There are numerous strategies to coordinate distributed energy resources (DERs) to provide a variety of services to the power grid. DER coordination can affect resources and participants unequally, for example, by excessively degrading or curtailing particular DERs more than others. However, few DER coordination strategies explicitly take into account fairness. In this talk, we explore fairness metrics and their applicability to the DER coordination problem. In particular, we investigate metrics from machine learning to identify metrics that could be incorporated into DER coordination problems and we summarize fairness metrics that have been used in the power systems literature. A key challenge is that most existing fairness metrics are static – ensuring fairness at a point in time. DER coordination problems are inherently dynamic and we often care about fairness over time, not at each time. The machine learning literature offers some ways to think about fairness over time and, more generally, how to incorporate fairness into dynamic power systems problems. We use a specific DER coordination problem – the problem of computing dynamic operating envelopes – to demonstrate how incorporation of a fair-over-time metric changes DER coordination solutions, and highlight the trade-offs that arise.

3 - A Prudent Framework for Understanding Risk-Awareness in Demand Response

Liudong Chen, Columbia University, New York, NY, United States, Bolun Xu

We show that risk-aware behaviors in demand response originate from superquadratic state-dependent cost functions and price uncertainty with skewed distributions. We obtain such results through developing a novel theoretical demand response framework that combines non-anticipatory multi-stage decision-making with superquadratic cost functions. We introduce the concept of prudent demand, defined by a positive third-order derivative of the cost function, which is the first principle for risk-averse behavior despite a risk-neutral objective. Our analysis establishes that future price uncertainty affects immediate consumption decisions, and the extent of this response scales proportionally with the skewness of the price distribution. We visualize our theoretical findings through numerical simulations and illustrate their practical implications using a real-world case study.

4 - End-to-End Learning for Reliable Energy System Operation

Nicolas Christianson, California Institute of Technology, Pasadena, CA, United States

Machine learning (ML) can significantly improve efficiency in energy system operation. However, conventional ML approaches come with no a priori guarantees on reliability, and thus pose potential risks when deployed in the real world. In this talk, I will discuss recent work developing an end-to-end framework for training ML models for critical energy applications that are reliable by design. I will focus primarily on the application of training classification models for power grid contingency screening with provable guarantees on false negative rate - i.e., guarantees ensuring that no unsafe dispatch scenarios are misclassified as safe, which are critical for maintaining system reliability. I will also highlight how this framework can be extended to broader notions of reliability, such as enforcing market participants' varied risk preferences. In both cases, our end-to-end approach enables significant, data-driven performance improvements while providing provable guarantees on reliability.

5 - Optimal Pricing for Equitable Energy Access in Energy Communities

Siying Li, Cornell University, Ithaca, NY, United States, Timothy Mount, Lang Tong

We consider the design of an optimal pricing mechanism in an energy community consisting of members with diverse socioeconomic backgrounds, including varying income levels and differing capacities to access distributed energy resources such as solar power and storage systems. As part of the regulated retail market in a distribution system, the energy community is operated by a non-profit operator that sends pricing signals to its members, and each member maximizes individual consumption surplus. We formulate a bilevel optimization where the operator sets the pricing policy to maximize community welfare subject to constraints that (i) the community meets the desired equity level defined by the Rawlsian equity measure, and (ii) each community member has a higher consumption surplus within the community than being outside the community under the regulated net energy metering tariff. We show that an optimal pricing policy is the Dynamic Net Energy Metering with a discriminative connection charge, which achieves all points on the Pareto front of the equity-community welfare tradeoff. We show further that the optimal pricing with a higher Rawlsian equity must Lorenz-dominate one with a lower Rawlsian equity.

1 - Decoding Diversity: Whether, when, and Why Female Directors Enhance It Governance

Anqi Wu, Florida International University, Miami, FL, United States, Sebastian Schuetz, Xueping Liang

This study addresses the ongoing debate about the impact of female directors on corporate governance. While skepticism persists regarding the value women bring to corporate boards, and mixed evidence complicates the picture, this research examines whether, when, and why female directors make unique contributions in the realm of IT governance and data breach risks. By integrating arguments from prior literature, research on gender differences, and critical mass theory, we theorize the mechanisms explaining when and why female directors should make a difference. We test our hypotheses using a dataset from firms between 2011 and 2021. Our findings indicate that female directors reduce firms' data breach risks by 7.94%, with the effect being driven by their lower risk preferences and more participative leadership style. We also find that female directors need to reach a critical mass on corporate boards (i.e., $n > 2$) for these effects to materialize. These results are robust to alternative specifications and explanations. Collectively, our study challenges prevailing skepticism against female directors by highlighting the unique contributions—lower risk preferences and participative leadership style—that female directors bring to IT governance. Given the ongoing under-representation of women on corporate boards, our findings inform director recruitment practices by supporting the case for more equitable representation.

2 - Supply Chain Cyberattacks and Their Stock Market Impacts on Downstream Firms

Shreya Gokhale, University of Illinois Urbana-Champaign, Champaign, IL, United States, Gopesh Anand, Abhijeet Ghoshal, Yang Gao

Supply chain cyberattacks exploit vulnerabilities in upstream suppliers to compromise downstream customer firms. Unlike cyberattacks that directly target firms, supply chain cyberattacks infiltrate trusted supplier-customer relationships, causing widespread disruptions. While extensive research has examined the effects of cyberattacks on directly targeted firms, little is known about the impact of supply chain cyberattacks on downstream firms reliant on compromised suppliers. Given the increasing sophistication and the growing numbers of such attacks, understanding their financial consequences is crucial. This study examines whether supply chain cyberattacks affect the stock market performance of downstream firms. Using a novel dataset of supply chain cyberattacks between 2020 and 2023, we employ event study analyses to measure cumulative abnormal returns for downstream firms following cyberattacks on their suppliers. Our findings reveal a significant negative impact on the stock market performance of downstream firms, indicating that these cyberattacks extend beyond directly targeted suppliers to disrupt the supply chain. We further investigate the underlying mechanism and find that the supply chain contagion effect - which suggests that disruptions at compromised suppliers propagate downstream - plays a more dominant role than the blame attribution effect - which suggests that investors penalize downstream firms for failing to oversee their suppliers' cybersecurity practices. Additionally, we find that the negative stock market impact is more pronounced for downstream firms with weaker bargaining power, lower technical expertise, and explicit mentions in news reports. These findings underscore the importance of supply chain cyberattacks and provide actionable insights for firms to mitigate financial risks arising from these attacks.

3 - Innovation and Reputational Risk In Global Supply Chains

Kedong Chen, Rensselaer Polytechnic Institute, Troy, NY, United States

Despite growing regulatory pressure and corporate commitments to ethical sourcing, labor rights violations remain pervasive across global supply chains. Existing governance approaches, such as audits and certification schemes, have shown limited success in addressing these persistent challenges. Grounded in the relational capital perspective, this study intends to examine how buyers' process innovations, particularly those leveraging Artificial Intelligence (AI), can contribute to improving suppliers' labor practices and mitigating reputational risks. For instance, AI-driven demand forecasting in Unilever has stabilized supplier order volumes, enabling suppliers to reduce overtime and invest in workforce development, while in Walmart with its AI-powered inventory system reduced demand variability, allowing suppliers to better plan production and improve labor conditions. To account for heterogeneity in the relationships, the study further examines how the strength of buyer-supplier relationships and inter-firm power asymmetry moderate the relationship between process innovations of buyers and suppliers' labor compliance.

4 - Impact of Ransomware on Emergency Medical Services: Empirical Estimation and Risk Assessment Framework

Pouria Arsalani, THE UNIVERSITY OF ALABAMA, Tuscaloosa, AL, United States, Nickolas Freeman, Iman Dayarian, Youngsoo Kim, Xiaosong Peng, Ming Zhao, Jamie Gray, William Crawford

The healthcare industry has increasingly become a major victim of cyberattacks called ransomware, which poses nontrivial challenges to the sector because ransomware can disrupt their operations rather than merely breach data. A ransomware attack on a hospital often forces patients to be rerouted away from the closest facility, which can severely deteriorate the operations of emergency medical services (EMS). Utilizing a unique dataset that captures two ransomware breaches at large hospitals in Alabama, we empirically examine the impact of ransomware on ambulance patient transit, which is an integral part of EMS. We find that one ransomware breach significantly deteriorates the performances in three main segments of EMS operations, but the other ransomware breach does not. A further investigation suggests that the contrasting results between the two cases can be attributed to the network of available hospitals around the breached hospital. Motivated by our empirical findings, we develop a simulation model framework to assess the impact of ransomware attacks on EMS systems under various breach scenarios. We apply this framework to show that isolating hospital IT systems can substantially reduce operational disruptions during ransomware breaches and to explore a range of factors that shape EMS system susceptibility to ransomware disruptions. Overall, our findings can inform policymakers and healthcare administrators about the adverse effects of ransomware on EMS operations and highlight the importance of assessing the resilience of regional hospital networks, which can help develop more targeted and collaborative strategies to mitigate ransomware disruptions.

5 - Cybersecurity Starts at Home: Modeling Parental Behavior with Com-B

Ning Yang, Loyola University Chicago, Chicago, IL, United States, Inaiya Armeen

Despite growing awareness of online threats, children's digital activities have become an overlooked vector of cybersecurity risk. This study introduces a behaviorally informed framework to understand parental roles in managing and mitigating these risks, applying the COM-B (Capability, Opportunity, Motivation, Behavior) model to analyze protective behaviors within the household. We took a mixed-method approach, including 33 parent-child online interviews and surveying over one hundred U.S. parents, to assess psychological readiness, resource availability, and motivational drivers of digital safety practices regarding domestic devices and the environment. The results from the structural equation modeling show that motivation and opportunity significantly predict parental protective behavior, while capability exhibits an indirect impact on parental behaviors via motivation. Parents are often aware of cyber risks but lack the tools, time, or social support to sustain protection behaviors. Our studies indicate that parents should stop considering household cybersecurity as a technical problem requiring knowledge and skills. Instead, they need to approach this issue as a behavioral risk management challenge and actively seek interventions to strengthen their motivation and build resilience to shield their children from evolving digital threats. To support this, schools and communities must play a greater role in equipping parents with the resources, guidance, and social reinforcement needed to succeed.

1 - Improving Access to Essential Medicines in the Sierra Leone via Machine Learning

Tsai-Hsuan (Angel) Chung, The Wharton School, UPenn, Philadelphia, PA, United States, Jatu Abdulai, Patrick Bayoh, Lawrence Sandi, Francis Smart, Hamsa Bastani, Osbert Bastani

A critical challenge in healthcare systems in Low- and Middle-Income Countries (LMICs) is the efficient and equitable allocation of scarce resources, particularly essential medicines. This problem is complicated by limited high-quality data, which restricts the applicability of traditional data-driven techniques. We propose a novel machine learning framework for essential medicines allocation, which leverages a combination of multi-task learning and decision-aware learning to improve sample efficiency and ensure equitable allocation. In collaboration with the Sierra Leone national government, our framework has been deployed nationwide as a decision support tool to help reduce waste and improve essential medicines allocation. Our evaluation using synthetic difference-in-differences analysis demonstrates a 19% increase in medicine consumption, with no changes to the supply, improving access for approximately 3.7 million women and children under five. Through experimental validation,

we demonstrate that our approach also significantly outperforms baseline approaches. Our work demonstrates the tangible impact of machine learning in optimizing high-stakes decisions in resource-constrained settings, improving efficiency while ensuring equity and cost-effectiveness.

2 - Optimization, Simulation and Predictive Models to Improve Response TIMES in Out-of-Hospital Cardiac Arrest

Marziehsadat Rezaei, University of Louisville, Louisville, KY, United States, Monica Gentili, Evan Kuhl

Over 350,000 out-of-hospital cardiac arrests (OHCA) occur annually in the U.S., with survival rates as low as 8–10%. Early defibrillation within 3–5 minutes can raise survival above 50%, highlighting the need for timely intervention. Delays often stem from Emergency Medical Service (EMS) operational limitations and challenging geographic access. Unmanned Aerial Vehicles (UAVs), or drones, present a promising solution to overcome these barriers by rapidly delivering Automated External Defibrillators (AEDs) to the scene. Prior studies suggest drones reduce response times and improve outcomes, yet many rely on i) narrow settings (e.g., regional focus), ii) simplified assumptions (e.g., fixed OHCA rates), and iii) lack of EMS coordination. My research aims at filling these critical gaps by designing and evaluating a coordinated drone-EMS AED delivery system using predictive, optimization and simulation models to improve emergency response time to OHCA. I have begun preliminary OHCA risk mapping and EMS data collection in Jefferson County as the initial testbed, but the approach will be scalable and generalizable to be applied to other regions. My research is structured around three objectives. Objective 1 develops optimization models for the optimal design of a coordinated drone-EMS AED delivery system. Objective 2 develops predictive and survival models to evaluate the impact of different delivery strategies. Objective 3 builds a simulation model to assess the performance of the coordinated system. The coordinated system will be compared with the current EMS system in terms of (1) survival outcomes, (2) response times, (3) resource utilization, and (4) scalability and cost-effectiveness.

3 - Context-Aware Optimization Models for Improving Population-Level Healthcare Delivery

Abel Sapirstein, Georgia Institute of Technology, Atlanta, GA, United States, Lauren Steimle, Mathieu Dahan, Meghan Meredith, Geir Godager

Outcomes for non-communicable diseases, such as cancers, heart disease, and diabetes, have significantly improved over the last half century due to medical advances, such as improved screening and biopsies. However, systemic barriers, including limited geographic access, low patient awareness, and poor cooperation between health systems planners, prevent some populations from receiving needed care. In this talk, I will discuss my proposed research agenda to address three practically motivated problems from different global contexts: access to cancer care in Rwanda, regionalization of maternity care in the US, and capacity building in long-term care facilities in Norway. These problems require the relaxation of common modeling assumptions surrounding provider and patient behaviors. As a result, we formulate novel models that require new solution approaches to solve. More specifically, in Rwanda, we model investments in the road network and cancer centers simultaneously under uncertainty in patient demand and the impact of seasonal weather events. We use stochastic optimization and develop a purpose-built branch-price-and-cut algorithm and approach optimality. In our ongoing work on maternal health in the US, we relax the assumption that patients always seek care at their closest facility to capture patients' bypassing behaviors. Finally, I'll share our planned work in Norway, in which we will model sustainable collaborative decision making, relaxing the assumption of a single, central planner. This work will consider uncertainty in disease costs and burdens when constructing long-term care facilities with large fixed costs. I will outline how this research agenda is aligned with my longer-term career goals.

Statistical Learning and Data-driven Decision-making

Invited Session

OPT: Machine Learning

Chair: Kaizheng Wang, Columbia University, New York, NY, United States

1 - Surprises in Mean Estimation and Regression over Lp Balls

Reese Pathak, UC Berkeley, Berkeley, CA, United States

Empirical risk minimization and its regularized counterparts are the optimization workhorses of modern machine learning and statistical practice. On the other hand, despite years of study, the performance of these methods is poorly understood in even the simplest scenarios. We discuss new results on empirical risk minimization in mean estimation and linear regression setups where the underlying parameter is assumed to lie in an ℓ_p ball. Depending on the signal to noise ratio, we characterize the rate-suboptimality or optimality of some standard methods: empirical risk minimization (ERM), regularized ERM, and least-norm interpolation. These results point to the type of shrinkage that is required to attain rate optimality in these problems. We discuss the consequences of these results for modern learning setups which may entail distribution shift or learning in the presence of low noise.

Based on multiple papers, joint work with Liviu Aolaritei (UC Berkeley), Michael I. Jordan (UC Berkeley & INRIA), Gil Kur (ETH Zurich), Cong Ma (U. Chicago), and Annie Ulichney (UC Berkeley).

2 - Uncertainty Quantification for LLM-Based Survey Simulations

Chengpiao Huang, Columbia University, New York, NY, United States, Yuhang Wu, Kaizheng Wang

We investigate the use of large language models (LLMs) to simulate human responses to survey questions, and perform uncertainty quantification to gain reliable insights. Our approach converts imperfect LLM-simulated responses into confidence sets for population parameters of human responses, addressing the distribution shift between the simulated and real populations. A key innovation lies in determining the optimal number of simulated responses: too many produce overly narrow confidence sets with poor coverage, while too few yield excessively loose estimates. To resolve this, our method adaptively selects the simulation sample size, ensuring valid average-case coverage guarantees. It is broadly applicable to any LLM, irrespective of its fidelity, and any procedure for constructing confidence sets. Additionally, the selected sample size quantifies the degree of misalignment between the LLM and the target human population. We illustrate our method on real datasets and LLMs.

3 - A Statistical Theory of Overfitting for Imbalanced Classification

Kangjie Zhou, Columbia University, Philadelphia, PA, United States, Jingyang Lyu, Yiqiao Zhong

Classification with imbalanced data is a common challenge in data analysis, where certain classes (minority classes) account for a small fraction of the training data compared with other classes (majority classes). Classical statistical theory based on large-sample asymptotics and finite-sample corrections is often ineffective for high-dimensional data, leaving many overfitting phenomena in empirical machine learning unexplained.

In this paper, we develop a statistical theory for high-dimensional imbalanced classification by investigating support vector machines and logistic regression. We find that dimensionality induces truncation or skewing effects on the logit distribution, which we characterize via a variational problem under high-dimensional asymptotics. In particular, for linearly separable data generated from a two-component Gaussian mixture model, the logits from each class follow a normal distribution $\mathcal{N}(0,1)$ on the testing set, but asymptotically follow a rectified normal distribution $\max\{\kappa, \mathcal{N}(0,1)\}$ on the training set—which is a pervasive phenomenon we verified on tabular data, image data, and text data. This phenomenon explains why the minority class is more severely affected by overfitting. Further, we show that margin rebalancing, which incorporates class sizes into the loss function, is crucial for mitigating the accuracy drop for the minority class. Our theory also provides insights into the effects of overfitting on calibration and other uncertain quantification measures.

4 - Transfer Learning of Cate with Kernel Ridge Regression

Seok-Jin Kim, Columbia University, New York, NY, United States, Hongjie Liu, Molei Liu, Kaizheng Wang

The proliferation of data has sparked significant interest in leveraging findings from one study to estimate treatment effects in a different target population without direct outcome observations. However, the transfer learning process is frequently hindered by substantial covariate shift and limited overlap between (i) the source and target populations, as well as (ii) the treatment and control groups within the source. We propose a novel method for overlap-adaptive transfer learning of conditional average treatment effect (CATE) using kernel ridge regression (KRR). Our approach involves partitioning the labeled source data into two subsets. The first one is used to train

candidate CATE models based on regression adjustment and pseudo-outcomes. An optimal model is then selected using the second subset and unlabeled target data, employing another pseudo-outcome-based strategy. We provide a theoretical justification for our method through sharp non-asymptotic MSE bounds, highlighting its adaptivity to both weak overlaps and the complexity of CATE function. Extensive numerical studies confirm that our method achieves superior finite-sample efficiency and adaptability. We conclude by demonstrating the effectiveness of our approach using a 401(k) eligibility dataset.

5 - Causal Inference with High-Dimensional Discrete Covariates

Zhenghao Zeng, Carnegie Mellon University, Pittsburgh, PA, United States, Sivaraman Balakrishnan, Yanjun Han, Edward Kennedy

When estimating causal effects from observational studies, researchers often need to adjust for many covariates to deconfound the non-causal relationship between exposure and outcome, among which many covariates are discrete. The behavior of commonly used estimators in the presence of many discrete covariates is not well understood since their properties are often analyzed under structural assumptions including sparsity and smoothness, which do not apply in discrete settings. In this work, we study the estimation of causal effects in a model where the covariates required for confounding adjustment are discrete but high-dimensional, meaning the number of categories d is comparable with or even larger than sample size n . Specifically, we show the mean squared error of commonly used regression, weighting and doubly robust estimators is bounded by $d^2/n^2 + 1/n$. We then prove the minimax lower bound for the average treatment effect is of order $d^2/n^2 \log^2 n + 1/n$, which characterizes the fundamental difficulty of causal effect estimation in the high-dimensional discrete setting, and shows the estimators mentioned above are rate-optimal up to log-factors. We further consider additional structures that can be exploited, namely effect homogeneity and prior knowledge of the covariate distribution, and propose new estimators that enjoy faster convergence rates of order $d/n^2 + 1/n$, which achieve consistency in a broader regime. The results are illustrated empirically via simulation studies.

Disrupting Human Trafficking

Invited Session

Public Sector OR

Chair: Daniel Lopes da Silva, Florida Polytechnic University, Lakeland, FL, United States

1 - Identifying the Digital Fingerprint of Illicit Massage Businesses

roya shomali, The University of Alabama, Tuscaloosa, AL, United States, Nickolas Freeman, Gregory Bott, Iman Dayarian

Illicit massage businesses (IMBs) masquerade as legitimate massage parlors while facilitating illicit activities, including sex trafficking. Traditional detection methods, which often rely on online reviews, fall short in revealing these covert operations. This research investigates how cell phone mobility data can be leveraged to uncover the digital fingerprint of IMBs by designing features that describe these businesses' operation and demand patterns. IMBs are key nodes in human trafficking networks, posing significant risks to exploited individuals and challenging law enforcement. A deeper understanding of mobility patterns and operational anomalies can enhance surveillance capabilities and inform targeted intervention strategies by governmental and non-profit organizations. Our study integrates large-scale mobility datasets with a well-delineated feature design process that spans temporal, spatial, and anomalous traffic dimensions. We employ a factorial experimental design to evaluate feature granularity and interaction effects and develop an XGBoost classifier to distinguish illicit from legitimate massage businesses. We apply our model to a nationwide holdout dataset to identify illicit businesses and delineate their spatial clusters, thereby pinpointing hot spots.

The proposed approach demonstrates robust performance across evaluation metrics, highlighting the framework's ability to flag IMBs across varied geographic contexts. Key features—assessed at specific granularity levels, including defined temporal visit patterns, catchment distance metrics, and elevated off-hours activity—emerge as strong indicators of illicit behavior. The digital fingerprints and predictive insights we derive provide law enforcement and social service agencies with actionable intelligence, enabling more effective prioritization of investigations and targeted interventions to disrupt illicit trafficking networks.

2 - Minimum Cost Flow Interdiction with Shifting Capacity for Human Trafficking Networks

Frederick Miller, Northeastern University, Somerville, MA, United States, Kayse Maass

Traditional network interdiction problems assume that the interdictor is the player that affects the network's performance. In reality, followers may adapt to interdictions by changing certain aspects of the network. This behavior is representative of applications in human trafficking (HT), where traffickers aim to respond to interdictions to recover lost supply or revenue. We present a multiperiod max - min cost flow network interdiction problem in which the graph capacities have the ability to shift over time. Specifically, we model the follower's ability to change the capacities of supply and demand nodes or arc capacities in response to the round's interdictions. This allows the follower's flow network to become more resilient to interdiction, making the interdictor's decisions less effective than it was in previous rounds. To model this, we developed a bilevel mixed integer nonlinear optimization problem. We study how supply and demand shift to nearby victims, showing how interdiction impacts those that remain in the network.

3 - Robust Link Prediction Models for Transnational Illicit Trafficking Networks

Hasini Balasuriya, University of Louisville, Louisville, KY, United States, Cagla Acun, Monica Gentili

Illicit operations, such as human and organ trafficking, pose a serious global threat. These operations are designed strategically to avoid detection by law enforcement, using decentralized structures and hidden communication channels, which makes them difficult to analyze and disrupt. Furthermore, the data available on these types of operations is often highly sparse and incomplete, adding another layer of complexity to their study.

To address these challenges, our research applies novel link prediction models to identify interactions or connections that may be missing in the available data. The analysis is based on datasets provided by external collaborators, including web-scraped news articles and online sources processed using large language models to extract relevant information. We introduce two separate, tailored, and robust link prediction models aimed at uncovering hidden links of both human and organ trafficking networks. To assess the strength of our models, we explore their robustness under different levels of missing data. By examining how the models perform under simulated scenarios of extreme conditions, we aim to ensure their reliability when applied to similar real-world trafficking network data.

Beyond predicting hidden connections, our study includes structural analysis to find key hubs and influential nodes within these networks. This integrated view helps policymakers design more targeted and effective strategies to disrupt illicit networks and mitigate their societal impact.

