XGBoost and artificial neural networks (ANN)—demonstrated enhanced precision, scalability, and adaptability. These models effectively captured nonlinear relationships among both continuous (e.g., aging time, temperature) and categorical (e.g., surface finish, alloy type) variables. Evaluation metrics showed that ML predictions maintained high accuracy across all test conditions, with typical errors below 3%, outperforming both empirical and FEM strategies.

Overall, this study highlights the advantages of ML in predicting solder joint reliability, offering reduced computational requirements, simplified modeling processes, and improved predictive accuracy.

Emerging Topics in Behavioral Operations Management

Invited Session

Behavioral Operations Management

Chair: Swanand Kulkarni, Tuck School of Business, Dartmouth College, Hanover, NH, United States

1 - Discretionary Task Switching and Knowledge Worker Productivity

Samer Charbaji, New York Institute of Technology - Manhattan, New York City, NY, United States, Roman Kapuscinski, Stephen Leider

Knowledge workers are often given creative tasks and repetitive tasks to work on and can have some discretion in how they switch between them. Research has shown that task switching lowers performance on repetitive tasks, but can improve performance on creative tasks. It is unclear if and how knowledge workers assigned both tasks would switch between them and what impact that would have on their overall performance. Our paper examines this using a laboratory experiment that incentivizes participants based on their performance on a creative task and a repetitive task and that gives them the discretion to freely switch between them. We first replicate the effect of task switching in our experimental setting. We run one treatment that forces participants to continuously switch tasks and one treatment that forces participants to

not switch tasks and show that task switching does indeed increase (decrease) performance on the creative (repetitive) task. We then examine participant behavior in the discretionary switch treatment and find that participants rarely switch tasks. This infrequent task switching results in a similar decrease in repetitive task performance as in the forced switch treatment, but, interestingly, without the increase in creative task performance, resulting in a significantly worse overall performance. We show that adding time-based and/or performance based nudges that encourage participants to switch tasks more often are surprisingly effective at encouraging participants to do so. This results in participants having a creative task, repetitive task, and an overall performance that is similar to the forced switch treatment.

2 - Going Local: Authenticity of Retailers' Buy-from-Local-Suppliers Programs

Orchi Bhattacharyya, University of Minnesota, Carlson School of Management, Minneapolis, MN, United States, Necati Ertekin, Karen Donohue, Mehmet Gumus

This study investigates Buy-from-Local-Suppliers programs, in which grocery retailers offer local food products in their assortment. Using data from a Canadian online retailer and an online experiment, we explore the impact of local certifications on sales of local food products, offering insights for effectively leveraging certifications in grocery retailing.

3 - Pay Model Intuitiveness and Transparency on on-Demand Service Platforms

Swanand Kulkarni, Tuck School of Business, Dartmouth College, Hanover, NH, United States, Basak Kalkanci, Chris Parker

On-demand service platforms have been experimenting with models that determine compensation for their workers. While some use commission- or effort-based pay models that are intuitive to workers, others, in their efforts to better match customer demand, have transitioned to models where pay is not strictly tied to effort, but depends on other, potentially exogenous factors. Platforms have also kept these pay models opaque. Workers' reactions to such practices, however, are not systematically examined or understood. Through incentivized experiments, we examine how a pay model's intuitiveness to workers, its transparency, and a change that reduces the model's intuitiveness affect workers' participation on the platform. Results show the promise and limits of pay model intuitiveness and transparency in managing worker participation.

4 - Does Experience Shape Online Reviews? the Role of Platform Interventions

Nalin Shani, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Achal Bassamboo, Maria Ibanez

This paper investigates how user experience and platform design jointly shape the perceived helpfulness of online reviews. We begin by examining how a reviewer's experience—measured via playtime—affects the structure, content, and perceived helpfulness of their review. While more experience might intuitively signal greater credibility, we find that this relationship is non-monotonic and differs for positive and negative reviews. These patterns are driven in part by how experience alters the emotional tone of the review, particularly along valence and arousal dimensions.

We then study two platform interventions tied to consumer experience: review solicitation and refund policies. We leverage two natural experiments generated by platform interventions tied to user experience and find that review solicitation increases volume but reduces average helpfulness, while refund decisions serve as credibility signals that elevate helpfulness ratings. Taken together, these results highlight how both user experience and platform interventions influence the quality and credibility of user-generated content.

5 - Accuracy, Awareness, and Acceptance: How Attention Drives the use of Point Versus Interval Forecasting Algorithms

Rob Basten, Eindhoven University of Technology, Eindhoven, Netherlands, Bas van Oudenhoven, Philippe van de calseyde, Evangelia Demerouti

Many operations rely on forecasts of future events, with the allocation of substantial amounts of money depending on these forecasts' accuracy. Fortunately, algorithmic forecasts often achieve high levels of accuracy. Still, many decision-makers reject these algorithms upon observing they are not perfectly accurate. What determines whether decision-makers perceive an algorithm as inaccurate, and how are these perceptions related to their willingness to use the algorithm when forecasting future events? We propose that the tendency to dismiss algorithmic advice is partially due to the common practice of presenting forecasts as single points rather than intervals. In Experiment 1, we find that people perceive equally imperfect forecasts as more accurate when these forecasts are presented as intervals rather than points. In Experiment 2, we examine how these differential accuracy perceptions influence people's willingness to use algorithms. Here, we find that people do not necessarily favor interval over point forecasts when deciding whether to rely on the algorithm to make predictions. Instead, such a preference only occurs when people are explicitly prompted to evaluate the algorithm's accuracy before deciding whether to commit to its predictions or not. Together, these findings underscore the complex processes underlying people's perceptions of algorithmic errors and their subsequent reliance on algorithms. Moreover, they show how managers can implement interval forecasts to effectively increase human forecasters' reliance on forecasting algorithms..

Economics of AI

Invited Session

Artificial Intelligence

Chair: Stephanie Lee, University of Washington, Seattle, WA, United States

Co-Chair: Zibo Liu, Fudan University, Shanghai, 200433

1 - AI Pricing, Algorithmic Collusion, and Topological Structure

Yingying Chen, University of Washington, Seattle, WA, United States, XINGCHEN XU, Stephanie Lee, Yong Tan

Recent studies have extensively examined algorithmic collusion arising from AI-driven pricing algorithms, typically under the assumption that each seller competes directly with every other seller. However, in many practical contexts, competitive interactions are constrained by an underlying network topology. To address this, we develop a general repeated-game framework defined over arbitrary topological structures. Through extensive numerical experiments, we demonstrate how network topology shapes both dynamic pricing behavior and equilibrium outcomes, and we identify the key mechanisms driving these effects.

2 - Emotion in Echo: Understanding the Effectiveness of Group AI Emotional Support

Yuqing Hu, University of Washington, Seattle, WA, United States, Junyu Yao, Wendao Xue, Yifan Yu, Yong Tan

The use of artificial intelligence (AI) in emotional support conversations has received significant attention in both research and industry. While most studies have examined interactions with a single AI agent, little is known about the effects of interacting with a group of AI agents—a form of support that is beginning to emerge in practice. Drawing on social network and social support literature, we propose that merely increasing the number of AI agents may lead to inferior emotional support. Moreover, effective coordination among these agents in delivering complementary social support plays a critical role. To test these proposals, we conduct experiments in which participants interact with different AI systems designed to provide emotional support. This study aims to identify the potential of group AI in emotional support and contribute to both AI-in-emotional-support research and the broader body of social support literature.

3 - AI in Job Interviews: Promise OR Peril?

Zhen Fang, Fudan University, Shanghai, China, People's Republic of, Zibo Liu

Abstract: With the rapid development of artificial intelligence (AI), its application in job interviews has attracted firms seeking greater efficiency and lower hiring costs. While AI algorithms can effectively evaluate candidates with common characteristics, they often fall short when assessing applicants with niche or uncommon profiles due to lack of training data and the nature of AI algorithms. This study compares AI-led and human-led interview processes. By illustrating the potential weaknesses of AI in interview settings, we contribute to a more comprehensive understanding of its role in recruitment. Our study sheds light on the merits and drawbacks of AI in job interviews, and we provide managerial implications for firms aiming to integrate AI into their hiring practices.

4 - Search with AI-Simulated Future State Visuals: Evidence from the Pre-Owned Housing Market

Zhenbin Yan, Tongji University, Shanghai, China, People's Republic of, Shunyu Zhang

Customer search is challenging when future consumption experiences diverge significantly from a product's current state, such as in the pre-owned housing market where buyers often plan renovations. This makes search difficult, as customers must evaluate a property not just as it is but based on an uncertain vision of what it could become. While traditional mental simulations are often abstract and biased, advanced artificial intelligence (AI) technologies can simulate virtual product anticipation. This study investigates how AI-generated visualizations of renovated properties impact buyer search and market outcomes. Using data from a leading real estate platform, we find that AI virtual renovation reduces time-on-market by 9.3% and increases selling prices by 1.4%. However, there are underlying nuances. AI is most effective when information is balanced—neither too many options about the property's future nor too little detail about its current state. The effect is stronger for higher-value properties where anticipation is crucial for high-stakes choices and greater in markets with higher income and education, suggesting differential AI receptivity. In addition to online search, AI also increases online-to-offline conversions. This research highlights AI's potential to bridge the gap between current attributes and uncertain future experiences, thereby improving customer search and decision-making.

5 - More Human than Human: Empirical Evidence of the Effect of AI Generative Content in Online Communities

Jun Tan, University of Washington, Seattle, WA, United States, Lijia Ma, XINGCHEN XU, Yong Tan

AI generation tools have been widely used since their invention. However, how AI-generated content shapes discussions in online communities remains under-explored. In this paper, we conduct a field experiment to examine how an exogenous AI-generated content intervention affects subsequent discussion in a leading online forum.

6 - Rethinking Data Value: An Asymmetric Shapley Framework for Temporal and Context-Aware Valuation in Modern AI Systems

Xi Zheng, University of Washington, Seattle, WA, United States, Yinghui Huang, Xiangyu Chang, Ruoxi Jia, Yong Tan

As data emerges as a vital driver of technological and economic advancements, a key challenge is accurately quantifying its value in algorithmic decision-making. The Shapley value, a well-established concept from cooperative game theory, has been widely adopted to assess the contribution of individual data sources in supervised machine learning. However, its symmetry axiom assumes all players in the cooperative game are homogeneous, which overlooks the complex structures and dependencies present in real-world datasets. To address this limitation, we extend the traditional data Shapley framework to asymmetric data Shapley, making it flexible enough to incorporate inherent structures within the datasets for structure-aware data valuation. We also introduce an efficient k-nearest neighbor-based algorithm for its exact computation. We demonstrate the practical applicability of our framework across various machine learning tasks and data market contexts.

Application and Cautionary Notes of GenAI usage in OR/Analytics Classroom

Invited Session

INFORMS Committee on Teaching and Learning

Chair: Moses Chan, Northwestern University, Evanston, IL, 60208, United States

1 - Using OR Losing: Student Experiences with AI Tools and Knowledge Acquisition in Data Visualization

Rich Ross, University of Virginia, Charlottesville, VA, United States

Generative AI tools have been thrust into the hands of undergraduate students. Some courses and instructors deal with these tools by forbidding their use entirely; others turn a blind eye. Some have begun to adopt their use in or out of the classroom. One big question on the minds of instructors and students is: "What is the consequence of using GenAI throughout a course?"

In this talk, I'll approach GenAI use in Statistics courses from three perspectives. First, I'll share insights into how students do (and do not) use AI tools in classes with varying policies. Second, I'll discuss how I've incorporated a pros and cons relationship with GenAI tools in my classes. This includes examples both of places where I encourage its use and and places where I illustrate its shortcomings. Lastly, I'll talk about lessons learned and provide concrete solutions that I've used and helped others to implement in an interdisciplinary setting, showing some lessons learned which are not topic-dependent (while recognizing that some are content-specific).

2 - Balancing Assistance and Integrity: How Students use Genai in Business Analytics

Huy Huynh, Emory University, Atlanta, GA, United States

As generative AI tools like ChatGPT become increasingly integrated into higher education, educators face the challenge of promoting student learning while maintaining academic integrity. This talk explores how undergraduate students in Business Analytics courses use generative AI to support their coursework, drawing on surveys, classroom observations, and assignment analyses. We examine the spectrum of student behaviors—from responsible use that enhances understanding to overreliance that risks undermining learning outcomes. By analyzing patterns of usage, we identify strategies students use to balance AI assistance with personal accountability. The session concludes with practical recommendations for instructors seeking to incorporate GenAI in a way that fosters ethical engagement, critical thinking, and skill development in analytics education.

3 - Introducing Undergraduate Business Students to Genai: An Update

Neil Desnoyers, Saint Joseph's University, Philadelphia, PA, United States

Starting Fall 2025 in the Haub School of Business at SJU, the required undergraduate “Intro to Information Systems” course has morphed into a required “AI in Business” course. Interim results and lessons learned will be discussed.

4 - Rejoinder: GenAI Usage and Precautions in OR and Analytics Classroom

Moses Chan, Northwestern University, Evanston, IL, United States

This talk reflects on the usage and precautions of generative AI in teaching operations research and analytics. This portion of the session focuses on discussion and exchanges of lessons learned in preparing for student success, balancing the reliance on GenAI, and promoting learning effectiveness.

DM Best Student Paper Award

Award Session

Data Mining

Chair: Hadis Anahideh, University of Illinois Chicago, Chicago, IL, United States

1 - Inv-Entropy: a Fully Probabilistic Framework for Uncertainty Quantification In Language Model

Haoyi Song, University of Michigan, Ann Arbor, Ann Arbor, MI, United States, Ruihan Ji, Naichen Shi, Fan Lai, Raed Al Kontar

We model LLM input-output pairs via dual random walks through perturbations. Based on this, we propose a probabilistic framework featuring an inverse model and introduce Inv-Entropy, a novel uncertainty measure. We also present TSU (Temperature Sensitivity of Uncertainty), a new evaluation metric that directly assesses uncertainty without relying on correctness.

2 - The Power of Adaptivity in Experimental Design

Jiachun Li, Massachusetts Institute of Technology, Cambridge, MA, United States, David Simchi-Levi, Yunxiao Zhao

"Given n experiment subjects with potentially heterogeneous covariates and two possible treatments, namely active treatment and control, this paper addresses the question of determining the optimal accuracy in estimating the treatment effect. We propose an experimental design that approaches this optimal accuracy, giving a (non-asymptotic) answer to this fundamental question. The methodological contributions are as follows. First, we establish an idealized optimal estimator with minimal variance as benchmark, and then demonstrate that adaptive experiment is necessary to achieve near-optimal estimation accuracy. Second, by incorporating a doubly robust method into sequential experimental design, we frame the optimal estimation problem as an online bandit learning problem, bridging the fields of statistical estimation and bandit learning. Finally, using tools and ideas from both bandit algorithm design and adaptive statistical estimation, we propose a general low switching adaptive experiment framework, which could be a generic research paradigm for a wide range of adaptive experimental designs. Through novel lower bound techniques for non-i.i.d. data, we demonstrate the optimality of our proposed experiment. Numerical result indicates that the estimation accuracy approaches optimal with as few as two or three policy updates."

3 - Distributionally Robust Universal Classification: by Passing the Curse of Dimensionality

Siyuan Chen, Georgia Institute of Technology, Atlanta, GA, United States, Weijun Xie

The Distributionally Robust Universal Classification (DRUC) framework addresses overfitting in empirical risk minimization by incorporating Wasserstein-based robustness. We propose an in-sample DRUC reformulation, establish asymptotic and finite-sample guarantees, develop a MILP model, and design a 2-approximation algorithm. Numerical results confirm its efficiency and strong out-of-sample performance.

4 - Sample Complexity of Inventory Control with Setup Costs Beyond Plug-in Demand Estimation

Xiaoyu Fan, Stern School of Business, New York University, New York, NY, United States, Zhengyuan Zhou

We study the fundamental problem of how many samples are needed to learn an ϵ -optimal policy in inventory control with setup costs. Our proposed algorithm achieves superior sample complexity than that achieved by either the plug-in demand estimator or directly applying the recently developed optimal reinforcement learning algorithms.

Optimization and Surrogate Methods for Black-Box Systems

Invited Session

Data Mining

Chair: Hadis Anahideh, University of Illinois Chicago, Chicago, IL, United States

1 - Lipschitz Based Lower Bound Construction for Surrogate Optimization

Hadis Anahideh, University of Illinois Chicago, Chicago, IL, United States, Mohammadsina Almasi, Jay Rosenberger

Bounds play a vital role in guiding optimization algorithms by enhancing convergence, improving solution quality, and quantifying optimality gaps. While Lipschitz-based lower bounds are well-established, their effectiveness is often constrained by the function's topological properties. To address these limitations, we propose an approach that integrates nonlinear distance metrics with surrogate approximations, yielding more adaptive and accurate lower bounds. A key aspect of our methodology lies in the flexibility of the chosen distance metric, which can be adapted to various function behaviors. In particular, we explore sublinear and superlinear metrics under the Hölder continuity assumption, demonstrating their capacity to capture local function characteristics beyond the scope of conventional linear bounds. Empirical evaluations on diverse benchmark test problems show that our approach surpasses both standard Lipschitz-based and statistical methods in producing high-quality lower bounds. We further employ these refined bounds as an acquisition function within surrogate optimization, a common technique for expensive black-box problems wherein a surrogate model approximates the true objective function. By leveraging these bounds to balance exploration and exploitation, we effectively prioritize evaluations in regions with high potential for improvement. Overall, our framework not only offers more accurate and flexible lower bound estimates but also acts as a robust acquisition strategy that expedites convergence to near-optimal solutions in black-box optimization.

2 - Fairness-Aware Bandit Optimization with Delayed Feedback

Mohammadsina Almasi, University of Illinois at Chicago, Chicago, IL, United States, Hadis Anahideh

Decision-making under uncertainty with limited resources poses critical challenges in domains such as education, healthcare, and social services, particularly when the outcomes of actions are not observed immediately but manifest with delay, shaped by hidden dynamics beyond observed features. These settings introduce complex constraints: limited budgets, equity considerations, and the need to model long-term impact. Traditional approaches that assume immediate feedback and static environments are insufficient in capturing the nuanced, temporal structure of such problems. We propose a novel decision-making framework based on delayed-feedback multi-armed bandits that integrates a neural network trained on individual-level observational data. Rather than modeling reward at the level of individual actions alone, the framework learns latent factors that influence delayed outcomes and aggregates these signals to infer subgroup-level reward distributions. By modeling how past allocation patterns influence future responses, the algorithm learns a dynamic, temporally-aware policy that evolves in response to prior actions. The learned policy satisfies both budgetary constraints and fairness criteria by ensuring balanced performance across subgroups while optimizing overall outcomes. Our method provides a data-driven, adaptive mechanism for learning effective allocation strategies under uncertainty and delay, addressing both the structural and ethical demands of real-world policy problems. Empirical results on a large-scale educational dataset demonstrate the framework's ability to capture subgroup-specific reward dynamics, model temporal dependencies in delayed feedback, and achieve superior trade-offs between outcome quality and fairness in constrained environments.

3 - SO0GO: a Surrogate-Based Zero-Th Order Global Optimization Toolbox for Expensive Black-Box Problems

Juliane Mueller, National Renewable Energy Laboratory, Golden, CO, United States, Wesley da Silva Pereira

We present a toolbox for derivative free global optimization aimed at computationally expensive black-box problems. The toolbox integrates several of our previously developed derivative free optimization algorithms including continuous, mixed-integer, and multi-objective developments. The methods are based on the use of surrogate models (radial basis functions and Gaussian process models) that allow us to selectively query the true expensive objective functions only at the most promising points in the search space, thus significantly reducing the computational expense of the optimization. Several acquisition functions are implemented including approaches for batch sampling. The toolboxes is freely available at <https://github.com/NREL/soogo/tree/main>.

4 - Enhancing Bayesian Optimization with Large Language Models for Black-Box Problems

Andrea Carbonati, University of Illinois Chicago, Chicago, IL, United States, Hadis Anahideh

Bayesian Optimization (BO) is widely recognized for its effectiveness in optimizing expensive, black-box functions, particularly in experimental and computationally intensive contexts. However, traditional BO faces challenges in efficiently navigating complex, high-dimensional search spaces and leveraging rich domain-specific heuristics. Large Language Models (LLMs) have recently emerged as powerful heuristic reasoners capable of deriving context-rich insights through natural language interactions. Nevertheless, standalone LLM-driven optimization suffers from numerical inaccuracies, instability due to prompt sensitivity, and difficulty scaling to purely numeric optimization tasks. To overcome these limitations, we propose a robust hybrid framework integrating the heuristic reasoning strengths of LLMs with the rigorous statistical modeling capabilities of BO. Within this framework, LLMs proactively generate contextually informed priors and candidate solutions, effectively guiding the BO surrogate model towards promising regions in the solution space, while BO ensures robust numeric precision and rigorous uncertainty quantification. Empirical validation across diverse real-world benchmarks—including hyperparameter tuning and costly simulation-based optimization tasks—demonstrates substantial improvements in convergence speed, sample efficiency, and solution quality compared to traditional BO methods. This research paves the way for more effective, scalable, and practically applicable BO solutions, harnessing the complementary strengths of statistical rigor and contextual heuristic intelligence.

Chair: Tian Chan, Emory University, Atlanta, GA, United States

1 - AI-Based Group: The Impact of AI Advice on Group Decision-Making Process

Qiong Xia, INSEAD, FONTAINEBLEAU, France, Vivek Choudhary, Yash Shrestha, Sezer Ulku

Group decision-making often involves a discussion process where individuals exchange ideas, discuss issues, and influence each other's opinions. With the growing adoption of AI in organizations, understanding its impact on this process is critical. Using a laboratory experiment where group members form their own predictions and engage in discussions, we compare the effects of AI advice introduced individually before (Early AI) and after (Late AI) discussion, as well as AI advice introduced collectively to the group before discussion (Group AI), to scenarios where there is no AI advice (No AI).

The results reveal that groups receiving AI advice outperform No AI groups, with Early AI achieving the highest prediction accuracy. However, group dynamics vary depending on whether AI is introduced before or after group discussions, regardless of whether it is introduced individually or collectively. When AI advice is introduced before group discussion, groups in both Early AI (individual) and Group AI (collective) engage in shorter discussions to reconcile the differences in individuals' predictions compared to No AI groups. Additionally, these groups discuss less the features of the prediction variables, leading to increased prediction errors in their own predictions over time compared to No AI groups. In contrast, when AI is introduced after group discussion (Late AI), it disrupts group dynamics by increasing disagreement on final predictions, thereby reducing consensus compared to No AI groups. However, Late AI groups exhibit significantly greater cognitive engagement in performance feedback.

2 - Team Building and Incentive Schemes in Collaborative Projects

Ignacio Rios, The University of Texas at Dallas, Richardson, TX, United States, Ruth Beer, Anyan Qi

Worker-induced delays pose a major challenge in collaborative project environments. This paper investigates how incentive structures and managerial interventions—particularly team-building activities—can reduce such delays. We focus on two prevalent incentive schemes: (i) individual incentives, which reward workers based on their own performance, and (ii) group incentives, which tie rewards to overall team outcomes. We hypothesize that the effectiveness of group incentives hinges on the strength of interpersonal ties within teams and explore how team-building activities may enhance their impact.

We develop a game-theoretic model of a two-worker project involving sequential tasks, where each worker decides whether to proceed with their task or delay it by pursuing an alternative option. The model predicts that delays are more likely when workers face attractive outside options or when there is excess slack in the project timeline. Group incentives can reduce delays, but only when workers care about each other's payoffs. We then test these predictions in a laboratory experiment, varying both the incentive scheme and the presence of a team-building activity.

The results confirm the behavioral regularity of *slack-based procrastination*: workers are more likely to delay tasks when more slack is available. Importantly, we find that team-building activities reduce delays by nearly 10% under group incentives—but not under individual incentives—highlighting a strong interaction effect. These findings suggest that pairing group incentives with light-touch interventions like team-building can meaningfully reduce delays in collaborative settings, and that the timing and structure of such interventions are critical for their success.

3 - What Brings Lurkers to the Online Table: The Role of Goal Gradient Effect

Shizhen Chen, Emory University, Atlanta, GA, United States, Tian Chan, Anandhi Bharadwaj

Online communities (OCs) are dominated by lurkers—individuals who consume content without contributing—yet collective action projects, which harness dispersed contributions to generate public goods, drive innovation, and foster civic engagement, depend critically on engaging these silent participants. Understanding how to activate lurkers is therefore vital to the success of citizen science initiatives, crowdfunding campaigns, online petitions, and similar efforts. Drawing on data from Reddit's r/place 2022 social experiment and goal-gradient theory, we argue that clearly defined, singular, and achievable objectives function as powerful visual cues that prompt latent users to take action.

We test three main hypotheses in this setting. First, greater goal completion accelerates a project's productive work rate (H1a), an effect that is stronger when goals are presented with higher visual complexity (H1b). Second, this goal-completion effect is most pronounced in communities with large latent user bases, suggesting that realistic goals primarily spur lurker engagement rather than merely boosting activity among existing contributors (H2). Third, significant setbacks diminish the goal-gradient effect, indicating the importance of dynamically recalibrating objectives to maintain momentum (H3).

Our results offer actionable guidance for OC managers: maintain high goal visibility, adapt targets in response to setbacks, and leverage visual complexity to mobilize the silent majority essential to collective online endeavors.

4 - Cultures for Innovation

Rob Glew, McGill University (Desautels), Montréal, QC, Canada, Jeremy Hutchison-Krupat

Many organizations face the challenge of pursuing novel innovation, where the actions required to uncover the technology are unknown. As management of innovation projects is typically delegated to an R&D unit, ensuring resources are committed to experiments with the greatest chance of success is a central concern for senior management. Yet, their ability to do so is limited, as the specific steps to take cannot be articulated and the productivity of experiments is only known ex-post, creating a risk of moral hazard. In this paper, we examine how an organization's innovation culture may be used to resolve this problem. We study the situation where senior management delegates operational decisions for innovation to an R&D manager, whose efforts and actions cannot be fully verified. Instead, senior management may only set targets for the resources allocated to derivative innovation (which can be verified) and their tolerance for failure, creating the organizations' innovation culture. Recognizing that, in practice, organizations vary in terms of the autonomy and tolerance they assign to innovation projects, we analyze both cultural levers separately and in combination. Our results provide an alternative view of tolerance for failure by including moral hazard: reducing tolerance for failure can enable organizations to pursue riskier innovation projects. We verify that setting targets for derivative innovation can increase the rate of novel innovation, but only for a subset of projects. Otherwise the cost of such measurement may be unjustified. Moreover, some organizations may benefit from prohibiting derivative innovation to pursue riskier projects.

1 - Ransac Revisited: An Improved Algorithm for Robust Subspace Recovery Under Adversarial and Noisy Corruptions

Guixian Chen, University of Michigan, Ann Arbor, MI, United States, Jianhao Ma, Salar Fattahi

In this paper, we study the problem of robust subspace recovery (RSR) in the presence of both strong adversarial corruptions and Gaussian noise. Specifically, given a limited number of noisy samples---some of which are tampered by an adaptive and strong adversary---we aim to recover a low-dimensional subspace that approximately contains a significant fraction of the uncorrupted samples, up to an error that scales with the Gaussian noise. Existing approaches to this problem often suffer from high computational costs or rely on restrictive distributional assumptions, limiting their applicability in truly adversarial settings. To address these challenges, we revisit the classical random sample consensus (RANSAC) algorithm, which offers strong robustness to adversarial outliers, but sacrifices efficiency and robustness against Gaussian noise and model misspecification in the process. We propose a two-stage algorithm, RANSAC+, that precisely pinpoints and remedies the failure modes of standard RANSAC. Our method is provably robust to both Gaussian and adversarial corruptions, achieves near-optimal sample complexity without requiring prior knowledge of the subspace dimension, and is more efficient than existing RANSAC-type methods.

2 - Fair Supervised Learning via Smooth Nonconvex Constraints

Zahra Khatti, Lehigh University, Bethlehem, PA, United States, Daniel Robinson, Frank E. Curtis

We propose a new strategy for fair supervised machine learning, emphasizing computational efficiency and reliable fairness enforcement. Our approach introduces a novel smooth nonconvex surrogate to approximate discontinuous unfairness measures, ensuring tight and effective fairness guarantees compared to conventional convex approximations. Unlike traditional regularization methods, our strategy employs hard constraints, allowing explicit control over fairness tolerances without extensive tuning of regularization parameters. Additionally, our framework efficiently handles multiple, potentially conflicting fairness criteria simultaneously, resulting in tractable optimization problems with minimal parameter tuning.

3 - A Bilevel Optimization Method Using Synthetic Data to Mitigate Unfairness and Preserve Privacy in Collaborative Machine Learning

Chia-Yuan Wu, Lehigh University, Bethlehem, PA, United States, Frank E. Curtis, Daniel Robinson

We propose a two-stage strategy for collaborative machine learning that promotes fair predictions, prevents client-data leakage, and reduces communication costs without iterative communication. In the first stage, each client generates a synthetic dataset by solving a bilevel optimization problem aimed at ensuring that the global model yields fair predictions. In the second stage, a differentially private method is applied to the first-stage synthetic data to obtain a second synthetic dataset. Each client then sends its second-stage synthetic data to the server. These data are used to train the global model using conventional machine learning techniques, eliminating the need to handle fairness-specific aggregation while preserving privacy. Our approach requires only a single communication round, is communication-efficient, maintains data privacy, and promotes fairness. Empirical results demonstrate that our method effectively reduces unfairness while preserving client privacy through synthetic data.

4 - Higher Order Polynomial Model-Based Derivative-Free Methods

Abraar Chaudhry, Georgia Institute of Technology, Atlanta, GA, United States, Katya Scheinberg

Traditional model-based derivative free methods, such as those pioneered by Powell, iteratively construct second-order interpolation models of the objective function and optimize these models over trust-regions. Higher order polynomials may provide better models, however, they are hard to optimize. We propose a new approach of constructing and optimizing higher degree polynomial models for derivative free optimization. This is done using techniques from polynomial optimization and sum of squares. We will discuss the practical and theoretical properties of our method.

5 - Zeroth Order Schemes for Nonsmooth, Nonconvex, Stochastic Optimization

Luke Marrinan, Penn State University, State College, PA, United States, Farzad Yousefian, Uday Shanbhag

We consider the minimization of a Lipschitz continuous and expectation-valued function over a closed and convex set. Our focus lies on obtaining both asymptotics as well as rate and complexity guarantees for computing an approximate stationary point (in a Clarke sense) via zeroth-order schemes. We adopt a randomized-smoothing-based approach reliant on minimizing a smooth approximation of our objective function. In such a setting, we develop a zeroth-order stochastic gradient and quasi-Newton schemes reliant on a combination of randomized and Moreau smoothing is proposed and analyzed, for which iteration and sample complexities are derived.

1 - Multi-Agent Markov Entanglement

Shuze Chen, Columbia University, New York City, NY, United States

Value decomposition is fundamental in multi-agent reinforcement learning, yet its theoretical justifications remain uncharted. This work establishes that a Markov decision process (MDP) permits exact value decomposition iff. it's not 'entangled'—a concept akin to quantum entanglement. We further introduce the measure of Markov

entanglement, quantifying decomposition error in general MDPs. Using this framework, we prove a widely-used class of index policies is weakly-entangled. Finally, we show efficient estimation of Markov entanglement, guiding practitioners on the decomposition feasibility.

2 - A Simple Uniformly Optimal Method Without Line Search for Convex Optimization

Tianjiao Li, Georgia Institute of Technology, Atlanta, GA, United States

In this paper, we present a novel auto-conditioned fast gradient method (AC-FGM) that can achieve an optimal $O(1/k^2)$ rate of convergence for smooth convex optimization without requiring the estimate of a global Lipschitz constant or the employment of line search procedures. We then extend AC-FGM to solve convex optimization problems with Hölder continuous gradients and show that it automatically achieves the optimal rates of convergence uniformly for all problem classes with the desired accuracy of the solution as the only input. Finally, we report some encouraging numerical results.

3 - Dynamic Matching with Post Allocation Service and Its Application to Refugee Resettlement

Soonbong Lee, Yale University, New Haven, CT, United States

Motivated by our collaboration with a major U.S. refugee resettlement agency, we study a dynamic matching problem where each arrival must be matched immediately and irrevocably to a static resource and require post-allocation services from a dynamic resource. The central planner aims to balance matching rewards with the costs of congestion and over-allocation. We design learning-based algorithms that are distribution-free, asymptotically optimal in certain regimes, and computationally efficient. When tested on real data from our partner agency, our methods outperform the existing ones.