4 - Strategic Disruption of Human Trafficking Networks: a Multi-Layer Network Science and Interdiction Optimization Framework

Riad Al Hasan Abir, OHIO UNIVERSITY, Athens, OH, United States

Human-trafficking investigations rely heavily on surveillance and survivor testimony. This produces fragmented views of criminal enterprises and exposes victims to traumatization. Using network analytics and optimization, the project aims to deliver actionable intelligence to law enforcement. The main goal is to optimally allocate resources on the most vulnerable points in trafficking networks, accelerating case closure while minimizing harm. It also offers a blueprint for cross-agency data-sharing protocols. This presentation proposes an integrated network-science and interdiction-modeling framework that brings together heterogeneous digital traces, financial transactions, phone records, ads, geolocation activity, and investigative interviews, into a dynamic, multi-layer network. This method allows us to capture flows of money, communication, and control; key evidential features in an investigation. Temporal evaluation of the networks are analyzed with centrality, k-core, and role-equivalence metrics to reveal resilient organizing kernels and hidden brokers. These metrics feed a stochastic bilevel max-flow interdiction model that determines which nodes or edges to investigate, freeze, or disable so the maximum amount of illicit funds and victim movement is blocked under a fixed investigative budget. Column-and-constraint generation and decomposition heuristics enable the solution of realistically sized enterprise graphs drawn from real human trafficking investigations. We produce a set of experiments that include budget sweeps, layer-specific strikes, and simultaneous versus sequential actions quantify trade-offs among disruption effectiveness, resource

expenditure, and impact on survivors. The main goal of the project is to produce prioritization dashboards, visualizations, and reproducible notebooks that support law enforcement agencies producing “what-if” strategies before deploying agents.

5 - From Darknet to Daylight: Mapping Technology’s Role in Trafficking Control

Wojtek Wolfe, Rutgers University, Camden, NJ, United States, Srinivasa Puranam

Human trafficking exploits the same digital networks that power global commerce. Social platforms, encrypted messaging, and cryptocurrency let recruiters reach vulnerable targets, control victims, and wash profits. The same technologies also arm investigators through machine learning pattern matching, transparent blockchain ledgers, and mobile reporting tools. This study maps that contest.

A systematic scan of academic, industry, and open source evidence tracks how online recruitment, surveillance, and illicit finance evolve. Case studies then test countermeasures, from artificial intelligence triage of classified ads to tamper resistant logistics monitoring. Data sources include web scraped social content, synthetic vulnerability models, and darknet market tracking. Privacy and victim safety guide every step.

Findings show impact depends on policy alignment. Blockchain pilots cut forced labor risk when buyers share data in real time, yet predictive policing stalls where privacy law blocks intelligence exchange. As firms reshore to stricter jurisdictions, trafficking pressure shifts toward regions with weaker oversight, deeper capital stress, and rising displacement.

The project delivers two outcomes. A diagnostic matrix ranks technical tools by readiness, scalability, and potential harm. A policy playbook links those ratings to procurement rules, transparency statutes, and multilateral data sharing accords. Aligning technology with legal and economic incentives can shrink the space in which traffickers operate even in increasingly fragmented markets.

Chair: Scott Nestler, University of Florida, Gainesville, FL, United States

1 - The Economics of Income Sharing for Athletes: An Insurance-Based Approach

Christopher Gaffney, Drexel University, Philadelphia, PA, United States

Income Sharing Agreements (ISAs) have emerged as a popular financial tool for early career athletes, allowing them to trade a percentage of future earnings for immediate capital. This creates a dual benefit: athletes gain near-term financial stability while investment firms capture value through calculated risk exposure. In this study, we develop a mathematical framework to analyze and optimize the structure of these agreements. We draw parallels between ISA variables such as advance size, repayment rates, and repayment maximums, and traditional insurance concepts such as coverage, deductible, and premium loading. Using these features, we derive Pareto-optimal agreement structures. This research contributes to the growing literature on innovative sports financing mechanisms and provides actionable insights for athletes, agents, and financial institutions in the sports industry.

2 - Comparing Nba and Wnba Fan Reactions: a Topic Modeling Analysis of X (Twitter) Discussions

Scott Nestler, University of Florida, Gainesville, FL, United States

This study compares how NBA and WNBA fans discuss games on Twitter, focusing on differences in player versus team emphasis and emotional tone. Using Latent Dirichlet Allocation (LDA) topic modeling, we analyzed 50,000 tweets collected during the 2023 NBA and WNBA Finals. The analysis is grounded in social identity, arousal, and expectancy violation theories to interpret fan loyalty, emotional engagement, and reactions to unexpected outcomes. Data were preprocessed with tokenization, lemmatization, and emoji conversion. Five main topics were identified for each league. NBA discussions were predominantly player-focused, with frequent mentions of stars like Jamal Murray, Jimmy Butler, and Nikola Jokic. In contrast, WNBA conversations centered more on teams, especially the Las Vegas Aces and New York Liberty, with terms like “A’ja Wilson,” “team,” and “win” appearing often. Player mentions in NBA tweets were 40% higher than in WNBA tweets, while team dynamics comprised 35% of WNBA discussions but only 15% in NBA tweets. Sentiment analysis revealed that 65% of WNBA-related tweets were positive, compared to 38% for NBA tweets, which also contained more negative terms. NBA fan conversations more frequently referenced specific game moments, such as scoring and rebounds. These findings highlight distinct cultural and structural patterns in fan engagement across the two leagues. Implications for social media managers and content creators aiming to engage NBA and WNBA audiences will be discussed.

3 - Creating a Crystal Ball for English Premier League Clinch and Relegation

Alexandra Newman, Colorado School of Mines, Golden, CO, United States

The English Premier League is one of soccer's most competitive professional sports leagues. We discuss magic numbers of interest, e.g., avoiding relegation, and how we construct mixed-integer programming models to produce these numbers. We compare our results against those available in the mainstream media, and showcase a website with said numbers.

4 - Variations in Player Valuations in Expanded and Contracted Labor Markets: Evidence from Indian Premier League Auctions

Sachin Narayanan, Florida State University, Tallahassee, FL, United States

Entering its 18th season, the financially lucrative Indian Premier League (IPL) ranks only behind the NFL in per-game revenue (Jamkhandikar & Ganguly, 2022). IPL teams build their roster annually through single-item English auctions, bidding on players based on talent and team needs. Auctions occur in two forms: a mega auction every 3-4 years, with more roster spots, and an annual mini auction to fill unexpected vacancies. This introduces a dynamic labor market for cricketers that expands (mega) and contracts (mini), potentially altering player valuations. Neoclassical economics propose that wages reflect supply and demand (Hicks, 1963). Expanding demand with unmatched supply tends to raise wages; contracting demand may decrease them (Rebitzer, 1995). The dynamic nature of the IPL auction, coupled with the criticism surrounding disproportionate wage distributions, raises the following questions about how firms value labor under varying market conditions: RQ1: How does a player’s Marginal Revenue Product (MRP) compare to their compensation under expanded and contracted labor markets? RQ2: Do factors affecting player wages (valuation) vary between auction types? Methodology Using advanced player/team performance (espnricinfo.com), auction (IPLT20.com) data, and team valuation reports (Forbes) we estimate MRP models (Humphreys & Pyun, 2017) for auctioned players, compare MRP with wages, and regress wages (MRP) on performance factors. Findings and Implications Findings indicate higher wages in mega auctions, positional preference for offense in mega, and overcompensation for veterans in mini auctions. These findings can guide fairer player pricing, identify undervalued talent, and inform efficient bidding strategies, offering insights applicable to other dynamic labor markets.

Learned Optimizers and Decision-Focused Learning

Invited Session

OPT: Optimization Under Uncertainty

Chair: Paul Grigas, University of California, Berkeley, Berkeley, CA, United States

Co-Chair: Wyame Benslimane, University of California, Berkeley, Berkeley, 94705, United States

1 - Self-Supervised Penalty-Based Learning for Robust Constrained Optimization

Wyame Benslimane, University of California, Berkeley, Berkeley, CA, United States, Paul Grigas

We introduce a novel self-supervised learning framework for parameterized constrained robust optimization, an important class of optimization problems. Inspired by the exact penalty method used to solve constrained optimization problems, we propose a self-supervised penalty-based loss function to learn an approximate optimal solution mapping for parametric robust optimization problems. Our approach offers significant advantages as it leverages the problem's inherent structure to train our approximation without requiring prior knowledge of optimal solutions, thus bypassing the need for data labeling. This is particularly beneficial as data labeling often relies on traditional solvers that tend to scale poorly for large scale optimization problems. Additionally, we adapt our framework for robust constrained combinatorial optimization problems by incorporating a surrogate linear cost over mixed-integer domains, and a smooth approximation thereof, into the final layer of the network architecture.

We evaluate our method on three applications: a continuous multidimensional knapsack problem, its combinatorial (discrete) variant, and an inventory management problem. Experimental results show that our approach achieves high-quality approximations with significantly faster inference times compared to traditional solvers. Moreover, we demonstrate that adjusting the penalty parameter allows for effective control of the trade-off between solution optimality and robust feasibility.

2 - Overworking or Outsourcing: Integrated Prediction-Optimization for Human-Centric Last-Mile Delivery Zone Assignment

Meng Qi, Cornell University, Ithaca, NY, United States, Haoran Guo, Wei Qi

As courier overtime and burnout are increasingly exacerbated by significant fluctuations in e-commerce demand, emerging crowd-sourced delivery provides a flexible solution to manage service peaks and protect the full-time workforce. When determining delivery zone assignments between couriers and gig workers, the process often involves an objective function that aims to balance operational costs against courier overtime. However, in two-step predict-then-optimize approaches, simply introducing a human-centric objective in the optimization stage may not be effective due to its misalignment with the prediction goal. To address this critical challenge and ensure courier welfare, we propose an integrated prediction-optimization (IPO) approach that leverages the problem structure to guide the construction of a decision-focused feature-based service time estimator. Theoretically, we demonstrate that a point estimator suffices, which is a property that typically does not hold when the objective function is nonlinear. It avoids learning a distributional prediction, which is more complicated but often required with nonlinear objective functions. We also utilize geometric structures to identify tractable cases, the resulting estimators achieve a bounded excess decision risk. More broadly, this paper demonstrates how IPO approaches can be leveraged for employee well-being alongside operational efficiency.

3 - Understanding Fixed Predictions via Confined Regions

Connor Lawless, Stanford University, Stanford, CA, United States, Tsui-Wei Weng, Berk Ustun, Madeleine Udell

Machine learning models are designed to predict outcomes using features about an individual, but fail to take into account how individuals can change them. Consequently, models can assign fixed predictions that deny individuals recourse to change their outcome. This work develops a new paradigm to identify fixed predictions by finding confined regions in which all individuals receive fixed predictions. We introduce the first method, ReVer, for this task, using tools from mixed-integer quadratically constrained programming. Our approach certifies recourse for out-of-sample data, provides interpretable descriptions of confined regions, and runs in seconds on real world datasets. We conduct a comprehensive empirical study of confined regions across diverse applications. Our results highlight that existing point-wise verification methods fail to discover confined regions, while ReVer provably succeeds.

4 - Diffusion Models for Uncertainty-Aware Decision-Focused Learning

Zihao Zhao, Georgia Institute of Technology, Atlanta, GA, United States, Linghai Kong, Kai Wang

Decision-Focused Learning (DFL) integrates predictive modeling and optimization by training predictors to optimize the downstream decision target rather than merely minimizing the prediction error. While existing DFL frameworks have achieved significant success using deterministic neural networks to characterize uncertain parameters, we show that point predictions are often insufficient to capture the intrinsic stochasticity of real-world phenomena. To address this challenge, we propose the first diffusion-based DFL approach, which trains a diffusion model to represent the distribution of the uncertain parameters, and optimizes the decision by solving a stochastic optimization with samples drawn from the diffusion model. We show that backpropagating through stochastic optimization is equivalent to a weighted score function formulation that can be used to train the diffusion model, which provides a simple yet effective algorithm for training diffusion models end-to-end. This new integration of diffusion models and stochastic optimization leads to a new DFL approach for training diffusion models. Lastly, we empirically show that our diffusion-based DFL approach consistently outperforms state-of-the-art baselines in decision quality.

1 - Multi-Region Competitive Pricing and Market Dynamics of Hurricane Insurance Under Climate Change Risks

Dahui Liu, Donghua University, Shanghai, China, People's Republic of, Linda Nozick, Meghan Millea, Jamie Kruse, Rachel Davidson, Junkan Li

Homeowner insurance plays a crucial role in mitigating the impact of hurricanes on households and regional economies. Pricing the insurance is challenging, as premiums must balance between covering large, localized payouts and remaining affordable. Excessive premiums may result many homeowners uninsured, while inadequate pricing threatens insurer solvency. Climate change intensifies hurricane severity, leading to greater losses, yet homeowners and insurers perceive these risks differently—homeowners often underestimate the impact, whereas insurers anticipate it to safeguard against insolvency.

This study develops a Cournot-Nash oligopoly model to explore multi-region pricing strategies in the hurricane insurance market. A heuristic-based search method is employed to find equilibrium prices under complex demand and cost structures. We further explore scenarios with varying homeowner beliefs in climate change, assessing impacts on insurance prices, reinsurance costs, market penetration, and insurer profitability.

Applying the model to coastal North Carolina, results show that insurers offer lower rates per expected loss in high-risk coastal areas. Increased competition from new entrants drives prices down and boosts insurance uptake, benefiting homeowners but pressuring insurer finances. Climate change escalates premiums and reinsurance costs, placing growing financial burdens on both insurers and homeowners. However, as more homeowners acknowledge climate risks, insurers experience reduced financial stress and can achieve higher profitability through adjusted pricing strategies. These findings underscore the critical interplay between market dynamics, climate perception, and insurance system resilience in hurricane-prone regions.

2 - Bayesian Optimization Under Functional Uncertainty: a Robust Approach in Function Space

Pouya Ahadi, Georgia Institute of Technology, ATLANTA, GA, United States, Kamran Paynabar

We propose Functional Robust Bayesian Optimization (FRBO), a new framework for optimizing under functional uncertainty, where the entire mapping from design inputs to responses may vary within a structured function space. Unlike prior methods that model scalar input or output uncertainty, FRBO assumes the true function lies within a smooth, norm-bounded region around an unknown reference. We model this ambiguity using an RKHS ball and derive a robust surrogate objective that accounts for both interpolation error and epistemic variability. This enables principled acquisition without reliance on posterior sampling, allowing for nonparametric robustness in

black-box settings. FRBO supports both scalar and functional-valued responses and applies to diverse domains such as optics and materials design. We provide theoretical guarantees on worst-case regret and demonstrate that FRBO consistently outperforms baseline methods by reducing functional regret across a range of uncertainty levels.

3 - Applying Uncertainty Quantification to Improve Plans for Place-Based Projects

Brent Houchens, Sandia National Laboratories, Albuquerque, NM, United States, Mika Armenta, Amanda Wachtel, Sandra Begay

A framework will be presented that facilitates efficient, objective assessments of project plans for place-based (PB) work, offering guidance on attributes that are particularly impactful or critical. This framework is designed to improve the outcomes of PB projects that receive technical assistance (TA), which is often provided by the national labs on projects such as improving energy infrastructure and resilience. Currently there isn't a well-established structure for guiding communities or executing such TA work. While every project has unique characteristics and challenges, there is a recognition that, at a high level, there is a common workflow to projects, and critical attributes throughout that can determine the success.

Unique to this framework is the use of uncertainty quantification (UQ) to predict sensitivities of project outcomes to input attributes across the project space – spanning community buy-in, resource evaluation, permitting, integration, funding mechanisms, operations and maintenance, workforce development, decommissioning, etc. This identifies the most sensitive input attributes and propagates them through the project model, determining when these need to be strengthened, and preventing future bottlenecks and single-point failures.

A case study will be presented demonstrating the capabilities of the framework. Potentially conflicting attribute assessments will be considered from both subject matter experts and community members. This will help identify low, high and conflicting value attributes and potential model-form error or input bias.

Sandia National Laboratories is managed and operated by NTESS under DOE NNSA contract DE-NA0003525.

4 - Data-Driven Planning of Renewable Distributed Generation Under Uncertainty via Distributionally Robust Optimization

Azadeh Farsi, University of Arizona, Tucson, AZ, United States, Canqi Yao, Jianqiang Cheng, Kai Pan

As the integration of renewable distributed generation (RDG) into modern power grids accelerates, it becomes increasingly critical to develop effective planning methodologies that enhance renewable energy utilization while mitigating adverse effects such as phase unbalance. In this talk, we propose a novel two-stage distributionally robust optimization (DRO) model for the optimal siting and sizing of RDG units. The model captures uncertainty in carbon emission pricing and the active power output efficiency of renewable generators through a data-driven ambiguity set. The objective is to minimize the total cost, including both the capital investment in RDG installations and the operational costs incurred over the planning horizon. To promote social equity, the model incorporates energy equity constraints to ensure fair energy access across all buses in the distribution network. Moreover, to address the computational challenge caused by the uncertainties in both the objective function and the constraints, we develop an innovative approximation framework based on the Partial Sample Average Approximation method. The effectiveness of the proposed approach is demonstrated through numerical experiments conducted on the IEEE 33-bus radial distribution system.

5 - Solving the Pollution Routing Problem with Hilly Topography

Yasel Costa, Zaragoza Logistics Center (ESG50985993), Zaragoza, Spain, David Lai, Tom van Woensel

This study addresses the pollution routing problem under a particular setting that includes irregular topography and speed optimization. We propose two solution approaches (approximate and exact) for solving modified Solomon benchmarks and newly constructed real-life problem instances. Results show the good performance of proposed methods and suggest several managerial insights.

6 - Cloud Computing Resource Provisioning Under Uncertainty

Melis Boran, Middle East Technical University, Ankara, Turkey, Secil Savasaneril, Demet Batur

Cloud computing allows users to flexibly control, customize, and scale computing resources without infrastructure investment. Although its adoption has grown since the 2000s, effective cloud cost management remains a challenge. Infrastructure-as-a-Service (IaaS) providers offer computing resources through various pricing plans, and users must decide how much resource to provision with the best pricing plan in advance to meet their workload requirements over a planning horizon. This decision is challenging due to the inherent uncertainty in workloads; the demand for computing resources may vary significantly in both scale and timing.

We address this resource provisioning problem by modeling it as a Markov Decision Process (MDP) aiming to derive a cost-minimizing policy. The solution of the model yields a dynamic optimal provisioning policy. For small-scale problems, we prove that the optimal policy is a state-dependent provisioning policy, which is monotone and non-increasing in the number of available resources. Large-scale problems are intractable due to the curse of dimensionality. Thus, we propose a simple yet effective heuristic policy. We benchmark its performance against the optimal policy in small-scale instances and against commonly used benchmark policies in larger-scale settings. The results show that the heuristic closely approximates the optimal policy in small instances and outperforms benchmark policies in more complex settings.

7 - Sequential Resource Allocation for Humanitarian Operations Using Approximate Dynamic Programming

Sina Ansari, Driehaus College of Business, DePaul University, Chicago, IL, United States, Masih Fadaki, Ahmad Abareshi, Paul Tae-woo Lee

In humanitarian and nonprofit operations, distributing aid such as food, shelter, and medical supplies becomes challenging in an online setting, where the future demand is unknown, since allocation decisions are made in real time as uncertainties unfold. Being overly conservative in allocating items at the beginning of the supply chain to save stock for fulfilling demand further down the supply chain increases the likelihood of unallocated items (waste). On the other hand, fully addressing the demand of nodes in the earlier stages of the supply chain may negatively impact the equity of the allocation policy, as downstream nodes may receive significantly fewer items in proportion to their demand. This study proposes a framework for modeling the sequential decisions involved in this online resource allocation problem as a Markov Decision Process (MDP). Given that the size of the state-action space can become very large for this problem, standard dynamic programming methods in the reinforcement learning domain reach their limits, so using Approximate Dynamic Programming (ADP) is a practical solution. In this study, two methods of measuring downstream uncertainty are proposed, and Policy Function Approximation (PFA) is used to develop an optimal allocation policy. Numerical results and the application of the proposed model to the Food Bank of Southern Tier in New York suggest a reasonable balance between maximizing efficiency (minimizing the waste of unallocated items) and ensuring an equitable allocation.

8 - A Decision-Support Model for Irrigation Planning Under Flash Drought and Flood Risks Using Remote Sensing and Stochastic Optimization

Rui Xi, University of Tennessee, Knoxville, TN, United States, Yuefeng Hao, Mingzhou Jin

Climate change has increased the frequency and intensity of flash floods and droughts, posing serious challenges for agricultural systems. This project develops a decision-making model to help manage these risks. It uses GRACE and MODIS satellite data to track large-scale water storage and vegetation activity. It also includes SWAT hydrologic model outputs to simulate local water processes. These inputs capture daily water availability and crop stress. A stochastic programming framework is used to represent uncertainty in the timing and intensity of extreme weather events. The model supports both long-term investment planning and short-term operational decisions, such as irrigation scheduling and water removal. The expected outcome is a flexible and practical tool that provides farmers and agricultural decision-makers with more accurate and timely information. We also expect the framework to be adaptable to other regions and climate-related challenges.

Submodular Function Minimization: An Interplay between Discrete and Continuous Optimization

Invited Session

OPT: Integer and Discrete Optimization

Chair: Andrei Graur, Stanford University, 729 Escondido Road, Apt 110, Stanford, 94305-7573, United States

1 - Sparse Submodular Function Minimization

Andrei Graur, Stanford University, Stanford, CA, United States

The submodular function minimization (SFM) problem is a foundational combinatorial optimization problem that encompasses directed hypergraph minimum cut problems and computing the size of the largest set in the intersection of two matroids. Given access to an evaluation oracle for a submodular function defined on subsets of a ground set of n elements, the goal of SFM is to compute a minimizer (possibly approximate) with as few queries and additional computation as possible. While SFM is a well-studied problem, its complexity has not been settled. In particular, the state-of-the-art upper bounds on queries for algorithms with $\text{poly}(n)$ additional computation are $O(n^3)$ queries, while the lower bound is $\Omega(n \log n)$. Consequently, we ask the question of whether better runtimes are possible when the minimizer is known to be k -sparse. We title the problem as k -sparse SFM and answer the question in the affirmative, providing an algorithm which makes $O(n \text{poly}(k))$ queries. In this talk, I will introduce the k -sparse SFM problem and some of the tools that enable us to obtain improved runtimes. I will start by presenting some structural properties that arise due to the sparsity assumption in the context of SFM. I will then present how we leverage these properties to obtain an algorithm that finds a minimizer in $\text{poly}(k)$ rounds (each round taking n^2 queries). Finally, I will briefly sketch the technical tools that enable us to obtain our $O(n \text{poly}(k))$ algorithm.

2 - Quadratic Decomposable Submodular Function Minimization with Application in Pagerank Computation for Hypergraphs

Pan Li, Georgia Institute of Technology, Atlanta, GA, United States

Hypergraphs are powerful tools for modeling complex, higher-order interactions in real-world data. When each hyperedge is assigned a submodular weight function, we obtain a submodular hypergraph, capturing intricate dependencies beyond pairwise relationships. Solving min-cut problems on such structures leads to Decomposable Submodular Function Minimization (DSFM), a convex optimization framework that effectively handles these challenges. However, DSFM primarily addresses cut-based objectives. To model diffusion processes—like those captured by PageRank in standard graphs—we extend this framework to incorporate quadratic regularization, resulting in Quadratic Decomposable Submodular Function Minimization (QDSFM). In this talk, we briefly introduce QDSFM, highlighting its formulation that combines quadratic terms with squared Lovász extensions of submodular functions. We present efficient optimization strategies, including a novel dual formulation and double-loop algorithms that integrate Random Coordinate Descent or Alternating Projections in the outer loop with modified Min-Norm-Point or Frank-Wolfe methods in the inner loop. These algorithms come with provable linear convergence rates, ensuring both theoretical robustness and practical efficiency. Applications of QDSFM demonstrate its versatility and effectiveness. Notably, it enables a hypergraph-adapted PageRank algorithm for local partitioning, offering provable performance guarantees. Additionally, in semi-supervised learning scenarios, QDSFM-based methods have shown significant improvements in prediction accuracy compared to existing approaches.

3 - Minimum Cost Adaptive Submodular Cover

Blake Harris, University of Michigan, Ann Arbor, MI, United States, Hessa Al-Thani, Yubing Cui, Viswanath Nagarajan

Adaptive submodularity is a fundamental concept in stochastic optimization, with numerous applications such as sensor placement, hypothesis identification and viral marketing. We consider the problem of covering an adaptive-submodular function at minimum expected cost, which generalizes the classic set cover and submodular cover problems to the stochastic setting. We show that the natural greedy policy has an approximation ratio of $4 \cdot (1 + \ln Q)$, where Q is the goal value. In fact, we consider a significantly more general objective of minimizing the p^{th} moment of the coverage cost, and show that the greedy policy *simultaneously* achieves a $(p + 1)^{p+1} \cdot (\ln Q + 1)^p$ approximation guarantee for all $p \geq 1$. All our approximation ratios are best possible up to constant factors (assuming $P \neq NP$). Moreover, our results extend to the setting where one wants to cover *multiple* adaptive-submodular functions, for which we obtain the same approximation guarantees. Finally, we evaluate our algorithm empirically on instances of hypothesis identification and observe that it performs very well in comparison to a lower bound that we compute.