4 - Maximum Load Assortment Optimization: Approximation Algorithms and Adaptivity Gaps

Marouane Ibn Brahim, Cornell Tech / Cornell University, New York, NY, United States

We study Maximum Load Assortment Optimization, where the goal is to steer a stream of customers toward selecting the same product from an offered assortment. Motivated by applications like Attended Home Delivery and group scheduling, each customer chooses a product or opts out, with choices governed by the Multinomial Logit model. The decision maker selects assortments to maximize the expected maximum number of selections for any single product. We present near-optimal algorithms for both static and dynamic versions of the problem, addressing key computational challenges.

Invited Session

Multi Criteria Decision Making

Chair: Eduarda Frej, Universidade Federal de Pernambuco, Recife, Brazil

Co-Chair: Danielle Costa Morais, Universidade Federal de Pernambuco, Recife, N/A, Brazil

1 - Analyzing the Effects of Holistic Evaluation in the Fitradeoff Method: Results of A Simulation Study

Eduarda Frej, Universidade Federal de Pernambuco, Recife, Brazil, Manoel Ribeiro, Tarsila Vasconcelos, Adiel De Almeida

The FITradeoff method combines two types of preference modelling in its structure: elicitation by decomposition and holistic evaluation. This combination enhances the flexibility of the method, improving the preferences elicitation task in a sense that fewer elicitation questions are expected to be answered by the Decision Maker (DM) to find a recommendation for the multicriteria decision problem. In this context, this work aims to evaluate the impact of conducting holistic evaluations in FITradeoff, evaluating the potential for reduction in the number of questions answered by the DM to achieve a recommendation. We present results of a simulation study, carried out considering different scenarios for number of criteria, number of alternatives and weights distribution pattern. Hypotheses on the reduction of the number of questions were tested for identifying the actual effect of performing HE after the step of the ranking of criteria weights, in the beginning of the elicitation process. The results have shown that holistic judgments have a significant impact on the reduction of the number of questions answered by the DM in the elicitation process, in a sense that the total effort spent by DMs reduces in a significant manner, improving the decision process.

2 - An Analysis of the Heuristics Associated with the Decomposition Elicitation Procedure of the Fitradeoff Method

Jonatas Almeida, Federal University of Pernambuco, Caruaru, Brazil, Eduarda Frej, Adiel de almeida

The FITradeoff method, which belongs to the MAVT set of methods, combines two approaches to flexible elicitation of scale constants, the decomposition procedure and the holistic evaluation procedure. The first approach, decomposition, is based on the tradeoff procedure, which has a very robust axiomatic structure, but which can

prolong elicitation and make it cognitively challenging, leading to mistakes in the decision maker's statements. The flexible approach of the FITradeoff decomposition procedure allows the use of partial information to evaluate alternatives according to the information needed for the problem, making elicitation faster and easier. However, elicitation efficiency is still an important objective, so methodological improvements that seek to speed up elicitation and provide greater flexibility to the decision maker are important contributions. In this context, an adjustment at the beginning of the decomposition procedure allows the use of a heuristic that speeds up elicitation, with the potential to significantly reduce the number of questions asked to the decision maker. The heuristic acts by accelerating the reduction of the feasible region of the weight space; however, its efficiency depends on the preference scenario.

3 - Artificial Intelligence in Multi-Criteria Decision Making/Aid Methods: A Systematic Literature Review

BRUNO CICCUI, Federal University of Pernambuco, Recife, Brazil, Eduarda Frej, Adiel T. de Almeida

Over the past two decades, Artificial Intelligence (AI) has experienced substantial development, progressing from traditional predictive models and human-like computational methods to becoming an integral part of complex decision-making processes. A notable contemporary trend is the integration of AI with Multi-Criteria Decision-Making/Aid (MCDM/A) methods, aimed at providing more effective and intelligent decision support in multifaceted and uncertain environments. This study presents a systematic literature review that explores how AI techniques have been integrated with MCDM/A methods. Based on 106 peer-reviewed articles sourced from major scientific databases, the review is structured around six research questions and employs both bibliometric analysis and qualitative content assessment to uncover prevailing patterns, applications, and gaps in the literature. The findings highlight several benefits of combining AI with MCDM/A methods, including the ability to handle imprecise and vague data, manage high-dimensional information, and conduct predictive modeling and scenario-based simulations. These capabilities are particularly useful in engineering fields such as logistics and intelligent transportation systems, production and resource allocation, energy systems, and environmental planning. Despite these benefits, the review identifies critical challenges related to data quality and resolution, explainability and biases of learning algorithms, complexity and scalability of AI algorithms, and concerns related to human-AI interactions within the AI-enhanced MCDM/A methods. In summary, this paper offers a comprehensive overview of the synergistic relationship between AI and MCDM/A methods, providing insights into how this integration can overcome existing limitations and support robust, efficient decision-making in engineering and other complex domains.

4 - Public Procurement and Social Sustainability: a Multicriteria Decision-Making Model for Contractor Selection

George da Mota Passos Neto, UFPE, Recife, Brazil, Luciana Alencar, Rodolfo Valdes-Vasquez

Traditional contractor selection practices in public procurement often overlook broader societal impacts, despite their critical role in ensuring successful and sustainable project outcomes. This study proposes a model for public procurement that integrates social sustainability, improving transparency and alignment with societal values of contractor selection. Social sustainability criteria were identified through a literature review and include stakeholder participation, occupational safety and health, employment, community impacts, socioeconomic compliance, environmental impact, neighborhood amenities, user considerations, diversity, cultural heritage, supply chain, ethics, and innovation. The model integrates Multi-Criteria Decision-Making/Aiding (MCDM/A) methods and emphasizes the importance of the decision-maker (DM) in this process. The FITradeoff method, an MCDM/A approach based on partial information, was employed to reduce the DM's cognitive effort and, consequently, lower the model's inconsistency rate. The primary contributions of the proposed model are twofold: i) incorporation of social sustainability criteria in public procurement for contractor selection, thus promoting accountability and societal well-being, and ii) offering practical techniques for managing decision-making complexities through partial information, thereby ensuring the contractor selection process is transparent, and aligned with societal goals. The study also presents an application of the model for selecting a contractor to design and construct a school in Brazil.

5 - Data-Driven Team Formation: a Machine Learning Approach for Effective Student Team Formation

Esmat Ghasemi Saghand, university of south florida, Tampa, FL, United States, Susana Lai-Yuen

Forming effective student teams significantly impacts collaborative learning and project success. However, traditional team formation methods rely heavily on predefined criteria or skills, which may not accurately capture the complex factors influencing actual team performance. These methods overlook valuable insights available from real-world team data, resulting in suboptimal team compositions and reduced effectiveness.

In this project, we propose a data-driven approach that leverages historical student survey data to build predictive machine learning models. The student data was obtained from CATME, a widely used team formation tool. The dataset includes individual student attributes such as GPA, weekly availability, English proficiency, and writing skills, combined with real-world team performance outcomes like final project scores.

We start by processing and converting qualitative CATME survey responses into structured numerical features. These individual attributes are then aggregated into comprehensive team profiles. Supervised learning models, including Random Forest and XGBoost, are trained to identify patterns predicting team success. Cross-validation techniques ensure the models' reliability, and methods such as SHAP analysis reveal which attributes most strongly correlate with effective team performance. The most influential features identified through this analysis can be explicitly defined and incorporated into future team formation processes.

Using the trained model, we identify key student attributes that positively impact team performance based on final project outcomes. Our analysis reveals how these factors correlate with successful collaborations, enabling instructors to prioritize attributes most predictive of effective teamwork. By leveraging these insights, student teams can be formed that improve performance outcomes and foster collaborative interactions.

6 - From Leaf to Logistics: Multi-Objective Optimization and Scenario Analysis in Tea Supply Chains

Zehra Melis Teksan, ICRON , Amsterdam, Netherlands

Managing blending and procurement operations in the food industry involves complex trade-offs among cost, quality, and customer satisfaction. This presentation details the real-world implementation of an advanced decision support system for a leading tea producer. The solution leverages multi-objective optimization, machine learning, and real-time scenario analysis within a collaborative, multi-user environment. Designed to support both medium- and long-term planning, the system enables accurate operational cost forecasting and dynamic decision-making. By integrating these advanced analytics capabilities, the platform significantly enhances the agility and profitability of blending and procurement processes, while boosting customer satisfaction. The case illustrates how such a system can deliver substantial strategic value to companies in the blended food product sector.

1 - Asset Pricing with Higher-Order Dependence in Labor and Stock Markets

Wei Jiang, Hong Kong University of Science and Technology, Hong Kong, Hong Kong

This study investigates higher-order dependence, which captures the joint occurrence of extreme values in labor and stock markets, and its implications for asset pricing. Higher-order dependence significantly affects household portfolio decisions by altering wealth risk profiles through skewness and kurtosis channels. Incorporating this dependence into asset pricing frameworks reveals that households reduce risky asset holdings and adjust participation thresholds, while ignoring it leads to economic inefficiencies and increased wealth inequality. These findings emphasize the critical role of higher-order dependence in shaping asset pricing models, household financial behavior, and the broader dynamics of labor and stock markets.

2 - Adaptive Window Selection for Financial Risk Forecasting

Ruodu Wang, University of Waterloo, Waterloo, ON, Canada

Risk forecasts in financial regulation and internal management are calculated through historical data. The unknown non-stationarity of financial data poses a substantial challenge in selecting an appropriate look-back window for risk modeling and forecasting. We develop a statistical learning method based on a stability principle to adaptively determine a window size for risk forecasting. A central component of the proposed methodology is to compare the realized scores with a threshold, which we evaluate based on an idea of bootstrap. The proposed method is applicable to the forecast of risk measures that are elicitable individually or jointly, such as Value-at-Risk (VaR) and the pair of VaR and Expected Shortfall (ES). Through simulation studies and empirical analyses, we demonstrate that the proposed approach outperforms the standard rolling window approach and a recently developed online learning approach, especially when there are structural changes in the data-generating process.

3 - Arbitraging on Decentralized Exchanges

Yutian Zhou, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Xuedong He, Chen Yang

Decentralized exchanges (DEXs) are alternative venues to centralized exchanges to trade cryptocurrencies (CEXs) and have become increasingly popular. An arbitrage opportunity arises when the exchange rate of two cryptocurrencies in a DEX differs from that in a CEX. Arbitrageurs can then trade on the DEX and CEX to make a profit. Trading on the DEX incurs a gas fee, which determines the priority of the trade being executed. We study a gas-fee competition game between two arbitrageurs who maximize their expected profit from trading. We derive the unique symmetric mixed Nash equilibrium and find that (i) the arbitrageurs may choose not to trade when the arbitrage opportunity and liquidity is small; (ii) the probability of the arbitrageurs choosing a higher gas fee is lower; (iii) the arbitrageurs pay a higher gas fee and trade more when the arbitrage opportunity becomes larger and when liquidity becomes higher; (iv) the arbitrageurs' expected profit could increase with arbitrage opportunity and liquidity. The above findings are consistent with our empirical study.

4 - Equity Crowdfunding vs. Ipos: Leveraging Dynamic Pricing for Blockchain Venture Success

Bretislav Hajek, National University of Singapore, Singapore, Singapore, Jussi Keppo, Steven Kou

Equity crowdfunding has emerged as a compelling alternative to traditional initial public offerings (IPOs) for blockchain-based ventures seeking early-stage capital. By issuing governance tokens—which may confer voting rights and participation in project direction—blockchain companies can bypass costly intermediaries such as investment banks, significantly reducing transaction costs associated with traditional IPO processes. Furthermore, blockchain-enabled equity crowdfunding empowers entrepreneurs to dynamically adjust pricing and marketing strategies in real-time, effectively responding to investor demand signals. This study analyzes the strategic advantages of equity crowdfunding relative to IPOs, emphasizing key benefits for both entrepreneurs and investors, while also considering challenges such as regulatory uncertainty and the evolving legal status of governance tokens as equity instruments.

5 - Dynamic Asset Allocation Under Monotone Additive Statistics in the Heston Model

Xuedong He, The Chinese University of Hong Kong, Shatin, Hong Kong, ZHAOLI JIANG, jianming xia

The monotone additive statistic is appealing due to its axiomatic foundation and its ability to exhibit behavior that is neither risk-averse nor risk-seeking. In this study, we apply the monotone additive statistic to dynamic portfolio selection within Heston's stochastic volatility model. To address the issue of time inconsistency induced by the monotone additive statistic, we consider equilibrium portfolio strategies that can be consistently implemented by the investor. We derive the equilibrium portfolio strategies for two scenarios, where preferences are characterized by the monotone additive statistics of terminal wealth and log return of investment, respectively. In both cases, we establish comparative results between the equilibrium strategy and the expected risk aversion strategy. Finally, our numerical studies reveal that the equilibrium strategy outperforms the expected risk aversion strategy when evaluated using monotone additive statistics.

1 - Reproducing Kernel Hilbert Space Choice Model

Yiqi Yang, Shanghai Jiao Tong University & The University of Texas at Austin, Shanghai, China, People's Republic of

We propose a flexible discrete choice modeling framework using vector-valued Reproducing Kernel Hilbert Spaces over choice-set and feature pairs, capturing context-dependent interactions without strong structural assumptions. We design kernels for both featureless and feature-based settings, enabling convex estimation via the Representer Theorem. For scalability, we incorporate random feature approximations and a Neural Tangent Kernel with multi-head attention. Our method achieves linear complexity and provable generalization, outperforming benchmarks on synthetic and real-world datasets.

2 - Exact Rounding for Fair K-Median Under Quasi-Convex Costs

Alireza Rezaeimoghadam, Sharif University of Technology, Tehran, Iran, Alireza Danaei

We study a constrained variant of the k-median problem imposing a partition matroid constraint to promote fairness. To make this NP-complete problem tractable, we assume that for each client, service costs are quasi-convex over an ordering of facilities. We design an exact poly-time rounding algorithm using a novel coloring scheme to convert any optimal fractional LP solution into an integral one. Our framework extends to settings with facility opening costs and robust multi-assignment variants. Experiments on healthcare facility placement in Alabama demonstrate strong empirical performance.

3 - Power Constrained Nonstationary Bandits with Habituation and Recovery Dynamics

Fengxu Li, University of Wisconsin–Madison, Madison, WI, United States

While existing algorithms minimize regret for personalized interventions, they often lack statistical power to infer population-level effects due to limited sampling. We introduce ROGUE-TS, a Thompson Sampling algorithm for ROGUE (Reducing or Gaining Unknown Efficacy) bandits which models non-stationary dynamics influenced by behavior effect such as habituation and recovery, along with a probability clipping method that balances personalization and power. Theoretical guarantees and validation on physical activity promotion data show improved regret and robust detection of treatment effects.

4 - Llm Serving with Variable Prefill and Decode Lengths

Meixuan Wang, Tsinghua University, Beijing, China, People's Republic of

We study scheduling LLM requests with heterogeneous input prompt and output token lengths to minimize total latency. We prove that the problem is NP-hard due to batching, memory constraints, and dynamic KV cache usage. We analyze FCFS and Shortest-First, showing that their competitive ratios are unbounded when the problem

scales up. To address this, we propose a novel algorithm, Sorted-F, with a provable competitive ratio of 48. We also develop practical heuristics (dynamic programming, local search, LP-based) that outperform baselines in simulations while remaining computationally efficient.

Human Transportation Networks

Job Market Showcase

Job Market Showcase

Chair: Tianming Liu, University of Michigan, Ann Arbor, United States

1 - Learning to Generate Synthetic Human Mobility Data: a Physics-Regularized Gaussian Process Approach Based on Multiple Kernel Learning

Ekin Ugurel, University of Washington, Seattle, WA, United States, Shuai Huang, Cynthia Chen

Passively-generated mobile data has grown increasingly popular in the travel behavior literature. A relatively untapped potential for passively-generated mobile data is synthetic population generation, which is the basis for any large-scale simulations for purposes ranging from state monitoring, policy evaluation, and digital twins. And yet, this significant potential may be hindered by the growing sparsity or rate of missingness in the data, which stems from heightened privacy concerns among both data vendors and consumers (users of service platforms generating individual mobile data). To both fulfill the great potential and to address sparsity in the data, there is a need to develop a flexible and scalable model that can capture individual heterogeneity and adapt to changes in mobility patterns. We propose a conditional-generative Gaussian process framework that learns kernel structures characterizing individual mobile data and can provably replicate observed patterns. Our approach integrates physical knowledge to regularize the framework such that the generated data obeys constraints imposed by the built and natural environments (such as those on velocity and bearing). To capture travel behavior heterogeneity at the individual level, we propose a data-driven multiple kernel learning approach to determine the optimal composite kernel for every user. Our experiments demonstrate that: (1) the impact of kernel choice on mobility metrics derived from synthetic data is non-negligible; (2) physics-regularization not only reduces model bias but also improves uncertainty estimates associated with the predicted locations; and (3) the proposed method is robust and generalizes well to varying individuals and modes of travel.

2 - Choice-Based Transportation Network Design Using Hybrid Reweighted L1-Norm Minimization

Pushpendra Singh, Dartmouth College, Hanover, NH, United States, Vikrant Vaze

Network design is a well-known problem in transportation systems. Most of the existing transportation network design studies treat customer demand as exogenous. In reality, demand is impacted by the level of service, which is itself determined by the network design. A network that carries the passengers/goods from origin to destination with a lower travel time is expected to attract a higher demand. Thus, optimal network design affects and is affected by demand. Capturing this two-way relationship requires modeling endogenous customer choice, significantly increasing the problem complexity. We formulate a mixed-integer non-convex optimization model for network design that embeds a discrete choice customer demand model within it. Integrality arises from arc and path selection variables which are binary, while non-convexity stems from embedded choice models such as the logit model. We propose a general and compact formulation to represent this class of problems.

We propose the Reweighted Iterative Partial Penalty L1-norm minimization (RIPPL) heuristic, which iteratively updates variable-wise penalty weights to better approximate the L0-norm through adaptive, partial penalties. By selectively penalizing small variable magnitudes, RIPPL efficiently promotes sparsity and ensures reliable convergence. This targeted reweighting outperforms standard L1 minimization, enhancing both solution quality and scalability.

Extensive experiments on real-world case studies and simulated networks validate our approach, demonstrating significantly faster runtimes and up to a 74.43% improvement in optimality gaps over state-of-the-art methods. Our solution's scalability enables results within just 3.12% of the optimal solution for large instances.

3 - Data-Driven Behavioral Science for Smarter Transportation Systems

Tianming Liu, University of Michigan, Ann Arbor, MI, United States

Modern transportation systems are rapidly evolving, creating complex challenges that demand a deeper understanding of human behavior. In this talk, I will present my research on developing data-driven and behaviorally-informed solutions for these challenges. My approach integrates diverse data sources with advanced modeling techniques, from econometrics to generative AI, to create fine-grained representations of user decision-making. First, I will discuss my work analyzing large-scale operational data from ride-sourcing platforms. This research uncovered how individuals respond to system incentives and led to the design of novel strategies that significantly enhance system performance and user welfare. Second, I will explain how I've used behavioral queuing theory to understand and mitigate seemingly irrational behaviors, such as excessive driver waiting at terminals, resulting in effective non-pricing management solutions. Finally, I will present my work in pioneering the use of large language models to simulate complex and diverse human travel behavior. This line of research, which bridges AI with behavioral science, is foundational to developing more realistic and adaptable behavior simulation tools for creating efficient, equitable transportation systems.

4 - Friends OR Foes: Do Interference and Staggered Introduction Matter for the Impact of Bike-Sharing on Public Transit?

Yanchao Li, New York University, New York, NY, United States, Daniel Vignon

The rapid expansion of bike-sharing systems has reshaped urban transportation, raising key questions about their interaction with public transit. Accurately evaluating this relationship is critical for guiding infrastructure investment and policy. However, most causal analyses of bike-sharing effects overlook two key challenges: interference—where treatment in one area (e.g., bike station installation) affects outcomes in neighboring areas—and staggered, time-varying treatment, as bike-sharing programs often expand gradually over time. These complexities violate core assumptions in standard causal models, such as SUTVA, potentially leading to biased estimates and misguided policy conclusions.

This study investigates the extent to which interference and staggered treatment assignment influence estimates of bike-sharing's effect on public transit, focusing on New York City's CitiBike program. We: (1) quantify the bias introduced by ignoring spatial spillovers; (2) compare traditional causal estimates with models that account for both interference and treatment timing; and (3) assess how these differences impact infrastructure planning and subsidy allocation.

By applying advanced causal inference methods that explicitly incorporate spatial and temporal complexities, this research provides a more accurate and policy-relevant understanding of bike-sharing's role in urban mobility systems. Findings aim to support more effective coordination between bike-sharing and public transit, maximizing accessibility, efficiency, and investment impact.

1 - Enhancing Nonprofit Operations with AI Chatbots: the Role of Humanization and Emotion

SIDDHARTH BHATTACHARYA, George Mason University, Fairfax, VA, United States

As nonprofit organizations increasingly adopt artificial intelligence (AI) technologies to sustain engagement and optimize resource allocation, the design of AI-enabled chatbots remains a critical consideration. This study examines the effects of emotional appeals and anthropomorphism in chatbot interactions within a nonprofit context. Through a randomized field experiment at an organization that advocates for minority women's health, we analyze how varying levels of emotional intensity and human-like features influence service completion rates. Our findings reveal an inverted U-shaped relationship between emotional appeals and engagement, wherein moderate emotional intensity enhances service completion, but intense emotional content leads to disengagement. Notably, increased anthropomorphism negatively impacts service completion, suggesting that human-like chatbots may trigger expectancy violations in nonprofit contexts. Furthermore, anthropomorphism moderates the effects of emotional appeals, amplifying their negative impact when emotional intensity is high. These results highlight the complexities of chatbot design in nonprofit contexts, challenging conventional wisdom on persuasive messaging and human-like AI interactions. Our study provides actionable insights for organizations deploying AI-driven engagement tools, emphasizing the need for a balanced approach to emotional framing and anthropomorphic design to optimize user experience and service effectiveness.

2 - When Benevolence Backfires: the Paradoxical Effect of Transparency on Chatbot Donations

Mahmood Farahrooz, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, Scott Schanke, Shweta Singh

As the use of artificial intelligence, particularly chatbots, has increased, so too have privacy concerns. While some believe that transparency could create trust in users and improve engagement, other research shows that it may harm downstream consumption outcomes. This study, in the context of charitable giving, investigates how data disclosure affects donation behavior when people interact with a chatbot. We used a between-subjects experiment (N = 218) and randomly assigned participants to transparent and non-transparent data disclosure conditions and subsequently engaged them on behalf of a charity. Our results show that transparency alone does not have a direct effect on individual donation; instead, transparency greatly impacts an individual's perception of benevolence, which surprisingly, negatively influenced donation, and chatbot likeability. People who were more concerned about privacy were less likely to donate when they were told how their data would be used. These findings highlight the complex and sometimes counterproductive role of transparency in AI-driven charitable interactions.

3 - Minimizing Coordination Costs, Maximizing Care: Clinical Teams Under Emrs Through the Lens of Transaction Cost Economics

Bryan Sullivan, George Mason University, Fairfax, VA, United States

Electronic Medical Records (EMRs) promise to streamline clinical coordination and enhance care quality, yet empirical evidence is mixed, with some studies showing higher costs and clinician burden when vendor differences are ignored. This paper asks: How do Epic and Cerner systems differentially moderate perioperative coordination costs and quality reporting? Drawing on Transaction Cost Economics and Task-Technology Fit, we analyze 15.3 million U.S. anesthesia encounters (2018–2024) linked to CMS quality metrics and facility go-live dates using event-study models and provider-clustered fixed-effects OLS. We find that Cerner implementations reduce missed quality reports by 10 percentage points (versus no change under Epic), attenuate the increase in case duration (3.99 vs. 4.43 minutes), and lower mean professional charges by \$102 per encounter compared to Epic. By unpacking vendor-level EMR effects, we challenge the one-size-fits-all assumption and offer actionable guidance for hospital IT strategy and system selection.

4 - Now You See Me: How Streaming Platforms Enable Diversity in Movies

Naveen Thotadamane Basavaraj, Carnegie Mellon University, Irving, TX, United States

Our research analyzes the degree to which the unique economic characteristics of streaming platforms have allowed for the distribution of movies — in our case movies with diverse casts — that would not have been economically feasible in traditional time- and space-bound physical channels. To do this, we combine several datasets documenting cast diversity in movies, the consumption of movies across theatrical and streaming platforms, and detailed information on the promotion of movies within streaming platforms. Our results show that racial diversity is 16.8% higher for movies made for streaming platforms compared to movies made for theatrical channels. Beyond casting, we apply large language models to extract plot and character archetypes and find that minority actors in streaming movies are more evenly distributed across narrative and character types, suggesting that they are less likely to be typecast into stereotypical roles. We also show that the differences in racial representation between streaming and theatrical channels stem from the structural and algorithmic advantages of streaming platforms, namely unlimited shelf space, data-driven personalization, and recommendation algorithms that promote diverse content to broad audiences. We also find that major social movements like Black Lives Matter are associated with increased consumption but not immediate production of diverse content. Our results highlight the potential for streaming platforms to act as a corrective force against long-standing inequalities in media representation.

1 - How Do Humans Respond to Creators' Adoption of Generative AI? Insights from the Digital Artwork Market

Yingxin Zhou, Georgia State University, Atlanta, GA, United States, Ling Xue, Arun Rai

As generative artificial intelligence (AI) tools become increasingly prevalent in the creation of artistic content, questions emerge regarding how audiences respond to creators who adopt such technologies. Drawing on data from an online art community, this study examines the impact of artists' generative AI adoption on audience attitudes and explores how these effects may vary based on artists' professional experience. The findings reveal a nuanced relationship between AI adoption and audience perceptions, with distinct patterns across experience levels. This research contributes to ongoing discussions about human responses to AI adoption and offers implications for platforms, creators, and policymakers navigating the evolving boundaries of human-AI collaboration.

2 - Enhancing Security and Fairness in AI-Driven Natural Language Systems

Dorde Klisura, The University of Texas at San Antonio, San Antonio, TX, United States

AI-driven natural language systems increasingly shape decisions in critical sectors such as healthcare, finance, and public administration. However, as these systems embed deeper into sensitive domains, ensuring their security, fairness, and accountability has become essential.

My research addresses these challenges through three interrelated approaches:

- Mitigating dialect bias:** To ensure fair treatment of users from diverse linguistic backgrounds, I developed a multi-agent framework that translates dialect-specific queries into standardized language, significantly reducing performance disparities across over 50 English dialects. This approach achieved an 82% reduction in dialect bias, ensuring equitable access to critical information.
- Securing AI-driven database interfaces:** I discovered zero-knowledge schema inference attacks against Text-to-SQL systems, demonstrating that adversaries can reconstruct hidden database structures merely by querying the system. In response, I designed adaptive defenses that safeguard database schemas while preserving query accuracy, effectively mitigating this critical security vulnerability.
- Permission-aware LLM access control:** I introduced a novel approach embedding explicit access control directly into Large Language Models (LLMs). By integrating user permissions at the prompting and verification stages, the models proactively enforce fine-grained access constraints, achieving 97% accuracy in permission adherence and blocking 94% of unauthorized information disclosures.

Collectively, my research advances AI systems that not only perform efficiently but also uphold stringent standards for security, fairness, and responsible use, ensuring technology empowers and protects all users equally.

3 - Uncovering the Cognitive Mechanisms of Large Language Models in Behavior Modeling

Yu Qin, Arizona State University, Tempe, AZ, United States, Olivia Sheng

Large Language Models (LLMs) are catalyzing a significant paradigm shift in Artificial Intelligence (AI) and reshaping business research through their remarkable proficiency and emulation of complex human-like behaviors. Despite their widespread application, a critical gap exists in understanding the underlying cognitive mechanisms driving these behaviors. Current evaluation methods, primarily observing LLM responses, are insufficient as responses may not faithfully reflect internal knowledge or computational processes. This research proposes to employ Sparse Autoencoders (SAEs) to identify and interpret these latent cognitive features, moving beyond surface-level observations. The principal contribution of this study is to pioneer a deeper, more mechanistic understanding of LLM cognition. By aiming to genuinely uncover the internal features that dictate LLM behaviors, this research provides crucial insights essential for assessing and enhancing their reliability, trustworthiness, safety, and stability – foundational elements for their responsible adoption in high-stakes business environments. This investigation unlocks novel perspectives, opening new frontiers for business research and practice. It equips researchers and practitioners with a more nuanced comprehension, enabling the development of more robust, fair, and transparent AI-driven solutions. Ultimately, by illuminating the cognitive underpinnings of LLMs, this work will foster more informed, effective, and ethical integration of these powerful technologies, significantly advancing how businesses leverage AI for innovation and decision-making.

4 - Modeling Interpretation in Data Visualization: Bridging Computation, Language, and Decision Making

Anjana Arunkumar, Northeastern University, Oakland, CA, United States

As artificial intelligence systems generate, annotate, and mediate ever more of the world's information, a critical question emerges: how do people make sense of it? This research program models the process of interpretation itself—how humans extract meaning from visualizations and language, especially when navigating complex or unfamiliar data.

Situated at the intersection of data visualization, cognitive science, and natural language processing, the work combines empirical studies with interactive system design to examine how users perceive, recall, and reason with data. It introduces modeling frameworks that capture how annotation strategies, linguistic framing, and individual differences shape understanding, trust, and decision quality. These insights inform the creation of human-in-the-loop tools that support generalization, reduce bias, and make AI-driven outputs more transparent and context-aware.

Rather than isolating visualization or language as endpoints, this research treats them as generative interfaces—sites where human and machine interpretations converge. Applications span multilingual visualization, instruction tuning, and decision support, with a shared emphasis on adaptive systems that respond to diverse user needs and cognitive constraints. The result is a design and modeling agenda for building interpretable, equitable systems—tools that go beyond generating outputs to actively support how people think, reason, and decide with data.

Generative AI in Finance

Invited Session

Finance

Chair: Renyuan Xu, Stanford University, Palo Alto, CA, United States

Co-Chair: Haoyang Cao, Johns Hopkins University, Baltimore, MD, United States

1 - Financial TIME Series Forecasting via Generative Adversarial Networks

Mihai Cucuringu, UCLA, Los Angeles, CA, United States

We investigate the use of Generative Adversarial Networks (GANs) for probabilistic forecasting of financial time series. To this end, we introduce a novel economics-driven loss function for the generator. This newly designed loss function renders GANs more suitable for a classification task, and places them into a supervised learning setting, whilst producing full conditional probability distributions of price returns given previous historical values. Our approach moves beyond the point estimates traditionally employed in the forecasting literature, and allows for uncertainty estimates. Numerical experiments on equity data showcase the effectiveness of our proposed methodology, which achieves higher Sharpe Ratios compared to classical supervised learning models, such as LSTMs and ARIMA. Finally, we discuss extensions to the multi-asset setting by leveraging cross-asset relationships through a graph-based probabilistic ensemble framework.

2 - Training Foundation Models for Algorithmic Trading

Atlas Wang, XTX Markets & UT Austin, New York, NY, United States

In this talk, I will introduce the pioneering efforts of XTX Markets in applying large-scale foundation models to algorithmic trading. I will highlight both the unique challenges and exciting opportunities in forecasting financial markets using sophisticated deep neural networks trained on massive, heterogeneous datasets. Specifically, I will present a high-level discussion how our models can be trained to utilize diverse market data to generate robust forecasts across thousands of financial instruments globally. I will also cover our experiences in "neural scaling laws" on market data as a novel modality, amid extreme market noise and volatility. Finally, I will introduce our latest research initiatives, emphasizing XTX's substantial investments in computational infrastructure, innovative modeling approaches, and proprietary research.

3 - Diffusion Models for Sequential (Financial) Data Generation

Yinbin Han, New York University, New York, NY, United States, Haoyang Cao, Minshuo Chen, Renyuan Xu

We propose a novel paradigm for sequential data generation based on diffusion models. To ensure the adaptedness of the generated sequences, we introduce an enlarged filtration that aligns with the spatial-temporal structure of the data. By decomposing the generation process in the spirit of next-token prediction, our framework effectively incorporates diffusion models for sequential synthesis while preserving training efficiency. We further establish theoretical guarantees, including universal approximation, score estimation, and distribution estimation, while addressing the technical challenges posed by unbounded domains. Numerical experiments demonstrate the effectiveness and efficiency of the proposed approach.