4 - Discrete and Continuous Difference of Submodular Minimization

Marwa El Halabi, Samsung AI Lab, Montreal, QC, Canada, George Orfanides, Tim Hoheisel

Submodular functions, defined on continuous or discrete domains, arise in numerous applications. We study the minimization of the difference of submodular (DS) functions, over both domains, extending prior work restricted to set functions. We show that all functions on discrete domains and all smooth functions on continuous domains are DS. For discrete domains, we observe that DS minimization is equivalent to minimizing the difference of two convex (DC) functions, as in the set function case. We propose a novel variant of the DC Algorithm (DCA) and apply it to the resulting DC Program, obtaining comparable theoretical guarantees as in the set function case. The algorithm can be applied to continuous domains via discretization. Experiments demonstrate that our method outperforms baselines in integer compressive sensing and integer least squares.

Data Mining

Chair: Ruoxuan Xiong, Emory University, Atlanta, GA, United States

1 - Estimating Bounds on Selection Bias with Outcomes Measured on the Selected

Adam Glynn, Emory University, Atlanta, GA, United States, Elisha Cohen

Outcome tests are a method for detecting bias in selection procedures using data on selected units. We use a principal stratification approach to establish lower bounds on this bias for general outcomes. We show that the Knox et al. (2020) bound is sharp for a binary outcome, and weaken the assumptions required for that bound. We also show that the analogous bound for non-binary outcomes is not sharp and provide sharper lower bounds. We illustrate these methods with a re-analysis of the data in Anzia and Berry (2011) on the delivery of federal spending by male and female members of Congress. Using their data, and the covariates from their analysis, we find that the unsharpened lower bound estimates that roughly 4% of men elected, would not have been elected, had they been women. That estimate increases to roughly 20% when sharpening the lower bound using our method.

2 - Strategic Experimentation: A Data-Driven Approach to Theory and Practice

Molly Offer-Westort, University of Chicago, Chicago, IL, United States

On digital platforms, experiments—especially A/B tests—are often used to evaluate whether a pre-specified intervention improves outcomes relative to a pre-specified control condition. The interventions may represent a test of a theory or evaluation of a product or design feature. However, there may be multiple interventions that could be consistent with this test and a single intervention may only imperfectly reflect the underlying construct of interest. When experiments yield null results, how should we interpret them: as evidence against the theory or feature, or only against that specific realization of the intervention?

This question becomes especially salient in large-scale digital environments, where we can leverage rich data and adaptive experimentation to explore the space of possible interventions. In this paper, I propose a framework for theory-informed experimental design that integrates both theory testing and theory building. First, I illustrate how strategically designed experiments allow us to explore the "theory space" for more informative data driven hypothesis tests. Second, I extend this framework to theory building, addressing cases where minimal theoretical grounding exists. This approach is especially valuable in digital contexts where we have scale but possibly limited prior theory, and where there may be a large range of candidate interventions. Through designs with strategic assignment algorithms, we can improve statistical power, manage multiple testing concerns, and guide experiments toward effective interventions. I discuss relevant applications to social media experiments conducted over Facebook Messenger.

3 - Designing Staggered Rollout Experiments with Indefinite Effect Lengths

Weibin Mo, Purdue University, West Lafayette, IN, United States

We consider the experimental design of staggered rollouts, where the treatment effects since intervention can last for a long and even infinite number of periods. In this case, the two-way-fixed-effect regression with a fixed length of effect window is generally misspecified, but the treatment effect coefficients can still be consistent estimates of the cumulative treatment effect in long run. We quantify the bias-variance trade-off under a large-panel asymptotic regime, that is, the numbers of treatment units and periods tend to infinity proportionally. Under such an asymptotic regime, we prove the consistency of the misspecified cumulative effect estimate, and the optimality of linear symmetric staggered rollouts. We also obtain an optimal design of always-treated, never-treated, and linear-rollout units that minimizes the asymptotic mean-squared error of the cumulative effect estimate. As two extreme special cases, the “flat” design with all units either always-treated or never-treated over time is bias-optimal, while the “diagonal” design with all linear-rollout units is variance-optimal. This complements Xiong et al. (2023)’s design with the optimality of linear rollout and the trade-off under lag misspecification. The managerial implication of such a trade-off is that, the linear staggered rollout can incur bias due to long-lasting treatment effects, and such a bias can be offset in a long-run design (large panel) with additional always-treated and never-treated units.

4 - Model-Assisted Inference for Dynamic Causal Effects in Staggered Rollout Cluster Randomized Experiments

Xinyuan Chen, Mississippi State University, Mississippi State, MS, United States

Staggered rollout cluster randomized experiments (SR-CREs) are increasingly used for their practical feasibility and logistical convenience. These designs involve staggered treatment adoption across clusters, requiring analysis methods that account for an exhaustive class of dynamic causal effects, anticipation, and non-ignorable cluster-period sizes. Without imposing outcome modeling assumptions, we study regression estimators using individual data, cluster-period averages, and scaled cluster-period totals, with and without covariate adjustment from a design-based perspective, where only the treatment adoption time is random. We establish consistency and asymptotic normality of each regression estimator under a finite-population framework and formally prove that the associated variance estimators are asymptotically conservative in the Lowner ordering. Furthermore, we conduct a unified efficiency comparison of the estimators and provide practical recommendations. We highlight the efficiency advantage of using estimators based on scaled cluster-period totals with covariate adjustment over their counterparts using individual-level data and cluster-period averages. Our results rigorously justify linear regression estimators as model-assisted methods to address an entire class of dynamic causal effects in SR-CREs and significantly expand those developed for parallel-arm CREs by Su and Ding (2021, JRSSB) to accommodate a wider class of complex experimental settings with staggered randomization.

5 - Asymptotic Theory of the Best-Choice Rerandomization Using the Mahalanobis Distance

Yuhao Wang, Tsinghua University and SQZ, Haidian District, China, People's Republic of, Xinran Li

Rerandomization, a design that leverages pretreatment covariates to improve balance between treatment groups, has gained increasing attention in both theory and practice. Bruhn and McKenzie (2009) identify two common approaches: (i) rerandomizing until covariate imbalance is below a prespecified threshold, and (ii) generating multiple randomizations and selecting the one with the best covariate balance. This paper studies the second approach, best-choice rerandomization, for which theoretical foundations remain underdeveloped.

We focus on best-choice rerandomization using the Mahalanobis distance to measure covariate imbalance, a widely used criterion due to its invariance to affine transformations of covariates. Our analysis examines the large-sample repeated sampling properties of this design, allowing both the number of covariates and the number of tried randomizations to increase with sample size.

We show that under best-choice rerandomization, the asymptotic distribution of the difference-in-means estimator is more concentrated around the true average treatment effect than under complete randomization. Based on this, we propose large-sample confidence intervals that are both valid and shorter than those from standard randomized experiments.

Furthermore, we demonstrate that with a moderate number of covariates and a polynomially increasing number of randomizations, best-choice rerandomization can attain nearly optimal precision, approaching that achievable with perfectly balanced covariates. The proposed theory and methods are also illustrated with real field experiments, highlighting their practical relevance.

Advancing Cancer Care with Data Driven Approach

Invited Session

Health Applications Society

Chair: Sayaka Ishizawa, The University of Texas MD Anderson Cancer Center, Houston, TX, 77030, United States

1 - Validation of Integrating Non-Smoking Risk Factors into Engage Using the NLST Dataset

Maryam Eghbalizarch, Kennesaw State University, Marietta, GA, United States, C. Martin Tammemagi, Sayaka Ishizawa, Seyyed Mostafa Mousavi Janbeh Sarayi, Rafael Meza, Iakovos Toumazis

The ENGAGE framework uses a partially observable Markov decision process to optimize lung cancer (LC) screening for ever-smokers at a personalized level by balancing the potential benefits and harms of screenings. A limitation of ENGAGE is that it only considers age, sex, smoking status, smoking intensity, and years since smoking cessation for dynamically estimating LC risk over time. This study extends the original ENGAGE framework by integrating non-smoking related risk factors (i.e. race/ethnicity, body mass index, education, family and personal cancer history, COPD, and comorbidities including diabetes, hypertension, stroke, and cardiovascular disease) into its risk estimation model. Three versions of Cox regression models (6-race, 3-race, and no-race PLCOENGAGE2025) were developed using data from the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (PLCO) to predict LC incidence, and one model to predict death from non-LC causes. These models were validated both on the PLCO intervention arm and the National Lung Screening Trial (NLST). We integrated these risk models into ENGAGE and derived personalized screening schedules for NLST subjects and compared the effectiveness and efficiency of ENGAGE versus NLST. ENGAGE using the Bach model reduced the number of screening exams to 81% and false positives to 84%, while delaying 2.8% of screen-detected LC diagnoses compared to the NLST. ENGAGE-derived schedules based on the PLCOENGAGE2025 risk models reduced screening exams to 79.6%–80% and false positives to 82.1%–82.5%, while delaying 2.7%–3.3% of screen-detected LC diagnoses. Therefore, including non-smoking risk factors in the risk models can enhance effectiveness of screening across diverse cohorts.

2 - Will Machines Take over? Algorithms for Human-Machine Collaborative Decision Making in Healthcare

Mehmet Ahsen, University of Illinois at Urbana-Champaign, Champaign, IL, United States, Mehmet Ayvaci, Radha Mookerjee

This study presents a cost-effective diagnostic system for allocating mammography interpretation tasks between AI and radiologists, ensuring patient

safety. Using a two-threshold policy based on algorithmic risk scores, it minimizes costs by combining automation and delegation strategies. Back-testing shows potential savings of 20.9%, with broader implications for AI-human collaboration workflows.

3 - Metamodeling Population Health Outcomes: Accounting for Varied Crc Screening Behaviors and Intervention Strategies

Ashley Stanfield, North Carolina State University, Raleigh, NC, United States, Maria Mayorga, Meghan O'Leary, Kristen Hassmiller Lich

Colorectal cancer (CRC) is the third leading cause of cancer-related deaths in the United States. When detected early through screening, CRC can often be treated effectively or prevented by removing precancerous lesions during a colonoscopy. Routine screening—either with fecal immunochemical tests (FIT) or colonoscopy—is recommended for individuals aged 45 to 74. However, as of 2023, only 58% of age-eligible individuals were up-to-date with screening. Increasing adherence is a public health priority, as higher screening rates are associated with more cancer deaths averted. A validated simulation model has been used to estimate health outcomes under different screening scenarios. Using this model, we previously developed metamodels to rapidly estimate outcomes such as cancer cases and life years lost for individuals who originally screened with FIT and received a FIT-based intervention. In this work, we extend the framework to account for population subgroups defined by three factors: their original screening modality (FIT or colonoscopy), the type of intervention they receive (FIT or colonoscopy), and their screening level. We estimate outcomes for each subgroup and then aggregate these to generate population-level results. This enables comparisons between strategies such as targeting all individuals with FIT, all with colonoscopy, or tailoring the intervention to each subgroup to maximize health gains. We also identify the screening increases required across intervention-modality combinations to achieve similar outcomes. This approach helps decision-makers evaluate and compare targeted interventions based on real-world screening behaviors.

4 - Machine Learning-Based Models for Personalized Decision Making in Acute Myeloid Leukemia

George Atherton, The University of Oklahoma, Norman, OK, United States

Acute myeloid leukemia (AML) remains the most common type of acute leukemia cases in adults and affects more than 21,000 people in the US each year with incidence rates projected to rise. Existing treatment protocols prescribe induction chemotherapy (and possibly radiation therapy) with the aim of achieving complete remission. However, certain patients may require hematopoietic stem cell transplantation. Despite its desirable overall survival outcomes in the AML patients, the presence of comorbidities can complicate the transplant leading to negative outcomes, particularly non-relapse mortality (NRM). In this talk, we will explore how machine learning models can support personalized treatment decisions for AML by predicting NRM risk. Specifically, we utilize data from AML patients treated at the OU Stephenson Cancer Center to train and evaluate our proposed models.

AI Models in Healthcare

Invited Session

MSOM: Healthcare

Chair: Hossein Piri, Haskayen School of Business-University of Calgary, Calgary, AB, Canada

1 - Navigating Spatial Queueing Networks with Travel and Delay Tradeoffs

Marco Bijvank, University of Calgary, Calgary, AB, Canada, Sandjai Bhulai

We study a queueing network where customers decide which physical queue to join based on announced delay information and their respective travel times to each queue. The waiting times of each queue are approximated by modeling the system as a Markov-modulated Poisson process. Additionally, each queue location can decide to inflate or deflate their announced wait time from the predicted wait time. However, queue locations are getting a reward based on customer satisfaction that is determined by the over- or underperformance compared to the announced wait time. As a result, servers have to make a trade-off between customer throughput and customer satisfaction. An obvious application is a network of Emergency Departments (EDs) where patients can decide which ED location to visit.

2 - Optimizing Ambulance Location and Relocation in Conflict Zones: a Case Study from Northwest Syria

Sara Ahmed, University of Toronto, Toronto, ON, Canada, Sheng Liu, Timothy Chan

In conflict-affected regions, ambulance services face unique challenges. Unlike typical emergency systems, operations in these settings are decentralized, with multiple stakeholders managing separate fleets, each with different priorities. Ambulance services must operate under sudden demand surges triggered by conflict, along with fluctuating vehicle availability. This study considers ambulance planning over a multi-period horizon, motivated by operations in Northwest Syria, where ambulances respond to both emergency calls and inter-facility transfers. These two service types differ in dispatch rules, operational requirements, and how their demand varies with conflict dynamics. The first part of the work focuses on empirically modeling how changes in conflict intensity affect service demand across space and time, using historical conflict and ambulance data. Building on this, a decision model is developed to determine ambulance placements and relocations, accounting for conflict-driven shocks and partner-specific objectives. The study is part of ongoing work with the World Health Organization and implementing partners, aiming to support more adaptive, data-driven planning in decentralized, high-risk settings.

3 - Behavior-Based Price Discrimination in AI Product Markets: Incentivizing User Contributions Under Duopoly Competition

Bo Feng, Soochow University, Suzhou, China, People's Republic of, JIXIN ZHAO, Tianhu Deng

In user-generated markets, such as those for AI products and databases, product quality evolves with user participation and effort. This paper studies how firms can leverage these user driven quality improvements using behavior-based price discrimination (BPD) in a two-period vertical duopoly comprising a private firm and an open-source firm. In Period 1, users choose between purchasing the private firm's established product or by adopting the open source firm's base product and contributing effort to improve its future quality. Before Period 2, the open-source firm announces a contributor discount; both firms then set prices that discriminate based on user purchase

histories. We find that higher contributor discounts do not always incentivize greater user effort, as strategic users may anticipate future price reductions by the private firm and delay contributions. The optimal discount for the open-source firm increases with the marginal quality gain from user effort but decreases with greater user heterogeneity or a larger incumbent quality lead. Contribution-based BPD improves consumer surplus and total welfare, but can erode firm profits if discounts are misaligned. These results highlight key strategic trade-offs: open-source firms should link discounts to the quality value each user generates and avoid overly aggressive incentives that provoke competitive undercutting. Private firms can counter by targeting poaching strategies, while policymakers aiming to promote innovation and welfare may support stronger contributor rewards through subsidies.

4 - Mitigating Missing Outcome Bias in Multi-Site Healthcare Data Using Auxiliary Outcomes for Wait TIME Estimation

Jae Park, University of Central Florida, Orlando, FL, United States, Antonio Castellanos, Joseph Zourob

Building machine learning models using multi-site healthcare data is essential for ensuring generalizability. Models trained on data from a single site may be limited, as their findings might not be applicable to other institutions. To enhance generalizability in healthcare research, federal agencies (e.g., the Agency for Healthcare Research and Quality) manage data from numerous healthcare institutions across the United States. Additionally, data consortiums (e.g., OneFlorida) establish data-sharing agreements with multiple institutions, centralizing data collection from affiliated sites.

Despite these efforts, multi-site data frequently suffer from quality issues due to inconsistencies in clinical practices and data availability. For example, some hospitals collect a particular health outcome while others do not, leading to missing data. This can result in biased models that perform better for hospitals with more complete data. In this study, we tackle this challenge by leveraging an auxiliary outcome that is closely related to the primary outcome of interest.

Our numerical experiments focus on estimating emergency department (ED) waiting times using the national ED data from 2016 to 2022. Among the 1,219 hospitals in the dataset, 57 do not report waiting time data, and 9,464 (9.5%) out of 99,491 records are missing this outcome. Since the length of ED visit provides an upper bound on the wait time, it can serve as an auxiliary outcome. By incorporating this additional information, we enhance prediction performance across participating hospitals and mitigate the bias introduced by incomplete data.

5 - Detecting Positive Cognitive Aging Using Diffusion MRI

Guiping Hu, Oklahoma State University, Stillwater, OK, United States, Mohammad Fili, Parvin Mohammadiarveje, Auriel willette

While most adults experience some degree of age-related cognitive decline, a subset known as “Positive-Agers” show superior cognitive abilities compared to their age-matched peers. Identifying individuals with exceptional cognitive performance versus those experiencing decline is critical for guiding targeted interventions in older populations. In this study, we introduce *Optimal Cognitive Scoring* (OptiCS) algorithm, designed to distinguish Positive-Agers from Cognitive Decliners. Drawing on longitudinal data from 5,797 participants in the UK Biobank, our predictive pipeline achieved strong classification performance, with an area under the curve (AUC) of 0.83. The most informative features were diffusion MRI metrics from tracts associated with pathological aging, including the hippocampal fornix, the tapetum of the corpus callosum, and other key white matter pathways. This work offers three major contributions: (1) a reliable scoring system to detect cognitive shifts, (2) evidence that diffusion MRI can serve as a powerful biomarker for cognitive status in healthy adults, and (3) a predictive framework for the early identification of cognitive decline.

MSOM: Healthcare

Chair: Guihua Wang, The University of Texas at Dallas, Richardson, TX, United States

Co-Chair: Minmin Zhang, University of Texas at Dallas, Richardson, TX, United States

1 - Impact of Regulation on Deceased-Donor Liver Offer Acceptance and Patient Welfare

Shubham Akshat, University of Houston, Houston, TX, United States, Liye Ma, Christopher Hughes

The public reporting of a transplant program (TP)'s post-transplant outcomes has been a contentious issue in the transplant community in the United States. TPs are also regulated by the Department of Health and Human Services, which periodically monitors their post-transplant outcomes. While they aim to uplift the underperforming TPs and enable informed decision-making (by patients and insurance companies), there can be important unintended consequences. To maintain a good public image and comply with regulations, a TP might deviate from fulfilling its core responsibility of maximizing patient welfare when deciding to accept an organ offer for a patient.

We develop a novel empirical framework to study the impact of regulations on deceased-donor liver offer acceptance decisions at a TP. Our framework integrates patient-centric and regulatory considerations, whereas existing literature has focused only on the former. Further, we incorporate a TP's response to its regulatory standing into a discrete-event simulation to evaluate the impact of regulations on organ non-utilization and patient welfare.

We find that a TP becomes increasingly selective in its offer acceptance decisions as its regulatory standing worsens. This behavior exhibits a near-monotonic pattern for marginal quality organs. Broadly speaking, a TP deviates from a patient-optimal decision more when an organ is of marginal quality. When a TP was in poor regulatory standing, the non-utilization rate of marginal quality organs more than doubled (w.r.t. intermediate standing). More patients died on the waiting list (40 more deaths annually), disproportionately affecting high-risk patients. Lastly, we outline several policy implications.

2 - Causal Evidence of Task-Switching Cost in Organ Transplantation

Yiwen Jin, Haskayne School of Business, University of Calgary, Calgary, AB, Canada, Jiayi Liu, Joel Adler

Laboratory studies have demonstrated that switching between tasks increases cognitive load and error rates, yet its consequences in high-stakes professional contexts remain unclear. Here, we provide causal evidence of the impact of task switching in organ transplantation. Leveraging the unpredictable arrivals of donor organs as a natural experiment, we analyze national data on 316,743 abdominal transplants performed by 982 surgeons over 13 years. We find that switching between organ types (e.g., from liver to kidney) significantly increases one-year post-transplant mortality by 0.58 percentage points (a 12.3% relative increase). These adverse effects can be substantially reduced through structured scheduling practices, increased surgeon experience, and longer intervals between surgeries. Our findings identify task switching as a critical, previously unrecognized risk in organ transplantation and highlight the need for training programs and clinical practices to implement targeted interventions to improve patient survival.

3 - A Heterogeneous Transition Forest Approach for Analyzing Changes in Health States: Implications for Organ Transplantation

Minmin Zhang, The University of Texas at Dallas, Richardson, TX, United States, Guihua Wang

State transitions are crucial for modeling changes in conditions such as patient health. While existing models use this concept in decision-making, they typically assume homogeneity across all units, overlooking individual variability—particularly important in contexts like disease progression. This study introduces a novel method, the Heterogeneous Transition Forest (HT forest), to capture patient-specific transitions in health states. We apply this approach in the context of organ transplantation, modeling how patients' health evolves while waiting for a transplant. Our findings reveal significant variability in transition patterns based on individual patient features, underscoring the limitations of homogeneous models. To evaluate the impact of this heterogeneity, we develop a Markov decision process that incorporates personalized transition probabilities. The results show that using patient-specific transitions in decision-making significantly improves patient outcomes, measured in total expected life days. This research offers a new methodological contribution for estimating heterogeneous transition probabilities, which has practical implications for healthcare. By incorporating individual patient characteristics into decision models, healthcare providers can enhance the effectiveness of treatment strategies and potentially extend patient lifespans.

4 - Data-Driven Approach to the Surgical Block Auto-Release Decision

Sandeep Rath, University of North Carolina at Chapel Hill - Kenan Flagler, Chapel Hill, NC, United States, Moe Lim

Surgical block allocation balances surgeon scheduling and OR utilization. Unused blocks are auto-released for open access before surgery, requiring a trade-off between predictability and efficiency. Using historical booking data, we developed a data-driven approach to optimize auto-release timing, enhancing OR utilization without compromising scheduling predictability in a large medical center

1 - Dining Disrupted: the Impact of Food Delivery Platforms on the Restaurant Industry Market Structure

Sandeep Srinivas, University of Illinois at Urbana Champaign, Champaign, IL, United States, Ujjal Mukherjee, Gautam Pant

Food delivery platforms have transformed the restaurant industry and consumer dining habits. This study examines how their introduction has reshaped the restaurant industry's market structure. Specifically, we focus on which types of restaurants—full-service restaurants versus others—stand to gain or lose from the presence of these platforms. Using multiple empirical techniques, we show that platform entry has shifted market share away from non-full-service restaurants and toward full-service establishments. To uncover the mechanisms behind this shift, we analyze Google reviews and find that non-full-service restaurants receive systematically lower ratings after platforms arrive. We examine different aspects of consumer reviews to understand specific attributes driving this change. Our findings clarify the dominant mechanisms at work in the food delivery platform context and offer strategic insights for restaurateurs and investors to navigate the expanding food delivery market.

2 - Estimating Scope 3 Emissions via Supply Chain Tracing

Sanjith Gopalakrishnan, McGill University, Montreal, QC, Canada, Michael E. Raynor

In the pursuit of global net-zero emissions, hard-to-abate (HTA) upstream sectors like steel and cement pose significant challenges. Meanwhile, several consumer-facing firms in sectors such as retail and consulting have adopted ambitious net-zero supply chain targets. However, these efforts often rely on ad hoc supply chain tracing that rarely extends to deep upstream tiers, thereby excluding high-emission HTA sectors and undercounting supply chain emissions, i.e., Scope 3 emissions. This work therefore addresses a critical challenge in environmental supply chain management: the accurate estimation of Scope 3 emissions. We describe a hybrid carbon footprinting method that combines conventional estimation methods that rely on supply chain tracing with an input-output life cycle analysis approach. By situating a traditional supply network model within an input-output framework, we map the problem of identifying the optimal supply chain tracing strategy to a graph-theoretic optimization problem and provide an exact solution approach to improve the accuracy of Scope 3 emissions estimates.

3 - A Fast Ecological Inference Algorithm for the R times C Case

Charles Thraves, University of Chile, Santiago, Chile, Pablo Ubilla, Daniel Hermosilla

The RxC ecological inference problem is known to be difficult to address. In the past, researchers have approached this problem from various angles, including parametric probability models, entropy-maximization, and mathematical programming. In this work, the ecological inference problem is based on an election context where, at each ballot box, we observe candidates' votes and the number of voters from each demographic group. We estimate non-parametric voting probabilities for each group by applying the EM algorithm, in which the M-Step can be solved in closed-form, whereas the E-Step can only be solved in practice for small instances. We show that the M-Step can be solved with a closed-form solution, while the E-Step requires an exponential number of steps to be solved exactly. To address this, we propose four approximation methods to compute the E-Step in polynomial time. Through simulated instances, we observe that the resulting probability estimates using these methods are very close to the real values, with running times less than a thousandth of a second. We then introduce a methodology to perform group aggregation when the observed data is insufficient to estimate voting probabilities accurately. We apply this technique to the 2021 Chilean Presidential election, obtaining estimates of voting probabilities for different age ranges. We observe that older voters tend to support right-wing candidates and long-established parties, whereas younger voters show the opposite tendency. The described method is also used to detect outlier ballot boxes. Developed methods are available in the R library 'fastei'.