4 - Diffusion Factor Models: Generating High-Dimensional Returns with Factor Structure

Yumin Xu, Peking University, Beijing, China, People's Republic of, Minshuo Chen, Renyuan Xu, Ruixun Zhang

Financial scenario simulation is essential for risk management and portfolio optimization, yet it remains challenging especially in high-dimensional and small data settings common in finance. We propose a *diffusion factor model* that integrates latent factor structure into generative diffusion processes, bridging econometrics with modern generative AI to address the challenges of the curse of dimensionality and data scarcity in financial simulation. By exploiting the low-dimensional factor structure inherent in asset returns, we decompose the score function—a key component in diffusion models—using time-varying orthogonal projections, and this decomposition is incorporated into the design of neural network architectures. We derive rigorous statistical guarantees, establishing non-asymptotic error bounds for both score estimation at $O(d^{5/2} n^{-2/(k+5)})$ and generated distribution at $O(d^{5/4} n^{-1/(2k+10)})$, primarily driven by the intrinsic factor dimension k rather than the number of assets d , surpassing the dimension-dependent limits in the classical nonparametric statistics literature and making the framework viable for markets with thousands of assets. Numerical studies confirm superior performance in latent subspace recovery under small data regimes. Empirical analysis demonstrates the economic significance of our framework in constructing mean-variance optimal portfolios and factor portfolios. This work presents the first theoretical integration of factor structure with diffusion models, offering a principled approach for high-dimensional financial simulation with limited data.

5 - Robust Financial Modeling: a Principled Framework for Generative Data Augmentation

Amine Aboussalah, New York University, New York, NY, United States

Effective machine learning for financial modeling is often challenged by limited data, leading to overfitting and poor out-of-distribution generalization. This talk introduces a principled framework for data augmentation to address these critical challenges. This framework models diverse data structures, from time series to graph-

structured networks. We establish a theoretical foundation for our framework using Rademacher complexity to offer a regret bound on the generalization error, thereby guaranteeing performance under specific conditions. Through empirical evaluation on diverse datasets, we demonstrate that our approach not only significantly outperforms state-of-the-art augmentation techniques but also offers superior computational efficiency. This research provides a robust, theoretically-grounded solution for enhancing the performance and reliability of generative AI models in real-world applications such as finance.

1 - Interpretable Design of Multi-Agent Reinforcement Learning In Mobile Health Applications

Hossein Hejazian, Harvard University, Cambridge, MA, United States, Mohammad Zhalechian, Soroush Saghaian

Multi-agent mHealth strategies can effectively address multifaceted health goals by coordinating multiple interventions. Existing micro-randomized trials are single-agent and lack data on agent interactions. Reinforcement learning offers an online framework to optimize multi-agent policies but faces engagement, exploration-exploitation, and interpretability challenges. We provide novel solutions for holistic mobile health interventions by proposing an algorithm designed to deliver personalized interventions to users with the aim of forming an overall health habit. We introduce the multi-agent analytical framework, where decisions are made by an automated manager as well as several agents. In this framework, each agent is responsible for one aspect of the user's health (e.g., sedentary behavior, diet, or physical activity). The manager's role is to coordinate the agents such that the system achieves its goal. Our framework sequentially determines the agent the manager should select at each interaction with a user, as well as the intervention taken by the designated agent. We develop a holistic framework with a provable performance guarantee which provides a data-driven policy in our setting. Our results provide insights into how such a holistic framework helps form healthy habits for users by taking advantage of mobile health technologies.

2 - Identifying and Predicting Vaccine Hesitancy Using Data-Driven Behavioral Modeling

Citina Liang, University of Southern California, los angeles, CA, United States, Sze-chuan Suen

Understanding vaccine uptake behavior is critical to effective vaccination deployment, especially for diseases like COVID-19 where both the rate and timing of vaccination can influence transmission dynamics. Despite widespread vaccination campaigns, challenges remain in promoting vaccine uptake effectively due to limited insight into population subgroups with varying attitudes and behaviors.

In this work, we use survey and surveillance data to identify population subgroups with distinct vaccine uptake behaviors and predict vaccination timing using demographic characteristics and self-reported attitudes. We leverage longitudinal survey data capturing individual beliefs, behaviors, and demographics, along with vaccination registry records. These datasets present distinct information on the population and present unique challenges. The longitudinal survey data contain non-uniformly timed attitudinal measures, with key questions asked at different waves, leading to missing or inconsistent responses across individuals. Meanwhile, the vaccination registry data offer basic demographics but lack behavioral context, limiting direct insight into vaccine decision-making.

To address this, we apply latent class analysis and unsupervised machine learning methods such as k-means to identify evolving subgroups of vaccine hesitancy. We then use supervised learning models, including regression and gradient boosting classifiers, to predict both likelihood and timing of vaccine uptake based on subgroup membership and individual-level features. Our findings reveal meaningful behavioral subgroups and predictive patterns that support targeted public health interventions. This data-driven approach enhances the precision of vaccination strategies, particularly in diverse populations such as those in Los Angeles County.

Acknowledgments: This research was supported by the Merck Investigator Studies Program (MISP), Merck & Co., Inc.

3 - Early Prediction of Patient Admission Likelihood in Emergency Departments

Farzad Zeinali, Clemson University, Clemson, SC, United States

Emergency Department (ED) overcrowding remains a persistent challenge in U.S. hospitals, driven largely by admitted patients who wait in the ED for inpatient beds. This study aims to predict the likelihood of patient admission during the early stages of an ED visit, particularly before physician evaluation. Anticipating inpatient demand early in the care process is a critical step toward operational planning and improving patient flow between the ED and other hospital departments. We developed a machine learning (ML) framework that integrates both structured data and unstructured triage notes to support real-time decision-making. The dataset includes demographic, clinical, and visit-related features. Importantly, we identified impactful variables not available in tabular format and extracted them from free-text triage notes using open-source large language models (LLMs). In total, over 30 variables were used to train and evaluate multiple state-of-the-art classification algorithms. By identifying the top-performing models and the most influential predictors, our analysis shows that accurate prediction of admissions is feasible early in the ED process. These findings demonstrate the potential of data-driven decision support systems to enhance coordination between the ED and inpatient units, improve operational responsiveness, and enable proactive interventions that reduce boarding delays and alleviate ED overcrowding.

4 - Integrating AI and Multilevel Modeling to Study Sdoh Impacts on Diseases of Despair

Haya Alshayji, Pennsylvania State University, State College, PA, United States

This talk explores integrating AI-driven methods and multilevel statistical modeling to examine the impact of Social Determinants of Health (SDoH) on Diseases of Despair (DoD). This research uses hierarchical models and machine learning to enhance risk prediction and inform targeted interventions to address health disparities in vulnerable populations.

1 - Combating Overbilling in Outsourced Projects: a Dynamic Auditing Mechanism

Like Bu, The University of Texas at Dallas, Richardson, TX, United States, Shivam Gupta, Milind Dawande, GANESH JANAKIRAMAN

Firms routinely outsource their business requirements to external agents for many reasons; e.g., to focus on their core competencies or to save costs. However, overbilling by agents has been well-acknowledged as a notorious problem across major industries, including healthcare, information technology, legal services, engineering, and consulting. Mitigating overbilling is challenging in practice; typical options for firms include auditing agents or suspending relationships with them. While firms would like to combat overbilling by utilizing these options, they also want to minimize their total cost, including agents' payments and auditing cost. We consider a repeated

principal-agent setting in which, in each period, the principal makes two decisions: (i) Whether to allocate the task to the agent or an outside option. (ii) If the agent executes the task, whether to audit the agent's cost. We propose a class of *Dynamic Auditing* mechanisms under which it is near-optimal for the agent to report his costs truthfully and the principal's cost is also near-optimal, for sufficiently large discount factors. We are the first to investigate the role of auditing in repeated settings – we show that auditing is an effective tool for the principal if either (i) the unit cost of auditing is sufficiently small, or (ii) the principal lacks knowledge of the agent's cost distribution. We also show that our results are robust when there is competition among multiple agents for the principal's business.

2 - Segmentation and Market-Based Pricing for Uncertain Episodic Service Demand: Case Study of Truckload Service Procurement for Fema

Shraddha Rana, INSEAD, Fontainebleau, France

Following natural disasters and man-made disruptions, the uncertain, episodic, and time-sensitive demand for relief services makes it difficult for humanitarian actors to compete with private-sector customers in securing commercial service capacity, leading to high costs without guarantee of higher service levels. Our aim is to strategically design and implement flexible contracts that can help humanitarian organizations get the relief services on time and economically. We study a case of transportation service procurement for the US Federal Emergency Management Agency (FEMA). Most disaster management literature focus on the procurement, allocation, and routing of the relief supplies. However, it is imperative to first ensure that transportation capacity would be available to move the supplies. We contribute to the disaster management, truckload procurement, and dynamic-pricing literature by i) studying transportation service procurement for FEMA, without capacity guarantee; ii) considering uncertain episodic demand in response to disasters; iii) modeling a market-based price contract; and iv) examining the case of dynamic-pricing where the buyer, i.e., FEMA offers the price as opposed to the seller, i.e., transportation service providers. We propose a segmentation framework that leverages the certainty of location of supply nodes and general timing of weather-based disasters, while also allowing flexibility of real-time pricing. We find that on implementing the proposed segmentation and market-based pricing, FEMA would have saved \$9.85 million in transportation service procurement costs in 2 years while still paying 71% over market rates leading to high service levels.

3 - Income Pools for Superstar Markets

Craig Fernandes, University of Toronto, Toronto, ON, Canada, Timothy Chan, Ningyuan Chen

"Superstar" markets, where a small portion of individuals earn disproportionately high incomes, are common in fields like entrepreneurship, sports, and entertainment. Participants in these markets face significant income uncertainty, which can deter entry or prompt early exit. To address this difficulty, we propose income pools -- contracts where individuals agree to share a portion of future earnings with pool members if a specific salary milestone is achieved. To date, hundreds of income pool contracts have been signed in practice. This paper develops the first mathematical model to analyze such contracts, focusing on stability (i.e., pools where no agents leave or join). When constrained to creating a single pool, we show that a stable pool always exists with specific structural properties. Generally, stronger agents tend to be more "collaborative" and favor larger pools, while weaker agents are more "selfish" and prefer smaller pools. Next, we analyze pools that adhere to a maximum size (mirroring current practice) and show that stability persists. These pools typically require more weaker agents than strong ones and we find an interesting "Pareto dominance" result, whereby all agents in a stable pool prefer a particular unique stable pool. Finally, we study general partition structures, prove that a stable partition always exists under certain conditions, and provide an algorithm to construct such a partition. We conclude with a case study on data from 2000 professional baseball players to demonstrate a 20%-30% increase in social welfare if players join income pools, under varying contract parameters.

4 - Profit Maximization and Compensation Stability in Service-Oriented Businesses

Kathleen Tomon, Colorado School of Mines, Golden, CO, United States, Alexandra Newman

Service-oriented businesses rely heavily on labor and expertise, making compensation structures critical to their operational success. Various commission structures exist, but current research lacks effective methods to optimize these systems in service-oriented settings. We present a generalized optimization model that revises existing commission and bonus scales to: (i) ensure target business gross profits, (ii) minimize deviation from prior employee compensation levels, (iii) institute a service price increase, and (iv) maintain internal consistency across bonus tiers. Applied to real-world data from a service-oriented business in a major U.S. metropolitan area, our model improves average gross profit per commission tier by 29%, while preserving compensation equity and outperforming current methods.

Optimization Under Uncertainty I

Job Market Showcase

Job Market Showcase

Chair: Yizhe Huang, University of Texas at Austin, Austin, TX, United States

1 - Robust Decision-Making in Partially Observable Markov Decision Processes

Tong Li, University of Houston, Houston, TX, United States

We study robust decision-making in partially observable Markov decision processes (POMDPs) under two key challenges: distributional uncertainty and adversarial perturbations. First, we develop a distributionally robust POMDP framework using distance-based ambiguity sets to model uncertainty in rewards and transitions. We prove value function convexity and derive tractable reformulations for commonly used statistical distances. Second, we address state adversarial perturbations by proposing a risk-aware certification approach based on exponential utility. This method quantifies the lower bound of cumulative reward under adversarial noise and risk-sensitive evaluation. Experiments on OpenAI Gym and a machine replacement problem show that distance-based robustness improves out-of-sample performance, while risk-averse training enhances certified policy performance under state perturbations. These complementary approaches together advance the robustness of POMDPs in adversarial and uncertain environments.

2 - Stochastic Dual Dynamic Programming (SDDP) for Decision Making Under Conflict and Uncertainty

Benjamin Hamlin, Clemson University, Clemson, SC, United States, Cheng Guo

We introduce a Stochastic Dual Dynamic Programming method for multiobjective or single-objective-parametric multistage stochastic programming problems. A parametric approach eliminates the bottleneck caused by the Simplex method allowing for only two objectives. Commercial solvers are used to efficiently perform forward and backward passes. We demonstrate the algorithm on a triobjective Brazilian hydrothermal problem.

3 - A Deep Learning Approach to Multistage Stochastic Programming

Yizhe Huang, University of Texas at Austin, Austin, TX, United States

Multistage stochastic programming (MSP) is a powerful framework for sequential decision-making under uncertainty with complex constraints, but solving large-scale instances remains challenging due to the curse of horizon and nested optimization structure. Existing value-based methods approximate the cost-to-go function recursively, but suffer from compounding approximation errors, require solving constrained subproblems at every stage, and lack direct policy representations. In this work, we propose a principled policy-based alternative that parameterizes decision rules with neural networks and optimizes them via an augmented Lagrangian minimax formulation. Our single-loop stochastic gradient algorithm avoids nested subproblem solvers and handles constraints through dual updates, enabling scalable learning in constrained MSPs. We provide theoretical guarantees on feasibility, optimality, and generalization, and demonstrate superior empirical performance over value-function methods such as DVFN and SDDP across high-dimensional benchmark problems in energy and production planning.

Algorithmic Fairness and Equity in Operations

Contributed Session

Contributed

Chair: Nowshin Sharmile, North Carolina A&T State University, 3533 Ivy Commons Drive, Raleigh, NC, 27606, United States

1 - Bias in AI Hiring: Assessing Fairness in Algorithmic Resume Screening

Xiahua Wei, University of Washington, Bothell School of Business, Bothell, WA, United States, Naveen Kumar

The rapid adoption of AI in hiring processes, particularly in resume screening, raises pressing concerns about fairness and bias. This study investigates the potential biases in large language models (LLMs) by analyzing Generative AI's evaluation of resumes that vary systematically across legally protected attributes (such as race, color, gender, age, and disability status) and non-protected attributes (such as employment gap, education, and writing quality), both of which can trigger explicit and implicit biases. Drawing from prior research on employment discrimination, we assess how Generative AI responds to these variations and the potential heterogeneity in biases. While our findings show limited evidence of bias for some protected attributes, results for others are mixed, especially when protected and non-protected attributes appear together. These results demonstrate the complexity of detecting and interpreting bias in AI systems. Our work contributes to ongoing efforts to promote fairness in algorithmic hiring and highlights the need for scrutiny of AI tools to support equitable employment practices.

2 - Fair to Fare Well: How Algorithmic Fairness Benefits Firms on a Platform?

Yaping Li, College of Management and Economics, Tianjin University, Tianjin, China, People's Republic of, Yunchuan Liu, Zhe Yang, Jianxiong Zhang

In this paper, we examine the impact of algorithmic fairness—through unawareness (e.g., equal treatment) or awareness (e.g., equal opportunity)—on firms that rely on platform algorithms for decision-making. Specifically, in industries such as lending and hiring, lenders and employers use platform algorithms to predict candidates' qualifications. We develop a game-theoretic model involving a platform and a firm, the platform can invest in learning to improve algorithm accuracy for better prediction of candidates' qualifications and the firm can decide which candidates to accept by setting score thresholds, whereas the candidates belong to either a regular group or a protected group that is biased against by platform algorithms. Counterintuitively, we show that algorithmic fairness, while seemingly detrimental to firms' profitability due to the constraints it imposes, can actually benefit firms. Interestingly, we find that algorithmic fairness can hurt the protected group or benefit the regular group. Our study also shows that whether equal opportunity or equal treatment outperforms in maximizing firms' profits depends on the benefit-loss ratio. When this ratio is sufficiently high, the firm has higher profits under equal opportunity; otherwise, the firm has higher profits under equal treatment. This study also provides implications for policymakers on when to allow or prohibit the use of sensitive attributes in platform algorithms.

3 - On Fairness of Process Flexibility

Lyu Hongyao, Shanghai Jiaotong University, Shanghai, China, People's Republic of, Hanzhang Qin, Huan Zheng

In the process flexibility literature, it is well known that "a little flexibility goes a long way" (Jordan and Graves 1995). This flexibility folklore states that a sparse process flexibility structure can capture nearly all the benefits of full flexibility regarding demand satisfaction and/or capacity utilization. While the efficiency metrics have been well assessed in the literature, the performance of sparse structures concerning fairness measures remains under-explored. Fairness is a crucial objective in resource allocation, driven by companies' social responsibility and the needs of humanitarian operations. In this study, we investigate the worst-case performance of sparse flexibility structures regarding the max-min demand fill rate. Through primal-dual analysis, we show that the max-min fill rate of a structure is determined by the demand nodes subset with the minimum ratio of neighboring capacity to demand. We further characterize the worst-case max-min fill rate of k -chain and Ψ -expander structures. The results suggest that a more connected structure is needed to achieve outcomes close to full flexibility. Additionally, we demonstrate that there exists an allocation that can achieve both efficiency (i.e., max-flow) and fairness (i.e., max-min fill rate). Based on our theoretical findings, we propose a computationally efficient heuristic, the Cover Ratio heuristic, to generate effective flexibility structures. Our theoretical analysis also extends to the min-max shortfall metric. We validate our theoretical findings using real-world data from the Texas Department of State Health Services and conclude that incorporating flexibility structure design can substantially enhance both fairness and efficiency in vaccine allocation.

4 - Designing Truthful Mechanisms for Asymptotic Fair Division

Yuang Shen, UIUC, Urbana, IL, United States, Jugal Garg, Vishnu V Narayan

We study the problem of fairly allocating a set of m goods among n agents in the asymptotic setting, where each item's value for each agent is drawn from an underlying joint distribution. Prior works have shown that if this distribution is well-behaved, then an envy-free allocation exists with high probability when $m = \Omega(n \log(n))$. Under the stronger assumption that item values are independently and identically distributed (i.i.d.) across agents, this requirement improves to $m = \Omega(n \log(n)/\log(\log(n)))$, which is tight. However, these results rely on non-strategyproof mechanisms, such as maximum-welfare allocation or the round-robin algorithm, limiting their applicability in settings with strategic agents.

In this work, we extend the theory to a broad and more realistic class of joint value distributions, allowing for correlations between agents, atomicity, and unequal probabilities of having the highest value for an item. We show that envy-free allocations continue to exist with high probability when $m = \Omega(n \log(n))$. More importantly, we give a new randomized mechanism that is truthful in expectation, efficiently implementable in polynomial time, and outputs envy-free allocations with high probability. We further extend our mechanism to the settings of asymptotic weighted fair division, and multiple agent types and good types, proving new results in each of these cases.

5 - Improving Fairness of Spatiotemporal Travel Demand Modeling with Dynamic Weighting

Xiaojuan Zhang, University of Florida, Gainesville, FL, United States, Xilei Zhao

Fairness has been a critical concern in travel demand modeling, as inequitable predictions can lead to disproportionate service allocation and reinforce existing mobility disadvantages. Recent studies have proposed methods to improve the fairness of demand forecasts, particularly focusing on reducing spatial disparities such as unequal prediction accuracy across different neighborhoods. However, fairness over time has received far less attention, despite being equally important. Inaccurate and unfair predictions during certain times of day, especially peak commuting hours, can result in misallocated transportation resources and severe service mismatches, causing delays and reduced service quality for those who depend on timely and reliable mobility options. This study addresses this challenge by proposing a novel dynamic weighting methodology called Fair Focal Loss. Specifically, Fair Focal Loss can dynamically learn and adjust the weights of different losses based on each loss's performance throughout the course of training. This mechanism can guide the travel demand models to prioritize time periods and locations where fairness improvements are most needed. We apply the methodology to real-world ridesourcing-trip data in Chicago, framing predictions at different hours of the day as separate losses. Results show that the proposed method significantly improves the fairness of travel demand prediction at both spatial and temporal scales. Also, we find that the dynamic-weighting mechanism balances the learning process by driving the model to prioritize peak-hour predictions over off-peak hours. Overall, this study offers transportation professionals a powerful tool to enhance fairness in spatiotemporal travel demand modeling for better real-time traffic management and resource allocations.

6 - Optimizing Weight-Based and Nutritional Fairness Metrics in Charitable Food Distribution

Nowshin Sharmile, North Carolina A&T State University, Greensboro, NC, United States, Lauren Davis

Food insecurity—defined as limited or uncertain access to sufficient food for a healthy, active life—continues to be a major concern in the United States. In 2023, 13.5% of households, representing 47.4 million people, faced food insecurity. Food banks and nonprofit organizations play a vital role in supporting these communities by distributing donated food. Traditionally, their performance has been measured by the total pounds of food delivered. However, this approach often overlooks the nutritional quality of the food provided. This study focuses on the Food Bank of Central and Eastern North Carolina (FBCENC) and applies the Healthy Eating Research (HER) Nutrition Guidelines to assess distribution fairness from both a weight and nutritional perspective. We classified distributed food into tiers based on HER criteria and built a multi-branch, multi-agency network optimization model. The model incorporates two key objectives: maximizing fairness in agencies' serving capacities and minimizing shortfalls in the distribution of nutritious food. A lexicographic approach is used to explore how prioritizing one objective affects the other. Our findings highlight the trade-off: focusing solely on weight improves overall coverage but can worsen nutritional disparities, while prioritizing nutrition may limit the total amount

of food served. The lexicographic method offers a middle ground, enhancing nutritional equity while maintaining reasonable service levels. These results point to the importance of integrated, multi-objective strategies for food banks aiming to ensure both fair and health-conscious food distribution.

Operational Resilience in Aviation

Invited Session

Air Transportation Section

Chair: Alexander Estes, University of Maryland, College Park, MD, United States

1 - Stress-Testing Nas Resilience with Disruptive Scenario Generation

Sinan Abdulhak, University of Michigan, Ann Arbor, MI, United States

Bolstering stakeholders' (e.g., Traffic Managers) ability to respond to common and extraordinary disruptive scenarios is key to national airspace system (NAS) resiliency. Training is a vital tool to building the specialized skills needed to respond to disruptive (e.g., severe weather) events by exposing trainees to commonly encountered scenarios in a low-stakes environment. However, training on historical data neglects the novelty of future events. Furthermore, generating training scripts is highly time consuming, requiring hours of specialized expertise and the need to account for several courses of action, which compounds script writing requirements. We propose generating novel training scenarios that draw upon structural similarities of historical events, and display them intuitively in formats with operational meaning to facilitate immersive training exercises. To accomplish this, we use stochastic optimization models to rigorously generate parameters of synthetic, plausible disruptive scenarios. We then translate these quantitative parameters into a detailed training script using a retrieval-augmented generation (RAG) pipeline built on the GPT-4o large language model (LLM), displayed to stakeholders in a format that carries operational significance. To understand how training scenarios should be displayed, we conduct over 14 stakeholder interviews with Federal Aviation Administration (FAA) Traffic Managers, airport operators, and airline ATM teams. Preliminary results include an LLM-based web app that generates training scripts using key disruptive parameters from the optimization model for the major US 30 airports.

2 - Exploring Multimodal Air Transportation Network Design Through Intelligent Inference

Micah Borrero, University of Michigan, Ann Arbor, MI, United States, Max Li

In the context of short, regional routes, the use of relatively low-capacity vehicles is a practical and often necessary consideration. Preliminary studies suggest that integrating multiple modes of transportation offers distinct advantages, particularly in mitigating congestion associated with the hub-and-spoke structure of conventional air transportation networks. To determine the optimal deployment scenarios for such vehicles, it is essential to have accurate knowledge of origin-destination (OD) demand and true passenger flows. However, publicly available datasets commonly used to estimate air transportation demand are limited, often exhibiting inconsistencies between OD pairs and actual passenger flow data. These inconsistencies are particularly pronounced at the regional level, introducing stochasticity into demand estimates that undermines the interpretability of network construction models and reduces confidence in the resulting deployment strategies. To overcome these limitations, we propose a unified methodology that leverages techniques rooted in Reinforcement Learning to model the stochastic nature of estimated demand within the network design process. Specifically, we simultaneously infer a complete demand dataset while capturing its inherent stochasticity, allowing uncertainty to be directly incorporated into the decision-making process. This enables the development of deployment strategies that are resilient to variability in demand, supporting more reliable and adaptive planning of multimodal air transportation systems.

3 - Pathfinders in the Sky: Formal Decision-Making Models for Collaborative Air Traffic Control in Convective Weather

Jimin Choi, University of Michigan, Ann Arbor, MI, United States, Max Li

Convective weather remains one of the most disruptive factors in air traffic operations, often leading to significant delays and rerouting. A practical response employed by controllers is the use of pathfinder, which is a flight that tests whether weather-affected routes are once again viable. Despite their operational relevance, the underlying decision mechanisms for pathfinding have not been systematically studied. In this talk, we introduce formal decision models that support resilient airspace recovery through collaborative pathfinder operations. Using a Markov chain framework, we capture transitions between operational states such as flight selection and airspace status. Additional models represent flight-level decisions driven by utility trade-offs, as well as offer allocation strategies for pathfinder designation. We also perform an all-rejection scenario analysis to assess systemic vulnerabilities, highlighting how coordination and behavioral factors affect overall resilience. Analysis of data from the US Federal Aviation Administration provides real-world insights into the impact of pathfinder operations and helps guide future model adjustments.

4 - Identification and Case Studies of Operational Disruptions in the U.S. National Airspace System

Jing Xu, University of California, Berkeley, Oakland, CA, United States

Disruptions in the National Airspace System (NAS) lead to significant losses to air traffic system participants and raise public concerns. We apply two methods, cluster analysis and anomaly detection models, to identify operational disruptions with geographical patterns in the NAS since 2010. We identify four types and twelve categories of days of operations, distinguished according to air traffic system operational performance and geographical patterns of disruptions. Anomaly detection results show good agreement with cluster results and further distinguish days in the same cluster by severity of disruptions. Results show an increasing trend in frequency of disruptions, especially post-COVID. Additionally, disruptions happen most frequently in the summer and winter.

5 - Generation of Synthetic National Airspace System Weather Disruptions

Yuhan Miao, University of Maryland, College Park, MD, United States

We develop a data-driven method for developing synthetic weather disruptions. Such disruptions could be used for training of operations managers at airlines or air navigation service providers, or could be used as stress-tests to evaluate national airspace system resilience. Our method combines deep machine learning methods with a heuristic optimization approach.

Optimization Meets Generative AI: Applications and Insights from the Industry/Academia

Invited Session

The Practice Section of Informs

Chair: Konstantina Mellou, Microsoft Research, Redmond, WA, United States

Co-Chair: Burcin Bozkaya, NVIDIA Corporation, Sarasota

1 - Hybrid Metaheuristic Framework for Large-Scale Production Scheduling Using LLM-Generated Heuristics

Amit Kumar, Lyric.tech, Luxembourg, Luxembourg, Sarang Jagdale

Production Planning and Detailed Scheduling (PPDS) presents an NP-hard optimization challenge requiring simultaneous lot-sizing and sequence-dependent changeover optimization across multi-line systems. Traditional mixed-integer programming (MIP) approaches in industrial settings (e.g., >100 SKUs, 50+ periods) suffer from scalability limitations due to solution space fragmentation. We propose a hybrid framework integrating large language model (LLM)-generated heuristics with mathematical optimization to address computational intractability. Our methodology combines: 1) A constraint-guided greedy heuristic (developed via iterative LLM interactions with targeted problem context) achieving 96.2% demand fulfillment in 300 seconds, and 2) A sliding window neighborhood search reducing cumulative changeovers by 29.8% through symmetry-aware permutation analysis. The heuristic solution warmstarts MIP solvers, enabling optimal solutions within 15-20 minutes (vs. >4 hours without initialization) while maintaining a 1.4% average optimality gap. Key innovations include the LLM's synthesis of domain-specific neighborhood

structures that exploit temporal and product-based symmetries invisible to standard branching rules. Computational tests demonstrate resolution of 83% previously unsolvable industrial instances. The framework's effectiveness stems from decoupling lot-sizing feasibility (handled via heuristic search) from changeover optimization (intensified through local search), overcoming MIP's tight constraint coupling. This work establishes a paradigm shift for high-dimensional scheduling by combining generative AI's pattern recognition with operations research's exact methods, particularly where fragmented solution spaces hinder traditional approaches. Practical implications include scalable tools for multi-line capacity balancing and changeover cost minimization in process industries.

2 - Optiguide: Genai for Optimization and Decision Intelligence

Konstantina Mellou, Microsoft Research, Redmond, WA, United States

In this talk, we will describe how LLMs and optimization techniques are leveraged in Microsoft's cloud supply chain to improve efficiency, give insights to planners and answer what-if questions. More broadly, we will discuss ongoing research and future directions in the intersection of operations research and AI.

3 - Solving Supply Chain Planning Problems with Cuopt in Agentic Workflows

Burcin Bozkaya, NVIDIA Corporation, Sarasota, FL, United States

Supply Chain Planning and Management involves various players (eg. suppliers, factories, distribution centers, retail outlets) that require major coordination and complex set of inter-connected decisions. This leads to very large and complex optimization models, which are a major challenge for organizations operating at a global scale who need to build, maintain, solve, interpret and implement them. Add disruption management to this picture, and the complexity multiplies. LLMs and Generative AI has introduced in recent years ability to understand a given set of instructions or modeling constructs, which in turn helps in building, modifying and interpreting complex optimization models. Combined with an agentic AI workflow and tool-calling, Generative AI-assisted end-to-end optimization workflows can now be built and deployed. In this talk, we present NVIDIA's approach and framework to LLM-assisted supply chain planning and optimization in an agentic workflow. We employ cuOpt, NVIDIA's decision optimization library for solving a supply chain planning problem and build an agentic workflow around it. The workflow takes inputs from the user to build and solve an optimization model and generates natural language explanation of the optimization results. The user can then ask questions to explain parts of the resulting solution. The user can further conduct near-realtime what-if analysis by sending prompts to the agent that translates them into model updates and re-solves the problem. We implemented this framework for various business cases and achieved favorable feedback towards explainability of complex models, also providing near-real-time answers via the accelerated cuOpt engine in the context of disruption management.

4 - Learning-Guided Rolling Horizon Optimization for Long-Horizon Flexible Job Shop Scheduling

Cathy Wu, Massachusetts Institute of Technology, Cambridge, MA, United States

Long-horizon combinatorial optimization problems (COPs), such as the Flexible Job-Shop Scheduling Problem (FJSP), often involve complex, interdependent decisions over extended time frames, posing significant challenges for existing solvers. While Rolling Horizon Optimization (RHO) addresses this by decomposing problems into overlapping shorter-horizon subproblems, such overlap often involves redundant computations. In this paper, we present L-RHO, the first learning-guided RHO framework for COPs. L-RHO employs a neural network to intelligently fix variables that in hindsight did not need to be re-optimized, resulting in smaller and thus easier-to-solve subproblems. For FJSP, this means identifying operations with unchanged machine assignments between consecutive subproblems. Applied to FJSP, L-RHO accelerates RHO by up to 54% while significantly improving solution quality, outperforming other heuristic and learning-based baselines. We also provide in-depth discussions and verify the desirable adaptability and generalization of L-RHO across numerous FJSP variates, distributions, online scenarios and benchmark instances. Moreover, we provide a theoretical analysis to elucidate the conditions under which learning is beneficial.