4 - Coproduction in the Classroom: Optimally Allocating Incentives Between Teachers and Students

Vanitha Virudachalam, Gies College of Business, UIUC, Champaign, IL, United States, Nan Liu, Sergei Savin

Schools have long experimented with monetary incentives to encourage high levels of teacher effort. Less common is the use of monetary incentives for students, even though education is a coproduced service in which both teachers and students must exert effort to achieve a successful outcome. We study the problem faced by a school district that must optimally allocate a monetary incentive between teachers and students to achieve a baseline threshold of student proficiency levels. In our model, teachers manage a classroom of N students, where there are two types of students: high- and low-performing students. Teachers must choose their optimal effort allocation between the two types of students, whereas students individually determine how much effort to exert. For both teachers and students, effort is costly. Using a single-period Bertrand model, we study the optimal allocation of a merit-based incentive between teachers and students and the resulting effort decisions of each party.

5 - A Moment for Reflection: De-Biasing Service Evaluations

Hallie Cho, Georgetown University, Washington, DC, United States, Dawson Kaaua

Problem definition: Service evaluations typically solicit feedback in two ways: star ratings and written feedback (i.e., comments). Although star ratings are typically collected before comments, we propose that switching this order to ask for comments first can mitigate bias present in star ratings since the process of writing provides time and space for the evaluator to reflect on their experience. Methodology/results: We conducted an experiment on Amazon Mechanical Turk where 4261 participants received a sequence-based service, with the same overall level of service, from servers who varied in their demographic characteristics. Following the service, the participants were asked to evaluate the performance of the servers with the order of star ratings and written feedback randomized. We find no evidence of demographic bias toward the servers (e.g., race, gender, sexuality, age, and body size) but find that the sequence of good and bad experiences in the service leads to biased star ratings. Most importantly, we find that collecting comments prior to star ratings effectively mitigates the detected sequential bias in subsequent star ratings due to participants reflecting on the service experience. Managerial implications: Our paper shows that the most widely used quantitative feedback (i.e., average star ratings) can be biased if collected in the traditional manner and that this bias can be reduced if qualitative feedback (i.e., comments) is collected first. Implementing such a change in the way organizations conduct service evaluations could yield many benefits.

Decision Analysis Award session

Award Session

Decision Analysis Society

Chair: Robin Dillon-Merrill, Georgetown University, Washington, DC, United States

1 - Awards Session**Robin Dillon-Merrill, Georgetown University, Washington, DC, United States**

Award Session Chair

2 - Student Paper Award Chair**Rupert Freeman, University of Virginia, Charlottesville, VA, United States**

Award Chair

3 - Publication Award Chair**alessandra cillo, LIUC University, Castellanza (Va), Italy, Johannes Muller-Trede**

The Decision Analysis Society Publication Award is given annually to the best decision analysis journal article or book published in the second preceding calendar year, as judged by an award committee. Publications appearing in the year 2023 would be eligible for consideration in the year 2025. For this award, decision analysis is defined as a prescriptive approach to provide insight for decision making based on axioms that are logically consistent with the axioms of von Neumann and Morgenstern and of Savage. Key constructs of decision analysis are utility to quantify one's risk preferences and probability to quantify the state of one's knowledge. The intent of the award is to recognize the best publication in decision analysis. Contributions could include, but are not limited to, theoretical, methodological, and procedural contributions to decision analysis, descriptions of applications and experimental studies. Nominated publications will be judged for significance, relevance, originality, and readability.

4 - Ramsey Medal Award Chair**Yael Grushka-Cockayne, Darden School of Business, University of Virginia, Charlottesville VA, VA, United States**

The Frank P. Ramsey medal is awarded for distinguished contributions in decision analysis. Distinguished contributions can be internal, such as theoretical or procedural advances in decision analysis, or external, such as developing or spreading decision analysis in new fields.

1 - Optimal Regulation Paradigm Design with Privacy Protection and R&D Incentive**Qian Zhang, California State Polytechnic University Pomona, Pomona, CA, United States, Luying Wang**

Consumer privacy refers to the safeguarding of personal information shared by individuals with businesses, ensuring that such data is not misused or improperly disclosed. This has led to public discussions on whether individuals' privacy should be better protected by restricting the amount or the precision of information that commercial institutions collect on their participants. We design a model by addressing the impact of optimal privacy regulation on the firm's production investment in the context of Bayesian persuasion, where one regulator can design an information revelation policy to reveal a certain degree of consumers' private information. A monopolistic firm observes the signal about consumers, then makes a recommendation and price offer to uninformed consumers who have recourse to some outside option. Since such a signal reveals certain private information about consumers, and the firm cannot learn more than the signal, we define such signal as privacy regulation, i.e., the maximum amount of consumer information that can be revealed to the firm. We show that if the regulator's objective is to maximize a combination of consumer surplus and R&D investment, then there always exists a unique optimal privacy protection policy to reveal a certain degree of consumer privacy information to the firm. Further, if the

regulator is able to further design other regulations such as minimum quality regulation or price fairness regulation, then potentially it is possible to further improve social welfare. We show that it is optimal for the regulator to design a combination of regulations endogenously to maximize social welfare.

2 - Optimal Data Pricing Decisions of Competitive Two-Sided Platforms with Heterogeneous Data Costs

Jinpu Li, Tsinghua University, Beijing, China, People's Republic of, Ronghua Sui, Ruize Gao

Two-sided platforms play the role of data intermediaries in the era of the digital economy. Data are byproducts of users' activities and are replicable, creating an important profit source and competitive advantage for the platforms. In this paper, we build a Hotelling model to study data collection and the related pricing of competitive platforms with heterogeneous costs. Our study identifies differences in the pricing scheme based on whether platforms adopt consistent or differentiated collection strategies, and examines the impact of data usage and affiliation behavior on platform decisions. Our main findings are as follows: First, when one platform holds a significant cost advantage, adopting differentiated data collection strategies for both platforms is optimal; otherwise, consistent strategies are preferable. Notably, in scenarios where both platforms adopt consistent collection decisions (i.e., both partially collect data), the cost-disadvantaged platform benefits more from increased data collection compared to its cost-efficient counterpart, heavily influencing its pricing based on internal costs. Second, for any platform, lowering pricing can become a wise strategy as the value derived from data usage increases under certain condition. This approach not only attracts more users but also enhances overall profitability by leveraging the higher utility that each unit of data provides. Third, two-sided users' affiliation behaviors will influence the platforms' data decisions in distinct aspects. The change of consumer affiliation behavior primarily impacts the platforms' data pricing, whereas provider affiliation behavior will change data collection strategies significantly.

3 - The Design and Price of Influence

Raphael Boleslavsky, Indiana University, Bloomington, IN, United States, Aaron Kolb

A sender with private preferences would like to influence a receiver's action by providing information through a statistical test. The technology for information production is controlled by a monopolist intermediary, who offers a menu of tests and prices to screen the sender's type. We characterize the intermediary's optimal screening menu and the associated distortions, which may benefit the receiver by increasing test informativeness. Because of these distortions, seemingly unfavorable changes in the prior belief may actually benefit the sender. In extensions, we study (i) a stronger intermediary who can commit to a "coercive" test to punish non-participation and (ii) a weaker intermediary who cannot control test design but can charge for access.

4 - Your Data, My Data: Information Disclosure and Competition in Marketplace Platforms

Noam Shamir, Tel Aviv University, Tel Aviv, Israel, Sarit Markovich, Yaron Yehezkel

The dominance of e-commerce platforms has raised concerns about potential anti-competitive practices, particularly due to their dual roles as marketplace operators and sellers. This study examines when sellers choose to disclose their private information concerning characteristics of potential buyers to a market place platform. Such disclosures can result in "informational spillovers," where platforms exploit this information to compete against sellers. This dynamic may discourage sellers from sharing critical information, leading to market inefficiencies. We analyze the conditions under which these inefficiencies arise and evaluate two policy remedies: vertical separation and informational firewalls. Our findings reveal that sellers choose to conceal buyer information under moderate substitution levels between products to prevent strategic competition, resulting in welfare losses due to reduced market competition and inefficient advertising allocation. Vertical separation, while encouraging information sharing, can reduce competition, resulting in mixed welfare outcomes. Informational firewalls, by restricting platforms from using seller information to gain a competitive advantage, promote consistent information sharing but may, in some cases, also limit competition and lead to inefficient advertising allocation. These findings highlight the intricate interplay between platform competition, seller information sharing, and regulatory interventions, offering valuable insights for policymakers and businesses operating in platform-driven markets. Our study also underscores the tension between maximizing welfare and protecting seller's private information because welfare is highest when the platform utilizes the seller's information. We also show that in some cases, the seller prefers the platform to use its private information because doing so leads the platform to avoid competition.

Innovative Strategies in Supply Chain and E-Commerce Operations

Invited Session

MSOM: Supply Chain

Chair: Lu Kong, University of South Florida, Tampa, FL, United States

Co-Chair: Ting Wang, University of Science and Technology of China, Hefei, N/A

Co-Chair: Kejia Hu, University of Oxford Said Business School, Oxford, United Kingdom

1 - Competitive Partial-Payment Presale with Consumer Switching

xuhan tian, Shanghai Tech University, Shanghai, China, People's Republic of, Xiangtong Qi, Yusen Xia

Common E-commerce platforms have increasingly adopted partial-payment presale promotions as a marketing tactic. This promotion allows consumers to secure a product by paying a non-refundable deposit before the product is released, capitalizing on consumers' uncertain and often fluctuating purchasing intentions. The inconsistency of consumers' purchasing intentions is reported to be amplified during highly competitive sales events, manifesting as impulsively pre-ordering after being exposed to targeted pop-up ads, frequent regretting and switching to later found alternatives. Such behaviors have added a new structural element to the conventional presale competition, impacting online sellers' profitability and calling for a focused study for the platform to enhance promotion design and management. We construct an analytical model to study the presale competition in the presence of switching consumers, from which we further investigate how sellers' profitability may be affected by how the presale is organized. Our results suggest that competition can drive sellers to prevent consumers from switching through price reductions, potentially diminishing presale advantage and reducing profitability. However, the platform can mitigate this effect by strategically facilitating consumer switching through appropriate deposit control, which can also increase social welfare with higher equilibrium profits and consumer

2 - Collaborative Prepositioning with Postponement and Stock Sharing in a Network with Regional and Country Warehouses

Lamia Gulnur Kasap Simsek, NA, Dallas, TX, United States, Birce Adsanver, Burcu Balcik, Marie-Ève Rancourt

We evaluate the impacts of postponement and stock-sharing strategies among humanitarian organizations (HOs) operating within regional and country-level depots for prepositioning supplies. In our setting, HOs in both regional and country warehouses respond to disasters within their designated areas in a specific region. Our proposed system involves HOs stocking supplies in both branded (final product) and unbranded (shareable standard) forms at the regional depot, while limiting stocks to branded form only at country depots for faster response. To operationalize postponement and stock sharing, we develop a two-stage stochastic optimization model that minimizes expected response time weighted by disaster severity under fixed total base stock constraints. This model optimizes the levels of branded and unbranded items for each HO across warehouses, facilitates stock sharing in the regional warehouse, and devises optimal stock mobilization strategies to affected countries. We test our approach using historical hurricane scenarios from the Caribbean region and data from HOs. We demonstrate substantial savings in fill rate, response time, and inventory utilization.

3 - Serving E-Commerce and E-Grocery Deliveries Together with Learning-Based Vehicle Dispatching

Oguz Sohret, Koc University, Istanbul, Turkey, Baris Yildiz, Gurhan Kok

We present a machine-learning based approach to support routing optimization in a collaboration model between a grocery and an e-commerce company, both of which agree to deliver online orders together using a single vehicle. Grocery orders including same-day delivery are delivered within time windows, whereas e-commerce orders are delivered anytime in the day.

1 - Mitigating Gender Bias in Higher Ed Instructor Evaluations

Tong Wang, Chicago Booth, Chicago, IL, United States, Monika Heller, Kamalini Ramdas

Instructor ratings play a crucial role in learners' course selection and significantly impact key career outcomes for instructors, including recruitment and promotion. While gender bias in traditional classroom evaluations is well-documented, operational strategies to mitigate such bias have received limited attention. We ran three preregistered online experiments to examine how instructor gender and prior ratings impact instructor evaluations, under identical teaching quality. Our findings show that both female and male learners exhibit bias against instructors of the opposite gender, mainly when they face a higher cognitive load due to time pressure. Furthermore, male learners tend to correct unfairly low ratings only for male instructors, introducing a gender bias against female instructors. Learners exposed to high prior ratings tend to increase their ratings for instructors of the same gender, exhibiting confirmation bias. Our findings that publishing prior ratings or increasing cognitive load could exacerbate gender inequity highlight two previously unexplored operational levers to mitigate gender bias.

2 - The Impact of Race-Blind and Test-Optional Admissions on Racial Diversity and Merit

Allen Sirolly, Columbia Business School, New York, NY, United States, Hongyao Ma, Yash Kanoria

How significant was the role of racial preferences in U.S. college admissions before the Supreme Court's 2023 decision to ban race-based affirmative action? How much might test-optional admission policies impact racial diversity and academic merit? In this work, we estimate a simple model of college admissions decisions from 2012–2020, leveraging a novel dataset of applicant profiles and admissions outcomes across the full spectrum of college selectivity. We find that, broadly, the impact of race and testing policies on diversity and merit of admits decreases by college selectivity. For America's less selective colleges that collectively enroll over three-quarters of students, fully eliminating preferences for race (and for unobserved factors which are correlated with race) has little impact on the proportion of underrepresented minorities (URM) and on the average SAT score of admitted students. In contrast, for the 34 most selective colleges accounting for 3 percent of total enrollment, our estimates suggest that admissions going "race blind"—absent any compensating changes in admissions criteria—could reduce URM admission by one-third while increasing the average SAT score of admits by no more than 10 points. We also estimate that universal test-optional admission may lead to a small increase in the proportion of URMs at the most selective colleges, while decreasing the average SAT score by up to 10 points. At less selective institutions, the effects are estimated to be negligible.

3 - Non-Profit Support in Education: Resource Allocation and Students' Lifetime Outcomes

Harish Guda, Arizona State University, Tempe, AZ, United States, Goutham Takasi, Milind Dawande, GANESH JANAKIRAMAN

Our work focuses on the operations of non-profit organizations (NPOs) that broaden access to high-quality education for underprivileged students. Specifically, we analyze the resource-allocation strategy of an NPO that adopts a two-stage structure in allocating resources to its beneficiaries, e.g., free pre-secondary education (first stage) for all students in a target population, followed by sponsorships for post-secondary education (second stage) at leading institutions to students who demonstrate commendable performance in the first stage. The lifetime outcomes of the beneficiaries depends on their own effort and on the quality of the resources that the NPO provides.

We establish the strategic role of an NPO's resource-allocation strategy on the effort beneficiaries exert and their lifetime outcomes. In particular, despite possessing an adequate quantity of resources to support all its beneficiaries, we show why the NPO benefits from *strategically throttling access* to the resources. Our findings have implications for the design of such support policies of NPOs. For a fixed endowment of resources, we demonstrate the effect of competition among the beneficiaries on their effort and lifetime outcomes, and show the value of creating a *strategic scarcity* of resources for incentivizing beneficiaries to exert more effort. Finally, when faced with multiple beneficiary subgroups, we identify when the NPO benefits from pooling the beneficiary subgroups vs. earmarking dedicated resources for each subgroup.

4 - Teaching at a Distance, Scrutinized up Close: Bias in the Online Student Evaluation of Teaching

Lu Kong, University of South Florida, Tampa, FL, United States, Kejia Hu, Lanfei Shi

This study investigates how the shift to online education has influenced student evaluations of teaching (SETs), with a focus on whether instructor gender and racial biases have intensified compared to in-person settings. SETs remain a central tool for assessing faculty performance in U.S. higher education, yet they are prone to systematic bias. Understanding how digital learning environments shape these biases is critical for ensuring fair and effective evaluation systems. Drawing on 598,252 teaching evaluations across the top 150 U.S. colleges, we employ a Difference-in-Differences-in-Differences (DDD) model with Propensity Score Weighting to examine changes in evaluation scores before and after the COVID-19-induced transition to online instruction. We supplement this analysis with text mining of student comments to uncover behavioral mechanisms driving disparities. Our results reveal that non-white male instructors experienced a significant and persistent decline in ratings—0.69 points on a 5-point scale, or 16.2% lower than white male counterparts—following the move to online teaching. This disparity was most pronounced in institutions with low student and faculty diversity, in comments containing racial or gender-biased language, and among students who valued entertainment over educational substance. These findings suggest that online education can exacerbate existing biases by increasing psychological distance and reducing interpersonal cues. To mitigate these effects, we propose institutional strategies including the adoption of multi-method evaluation frameworks, redesign of SET instruments to raise bias awareness, and a stronger emphasis on inclusive hiring and curricular practices. Our study offers actionable insights for promoting fairness in digitally mediated teaching evaluations.

5 - Enhancing Student Engagement Through Gamified Reward Consumption Design: A Field Experiment in Education

Xiao Lei, The University of Hong Kong, Hong Kong, Hong Kong, Yimin Yin, Yipu Deng

We introduced a points-redemption feature into a school system that had previously only recorded the points students earned for academic tasks. To test its impact, we ran a four-month field experiment in four matched primary-school campuses. Students earned points for completing homework and correcting errors. Campuses were randomly assigned to one of four conditions: control (points only recorded), permanent purchase (points buy virtual cards kept forever), temporary purchase (cards expire after two weeks), or random draw (points buy a lottery card). Tracking weekly homework completion, accuracy, and error correction shows that gamification boosts performance overall, but the effects differ across conditions, underscoring the importance of game-element design in educational gamification.

1 - Optimal Sequential Screening with Private Budgets

Francisco Castro, UCLA Anderson School of Management, Los Angeles, CA, United States

We study the problem faced by a seller of designing an optimal sequential screening mechanism when a buyer's budget is privately known. Our mechanisms allow for sequential screening in that the buyer first reports their budget and, conditional on their budget, the mechanism determines the allocation and payment rule. For deterministic mechanisms, we show that each budget type can be associated with a fractional quantity of the item. From this, we derive a tight upper bound on the seller's profit by reformulating the problem as choosing a concave price function of the quantity purchased by each type. We further simplify the problem by proving that this optimal price function must be linear and characterized by the solution to a one-dimensional optimization problem. Consequently, the optimal mechanism is a pooling contract. For randomized mechanisms, using a similar approach to the deterministic case, we find that the optimal mechanism is also a pooling contract, although it may incorporate randomization for some valuation ranges.

2 - Revenue Maximization in Choice-Based Matching Markets

Alfredo Torrico, Cornell University, New York, NY, United States, Dan Nissim, Danny Segev

The primary contribution of this paper resides in devising constant-factor approximation guarantees for revenue maximization in two-sided matching markets, under general pairwise rewards. A major distinction between our work and state-of-the-art results in two-sided assortment optimization is that, for the first time, we are able to address *reward maximization*, reflected by assigning each customer-supplier pair an arbitrarily-valued reward. The specific type of performance guarantees we attain depends on whether one considers the *customized* model or the *inclusive* model. The fundamental difference between these settings lies in whether the platform should display to each supplier all selecting customers, as in the inclusive model, or whether the platform can further personalize this set, as in the customized model. Technically speaking, our algorithmic approach and its analysis revolve around presenting novel linear relaxations, leveraging convex stochastic orders, employing approximate dynamic programming, and developing tailor-made analytical ideas. In both models considered, these ingredients allow us to overcome the lack of submodularity, monotonicity and subadditivity that stems from pairwise rewards, plugging the applicability of existing methods.

3 - Personalization vs. Marketplace Diversity: How Recommendation Algorithms Shape Pricing, Participation, and Consumer Search

Anil Omer Saritac, Singapore Management University, Singapore, Singapore, Nur Kaynar, Ozge Sahin

Online marketplaces use recommendation algorithms to steer shoppers toward products, generating about 30 % of page views and sizable welfare gains. Most research optimizes these algorithms for buyer satisfaction, treating sellers as passive and overlooking how recommendations shape pricing, entry, and market diversity. This bias can crowd out niche sellers, erode variety, and weaken long-run platform health.

We build a dynamic search model with a continuum of horizontally differentiated sellers who choose fixed, type-dependent prices to maximize discounted profits, and heterogeneous customers who arrive each period. Upon arrival a customer receives a personalized product list—formally, a probability distribution over sellers—generated by the platform. After clicking, the customer observes match utility and either buys or continues searching, facing a departure probability that captures search costs. The recommendation distribution therefore mediates both seller pricing incentives and customer search paths.

Analytically, we convert the high-dimensional game into a tractable form that reveals clear comparative statics. We characterize how the degree of personalization and an increased emphasis on diversity in recommendations affect market outcomes: Welfare-maximizing or profit-maximizing recommendations do **not** necessarily fully personalize. The first-best balances relevance with deliberate exposure to niche sellers, which sustains marketplace diversity. The model pinpoints when this balance shifts under alternative platform objectives or greater time pressure, and offers a template for other strategic search settings.

4 - Information Design for Spatial Resource Allocation

Ozan Candogan, University of Chicago, Chicago, IL, United States, Manxi Wu

In this paper, we study platforms where resources and jobs are spatially distributed, and resources have the flexibility to strategically move to different locations for better payoffs. The price of the service at each location depends on the number of resources present and the market size, which is modeled as a random state. Our focus is on how the platform can utilize information about the underlying state to influence resource repositioning decisions and ultimately increase commission revenues. We establish that in many practically relevant settings a simple monotone partitional information disclosure policy is optimal. This policy reveals state realizations below a threshold and above a second (higher) threshold, and pools all states in between and maps them to a unique signal realization. We also provide algorithmic approaches for obtaining (near-)optimal information structures that are monotone partitional in general settings.

Sustainable and Socially Responsible Operations

Invited Session

MSOM: Sustainable Operations

Chair: Soudipta Chakraborty, University of Kansas, Lawrence, United States

1 - Buyer Management of a Supplier's Social Responsibility Risk: Prevention, Detection, and Remediation

Junhao Yu, Miami University, Oxford, OH, United States, Tim Kraft

We study how retailers can proactively manage their suppliers' responsibility risk. We focus on a retailer's risk management strategy and consider three tactics the retailer can deploy—prevention, detection, and remediation—and study how combining the three can help the retailer achieve optimal results.

2 - Spreading the Wings: Understanding Optimal Strategies for Social Enterprise Growth

Wei Wei, University of New Hampshire, Durham, NH, United States, Priyank Arora, Gokce Esenduran

We study the growth dilemma faced by a social enterprise that pursues a dual objective: Delivering societal impact for its beneficiaries (typically underserved and vulnerable individuals) while generating profit from paying customers by offering essential services such as healthcare and education. Motivated by the real-world example of Aravind Eye Care System that uses profit generated from paying customers to subsidize service delivery to beneficiaries, we examine the choice between the following two growth strategies: (1) Expanding at the existing location by adding more capacity and offering additional value-adding services to beneficiaries; or (2) Entering a new location by building capacity at a distant location. The former strategy relies on costly investments in adding capacity and expanding the scope of services for beneficiaries, but all the operational elements are known to the enterprise. The latter strategy relies on potentially less costly investment in capacity (due to lower diminishing returns when starting anew), but it also entails uncertainty in the cost of providing services to beneficiaries at the new location (due to localized needs of vulnerable populations). We develop an analytical model to capture these trade-offs and interrelate the social enterprise's investment decisions under each strategy with key operational elements. We identify conditions under which each strategy is optimal. To the best of our knowledge, ours is the first study to provide guidance to social enterprises on whether to grow by enhancing their footprint at the same or a new location, taking into account the operational elements.

3 - Additionality of Carbon Offsets: Project-Specific vs. Standardized Baselines

Soudipta Chakraborty, University of Kansas, Lawrence, KS, United States, Vishal Agrawal, Safak Yucel

A carbon offset represents reduction in emissions that can be used to compensate for emissions elsewhere. Developers generate offsets through emissions-reduction projects. A non-profit carbon registry issues offsets to developers while ensuring additionality: an offset needs to represent one unit of reduction from a developer's business-as-usual emissions, i.e., what the developer's emissions would have been in the absence of the market for offsets. Accordingly, environmental groups raise greenwashing concerns against non-additional offsets. Ensuring additionality is challenging because business-as-usual emissions is a developer's private information and an unobservable counterfactual for the registry. In practice, the registry assigns a baseline to represent business-as-usual emissions through one of the two methods: Under the project-specific method, a developer self-reports its business-as-usual emissions to the registry, which then inspects the report and assigns reported emissions as the baseline if it accepts the project. Under the standardized method, the registry assigns a common baseline to a group of similar developers. We compare economic and environmental implications of these two methods.

1 - Menu Optimization for (Office) Meal Delivery Platforms**Saman Lagzi, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States**, Ningyuan Chen, Pin Gao, Sheng Liu, Chenhao Wang

We study the problem an office meal delivery platform faces every day. Such platforms connect client firms, with catering needs for their employees, to restaurants, by offering a menu of compatible restaurants to all the employees in an office. The platform's revenue is a fixed percentage of the value of the restaurant's orders. The platform incurs the delivery cost. Each restaurant allocates a fixed capacity to the platform, regarding how many meals it can prepare on a given day. We model the problem as a capacitated joint assortment optimization on a bipartite graph with supply and demand nodes. We prove the problem is APX-hard while its special cases with only one restaurant or one client are NP-hard. Under some mild conditions on restaurant capacities, we develop fixed-ratio and near optimal approximation algorithms for this problem. Moreover, for the general case, using a Linear Programming relaxation of a reformulation of the original model, and by leveraging the rather soft nature of the capacity constraints in practice, we devise an asymptotically optimal assortment sampling algorithm that we show may breach any capacity constraint only by a negligible probability, as the number of clients and the restaurant capacities grow. In collaboration with one of North America's largest office meal delivery platforms, we test the performance of our LP-based sampling algorithm in a carefully controlled field experiment. Our results suggest that our methodology improves the platform's per-employee profit and revenue by at least 14%, and 10%, respectively.

2 - Exploration Optimization for Dynamic Assortment Personalization Under Linear Preferences**Sajad Modaresi, UNC Chapel Hill, Kenan-Flagler Business School, Durham, NC, United States**, Fernando Bernstein, Denis Saure

We study efficient real-time data collection approaches for an online retailer that dynamically personalizes assortments based on customers' attributes. We study the structure of efficient exploration in this setting, propose efficient learning policies, and prove theoretical performance lower and upper bounds. We test the performance using a dataset from a large Chilean retailer.

3 - Basic Reusability and Beyond: Joint Inventory and Online Assortment Optimization with Reusable Resources**Yukai Huang, WashU, St Louis, MO, United States**, Jacob Feldman, Heng Zhang

We introduce a joint optimization framework for deciding initial inventory levels and offering personalized assortments over a finite selling horizon under a multinomial logit choice model, when resources are reusable. In the classical setup—where each unit returns after a random duration with an increasing failure rate (IFR) distribution—we develop a constant-factor approximation by formulating a fluid relaxation that replaces IFR durations with geometric analogues. A key technical contribution is a novel comparison between the CDFs of geometric and IFR random variables. We then generalize to a network reusability model in which returned resources may transform (e.g., be damaged or relocated) and propose an iterative inventory refinement procedure that adapts to online assortment feedback. We prove strong, network-dependent performance bounds for this scheme. Numerical experiments over a variety of reusability scenarios demonstrate that our algorithms achieve near-optimal revenue, underscoring both the robustness and practical efficacy of our approach.

4 - Maximum Load Assortment Optimization-- Approximation Algorithms and Adaptivity Gaps**Marouane Ibn Brahim, Cornell Tech, New York, NY, United States**, Omar El Housni, Danny Segev

Motivated by applications such as attended home delivery and preference-based group scheduling, where decision makers aim to steer many customers toward choosing the same alternative, we introduce a novel class of assortment optimization problems called *maximum load assortment optimization*. In these settings, given a set of substitutable products, we face a stream of customers, each deciding between selecting a product from an offered assortment or leaving without making a selection. Assuming these decisions follow the multinomial logit choice model, we define the random load of a product as the number of customers who select it. Our objective is to offer assortments to maximize the expected *maximum* load across all products. We consider both static and dynamic formulations. In the static setting, a single assortment is used throughout customer arrivals. In the dynamic setting, assortments are personalized based on all information available at the time. Both formulations present significant computational and analytical challenges. Our main contribution is to develop efficient algorithms to compute near-optimal static and dynamic policies. Specifically, we propose a polynomial-time approximation scheme for the static problem. We also show that a policy using weight-ordered assortments yields a 1/2-approximation in the static case, and a 1/4-approximation relative to the dynamic case, establishing a constant bound on the adaptivity gap. Finally, we design an adaptive policy whose expected maximum load is within a factor $1-\epsilon$ of optimal, with a quasi-polynomial time implementation.

5 - A/B Testing Under Product Stockouts**Liting Chen, McGill University, Montreal, QC, Canada**, Maxime Cohen, Sentao Miao

This paper addresses a critical challenge in e-commerce experimentation: the bias in A/B testing on total demand caused by product stockouts. When products have limited inventory and may become unavailable during an experiment, standard randomized controlled trial (RCT) estimators systematically overestimate treatment effects. This occurs because stockouts create a dynamic interference between treatment and control groups, violating the Stable Unit Treatment Value Assumption. We develop a fluid limit analysis to characterize this bias and propose a novel Stockout-Discounted (SD) estimator that accounts for demand transfer patterns when products become unavailable. By applying appropriate discount weights based on product substitution behaviors, our estimator reduces bias while maintaining equal or lower variance compared to standard RCT approaches. We establish theoretical guarantees for our approach under general choice models without assuming specific underlying customer choice behavior. Our findings provide practical guidance for e-commerce platforms seeking accurate treatment effect estimation in inventory-constrained environments, where traditional A/B testing methods fail to account for the dynamic nature of product availability.

1 - Designing Surprise Bags for Surplus Foods**Hansheng Jiang, University of Toronto, Rotman School of Management, Toronto, ON, Canada**, Fan Zhou, Andrea Li, Joline Uichanco

Too Good To Go (TGTG) has emerged as a global leader in reducing food waste by connecting consumers with retailers' surplus food through "surprise bags." While TGTG provides both environmental and economic benefits, participating stores face significant operational challenges in determining the optimal number of bags to offer. Specifically, stores must decide on the number of surprise bags before knowing the actual surplus for the day. Additionally, key questions such as whether to include regular sale items in the bags and how to allocate food across bags are critical for balancing customer satisfaction and profitability. We explore these challenges and model the stores' decision-making process by stochastic dynamic programming. Our analysis reveals that the commonly adopted practice of evenly distributing surplus food across all surprise bags may not maximize consumer satisfaction, particularly when customer utility functions are non-concave. We

propose an alternative---offering up to two types of bags---that achieves maximal consumer satisfaction while still remaining simple to implement. Determining the optimal number of bags and the total food volume to allocate at each period is a non-convex two-stage stochastic optimization problem. To address both the analytical and computational complexities, we propose two approximation policies that are computationally efficient with intuitive managerial insights and provable performance guarantees.

Our findings provide practical guidance for stores in balancing revenue generation, customer satisfaction, and sustainability objectives, thereby enhancing the long-term viability of TGTG's mission to reduce food waste.

2 - Coordinating Perishable Product Supply Chains

Xiaoyue Yan, University of Oregon, Eugene, OR, United States, Elena Belavina

Traditional supply chain coordination strategies, such as increasing order quantities to address double marginalization, may be ineffective for perishable products. We develop a two-echelon perishable-inventory model showing that perishability creates a non-monotonic relationship between order quantity and variability propagation, driven by product expiration. This leads to the coexistence of bullwhip and reverse bullwhip effects, even without traditional bullwhip drivers.

Using real-world data on 513 perishable products across 22 retail stores, we observe that 33.8% of products exhibit a reverse bullwhip effect, where variability attenuates upstream, consistent with our theoretical predictions. Empirical analysis further confirms that product characteristics non-linearly influence variability amplification, explaining more than half of the observed variation. Through structural estimation, we find that for most perishables, reducing order quantities improves supply chain profits by mitigating variability propagation, despite exacerbating double marginalization. This generates a win-win outcome: higher profitability and lower food waste.

Our findings challenge the conventional view that higher order quantities improve coordination. For perishables, smaller orders better align incentives, stabilize supply chains, and enhance sustainability. We further propose contract designs that reduce supplier demand variability and food waste, offering new insights for designing more sustainable and efficient perishable supply chains.

3 - From Waste to Taste: Structural Estimation and Market Design in Secondary Food Markets

Alexandra Yizhuo Dong, UCLA Anderson, Los Angeles, CA, United States, Auyon Siddiq, Jingwei Zhang

Commercial food waste remains a significant challenge, with roughly one-third of all produced food wasted. In response, digital marketplaces now connect food retailers with consumers willing to purchase surplus at discounted prices. The effectiveness of these secondary markets hinges on broad seller participation. This study examines how two features of market design — price competition and the presentation of store ratings — shape seller entry decisions on a leading food waste platform.

We develop a structural model that jointly captures consumer demand and seller entry behavior. On the demand side, we combine consumer arrivals with a multinomial logit choice model that captures spatial, temporal, and demographic factors, as well as store-level features such as pricing and platform ratings. On the supply side, we model seller entry as a non-cooperative game and propose a novel discrete optimization-based estimation approach that improves both estimation accuracy and computational efficiency relative to the conventional Simulated Method of Moments (SMM).

Our empirical analysis draws on a rich dataset of hourly transactions from approximately 3,000 retailers over a three-month period, spanning four major U.S. cities. We supplement this with demographic information and data from Google Places. The results demonstrate that both pricing policies and information design meaningfully affect seller participation and overall marketplace performance. These findings offer actionable insights for platform operators aiming to increase participation, reduce food waste, and advance more sustainable retail practices.

4 - Hyperlocal P2p Food Sharing: Estimating the Effect of the Entry of the Commercial Food Donation Channel

Ekaterina Astashkina, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, Masha Shunko, Yixin Iris Wang

We are examining data from the largest global peer-to-peer food sharing platform. This platform facilitates the exchange of soon-to-expire food items among platform's users. We investigate the impact of introducing a new commercial donation channel, which allows various food establishments (e.g., supermarkets, grocery stores, bakeries) to donate surplus food directly to households. Specifically, we aim to understand how this addition influences donation patterns among users of the platform.

1 - Magnolia: Matching Algorithms via Gnns for Online Value-to-Go Approximation

Ellen Vitercik, Stanford University, Stanford, CA, United States, Alexandre Hayderi, Amin Saberi, Anders Wikum

Online Bayesian bipartite matching is a central problem in digital marketplaces and exchanges, including advertising, crowdsourcing, ridesharing, and organ allocation. We introduce a graph neural network (GNN) approach that emulates the problem's combinatorially-complex optimal online algorithm, which selects actions (e.g., which nodes to match) by computing each action's value-to-go (VTG) -- the expected weight of the final matching if the algorithm takes that action, then acts optimally in the future. We train a GNN to estimate VTG and show empirically that this GNN returns high-weight matchings across a variety of tasks. Moreover, we identify a common family of graph distributions in spatial crowdsourcing applications, such as rideshare, under which VTG can be efficiently approximated by aggregating information within local neighborhoods in the graphs. This structure matches the local behavior of GNNs, providing theoretical justification for our approach.

2 - Marketplace Operators Can Induce Competitive Pricing

Tiffany Ding, University of California, Berkeley, Berkeley, CA, United States, Dominique Perrault-Joncas, Orit Ronen, Michael Jordan, Dirk Bergemann, Dean Foster, Omer Gottesman

As e-commerce marketplaces continue to grow in popularity, it has become increasingly important to understand the role and impact of marketplace operators on competition and social welfare. We model a marketplace operator as an entity that has both the ability to facilitate sales by third parties as well as sell the product on its own. We formalize this market structure as a price-quantity Stackelberg duopoly in which the leader is a marketplace operator and the follower is an independent seller who shares a fraction of their revenue with the marketplace operator for the privilege of selling on the platform. The objective of the marketplace operator is to maximize a weighted sum of profit and a term capturing positive customer experience, whereas the independent seller seeks solely to maximize their own profit. We derive the subgame-perfect Nash equilibrium and find that it is often optimal for the marketplace operator to induce competition by offering the product at a low price to incentivize the independent seller to match their price.

3 - Learning to Coordinate Bidders in Non-Truthful Auctions

Tao Lin, Microsoft, Cambridge, MA, United States

In non-truthful auctions such as first-price and all-pay auctions, the independent strategic behaviors of bidders, with the corresponding equilibrium notion -- Bayes Nash equilibria -- are notoriously difficult to characterize and can cause undesirable outcomes. An alternative approach to designing better auction systems is to coordinate the bidders: let a mediator make incentive-compatible recommendations of correlated bidding strategies to the bidders, namely, implementing a Bayes correlated equilibrium (BCE). The implementation of BCE, however, requires knowledge of the distribution of bidders' private valuations, which is often unavailable. We initiate the study of the

sample complexity of learning Bayes correlated equilibria in non-truthful auctions. We prove that the BCEs in a large class of non-truthful auctions, including first-price and all-pay auctions, can be learned with a polynomial number $O(n/\epsilon^2)$ of samples from the bidders' value distributions. This moderate amount of samples means that learning to coordinate bidders is statistically efficient. Our technique is a reduction to the problem of estimating bidders' expected utility from samples, combined with an analysis of the pseudo-dimension of the class of all monotone bidding strategies of bidders.

4 - Envy-Inefficiency Scaling Laws

Siddhartha Banerjee, Cornell University, Ithaca, NY, United States

In many resource allocation settings with stochastic demands and supplies, a principal must tradeoff between allocating in a way which is globally optimal but unequal across agents, or can enforce equality across allocations resulting in unavoidable efficiency losses. The specific functional form of these envy-inefficiency tradeoffs depends in subtle ways on the structure of the underlying allocation problem. I will illustrate this with three examples -- fixed supply (i.e., knapsack) settings, fixed supply with perishable items, and variable supply (i.e., inventory) settings. In each case we obtain sharp characterizations of the envy-inefficiency scaling laws, and in the process, get better qualitative insights into these various settings, as well as understand how to design allocation policies to achieve Pareto optimal points on these tradeoff curves.

Based on joint work with Chido Onyeze, Sean Sinclair, Chamsi Hssaine and Christina Lee Yu.

5 - Clock Auctions Augmented with Unreliable Advice

Daniel Schoepflin, Rutgers University, New Brunswick, NJ, United States

We provide the first analysis of clock auctions in the learning-augmented framework. These auctions satisfy a unique list of very appealing properties making them particularly well-suited for real-world applications. Early work that evaluated their performance from a worst-case analysis perspective concluded that no deterministic clock auction with n bidders can achieve a $\log^{1-1/n}(n)$ -approximation of the optimal social welfare for a constant $t > 0$, even in simple settings. This pessimistic impossibility result heavily depends on the assumption that the designer has no information regarding bidders' values. Leveraging the learning-augmented framework, we instead consider a designer equipped with some advice regarding the optimal solution; this advice can provide useful guidance if accurate, but it may be unreliable.

Our main results are learning-augmented clock auctions that use this advice to achieve much stronger performance guarantees whenever the advice is accurate, while maintaining worst-case guarantees even if this advice is arbitrarily inaccurate. Our first clock auction achieves the best-of-both-worlds: $(1+c)$ -consistency for any desired constant c and $O(\log(n))$ -robustness; we extend this auction to achieve error tolerance. We then consider a much stronger notion of consistency, which we term "consistency-infinity", and provide an auction that achieves a near-optimal trade-off between consistency-infinity and robustness. Finally, using our results, we prove bounds on the "cost of smoothness," i.e., the robustness achievable if we require that the performance of the auction degrades smoothly as a function of error.

This work is based on a paper which originally appeared at SODA 2025 with co-authors Vasilis Gkatzelis and Xizhi Tan.

1 - Data Monetization Through Strategic Coordination of Privately Informed Agents

Thibaut Horel, Massachusetts Institute of Technology, Cambridge, MA, United States, Alessandro Bonatti, Munther Dahleh

We consider linear-quadratic games of incomplete information with Gaussian uncertainty, in which players' payoffs depend both on a privately observed type and an unknown but common state. A monopolist data platform observes the state, elicits the players' types, and sells information back to them via (possibly correlated) action recommendations. We fully characterize the class of all such implementable Gaussian mechanisms (where the joint distribution of actions and signals is multivariate normal) as well as the player-optimal and revenue-maximizing mechanisms within this class. For games of strategic complements (substitutes), both optimal mechanisms maximally correlate (anticorrelate) the players' actions. When uncertainty over private types is large, the recommendations are deterministic and linear functions of the state and reported types but are not fully revealing. We apply our results to algorithmic pricing recommendations used by platforms such as Amazon and those challenged in *U.S. v. RealPage*.

2 - Equilibrium of Data Markets with Externality

Safwan Hossain, Harvard University, Boston, MA, United States, Yiling Chen

We model real-world data markets, where sellers post fixed prices and buyers are free to purchase from any set of sellers, as a simultaneous game. A key component here is the negative externality buyers induce on one another due to data purchases. Starting with a simple setting where buyers know their valuations a priori, we characterize both the existence and welfare properties of the pure Nash equilibrium in the presence of such externality. While the outcomes are bleak without any intervention, mirroring the limitations of current data markets, we prove that for a standard class of externality functions, platforms intervening through a transaction cost can lead to a pure equilibrium with strong welfare guarantees. We next consider a more realistic setting where buyers learn their valuations over time through market interactions. Our intervention is feasible here as well, and we consider learning algorithms to achieve low regret concerning both individual and cumulative utility metrics. Lastly, we analyze the promises of this intervention under a much richer externality model.

3 - Data-Sharing Markets: Models, Protocols, and Algorithms

Raul Castro Fernandez, The University of Chicago, Chicago, IL, United States

Data-sharing consortia unlock the latent value of siloed data across organizations, yet they often fail to materialize due to uncertainties around benefits, cost allocations, and incentives. In this work, we study an economic and algorithmic approach to incentivize the formation of such consortia. The protocol ensures every participant benefits from joining and that the consortium is sustainable only when socially valuable. A key insight of our work is the tradeoff between precision and operational cost in revenue allocation: accurate but expensive methods, such as the Shapley value, can consume so much of the value generated that they disincentivize participation or prevent consortium formation altogether. We show a simple revenue allocation algorithm that—while computationally cheaper—preserves fairness and incentive compatibility in practice, thereby leaving more revenue for participants. This tradeoff between computational exactness and allocative surplus is critical for the practical formation of data-sharing markets. We evaluate our protocol empirically and show that cheaper algorithms lead to more consortia forming, with limited impact on perceived fairness. During the talk, I will also present updates to this line of research, including opportunities for improvement. This work contributes to the growing literature at the intersection of data management, market design, and platform engineering, and suggests new opportunities for sustainable, incentive-compatible data collaboration.

Scheduling Operations and Optimization

Contributed Session

Contributed

Chair: Thomas Lavastida, University of Texas at Dallas, Addison, United States

1 - An Online Algorithm for Scheduling Appointments Under Endogenous No-Show Uncertainty Using Machine Learning

Maxim Frankish, Ghent University, Ghent, Belgium, Broos Maenhout

Patients not showing up for their medical appointments is a recurring issue that can negatively impact healthcare operations. Next to patient-related factors, such as no-show history and the patient's age, also schedule-dependent factors, such as access times, the time of the appointment and patient waiting times, possibly resulting from patient overbooking, directly impact the no-show behaviour. Therefore, we suggest minimising the probability of no-show upfront as also schedule-dependent factors, in combination with patient-related factors, influence the patient no-show. In this study, we develop an online appointment scheduling algorithm that leverages machine learning to predict no-show and proactively assign time slots with a low associated no-show risk. We evaluate the algorithm using real-world data from a dental department and demonstrate its effectiveness in reducing expected no-shows while maintaining a balanced schedule. The results show that integrating no-show risk into the scheduling process can provide a realistic and effective alternative to traditional overbooking practices.

2 - Data-Driven Procurement Design and Optimization: Scheduling Texas Road Construction Projects' Auctions

Hayri Alper Arslan, University of Texas at San Antonio, San Antonio, TX, United States, Alp Arslan, Dakshina De Silva

Public and private organizations frequently use auctions to procure goods and services, awarding multiple contracts at regular intervals known as letting periods. In these environments, bidders often pursue and win multiple contracts, generating cost interdependencies arising from shared resources, economies of scale, project proximity, and timeline overlaps. These interdependencies can significantly influence bidding strategies and, consequently, procurement outcomes.

This study investigates how optimizing auction schedules can leverage these cost interdependencies to improve efficiency and reduce procurement costs. Focusing on Texas road construction contracts—an ideal empirical setting due to its scale and detailed auction data—we construct project-level measures capturing material overlap, schedule overlap, and spatial proximity. Regression analyses reveal that while material and schedule overlaps generally lead to higher bids, spatial proximity encourages more competitive bidding.

To better understand strategic bidder responses, we develop a structural model incorporating contract-specific and combination-specific characteristics into bidders' decision-making processes. Using this model, we estimate equilibrium bid distributions and simulate how alternative auction schedules affect procurement outcomes.

Our simulations demonstrate that modest adjustments to auction timing—shifting individual projects one period forward or backward—reduce total expected bids by 0.7%. More substantial re-timing, allowing the 50 highest-value projects to shift across a full year, leads to a 1.4% reduction in total expected bids, translating to nearly \$40 million in savings. These findings underscore the potential for strategically designed auction schedules to significantly enhance procurement efficiency by aligning project timing and geography with bidder cost structures.

3 - Algorithms for Shipping Container Delivery Scheduling

Dimitrios Letsios, King's College London, London, United Kingdom, Anna Collins, Gueorgui Mihaylov

Motivated by distribution problems arising in the supply chain of Haleon, we investigate a shipping container delivery scheduling problem. The problem models a supplier dispatching ordered products with shipping containers from manufacturing sites to distribution centers, where orders are collected by the buyers at agreed due times. The supplier may expedite or delay item deliveries to reduce transshipment costs at the price of increasing inventory costs, as measured by the number of containers and distribution center storage/backlog costs, respectively. The goal is to compute a delivery schedule attaining good trade-offs between the two. This container delivery scheduling problem is a temporal variant of classic bin packing problems, where the item sizes are not fixed, but depend on the item due times and delivery times. An approach for solving the problem should specify a batching policy for container consolidation and a scheduling policy for deciding when each container should be delivered. Based on the available item due times, we develop algorithms with sequential and nested batching policies as well as on-time and delay-tolerant scheduling policies. We elaborate on the problem's hardness and substantiate the proposed algorithms with positive and negative approximation bounds, including the derivation of an algorithm achieving an asymptotically tight 2-approximation ratio.

4 - Heuristic Scheduling Approach for Pharmaceutical Resource Planning and End-to-End Sample Testing

Apoorva Nisal, Gilead Sciences, Oceanside, CA, United States

Pharmaceutical drug development entails extensive testing for product stability and rigorous high sample load throughput testing. Lab managers face the challenge of coordinating sample submission, scheduling studies, analysts and instruments while ensuring that the studies are performed on time. The time required for each study depends on the assay to be performed and sample specific processing. A manual sample submission and testing coordination process is replaced with an end-to-end workflow to forecast incoming studies.

The platform uses instrument data, analyst training information, other data sources such as mapping of assays to instruments, time required, etc. A heuristics-based approach is developed to generate an optimal schedule aligning trained analysts, studies, and instruments daily.

Heuristic models are rule-based algorithms that follow a set of priorities to make decisions. Scheduling and capacity modeling problems are typically modeled mathematically using the mixed integer linear programming approach. However, MILP (Mixed Integer Linear Programming) problems involve large constraints for a problem of the current size. Thus, there is a tradeoff between solution optimality, computational time and flexibility in the case of heuristics vs MILP. Both open-source solver-based MILP and a heuristic model were compared.

The heuristic model was observed to be faster compared to MILP based model and is ultimately selected to derive capacity-based insights. The integrated scheduler platform ensures that the users have the flexibility to generate on-demand schedule based on instrument and analyst availability and the prioritization of any studies as required.

5 - Single-Machine Scheduling with Cooperative Agents and Nondisjoint Job Sets

Johnson Phosavanh, The University of Sydney, Sydney, Australia, Daniel Oron

We consider a new class of multi-agent scheduling problems where some jobs are allowed to be completed by more than one agent, each with a different processing time, allowing us to represent workers with different skill sets. This problem can be considered as a multi-stage optimization problem, where the assignment of jobs to agents needs to be decided, followed by the determination of an optimal schedule or vice versa. We show that this class of problems is not strictly easier or harder than the conventional competing or nondisjoint job set scenarios, and we provide an extensive analysis of problems consisting of two agents on a single machine with various scheduling criteria.

6 - Scheduling a Single Parallel-Batching Machine with Run-to-Run Constraints

Xiajie Yi, IÉSEG School of Management, Lille, France, Fan Yang, Dries Goossens, Roel Leus

The rise of artificial intelligence has significantly increased the demand for semiconductors, intensifying scheduling challenges across complex, multi-stage manufacturing processes. To enhance yield and process stability, semiconductor manufacturers widely implement Advanced Process Control (APC) techniques, particularly run-to-run (R2R) control, which adjusts process parameters based on prior outcomes to reduce drift and variability. R2R constraints often involve time- or count-based rules, triggering qualification runs to maintain process accuracy.

This paper studies a scheduling problem involving a single parallel-batching machine with R2R constraints, motivated by practical semiconductor applications. The model accounts for incompatible job families and non-identical job sizes, where jobs from the same family can be batched within machine capacity. The objective is to minimize the total weighted completion time, which is a key performance metric linked to product holding costs. To solve this problem, we propose a time-indexed formulation and a set-covering formulation. For the latter one, we develop a column generation-based algorithm, in which the pricing problem is solved via zero-suppressed binary decision diagrams.