5 - Causal LLM Routing: End-to-End Regret Minimization from Observational Data

Wei Sun, IBM Research, Yorktown Heights, NY, United States, ASTERIOS TSIOURVAS, Georgia Perakis

LLM routing aims to select the most appropriate model for each query, balancing competing performance metrics such as accuracy and cost across a pool of language models. Prior approaches typically adopt a decoupled strategy, where the metrics are first predicted and the model is then selected based on these estimates. This setup is prone to compounding errors and often relies on full-feedback data, where each query is evaluated by all candidate models, which is costly to obtain and maintain in practice. In contrast, we learn from observational data, which records only the outcome of the model actually deployed. We propose a causal end-to-end framework that learns routing policies by minimizing decision-making regret from observational data. To enable efficient optimization, we introduce two theoretically grounded surrogate objectives: a classification-based upper bound, and a softmax-weighted regret approximation shown to recover the optimal policy at convergence. We further extend our framework to handle heterogeneous cost preferences via an interval-conditioned architecture. Experiments on public benchmarks show that our method outperforms existing baselines, achieving state-of-the-art performance across different embedding models.

6 - Llm-Enhanced Flexible and Dynamic Analyses for Model-Based Decision Optimization

Mohsen Bahrami, Massachusetts Institute of Technology, Cambridge, MA, United States

This work introduces an innovative approach to enhance business intelligence (BI) platforms using Large Language Models (LLMs) for flexible and dynamic analyses in model-based decision optimization. Traditional BI platforms often face limitations due to rigid structures. This new system integrates an LLM agent with a user interface, fine-tuned on relevant models, code examples, and data documentation.

The LLM dynamically interprets user requests, selecting appropriate predictive models and optimization techniques. For example, when estimating a new store's market share, the LLM selects and justifies model choices and employs suitable optimization methods such as Ordinary Least Squares (OLS), Generalized Linear Models (GLM), or Particle Swarm Optimization (PSO). This system allows users to define complex analytical tasks through natural language, without needing to write code.

Most important features of this design include dynamic model selection, code generation, real-time adaptability to evolving optimization strategies, and optimized data handling with structured storage of results and logs. The LLM also assists in interpreting optimization outcomes in a user-friendly manner, offering advantages over traditional BI dashboards by providing increased flexibility, efficiency, and user accessibility in decision optimization. This LLM integration bridges the gap between advanced analytical models and practical applications, enabling more informed strategic planning and decision-making.

1 - Labor Capacity Planning in Last-Mile Operations

Chengliang Zhang, Amazon, Bellevue, WA, United States, Luying Sun

In the rapidly evolving landscape of last-mile delivery operations, labor capacity management is critical for operational excellence and customer satisfaction. With increased customer expectations and evolving business complexity across multiple business lines and regions, traditional workforce planning approaches are no longer sufficient. To adapt to these complex challenges, we present a mathematical programming model that simultaneously optimizes across multiple dimensions—including varied labor skills, flexible working schedules, and diverse delivery time windows. The model generates labor planning solutions that meet delivery commitments, satisfy business tenets, and optimize operational costs. The scalable framework effectively addresses the dynamic challenges of modern last-mile delivery operations while providing the flexibility needed for future growth and adaptation.

2 - Robotic Solution to Improve Transportation Utilization

Zhikun Gao, Amazon, Bellevue, WA, United States, Andrew Bruce, Jochen Koenemann

Containerization is introduced in the Amazon Fulfillment Network to provide an efficient cross-docking operation to ship customer orders between Amazon facilities. A drawback of currently leveraged container is that it leaves unused head-space in trailers. A stackable container is introduced to utilize more vertical space in trailers. A small scale pilot was launched in the US network, including fulfillment centers, sort centers, and delivery stations, to test the new container operational safety and assess key performance metrics. We conduct simulation to estimate the space utilization entitlement of the new container and design rigorous statistical experiments to measure operation benefits as well as risks. Also, we discuss preparations for extending the application of new container to a broader scope, such as regional or network-wide applications.

3 - Sequential Testing for Operations Experiments and Resource Ramp up

Brayan Ortiz, Amazon, Seattle, WA, United States

Supply chain operations frequently test new hardware, software and processes to improve productivity and quality, while avoiding downstream disruptions. In this talk, we provide an overview of sequential testing strategies for operational improvements, including classical methods for ramp-up and superiority detection. We explore how sequential testing approaches can be applied to various operational contexts, including buffered systems where traditional A/B testing may be less effective. Using real operations experiments, we compare traditional A/B testing with sequential methods, demonstrating significant program-level time savings across different operational scenarios. Our findings show that with sequential testing, we observed a 2-4 week reduction in testing time, and speeding up decision-making. This is particularly important to refine and continually improve innovations. We conclude with practical recommendations for implementing sequential testing methodologies in diverse operational environments, highlighting the potential for improved agility and responsiveness in process optimization efforts.

4 - Closing the Gap Between Scheduling and Execution of Under the Roof Processes

Nikolaos Lappas, amazon.com, Bellevue, WA, United States

We present a framework designed to enhance deterministic optimization models' ability to handle uncertainty through learned parameter offsets. Instead of relying on stochastic or robust optimization techniques, our framework offers a practical approach by systematically searching for optimal parameter adjustments using historical data. We present a scheduling case study, demonstrating how these offsets can effectively hedge against uncertainty while preserving the simplicity and interpretability of deterministic models. The framework's adaptability to improved parameter estimates and its support for both grid search and Bayesian experimental design make it a flexible tool for real-world applications. While our focus is on scheduling problems, the methodology is generalizable to other optimization domains where uncertainty plays a significant role. This work contributes to bridging the gap between theoretical optimization models and practical implementation in uncertain environments.

1 - A Dynamic Unmanned Aerial Vehicle Routing Framework for Urban Traffic Monitoring

Yumeng Bai, Purdue University, West Lafayette, IN, United States, Yiheng Feng

Unmanned Aerial Vehicles (UAVs) have great potential in urban traffic monitoring due to their rapid speed, cost-effectiveness, and extensive field-of-view, while being unconstrained by traffic congestion. However, their limited flight duration presents critical challenges in sustainable recharging strategies and efficient route planning for long-term monitoring. Additionally, existing approaches for long-term monitoring often neglect the dynamic and evolving nature of urban traffic networks. In this study, we introduce a novel dynamic UAV routing framework for long-term, network-wide traffic monitoring, leveraging existing ground vehicles (GVs), such as public transit buses, as mobile charging stations without disrupting their operations. To address the complexity of long-term monitoring involving multiple flights, we decompose the problem into manageable single-flight tasks, each modeled as a Team Arc Orienteering Problem with Decreasing Profits (TAOP-DP), aiming to collectively maximize the spatiotemporal network coverage. Between flights, edge weights are adaptively updated to incorporate real-time traffic changes and revisit intervals. We validate our framework through microscopic simulations on a modified Sioux Falls network under various scenarios, including static and changing demand levels and varying historical information availability. Comparative results demonstrate that our model outperforms three baselines, especially when historical information is incomplete or absent. Moreover, our monitoring framework captures network-wide traffic trends and constructs accurate Macroscopic Fundamental Diagrams (MFDs). These findings demonstrate the effectiveness of the proposed UAV routing framework, underscoring its suitability for efficient, reliable long-term traffic monitoring. The framework's adaptability and high accuracy in capturing the MFD highlight its potential for real-time network-wide traffic control management applications.

2 - Mothership-Based Drone Routing with TIME Windows via a Branch-and-Price-and-Cut Algorithm

Reza Mirjalili, University of Houston, Houston, TX, United States, Gino Lim, Jonathan Bard

Drones are transforming logistics, particularly in hybrid delivery systems where a truck acts as a mobile base—referred to as the *mothership*—from which drones are dispatched. This research addresses the Mothership-Based Drone Routing on a Network with Time Windows (MDRNTW) problem, in which the truck follows a fixed route (denoted as PPP), while drones perform deliveries within specified time windows. To address scalability issues inherent in arc-based formulations, we propose a path-based model using Dantzig-Wolfe reformulation and solve it via an exact Branch-and-Price-and-Cut (BPC) algorithm. The BPC framework decomposes the problem into a master problem (MP) and multiple subproblems (SPs). Although each SP can be solved efficiently using bidirectional label-setting, the number of SPs per iteration is large. Hence, we introduce an inferred bounding strategy based on previously solved SPs to skip those unlikely to yield columns with negative reduced cost, reducing column generation time by 32%. To strengthen the LP relaxation of the MP, we incorporate two valid inequalities and one novel cut, which resulted in an improved root node optimality gap.

3 - Optimizing Charging and Dispatch Decisions for Medical Drone Deliveries Under Uncertainty via Deep Reinforcement Learning Methods

Amin Asadi, University of Twente, Enschede, Netherlands, Abolfazl Maleki

Drones are increasingly employed in healthcare logistics to deliver medical supplies to remote, congested, or disaster-affected areas where traditional transportation systems are inadequate. However, efficiently managing the drone delivery system's operations remains challenging due to uncertain demand, limited fleet availability, and trade-offs associated with battery charging modes. Fast charging enhances short-term drone availability but accelerates battery degradation, reducing flight range and increasing replacement costs in the long term, while slow charging preserves battery life but limits immediate responsiveness.

We introduce SMART (Stochastic Multi-class Allocation and Recharging model for Transportation), a sequential decision-making framework that jointly optimizes drone dispatching and battery-recharging policies under resource- and operational-constraints. SMART explicitly considers heterogeneous flight-range requirements, stochastic spatiotemporal demand, and dynamic trade-offs between fast and slow charging. We formulate the system as a Markov Decision Process (MDP) that tracks battery charge levels, mission durations, and fleet availability over time. To derive real-time, adaptive policies, we employ multiple deep reinforcement learning agents based on DQN and DDQN. Computational experiments demonstrate that our algorithms for solving SMART significantly improve cost-efficiency, drone availability, and responsiveness to demand compared to traditional heuristic strategies. The resulting policies offer actionable insights into managing medical drone delivery systems through adaptive fast and slow charging strategies that ensure immediate responsiveness while minimizing long-term replacement costs and battery waste.

4 - From Auction to Delivery: Fast Resource Exchange and Collaborative Routing with Microswap

Ozge Aygul, Worcester Polytechnic Institute, Worcester, MA, United States, Yunus Doğan Telliel, Sarah Stanlick, Jen Pazour, Andrew Trapp

Nonprofit organizations (NPOs) provide essential resources and services in response to time-sensitive community needs. Yet, these NPOs often face challenges in quickly securing resources and coordinating with other organizations. To address these challenges, we introduce a novel framework to share and transport resources, designed for NPOs operating under a strict time horizon. Extending the SWAP platform for resource sharing (Huang et al., 2023), the MicroSWAP auction mechanism allows time-sensitive nonprofits to exchange resources by declaring their needs and available resources, while simultaneously providing optimized allocation and routing plans. In particular, upon reaching a certain market saturation, our framework identifies optimal resource exchanges and assigns and schedules pickup and delivery tasks through selective vehicle routing. Our approach leverages horizontal vehicle routing collaboration to optimize routes, improving service speed, efficient coordination among nonprofits, and collective impact. We demonstrate our model's scalability and effectiveness through real-world inspired case studies, highlighting its ability to mobilize collaboration in the nonprofit sector for time-sensitive community needs.

5 - Anticipating Infeasibility: Decision Diagram-Guided Reinforcement Learning for Tsp with Time Windows

Macarena Navarro, Carnegie Mellon University, Pittsburgh, PA, United States, Karan Singh, Willem-Jan van Hoeve, Segev Wasserkrug

Recent advances in neural combinatorial optimization have shown that deep reinforcement learning can solve combinatorial optimization problems by training policies to generate near-optimal solutions. However, existing approaches struggle with constraints that require global reasoning on the entire decision space, such as time window constraints augmenting the traveling salesperson problem. Most existing approaches only handle simpler constraints, such as permutation structures, where one can ensure feasibility incrementally while generating the solution.

We address this limitation by integrating relaxed decision diagrams into the reinforcement learning framework. Our approach equips the learner with structured lookahead capabilities that enable it to anticipate and avoid decisions leading to downstream infeasibility during solution generation. We embed these decision diagrams directly into attention-based neural architectures and evaluate their effectiveness on the traveling salesperson with time windows problem.

1 - Optimal-PhiBE: a Pde-Based Model-Free Framework for Continuous-TIME Reinforcement Learning

Yuhua Zhu, University of California, Los Angeles, Los Angeles, CA, United States

This talk addresses continuous-time reinforcement learning (RL) in settings where the system dynamics are governed by a stochastic differential equation but remains unknown, with only discrete-time observations available. While the optimal Bellman equation enables model-free algorithms, its discretization error is significant when the reward function oscillates. Conversely, model-based PDE approaches offer better accuracy but suffer from non-identifiable inverse problems. To bridge this gap, we introduce Optimal-PhiBE, an equation that integrates discrete-time information into a PDE, combining the strengths of both RL and PDE formulations. Compared to the RL formulation, Optimal-PhiBE is less sensitive to reward oscillations, leading to smaller discretization errors. In linear-quadratic control, Optimal-PhiBE can even achieve accurate continuous-time optimal policy with only discrete-time information. Compared to the PDE formulation, it skips the identification of the dynamics and enables model-free algorithm derivation. Furthermore, we extend Optimal-PhiBE to higher orders, providing increasingly accurate approximations.

2 - Two Tales, One Resolution: Physics-Informed Test TIME Scaling and Precondition

Yiping Lu, Northwestern University, Evanston, IL, United States

In this talk, I will introduce a novel framework for physics-informed debiasing of machine learning estimators, which we call Simulation-Calibrated Scientific Machine Learning (SCaSML). This approach leverages the structure of physical models to achieve two key objectives:

Unbiased Predictions: It produces unbiased predictions even when the underlying machine learning predictor is biased.

Overcoming Dimensionality Challenges: It mitigates the curse of dimensionality that often affects high-dimensional estimators.

The SCaSML paradigm integrates a (potentially) biased machine learning algorithm with a de-biasing procedure that is rigorously designed using numerical analysis and stochastic simulation. Our methodology aligns with recent advances in inference-time computation—similar to those seen in the large language model literature—demonstrating that additional computation can enhance ML estimates.

Furthermore, we establish a surprising equivalence between our framework and another research direction that utilizes approximate (linearized) solvers to precondition iterative methods. This connection not only bridges two distinct areas of study but also offers new insights into improving estimation accuracy in complex, high-dimensional (PDE) settings.

3 - On the BSde-Based Methods for Solving Stochastic Optimal Control Problems

Baris Ata, University of Chicago, Booth School of Business, Chicago, IL, United States

I will give an overview of the BSDE-based methods for solving stochastic optimal control problems arising in operations management and provide a few applications from my recent work: Dynamic vehicle routing, dynamic bipartite matching, call-center scheduling, and stochastic joint replenishment problem. I will conclude with a discussion of effectiveness of the method.

4 - No-Regret Generative Modeling via Parabolic Monge-Ampère Pde

Nabarun Deb, University of Chicago, CHICAGO, IL, United States

We introduce a novel generative modeling framework based on a discretized parabolic Monge-Ampère PDE, which emerges as a continuous limit of the Sinkhorn algorithm commonly used in optimal transport. Our method performs iterative refinement in the space of Brenier maps using a mirror gradient descent step. We establish theoretical guarantees for generative modeling through the lens of no-regret analysis, demonstrating that the iterates converge to the optimal Brenier map under a variety of step-size schedules. As a technical contribution, we derive a new Evolution Variational Inequality tailored to the parabolic Monge-Ampère PDE, connecting geometry, transportation cost, and regret. Our framework accommodates non-log-concave target distributions, constructs an optimal sampling process via the Brenier map, and integrates favorable learning techniques from generative adversarial networks and score-based diffusion models. As direct applications, we illustrate how our theory paves new pathways for generative modeling and variational inference.

5 - Uniform-in-N Log-Sobolev Inequality for the Mean-Field Langevin Dynamics with Convex Energy

Matthew Zhang, UofT, Toronto, ON, Canada

We establish a log-Sobolev inequality for the stationary distribution of mean-field Langevin dynamics with a constant that is independent of the number of particles N . Our proof proceeds by establishing the existence of a Lipschitz transport map from the standard Gaussian measure via the reverse heat flow of Kim and Milman.

1 - Helping the Captive Audience: Advance Notice of Diagnostic Service for Hospital Inpatients

Miao Bai, University of Connecticut, Storrs, CT, United States, Nan Liu, Zheng Zhang

Inpatients are often treated as the “captive audience” for hospital diagnostic services, and they are notified only when service capacity is available. This arrangement causes significant chaos and inefficiencies in hospital operations. We propose an innovative scheduling approach called “advance notice” to manage hospital diagnostic practices. Advance notice is a brand-new scheduling paradigm in between classic allocation scheduling and advance scheduling. Patients are placed in a common queue waiting to be called for service, and they will be provided both a fixed preparation time and a guaranteed service time window in advance. The advance notice policy enjoys the benefit of allocation scheduling (giving the provider flexibility in using her capacity) and that of advance scheduling (reducing uncertainties in patient waiting for service). It calls for two decisions: who to serve now and who to send advance notices to. We formulate a Markov decision process model to optimize these decisions dynamically. Via a novel variable transformation, we reveal the hidden anti-multimodular structure of the problem and show how the optimal decisions should be adjusted in response to changes in the system load. Beyond solving the model for daily operations, we further investigate how the service and preparation time windows can be used as strategic levers to manage system performance. Our numerical study, populated by real data from a large academic medical center in the United States, demonstrates significant improvement in operational efficiency by switching from current practice to our proposed advance notice policy.

2 - Reducing Overdose Deaths and Mitigating County Disparities: Optimal Allocation of Substance use Treatment Centers

Matt Baucum, Oklahoma State University, Stillwater, OK, United States, Matt Harris, Larry Kessler, Guanyi Lu

Substance use disorder (SUD) is a pressing health concern in the U.S., and connecting communities with treatment is a growing public health imperative. We study the optimal allocation of substance use treatment centers across counties within U.S. states over a multi-year time horizon. We use a three-part objective function which minimizes (1) statewide overdose deaths, (2) mismatch between counties' treatment center access and overdose death rates ('inequity'), and (3) mismatch between counties' treatment center access and population ('inequality'). We also consider the temporal interdependence of counties' treatment center allocations and their death-rate-based 'equity' targets. We use a predict-then-optimize approach based on data from over 2,500 U.S. counties between 1999 and 2016. We first estimate SUD treatment centers' causal impact on county-level overdose death rates, using mental health parity laws as an instrument. We then use these estimates in a nonlinear program that reallocates states' observed levels of SUD treatment funding. Results suggest that this approach can meaningfully reduce statewide overdose deaths and between-county disparities in treatment access. Prioritizing death rate reductions over equity/equality results in more resources being directed to high-population counties, where treatment centers are most effective. Prioritizing equity/equality in treatment access results in more resources being directed to under-served low-population counties. We also find that states differ in their Pareto-optimal tradeoffs between death rates and inequity/inequality.

3 - Improving Access to Essential Medicines in Sierra Leone via Decision-Aware Machine Learning

Tsai-Hsuan (Angel) Chung, The Wharton School, UPenn, Philadelphia, PA, United States, Jatu Abdulai, Patrick Bayoh, Lawrence Sandi, Francis Smart, Hamsa Bastani, Osbert Bastani

A critical challenge in healthcare systems in Low- and Middle-Income Countries (LMICs) is the efficient and equitable allocation of scarce resources, particularly essential medicines. This problem is complicated by limited high-quality data, which restricts the applicability of traditional data-driven techniques. We propose a novel machine learning framework for essential medicines allocation, which leverages a combination of multi-task learning and decision-aware learning to improve sample efficiency and ensure equitable allocation. In collaboration with the Sierra Leone national government, our framework has been deployed nationwide as a decision support tool to help reduce waste and improve essential medicines allocation. Our evaluation using synthetic difference-in-differences analysis demonstrates a 19% increase in medicine consumption, with no changes to the supply, improving access for approximately 3.7 million women and children under five. Through experimental validation, we demonstrate that our approach also significantly outperforms baseline approaches. Our work demonstrates the tangible impact of machine learning in optimizing high-stakes decisions in resource-constrained settings, improving efficiency while ensuring equity and cost-effectiveness.

4 - Optimizing Initial Screening for Colorectal Cancer Detection with Adherence Behavior

Sarah Yini Gao, Singapore Management University, Singapore, Singapore, Yan He, Rujie Zhang, Zhichao Zheng, Sean Lam Shao Wei, Emile Tan

Two-stage colorectal cancer (CRC) screening programs typically begin with a fecal hemoglobin (f-Hb) test, where positive results lead to a follow-up colonoscopy. However, not all individuals adhere to the recommended second-stage test. We study how the design of the first-stage test—specifically, the choice of f-Hb cutoff values—affects both detection effectiveness (CRC and polyp identification) and efficiency (colonoscopy demand and cost). We develop an information design model that combines Bayesian persuasion with information avoidance behavior to analyze individual decision-making. The model is calibrated using diverse data sources, including a nationwide survey of 3,920 respondents in Singapore. We find that using a single cutoff can improve follow-up adherence, while revealing exact f-Hb values enhances detection. Raising the cutoff from the current standard to 39 µg/g could detect 21% more CRC and polyp cases, reduce unnecessary colonoscopies by 27%, and lower lifetime CRC risk by 11%. This policy change could also result in estimated cost savings of \$20 million in public healthcare spending and \$12 million in individual screening costs. Optimizing the cutoff for first-stage screening tests is key to balancing public health outcomes and resource use. The prevalent practice of using low thresholds to maximize sensitivity may be counterproductive, increasing false positives and straining follow-up adherence. Our findings provide evidence-based guidance for more effective CRC screening policy design.

1 - Optimization Under Rare Event Constraints

Bert Zwart, CWI Amsterdam and TU Eindhoven, Amsterdam, Netherlands

We consider a class of chance-constrained programs in which profit needs to be maximized while enforcing that a given adverse event remains rare. Using techniques from large deviations and extreme-value theory, we show how the optimal value scales as the prescribed bound on the violation probability becomes small and how convex programs emerge in the limit. We also use our results to show that the popular CVaR approximation is asymptotically optimal under light-tail assumptions, but it is sub-optimal in a heavy-tailed setting. Then, we apply point process techniques and random set theory to study the suboptimality gap in the Monte Carlo based scenario approach.

2 - Failure-Aware Dynamic Reserve and Checkpoint Scheduling for Sustainable Gpu Clusters

Weici Pan, Stony Brook University, Stony Brook, NY, United States, Tina Xing, Zhenhua Liu

Increasing demands of large-scale AI training and other workloads on GPU clusters pose both environmental and economic challenges due to stochastic GPU failures, volatile electricity prices, and fluctuating carbon intensities. We present a probabilistic framework that co-optimizes operational cost and CO2 emissions under realistic GPU failure behavior and time-varying resource characteristics. Our model captures dynamic reserve allocation (spare GPUs) and checkpoint scheduling as jointly controlled decision variables, integrating real-world electricity price and carbon intensity traces alongside cluster energy-efficiency parameters in each time slot.

We formulate a weighted objective that combines expected monetary expense and emissions, governed by a tunable trade-off parameter. In the joint decision problem as a stochastic optimization over a finite horizon, at each epoch, the system chooses a reserve level to hedge against failures and a checkpoint interval to bound rollback losses. GPU failures are represented by heavy-tailed distributions calibrated on production cluster logs. Reserve decisions trade off idle-holding and provisioning costs against failure-count probabilities. While checkpoint intervals are selected to minimize the sum of I/O overhead and expected rollback penalty based on the estimated mean time between failures

In simulation studies driven by real price, carbon, and failure traces, our dynamic policy consistently outperforms static reserve and checkpoint baselines on the combined cost-emissions metric across a range of failure regimes and cluster scales. These results demonstrate a practical pathway to embedding failure awareness and environmental objectives directly within GPU cluster fault-tolerance protocols.

3 - Learning Decision-Focused Uncertainty Representations for Robust and Risk-Constrained Optimization

Christopher Yeh, California Institute of Technology (Caltech), Pasadena, CA, United States, Nicolas Christianson, Adam Wierman, Yisong Yue

While deep learning models often achieve high predictive accuracy, their predictions typically do not come with any provable guarantees on risk or reliability, which are critical for deployment in high-stakes applications, such as medical diagnoses or controlling the power grid. Recent tools from conformal inference offer distribution-free, finite-sample guarantees for uncertainty calibration, but such tools generally have not been applied to controlling tail risks, and they are generally agnostic to downstream decisions, thus leaving significant room for performance improvement. In this work, we develop an end-to-end framework for learning decision-focused uncertainty representations that provide rigorous guarantees while optimizing downstream decision performance. We instantiate our framework in two contexts: robust optimization, and CVaR-constrained optimization. For robust optimization, our approach combines conformal prediction with partially input-convex neural networks to approximate arbitrary convex uncertainty sets. For CVaR-constrained optimization, we extend the framework of conformal risk control (CRC) to handle a broad class of Optimized Certainty Equivalent (OCE) risks, including conditional value-at-risk (CVaR). To overcome the limitations of post-hoc calibration, we introduce Conformal Risk Training, which differentiates through the conformal procedure to jointly learn model parameters and the uncertainty representation. Across applications in energy storage arbitrage, portfolio optimization, and medical image classification, our framework consistently outperforms standard two-stage or post-hoc approaches—achieving both provable robustness and improved average-case performance.

4 - Stochastic Optimization and Scenario Generation for Electric Grid Resilience

John Hasenbein, University of Texas at Austin, Austin, TX, United States, Ashutosh Shukla, Shunan Zheng

In this work we develop models to help decision makers increase resilience in electric grids when facing extreme weather events such as floods and heat waves. Our case studies involve the electric grid in Texas, which frequently suffers from hurricane and other flood events. A major challenge is to develop a sufficiently representative collection of scenarios in order to populate large, long-term, stochastic optimization models. We discuss classical methods such as NORTA, and more modern ML-style approaches to this problem.

Responsible Machine Learning via Mixed-Integer Optimization

TutORial session

TutORials

Chair: Nilay Noyan, AMAZON, Bellevue, WA, United States

1 - Responsible Machine Learning via Mixed-Integer Optimization

Nathan Justin, University of Southern California, Los Angeles, CA, United States, Qingshi Sun, Andres Gomez, Phebe Vayanos

In the last few decades, machine learning (ML) has achieved significant success across domains ranging from healthcare, sustainability, and the social sciences to criminal justice and finance. But its deployment in increasingly sophisticated, critical, and sensitive areas affecting individuals, the groups they belong to, and society as a whole raises critical concerns around fairness, transparency, and robustness, among others. As the complexity and scale of ML systems and of the settings in which they are deployed grow, so does the need for responsible ML methods that address these challenges while providing guaranteed performance in deployment. Mixed-integer optimization (MIO) offers a powerful framework for embedding responsible ML considerations directly into the learning process while maintaining performance. For

example, it enables learning of inherently transparent models that can conveniently incorporate fairness or other domain-specific constraints. This tutorial paper provides an accessible and comprehensive introduction to this topic discussing both theoretical and practical aspects. It outlines some of the core principles of responsible ML, their importance in applications, and the practical utility of MIO for building ML models that align with these principles. Through examples and mathematical formulations, it illustrates practical strategies and available tools for efficiently solving MIO problems for responsible ML. It concludes with a discussion on current limitations and open research questions, providing suggestions for future work.

Optimization Under Uncertainty in Service Systems

Invited Session

Computing Society

Chair: Aliaa Alnaggar, Toronto Metropolitan University, Toronto, ON, Canada

Co-Chair: Mucahit Cevik, Toronto Metropolitan University, Toronto, ON, Canada

1 - Sample-Path Clustering for Context-Sensitive Markov Decision Processes

Allison Grimsted, University of Michigan, Ann Arbor, MI, United States, Agni Orfanoudaki, Brian Denton

We address the problem of estimating transition probability matrices for heterogeneous longitudinal data representing sample-paths for stochastic systems. We formulate the clustering as a set partitioning problem and use column generation with a mixed integer nonlinear pricing problem to assign sample-paths to a parsimonious set of clusters, each associated with its own transition probability matrix to capture contextual variation in the system state transition probabilities. We benchmark our approach against a baseline maximum likelihood estimation method that pools all sample-paths to estimate a single "one-size-fits-all" transition matrix, using a highway bridge maintenance case study.

2 - Convexification Methods for Solving Two-Stage Distributionally Robust Optimization with Applications to Crowdsourced Delivery

Aliaa Alnaggar, Toronto Metropolitan University, Toronto, ON, Canada, Merve Bodur

We consider a service region planning problem faced by a crowdsourced delivery platform where drivers are commuters who are willing to deviate from their original routes to a make a delivery in exchange for a compensation. The availability of drivers and service demand are uncertain, and it is difficult to estimate their probability distributions due to the absence of service history. To mitigate the effects of data ambiguity, we propose a two-stage distributionally robust optimization (DRO) model. The first stage selects which nodes to offer service in, while the second stage matches drivers and orders after uncertainty is realized. We derive an exact reformulation of the DRO model and develop a monolithic approximation based on a convex relaxation of the subproblem. We further strengthen the proposed approximation by a set of valid inequalities inspired by the linearization reformulation technique. The benefit of the proposed approach for service region design in crowdsourced delivery is demonstrated through numerical experiments.

3 - Integrated Dynamic Pricing and Dispatching for Crowd-Shipping via Neural Approximate Dynamic Programming

Mucahit Cevik, Toronto Metropolitan University, Toronto, ON, Canada, Arash Dehghan, Merve Bodur

Crowd-shipping, which utilizes non-professional couriers for deliveries, presents a scalable and sustainable alternative to traditional logistics models. This work introduces a Neural Approximate Dynamic Programming (NeurADP) framework, which combines ADP and deep reinforcement learning (DRL), to optimize crowd-shipping operations. More specifically, we integrate dynamic pricing and dispatching to enhance efficiency and profitability. Extending prior work, our model incorporates features such as batching and courier queues, addressing the complexities of large-scale operations. Our experiments comparing NeurADP policy with myopic and DRL baselines demonstrate significant improvements in operational efficiency, cost reduction, and sustainability. Sensitivity analyses highlight the impact of pricing strategies, courier availability, and delivery constraints, offering actionable insights for real-world applications.

4 - Optimal Catheter Replacement Planning for Newborn Care

F. Safa Erenay, University of Waterloo, Waterloo, ON, Canada, Atahan Bayir, Cansu Dagsuyu, Sibel Alumur

Catheters facilitate fluid delivery and waste removal for vulnerable newborns. However, their need for frequent replacement increase the risk of infections depending on catheter type, and replacement time and sequence. The infection risk can be minimized by optimizing catheter replacement decisions. For this purpose, we develop a Markov Decision Process (MDP) model incorporating generally distributed stochastic hospital stay and catheter life time using non-homogeneous Bernoulli trials. The model dynamically tracks catheterization history in the state space, and performance metrics such as infection rate, cost, catheter lifetime wastage to balance infection control and operational efficiency. The proposed approach can reduce the infection risks by up to five-fold, and costs and material waste by two- to three-fold.

5 - Stochastic Revelation in Sequential Decision-Making with a Pharmaceutical Application

morteza davari, SKEMA Business School, Lille, France, Merve Bodur, Bernardo Pagnoncelli

In many real-life situations, such as medical product launches, energy investments, or the rollout of new policies, decision-makers must act before knowing exactly when critical information will become available. We develop new mathematical models that incorporate uncertainty about what will happen and when that uncertainty will resolve. Traditional decision-making tools assume fixed timelines for information revelation; instead, we address more realistic scenarios where information arrives at unpredictable moments, making planning more complex and costly if mishandled.

In this talk, we focus on a pharmaceutical application, in particular, the planning and production of medical devices, where firms must be mindful of regulatory approvals. We develop a framework enhanced by problem-specific decomposition methods to address this multistage stochastic problem.

Recent Advances in Deep Learning and Quantum Computing for AC Optimal Power Flow

Invited Session

ENRE: Energy

Chair: Yu Zhang, UC Santa Cruz, Santa Cruz, CA, 95064, United States

1 - Quantum Computing for Solving the AC-OPF

Vassilis Kekatos, Purdue University, West Lafayette, IN, United States

This work puts forth a hybrid quantum-classical approach to cope with large-scale instances of the AC optimal power flow (OPF) problem. We advocate encoding primal and dual variables as states of variational quantum circuits (VQC) and pursuing saddle points of the associated Lagrangian function via primal-dual algorithms. VQCs are parameterized quantum circuits, which can be trained using classical optimization methods and are well-suited for near-term quantum computers. Leveraging the power system structure, we also put forth novel protocols for efficiently measuring the quantum observables associated with power system optimization. Preliminary numerical tests on quantum simulators study the complexity-performance trade-off of the suggested methods.