7 - Stochastic Parallel Scheduling with Bandit Feedback

Thomas Lavastida, University of Texas at Dallas, Richardson, TX, United States, Gerdus Benade, Rathish Das

We study the fundamental problem of scheduling jobs with stochastic sizes to minimize the total completion time for both the single and parallel machine settings. Traditionally, the size distributions are assumed to be known to the scheduler; the challenge is accounting for the stochasticity. Departing from prior work on stochastic scheduling, we explore the problem of efficiently learning to schedule when the size distributions are unknown and we are unable to directly obtain samples from it. We adopt an online bandit learning framework in which an algorithm interacts with a scheduling environment over a series of discrete time periods. In each period, the algorithm commits to a schedule for the jobs on a collection of parallel machines and then observes only the random cost of the schedule, and not individual job sizes. This so-called bandit-feedback provides limited information about the underlying (unknown) job size distributions. The objective is to minimize the total regret - the difference in expected total completion time of schedules chosen by the algorithm from that of the optimal schedule under complete information.

Standard approaches based on multi-armed bandits or linear bandits are computationally inefficient. Thus, we utilize the structure of the scheduling problem to give simple, combinatorial, and computationally efficient algorithms for both settings with nearly optimal regret. In particular, both algorithms require only constant amortized time complexity per period asymptotically, making them highly efficient. Finally, we complement our upper bounds with an almost matching lower bound for the single machine setting.

1 - Gender Combination and Team Performance: Evidence from Heart Procedures

Dapeng Chen, Lehigh University, Bethlehem, PA, United States, Shin-Yi Chou, Xiaosong Peng

Despite growing interest in how gender composition shapes team performance, little is known about its impact in high-stakes healthcare settings. In this paper, I use inpatient discharge records for two common heart procedures - percutaneous coronary intervention (PCI) and coronary artery bypass grafting (CABG) - to investigate how the gender combinations between the attending physicians (who manage inpatient care during hospitalization) and proceduralists (who perform the procedures) affect patient health outcomes. Exploiting the quasi-random pairings of physicians and proceduralists, I find that mixed-gender teams reduce in-hospital mortality by approximately 12 percent. Further decomposition analysis suggests that female physicians outperforming their male counterparts when paired with male proceduralists, whereas no significant difference is observed when partner with female proceduralists. Additional tests show that the observed benefits are not driven by increased utilization of medical resources. Instead, the results appear consistent with communication or social norms mechanisms: the mortality gap narrows with higher patient severity and greater familiarity between physicians and proceduralists, as measured by prior collaboration and the share of male proceduralists among a physician's colleagues. However, physicians' own experience and patient demographics do not explain the observed gains. Moreover, pairing female physicians with male proceduralists lowers the likelihood of experiencing repeat surgery, which may explain part of the mortality reduction. These findings emphasize the importance of gender composition in healthcare teams and suggest potential improvement in patient outcomes with careful team assignment policies.

2 - From Reactive to Proactive: Transforming Emergency Department Full Capacity Protocols with AI and Simulation

Khalid Aram, Emporia State University, Emporia, KS, United States, Orhun Vural, Bunyamin Ozaydin, James Booth, Abdulaziz Ahmed

Emergency Department (ED) overcrowding negatively impacts the efficiency and effectiveness of healthcare systems. This study explores the transformation of ED capacity management from a reactive to a proactive approach. It integrates Discrete-Event Simulation (DES) with deep learning to test the effectiveness of proactive capacity decisions. Utilizing extensive historical ED data, the DES model evaluates a proactive Full Capacity Protocol (FCP) against the traditional reactive FCP. Preliminary results demonstrate that the proactive FCP, informed by AI-based predictions, leads to improvements in key performance indicators such as reduced ED Length of Stay, lower hourly wait counts, and decreased hold times, highlighting its potential to enhance operational efficiency and mitigate the adverse effects of ED overcrowding.

3 - A Joint Modeling Framework for Time-to-Fatigue Prediction with A Single Wearable Sensor Biomarker

Lin Lu, Fairfield University, Fairfield, CT, United States

Physical fatigue is a prevalent issue in the U.S. workforce and has resulted in reduced productivity and a higher incidence of workplace accidents. Being able to estimate time to fatigue facilitates proactive interventions before fatigue onset. Existing research has primarily focused on the state, intensity, and wearable sensor characteristics of fatigue while there remains a gap in predicting time to fatigue and identifying indicative biomarkers that can dynamically signal impending fatigue risks. In this study, we utilize simulated manufacturing work tasks and incorporate a single sensor as time-varying covariate, capturing both task and individual characteristics, into a joint modeling framework to predict individual workers' time to fatigue and evaluate its effectiveness. This study demonstrates the feasibility of joint modeling to link a single longitudinal sensor trajectory with time to fatigue, offering insights into fatigue progression and practical implications for timely interventions. It highlights the potential of online monitoring and interpretable statistical methods in enhancing occupational safety and productivity.

4 - Towards Effective Emergency Department Boarding Forecasting: a Real-World Study

Lily Poursoltan, University of California, San Diego (UCSD), La Jolla, CA, United States, Karandeep Singh, Kevin Zhu

Emergency department (ED) overcrowding and boarding pose critical challenges to patient safety, contributing to increased mortality, medical errors, and compromised care quality. While accurate short-term forecasting of ED boarding volumes can enable proactive planning and resource allocation, existing methods often underperform in practice. We address this gap through a comprehensive real-world study using two years of operational data (October 2022–October 2024) from two major UCSD Health emergency departments: La Jolla and Hillcrest. We develop a novel two-stage hybrid forecasting method that combines Vector Autoregression (VAR) to capture multivariate temporal interdependencies among covariates identified through domain experts and rigorous feature importance testing, followed by Extreme Gradient Boosting (XGBoost) to model complex nonlinear relationships for refined boarding volume predictions up to four days ahead. We implement and validate this approach through real-world deployment at both hospital sites. Our extensive field testing within UCSD Health's Mission Control command center demonstrates that the proposed method achieves the lowest RMSE and MAE—particularly in dynamic settings like the La Jolla ED—on average across forecasting horizons of up to four days, consistently outperforming classical econometric models, machine learning methods, and recent time series foundation models. The approach delivers reliable uncertainty quantification, with actual ED boarding volumes rarely falling outside the forecasted confidence intervals, thereby enabling robust surge planning. This real-world implementation has empowered Mission Control leadership to anticipate demand four days in advance, optimize staffing and bed management, and coordinate inter-facility transfers—ultimately maintaining consistent lengths of hospital stays despite growing patient volumes.

5 - Gender Differences in Workload Management: Evidence from Outpatient Services

Jiayu Chen, University of Science and Technology Beijing, Beijing, China, People's Republic of, Wei Gu, Shichen Zhang, Meng Li

Gender differences in workload management have long attracted scholarly attention. In particular, the gendered response to non-promotable workplace demands, particularly extra workload (EW)—defined as additional patient appointments beyond regularly scheduled hours—remains unclear. Female and male physicians may respond differently to EW, resulting in distinct outcomes in the efficiency-quality trade-off. In hospital contexts, EW expands patient access but may exacerbate tensions between service efficiency and care quality. This study investigates how physician gender moderates the relationship between EW and the efficiency-quality trade-off in outpatient departments. Drawing on a rich observational data set, we employ an instrumental variable two-stage least squares (IV-2SLS) strategy to address endogeneity and investigate these dynamics in depth. The results reveal that female physicians are more sensitive to EW pressures, exhibiting a stronger shift from efficiency to quality compared to their male counterparts. Specifically, female physicians allocate more time to patient interactions and diagnostic tests under high EW conditions, leading to a greater reduction in service efficiency. By contrast, male physicians tend to preserve efficiency under comparable workload conditions, suggesting a relatively lower prioritization of quality-enhancing behaviors.

These results highlight the importance of gender-sensitive workload management strategies in healthcare. By recognizing the gendered nature of workload responses, healthcare managers can more effectively address the challenges of balancing efficiency and quality in physician workloads.

6 - Long-Term Graft Survival Under the Kidney Allocation System: Paradoxical Effects of Low Estimated Post-Transplant Survival (Epts) Scores

Nani ZHOU, Shanghai Jiao Tong University, Shanghai, China, People's Republic of

Background: The U.S. Kidney Allocation System employs a "longevity matching" strategy, prioritizing high-quality donor kidneys (KDPI $\leq 20\%$) for low Estimated Post-Transplant Survival recipients to maximize patient survival. However, EPTS focuses solely on patient longevity, neglecting graft survival metrics, which may lead to systemic inefficiencies.

Methods: Utilizing data from the Scientific Registry of Transplant Recipients (2015–2024, $n = 133,213$), we employed competing risks regression and stratified analyses to evaluate the impact of EPTS and Kidney Donor Profile Index (KDPI) on long-term graft outcomes.

Results: Low-EPTS recipients ($\leq 20\%$) receiving high-KDPI kidneys exhibited significantly higher cumulative graft failure rates than high-EPTS cohorts (19.2% vs. 7.5%, $p < 0.001$), with risk inversion occurring post-800 days (adjusted HR = 0.986 per year of age, $p < 0.005$). Older recipients (> 60 years) demonstrated superior graft survival due to immunosenescence (reduced alloimmune injury), yet were systematically deprioritized under current protocols. Stratified analyses revealed consistent paradoxes across KDPI strata: low-EPTS recipients of high-quality kidneys faced the highest long-term graft attrition (adjusted sHR = 0.547–0.682, $p < 0.001$).

Conclusion: The EPTS framework's overreliance on age-centric survival prediction overlooks age's dual role in modulating immune tolerance, resulting in suboptimal allocation of high-quality kidneys. We propose: (1) integrating graft-specific predictors (e.g., HLA mismatch, donor-recipient age interaction) into EPTS; (2) adopting dynamic allocation models prioritizing middle-aged recipients (35–50 years) for optimal kidneys; and (3) establishing region-specific ethical frameworks to balance utility and equity. These reforms aim to harmonize patient survival, graft longevity, and organ stewardship amid rising global ESRD burdens.

7 - The Impact of Regulating Private Sector Profits on Dialysis Access to Care

Hedayat Alibeiki, California State University San Marcos, San Marcos, CA, United States, Michael Klein

In this work, we present an optimization model for analyzing the impact of regulating private sector profits on access to care for dialysis. We consider a dialysis system with a regulator and private sector dialysis providers. The proposed model identifies the optimal location of dialysis facilities and capacity requirements for dialysis stations at the facilities, considering patient preferences for home or facility-based dialysis, the regulator's budget and dialysis providers' profitability constraints. With travel time being an important access to care consideration, this large-scale case study resulted in over 48.5 million travel time calculations as input for the optimization model. To solve large-scale instances of the problem such as the state of California, we developed an efficient meta-heuristic algorithm.

8 - An Evaluation of Out-of-Sequence Placements in the U.S. Organ Transplantation System

Zihan Chai, University of Texas at Austin, Austin, TX, United States, Diwakar Gupta

Organ procurement organizations (OPOs) play an essential role in the U.S. deceased-donor organ transplantation system by coordinating the recovery of deceased-donor organs and implementing the Organ-Procurement-and-Transplantation-Network's (OPTN's) distribution and allocation policy. Since 2021, a series of policy changes has been associated with a sharp increase in OPOs not following the OPTN policy—specifically, making out-of-sequence (OOS) placements. Unlike cases involving patient refusal or medical ineligibility, these deviations occur at the OPO level rather than at the transplant center level and are not the result of clinical judgment. OOS organs and recipients have different characteristics relative to in-sequence (IS) organs and recipients, causing a debate in the research community about the merits of this practice. This paper's aim is to assess whether the OOS practice is detrimental or beneficial from a societal perspective, and to quantify the magnitude of its impact on measures of equity and post-transplant outcomes. Using OPTN data, we present a preliminary study in which we document distributional differences between OOS and IS organs and recipients, and estimate the effect of OOS transplants using an econometric model.

1 - Causality-Informed Anomaly Detection in Partially Observable Sensor Networks: Moving Beyond Correlations

Xiaofeng Xiao, Northeastern University, Boston, MA, United States, Bo Shen, Xubo Yue

Nowadays, as AI-driven manufacturing becomes increasingly popular, the volume of data streams requiring real-time monitoring continues to grow. However, due to limited resources, it is impractical to place sensors on every variable to detect unexpected shifts. Therefore, it is necessary to develop an optimal sensor-placement strategy that enables partial observability of the system while detecting anomalies as quickly as possible. Numerous approaches have been proposed to address this challenge; however, most existing methods consider only variable correlations and neglect a crucial factor: Causality. Moreover, although a few techniques incorporate causal analysis, they rely on interventions—artificially creating anomalies—to identify causal effects, which leads to limited scalability and high computational cost. In this paper, we introduce a causality-informed Q-network approach for partially observable sensor placement in anomaly detection. By integrating causal information at each stage of Q-network training, our method achieves faster convergence and tighter error bounds. Furthermore, the trained causal-informed Q-network agent significantly reduces the detection time for anomalies, demonstrating its effectiveness for sensor placement in large-scale, real-world data streams.

2 - Zero-Knowledge Cyberattack Detection for Regulatory Compliance in Critical Infrastructure Systems

Paritosh Ramanan, Oklahoma State University, Stillwater, OK, United States, H M Mohaimanul Islam

Industrial control systems (ICS) form the operational backbone of critical infrastructure networks (CIN) such as power grids, water supply systems, and gas pipelines. As cyber threats to these systems escalate, regulatory agencies are imposing stricter compliance requirements to ensure system-wide security and reliability. A central challenge, however, is enabling regulators to verify the effectiveness of detection mechanisms without requiring utilities to disclose sensitive operational data. In this talk, we introduce a cyberattack detection framework that leverages zero-knowledge proofs to reconcile these requirements and enable provable detection guarantees while preserving data confidentiality. Our approach builds on established residual-based statistical hypothesis testing methods applied to state-space detection models. Specifically, we design a two-pronged zero-knowledge architecture that enforces (i) temporal coherence of the state-space dynamics and (ii) statistical consistency of the detection tests—allowing regulators to temporally verify alarm correctness without visibility into utility-level data. We formally analyze the soundness and zero-knowledge properties of our framework and validate its practical feasibility through computational experiments on real-world ICS datasets. As a result, our work demonstrates a scalable, privacy-preserving alternative for regulatory compliance for ICS-driven critical infrastructure networks.

3 - Sequential Decision Making for Ride-Hailing Fleet Control: A Unifying Perspective

Murwan Siddig, University of Florida, Gainesville, FL, United States

Optimal control of ride-hailing systems is a challenging problem that has garnered significant attention in recent literature. Research on this topic is diverse but remains uncoordinated and lacks a unified framework. Specifically, the choice of features, decisions, constraints, and performance metrics is inconsistent across studies, and benchmark datasets are rarely published. This lack of standardization makes it difficult to analyze the impact of different problem features and to compare the performance of competing solution methods. To address this gap, we propose a unified modeling framework for controlling a fleet of ride-hailing vehicles under stochastic demand. Our framework consolidates many problem characteristics that were previously studied in isolation, including electric vehicles and ride-pooling. Furthermore, we develop reusable benchmark instances that capture a range of spatial structures and demand distributions and make them available to the scientific community. We also present preliminary results on these benchmarks using two policies from the literature, which we adapt to our unified framework.

4 - Distributed Primal&Ndash;Dual Optimization for General Empirical Risk Minimization

Runxiong Wu, University of Wisconsin, Madison, WI, United States, Andi Wang

We study primal-dual algorithms for general empirical risk minimization problems in distributed settings, focusing on two prominent classes of algorithms. The first class is the communication-efficient distributed dual coordinate ascent (CoCoA), derived from the coordinate ascent method for solving the dual problem. The second class is the alternating direction method of multipliers (ADMM), including consensus ADMM, proximal ADMM, and linearized ADMM. We demonstrate that both classes of algorithms can be transformed into a unified update form that involves only primal and dual variables. This discovery reveals key connections between the two classes of algorithms: CoCoA can be interpreted as a special case of proximal ADMM for solving the dual problem, while consensus ADMM is equivalent to a proximal ADMM algorithm. This discovery provides insight into how we can easily enable the ADMM variants to outperform the CoCoA variants by adjusting the augmented Lagrangian parameter. We further explore linearized versions of ADMM and analyze the effects of tuning parameters on these ADMM variants in the distributed setting. Our theoretical findings are supported by extensive simulation studies and real-world data analysis.

1 - Statistical Modeling of Surface Roughness and Its Impact on Fatigue Life in Additively Manufactured Parts

Shehzaib Irfan, Auburn University, Auburn, AL, United States, Jia Liu

Additive manufacturing (AM) has the potential to manufacture intricate parts at record speeds with fewer resources, which was not possible before using conventional manufacturing techniques. The static mechanical properties of AM parts are at par with conventional ones, but their fatigue lives are significantly shorter due to multiple factors. The most detrimental is the surface roughness, and despite advances in AM, there is no way of getting rid of it yet due to the complex dynamics of the process. This surface roughness adversely affects the fatigue life and is also a source of significant variation in it. This variation is typically caused by the stochastic nature of the surface, which can significantly vary even within parts printed using the same process conditions. The problem is further compounded by the scarcity of fatigue testing data. This work aims to address this challenge by leveraging statistical techniques that not only give accurate predictions but are also interpretable. The modeling framework will be developed by leveraging the mixed models that can take into account the global trends and the part-specific variation. This framework will be able to predict the fatigue life as well as the bounds for a given confidence level. This framework can potentially solve the data scarcity problem in studying the fatigue behavior of additively manufactured parts, hence encouraging their use in mission-critical components.

2 - Kolmogorov&Ndash;Arnold Networks-Enhanced Convolutional Autoencoders for Advanced Medical Image Analysis

Boris Oskolkov, Oklahoma State University, Stillwater, OK, United States, Chenang Liu, Yu Feng

Our work proposes a deep learning method incorporating convolutional autoencoders (CAE) with Kolmogorov–Arnold Networks (KAN) for analysis and learning representations in medical images. In particular, it utilizes the CAE's strong dimensionality reduction ability to extract meaningful, low-dimensional representations from complex, high-dimensional medical imaging data. The resultant features then feed into a KAN, an adaptive, flexible network design based on the Kolmogorov–Arnold representation theorem, capable of precisely learn complex, unknown relationships hidden within medical imaging data. By combining the expressiveness and interpretability of KANs with the robust feature extraction capabilities of CAEs, the proposed framework significantly enhances predictive performance and generalization in diverse medical imaging tasks, including diagnose assistance, preliminary signs of disease identification, and anomaly detection.

3 - Multiscale Spectral Analysis of Point Clouds for Layerwise Monitoring of Additive Manufacturing

Chen Kan, The University of Texas at Arlington, Arlington, TX, United States, Yujing Yang

Point cloud data have been increasingly collected for process monitoring and anomaly detection in additive manufacturing (AM). Extracting defect-pertinent information from point clouds, nevertheless, remains a critical challenge due to the high dimensionality and unstructured nature of the data. Existing approaches for point cloud

modeling and analysis mainly focus on the spatial domain information. They are limited in the ability to fully characterize defect-induced variations, especially subtle ones, and distinguish them from benign patterns. To fill this gap, we develop a new multiscale spectral analysis framework to extend point cloud-based defect detection from the spatial to the spectral domain. Leveraging graph signal processing, surface geometric patterns of point clouds are delineated across multiple scales. Further, an incremental one-class learning scheme is designed for adaptive layer-wise monitoring. The developed framework is evaluated through simulation and real-world case studies. Experimental results have demonstrated the effectiveness and computational efficiency of the developed framework in capturing both local and global defects in layerwise monitoring of AM.

4 - Recent Advances in Dynamic 4D Shape Modeling and 4D Printing

Michael Biehler, University of Wisconsin Madison, Madison, WI, United States, Nick Nachtmann

4D shape modeling and 4D printing represent two complementary frontiers in the design of dynamic, time-evolving structures. While 4D shape modeling focuses on the time-series modeling of 3D geometries that change over time, 4D printing refers to physical devices that exhibit such behaviors by embedding responsiveness into printed materials. Through stimuli such as heat, light, or moisture, 4D-printed objects can autonomously transform their shape or function post-fabrication.

This presentation highlights recent advances at the intersection of these two domains. We introduce novel methods for modeling, predicting, and optimizing the behavior of 4D structures, leveraging physics-based simulations, machine learning, and optimization techniques. Our approach enables the creation of adaptive, programmable systems with applications in soft robotics and beyond.

5 - Generative AI for Milling Chatter Prognosis with Imbalanced Data

Weihong Guo, Rutgers, The State University of New Jersey, Piscataway, NJ, United States, Yupei Shu, Yuebin Guo

Milling chatter is a lasting issue that significantly affects surface quality, tool life, and machine health. However, chatter prognosis, specifically the prediction of chatter occurrence and resulted surface roughness, is challenging using conventional mechanistic and simulation methods due to the complex process mechanics. This study develops a generative AI model to overcome the challenge of imbalanced training datasets due to data scarcity. Synthetic multimodal data—surface images, surface roughness, and acoustic time-series data, are generated to represent various chatter severity levels. By balancing experimental data with augmented data, the multimodal generative AI model effectively predicts diverse chatter scenarios and surface roughness.

Spatial AI for Context-Aware Task Guidance and Human-Machine Teaming

Invited Session

Artificial Intelligence

Chair: Mohsen Moghaddam, Georgia Institute of Technology, 30318

1 - Multimodal AI for Context-Aware Human-Robot Collaboration

Akhil Ajikumar, Georgia Institute of Technology, Atlanta, GA, United States, Sakib Reza

How can we leverage egocentric and bodily interaction cues to build multimodal AI models that enable context-aware collaboration between humans and robots in industrial settings? We introduce a multi-modal AI system, integrated with extended reality (XR) and robotics, to address two fundamental problems in this area: (1) action understanding and (2) intent estimation, both in an online, real-time fashion. Our system processes data from RGB-D video, inertial measurements, and interaction cues to infer human intent and task progression. We develop deep learning models specifically trained for multi-modal step classification and fine-grained action recognition using annotated datasets from human-robot interaction scenarios. These models operate in a real-time sensing architecture built using Microsoft's Platform for Situated Intelligence (PSI), which enables precise synchronization and processing of heterogeneous data streams. Validated through human-robot collaborative assembly tasks, the AI system adapts robotic assistance based on inferred human state, aiming to reduce cognitive workload and improve task performance (e.g., speed, accuracy). This work highlights how multi-modal AI can be applied to support real-time, context-aware adaptation in complex task execution assisted by robots. By interpreting diverse human signals during task execution, the AI enables robotic platforms and XR interfaces to respond more intelligently and supportively.

2 - Evaluating Adaptive Spatial Interactions in Ar Through Brain-Derived Metrics

Ranjana Mehta, University of Wisconsin Madison, Madison, WI, United States

Augmented Reality (AR) training serves as a cost-effective and safe alternative to conventional instructional methods. Nonetheless, instructing novices in fundamental mid-air AR interactions poses challenges. In this study, (a) we created a reliable metric for assessing user performance across various AR interaction techniques and developed adaptation models to predict additional training needs; (b) we assessed these adaptation models through a neuroergonomics lens. We conducted two user studies, tracking motor performance and neural activity using functional near-infrared spectroscopy, to investigate the effect of the adaptation model on users' skill acquisition in poking and raycasting-based AR interactions. Our findings highlight a notable gap in users' perception and learning of mid-air AR/VR interactions, the design of these interactions, and the influence of visuo-motor behavior on user effectiveness. For example, adaptation trials for poking interactions resulted in significant gains, whereas raycasting performance—characterized by complex visuo-motor requirements—showed modest improvement. From a neuroergonomics perspective, effective neural strategies associated with expertise development exhibit increased connectivity among brain regions, while heightened activation of specific areas signifies greater cognitive demands. Our research presents a multifaceted performance metric (what happens at the hand) informed by neuroergonomic evaluation (what occurs in the brain), providing crucial insights into the spatial processing characteristics of AR interactions that can drive the creation of innovative paradigms for tailored training in AR. We posit that blending psychomotor and neuroergonomic strategies creates a robust research foundation for AR/VR interfaces that prioritize visual cues or guides to enhance visual attention and aid motor preparation.

3 - Virtual Reality Research and Learning Applications: a Human-Centered Approach

Karen Chen, North Carolina State University, Raleigh, NC, United States

Virtual reality affords visualization of spatial and temporal information in three-dimensional space and enables a plethora of educational and training opportunities that would be otherwise infeasible or impossible. Despite its attractiveness and powerful abilities, studies have reported the likelihood of virtual content overload and visual distractions. This highlights the necessity of human factors, which is a discipline that concerns the interaction between humans and technologies, where capabilities, needs, and limitations of users are considered and integrated into the design of technologies.

This presentation will discuss the use of human behavior data, workload responses, performance measures, subjective preferences, and utility of large language models in understanding virtual reality systems for supporting interactive learning and cognitive load. Human factors research methodologies including usability evaluation, user-centered design methodology, and empirical experiments will be covered. This discussion is an accumulation of knowledge from project SCALE-VR, which aims to support students in conceptualizing abstract STEM concepts, specifically size and scale, as learners tend to hold an inaccurate understanding of scale. In addition, a project on the integration of large language models and gestures in extended reality to support cognitive mapping for knowledge acquisition will also be shared. Additional open-ended discussions on creating adaptive human-centered systems based on human behavioral data or physiological responses will be included.