2 - Unsupervised Learning for Solving AC Optimal Power Flows: Design, Analysis, and Experiment

Minghua Chen, The Chinese University of Hong Kong (Shenzhen), Shenzhen, China, People's Republic of, Wangjun Huang, Steven Low

With the increasing penetration of renewables, AC optimal power flow (AC-OPF) problems need to be solved more frequently for reliable and economic power system operation. Supervised learning approaches have been developed to solve AC-OPF problems fast and accurately. However, due to the non-convexity of AC-OPF problems, it is non-trivial and computationally expensive to prepare a large training dataset, and multiple load-solution mappings may exist to impair learning even if the dataset is available. In this work, we develop an unsupervised learning approach (DeepOPF-NGT) that does not require ground truths. DeepOPF-NGT utilizes a properly designed loss function to guide neural networks in directly learning a legitimate load-solution mapping. Kron reduction is used to remove the zero-injection buses from the prediction. To tackle the unbalanced gradient pathologies known to deteriorate the learning performance, we develop an adaptive learning rate algorithm to dynamically balance the gradient contributions from different loss terms during training. Further, we derive conditions for unsupervised learning to learn a legitimate load-solution mapping and avoid the multiple mapping issue in supervised learning. Results of the 39/118/300/1354-bus systems show that DeepOPFNGT achieves optimality, feasibility, and speedup performance comparable to the state-of-the-art supervised approaches, and a few ground truths can further improve its performance. This is a joint work with Wanjun Huang and Steven Low.

3 - Accelerated Learning Framework for AC Optimal Power Flow

Yu Zhang, UC Santa Cruz, Santa Cruz, CA, United States

We propose a physics-informed, semi-supervised learning framework for real-time AC optimal power flow (AC-OPF). To reduce dependence on slow solvers, we use ridge regression to generate pseudo-labels and augment training data efficiently. We introduce novel gradient estimation techniques—including batch-mean, linearized, and decoupled Jacobians—and a reduced branch set method to accelerate training while ensuring constraint satisfaction. Tested on large-scale systems, our approach achieves near-optimal, feasible solutions with over 30× speedup in inference and 10× faster training, making it practical for real-time grid operations.

4 - Neural Approximation for Distribution Optimization

Mohamad Chehade, University of Texas at Austin, Austin, TX, United States

The rise of distributed energy resources (DERs) is reshaping modern distribution grids, introducing new challenges in attaining voltage stability under dynamic and decentralized operating conditions. This paper presents NEO-Grid, a unified learning-based framework for volt-var optimization (VVO) and volt-var control (VVC) that leverages neural network surrogates for power flow and deep equilibrium models (DEQs) for closed-loop control. Our method replaces traditional linear approximations with piecewise-linear ReLU networks trained to capture the nonlinear relationship between power injections and voltage magnitudes. For control, we model the recursive interaction between voltage and inverter response using DEQs, allowing direct fixed-point computation and efficient training via implicit differentiation. We evaluated NEO-Grid on the IEEE 33-bus system, demonstrating that it significantly improves voltage regulation performance compared to standard linear and heuristic baselines in both optimization and control settings. Our results establish NEO-Grid as a scalable, accurate, and interpretable solution for learning-based voltage regulation in distribution grids.

Game Theory Applications in Power Systems

Invited Session

ENRE: Electricity

Chair: Wei Wang, Pacific Northwest National Laboratory, Richland, WA, United States

Co-Chair: Liping Li, Pacific Northwest National Laboratory, Columbus, OH, United States

1 - Gaming on Coincident Peak Shaving: Equilibrium and Strategic Behavior

Bolun Xu, Columbia University, New York, NY, United States, Liudong Chen, Jay Sethuraman

Power system operators and electric utility companies often impose a coincident peak demand charge on consumers when the aggregate system demand reaches its maximum. This charge incentivizes consumers to strategically shift their peak usage away from the system's collective peak, which helps reduce stress on electricity infrastructure. In this talk, we develop a game-theoretic model to analyze how such strategic behavior affects overall system efficiency. We show that depending on the extent of consumers' demand-shifting capabilities, the resulting coincident peak shaving game can exhibit concavity, quasi-concavity with discontinuities, or non-concavity with discontinuities. In a two-agent, two-period setting, we derive closed-form Nash equilibrium solutions for each scenario and generalize our findings to multi-agent contexts. We prove the stability of the equilibrium points and propose an algorithm for computing equilibrium outcomes under all game configurations. Our results indicate that while the decentralized game achieves peak-shaving outcomes comparable to those of a centralized model, it does so at the cost of higher anarchy. Under quasi-concave and non-concave conditions, this inefficiency grows with increased consumer flexibility and larger disparities in marginal shifting costs; we also examine how the number of agents influences system performance. Finally, numerical simulations validate our theoretical insights.

2 - A Stackelberg Game Model for Incentive Design to Align Distributed Energy Resource Investments with System Objective

Liping Li, Pacific Northwest National Laboratory, Richland, WA, United States, Wei Wang, Sarah Newman, Thiagarajan Ramachandran

Distributed Energy Resources (DERs) play a crucial role in enhancing the reliability and resilience of power systems at the community level. Their decentralized nature necessitates innovative strategies to promote coordinated and efficient investment. This presentation introduces a Stackelberg game theory model to create incentives that stimulate DER investments, thereby achieving system-wide objectives. In this model, a system operator acts as the leader, offering incentives to foster DER investments, such as photovoltaic panels and energy storage devices, within communities and microgrids. The community and microgrid operators, functioning as followers, aim to maximize their own benefits. By employing strategic incentive design, the leader influences the followers' investment and operational decisions, optimizing the overall welfare of the system. The presentation will include a demonstration and analysis of results from a case study involving three communities, focusing on minimizing the total unsatisfied demand across all communities.

3 - Design of Multi-Day Capacity Option Products to Improve Unit Compliance in Real-Time

qiwei zhang, University of Texas San Antonio, San Antonio, TX, United States

Generators need to secure fuel (e.g., natural gas contracts) in advance to ensure they can operate in real-time. This results in fuel advancement costs that are incurred before any revenue is realized from short-term market participation. However, current market settlements do not explicitly compensate these upfront costs. Consequently, suppliers face a disincentive to secure resources in advance, which may lead to insufficient availability during system needs. To address this gap, we propose a new payment mechanism that compensates generators for fuel advancement. Under this scheme, generators receive an upfront payment—a premium—for ensuring adequate resource is available ahead of operations. This payment reflects the value of fuel availability and covers expenses such as early fuel procurement, thereby enhancing system reliability.

4 - Toward Efficient Integration of Grid-Edge Flexibility in Voltage Regulation

Zhirui Liang, Johns Hopkins University, Baltimore, MD, United States, Rajni Bansal, Joshua Comden, Andrey Bernstein, Yury Dvorkin

This presentation addresses the challenges of integrating grid-edge Distributed Energy Resources (DERs) for voltage regulation in modern distribution systems. With increasing DER penetration, Distribution System Operators (DSOs) face issues such as uncertainty and limited visibility. DER Aggregators (DERAs) can mitigate these challenges by coordinating DERs for market participation and ancillary services, including voltage regulation. However, the role of DERAs in voltage regulation remains underexplored. We compare two approaches for procuring flexibility from DERAs: a market-based method, where the DSO and DERAs make decisions simultaneously through price signals, and an incentive-based method, where the DSO leads by offering incentives. Using game theory, we analyze the efficiency of each approach, examining equilibrium outcomes, social welfare, and the impact of deviations from ideal conditions. The study provides a detailed theoretical and numerical comparison, offering insights into which procurement method better supports voltage regulation. Our findings contribute to the design of more effective grid-edge management strategies, enhancing DSO-DERA coordination for voltage regulation.

5 - Learning in Stackelberg Games and Applications in Electricity Rate Design

Andrew Liu, Purdue University, West Lafayette, IN, United States, Jun He, Yihsu Chen

Designing socially optimal policies in multi-agent environments is a fundamental challenge in both economics and artificial intelligence. This paper studies a general framework for learning Stackelberg equilibria in dynamic and uncertain environments, where a single leader interacts with a population of adaptive followers. Motivated by pressing real-world challenges such as equitable electricity tariff design for consumers with distributed energy resources (such as rooftop solar and energy storage), we formalize a class of Stackelberg Markov games and establish the existence and uniqueness of stationary Stackelberg equilibria under mild continuity and monotonicity conditions. We then extend the framework to incorporate a continuum of agents via mean-field approximation, yielding a tractable Stackelberg–Mean Field Equilibrium (S-MFE) formulation. To address the computational intractability of exact best-response dynamics, we introduce a softmax-based approximation and rigorously bound its error relative to the true Stackelberg equilibrium. Our approach enables scalable and stable learning through policy iteration without requiring full knowledge of follower objectives. We validate the framework on an energy market simulation, where a public utility or a State energy commission sets time-varying rates for a heterogeneous population of prosumers. Our results demonstrate that learned policies can simultaneously achieve economic efficiency, equity across income groups, and stability in energy systems. This work demonstrates how game-theoretic learning frameworks can support data-driven policy design in large-scale strategic environments, with applications to real-world systems like energy markets.

Managing Online Retailers and Services

Invited Session

eBusiness

Chair: Hongmin Li, Arizona State University, Tempe, AZ, United States

Co-Chair: Yuqi Yang, Arizona State University, Tempe, AZ, United States

1 - Goodrx Effect in the Pharmaceutical Value Chain

Yishen Cai, University of Miami Herbert Business School, Miami, FL, United States, Xin Geng, Hongmin Li, Nan Yang

In recent years, coupon vending has become a popular method for patients to bypass high usual and customary (UC) off-counter prescription drug prices. GoodRX is most successful for this practice---they provide steeply discounted drug prices (often exceeding 60% off), for almost no charge to anyone with or without insurance, on a digital coupon redeemable at most popular pharmacies. We uncover the enabling value chain mechanism and examine the GDRX effect focusing on profit reallocation in the pharmaceutical retail market.

2 - Asymptotic Optimality and Performance Bounds of Partially Personalized Fixed Pricing Policies

ZHUYU LIU, the University of British Columbia, Vancouver, BC, Canada, Meichun Lin, Woonghee Huh

We study a dynamic pricing problem involving a single product, finite inventory, and multiple customer types with stochastic demand over a finite horizon. The retailer observes the customer's type before offering a price and must determine whether to employ fully dynamic personalized pricing or simpler fixed pricing strategies that group customers into a limited number of segments. Motivated by operational and fairness constraints, we analyze the theoretical performance of fixed pricing policies under varying degrees of personalization relative to the fully personalized dynamic pricing benchmark.

We first derive an asymptotically tight lower bound for the fully personalized fixed-price (FP) policy by leveraging a deterministic relaxation of the stochastic problem. We show that in the high-volume regime where both inventory and planning horizon scale proportionally, this policy is asymptotically optimal, and we provide a convergence rate. We also study a class of K-personalized FP policies, where customer types are partitioned into K groups, each offered a fixed price. We establish lower bounds for such policies. Our results provide a theoretical framework for evaluating the revenue implications of personalization granularity under fixed pricing

3 - Return Rate Estimation Under Complete and Incomplete Data

Eleanor Wang, Cornell University, Scottsdale, AZ, United States, Yuqi Yang, Hongmin Li, Miao Zheng

Fast fashion retailers like Zara and Shein have generous, cost-free return policies which stimulate demand but also incur high reverse-logistics costs, highlighting the need to analyze product returns, which can then be utilized to make sales decisions.

Our paper develops a model for product returns – specifically, we address the challenge of estimating SKU-level return rates when only aggregate return counts are available. Motivated by an Amazon apparel seller, we develop return rate estimation methods under two cases. In the complete-data case, when SKU-level returns are observed, we derive a maximum-likelihood estimator to obtain unbiased return-rate estimates, and prove its asymptotic efficiency. In the case of incomplete data, when only total returns are available, we solve the issue of identifiability of the maximum likelihood under classical distributional approximation. Finally, we embed our return-rate estimates into a price-optimization model to demonstrate practical gains and to inform optimal pricing decisions for retailers.

4 - Learning for New Products Under Costly Experimentations

Yuqi Yang, Arizona State University, Tempe, AZ, United States, Harish Guda, Hongmin Li

We consider an online retailing firm that leverages transaction-level data to guide sequential product experimentation. The firm is myopic, and new products are generated by recombining features of previously tested products. Each untested product is associated with a Bayesian posterior belief whose precision increases with its similarity to the experimented products.

We formulate this decision problem as a discrete-time, infinite-horizon dynamic search in which the state comprises the set of tested products and their realized performances. We establish the existence and uniqueness of the most promising product at each decision epoch. The firm then compares the expected improvement from experimenting on this candidate against the per-trial cost of delaying commitment. We prove that the optimal expected gain from search decreases in expectation over time. Our results yield tractable, threshold-based decision rules that can be readily implemented by online-retailing firms seeking to exploit rich product-performance data for innovative product development.

Healthcare Policy Optimization

Invited Session

Health Applications Society

Chair: Hyunwoo Shin, Virginia Tech, Blacksburg, VA, United States

Co-Chair: Sait Tunc, Virginia Tech, Blacksburg, VA, United States

1 - A Framework to Incorporate Human Behavior in Agent-Based Models for Infectious Disease

Maria Mayorga, North Carolina State University, Raleigh, NC, United States, Sebastian Rodriguez-Cartes, Osman Ozaltin, Julie Swann

Computational agent-based model (ABM) simulations are critical for projecting and responding to infectious disease outbreaks, yet the effectiveness of health interventions heavily relies on individual adherence, underscoring the importance of accurately representing human behavior. While some ABMs have incorporated behaviors, clear guidelines for leveraging the extensive literature on behavioral theories have been lacking. This study addresses this challenge by proposing a modeling framework that integrates classical behavioral theories and their psychological constructs, drawing upon well-established definitions and categorizations from the social sciences to guide operationalization. We present novel and existing modeling approaches to represent these constructs and their interactions with the environment and behavior. Furthermore, we discuss methods for determining an agent's likelihood of adopting a behavior and how empirical data can be used for calibration and validation. To illustrate the framework's application to disease-specific behaviors, we provide a modeling example. Ultimately, this proposed framework offers a roadmap for computational modelers to incorporate scientifically grounded behaviors in the design and evaluation of simulation models and interventions.

2 - Design of a Non-Profit Telemedicine-to-Hospital Network for Specialized Healthcare Services

Yuting Yuan, Penn State, University Park, PA, United States, Lan Jin, Hui Zhao, Nicholas Petrucci

Reliable and equitable access to specialized public healthcare services is a challenge for society. We investigate the optimal design of a Telemedicine-to-Hospital (T2H) network for a non-profit center that provides such a service to participating hospitals. If a hospital chooses to participate in the center's network, then all patients visiting the hospital in need of the specialized service are treated remotely by the telemedicine center with coordination from the hospital. The center's design problem is to determine the two-part hospital fee policy and corresponding staffing level to maximize total patient welfare subject to service, cost, and hospital participation constraints. This problem is inspired by a telemedicine center that provides treatment for victims of sexual assault. We develop a two-stage Stackelberg game, first, to determine the center's optimal solution and, second, to analyze the nuanced implications for external government funding, which helps provide such services. Our calibrated numerical study based on real data further investigates how the size and mix of hospitals within the center's service reach affect its optimal design. To the best of our knowledge, this is among the first studies designed to address the salient trade-offs and financial challenges of a non-profit T2H telemedicine network for specialized healthcare services. Among other things, our research demonstrates how well-designed fees paired with efficient levels of government funding can help expand public access to high-quality specialized healthcare services. Our work develops a much-needed model framework to provide these expensive yet critical public healthcare services to society.

3 - Dynamic Capacity Planning to Improve Healthcare Access

Duygu Soylemez, The University of Chicago, Booth School of Business, Chicago, IL, United States, Daniel Adelman, Kenneth Nunes

We examine a stylized appointment planning problem motivated by access issues in healthcare. Our analysis reveals structural insights and identifies optimal policies under certain conditions.

4 - Diagnostics to Detect *Dracunculus Medinensis* Analytes in Biospecimens in the Last Mile of Disease Eradication: the Impacts of Diagnostic Accuracy, Deployment Protocol and Tethering Compliance

Hannah Smalley, ISyE Georgia Tech, Atlanta, GA, United States, Pinar Keskinocak, Maryann Delea, Obiora Eneanya, Philip Ouakou Tchindebet, Jessica Van Loben Sels, Adam Weiss

Guinea worm disease (GWD) has been targeted for eradication, and much progress has been made towards this goal, with a 99.99% reduction in human cases since 1986. However, animal infections, particularly among dogs, create challenges to reaching disease eradication. Diagnostics to detect *Dracunculus medinensis* analytes in dogs are under development with the goal of identifying infected dogs prior to worm emergence and thus providing national Guinea worm eradication programs with additional data to inform decisions about intervention implementation, such as proactive tethering of dogs in GW-endemic areas to prevent contamination of water sources with Guinea worm larvae and interrupt disease transmission. We use infection data provided by Chad's Guinea Worm Eradication Program in an agent-based simulation which models Guinea worm infections among dogs and interactions between dogs and water sources to determine the impact of interventions to prevent GWD over time. Based on the potential characteristics of diagnostics that could detect prepatent, recent, or past GW infections, we analyze a variety of testing accuracy levels (i.e., test sensitivity and specificity) and deployment protocols which incorporate screening and secondary diagnostics. Diagnostic testing can have a positive impact due to the increase in tethering triggered by dogs testing positive for GWD, particularly in areas having low compliance with proactive tethering recommendations. Increasing compliance with proactive tethering reduces the impact of diagnostic testing.

Recent Techniques in Multi-Level Optimization

Invited Session

OPT: Global Optimization

Chair: Anil Aswani, UC Berkeley, Berkeley, CA, United States

Co-Chair: Sukanya Kudva, UC Berkeley, Berkeley, CA, United States

1 - Algorithm for Trilevel Optimization

Sukanya Kudva, UC Berkeley, Berkeley, CA, United States, Anil Aswani

Multi-level optimization problems can help the industry and the government in making decisions that involve a hierarchy of players or a chronology of events in time. The first player in a hierarchy or the first chronological event takes the first action, followed by the next in hierarchy/ chronology, and so on. And at each level, the action optimizes an objective subject to the actions previously taken and is dependent on future actions that could be taken. In this work, we propose an algorithm for a trilevel optimization problem, when there are three such levels. This algorithm can be used when actions are taken in a continuous space of variables, and we assume quadratic objectives and linear constraints. We then prove the convergence of our algorithm in a finite number of iterations.

2 - Mathematical Program Networks

Forrest Laine, Vanderbilt University, Nashville, TN, United States

Mathematical Program Networks (MPNs) are introduced in this work. An MPN is a collection of interdependent Mathematical Programs (MPs) which are to be solved simultaneously, while respecting the connectivity pattern of the network defining their relationships. The network structure of an MPN impacts which decision variables each constituent mathematical program can influence, either directly or indirectly via solution graph constraints representing optimal decisions for their decedents. Many existing problem formulations can be formulated as MPNs, including Nash Equilibrium problems, multilevel optimization problems, and Equilibrium Programs with Equilibrium Constraints (EPECs), among others. The equilibrium points of an MPN correspond with the equilibrium points or solutions of these other problems. By thinking of a collection of decision problems as an MPN, a common definition of equilibrium can be used regardless of relationship between problems, and the same algorithms can be used to compute solutions. The presented framework facilitates modeling flexibility and analysis of various equilibrium points in problems involving multiple mathematical programs.

3 - Contextual Stochastic Bilevel Optimization

Yao Xie, Georgia Institute of Technology, Atlanta, GA, United States, Yifan Hu, Jie Wang, Andreas Krause, Daniel Kuhn

We introduce contextual stochastic bilevel optimization (CSBO) -- a stochastic bilevel optimization framework with the lower-level problem minimizing an expectation conditioned on some contextual information and the upper-level decision variable. This framework extends classical stochastic bilevel optimization when the lower-level decision maker responds optimally not only to the decision of the upper-level decision maker but also to some side information and when there are multiple or even infinite many followers. It captures important applications such as meta-learning, personalized federated learning, end-to-end learning, and Wasserstein distributionally robust optimization with side information (WDRO-SI). Due to the presence of contextual information, existing single-loop methods for classical stochastic bilevel optimization are unable to converge. To overcome this challenge, we introduce an efficient double-loop gradient method based on the Multilevel Monte-Carlo (MLMC)

technique and establish its sample and computational complexities. When specialized to stochastic nonconvex optimization, our method matches existing lower bounds. For meta-learning, the complexity of our method does not depend on the number of tasks. Numerical experiments further validate our theoretical results.

4 - Hybrid Algorithms for Enhanced Efficiency and Scalability of Network-Based Tri-Level Interdiction Models

Kash Barker, University of Oklahoma, Norman, OK, United States, Nafiseh Ghorbani-Renani, Andres Gonzalez

This study focuses on optimizing resilience strategies for interdependent infrastructure networks (e.g., electric power, water supply, transportation system) against intelligent attacks. We formulate this problem as a tri-level defender-attacker-defender (DAD) model, which is known for its computational complexity. To address this challenge, we propose two novel hybrid decomposition-based algorithms: the hybrid Benders decomposition-based (HBD) algorithm and the hybrid set covering-based (HSC) algorithm. These algorithms efficiently solve the nested subproblems (master problem and subproblem) of the tri-level DAD formulation, incorporating metaheuristic algorithms for improved performance. The proposed algorithms are applied to a tri-level protection-interdiction-restoration model to optimize network resilience. Two case studies are used to evaluate the effectiveness of the solution techniques: (i) an interdependent system of water, gas, and power networks with 125 nodes and 164 links, and (ii) a simulated system of two networks with 252 nodes and 507 links. Our results demonstrate that both hybrid algorithms offer high-quality solutions with significantly improved computational efficiency compared to the existing exact solution method based on the set covering approach.

5 - Optimal Distance Protection in Power Systems

Josh Taylor, New Jersey Institute of Technology, Newark, NJ, United States

Power system protection schemes today rely on large, unbalanced currents to detect faults. In inverter-dominated power systems, a fault current might be roughly balanced and just a few percent larger than normal, making fault detection more difficult. One solution is for the inverter to slightly perturb its output current and/or voltage, i.e., to inject an auxiliary signal, so as to make the system's behavior under faults easier to distinguish from normal. In this paper, we optimize auxiliary signals for fault detection with distance relays.

We formulate a general auxiliary signal design problem with constraints imposed by system operational requirements, and additive and multiplicative noise. We use a relaxation and duality to reformulate the bilevel program as a semidefinite bilinear program. In the special case of additive uncertainty and no constraints, we obtain an analytical lower bound on the magnitude an auxiliary signal must have to guarantee detection. We solve the optimizations in an example based on distance protection, in which the auxiliary signal is negative sequence current.

6 - Learning-to-Optimize for Consolidation and Transshipment in Multi-Store Order Delivery

Xin Wang, HEC Montréal, Montreal, QC, Canada, Okan Arslan, Jean-François Cordeau, Erick Delage

This study investigates multi-store order delivery services where customers can order from multiple stores for home delivery. We first consider separated-order delivery, where orders from different stores are processed and delivered individually. To improve customer convenience and operational efficiency, we introduce consolidated-order delivery, enabling customers to place a single order across stores and receive all items in one combined delivery. While this enhances convenience, it can increase delivery times due to additional routing for visiting multiple stores. To mitigate this shortcoming, we propose a consolidated-order delivery system with transshipment, allowing drivers to transfer orders at transshipment nodes for higher efficiency. We develop a mixed-integer linear program for the multi-store order problem that models different delivery systems, including separated-order delivery and consolidated-order delivery with or without transshipment. Due to computational challenges arising from routing decisions and time variables, we adopt a learning-to-optimize approach that integrates machine learning and optimization. Our experimental study reveals that Graph-based Neural Network consistently performs the best among four learning methods in terms of accuracy, optimality gap, efficiency, and scalability to larger problem instances beyond the training set. We conduct experiments across four U.S. regions in a realistic setting with dynamic customer arrivals. We find that consolidated-order delivery with transshipment, coupled with a short-duration waiting strategy, consistently delivers superior performance, yielding shorter order completion times and reduced driver travel times through effective spatial and temporal consolidation. Waiting longer to batch more customers is advantageous under conditions of frequent customer arrivals and limited driver availability.

Building B Level 2 B209

Humanitarian and Non-Profit Operations

Invited Session

Public Sector OR

Chair: Reut Nocham, Tel-Aviv University, Tel-Aviv, Israel

1 - Balancing Effectiveness and Equity in the Face of Uncertainty: the Case of Humanitarian Lateral Transshipments

Reut Nocham, Tel-Aviv University, Tel-Aviv, Israel

Humanitarian organizations often struggle to allocate limited resources efficiently while ensuring fair outcomes for disaster-affected communities. This paper addresses the Humanitarian Transshipment Problem (HTP), focusing on the joint optimization of pre-positioned inventory and post-disaster lateral transshipments. The challenge lies in balancing effectiveness (meeting needs) and equity (fair aid distribution), especially under uncertainty. We propose a novel modeling framework for HTP that formally incorporates equity under uncertainty. While earlier studies have explored the effectiveness–equity trade-off, fairness models under uncertainty often lack rigorous justification. To address this, we extend an established social welfare metric to a stochastic setting, linking within-scenario and between-scenario trade-offs. This results in an axiomatic approach that maintains desirable properties across scenarios. Using real and synthetic data, we show our model improves system performance and supports more equitable decision-making under uncertainty. For managers, this framework offers a practical tool to allocate resources more fairly and effectively. By modeling trade-offs at multiple decision levels, it enables more balanced outcomes. Our findings underscore the strategic importance of lateral transshipments, especially in low-budget, high-uncertainty conditions typical of disaster preparedness. While factors like demand correlation may be uncontrollable, operational budgets can be used strategically to boost performance. This work provides concrete guidance for humanitarian organizations aiming to enhance fairness, responsiveness, and efficiency in their operations.

2 - Shelter Location and Evacuation Planning Under Demand Uncertainty: An Adaptive Robust Optimization Approach

Jaehyuk Kim, North Carolina State University, Raleigh, NC, United States, Osman Ozaltin, Maria Mayorga, Merve Bodur

No-notice disasters, such as earthquakes, that occur with little to no warning pose unique challenges to emergency managers and greatly affect vulnerable populations. Emergency managers must develop plans in advance under uncertainty and act quickly when a disaster occurs. We consider the problem of developing an evacuation plan by determining the locations of shelters to open, the number of trailers that establish initial capacities at each shelter, and the assignment of evacuees to routes and shelters. We propose a two-stage adaptive robust mixed-integer optimization model that allows shelter capacities to be adjusted after observing realized shelter demands. In the first stage, the locations of shelters and trailers and the evacuation routes are pre-determined before uncertain shelter demand is known. In the second stage, after the number of evacuees at each impacted location is realized, evacuees are assigned to shelters via planned routes, and shelter capacities are adjusted as needed. The value of the proposed evacuation planning is assessed by comparing it to the case where evacuees select routes according to their preferences. We solve the adaptive robust mixed-integer optimization model using a partition-and-bound algorithm to minimize the maximum total unmet demand. We conduct numerical experiments using the Sioux Falls network and demonstrate the benefits of our model. The results verify the benefit of evacuation route planning and flexible shelter capacity.

3 - An Empirical Investigation of the Trade-off Between Effectiveness and Equity in Resource Allocation Problems

Ohad Eisenhandler, Afeka College of Engineering, Tel Aviv, Israel, Joachim Meyer, Michal Tzur

The trade-off between effectiveness and equity in resource allocation is a key concern in the public and humanitarian sectors. Utilizing an innovative experimental framework, we capture how decision-makers evaluate various allocation approaches from a centralized perspective rather than the individual-focused analyses commonly

found in the literature. As such, our methodology provides first-of-their-kind insights into balancing these often conflicting objectives. The results reveal that integrating both effectiveness and equity leads to solutions that align more closely with respondent preferences than approaches that focus solely on either aspect. Moreover, as opposed to our upfront conjecture, measures with a stronger emphasis on equity were favored, as long as effectiveness was not substantially compromised. This suggests that decision-makers might be more concerned about equity than previously thought. Gini-based measures emerged as the most accurate in capturing these preferences, while the max-min approach was less aligned with them, indicating a potential disconnect between theoretical models in the literature and actual decision-making practices. Additionally, significant variability in individual responses highlighted differing views on the effectiveness-equity trade-off, suggesting the need for adaptable allocation models to accommodate different preference profiles. These findings provide valuable insights for researchers and practitioners seeking quantitative models to navigate the complex trade-offs involved in resource allocation.

4 - A Chance-Constrained Optimization Framework for Building Retrofitting Decisions Under Natural Hazards

Tanmoy Palit, University of Oklahoma, Norman, OK, United States, Saeid Ghasemi, Andrés D. González, Milad Roohi

Natural hazards such as earthquakes present a major threat to the safety, functionality, and economic stability of communities. The increasing frequency and severity of such events have emphasized the importance of proactive planning and strategic investment in mitigation. This study proposes a chance-constrained optimization framework for determining optimal retrofitting strategies for buildings exposed to natural hazard risks. The model accounts for uncertainty by incorporating multiple scenarios and aims to minimize the maximum expected value loss, subject to budgetary constraints and a probabilistic performance requirement. A case study is conducted in Shelby County, TN, where various earthquake scenarios are simulated to evaluate their potential impacts on the buildings of the community. The chance constraint ensures that the total expected loss stays within an acceptable limit in the required percentage of scenarios, allowing for risk-informed decision-making. The model is tested with different chance-constrained thresholds and budgetary performance levels to evaluate its effectiveness. Results demonstrate the model's ability to target high-risk buildings and allocate limited resources efficiently. This work highlights the value of integrating risk analysis and optimization in resilience planning and offers a practical tool for policymakers aiming to enhance community resilience. By helping communities prioritize retrofitting actions based on potential losses and scenario probabilities, the framework supports long-term resilience and disaster preparedness in a data-driven manner. Although applied to earthquake hazards in this study, the model can also be adapted to support resilience planning for diverse types of hazards or communities.

5 - Towards a Generalized Network Optimization Model for Community Resilience Decision Support

Kenneth Harrison, National Institute of Standards and Technology (NIST), Gaithersburg, MD, United States, Tasnim Faiz, William Hughes

Natural disasters, like floods, tornadoes, earthquakes, and wildfires, wreak havoc on a community's interdependent physical, social, and economic systems, or networks. These natural hazards present loadings (e.g., winds, inundation, ground acceleration) that cause network components to fail, in turn triggering outages impairing the social functions of the community (e.g., housing, businesses, and healthcare); importantly, a protracted period of recovery typically follows. NIST has developed several network optimization models to support community resilience decision-making. Recent advances include modeling the voluntary uptake of mitigation actions (e.g., new building retrofits) under incentive programs, addressing the extended implementation period of mitigation decisions, modeling access to healthcare services, and giving decision-makers tools for addressing risk. This talk describes work towards a generalization of the model for application to multiple communities confronting a range of hazards. Various complicating issues are addressed, including network component failure modeling differences across hazards, aligning with the community's other planning objectives, and satisfying multiple stakeholders. Case studies of communities facing various hazards demonstrate this work towards a common decision support framework for community resilience planning.

Efficiency and Robustness in Data-Driven Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Henry Lam, Columbia University, New York, NY, United States

Co-Chair: Tianyu Wang, Columbia University, New York, NY, United States

1 - Learning with Local and Global Adversarial Corruptions

Soroosh Shafiee, Cornell University, Ithaca, NY, United States

We study learning in an adversarial setting, where an epsilon fraction of samples from a distribution P are globally corrupted (arbitrarily modified), and the remaining perturbations have an average magnitude bounded by ρ (local corruptions). With access to n such corrupted samples, we aim to develop a computationally efficient approach that achieves the optimal minimax excess risk. Our approach combines a data-driven cleaning module with a distributionally robust optimization (DRO) framework. We demonstrate that if the data cleaning module is minimax optimal with respect to the Wasserstein loss, solving an optimal transport-based DRO problem ensures a minimax optimal decision. We further provide tractable reformulations for both modules.

2 - Stochastic Optimization with Decisions Truncated by Random Variables

Jie Wang, Georgia Institute of Technology, Atlanta, GA, United States

Stochastic optimization with decisions truncated by random variables has broad applications in revenue management. However, the training objective is generally nonconvex, even when the transformation function is convex. To address this challenge, we develop a convex hull relaxation that provides an exact reformulation under the assumption of positive dependence in the distribution of the random variable. This leads to an infinite-dimensional convex optimization problem over high-dimensional probability measures, where conventional methods suffer from the curse of dimensionality. To ensure computational tractability, we exploit the problem structure and show that it is equivalent to optimizing over marginal distributions. Based on this insight, we propose a finite-particle approximation that breaks the curse of dimensionality and establish its global convergence guarantees. Finally, we demonstrate the superior performance of our algorithm on a booking limit control problem.

3 - Robust Offline Policy Learning Under Covariate Shifts

Bill Tang, University of Southern California, Los Angeles, CA, United States, Cagil Kocyyigit, Phebe Vayanos

We study the problem of distribution shifts in offline policy learning, where the policy training distribution is different from the deployment distribution and may lead to harmful or sub-optimal policy actions at deployment. In real world applications, changes to an allocation system can cause shifts in measured covariates, such as wording changes in survey questions that elicit different responses from individuals experiencing homelessness. As a result, a non-robust allocation policy may incorrectly over or under allocate resources based on the original offline data distribution. Adopting a Wasserstein distributionally robust approach, we learn an allocation policy that is not restricted to any functional form and robust to potential covariate shifts in the population of allocatees.

4 - Optimizer's Information Criterion: A Diagnostics Framework for Data-Driven Optimization

Tianyu Wang, Columbia University, New York, NY, United States, Henry Lam, Iyengar Garud

Different data-driven optimization methods -- varying in model classes and algorithmic design -- can outperform one another across different data instances. This variability underscores a fundamental yet challenging question: how can we reliably evaluate and compare the out-of-sample objective performance of data-driven decisions when standard sample-based evaluations are often biased relative to the truth? We introduce the Optimizer's Information Criterion (OIC), a general, decision-focused approach that extends Akaike's Information Criterion from model adequacy to decision selection. OIC analytically approximates and removes the bias arising from the interaction between model fitting and downstream optimization, delivering reliable performance estimates without repeatedly re-solving optimization problems as in cross-validation and applying more broadly than existing bias-approximation methods. The framework covers a wide range of formulations including empirical and parametric models, their regularized counterparts, and furthermore contextual and risk-averse optimization formulations.

5 - Distributionally Robust Optimization with Incomplete Covariate Information

Ruiwei Jiang, University of Michigan, Ann Arbor, MI, United States, Qingyuan Xu

Modern decision-making systems increasingly rely on contextual features (covariates) to improve optimization under uncertainty. However, in many datasets covariate information is incomplete. This talk proposes a method based on distributionally robust optimization to leverage those incomplete covariates for robust decision. We discuss the computational tractability and statistical guarantees for the proposed approach and demonstrate its performance in comparison with several impute-then-optimize alternatives.

1 - The Graph Coupling Problem in Quantum Computing

Saber Dinpazhouh, Rice University, Houston, TX, United States, Illya Hicks

We study an operation compilation problem, associated with the hybrid quantum-classical algorithm, QAOA, for the max-cut problem on trapped-ion quantum computers. The goal is to compile the cost Hamiltonian for max-cut QAOA to global coupling operations and individual qubit flips, as opposed to the standard gate compilation. Rajakumar et al have proposed this compilation and showed such a compilation exists for any graph. To mitigate operation error a short sequence of operations is desired. The problem is a low-rank semi-discrete matrix decomposition for the adjacency matrix of a given graph. The lowest possible rank for this decomposition is known as the graph coupling number, $g_{\text{gc}}(G)$, where G is the input graph. They gave a combinatorial construction, named union of stars, with the rank of at most $3n-2$ for any unweighted graph with n vertices. They gave an $\mathcal{O}(m)$ construction for weighted graphs as well. Here we focus on the unweighted graphs. We prove the order-optimality of the union of stars algorithm for unweighted graphs by discovering a family of graphs with a lower bound of $n-1$ on their g_{gc} . Additionally, we decrease the upper bound from $3n-2$ to $2.5n+2$ for any unweighted graph with n vertices. For specific graph families like cliques, perfect matching graphs, paths, and cycles, we find tighter bounds. Additionally, we propose a compact mixed integer program, which is competitive against their method which has exponential size in the input graph. We also discover a connection of the problem with the Hadamard matrices.

2 - Probabilistic Zero-Forcing

Noah Lichtenberg, Rice University, Houston, TX, United States, Illya Hicks

On a given graph $G = (V, E)$ where each vertex can be colored blue or white, a zero forcing set on G describes a starting set of vertices to color blue, where every other vertex is colored white, such that by applying an iterative deterministic coloring rule, all vertices of G will be blue after a number of iterations. Probabilistic zero forcing is a variation of zero forcing where the iterative color changing rule is no longer deterministic but rather probabilistic. One desired quantity in probabilistic zero forcing would be the expected propagation time, which can be seen as the probabilistic analogue to the number of iterations required to color all vertices blue in zero forcing. In this work, computational implementations for finding expected propagation time are explored.

3 - A New Approach for Solving the Mixed Integer PDE Constrained Source Inversion Problem

Damon Spencer, Rice University, Houston, TX, United States, Mattias Heinkenschloss, Illya Hicks

This talk discusses the numerical solution of a source inversion problem with a linear PDE constraint and sources on the right hand side of the PDE. It has applications to optimal borehole selection. Selecting each source is modeled with a binary variable. The PDE solution is expressed as a function of the possible sources. Because the PDE is linear and the sources are in the right hand side, this leads to a 0-1 quadratic knapsack problem. Glover's linearization is applied to equivalently express the 0-1 quadratic knapsack problem as a mixed integer linear program. For the numerical realization, a finite difference discretization and a quadrature rule are applied. The importance of rescaling the problem is demonstrated. Various techniques such as variable fixing and warm starting are applied to explore the special structure of the source inversion problem. The presented approach performs well compared to other mixed integer nonlinear programming solvers from the literature on this problem class.

4 - New Techniques for the Virtual Network Embedding Problem

Avhan Misra, Rice University, Houston, TX, United States, Illya Hicks

Virtual Network Embedding (VNE) is an NP-hard problem with real-world applications in distributed computing, military networks, high frequency trading, and robotic control. It involves optimally mapping virtual request graphs onto an infrastructure graph under various constraints and conditions. Although Mixed Integer Linear Programming (MILP) formulations exist, they often struggle with scalability and optimality in large instances. To overcome these limitations, we explore reinforcement learning (RL) as a scalable alternative for learning effective embedding strategies. Our work addresses multiple VNE variants, including the minimum resource utilization and subdivision containment variants, and demonstrates how RL-based approaches can approximate high-quality embeddings in large-scale network scenarios where traditional methods fall short.

5 - An Improved Algorithm for Solving A Trilevel Network Interdiction Problem to Optimality by Utilizing Suboptimal Solutions

Joshua Ong, Lawrence Livermore National Laboratory, Livermore, CA, United States

We consider the interdiction defense (ID) problem, a three-stage defender-attacker-defender (DAD) problem where the defender and attacker have access to the same set of components. In the first stage a defender mitigates vulnerabilities by protecting a subset of components. In the second stage an attacker removes a subset of assets from the network to cause the maximum disruption. In the third stage the defender stabilizes the system by routing flow. The best response intersection (BRI) algorithm leverages the ID problem structure to obtain optimal solutions an order of magnitude faster than comparable column and constraint generation algorithms. In this talk, we utilize features of off-the-shelf optimization solvers to obtain suboptimal solutions without incurring additional computational overhead to speed up the BRI algorithm. With this additional information, the BRI algorithm converges in fewer iterations while maintaining optimality guarantees. We show the efficacy of the improved algorithm on a power grid interdiction application. Experiments show that the improved algorithm scalability as the combinatorial complexity increases, achieving three to five times faster run times.

1 - Modeling Reputation-Based Behavioral Biases in School Choice

Emily Ryu, Cornell University, Ithaca, NY, United States, Jon Kleinberg, Sigal Oren, Eva Tardos

A fundamental component in the theoretical school choice literature is the problem a student faces in deciding where to apply. Recent models have considered a student who is unsure of their strength as an applicant and can apply to at most k schools of varying selectiveness, caring solely about maximizing their admissions outcome (the quality of the school they attend). However, experience suggests that students' decisions are additionally influenced by crucial behavioral biases based on reputational effects: a subjective reputational benefit when admitted to a selective school, and a subjective loss based on disappointment when rejected. Guided by behavioral

economics work on loss aversion relative to expectations, we propose a behavioral model by which a student balances these subjective effects with the quality of the school they eventually attend, changing their choices in interesting and dramatic ways. In particular, where a rational applicant spreads their applications evenly across the spectrum of selectiveness, a biased student applies very sparsely to highly selective schools and instead primarily targets less selective schools, consequently underperforming a rational student even when the rational student is restricted to a sufficiently large upper bound on applications and the biased student can apply to arbitrarily many. Simultaneously, our model is also rich enough to cover a range of different ways that biased students cope with fear of rejection, including occasionally applying to schools that are too selective. As a result of these "mistakes," biased students obtain a quantitatively lower expected admissions outcome.

2 - Fairness of Normalized P-Means for Allocating Goods and Chores

Paritosh Verma, Purdue University, West Lafayette, IN, United States

Allocating items in a fair and economically efficient manner is a central problem in fair division. For additive preferences, the celebrated notion of Nash welfare is known to produce fair and efficient allocations for both divisible and indivisible goods; there is no known analogue for dividing chores. The Nash welfare objective belongs to a large, parameterized family of objectives called the p-mean welfare functions, which includes other notable members, like social welfare and egalitarian welfare. However, among the members of this family, only the Nash welfare produces fair allocations for goods. Incidentally, Nash welfare is also the only member that satisfies the axiom of scale invariance, which is crucially associated with its fairness properties. In the talk, we will define a class of "normalized p-mean" objectives, which imparts the missing key axiom of scale invariance to the p-mean family. We will show that optimizing the normalized p-mean objectives produces fair and efficient allocations when the items are goods or chores, divisible or indivisible. For instance, the normalized p-means gives us an infinite class of objectives that produce (i) proportional and Pareto efficient allocations for divisible goods, (ii) approximately proportional and Pareto efficient allocations for divisible chores, (iii) EF1 and Pareto efficient allocations for indivisible goods for two agents, and (iv) EF1 and Pareto efficient allocations for indivisible chores for two agents.

3 - Metric Distortion of Small-Group Deliberation

Mohak Goyal, Stanford University, Stanford, CA, United States, Ashish Goel, Kamesh Munagala

We consider models for social choice where voters rank a set of choices (or alternatives) by deliberating in small groups of size at most k , and these outcomes are aggregated by a social choice rule to find the winning alternative. We ground these models in the metric distortion framework, where the voters and alternatives are embedded in a latent metric space, with closer alternative being more desirable for a voter. We posit that the outcome of a small-group interaction optimally uses the voters' collective knowledge of the metric, either deterministically or probabilistically. We characterize the distortion of our deliberation models for small k , showing that groups of size $k=3$ suffice to drive the distortion bound below the deterministic metric distortion lower bound of 3, and groups of size 4 suffice to break the randomized lower bound of 2.11. We also show nearly tight asymptotic distortion bounds in the group size, showing that for any constant $\epsilon > 0$, achieving a distortion of $1+\epsilon$ needs group size that only depends on $1/\epsilon$, and not the number of alternatives. We obtain these results via formulating a basic optimization problem in small deviations of the sum of i.i.d. random variables, which we solve to global optimality via non-convex optimization. The resulting bounds may be of independent interest in probability theory.

4 - Stable Many-to-Many Matching in Opportunity-Aware Employment Systems via Data-Driven Integer Optimization

Sepideh Sedghi, Worcester Polytechnic Institute, Worcester, MA, United States, Marcela Vasconcellos, Andrew Trapp

Current employment systems for assisting the over 123 million worldwide displaced persons, as well as other vulnerable groups such as single mothers and older workers, are largely fragmented and manual. This work builds preference-aware, efficient matching methods to secure formal employment for those too often left at the margins. We model the problem as a many-to-many, cardinal preference-based matching problem with ties, incomplete preference lists, and elastic lower and upper quotas. While prior optimization-based approaches focus on one-to-one and many-to-one settings, we propose a novel integer optimization model for the many-to-many stable matching that accounts for both candidate preferences and job requirements, producing actionable recommendations for a job-matching platform. We start by developing data-driven predictive estimates of candidate-job fit probabilities, which we then use as inputs to enable personalized matching of jobs and candidates. We then introduce first-of-its-kind constraint-based representations of stability into our formulation that eliminate justified envy and waste and incorporate flexible matching bounds to improve outcomes for vulnerable individuals. We demonstrate scalability of our methods to solve instances of size beyond even those observed in practice.

5 - Navigating the Fairness Frontier: Portfolios for Optimization and Machine Learning

Jai Moondra, Georgia Institute of Technology, Atlanta, GA, United States, Swati Gupta, Mohit Singh

Many real-world problems involve balancing multiple conflicting objectives, and the appropriate trade-off among these objectives is often unclear. We introduce the notion of portfolios—small sets of solutions that are approximately optimal for any way of balancing the given objectives. We present general techniques for constructing such portfolios and study their application in three settings: (1) facility location, where different groups experience varying travel distances; (2) scheduling, where machines incur heterogeneous loads; and (3) reinforcement learning, where policy impacts differ across stakeholders. In each case, we consider different families of objective aggregation functions—such as Lp norms, ordered norms, and generalized p-means. We propose algorithms to construct portfolios and provide theoretical guarantees relating the trade-offs between approximation quality, portfolio size, and computational efficiency. Experiments on synthetic and real-world datasets show that our approach effectively summarizes the solution space across diverse trade-off parameters, offering interpretable and robust choices for decision-makers.

1 - The Impact of Capacity Limitations on The Value of Segmentation as a Marketing Strategy

Muge Yayla Kullu, University of Texas at San Antonio, San Antonio, TX, United States, Isil Koyuncu Kilci, Dongling Huang

We empirically investigate how differentiation among the products of the same firm in terms of their quality and capacity use impact a firm's product line decisions, and how they relate to its market performance. We challenge the common wisdom in practice that states that "bigger is better" as measured by seat sizes in the airline industry. Following the analytical assertions found in the literature, we posit that this catchphrase may not hold true due to inefficient management of critical resources. We find that an increase in capacity use has a negative impact on the high-end segment offerings and on the overall performance therein. In other words, "size matters," albeit in the opposite direction than what is thought in practice. Our results also supported the significant impact of segmentation on market performance indirectly through the high-end offerings of the firm. Finally, we find evidence for the halo effect in which increased high-end product offerings would have a positive impact on the overall market share of a multi-product firm, but with diminishing returns.

2 - Fuel Tax Increases and Indexing Under Uncertainty: a Risk-Averse Stochastic Optimization Approach

Isil Koyuncu Kilci, The University of Texas at San Antonio, San Antonio, TX, United States, Abhay Lidbe, Olga Bredikhina, Tim Barnett

Transportation funding based on fuel taxes is becoming unviable due to fuel-efficient vehicles, inflation, rising construction costs, and alternative fuels. Indexing fuel taxes offers a potential solution but involves challenges in choosing methods that account for risks and uncertainties in future revenue streams. This study presents a framework to evaluate fuel tax indexing methods with risk considerations and their impact on one-time tax rate increases to achieve targeted revenues over time. The problem is modeled as a two-stage stochastic optimization, where the first stage determines the index choice, and the second stage calculates the optimal initial tax increase. Using Sample Average Approximation, a Monte Carlo method, the study demonstrates convergence to expected values with large samples. A risk-averse version is also analyzed with chance constraints, showing that increased risk aversion leads to higher initial tax increases and shifts in preferred indexing methods. Sensitivity analyses on crude oil prices, alternative fuel adoption rates, and gas price elasticity provide robust insights. Findings highlight how risk acceptance impacts tax policies, assisting policymakers

in selecting effective fuel tax indexing methods to ensure revenue adequacy while managing user burdens. This study offers a practical tool for policymakers to design adaptive and sustainable transportation funding strategies.

3 - Impact of Short-Term Vacation Rentals on Discretionary Spending and Utilization of Auxiliary Services

Haibo Zhu, University of South Carolina, Columbia, SC, United States, Priyank Arora, Necati Tereyagolu, Sriram Venkataraman

In this study, we investigate the impact of short-term vacation rentals (STVRs) on the demand- and supply-side benefits and costs in the area. We aim to empirically measure the impact of STVRs on discretionary spending in the area as well as the utilization of auxiliary government services, including trash pickup and emergency medical services in the area. Further, our goal is to examine the moderating impacts of various characteristics of the listed property on the relationships between STVRs and discretionary spending and utilization of auxiliary government services in the area. For our empirical analysis, we use data from multiple sources, including AirDNA, South Carolina Revenue and Fiscal Affairs Office, and South Carolina Department of Health and Environmental Control.

4 - Pricing and Delivery Lead TIME Policies for Online Retailers

Zumbul Atan, Eindhoven University of Technology, Eindhoven, Netherlands, Bartu Arslan, Albert Schrotenboer, Saeed Poormoaeid

Online retailers face the critical challenge of jointly managing price and delivery lead time decisions to attract demand while maintaining operational efficiency and profitability. Fast deliveries and low prices can boost sales but may strain last mile logistics and reduce margins. This study addresses the retailer's problem of designing effective pricing and delivery strategies in the face of uncertain demand and customer heterogeneity in reservation prices. We examine three policy structures: (1) a static M option policy, where up to M fixed price and lead time combinations are predetermined and dynamically offered based on inventory levels; (2) a dynamic policy, allowing real time adjustment of one or two options per period depending on inventory; and (3) a hybrid policy, combining a fixed base option with a second dynamically adjustable option. We develop exact and heuristic algorithms to optimize these policies and analyze their structural properties. Through numerical experiments, we assess the operational and revenue implications of flexibility in option design. Our results show that offering more options and using dynamic adjustments can significantly enhance performance, particularly in long selling seasons or when inventory holding and goodwill loss costs are high. These insights can guide retailers in balancing simplicity and flexibility to better match customer expectations and supply constraints.

5 - Joint Spectrum Leasing and Admission Control for 5G Spectrum Sharing Networks Using Reinforcement Learning

Demet Batur, University of Nebraska-Lincoln, Lincoln, NE, United States, Romina Raafat, Jennifer Ryan, Mehmet C Vuran

We propose a continuous-time Markov decision process (CTMDP) to model the real-time admission and leasing decisions of a primary user (PU) in a wireless network. The central resource in such networks is radio spectrum, a limited asset whose usage rights are granted to PUs through licenses. PUs are responsible for providing wireless connectivity to their own customer base, but may also choose to lease excess spectrum to secondary users (SUs) to generate additional revenue. However, mismanaged leasing decisions can lead to spectrum shortages, resulting in network slowdown for the PU's customers. When slowdown occurs, the PU must decide whether to admit new customer arrivals—knowing that further congestion will degrade service quality—or to reject incoming requests to maintain service standards. A slowdown penalty is incurred when service quality degrades. Similarly, rejecting new customers leads to a rejection penalty. This problem is modeled as a CTMDP with a large state space and stochastic dynamics. To address the computational complexity, we implement a reinforcement learning (RL) approach using a tailored Q-learning algorithm. This algorithm learns effective admission and leasing policies without requiring full knowledge of the underlying transition probabilities. It incrementally updates value estimates based on observed state transitions and explicitly accounts for both slowdown penalties and rejection costs in the reward structure. The Q-learning algorithm is designed to balance immediate rewards with long-term system performance. Numerical experiments demonstrate that the policies learned via Q-learning closely approximate the optimal strategies derived from value iteration, while providing significant improvements in scalability.

Resource Optimization and Regulation in Healthcare

Invited Session

Health Applications Society

Chair: Shubham Akshat, University of Houston, Houston, TX, United States

1 - Resource-Constrained Healthcare Optimization: Comparing Objectives' Effect on Multi-Patient Treatment Allocation

Yuanxin Zhu, Carnegie Mellon University, Pittsburgh, PA, United States, Alan Scheller-Wolf, Jon Caulkins, Rahul Telang

This study investigates how objective function selection affects treatment allocation in resource-constrained healthcare environments using Markov Decision Process (MDP) modeling. We compare the impacts of welfare maximization, utility improvement, and readmission minimization objectives on resource distribution across diverse patient status. Our MDP framework captures the stochastic nature of patient health trajectories while incorporating limited resource constraints. Results reveal significant variations in allocation patterns and outcomes depending on the chosen objective, with distinct tradeoffs between immediate welfare gains and long-term readmission rates. These findings provide critical insights for healthcare policy design, suggesting that hybrid objective approaches may better balance short-term utility improvements with sustainable reduction in hospital readmissions.

2 - Turning a Blind Eye: Role of Pharmacy and Supplier Distribution Channels in the Opioid Epidemic

Iman Attari, University of Cincinnati, Cincinnati, OH, United States, Jonathan Helm, Jorge Mejia, Robert Wiedmer

The opioid crisis is driven by the oversupply of prescription opioids. While the DEA has blamed large national suppliers for their role in the oversupply of drugs, we show that other distribution channels, such as small suppliers and self-distribution through vertically integrated supply structures also contribute significantly to the crisis.

3 - Evaluating the Effectiveness of Optn Regulations in Organ Transplantation

Michael Olabode, University of Minnesota - Twin Cities, Minneapolis, MN, United States, Saumya Sinha

Organ transplantation is often the only therapy available to patients with end-stage organ failure. In 2024, over 48,000 transplants were performed in the US, while another 67,000 candidates joined the national waitlist. The Organ Procurement & Transplantation Network (OPTN) manages the national transplant system and oversees the operation of transplant programs (i.e., hospitals that perform transplants). The OPTN has historically monitored transplant program performance using 1-year post-transplant survival metrics. Recently, the OPTN introduced a new set of criteria with additional evaluation metrics to improve performance monitoring. Our study investigates the effectiveness and possible limitations of these regulations using a simulated environment. As a first step, we aim to quantify the prevalence of 'false flagging', i.e., the likelihood that a well-performing transplant program is incorrectly flagged and vice-versa. We develop a Monte Carlo simulation framework comprising three phases: (i) preliminary phase, where we estimate patients' pre- and post-transplant mortality; (ii) simulation phase, where we assign patients to virtual transplant programs and generate simulated patient outcomes; and (iii) evaluation phase, where we assess the accuracy of the new metrics. Because true program-level risks are unobservable, we artificially designate certain programs as high-risk and simulate patient outcomes using preliminary regression models. The models are calibrated using national data on adult first-time kidney transplant candidates waitlisted between 2012 and 2019. Our findings aim to substantiate the OPTN's efforts to refine performance metrics, prioritize patient safety, and promote increased utilization of deceased-donor organs.

From Waiting Rooms to Pharma Markets: Algorithmic and Informational Solutions for Equitable Healthcare

Invited Session

Health Applications Society

Chair: Jiatao Ding, Nanyang Technological University, Singapore, Singapore

1 - Improving Operational Design of Genomic Surveillance to Detect Novel Variants of Infectious Diseases

Pankaj Jindal, Indian School of Business, Hyderabad, India, Sarang Deo, Sripad Devalkar

Genomic sequencing-based surveillance (GSS) enables the detection and monitoring of novel pathogen variants at the population level. However, as demonstrated during the COVID-19 pandemic, limited sequencing capacity can delay variant detection and prevent effective public health responses. It is thus crucial to study ways to improve the operational design of GSS, specifically determining the proportion of positive cases selected for sequencing, to effectively utilize the limited sequencing capacity. This allows for quicker detection of novel variants and timely, targeted implementation of public health interventions.

In this paper, we develop an analytical model of GSS in which we abstract disease transmission dynamics and model the genomic sequencing process as a continuous-time Markov chain. This is complemented by a realistic simulation model in which we relax the assumptions made in the analytical model and explicitly model the disease transmission dynamics, using a compartmental epidemiological model, along with the genomic sequencing process. We prove that sequencing a higher proportion of disease-positive samples is not always optimal. While a higher sampling proportion increases the probability of selecting a sample infected with the novel variant for sequencing, it can delay detection due to longer wait times caused by congestion in the genomic sequencing process. Finally, we demonstrate the benefit of utilizing our analytical model as a decision-making heuristic for several real-world scenarios.

Our results have practical implications in public health decision making for effective management of evolving epidemics and can lead to efficient provision and utilization of genomic sequencing capacity and public health interventions.

2 - Optimized Routing of the Mobile Lung Cancer Screening Units

Kiana Amani, School of Industrial and Systems Engineering, University of Oklahoma, Norman, OK, United States, Iakovos Tournazis, M. Soheil Hemmati

Oklahoma ranks 8th in the nation for age-adjusted lung cancer incidence rates (63.3 per 100,000) and 5th for lung cancer mortality (45.3 per 100,000). Low-dose CT (LDCT) scanning remains the most effective screening modality for lung cancer. While the national participation in lung cancer screening programs remains low, Oklahoma suffers from far lower uptake (11% vs. 16% nationally). As a remedy, mobile lung cancer screening programs have been introduced to bring the LDCT to areas with limited access to screening facilities. However, most mobile lung cancer screening programs remain limited to on-demand visits to patients located in remote sites. An alternative approach is to schedule more regular visits, guided by the lung cancer prevalence. In this work, we develop a routing optimization model for a mobile lung cancer screening under uncertainties in screening participation and outcomes. The model is informed by the county-stratified incidence rates from the Oklahoma Central Cancer Registry and geo-spatial characteristics of Oklahoma. We demonstrate the results of our model when applied to counties with limited access to LDCT facilities and quantify the outcomes of the optimized mobile screening program.

3 - The Role of Information Asymmetry Between Brand-Name and Generic Firms in Pharmaceutical Markets: Limit Pricing and The Generic Competition Paradox

Qinquan Cui, UCL School of Management, University College London, London, United Kingdom, Kenan Arifoglu, Dongyuan Zhan

Brand-name firms, leveraging their extensive resources and patent protection, possess more information about consumers compared to generic firms. This *information asymmetry* plays a crucial role in shaping pharmaceutical markets. Moreover, following the entry of their generic alternatives, some brand-name drug prices experience a paradoxical increase (i.e., the *Generic Competition Paradox (GCP)*). However, existing research overlooks the information asymmetry between brand-name and generic firms, failing to provide a comprehensive understanding of pharmaceutical markets. To address this, we develop a game-theoretic model with signaling to analyze interactions between a brand-name firm and a generic firm over two periods (signaling and full-information). We find that the brand-name firm can use *limit pricing* during the signaling period to deter generic entry by charging below its monopoly price, then increase its price and allow entry in the full-information period, leading to the GCP. Consequently, under information asymmetry, limit pricing may arise from the brand-name firm's *anticompetitive* practices, offering an *alternative* explanation for the GCP. While typically resulting in higher drug prices and reduced consumer choice, limit pricing and the GCP can sometimes *benefit* consumers and society. This challenges the prevailing belief that information asymmetry and the GCP are always detrimental, highlighting their nuanced impacts.

4 - Attention is What You Need: The Impact of an Information Support Tool in Addressing Trauma Center Deserts

Zidong Liu, Cambridge Judge Business School, Cambridge, United Kingdom, Feryal Erhun, Houyuan Jiang

Major trauma is a critical medical emergency requiring rapid intervention. In the UK, inclusive trauma networks (TNs) operate under a tiered model, balancing centralized resources with geographical access. However, trauma center deserts—regions with limited access to Major Trauma Centers (MTCs)—worsen health inequalities. To support pre-hospital teams in the triage process, a standardized trauma triage tool was introduced to enhance decision-making, improve awareness of patient conditions, and facilitate rapid medical decisions in emergencies. This study evaluates the impact of this information support tool on system efficiency and patient outcomes, particularly in trauma center deserts.

Analyzing nine years (2013–2021) of trauma submission data from the East of England Trauma Audit and Research Network (TARN), we assess the tool's impact. Our findings indicate that while the triage tool does not significantly affect survival rates, it reduces the average hospital length of stay by 0.5 days. More importantly, it increases good recovery rates by 11% overall, with a notable 17% improvement for patients located more than 45 minutes from an MTC.

These results highlight the critical role of operational decision-support tools in optimizing trauma care and reducing geographical disparities. By standardizing assessments, enhancing healthcare workers' awareness, and improving real-time triage decisions, such tools ensure timely and appropriate treatment, particularly in underserved areas.

Our study provides empirical evidence for policymakers and healthcare providers to enhance trauma system efficiency and address geographical healthcare inequities in trauma center deserts.

Building B Level 3 B303

Enhancing Healthcare Access: Drone Logistics and Remote Care Solutions

Invited Session

Health Applications Society

Chair: Shakiba Enayati, University of Missouri - Saint Louis, St Louis, MO, United States

1 - Optimizing Spatial Access to Healthcare Services with Emerging Human Mobility Data

Zhiyuan Wei, California Polytechnic State University, San Luis Obispo, San Luis Obispo, CA, United States

Improving spatial access to healthcare facilities is essential for enhancing overall well-being and health outcomes. People living in healthcare deserts are often associated with lower healthcare utilization and increased risks of morbidity and mortality. In the literature, people's access is often conceptualized as proximity, representing their potential access to healthcare services. However, potential access may not reflect people's actual access patterns that reveal how people utilize healthcare services in practice. Thus, to address this gap, this study first extracts human mobility patterns from large-scale mobile phone data to better characterize people's actual access to healthcare services. Then, we develop a data-driven optimization framework that integrates human mobility behaviors into location modeling to improve the spatial

accessibility of healthcare facilities. Specifically, we formulate a choice-based mobility model to capture human mobility patterns, which is then embedded into a facility location model. Finally, we conduct a case study aimed at improving spatial access to healthcare services through optimized facility locations. Overall, this study presents a new perspective on healthcare access by leveraging emerging human mobility data to improve people's actual access patterns to healthcare services.

2 - Predictive Analytics Driven Virtual Appointment Scheduling for a Psychiatry Clinic

Emirhan Uzunlar, University of Nebraska-Lincoln, Lincoln, NE, United States, Ali Dogru, Ibrahim Capar, Ozgur Araz

Telemedicine has improved healthcare accessibility by reducing travel burdens, increasing patient attendance, and enhancing follow-up care, particularly for rural and underserved populations. This study develops a machine learning-based approach to predict whether patients are likely to use telemedicine or in-person appointment options using Medical Expenditure Panel Survey (MEPS) data, focusing on demographics and insurance information. The first phase evaluates various machine learning models, finding that Random Forest achieves the highest AUC (96%) for psychiatry patients. In the second phase, the predicted outcomes inform an optimized scheduling system for a psychiatry clinic, which is evaluated using Sample Average Approximation (SAA) over multiple simulated days. The proposed hybrid appointment system aims to minimize patient waiting time, physician idle time, and overtime, improving overall clinic efficiency. Our computational experiments lead to several critical insights: 1) uneven capacity allocation between service modes can challenge common heuristics, with both smaller variance first (SVF) and larger variance first rules showing advantages in specific a scenario 2) modeling service mode-specific no-show behavior and unpunctuality are crucial for balancing patient experience and resource utilization 3) when a patient group with a longer service duration dominates the schedule, they are scheduled toward the end of the session. Otherwise, scheduling the patient group with a shorter service duration later in the session is more effective.

3 - A Multimodal Optimization Model for Drone-Integrated Organ Transportation Networks

Bahare Askarian, University of Missouri, Columbia, MO, United States, Suchithra Rajendran, Shakiba Enayati

The increasing demand for organ transplants has heightened logistical complexities within healthcare systems, leading to significant losses of viable organs due to transportation inefficiencies. To address these pressing challenges, we introduce a novel multimodal logistics framework combining drones with conventional transport methods to optimize organ delivery and reduce cold ischemia time (CIT), a critical factor contributing to organ wastage. Our research presents an innovative mixed-integer linear programming (MILP) model designed to strategically coordinate vehicle routing, mode selection, timing constraints, and drone energy consumption management specifically for transporting various organ types from donor hospitals to transplant centers. The model captures a detailed network that includes depots, transplant facilities, organ procurement sites, and drone battery-swapping stations. It rigorously accounts for operational constraints such as vehicle capacities, strict delivery timing and schedules, heterogeneous drone capabilities, energy consumptions, and necessary battery-swapping procedures during transit. Validated through a realistic case scenario, our methodology demonstrates tangible improvements in reducing delivery durations, enhancing operational flexibility, and achieving cost efficiencies compared to traditional approaches. By incorporating drone technology into organ logistics, this research significantly advances the operations research literature and provides actionable recommendations for policymakers, healthcare logistics managers, and infrastructure planners. Our findings enable informed decision-making and promote strategic investment in drone-based transport infrastructure, ultimately modernizing and enhancing the effectiveness of organ transportation networks.