In sum, human-centered approach can help ensure that task demand does not exceed the capabilities of a user and thereby increase the utility of virtual reality technologies for embodied, gestured-based learning experiences enhanced by immersive, stereoscopic visualization.

4 - Context-Aware LLM Assistant for Augmented-Reality Real-Time Task Guidance: a Study on the Holoassist Dataset

Mahya Qorbani, Georgia Institute of Technology, Atlanta, GA, United States, Kamran Paynabar, Mohsen Moghaddam

With the rapid growth of data generated by augmented reality (AR) headsets and related equipment, there is a need to integrate diverse multimodal information into robust, real-time assistant systems. In this work, we propose a novel context-aware Large Language Model (LLM) assistant that fuses different data modalities, like hand action data, task steps, dialogues, and etc, as historical context for on-the-fly question answering. To explore how context affects model performance, we introduce an incremental prompting framework, where each model version receives progressively richer contextual inputs. We demonstrate the feasibility of our approach using the HoloAssist dataset, where workers receive real-time support while performing AR/VR-enabled tasks. Our experiments systematically evaluate how each modality contributes to the assistant's performance, revealing that a careful combination of these data types boosts accuracy and relevance in responses. An ablation study further highlights the individual impact of each input modality. These findings underscore the potential of multimodal integration in LLM-driven AR/VR assistance, paving the way for more intuitive, contextually aware solutions in industrial settings.

1 - Enhancing the Wisdom of Crowds when Experts use AI Advice

Angshuman Pal, Indiana University Kelley School of Business, Bloomington, IN, United States, Asa Palley, Ville Satopaa

Good decision making depends on obtaining an accurate forecast of an uncertain variable of interest. An effective method of combining algorithmic precision with human intuition is to provide AI advice to human experts. The collective private information may observed by an individual expert as a noisy signal, so tapping into the wisdom of the crowd by combining AI-assisted forecasts from multiple experts can further improve prediction accuracy. We demonstrate that an AI-assisted crowd can suffer from two forms of bias. First, individual experts aware of the noisiness of their prior belief would over-rely on AI advice to maximize their own accuracy, which leads to the borg effect influencing the aggregate forecast. Second, a crowd of experts with behavioral predispositions against the AI would fail to update their belief rationally and therefore under-utilize the AI advice on average, leading to algorithm aversion affecting the aggregate forecast. The resultant effect of the two mutually-opposing sources of bias impacts the AI-assisted crowd's prediction accuracy. Using a stylized Bayesian model of information, we derive an optimal pivoting procedure that re-calibrates the AI-assisted crowd forecast by shifting either toward or away from the crowd's initial prediction, depending upon the relative strengths of the two biases. We provide a prescriptive empirical pivoting method that uses historical data from similar crowds of experts to numerically estimate the optimal amount of pivoting to be applied. We experimentally examine the performance of our method under different conditions of the forecasting environment using data from an online study on Prolific.

2 - How Human-AI Interaction Affects Human-Human Interactions

Kyle Hyndman, UT Dallas, Richardson, TX, USA, TX, United States, Brandon Jones

We seek to understand how Human-AI interactions affect Human-Human interactions. We study this through the lens of the indefinitely repeated prisoner's dilemma in which cooperation is strictly dominated but socially optimal. We conduct experiments where, in a first stage, human decision makers may interact with either a human or an AI algorithm. In a second stage humans interact with other humans in an identical decision environment. We seek to uncover the effects of the initial experience on subsequent cooperative behavior.

3 - 1+1>2: Adaptive Learning System for Human-AI Integrated Forecasting

Yuxuan Zhu, Technical University of Munich, Munich, Germany, Kejia Hu, Stefan Minner

Human-AI cooperation has emerged as a promising approach for better forecasting across various domains. However, current paradigms often fall short in fully exploiting the complementary strengths of human expertise and machine intelligence, resulting in the forecast being either from the algorithm or human's judgment, rather than an effective integration. To address this gap, we propose an adaptive forecasting system that dynamically integrates algorithm-driven predictions with valuable human insights. Central to our approach is a self-adaptive learning algorithm that learns from past data and selectively incorporates rational human inputs while mitigating irrational biases. Evaluation on real-world sales data from an industry partner demonstrates that our integrated system effectively enhances forecast accuracy. Additionally, we introduce comprehensive evaluation metrics to assess human performance in the forecasting process and offer practical guidance for further improvements. Our solution presents an innovative pathway for businesses to elevate decision quality and operational efficiency.

4 - How Forced Intervention Facilitates Long-Term Algorithm Adoption

Chenshan Hu, University of Colorado Boulder, Boulder, CO, United States, Xinyu Cao, Jiankun Sun, Dennis Zhang

Using the field experiment in an online education company, we find that forced algorithm usage increases its post-experiment usage by 15.8 percentage points. We develop a theoretical model to derive empirical strategies for exploring mechanisms behind and find that learning is a key driver for long-term algorithm adoption.

5 - How Does Algorithmic Assistance Impact Human Performance in Collaboration? Evidence from Algorithm-Assisted Evaluation in Software Development

Jong Sig Chung, University of Wisconsin-Madison, Madison, WI, United States

Algorithmic assistance is increasingly deployed to assist human performance in knowledge-intensive work, yet its integration may inadvertently undermine the human collaborative processes essential for human performance in knowledge-intensive work. Focusing on the introduction of algorithms in human collaboration, this study argues that it will stifle collective discussion essential for developing their shared understanding. Therefore, it will lower human's performance. Using a stacked cohort generalized Difference-in-Differences design and data about software development projects on GitHub, the study finds that although the adoption of Continuous Integration (CI) bot within a project—algorithms that assist evaluation—accelerate evaluation decisions, they also narrow the scope of collective discussions among developers during evaluation. Ultimately, this leads to a decline in developer's performance in two essential tasks where shared understanding about the project is valuable: recognizing problem areas and exploring new improvements within the project. Plus, it increases total un-resolved problem areas within the project, possibly due to reduced developer's performance. Lastly, these adverse effects are magnified when projects receive contributions from diverse knowledge domains. These findings challenge prevailing perspectives about human-algorithm augmentation, highlighting the need for a balanced approach to integrating algorithmic assistance.

6 - Tailoring Explainable Artificial Intelligence to Reduce Algorithm Aversion and Improve Profitability

Stephanie Kelley, Sobey School of Business, Saint Mary's University, Halifax, NS, Canada, Anton Ovchinnikov, Adrienne Heinrich, Sook Yee Chong

We conduct a series of lab-in-the-field and lab experiments to investigate the preferences of real AI users concerning the tailoring of explainable artificial intelligence (XAI) and its impact on reducing algorithm aversion and improving profitability. Study #1 involves a choice-based conjoint (CBC) survey to study the effect of tailoring the XAI approach, AI model, number of features, aggregation level, and lending outcome on AI user preferences. Study #2 integrates these preference results into a series of lab-in-the-field and lab experiments to determine whether tailoring the XAI visualizations reduces AI user algorithm aversion. Study #3 then measures the impact of tailoring XAI visualizations on firm profitability. We find that AI users (i) are most swayed by the XAI approach, (ii) prefer certain combinations of XAI approaches and models, (iii) prefer to see more features, (iv) do not have a preference between individual and group aggregation levels, and (v) their preferences do not change across favourable or unfavourable model outcomes. We then observe that (vi) tailoring XAI visualizations to AI user preferences leads to reduced algorithm aversion; however, this gain is restricted to favourable model outcomes. Lastly, we find that (vii) tailoring XAI visualizations allows firms to capture more profit. All studies are conducted in a lending setting, using real loan data and models developed in collaboration with data scientists from a large institutional lender in Asia. The lab-in-the-field experiments involve real AI users—the firm's loan officers—and the results are supported by a student lab experiment.

Multi-Agent Optimization in Federated Learning, Markets, and Mechanism Design

Invited Session

Artificial Intelligence

Chair: Zhengyuan Zhou, Stern School of Business, New York University, New York, NY, United States

Co-Chair: Mingxi Zhu, Georgia Institute of Technology, Atlanta, GA, 30033, United States

1 - Mechanism for Collaborative Federated Learning: Pitfalls of Shapley Value**Mingxi Zhu, Georgia Institute of Technology, Atlanta, GA, United States**

This work investigates the design of incentive mechanisms for collaborative learning platforms, where strategic agents contribute data and jointly train federated learning (FL) models. We introduce a unified Multi-Action Collaborative Federated Learning (MCFL) framework that captures the “three-body” problem -- the complex interplay between strategic agents' participation, platform mechanisms, and federated learning algorithms. Our key insight is that, the FL convergence rate is endogenously shaped by the equilibrium of agents' participation level induced by the platform proposed mechanism. We consider two widely adopted mechanisms in cooperative game: Shapley Value (SV) and Marginal Contribution (MC) and compare the agents' equilibrium and the subsequent algorithm convergence induced by these mechanisms. While the Shapley Value is often preferred due to its fairness guarantees and budget balance property, we identify a critical pitfall of SV -- it encourages agents to create duplicated fake identities and split data among them, causing slow convergence of the FL algorithm and inflated cost of communication. In contrast, although the MC mechanism is not budget-balanced, it is robust to data splitting. We also introduce the system efficiency to quantify this trade-off between surplus generated from learning and communication cost. Our finding challenges the success of SV in conventional cooperative games and identifies a critical pitfall in the context of collaborative FL.

2 - Privacy-Aware Federated Learning for Heterogeneously Sensitive Data: An Example of Cross-Region Recommendation Using LLMs**Shuang Gao, Arizona State University, Tempe, AZ, United States, Mingxi Zhu**

Global E-commerce platforms operate across diverse regions—such as Amazon Asia, Amazon Europe, and Amazon US. It raises particular challenges to privacy-preserving platform algorithms design. Firstly, different regions may have varying privacy constraints, depending on local regulations (e.g. GDPR in Europe, CCPA in US). Secondly, the platform deploys different types of data that may have varying privacy sensitivities, from private data such as personal view history to public data such as product description and reviews. In this study, we propose a novel federated learning framework that highlights the hybrid training with heterogeneously sensitive data for global platforms. Particularly, we focus on cross-regional recommendation systems. While using LLM to bridge the gap in understanding multi-lingual item attributes, the platform needs a privacy-preserving solution to finetune LLMs or prompt-tuning for the recommendation tasks. We show that this hybrid FL framework is more efficient than conventional FL and it can be extended to other contexts and platform algorithms.

3 - Learning to Bid in Non-Stationary Repeated First-Price Auctions**ZIHAO HU, The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Xiaoyu Fan, Yuan Yao, Jiheng Zhang, Zhengyuan Zhou**

First-price auctions have recently gained significant traction in digital advertising markets, exemplified by Google's transition from second-price to first-price auctions. Unlike in second-price auctions, where bidding one's private valuation is a dominant strategy, determining an optimal bidding strategy in first-price auctions is more complex. From a learning perspective, the learner (a specific bidder) can interact with the environment (other bidders) sequentially to infer their behaviors. Existing research often assumes specific environmental conditions and benchmarks performance against the best fixed policy (static benchmark). While this approach ensures strong learning guarantees, the static benchmark can deviate significantly from the optimal strategy in environments with even mild non-stationarity. To address such scenarios, a dynamic benchmark—representing the sum of the best possible rewards at each time step—offers a more suitable objective. However, achieving no-regret learning with respect to the dynamic benchmark requires additional constraints. By inspecting reward functions in online first-price auctions, we introduce two metrics to quantify the “regularity” of the bidding sequence, which serve as measures of non-stationarity. We provide a minimax-optimal characterization of the dynamic regret when either of these metrics is sublinear in the time horizon. Our main technical tool is the Optimistic Mirror Descent (OMD) framework, a tool largely developed within the machine learning theory community, and is well-suited for achieving minimax-optimal dynamic regret rates in this context.

4 - Optimization of Network Inventory Systems: the (Potential) Perils of the Hindsight Approach**Sheng Liu, University of Toronto, Toronto, ON, Canada, Stefanus Jasin, Jinglong Zhao**

We consider an online retailer with multiple warehouses and multiple demand locations. We assume that the retailer uses the greedy fulfillment policy (i.e., ship from the closest and/or cheapest warehouse) and consider the performance of the initial inventory allocation given by the hindsight or the stochastic programming approach, under which the retailer can first observe all the realized demands before simultaneously making the fulfillment decisions to minimize the total cost. The hindsight approach has been proposed by recent works in the literature, and is practically appealing. While this approach has its merits and performs relatively well in some cases, in general, its limitations are not well understood. In this paper, we first show that the hindsight solution is equivalent to the optimal inventory allocation under the greedy fulfillment policy but on a misspecified (more optimistic) demand arrival distribution. This optimism is sometimes benign but can also severely backfire. We provide three necessary and sufficient conditions for the hindsight solution to be asymptotically optimal (as the unit lost sale cost grows large) under the greedy fulfillment policy.

5 - Modeling and Optimizing Endogenous Consumer Acquisition in Live-Streaming Commerce**Zhiqi Qin, Zhejiang University, Hangzhou, China, People's Republic of, Shouchang Chen, Hongpeng Wang**

Live-streaming commerce—an emerging and immersive business model—thrives on real-time interactions between celebrities and consumers. This paper uncovers an intriguing phenomenon: a celebrity's follower base is endogenous to promotional activities. We study the resulting joint-pricing and traffic investment problem in live-streaming commerce. Specifically, we propose two simple yet elegant models, the EMMNL and GEMMNL, to characterize the endogeneity of follower-size in response to pricing and traffic investment. We formulate the joint optimization problem with endogenous follower size as a non-convex program. By quantifying the marginal value of acquiring viewers, we derive the optimal traffic investment policy and offer actionable managerial guidance. This analysis further reduces the joint-problem to a pricing problem with fixed traffic investment, for which we develop tractable solution methods. Under the EMMNL-model, the pricing problem admits univariate reformulation, whereas under the GEMMNL-model, we design a Fully Polynomial-Time Approximation Scheme (FPTAS). A case study using real-world data demonstrates that ignoring follower endogeneity can lead to substantial prediction errors and profit losses. Our analysis yields several key insights: (i) A modest 8% reduction in procurement cost can double total profits, explaining the prevalence of low-cost, low-price products in live-streaming commerce; (ii) Although followers account for only 10.97% of total consumers, their contribution to profits rivals that of non-followers, highlighting their outsized economic importance; (iii) The short-term marginal-value of a follower exceeds that of a non-follower, yet this relationship reverses in the long-run—implying a strategic pivot: invest in follower acquisition for short-term gains, and in non-follower engagement for sustained long-term growth.

1 - Explainable Graph Learning for Infrastructure Resilience

Parvathinathan Venkitasubramaniam, Lehigh University, Bethlehem, PA, United States

Ensuring the resilience of critical infrastructure under natural or man-made disruptions requires both accurate prediction of system behavior under previously unseen conditions and human-understandable explanations of emerging failures. This presentation introduces two complementary approaches that use graph learning and explainable AI to strengthen infrastructure resilience. First, we present a domain-informed graph learning architecture designed to predict system performance under previously unseen conditions, such as extreme weather events, cyberattacks, or cascading failures. By integrating physical dynamics, topological features, and historical data into novel graph convolutional architectures, we demonstrate, theoretically and with practical examples, that the approach can generalize effectively to out-of-distribution scenarios, even when no prior data exists for specific conditions. Second, we introduce a post-hoc explainable AI approach that performs root cause analysis on anomalies detected within complex cyber-physical systems. This method uses causal graph extraction to identify the key interactions and dependencies across the system and derive insight into pathways responsible for abnormal system behaviors. Once an anomaly is flagged through monitoring data streams and predictive models—we show how the causal extraction framework can be used both to localize the cause of the anomaly, as well as separate sensor anomalies from process failures and cyber attacks. Both these approaches bring together graph-learning methods and domain knowledge expressed through topological features and dynamical equations, with the eventual goal to produce human-interpretable explanations that help engineers and operators diagnose failures, assess systemic vulnerabilities, and design targeted interventions.

2 - Steering Dialogue Dynamics for Robustness Against Multi-Turn Jailbreaking Attacks

Hanjiang Hu, Carnegie Mellon University, Pittsburgh, PA, United States, Alex Robey, Changliu Liu

Abstract Large language models (LLMs) are shown to be vulnerable to jailbreaking attacks where adversarial prompts are designed to elicit harmful responses. While existing defenses effectively mitigate single-turn attacks by detecting and filtering unsafe inputs, they fail against multi-turn jailbreaks that exploit contextual drift over multiple interactions, gradually leading LLMs away from safe behavior. To address this challenge, we propose a safety steering framework grounded in safe control theory, ensuring invariant safety in multi-turn dialogues. Our approach models the dialogue with LLMs using state-space representations and introduces a novel neural barrier function (NBF) to detect and filter harmful queries emerging from evolving contexts proactively. Our method achieves invariant safety at each turn of dialogue by learning a safety predictor that accounts for adversarial queries, preventing potential context drift toward jailbreaks. Extensive experiments under multiple LLMs show that our NBF-based safety steering outperforms safety alignment, prompt-based steering and lightweight LLM guardrails baselines, offering stronger defenses against multi-turn jailbreaks while maintaining a better trade-off among safety, helpfulness and over-refusal. Check out the website here <https://sites.google.com/view/llm-nbf/home>.

3 - Strategic Coordination of Heterogeneous Resources for Attack Detection

Pichamon Anukularkusol, Georgia Institute of Technology, Atlanta, GA, United States, Mathieu Dahan

We study a two-player network inspection game in which the defender coordinates sensors with potentially heterogeneous detection capabilities to detect attacks placed by a strategic attacker. We assume that there are multiple types of sensors, each determined by the detected area coverage when placed at each detector location. The objective of the defender (resp. attacker) is to minimize (resp. maximize) the expected number of undetected attacks. We analytically characterize Nash equilibria of this zero-sum game in scenarios where there is no overlapping detected area coverages upon placing sensors at any detector location, and both players possibly perform a randomized strategy. We then introduce a new solution approach derived from our analysis and validate its efficacy through computational experiments.

4 - Temporal Robustness in Discrete TIME Linear Dynamical Systems

Nilava Metya, Rutgers University, New Brunswick, NJ, United States, Arunesh Sinha

Discrete-time linear dynamical systems, including Markov chains, have found many applications. However, in some problems, there is uncertainty about the time horizon for which the system runs. This creates uncertainty about the cost (or reward) incurred based on the state distribution when the system stops. This decision is critical when one needs to understand the state of the model within finite wall clock time. For example, such models are used to model attack propagation in cybersecurity, where it is important to understand worst-case outcomes and costs within a fixed wall clock time in order to take remedial actions. Given past data samples of how long a system ran, we propose to theoretically analyze a distributional robust cost estimation task in a Wasserstein ambiguity set, instead of learning a probability distribution from a few samples. Towards this, we show an equivalence between a discrete-time Markov Chain on a probability simplex and a globally asymptotically stable (GAS) discrete-time

linear dynamical system, allowing us to base our study on a GAS system only. Then, we provide various polynomial-time algorithms and hardness results for different cases in our theoretical study, including a fundamental result about the Wassertein distance-based polytope.

1 - Machine-Learning-Based High-Resolution Aftershock Catalog Reveals Fault Complexity of the 2023 Kahramanmaraş Earthquake Sequence

Phuc Mach, Georgia Institute of Technology, Atlanta, GA, United States, Zhigang Peng, Xu Si, Eric Sandvol, Ekrem Zor, Mehmet Ergin

The 2023 Mw 7.8 and 7.5 doublet earthquakes in Southeastern Türkiye caused widespread devastation and triggered complex aftershock sequences along the East Anatolian Fault system. To better characterize the evolving seismicity and underlying fault structures, we deployed over 200 SmartSolo nodal stations across major clusters and high-risk areas, recording continuous 500-Hz waveforms for more than 100 days starting in May 2023. With the collected data, we built a high-resolution earthquake catalog using enhanced machine-learning-based phase-picking and association techniques. To address the challenge of limited pre-built models for high-frequency data, we developed a deep learning-based phase-picking model tailored for 500-Hz signals. Starting with using high-confidence phase picks from the Türkiye Disaster and Emergency Management Authority (AFAD) catalog, we applied rigorous quality control to create a labeled dataset. This dataset are used for training a 500-Hz phase-picking model based on a revised PhaseNet architecture. With the retraining model, our result shows approximately 100 million picks corresponding to over 50,000 events during deployment time. This model achieved superior accuracy and phase detection compared to initial 100-Hz model, generating more than 100 million picks and over 50,000 seismic events. We also performed phase association, event location, and double-difference relocation to construct a high-resolution aftershock catalog, which reveals the intricate fault structures. The detected events also serve as templates for ongoing matched-filter-based detection. Our study highlights the power of AI-driven data mining in seismology and provides new insights into rupture dynamics and seismic hazard in tectonically active regions.

2 - Physics-Informed Machine Learning for Sub-Seasonal Prediction of Tropical Cyclone Genesis

Aren Russ, Georgia Institute of Technology, Atlanta, GA, United States, Ali Sarhadi

Tropical cyclones (TCs) are among the most destructive and costly natural disasters, causing billions of dollars in damages annually. Despite their global impacts, the physical mechanisms governing their genesis remain poorly understood. Recent advances in machine learning (ML) offer promising avenues for improving the prediction of TC formation and subsequent track evolution, particularly as traditional linear models fall short in capturing the nonlinear, chaotic nature of these systems. This research develops a physics-informed machine learning framework to predict TC genesis locations globally on sub-seasonal to seasonal timescales. The model integrates a time-dependent convolutional neural network (CNN) with a Long Short-Term Memory (LSTM) network to capture both spatial and temporal dependencies in environmental conditions. Predictor variables include key surface and atmospheric drivers obtained from the ERA5 reanalysis, while storm track data for training are drawn from the IBTrACS database. The framework is trained to reconstruct snapshots of potential genesis hotspots based on historical environmental states. The combined CNN–LSTM architecture demonstrates strong skill in learning spatiotemporal patterns associated with TC genesis, effectively linking physical precursors to eventual formation. Preliminary results indicate that the model can forecast TC genesis up to four weeks in advance, highlighting its potential as a tool for early warning and disaster preparedness in a warming climate.

3 - Tuning into Earth's Voice: Leveraging Foundation Models for Earthquake Detection

Xu Si, Georgia Institute of Technology, Atlanta, GA, United States, Zhigang Peng

Recent advances in deep learning are bringing new possibilities to seismology. Although current deep learning models have achieved success in tasks such as earthquake monitoring, they are often limited to specific regions or applications. Inspired by breakthroughs in natural language processing, where large pre-trained models like the GPT series can be adapted for a wide range of tasks, we explore whether similar approaches can benefit seismology. Since both earthquake signals and natural language involve analyzing sequential data over time, we investigated whether large language models could be fine-tuned to identify seismic events. In this study, using earthquake data from California and Japan, we present a method that adapts these pre-trained language models for earthquake detection. Our results show that this approach performs comparably to traditional deep learning methods and provides greater flexibility and adaptability. These findings highlight the potential of foundation models to advance the development of more general and adaptable AI tools for earthquake monitoring.

4 - Robust Path: Geometry and Algorithms

Hao Hao, Carnegie Mellon University, Pittsburgh, PA, United States, Peter Zhang

This work aims to connect a) the set of robust optimization solutions under varying uncertainty set size and shape (robust path) with b) the optimization paths of proximal methods for the deterministic problem. We reveal the two conceptually distinct paths are indeed geometrically similar. Leveraging this geometric view, we show that the entire robust path solution sets can be approximated via first-order method optimization paths. We apply our results for: 1) generalization of a classic result in finance. 2) fast computation of adversarially robust deep learning models.

Advancing Entrepreneurial Operations and Innovation

Invited Session

Technology, Innovation Management and Entrepreneurship

Chair: Morvarid Rahmani, Georgia Institute of Technology, Atlanta, GA, United States

Co-Chair: Zeya Wang, University of Dayton, Dayton, OH, United States

1 - AI use, Startup Funding and Performance: Evidence from British Startup Firms

Yiyao Zhou, UCL School of Management, London, United Kingdom, Bilal Gokpinar, Onesun Yoo

We examine the investment patterns of venture capitalists related to AI in British startup firms. We try to answer key questions such as: Whether AI ventures attract more funding? Whether the novelty of AI affects the amount of VC funding? And whether the investment contributes to firm success?

2 - Strategies for Milestone-Driven Entrepreneurial Start-Ups in Multi-Control Settings

Zhengli Wang, The University of Hong Kong, Hong Kong, Hong Kong

New venture start-ups need to survive through multiple stages of milestone targets. This study investigates strategies in a milestone-oriented environment, by modeling a start-up with its state captured by a diffusion process. The entrepreneur can choose among multiple activities with different costs, drifts and variances. Depending on whether the process reaches an upper or lower boundary, the start-up succeeds or fails. The optimal policy's structure is defined by an efficient frontier that orders the activities by two intuitive measures: effective drift and cost-effectiveness. The results can potentially provide a foundational block in the study of entrepreneurial decision-making.