4 - Drone-Enhanced Medical Supply Chains in Rural Areas: a Weather-Integrated Optimization Approach

Pardis Bahmani, University of Missouri - Saint Louis, St Louis, MO, United States, Shakiba Enayati, Sina Ansari, Srikanth Gururajan, Ziteng Wang

Rural regions face persistent challenges in healthcare delivery due to limited infrastructure, long travel distances, rugged terrain, and adverse weather. These barriers often delay medical supply transport, reducing the timeliness and quality of care. While drones offer promise for last-mile healthcare logistics, existing models often overlook realistic, context-aware assessments of drone energy consumption under variable environmental conditions. This study develops a multi-modal optimization framework that coordinates drone and ground vehicle operations to enhance rural healthcare logistics. The model jointly determines routing, siting, scheduling, and modal transitions to minimize total system costs while improving flexibility and reliability. It supports transshipment and vehicle-route interoperability, enabling agile logistics in dispersed, resource-limited areas. To account for environmental variability, the service area is partitioned into weather-informed zones using Voronoi tessellation based on nearby meteorological stations. Drone energy consumption is modeled using validated aerodynamic equations that incorporate wind speed and direction. A time-dependent component captures diurnal atmospheric effects, enabling temporally adaptive and weather-aware energy estimation. We demonstrate the model's utility through a case study of Shield Illinois, a statewide COVID-19 testing initiative. Results show that drone integration reduces operational costs, improves efficiency, and enhances the sustainability of healthcare delivery. The framework serves as a robust decision-support tool for reconfiguring rural health supply chains, promoting equitable access, and guiding data-driven investments in emerging healthcare logistics technologies.

5 - Assessment of Primary Healthcare Accessibility in Rural Areas

Valentina Castaneda-Torres, Georgia Institute of Technology, Atlanta, GA, United States, Sofia Perez-Guzman, Valentina Gutierrez-Gutierrez

Providing primary healthcare (PHC) is a global challenge, particularly in rural areas where nearly half of the population lives and lacks adequate access to essential healthcare services. This research addresses the assessment of accessibility to PHC in rural areas, where multiple socioeconomic, geographic, and infrastructure factors limit service accessibility and exacerbate populations' vulnerability. We propose a p-median facility location problem and explicitly model vulnerability by employing deprivation cost functions. We conduct a case study in a rural region in Colombia, and a series of sensitivity analyses of the impact of deprivation and terminal costs on PHC access. The findings show that 22% of the municipalities lacks access to PHC service points, and among those with access, 20% shared PHC service points and ranked highest in deprivation costs. This research also shows that terminal costs highly influence the optimal allocation of PHC service points to populations, conditioning the prioritization of more vulnerable populations when allocating essential resources.

Co-Chair: Tharanga Rajapakshe, University of Florida, Gainesville, FL, United States

1 - Understanding Federal and State Authorities' Disagreement over the Allocation of Critical Equipment Inventory During the COVID-19 Pandemic

Diwakar Gupta, University of Texas, Austin, TX, United States, Mili Mehrotra

Early in the COVID-19 pandemic, a disagreement between federal and regional governments erupted in the public arena. It was about the allocation from the federally held stockpile of critical-equipment (CE) inventory, specifically the ventilator inventory. Whereas the regions preferred to know their allocations with certainty, the federal government kept such information ambiguous. We develop a novel game-theoretic model that captures the impact of allocation ambiguity on the interplay between two possible actions by the regional governments, i.e., exerting effort on reducing the spread of infection and purchasing CE inventory on their own. We obtain equilibrium actions (purchase quantities and effort levels) of regional authorities under certainty of allocation and various levels of ambiguity. We show that the regions would always prefer certainty, whereas the federal government may not. We refer to the federal government's choice of optimal level of ambiguity as strategic ambiguity. We also identify special cases in which their preferences will be aligned and illustrate the impact of strategic ambiguity on regions' costs through numerical examples. Our analysis not only helps explain why disagreements arise, it could be used to compare costs of strategic ambiguity with those of alternative approaches that align federal and regional decision makers' preferences.

2 - A Large Language Model Agent Framework for Balancing Physician Workload in Online Health Platforms

Xiguang Liu, University of Florida Warrington College of Business Administration, Gainesville, FL, United States, Xinyuan Wang, Liangfei Qiu

Physicians practicing online face increasing performance challenges due to workload overload from excessive patient requests, leading to degraded treatment outcomes and diminished patient experience. However, studying these issues through real-world data is often constrained by privacy concerns, limited data availability, and the slow,

costly nature of empirical research. To address this, we propose a Large Language Model (LLM) agent-based simulation framework to investigate and optimize physician-patient-platform dynamics in online healthcare environments. This study focuses on three core challenges: (1) factors influencing doctors' patient acceptance decisions, (2) benefits of physician collaboration groups, and (3) platform-level request allocation optimization. The framework deploys LLM agents in two primary roles: (1) Single-agent decision systems simulating doctors' real-time workload assessments; (2) Multi-agent operational systems simulating patient-platform-doctor interactions to optimize consultation request allocation through medical specialization and physician availability. This approach provides implementable solutions to prevent physician overload and enhance care quality. The proposed framework can also be adapted to other scenarios where three key elements coexist: single-expert dominance, collaborative synergy formation, and cross-modal coordination.

3 - Capacity Management for Sudden Demand Surge: a Queuing Approach

Yu Wang, University of North Carolina, Wilmington, NC, United States, David Cho

This research analyzes operational strategies hospitals can adopt to manage capacity when facing sudden overwhelming demand stream in addition to the ordinary demand. We develop an analytical queuing model based on findings from data reported by the State of California Office of Statewide Health Planning and the U.S. Department of Health & Human Services on performance measures such as patient average length of stay for over 300 hospitals in California.

4 - Hasan's presentation

1 - Generative AI in Action: Field Experimental Evidence on Worker Performance in E-Commerce Customer Service Operations

Lauren Lu, Dartmouth College, Hanover, NH, United States, Xiao Ni, Yiwei Wang, TIANJUN FENG, Yitong Wang, Congyi Zhou

In collaboration with Alibaba, this study leverages a large-scale field experiment to quantify the impact of a generative AI (gen AI) assistant on worker performance in an e-commerce after-sales service setting, where human agents provide customer support through digital chat. Agents were randomly assigned to either a control or treatment group, with the latter having access to a gen AI assistant that offers two automated functions as text messages: 1) diagnosis of customer order issues in real time and 2) solution suggestions. Agents exhibited varied gen AI usage behavior, choosing to use, modify, or disregard AI suggested messages. We employ two empirical approaches: 1) an intention-to-treat (ITT) analysis to estimate the average treatment effect of gen AI access, and 2) a local average treatment effect (LATE) analysis to estimate the causal impact of gen AI usage. Results show that the gen AI assistant significantly enhanced both service speed and service quality. Interestingly, gen AI automation did not lead agents to reduce effort; rather, it increased their engagement, evidenced by a higher message volume and agent-to-customer message ratio. Analysis by agents' pretreatment performance reveals that low performers experienced greater improvements in speed and quality, narrowing the performance gap, while high performers saw a decline in service quality, likely because gen AI suggestions fell below their expertise. These findings underscore the potential of gen AI to improve operational efficiency and service quality while highlighting the need for tailored deployment strategies to support workers with varying skill levels.

2 - Can LLM Chatbots Replace Flow-Driven Nlp Chatbots in Customer Service?

Bolin Song, Cornell University, Ithaca, NY, United States, Vishal Gaur, Ruihao Zhu

Flow-driven natural language processing (NLP) chatbots, such as those built on Google Dialogflow, are increasingly used in customer service for automation, reliability, and cost efficiency, but struggle with complex, unstructured customer queries due to rigid intent-matching mechanisms. The rise of large language models (LLMs) promises to transform customer service with fully autonomous chatbots that can flexibly infer user intent, dynamically generate responses using retrieval-augmented generation (RAG), and provide empathetic tone, though this flexibility may introduce response variability and hallucination. We assess these trade-offs in the deployment of LLM technology in customer service by building an LLM chatbot and analyzing its performance drivers compared to an NLP chatbot in collaboration with a large online marketplace. Our offline evaluations with expert judges reveal that the LLM chatbot outperforms the NLP chatbot in factual accuracy, contextual fit, specificity, and tone even when handling queries programmed into the NLP chatbot. It is further capable of synthesizing answers to complex, multiple-intent queries without direct answers in the training set. In our online field experiment conducted over five months, the LLM chatbot significantly increases overall user satisfaction by 53.6%, better sustains longer conversations, and maintains higher user engagement, whereas the NLP chatbot achieves comparable user satisfaction only when users interact with it through clickable buttons rather than free-typing. Critically, the performance of LLM chatbot depends on its design parameters and generation of training data. Our results demonstrate that LLM-based autonomous chatbots significantly improve customer service and emphasize the complementary strengths of both architectures.

3 - Llm for Large-Scale Optimization Model Auto-Formulation: a Lightweight Few-Shot Learning Approach

Ruihao Zhu, Cornell University, Ithaca, NY, United States, Chung Piaw Teo, Hanzhang Qin, xiao JIN, Kuo Liang, Chunwei Yang, Yuhang Lu, Jianming Mao, Shuyi Sun, Congcong Zeng

Large-scale optimization is a key backbone in modern business decision-making. However, the process of building these models is often labor-intensive and time-consuming. We address this by proposing LEAN-LLM-OPT, a LightwEight few-shot leArNing framework for LLM-assisted large-scale OPTimization modeling, which takes a query (a problem description and associated datasets) as input and orchestrates a team of LLM agents to output the optimization formulation. LEAN-LLM-OPT innovatively applies few-shot learning to guide LLMs to build optimization models through reasoning and customized retrieval-augmented generation (RAG) tool usage. Specifically, upon receiving a query, a problem classification agent first determines the type of the problem. Then, a few-shot example generation agent consolidates a set of examples that demonstrate how optimization models are built for problems of the same type step-by-step. Finally, a model classification agent follows these examples to extract relevant information from the input datasets and generate the final output. Extensive simulations validate that LEAN-LLM-OPT attains state-of-the-art modeling accuracy compared to existing methods, especially on large-scale optimization modeling. Additionally, in a Singapore Airlines choice-based revenue management use case, LEAN-LLM-OPT demonstrates its value by achieving less than 1% revenue loss across a variety of scenarios while o4-mini (OpenAI's latest reasoning LLM) usually suffers from at least 55% revenue loss. Along the way, we introduce Large-Scale-OR and Air-NRM, the first set of large-scale optimization model formulation benchmarks. A demo of LEAN-LLM-OPT is available at <https://lean-opt-llm.streamlit.app/>.

Risk Management in Public Policy

Invited Session

Decision Analysis Society

Chair: Katharina Best, The RAND Corporation, Pittsburgh, PA, United States

1 - An Updated Aimpoint Investment Model

Jeremy Eckhause, RAND Corporation, Arlington, VA, United States, Katharina Best

We present an updated version of the Aim Point Investment Model (APIM), a mixed-integer programming model for portfolio-level investment allocation across military technology acquisition programs based on those programs' utility, subject to constraints on the ability to employ the invested funds productively within the required timeframes. We update the model to handle constraints that provide for more balanced investments over each time period.

2 - Quantifying Risk to Future Readiness: a Simulation-Based Framework for Evaluating Global Force Management Decisions

April Cho, Center for Naval Analyses, Arlington, VA, United States

Decisions to commit forces beyond baseline Global Force Management (GFM) requirements —such as extending deployment or shifting areas of operation—can support urgent priorities in the near-term but often carry long-term risks to fleet readiness and sustainability. This research presents a quantitative decision support framework developed for the Department of Defense to assess the impact of such force management decisions on future readiness.

The Operational Schedule Simulation (OSS) Model integrates simulation techniques with machine learning to generate realistic, forward-looking readiness projections that account for real-world constraints such as shipyard capacity and maintenance inefficiencies. Leveraging historical data, current fleet schedules, and force generation policies, OSS models how force management decisions—such as deployment extensions or reassignments— affect key outcomes including ship availability, fleet presence, maintenance delays, and service life over the long-term. This framework enables users to assess operational risk, compare scenarios side-by-side, and explore mitigation strategies ranging from policy adjustments to infrastructure investments.

By providing rigorous, data-driven insights into operational risk and future readiness, the OSS framework enables a better understanding of how today's operational decisions impact future force readiness. It supports strategic planning and high-level decision-making, helping Department of Defense leadership answer critical questions about the long-term implications of short-term force commitments.

3 - Unmanned Fleet Employment Optimization

Arpita Verma, Center for Naval Analyses (CNA), Arlington, VA, United States

The US Navy is increasingly relying on diverse robotic and autonomous systems (RAS) for a wide array of ISR missions. Effectively integrating these systems with varying capabilities into cohesive force packages and determining optimal employment strategies presents a significant challenge for supporting commanders, particularly when demand for surveillance exceeds available assets. This research addresses the critical need to quantify and select the most effective UxS force mix and employment plans for surveillance missions.

To this end, CNA developed two novel optimization models: the UxS-Route Optimization Algorithm for Monitoring (U-ROAM) and the UxS-Search path optimization tool (U-SPOT). U-ROAM generates optimal schedules for ISR missions over discrete locations, maximizing overall effectiveness and equitable coverage across localized sites to be monitored. U-SPOT optimizes patrol paths for multiple UxS types within a defined operating area (OPAREA) to maximize sensor coverage and the probability of detection. The primary value of these tools lies in their ability to provide optimal mission planning and quantify key performance metrics, such as area covered and time monitored. As the complexity of mission planning escalates with the proliferation of UxS, these tools empower operational planners to maximize asset effectiveness. Furthermore, these models serve as powerful analytical tools for exploring diverse operational scenarios and informing acquisition decisions by simulating the impact of different platforms and capabilities. The developed models are geographically and asset-agnostic, offering broad applicability for various missions and platforms across different areas of responsibility.

4 - Systemic risk in the AI era

Anton Shenk, RAND, Washington DC, DC, United States, Jonathan Welburn

This time is different...right? AI means a lot of things to a lot of people. It's the potential for transformative change. It's an existential risk. Somewhere between, it presents a familiar pattern; large models produced by few firms have gained widespread usage and GenAI tools are highly interconnected across systems deeply embedded in AI tech stacks. Shared dependence on vulnerable in critical sectors ranging from finance to healthcare present clear and growing sources of systemic risk. We explore this risk and what policy can do to get ahead of it.

5 - Robust Pathway Analysis of Electricity Investments Under Net-Zero Uncertainties

Erin Baker, Univ of Massachusetts-Amherst, Amherst, MA, United States

We use Robust Portfolio Decision Analysis to evaluate the sustainability of a set of candidate electricity investment pathways under a range of uncertainties and multiple objectives. Results show the importance of considering a range of objectives: considering cost alone or CO₂ alone resulted in just two non-dominated pathways in each case; adding in the consideration of co-pollutants increased the number of non-dominated pathways to six of the nine considered. Wind and solar generation play large roles in non-dominated pathways, while dominated pathways tend to retain more fossil fuel capacity, which can increase costs and emissions. This analysis highlights the importance of considering fuel price uncertainty and, in particular, the possibility of high natural gas prices, which can lead to high co-pollution in otherwise low-polluting pathways. Results illustrate trade-offs between emissions and costs; as well as between CO₂ and co-pollutants, which is largely due to carbon removal use.

1 - A Risk-Reduction Approach to Roadway Infrastructure Adaptation Prioritization

Ashkan Zare, George Mason University, Fairfax, VA, United States, Elise Miller-Hooks

Measures to safeguard transportation infrastructure from uncertain hazard events, such as a flooding event, are crucial for public safety, but require significant investment. As it is impractical to try to protect from all possible futures, a risk-based analysis approach for choosing a best protective strategy for adaptation can prove useful. This paper applies a risk-reduction-based methodology to more deeply understand how alternative approaches to mitigating risk via protective infrastructure investments can affect our neighborhoods. A risk measure, based on remaining connectivity to critical facilities, is employed that gives more weight to neighborhoods that have the greatest gap in protection and, therefore, are at greatest risk of being disconnected from critically needed services. The measure is compared against four alternative investment strategies. The analysis is applied to a study area in the Washington, D.C. Metropolitan area under a variety of hazard modelling assumptions. Trade-offs using ten distinct performance metrics are made. The results demonstrate that the choice of risk model in protective investment planning can greatly impact the recommended adaptation plan and which neighborhoods “win” and which “lose.” The method suggested in this paper provides a balanced distribution of risk and may be a more acceptable approach to a community seeking efficient investment prioritization.

2 - Classification of Discrete-Time Queues and Little's Law

Muhammad El-Taha, University of Southern Maine, Portland, ME, United States

We classify discrete-time queues with scheduling rules into classes and use this classification to address an unresolved issue that Little's law does not apply for all these systems. We also discuss the consequences of this classification on systems' characteristics.

3 - Improving the Uefa Champions League Schedule: a Mathematical Model Reducing Breaks from 64 to 4

Nasser Salmasi, SimpleRose, Wilmington, NC, United States

In the new format of the UEFA Champions League, 32 teams compete in a league phase comprising eight rounds, with each team playing one match per round. This study presents a very efficient mathematical optimization model designed to minimize the number of breaks during this phase, while accommodating the relevant constraints.

Applied to the 2024–25 season, the proposed model produces a schedule with only four total breaks—substantially improving upon the official schedule, which contains 62 breaks.

4 - An Application of Self-Organizing Subspace Clustering for Soccer Player Scouting

wenyong xu, Purdue University, West Lafayette, IN, United States, Nga Hin Ben Fong

Subspace clustering or Projective clustering are commonly used in sports data analytics due to their ability to handle high-dimensional player attributes and identify athlete types with different skill combinations. However, most algorithms only focus on linear relationships, and most of the time neglect the non-linear relationships such as interactive effects between attributes (e.g., how speed and acceleration combine multiplicatively) or threshold effects where performance reaches saturation. This study proposes an enhanced self-organizing subspace clustering algorithm that extends traditional self-organizing maps by incorporating deep feature learning layers. The multi-layer architecture first transforms player attributes through deep neural networks to capture complex non-linear interactions, then applies self-organizing map principles with adaptive subspace selection in the learned representation. Given a prototype player, our method identifies the relevant subspace for that player type with budget consideration and recommends similar players by computing distances in the learned non-linear subspace, while visualizing results in an intuitive 2D map with topological features. Our self-organizing subspace clustering algorithm could be effective in making sports-informed decisions by providing coaches and analysts with both accurate player comparisons and visually interpretable insights into what makes players similar, enabling efficient scouting and talent identification from massive player databases containing millions of potential candidates worldwide.

5 - Data-Driven Product Assortment Optimization Under Consumer Return Risk

Dan Dan Guo, University of Science and Technology of China, Hefei, China, People's Republic of

Fast fashion retailers face growing challenges due to high product return rates, short product life cycles, and increasingly volatile consumer preferences. While returns significantly erode revenue and increase operational costs, assortment decisions often continue to rely on heuristics or historical sales data. To address this gap, we propose a data-driven framework for assortment planning that jointly evaluates product attractiveness and return risk. By linking observable product attributes—such as style, color, and fabric—to both sales performance and returns, our approach enables more informed and profitable decision-making. Integrating feature-level predictions into the assortment optimization process, the framework aims to enhance revenue while mitigating the operational impact of returns.

6 - On the Design and Pricing of Add-On Services

Sreya Kolay, University at Albany, SUNY, Albany, NY, United States

Many firms offer add-on services to complement their core product or service. This paper examines how a firm should price such add-on services, and specifically whether to bundle or unbundle an add-on service with the core product. We find that this decision depends on the nature of the add-on service, i.e. whether its impact varies by customer type or by the quality of the core product, as well as whether the cost of providing the add-on service is incurred as a fixed or variable cost. We also extend the analysis to a product line of two products of varying quality and consider whether the add-on service is provided bundled or unbundled with the entire product line or with one of the products.

7 - Designing Fair Systems: Lessons from Gender Disparities in Competitive Settings

Hiroko Okajima, Nagoya University, Nagoya, Japan, Shigeharu Okajima, Tsuyoshi Nihonsugi, Yoshio Kamijo

This study explores how competition design influences gender differences in performance, using data from professional boat racing in Japan. The sport offers a natural setting in which men and women compete under two types of race formats: standard races, where racers make strategic maneuvers during the race, and fixed-lane races, where competitors are assigned a fixed course, minimizing interaction and emphasizing individual skill.

The analysis finds that in mixed-gender standard races, female racers perform worse than in single-gender settings, while male racers improve. However, in fixed-lane races, no significant gender performance gap is observed. This suggests that the performance decline among women is not due to inherent ability differences, but rather the strategic nature of the competition. When races involve high levels of tactical interaction, gender disparities emerge; when strategy is minimized, the gap disappears.

These findings imply that competitive environments themselves can produce performance gaps across genders. Rather than reflecting innate differences, such disparities may stem from how individuals engage with competitive pressures, expectations, or norms embedded in the structure of the contest.

By highlighting the role of competition design, this study contributes to broader discussions about gender equity in performance-based domains. The insights extend beyond sports to settings like education and workplaces, where strategic dynamics may similarly affect outcomes. Carefully designing systems to minimize unnecessary competitive complexity may promote more equitable opportunities for all individuals.

Co-Chair: Junfei Huang, The Chinese University of Hong Kong, Shatin, Hong Kong

1 - An Analytical Framework for Assessing the Impact of Policy Changes to the Kidney Allocation System in the US Under Endogenous Patient Choice

Yuwei Zhou, Indiana University, Bloomington, IN, United States, Baris Ata, John Friedewald, Cem Randa, Yue Hu

This paper develops a modeling framework for assessing the impact of policy changes to the deceased-donor kidney allocation system analytically. To do so, we formulate two models as building blocks: a fluid model of the transplant registry and a model of organ availability and geographic sharing. Both models incorporate the dynamic structural model of transplant candidates' accept/reject decisions for organ offers developed in Ata et al. (2020). They also incorporate important features of the kidney allocation system such as patient and donor heterogeneity, the degree of tissue matching, changes in the health status of transplant candidates as they wait, organ quality, cold-ischemia time as well as the geographical sharing structure. Combining the two models, we develop an equilibrium framework and prove that the equilibrium exists. The equilibrium characterization leads to efficient computations for counterfactual studies regarding possible changes to the kidney allocation system that have been considered by policy makers. In particular, we characterize the new system performance, e.g., the wastage, the waiting times for various patient demographics, and the composition of the transplant waitlist after the policy change. Our counterfactual studies rely on transplant data from 2007-2010 and we compare various allocation policies with the policy that was in effect prior to December 2014.

2 - Community Responder Crowdsourcing for Time-Sensitive Medical Emergencies

Weiliang Liu, University of Chicago Booth School of Business, Chicago, IL, United States, Timothy Chan

In parallel with traditional ambulance dispatch, community first responder (CFR) systems utilize mobile applications to locate and alert nearby registered volunteers (i.e., community responders) for rapid intervention in time-sensitive medical emergencies. A crucial decision is the strategic determination of alert recipients and timings. Insufficient alerts risk delayed intervention, while excessive alerts can reduce future responder engagement. This problem is challenging due to the heterogeneity and uncertainty in responders' behavior, which cannot be precisely predicted. Current CFR systems rely on ad-hoc rules for alert decisions.

In this paper, we develop a dynamic programming (DP) approach to model the alert decision problem and a model predictive control (MPC) algorithm that can generate high-quality solutions very quickly. Our MPC alert policy maintains the optimal DP policy's structure while challenging existing alert rules. Unlike existing rules that expand the alert radius over time, both our MPC policy and optimal DP policy strategically narrow the responder pool for consideration as time progresses. Our numerical studies reveal further limitations of existing rules: 1) Many CFR systems issue all alerts at the start, ignoring different travel times, response probabilities, and real-time behavior of responders. However, the optimal number of initial alerts is typically small and varies according to responder characteristics; 2) The common practice of alerting the nearest responders first is not always optimal. An optimal strategy might alert a more distant responder if the higher probability of alert acceptance outweighs the longer travel time. Our simulations using real-world data validate the superiority of our MPC policy.

3 - From Frustration to Engagement: the Role of Ancillary Services in a Queue

Baolong Liu, ShanghaiTech University, Shanghai, China, People's Republic of, Yang Li, Rowan Wang

Waiting in queues often frustrates customers, reduces service provider profits, and diminishes social welfare. Traditional queue management strategies address these issues either by reducing congestion or redistributing waiting costs, but often overlook opportunities to enhance the waiting experience itself. This paper studies an alternative approach: providing ancillary services that create additional customer value during the wait. We explore a fundamental trade-off: while ancillary services improve customer experience, they may also attract more customers and exacerbate congestion. We develop a game-theoretical queueing model featuring two customer segments: Type-P customers, who value only the primary service, and Type-A customers, who derive additional utility from an ancillary service while waiting. Contrary to conventional intuition, our analysis reveals that ancillary services deliver the greatest benefits precisely when primary service capacity is most constrained. Although ancillary services increase overall congestion, they induce customer self-segmentation: Type-P customers, facing higher delays, exit the system and are replaced by Type-A customers who value the enriched waiting experience. This substitution effect enhances system throughput, improves customer surplus, and increases provider profit. We further compare ancillary services to priority queues and show that ancillary services consistently generate higher throughput and, under broad conditions, deliver superior outcomes in terms of profit and social welfare. The results suggest that service providers, especially those operating under capacity constraints, can benefit from implementing ancillary services. By offering value-added experiences during the wait, providers can strategically reshape customer composition, improving throughput and customer welfare without expanding capacity.

4 - The Ergodic Properties and Invariant Measure of a Two-Dimensional Reflected Ornstein-Uhlenbeck Process

Dongzhou Huang, Colorado State University, Fort Collins, CO, United States, Guodong Pang

We consider a two-dimensional reflected Ornstein-Uhlenbeck (ROU) process, that arises as the diffusion approximation for a parallel server network with a randomly split Hawkes arrival process (or a multivariate Hawkes arrival process) in heavy traffic. We study the ergodic properties of the process, including positive recurrence, and rates of convergence in both the total variation distance and the Wasserstein distance. We also provide a numerical scheme based on a Monte-Carlo method to approximate the invariant measure of the process.

Advances in Sustainable Operations

Invited Session

MSOM: Supply Chain

Chair: Tao Lu, University of Connecticut, Storrs, CT, United States

Co-Chair: Sina Khorasani, Vanderbilt University, Nashville, TN, United States

1 - Does Sustainability Certification Promote Sustainability Investment?

Yurong Liang, Wuhan University, Wuhan, China, People's Republic of, Bin Dai, Tao Lu

While widely acknowledged as a market signaling mechanism, sustainability certification also critically functions as an internal governance tool, enabling firms to reduce their exposure to regulatory and reputation penalties. Although these dual effects—risk mitigation and market signaling—are individually recognized, their strategic interplay and collective influence on a firm's fundamental sustainability investment decisions have been less systematically examined. Notably, the incentives generated by these roles may diverge: information from certification could prompt investment scale-back or market exit due to high costs, even as its signaling value encourages increased investment. In this study, we develop a game-theoretic model to investigate how these strategic considerations interact to shape firms' investment behavior, further exploring the firm's trade-offs concerning certification costs, potential reputation gains, and market demand elasticity.

2 - The Impact of Planogram Design and Display Fees on Retail Category Management

Alper Nakkas, The University of Texas at Arlington, Arlington, TX, United States, Yasin Alan, Mumin Kurtulus

We study the impact of planogram design (i.e., placement of products on shelves) and display fees (i.e., fees manufacturers pay retailers for prime shelf space) on a retailer's category management strategy and interactions with national brand manufacturers (NBMs). We consider a game-theoretic model with one retailer and multiple NBMs. Each NBM offers one product. In addition, the retailer has the option to carry a store brand (SB) product. The NBMs determine their wholesale prices and how much they are willing to pay for the prime shelf space. The retailer not only makes assortment and planogram decisions but also sets the quantities for each product in its assortment, leading to market-clearing retail prices. Our analysis leads to three key findings: First, the presence of prime shelf space affects the retail and wholesale prices in the category and may even require the retailer to change its assortment. Second, there are cases in which the retailer uses SB introduction as a strategic lever to intensify the competition for the prime shelf space and thereby increase its revenue from display fees. Third, despite being an additional expense, display fees can increase the NBMs' profits by allowing them to influence the retailer's assortment and planogram decisions in their favor. We discuss the implications of these findings for managers and researchers.

3 - Sustainable Management of a Water Reservoir System Facing Climate Uncertainty

Martin Glanzer, University of Mannheim Business School, Mannheim, Germany, Felipe Caro, Kumar Rajaram

Water scarcity is a growing global issue. It affects even highly developed regions like California, the world's fifth largest economy, where years of severe droughts interspersed with unusually wet seasons have caused societal debates over the management of the water resources stored in the state's extensive reservoir system. This talk presents a strategic optimization model for the long-term, sustainable management of such a system. Introducing a new modeling paradigm based on cycles of stochastic length, defined by the event when all reservoirs are simultaneously full, we avoid the limitations of traditional models and obtain sustainable management policies. To address the unpredictable effect of climate change on future water supply, we adopt a distributionally robust framework where nature chooses adverse inflow distributions. This leads to a stochastic shortest path problem under distributional ambiguity. Using tools from stochastic dynamic programming and aggregation methods, we obtain policy insights and overcome the curse of dimensionality typically associated with systems models. We illustrate our approach with a case study of California's Sacramento River Basin, where we find suboptimality gaps between 3% and 15%, and show that our sustainable policy reduces average cycle shortage costs by 40% compared to the current policy, demonstrating the significant cost-saving potential of our framework.

4 - Optimal Product Return Insurance

Paolo Letizia, University of Tennessee, Knoxville, TN, United States, Gokce Esenduran, Anton Ovchinnikov

In response to the rising cost of returns, some firms have eliminated free return policies, instead offering customers the option to purchase return insurance. This insurance enables customers to return items and receive a refund. It can be offered by either the firm or an external insurer and purchased by the customer either before or after buying the product. We examine these scenarios to determine how to optimally design both the return policy and the insurance structure.

5 - Mergers of Consumer Cooperatives

Sina Khorasani, Vanderbilt University, Nashville, TN, United States, Cigdem Gizem Korpeoglu

We study consumer cooperatives that aim to achieve buyer power and maximize their member-consumers' welfare (rather than profits). We derive conditions under which mergers of consumer cooperatives benefit or harm their member consumers.

Technology-Enabled Service Operations

Invited Session

MSOM: Service Operations

Chair: Wilson Lin, Santa Clara University, Santa Clara, CA, United States

1 - To Digitalize or Not? the Stress Implications of Digital Transformation

Michela Carraro, NEOMA Business School, Reims, France, David Wuttke, Mrunal Mohadikar, Ankit Uphadhyay, Enno Siemsen, Alexandra Wuttke

Chronic stress is a growing concern in operations, especially as workers face pressure to adapt to new tasks under tight deadlines. Digital technologies like augmented reality (AR) promise to reduce this burden, but little is known about their actual impact on worker stress—particularly when such tools are later withdrawn. Building on Conservation of Resources theory, we examine how the availability of digital and traditional resources affects stress in operational tasks. Across three lab studies using both biological (cortisol) and subjective (perceived) stress measures, we find that use of AR reduces stress in both simple and learning-intensive tasks. However, while AR and traditional resources perform similarly in tasks without learning, the removal of AR in learning contexts triggers a sharp increase in physiological stress—whereas removing traditional support does not. Transitioning from digital to traditional resources is equally disruptive, yielding stress levels comparable to a complete loss of support. These findings reveal that while digital tools can ease stress in the short term, they may also undermine resilience if withdrawn later. Our study offers a new lens on the socio-technical tradeoffs of digital transformation in operations and provides actionable insights for technology adoption strategies.

2 - Algorithm-Enabled Decision Support and Worker Learning: A Large-Scale Field Experiment

Youngsoo Kim, Loyola University Chicago, Chicago, IL, United States, Benjamin Knight, Dmitry Mitrofanov, Yuqian Xu

While algorithmic decision support tools are increasingly adopted in workplaces and often deliver immediate performance gains, their long-term impact on workers' learning remains unclear. This paper explores how algorithm-enabled decision support affects learning dynamics through a large-scale randomized field experiment on the Instacart platform. Workers were randomly assigned to a treatment group with algorithmic support or a control group without it. Results show that access to the tool improved immediate productivity (e.g., picking times) and quality (e.g., refund rates). However, reliance on these tools dampened learning from repeated experience, suggesting reduced opportunities for hands-on problem-solving. We also examine how workers perform once algorithmic support is withdrawn. Those previously exposed to the tool initially experienced a productivity drop but then learned more quickly, implying potential for deeper cognitive development if algorithm use is well managed. Heterogeneity analyses reveal that workers with more prior experience or similar background tasks exhibit less learning substitution and gain more from prior exposure to algorithmic tools. Additionally, algorithmic support has stronger learning benefits in urban settings, pointing to a possible rural-urban divide in tool effectiveness. Overall, our findings suggest that while algorithmic tools can enhance short-term performance, their design and implementation must be carefully managed to avoid undermining long-term skill development. Striking the right balance between automation and learning is key to sustainable workforce performance in an increasingly algorithm-driven world.

3 - Human-in-the-Loop Optimization for AI-Generated Content

Fan ZHANG, University of Oxford, skokie, IL, United States

Artificial intelligence (AI) has revolutionized content creation workflows, yet the cognitive principles underlying effective human-AI collaboration remain poorly understood. This study investigates when human feedback most effectively complements AI processing in collaborative content creation. Using a controlled experimental design with 120 content professionals, we systematically varied human intervention timing across three stages: conceptualization, organization, and refinement. Results demonstrate that human intervention at the organization stage produces significantly higher quality content compared to earlier or later interventions. This advantage reflects cognitive complementarity principles where human analytical reasoning optimally enhances AI-gathered information before narrative structuring. The pattern is explained by three mechanisms: intermediate state processing advantage, dual-process cognitive integration, and reciprocal cognitive scaffolding. These findings establish foundational principles for human-AI cognitive collaboration that extend beyond content creation to domains including medical diagnosis, scientific discovery, and education.

Emerging Challenges and Opportunities in Sustainable Operations

Invited Session

MSOM: Sustainable Operations

Chair: Arzum Akkas, University of Massachusetts Amherst, Amherst, MA, United States

1 - Boosting Sales and Customer Welfare from Premade Foods (Let the Freshest Chicken Fly off the Shelf First)

Dan Iancu, Stanford Graduate School of Business, Stanford, CA, United States, Jaehyuck Park, Erica Plambeck

We examine a grocery retailer's management of a premade food product. The retailer's goal is to maximize a weighted sum of direct profit and customer welfare. Multiple items of the product are produced in batches, and immediately displayed for sale. Considering that each item's quality decreases while it sits on the shelf, the retailer chooses the shelf life, whether to issue items in FIFO or LIFO order, whether to timestamp items, and how to price items. We find that the retailer should use LIFO issuance and timestamp items only if customers are sufficiently heterogeneous. By extending the model, we identify several features -- such as a holding cost, upper bound on the shelf life, age-dependent disposal cost, or customer risk- or loss-aversion -- that can make FIFO optimal. Lastly, we show how a mandate to donate unsold food items (as implemented in several jurisdictions) can motivate a retailer to increase the shelf life, thereby reducing the quality and quantity of donated items.

2 - Achieving Rawlsian Justice in Food Rescue

Gerdus Benade, Boston University, Boston, MA, United States, Aydin Alptekinoglu

We study a problem faced by a national food rescue platform that matches each donation to the first recipient who claims it. Recipients have very different response rates, leading to a few highly responsive recipients claiming the bulk of the donations. We ask whether priority lists, which control when the donation is announced to each recipient, are a remedy for inequitable outcomes. We show that an n-stage priority list, with an individual notification time specific to each eligible recipient, can achieve any desired expected allocation, hence any fairness target, if the donation is non-perishable. Two-stage or binary priority lists, which notify eligible recipients in only two waves, are simpler to implement and administer but offer less fine-grained control over fairness outcomes. For both perishable and non-perishable donations, we give polynomial-time algorithms to find the n-stage and binary priority lists that optimize a class of Rawlsian objective functions -- maximize the minimum value -- representing a notion of fairness that focuses on the worst-off. The key insight that animates optimal priority list design throughout is to give higher priority (and thus more time to claim a donation) to recipients who have received less in the past and to those who were slower in responding to notifications. We prove that this idea can be codified into a simple index by which to rank order eligible recipients. Computational experiments calibrated by real data confirm that even simple, binary priority lists lead to significantly more fair allocations than the existing first-come-first-serve allocation system.

3 - From Deals to Dumps: the Effect of Promotions on Food Waste in Retail

Alexander Hübner, Technical University of Munich, Straubing, Germany, Konstantin Wink, Fabian Schäfer, Sebastian Georg

This study explores the overlooked connection between promotional activities and food waste in grocery retailing. While promotions are widely used to boost sales and store traffic, their unintended consequences on food waste have not been empirically analyzed until now. Drawing on extensive panel data from a major European retail chain—covering 414 products, 173 stores, and over 65,000 promotion events—this research demonstrates that promotions significantly increase food waste. On average, the waste rate doubles from about 2% to 4%, with short-shelf-life products experiencing up to a fivefold rise. The study also identifies cannibalization as a key factor, with nearly half the tested product groups showing increased waste due to sales being shifted from non-promoted to promoted items. Through counterfactual analysis, we estimate that food waste could be reduced by up to 9% if retailers optimize promotion strategies. This includes discontinuing promotions that fail to generate sales uplift, focusing on items with longer shelf lives, and minimizing promotions with strong cannibalization effects. The findings highlight a critical but often ignored trade-off between marketing objectives and sustainability goals. By showing a direct causal link between promotions and food waste, the paper emphasizes the need for a more integrated approach to promotions and operations planning. This work provides practical insights for retailers aiming to balance profitability with environmental responsibility, urging a shift toward more sustainable promotional practices.

4 - Coordination Contracts for Perishable Products with Returns: Models and Challenges

Ulku Gurler, Wharton School, Philadelphia, PA, Turkey, Emre Berk, M. Ali Ulku

Freshness of perishable products, is affected by the floor operations at a store, including produce handling, stocking, and improper ventilation of storage and display areas for ethylene-sensitive products. Poor in-store handling of the product leads to product returns after customer purchase, resulting in additional tangible and intangible costs for both parties. The supplier's brand and overall market share may suffer greatly due to local retailer-specific customer dissatisfaction. Perishability caused by floor operations can be improved with investments in physical infrastructure as well as training and changes in handling practices. Due to the disparities between suppliers and retailers in terms of capital resources, expertise, and market awareness, the centralized and decentralized decisions regarding the optimal level of investment for improvement may differ. Furthermore, store conditions and practices can be difficult and costly for suppliers to monitor and enforce. Therefore, there is a need to better understand the economic coordination mechanisms suitable for such settings. To that end, we consider a dyadic supply chain for a perishable product consisting of a Supplier and a Retailer under several types of coordinating contracts, where we incorporate payments based on the level of freshness-dependent customer returns into the contract design. We provide some analytical results on optimality in various models. Among the issues we discuss in this talk are (i) the conditions under which coordination can exist, (ii) fairness of the profit- / costsharing mechanisms, (iii) optimal levels of investment by different actors, (iv) impact of asymmetry of information, and the challenges in implementation.

5 - Price-Sensitive Supply: the Role of Uncertainty on Acquisition Pricing

Itir Karaesmen, American University, Washington, DC, United States, Ozden Cakici

We study the decisions of a procurement agent who engages with suppliers (markets) to procure a good. The agent decides on the acquisition prices, the unit cost for procuring the good from the markets. The supply is price sensitive and the quantity procured is known after the acquisition price(s) is (are) set. This is typical in remanufacturing where used products are bought from end users. First, we formulate the agent's decision problem as a newsvendor problem in a single market. We analyze the agent's decision on optimal acquisition price first and study the impact of problem parameters and uncertainty (noise) on the optimal acquisition price(s). We show that the agent may or may not increase the acquisition price as market uncertainty increases. However, we show that the acquisition price is monotonic in the noise when the noise changes according to a particular stochastic order that we call "acquisition price-sensitivity ratio". Then, for the two-market case, we provide conditions under which it is optimal for the agent to diversify and procure from both markets. We show that minimum acceptable acquisition prices in each market constrain diversification, preventing buyers from lowering total procurement costs by sourcing smaller quantities at lower prices across multiple markets. In addition, when markets differ in risk, optimal acquisition prices tilt toward the reliable market, though diversification may still occur. The agent should take advantage of diversification to pool risks and to lower unit procurement costs. However, diversification may not be optimal even when the markets are identical.

Design and Analysis of Niche and Emerging Markets

Invited Session

Revenue Management

Chair: Craig Fernandes, University of Toronto, Toronto, ON, Canada

Co-Chair: Raghav Singal, Tuck School of Business at Dartmouth, Hanover, NH, United States

1 - Optimal Capacity and Price Designs Under Ex Ante and Ex Post Theft

Mingliu Chen, The University of Texas at Dallas, Richardson, TX, United States, Feng Tian, Ruiting Zuo

Internal theft poses a significant challenge in retail firms' operations. Owing to a lack of effective monitoring tools, a firm cannot observe every action in daily operations from its employees, providing room for wrongdoings, such as capacity and cash stealing. A common practice is to increase the price of goods to offset the loss in revenue due to the increasing threat of theft. However, we show that such practices are not optimal. We model the internal theft problem in retailing as a principal-agent model, where the principal (firm) contracts an agent (retail manager) for capacity planning and daily sales. The agent is subject to moral hazard and may steal the capacity before demand realization or steal the sales revenue after demand realization. We solve for the optimal capacity, price, and agent's commission decisions to maximize the

principal's utility. We find that capacity and price decisions are not monotone in terms of the severity of moral hazards. In particular, the principal should first decrease and then increase (increase and then decrease) the price (the capacity) when ex post stealing becomes more prevalent. Simply increasing retail prices and shifting the margin to consumers to combat loss in revenue caused by internal theft can amplify the agency problem in some scenarios since it leads to a significant loss in demand and insufficient commission to the agent. Finally, we investigate the sensitivities of price and capacity decisions to demand uncertainties in the presence of moral hazard.

2 - Hiring Under Congestion and Algorithmic Monoculture: Value of Strategic Behavior

Shihan Chen, University of Pennsylvania, Philadelphia, PA, United States, Jackie Baek, Hamsa Bastani

We study the impact of strategic behavior in a setting where firms compete to hire a shared pool of applicants, and firms use a common algorithm to evaluate the applicants. Each applicant is associated with a score that is observed by all firms, provided by the algorithm. Firms simultaneously make interview decisions, where the number of interviews is capacity-constrained. Job offers are given to those who pass the interview, and an applicant who receives multiple offers accept one of them uniformly at random. We fully characterize the set of Nash equilibria under this model. Defining social welfare as the total number of applicants hired, we then compare the social welfare at a Nash equilibrium to a naive baseline where all firms interview the highest-scoring applicants. We show that the Nash equilibrium greatly improves upon social welfare compared to the naive baseline. In addition, the price of anarchy is small, providing further appeal for the equilibrium. We also show that when firms make interview decisions sequentially and each firm takes the best response action, this process converges to an equilibrium when interview capacities are small. However, we show that the task of computing the best response is difficult if firms have to use its own historical samples to estimate it, while this task becomes trivial if firms have information on the degree of competition for each applicant. Therefore, converging to an equilibrium can be greatly facilitated if firms have information on the level of competition for each applicant.

3 - Multi-Armed Bandit Design of Default Donations

Muzhi Ma, University of California, Los Angeles, Los Angeles, CA, United States, Francisco Castro, Scott Rodilitz

The increasing importance of online donations in charitable giving underscores the need for nonprofits to design effective default donation menus that maximize revenue. Despite the widespread use of such menus, considerable debate persists over how to set default amounts to optimize donations. The primary challenge is the vast number of possible menu configurations, which makes identifying the optimal one complex and resource-intensive. To address this, we present a novel approach using a multi-armed bandit (MAB) framework. We model the problem in a bandit setting, where each default menu serves as an "arm" and the rewards correspond to observed donation amounts. We then reformulate the problem as an online longest path problem in a directed acyclic graph (DAG), enabling an approach with minimal assumptions about donor behavior. Furthermore, we transform the problem into a linear bandit setting and implement the Optimism in the Face of Uncertainty for Linear bandits (OFUL) algorithm. In addition, we also develop a misspecified linear bandit algorithm that addresses scenarios where the reward structure is nonlinear and standard linear bandit methods fail, achieving a sublinear regret bound when the maximum misspecification error is correctly estimated. This research offers a robust, model-independent framework that nonprofit organizations can adopt to enhance their online fundraising strategies, minimizing experimental costs while maximizing revenue.

4 - Peer Review Market Design: Effort-Based Matching and Admission Control

Raghav Singal, Tuck School of Business at Dartmouth, Hanover, NH, United States

Peer review is fundamental to academic research, yet its effectiveness relies on reviewers voluntarily exerting costly effort. Current conference mechanisms, such as affinity-based matching, fail to properly incentivize effort, leading to suboptimal outcomes. This study examines how peer review markets can be designed to maximize high-quality acceptances while minimizing low-quality ones. We model a one-sided market where each agent acts as both an author and a reviewer, submitting papers of private quality and deciding whether to exert effort when reviewing. The conference organizer matches papers to reviewers, aiming to optimize market welfare. We first analyze a mechanism that mirrors current practice, denoted Random, which does not link the agents' dual roles. Next, we analyze a Symmetric mechanism, which segments the market based on agents' effort levels. We show that both mechanisms can perform arbitrarily poorly: Random induces no effort, while Symmetric, though an improvement, can be exploited by low-quality authors. To address these issues, we propose Admission Control (AC), which penalizes reviewers who fail to exert effort by rejecting their submissions. Under perfectly observable effort, AC achieves first-best welfare. When effort is noisily observed, AC uses stochastic penalties to ensure incentive compatibility and guarantees at least 1/2-optimal welfare, with simulations demonstrating stronger performance. Robustness analyses confirm the superiority of AC across various extensions, including noisy review outcomes, author biases, and status disclosures through preprints. Our findings highlight the importance of linking the roles of author and reviewer and conclude with actionable strategies for improving peer review markets.

Causal Inference for Social Systems

Invited Session

Revenue Management

Chair: Hannah Li, Columbia, New York, NY, United States

1 - Double Machine Learning for Causal Inference Under Shared-State Interference

Chris Hays, MIT, Cambridge, MA, United States, Manish Raghavan

Researchers and practitioners often wish to measure treatment effects in settings where units interact via markets and recommendation systems. In these settings, units are affected by certain shared states, like prices, algorithmic recommendations or social signals. We formalize this structure, calling it shared-state interference, and argue that our formulation captures many relevant applied settings. Our key modeling assumption is that individuals' potential outcomes are independent conditional on the shared state. We then prove an extension of a double machine learning (DML) theorem providing conditions for achieving efficient inference under shared-state interference. We also instantiate our general theorem in several models of interest where it is possible to efficiently estimate the average direct effect (ADE) or global average treatment effect (GATE).

2 - Discretion in the Loop: Human Expertise in Algorithm-Assisted Decisions

Lydia Liu, Princeton University, Princeton, NJ, United States

As algorithmic decision systems become increasingly integrated into high-stakes domains like education, understanding their real-world impact requires moving beyond predictive accuracy. This talk bridges AI and human expertise through the lens of causal inference and decision-making. We combine causal theory with empirical analyses of a randomized controlled trial of algorithm-assisted college advising to investigate how advisors use discretion to target interventions. We introduce a notion of non-algorithmic expert interventions based on structural causal modeling and develop a quantitative and qualitative framework to test for the value of human judgment in algorithm-supported contexts. Then, we explore how human behavioral responses to predictive models can shape outcomes in experimental evaluations of ADS. We show that design choices may induce cognitive biases and distort treatment effect estimates. Together, these studies highlight the importance of modeling both human behavior and causal mechanisms when deploying and evaluating AI systems for decision making in the real world. Based on joint work with Inioluwa Deborahaji Raji, Sofia Druchyna, Kara Schechtman, and Hannah Li.

3 - Leveraging Causal Inference for Achieving Human&Ndash;Algorithm Complementarity

Jann Spiess, Stanford GSB, Stanford, CA, United States, Bryce McLaughlin

We formulate an algorithmic-design problem that leverages the potential-outcomes framework from causal inference to achieve human–algorithm complementarity without making restrictive ex-ante assumptions about how algorithmic recommendations affect human decisions. We showcase the utility of our framework using an online experiment that simulates a hiring task. We argue that our approach can make sense of the relative performance of different recommendation algorithms and can help design solutions that realize human-AI complementarity. Finally, we leverage our approach to derive minimax optimal recommendation algorithms that can be implemented with machine learning using limited training data.

Building B Level 3 B314

Advances in Mechanism Design

Invited Session

Revenue Management

Chair: Shixin Wang, Georgia Institute of Technology, Atlanta, GA, N/A, United States

1 - An Isotonic Mechanism for Overlapping Ownership**Jibang Wu, University of Chicago, Chicago, IL, United States**, Haifeng Xu, Yifan Guo, Weijie Su

This paper designs a simple, efficient and truthful mechanism to improve the peer review at large scientific conferences where papers often have multiple authors and authors have multiple papers. The mechanism elicits self-evaluations from authors and leverages this new source of review data to complement traditional peer reviews, notably striking a balance between statistical efficiency and incentive compatibility.

Our approach starts by partitioning conference submissions into disjoint blocks, each sharing a common set of co-authors. We then elicit the ranking of submissions from each author and employ isotonic regression to produce adjusted review scores, aligning with both the reported rankings and raw review scores. We prove that truth-telling by all authors is a payoff dominant Nash equilibrium for any valid partition of the overlapping ownership sets under natural conditions. Moreover, the truthfulness depends on eliciting rankings independently within each block, making block partition optimization crucial for improving statistical efficiency. Despite being computationally intractable in general, we develop a nearly linear-time greedy algorithm that provably finds a performant block partition with appealing robust approximation guarantees. Extensive experiments on both synthetic data and real-world conference review data demonstrate the effectiveness of our mechanism in practical settings.

2 - Optimal Procurement when Bidders Receive Competing Offers**Justin Burkett, Georgia Institute of Technology, Atlanta, GA, United States**, Anton Kleywegt

We study the problem faced by a buyer charged with procuring a service from one of many potential sellers on an online platform before a deadline. The primary challenge faced by the buyer is that the sellers' costs of providing the service evolve over time, as the sellers are assumed to collect stochastic outside offers from competing platforms as time passes. We show that the optimal mechanism for the buyer in this setting interacts with the sellers at just the first and the last time period. In the first period, the sellers pre-purchase a bid for an auction to be run in the last period. In the last period, the sellers each have the opportunity to adjust their bid upwards (to reflect an increase in their costs) before the auction is run. We discuss the potential application of this mechanism to various industries, including marketplaces for truckload transportation and short-term jobs.

3 - Multi-Item Robust Screening with a Maximin-Ratio Objective**Shixin Wang, The Chinese University of Hong Kong, Hong Kong, Hong Kong**

It is generally challenging to characterize the optimal selling mechanism even when the seller knows the buyer's valuation distributions in multi-item screening. A key insight from the robust mechanism design literature is that when only marginal distributions are known, separate selling is robustly optimal under the maximin revenue objective. However, its performance ratio relative to the fully optimal mechanism can be low. In this work, we address robust screening with a maximin ratio objective. We show that when the marginal support of valuations is known, the optimal mechanism remains a separable mechanism, where each item's allocation probability and payment depend only on that item's valuation. Crucially, we refine the allocation and payment rules by leveraging the available joint support information. This separable mechanism can be implemented through randomized pricing for each product individually, ensuring interpretability, ease of implementation, and strong performance. Our framework also applies to settings where the seller knows marginal support information for aggregate product bundle valuations in any partition of the product set. Beyond the independent support ambiguity set, our approach further demonstrates the optimality of randomized bundling mechanisms under a broad class of ambiguity sets.

4 - Robust Pricing for Cloud Computing**Rahul Deb, Boston College, Toronto, ON, Canada**, Dirk Bergemann

We study the robust sequential screening problem of a monopolist seller of multiple cloud computing services facing a buyer who has private information about his demand distribution for these services. At the time of contracting, the buyer knows the distribution of his demand of various services and the seller simply knows the mean of the buyer's total demand. We show that a simple "committed spend mechanism": it provides the seller with the highest profit guarantee against all demand distributions that have the known total mean demand. This mechanism requires the buyer to commit to a minimum total usage and a corresponding base payment; the buyer can choose the individual quantities of each service and is free to consume additional units (over the committed total usage) at a fixed marginal price. This result provides theoretical support for prevalent cloud computing pricing practices while highlighting the robustness of simple pricing schemes in environments with complex uncertainty.

Building B Level 3 B315

Robust and Responsible Market Design

Invited Session

Auctions and Market Design

Chair: Juba Ziani, Georgia Tech, Atlanta, GA, United States

1 - Centralization Vs Decentralization in Hiring and Admissions**Diptangshu Sen, Georgia Institute of Technology, Atlanta, GA, United States**, Benjamin Fish, Juba Ziani

There is a range of ways to organize hiring and admissions in higher education, as in many domains, ranging from very centralized processes where a single person makes final decisions to very decentralized processes where many people make decisions about who to admit or hire. Decentralized processes can enable individual and collective empowerment, but this may come at the cost of efficiency. With the advent of automated decision making, this question of centralization has a big impact on hiring and admissions, given that automated systems often are easier to implement, or even require, more centralized decision making.

In this paper, we develop a strategic model to explore the impact of the degree of centralization on both the candidates and the hirers, with a focus on university admissions. The model reflects a trade-off between a centralized committee where preferences may not capture individual hirers' preferences, and a decentralized process where individual hirers face extra costs to interview candidates themselves. We characterize when individual hirers prefer the decentralized process over the centralized process as a function of the degree to which the centralized process and hirers' preferences are aligned. We also show that decentralization can have devastating consequences for fairness, leading to major disparities in the likelihood of getting hired across candidates. Our results demonstrate the trade-offs that occur under the question of centralization vs decentralization, and point to how an answer to this question can impose significant harm to people in these systems.

2 - User Altruism in Recommendation Systems**Ekaterina Fedorova, MIT, Cambridge, MA, United States**, Madeline Kitch, Chara Podimata

Users of social media platforms based on recommendation systems (RecSys) (e.g. TikTok, X, YouTube) strategically interact with platform content to influence future recommendations. On some such platforms, users have been documented to form large-scale grassroots movements encouraging others to purposefully interact with algorithmically suppressed content in order to "boost" its recommendation; we term this behavior user altruism. To capture this behavior, we study a game between users and a RecSys, where users provide the RecSys (potentially manipulated) preferences over the contents available to them, and the RecSys—limited by data and

computation constraints---creates a low-rank approximation preference matrix, and ultimately provides each user her (approximately) most-preferred item. We compare the users' social welfare under truthful preference reporting and under a class of strategies capturing user altruism. In our theoretical analysis, we provide sufficient conditions to ensure strict increases in user social welfare under user altruism, and provide an algorithm to find an effective altruistic strategy. Interestingly, we show that for commonly assumed recommender utility functions, effectively altruistic strategies also improve the utility of the RecSys! We show that our results are robust to several model misspecifications, thus strengthening our conclusions. Our theoretical analysis is complemented by empirical results of effective altruistic strategies on the GoodReads dataset, and an online survey on how real-world users behave altruistically in RecSys. Overall, our findings serve as a proof-of-concept of the reasons why traditional RecSys may incentivize users to form collectives and/or follow altruistic strategies when interacting with them.

3 - Incentivizing Desirable Effort Profiles In Strategic Classification: the Role of Causality and Uncertainty

Vasiliki Efthymiou, Massachusetts Institute Of Technology, Boston, MA, United States, Chara Podimata, Juba Ziani

We study strategic classification in binary decision-making settings where agents can modify their features in order to improve their classification outcomes. Importantly, our work considers the causal structure across different features, acknowledging that effort in a given feature may affect other features. The main goal of our work is to understand **when and how much agent effort is invested towards desirable features**, and how this is influenced by the deployed classifier, the causal structure of the agent's features, their ability to modify them, and the information available to the agent about the classifier and the feature causal graph.

In the complete information case, when agents know the classifier and the causal structure of the problem, we derive conditions ensuring that rational agents focus on features favored by the principal. We show that designing classifiers to induce desirable behavior is generally non-convex, though tractable in special cases. We also extend our analysis to settings where agents have incomplete information about the classifier or the causal graph. While optimal effort selection is again a non-convex problem under general uncertainty, we highlight special cases of partial uncertainty where this selection problem becomes tractable. Our results indicate that uncertainty drives agents to favor features with higher expected importance and lower variance, potentially misaligning with principal preferences. Finally, numerical experiments based on a cardiovascular disease risk study illustrate how to incentivize desirable modifications under uncertainty.

4 - Robustness and Transparency in Online Strategic Classification

Kunhe Yang, UC Berkeley, Berkeley, CA, United States

In many real-world settings -- such as college admissions, loan approvals, or hiring decisions -- decision-makers interact with a dynamic population of agents who strategically manipulate their features to influence outcomes. The **online strategic classification** problem models these interactions and addresses the features the challenge of learning through trial and error by observing only the manipulated features, without prior knowledge of the population, their true features, or sometimes even the feasible manipulations. In this talk, we focus on two critical questions: How can decision-makers ensure **robustness** to strategic behavior borrowing techniques from online learning, and how does **transparency** -- revealing or withholding the classifier -- impact performance? We explore these two questions in a generic graph-based manipulation model and show that, contrary to common beliefs, lack of transparency can actually degrade the decision-maker's performance. We offer an algorithmic framework to adapt online learning techniques to be robust to strategic behaviors.

AI and the Future of Digital Engagement

Invited Session

Social Media Analytics

Chair: Sridhar Nerur, The University of Texas at Arlington, Arlington, TX, United States

Co-Chair: Sagar Mahesh Badve, The University of Texas at Arlington, Bedford, TX, United States

1 - The Impact of Emotional Tone on Online Behavior in Social Contexts

Sagar Mahesh Badve, The University of Texas at Arlington, Bedford, TX, United States

This study explores how emotional tone in social media content influences users' intentions to engage in prosocial behavior, particularly in the context of social justice. Focusing on affective responses, the research examines the role of empathy that connects emotional content with user engagement. By using a randomized controlled experiment, the study investigates how variations in emotional tone may activate empathetic responses that encourage supportive actions such as sharing or endorsing content. Grounded in established frameworks, the findings aim to offer insights into the emotional drivers of digital behavior. This research contributes to a growing body of work on the psychological effects of online content and provides guidance for the ethical design of emotionally resonant media. The results are relevant for scholars, content creators, and digital platforms seeking to promote constructive engagement and enhance the social impact of digital communication.

2 - Twitch Raids: Understanding Viewer Engagement in Digital Communities

Roopa Ramesh Desai, The University of Texas at Arlington, Arlington, TX, United States, Jie Zhang, Kay-Yut Chen

In the dynamic realm of online streaming, Twitch stands out as a vibrant platform where content creators engage with audiences in real-time, fostering communities centered around shared interests and interactive experiences. At the heart of Twitch's ecosystem lies the phenomenon of "raiding," wherein streamers direct their viewers to another channel at the end of their broadcast, amplifying visibility and engagement for the raided streamer. This study explores the dynamics of raiding behavior on Twitch, focusing on how raid frequency influences viewership and community engagement. By employing panel data models, we analyze the factors affecting raids and their implications for streamers and the broader Twitch community. Drawing on Social Exchange Theory, which suggests that individuals engage in interactions based on the exchange of rewards and costs, our findings reveal that streamers who receive raids tend to benefit from increased exposure and viewership, which positively influences their engagement and growth within the community. Additionally, we incorporate the Recency effect to model the temporal decay of raid effects, demonstrating that the influence of past raids diminishes over time. Only recent raids significantly affect viewership, with the impact of older raids becoming negligible. These findings provide valuable insights into the strategic decisions streamers make when participating in raids, emphasizing the importance of timely engagement and reciprocal interactions. By integrating these theories, this study provides practical strategies for streamers to navigate raid dynamics and boost community engagement. Ultimately, it helps streamers better understand raids and optimize their efforts to build active, thriving communities on Twitch.

3 - Small Data in the Big Data Paradigm: LLMs and Relevant use Cases

Fay Cobb Payton, Rutgers University, Newark, NJ, United States

Payton, Lui and Yeager (2024) referenced McClellan and colleagues (2017) for their application of time series analysis and forecasting techniques to identify periods of heightened interest in mental health topics on Twitter (now X). The researchers explored Twitter activities focused on depression or suicide, then forecasted the communication trends over the next thirty days using an autoregressive integrated moving average (ARIMA) model. Their analysis found that spikes in Twitter volume following a behavioral health event often last for less than two days, indicating that people circulate mental or behavioral health information associated with heightened periods of interest for a limited time frame.

As we continue to build and use large language models (LLMs), holistic approaches must be embraced in the ecosystem. AI developers will need to train systems and themselves on small data paradigms which are informed by human experiences, choices, knowledge and extend beyond social determinants of health.

This presentation will discuss a use case of the small data paradigm opportunities in evaluating social media data over a three year horizon with over one thousand observations. This use case challenges traditional data interpretation and offers some latitude to address structural, biological pathways, environmental, policy and missing nuisances.

4 - When Language Backfires: the Unintended Consequences of Disruptive Narratives in AI-Assisted Startup Evaluation

Samaneh Samiee, University of Texas at Arlington, Dallas, TX, United States, Sridhar Nerur, Edmund Prater

In the age of digital engagement, startups' communication of their vision is increasingly mediated through AI-analyzed language and platform-based signals. This study examines how the textual characteristics of startup descriptions influence funding outcomes in competitive digital ecosystems. Leveraging NLP and topic modeling techniques on a dataset of 2,176 early-stage companies, we extract AI-derived features such as disruption orientation, lexical diversity, topic entropy, and linguistic distinctiveness. Grounded in signaling theory and optimal distinctiveness theory, our results indicate that at the early stage, startups employing overly disruptive, complex, or unique language are less likely to secure continued investment. In contrast, firms that describe themselves in a manner aligned with competitive linguistic norms are more successful in securing funding rounds. This research contributes to the literature on digital entrepreneurship and language-as-strategy by demonstrating how AI can illuminate the subtle textual cues that shape investor perception and legitimacy in digital funding platforms.

5 - Innovating Against the Odds: Digital Technology as a Catalyst for Female-Led Venture Success

Siddhi Ramanand Nair, University of Texas at Arlington, Arlington, TX, United States

Women-led ventures often face structural barriers stemming from entrenched gender stereotypes, limiting their access to funding, networks, and growth opportunities. While initiatives such as mentorship and policy support have sought to address these challenges, their impact on enabling scalable, innovation-driven ventures remains limited. This study investigates whether the use of digital technologies helps female entrepreneurs overcome such barriers and improve venture outcomes. Drawing on theoretical perspectives that emphasize the inclusive potential of digital transformation, it explores how digital adoption may reshape access to resources and entrepreneurial participation. By focusing on the intersection of gender, digital technology, and venture performance, this research addresses a critical gap in the literature. The study contributes to broader conversations on digital entrepreneurship and gender equity, offering insights for scholars, policymakers, and practitioners interested in fostering more inclusive innovation ecosystems.

1 - A Two-Stage Stochastic Programming Model for Risk Pooling in Integrated Planning and Operation Under Supplier, Manufacturer, and Retailer Uncertainties

Thanaphorn Sornprom, Lally School of Management, Rensselaer Polytechnic Institute, Troy, NY, United States, Chanaka Edirisinghe

Raw material shortages, manufacturing yield variation, and demand fluctuations are three inevitable uncertainties in managing supply chains. To mitigate these challenges, we apply a risk pooling strategy, called postponement, to delay product shipment so as to gain information on some of the uncertainty in a two-echelon manner. An integrated model for two-period operation is formulated as a two-stage stochastic optimization model, where the second-period decisions are adapted to the first-period decisions and realized uncertainty. The main objective of this study is to address questions related to how much value can be gained using partial information on uncertainties by decomposing production and distribution over two periods, and how that value generated for the integrated supply chain is impacted by the degree of uncertainty of the above three sources, and also if demand' correlations at the retailers make the risk pooling effect even more significant.