3 - Noisy Sequential & Parallel Testing of Designs: Theory and Experiment**Sreekumar Bhaskaran, SMU-Cox School of Business, Dallas, TX, United States, Sanjiv Erat**

Many decision tasks, from choosing the appropriate product design to selecting the go-to-market strategy, may be conceptualized as a search process where the decision maker evaluates multiple alternatives with the goal of selecting one. We experimentally study how the managers make these decisions in the face of measurement errors.

4 - Look Before You Leap? An Operational Analysis of Hybrid Entrepreneurship**Zeya Wang, University of Dayton, Dayton, OH, United States, Morvarid Rahmani, Karthik Ramachandran**

In this paper, we investigate the ongoing debate between fully committed entrepreneurship and the hybrid approach. Different from committed entrepreneurship, hybrid entrepreneurship involves individuals concurrently pursuing traditional employment and entrepreneurial activities. To compare the merits of these two approaches, we develop a model where the entrepreneur's learning is proportional to their exploration effort. We identify the conditions that favor the hybrid approach, as well as situations where a full commitment is optimal. Furthermore, we derive the optimal allocation of effort for entrepreneurs who choose the hybrid approach. We find that committed entrepreneurship being suitable for high potential ventures. Further, different ways of supporting entrepreneurs are not equivalent because of their effect on the entrepreneur's exploration strategy. Finally, we consider the effect of employment contracts (which may require minimum effort) and the duration of the runway. Our results reveal a nuanced view of how entrepreneurs should exert effort to test their ideas.

UPS George D. Smith Prize

Plenary Keynote

Keynote

Chair: Anne Robinson, Robinson Insights, Ottawa, ON, Canada

1 - UPS George D. Smith Prize Winner Reprise: National University of Singapore**Jussi Keppo, National University of Singapore, Singapore, Singapore, James Pang**

Established in 2013, the Business Analytics Centre (BAC) at the National University of Singapore (NUS) is a result of a collaborative effort between NUS and IBM. The Centre is the operational hub for the NUS Master of Science in Business Analytics (MSBA) program, fostering applied research in business analytics through strong industry partnerships. The MSBA program, shaped and executed with NUS's academic expertise, benefits from IBM's industrial insights, integrating theory with real-world application. As an analytics hub at NUS, the BAC leverages the strengths of both the NUS Business School and the School of Computing. Over the past decade, BAC has established a robust industry network with over 100 partners, including leading multinational corporations like Accenture, Alibaba, Amazon, AXA, DBS, Ernest & Young, Google, Huawei, IBM, Johnson & Johnson, Morgan Stanley, SAP, State Street, Swiss Re, and dynamic unicorn startups such as Ant Financial, Grab, Shopee, TigerGraph, and TikTok. These collaborations extend into educational initiatives and translational research, enhancing the practical learning experience for students. Remarkably, over 800 real-world industrial analytics/OR projects have been successfully completed by NUS MSBA students in partnership with these corporations in the past 10 years. Furthermore, BAC has cultivated an engaging alumni community of MSBA graduates, who continue to contribute to and enrich the business analytics landscape at NUS.

Keynote - The UPS Advantage: Integrated Network Powered by OR & AI

Plenary Keynote

Keynote

1 - The UPS Advantage: Integrated Network Powered by OR and AI**Yentai Wan, UPS, Suwanee, GA, United States**

On a typical day, UPS delivers 22.4 million packages and documents to 10.1 million customers and collects packages from 1.6 million shippers. In 2024, it achieved total revenue of \$78 billion with 444,000 employees worldwide. UPS operates in more than 220 countries and territories with approximately 1,800 owned or leased facilities. To serve in a high-premium complex logistics customer base, it leverages a fleet of 291 aircraft it owns and another 243 it charters. UPS operates one of the world's largest civilian airlines, using 734 airports throughout the world. In addition, approximately 135,000 package cars, vans, tractors and motorcycles, including more than 19,000 alternative fuel and advanced technology vehicles are used to achieve marketing leading customer service. UPS has a rich history of operational excellence and is steeped in a culture of technology innovation. Any researcher will quickly notice the reference of Operations Research (OR) in UPS could dating way back to the 1950s and most recently, the 2016 Franz Edelman Award winner, ORION that optimizes final mile deliveries. In this talk, we will unveil the curtain of the first and middle-mile UPS network with its unique challenges and opportunities. More importantly, how UPS applies OR with supplemental AI innovations to dynamically scale our networks in a highly uncertain business environment

1 - Advancing Decision Intelligence with AI-Assisted Simulation: Case Studies from the Strategic Decision Lab

Alton Alexander, Veydra.io., Pleasant Grove, UT, United States

See how systems thinking and AI-assisted simulation can accelerate decision-making in education and practice. Through case studies in workforce scheduling, healthcare capacity, supply chains, and training pipelines, we show how the Strategic Decision Lab enables participants to design, calibrate, and compare scenarios rapidly. Attendees will see how AI assistants support model building, scenario exploration, and insight generation while maintaining transparency and rigor. Participants will gain practical methods to integrate AI-assisted simulation into their teaching or professional practice, learning how to enrich curricula, engage learners, and apply collaborative systems thinking for real-world decision support.

2 - Reducing Time-to-Value with Fico Xpress Optimization Suite and Gen AI

Carlos Zetina, FICO Xpress Optimization, Québec, QC, Canada

Time to Value measures how long it takes for technology projects to begin providing business value. Three critical milestones to achieve this are model creation, validation, and deployment. In this showcase, we'll show how FICO Xpress Optimization Suite shortens Time to Value and supercharges Return on Investment (ROI) by providing a unified platform for development, validation, and deployment. We'll show how FICO's suite of products and Gen AI come together to turbocharge building and adoption of enterprise optimization applications deployable on any tech stack, be it server-less or via virtual machines, hosted on any cloud provider or on-premises infrastructure. Hear from Rusty Burlingame from Southwest Airlines, on how Southwest is using Xpress to improve customer experience, enhance employee engagement, and streamline operations to maximize revenue and support growth.

Technology Showcase

Chair: Loraine Coleman, INFORMS, 5521 Research Park Drive, Catonsville, MD, 21228, United States

1 - Democratizing Digital Twins: From Real-Time Operations to Strategic Planning

Andrew Siprelle, ChiAha, Maryville, TN, United States

Digital twins serve different problem domains requiring different technical approaches. Traditional 3D kinematic simulation excels at spatial problems. Strategic capital investment decisions require different capabilities: rapid scenario analysis, statistical validation, and system interdependency revelation. This session presents a case study demonstrating time-compressed discrete event simulation methodology delivering strategic intelligence through rapid construction and statistical parameterization from historian data. The case reveals a critical insight: two equipment problems with similar historical downtime losses deliver 1.3x versus 5x actual gains when fixed. This gap illustrates why traditional loss analysis misleads prioritization decisions. The methodology enables Fortune 500-standard predictive modeling to become accessible.

2 - An Introduction to Modeling with GAMSPy

Adam Christensen, GAMS Development Corp, Fairfax, VA, United States, Steven Dirkse

Our showcase offers a hands-on introduction to GAMSPy. GAMSPy combines the high-performance GAMS execution system with the flexible Python language, creating a powerful mathematical optimization package. It acts as a bridge between the expressive Python language and the robust GAMS system, allowing you to effortlessly create complex mathematical models and applications. Join us to explore GAMSPy's fundamental functionalities through practical, interactive exercises. We'll cover everything from defining sets, parameters, variables, and equations to solving models and retrieving results, all within a familiar Python environment. Beyond the basics, we'll also provide a glimpse into more advanced features, demonstrating how GAMSPy can streamline complex modeling workflows and enhance your analytical capabilities. Whether you're a seasoned GAMS user looking to integrate with Python or a Python user curious about optimization, this workshop will equip you with essential skills needed to get started and demonstrate what is possible with GAMSPy.

1 - Deep Hedging Strategies for a Risk-Averse Hog Farm

Ye Liu, Syracuse University, Syracuse, NY, United States, Panos Kouvelis, Yunzhe Qiu, Danko Turcic

We employ machine learning techniques to develop a comprehensive, integrated risk management model tailored to the operations of a livestock farm. This model is designed to assist a risk-averse farmer in making optimal decisions under uncertainty by dynamically integrating production and financial risk considerations. Specifically, it provides guidance on both the timing and method of selling livestock, taking into account market conditions, price volatility, and the farmer's risk preferences. In addition, the model formulates effective hedging strategies using available financial instruments to mitigate exposure to adverse price movements. By leveraging data-driven methods, the framework adapts to changing environments and enhances the farmer's ability to manage risk in a systematic and forward-looking manner.

2 - Buying Under Fire: Inflation Ambiguity and Consumer Behavior in Hyperinflation Crisis

Haoran Yu, Syracuse University, Syracuse, NY, United States, Burak Kazaz, Scott Webster

In the context of hyperinflation, governments often underreport official inflation figures to conceal economic policy failures. This systematic understatement erodes public trust in official statistics and motivates independent organizations to publish alternative estimates. In Türkiye, for example, the inflation rates released by independent institutions are typically higher than those reported by the government. The coexistence of divergent inflation figures introduces significant ambiguity for consumers, complicating their perception of the economic environment. This paper investigates how both the level of official inflation rate and the ambiguity surrounding the true inflation rate affect consumer purchasing behavior. We leverage detailed sales data from Kombucha 2200, the largest kombucha producer in Türkiye, and compile monthly inflation rates reported by both the Turkish Statistical Institute (TURKSTAT) and independent sources such as Istanbul Chamber of Commerce (ITO). Our analysis reveals that higher reported inflation rates lead to increased consumption, consistent with intertemporal substitution under anticipated price hikes. Conversely, actual price increases reduce demand, as expected. Most notably, we provide the first empirical evidence that inflation ambiguity—captured by the discrepancy between government-declared and independently estimated inflation rates—negatively affects consumer demand. This finding suggests that when consumers face uncertainty about the true inflation rate, they may delay or reduce purchases due to heightened economic anxiety or distrust in market signals. Our results highlight the importance of credible and transparent inflation reporting, particularly in hyperinflationary economies, where informational integrity plays a critical role in sustaining consumer confidence and market stability.

3 - Contract Mechanisms to Enhance Compliance in Coffee Futures Under Price and Yield Uncertainty

Mariana Losada-Agudelo, Rensselaer Polytechnic Institute, Troy, NY, United States, Sebastian Souyris, M. Hakan Hekimoglu

Agriculture faces significant uncertainties due to volatile markets and unpredictable climate conditions that affect crop yields. Among agricultural commodities, coffee is particularly susceptible to price volatility, with recent price spikes driven by low yields caused by adverse weather. Futures contracts have been a common strategy to mitigate price volatility, providing financial stability to coffee farmers. However, the lack of flexibility in these contracts, continued price volatility, and limited financing have created incentives for non-compliance, undermining their effectiveness. This research proposes an analytical model that uses incentives and penalties to improve futures contract compliance by enabling farmers to make decisions under price and yield uncertainty. We design mechanisms that include upfront payments and penalties, aiming to balance risk between parties and reduce the likelihood of strategic default. The upfront payments provide farmers with early liquidity, allowing them to invest in their crops and improve productivity by addressing financial constraints. In turn, the penalty component discourages deviation after contract acceptance by increasing the cost of non-compliance once commitments have been made. The contracts aim to ensure product delivery while optimizing the financial stability of farmers. This study contributes to the literature on agricultural contract design, demonstrating how appropriate incentives can reduce the risk of supply chain disruptions and improve cooperation between farmers and buyers.

4 - Supply Chain Washing: Strategic Disclosure of Corporate Suppliers

Yilin SHI, Chinese University of Hong Kong, Hong Kong, China, People's Republic of, Jing Wu, Yu Zhang, Yuqing Zhou

This paper examines how firms manage their disclosure of customer-supplier relationships to create a favorable green image in their supply chain. Our study finds robust evidence that firms strategically disclose relationships with environmentally responsible ("good") suppliers while withholding relationships with "bad" suppliers, *ceteris paribus*. Our analysis suggests that this selective disclosure is driven by opportunistic supply chain greenwashing behavior rather than by a genuine effort to communicate improvements in ESG performance through partnerships with high-ESG suppliers. Further, we document that firms are more likely to feature green suppliers in the 10-K's Business section and ESG reports, while less environmentally responsible suppliers tend to appear in the 10-K's Risk Factors section. Moreover, the extent of this strategic disclosure decreases as regulations on environmental information transparency become more stringent. Additionally, we observe that companies that strategically disclose "green" suppliers have higher stock returns and asset turnover in the short term, although these effects diminish over time. This suggests that it takes time for investors and consumers to fully understand such strategic disclosures.

5 - Credit Chain and Sectoral Co-Movement: a Multi-Region Investigation

Hsiao-Hui Lee, National Chengchi University, Taipei, Taiwan, S. Alex Yang, Yuxuan Zhang, Kijin Kim

This paper empirically examines the relationship between sectoral co-movement and trade credit usage in a multi-region context. Building on the models of Shea (2002) and Raddatz (2010), we develop a framework that captures the effects of trade credit on sectoral co-movement, both within countries and across borders. Using the Multi-Regional Input-Output Table developed by the Asian Development Bank, we assemble a dataset covering 14 manufacturing industries across 53 countries. Our findings provide empirical evidence that trade credit is a key channel for propagating both domestic and cross-border shocks, amplifying their impact on global industries. We show that the influence of domestic credit chains on sectoral co-movement is twice as strong as that of international chains. Furthermore, we analyze two outsourcing strategies—friend-shoring and nearshoring—under current geopolitical tensions, and find that these strategies may actually exacerbate shock propagation.

1 - Stochastic Income and Optimal Policies: a New Analysis

Seyoung Park, University of Nottingham, Nottingham, United Kingdom, Alain Bensoussan, Adannah Duruoha, Viswanath Ramakrishna

This paper provides a new analysis for optimal consumption and investment policies with stochastic income. Our analysis gives some kind of procedure for solving the Bellman equation with the dimension reduction scheme developed. In particular, we provide an interpretation of the reduced problem based on the probabilistic approach. The value function and optimal strategies are all explicitly characterized with analytic comparative statics provided, which is helpful to understand much of the economics in the paper. We also develop with the convergence theorem a numerical algorithm for policy iteration and solve the Bellman equation as a sequence of solutions to ordinary differential equations. The decision to invest more or fewer equity in the stock market in the presence of stochastic income is influenced, to a large extent, by the way in which how high risk aversion and income-to-wealth ratio are exhibited. Finally, we provide more economic forecasts with borrowing constraints and various stochastic income scenarios.

2 - Liability-Driven Investment Under Inflation Risk and Regime Switching

MYUNGJUN KIM, Pohang University of Science and Technology, Pohang-si, Korea, Republic of, Bong-Gyu Jang, Hyeontae Jo

This paper investigates the optimal liability-driven investment (LDI) strategy for pension funds to manage explicit inflation risk while the financial market switches across economic regimes. Inflation rates, real interest rates, risk premia, and volatility are modeled as regime-dependent and evolve according to a Markov process. We cast the manager's problem in continuous time: maximize the expected utility of the funding ratio (asset-to-liability ratio), subject to a Value-at-Risk (VaR) constraint. By combining an option-based hedging framework with the regime-switching dynamics, we find the optimal portfolio weights for the inflation-linked bond, the risk-free asset, and the stock in every regime.

Numerical results highlight three distinctive patterns. First, in high-inflation regimes, the asset allocation tilts sharply toward the inflation-linked bond. Second, in low-inflation and low-volatility regimes, a larger equity investment is optimal if the plan is not severely under-funded. Third, in high-volatility regimes the VaR bound activates quickly, triggering rapid de-risking. These findings demonstrate that a regime-aware, inflation-conscious LDI policy can systematically adapt to macroeconomic conditions and improve the stability of pension funding ratios.

3 - Measuring Ceo Real Options Mindset Using Textual Analysis: Corporate Policy Implications

Oupin Tang, Xi'an Jiaotong-Liverpool University, Suzhou, China, People's Republic of, Tarik Driouchi, Lenos Trigeorgis

This paper studies the decision making and corporate policy implications of CEO real options mindset (ROM) in a large dataset of US-listed firms. We elicit CEOs' degrees of real options reasoning from corporate earnings calls through three key behavioral real options attributes (analytical thinking, forward-looking long-term orientation, and adaptability) and develop a composite score for ROM at the firm level. We find that high ROM CEOs are more risk averse but more managerially able than low ROM counterparts. This in turn influences firm performance outcomes, financial policy, innovation, investment, and governance decisions. Firms with higher ROM scores hold more growth options and option-embedded intangible assets, have lower dividend payouts, show higher organizational flexibility and investment efficiency, display higher skewness in market returns, and have more diverse boards and lower CEO relative pay.

4 - Optimal Inventory Control Under Stochastic Price with a Sell-Back Option

Peter Berling, NTNU, Trondheim, Norway

Stochastic purchase prices are a reality in many industries, e.g. metal manufacturing. It has been shown that a price dependent order-up-to policy is optimal under these circumstances. However, if the material can be sold back at market price this policy must be complemented with a price and location dependent sell-down-to policy. In this work we show the structure of such a policy and the money left on the table if the purchasing decision is made without accounting for the possibility to sell-back the material at a future date based on the observed demand and price.

5 - Optimal Information Disclosure with Rationally Inattentive Receivers

Bernardo Quiroga, West Virginia University, Morgantown, WV, United States, Mauricio Sauma-Webb

A privately informed receiver is being persuaded by a sender to take a given course of action. After the persuasion stage, the receiver may decide how much information to purchase from a private information technology. With this information at hand, the receiver must then choose between following the sender's recommended action or not. In this context, we characterize the receiver's information acquisition strategy and the sender's disclosure policy. We show that when the receiver is rationally inattentive, the sender will completely crowd out information acquisition. However, information acquisition may arise in equilibrium when the receiver's information structure is restricted.

6 - Time Preferences are Not Income Dependent: Evidence from the Lab

Cathleen Johnson, West Virginia University, Morgantown, WV, United States, Antonello Maruotti, Bernardo Quiroga

Using data from a lab-in-the-field experiment with 881 participants across 13 Canadian cities and communities, we examine the relationship between income and willingness to delay financial gratification. Participants faced 40 opportunities to choose between immediate and delayed cash payoffs.

Our findings show that, aside from those in the top income decile (earning over \$100,000 in 2022 CAD), participants—regardless of income level, including those classified as very poor (earning less than \$15,340 in 2022 CAD)—displayed similar levels of patience.

Mathematical numeracy is a strong, consistent predictor of patience. However, the interaction between income and numeracy does not enhance predictive power. Additionally, individuals with higher debt levels tend to be less patient. Only the wealthiest participants demonstrated a significantly higher propensity to wait for larger, later rewards. Income level does not predict relative patient time preferences for the majority of the population.

1 - Bundling OR Discounting? Field Experiments for Healthy and Unhealthy Food

Nymisha Bandi, Stony Brook University, Stony Brook, NY, United States, Maxime Cohen, Saibal Ray

Retailers routinely face the strategic decision of how to promote their products. Two of the most common promotion strategies are bundling and discounting. Determining which strategy is more effective, and how their effectiveness varies across product categories, is an open question in the world of retail. To address this, we conducted a multi-store field experiment with a global convenience store chain that regularly uses bundle promotions (particularly for certain unhealthy snacks). Our study focused on healthy and unhealthy food categories to understand how these promotions influence consumer behavior and financial outcomes. Specifically, we tested these strategies--- discounts and bundles---applied to (i) healthy snacks, (ii) unhealthy snacks, and (iii) both categories simultaneously. For healthy snacks, we found that while discounting was more effective at boosting sales, bundling was more effective at increasing revenue and profit. Additionally, both promotion strategies for healthy snacks increased the sales of other unhealthy items, as consumers may engage in moral licensing, using their healthy purchases as justification to indulge in less healthy options. In contrast, neither promotional strategy had an effect on sales for unhealthy snacks. Based on this surprising finding, we convinced the retailer to conduct a follow-up experiment to investigate the impact of discontinuing a long-standing bundle promotion on unhealthy snacks. The results of this second experiment revealed no change in sales but an increase in revenue and profit, confirming our initial conclusion. These insights provide valuable guidance for retailers seeking to optimize promotion strategies for different product categories.

2 - The Value of Last-Mile Delivery in Online Retail

Zhikun Lu, NYU Shanghai, Shanghai, China, People's Republic of, Ruomeng Cui, Tianshu Sun, Lixia Wu

Last-mile delivery, the most expensive stage of the shipment process, has become increasingly important in online retail, raising the strategic question of whether firms should outsource it to customers via pickup stations or offer home delivery. In this paper, we examine the economic value of last-mile delivery to inform this high-stakes decision. Partnering with Cainiao, Alibaba's logistics subsidiary, we exploit a quasi-experiment where home delivery was sequentially rolled out to pickup stations in 2021. A staggered difference-in-differences design reveals that home delivery significantly increases sales and customer spending on Alibaba's retail platform. Because last-mile delivery is labor-intensive and capacity constrained, effectively allocating delivery resources is crucial. To address this challenge, we propose a novel operations-aware targeting framework that integrates causal machine learning with constrained optimization to identify and prioritize the most valuable customers. The framework incorporates both capacity and fairness constraints to maximize profits while maintaining equitable service access. We further extend it with routing optimization to enable value-aware delivery planning that accounts for both sales uplift and spatial efficiency. Our results demonstrate that targeting and routing policies informed by causal machine learning enables firms capture these gains more effectively. Taken together, the findings suggest that last-mile home delivery is not merely a cost center but also a revenue driver. Online retailers can unlock substantial value by adopting tailored logistics strategies that balance customer needs with resource constraints.

3 - A Structural Analysis of Freight Delays in the Indian Railway Network

Kashish Arora, CUHK Business School, Hong Kong, Hong Kong, Himanshu Arha, Milind Sohon, Milind Sohon, Raja Gopalakrishnan

Despite being cost-effective and sustainable, rail freight has been steadily losing market share globally, largely due to slow speeds. In Indian Railways, the world's fourth-largest network, average freight speed has stagnated at 25 kmph for decades, mainly because passenger trains are prioritized by section controllers operating under real-time constraints. This paper examines the causes of freight delays by modeling section controllers' stop-and-hold decisions using high-frequency network-level data.

We estimate a structural model of controller decision-making that accounts for spatial correlation in unobservables (via a copula-based approach) and corrects for endogeneity using a network-based instrumental variables strategy. The model quantifies key preferences—such as prioritizing passenger trains, queue spillovers, and strategic holds at large stations—and enables evaluation of policy interventions.

We simulate infrastructure-heavy and operational counterfactuals. A Freight-Only Corridor (FOC), modeled as a network without passenger traffic, reduces delays by 37% and increases speeds by 16%. Enhancing this with design features from India's planned Dedicated Freight Corridor further boosts benefits.

We also evaluate two low-cost operational policies: a 60-minute dispatch threshold reduces dwell times by 34% and increases speeds by 14%, while vertically stacking freight to consolidate 30% of capacity raises speeds by 8%. These approaches, while accounting for real-world constraints such as passenger interference and consolidation delays, deliver benefits comparable to FOCs at significantly lower cost.

Our findings offer actionable insights and a policy-relevant menu of infrastructure and operational strategies to improve freight movement.

4 - Why the Best Machine May Not be the Best: Incentivizing Human-Machine Collaboration

Anyan Qi, The University of Texas at Dallas, Richardson, TX, United States, Xiaotong Guan, Shouqiang Wang

As AI reshapes our world, robust human-machine collaboration is paramount to modernizing crucial operational decisions such as demand forecasts. In this paper, we study how the machine should be designed to incentivize human contributions. In our setting, a principal designs a forecasting algorithm by specifying its precision and delegates the final forecasting task to an agent. After receiving the machine's forecast, the agent decides whether to acquire an additional private signal before making the final forecast. We find that the principal may optimally reduce the machine's precision below its technological limit—even when enhancing such precision within that limit is costless. Essentially, the machine's precision not only serves a functional role but also acts as an incentive instrument to motivate the agent to gather additional information. Interestingly, the agent may over-acquire more information, resulting in possibly higher forecasting accuracy, than what would be optimal if the forecasting task were not delegated. On an optimistic note, we find that humans and machines are complementary: the better the information the agent can acquire, the more precise the machine should be.

1 - A Behavioral Model for Multi-Armed Bandits: Thompson Sampling Meets Quantal Choice

Yifan Feng, National University of Singapore, Singapore, Singapore, Jingying Ding, Ying Rong

How do people navigate the exploration-exploitation (EE) trade-off when making repeated choices with unknown rewards? We study this question through the lens of multi-armed bandit problems and introduce a novel behavioral model, *Quantal Choice with Adaptive Reduction of Exploration* (QCARE). It generalizes Thompson Sampling, allowing for a principled way to quantify the EE trade-off and reflect human decision-making patterns. The model adaptively reduces exploration as information accumulates, with the reduction rate serving as a parameter to quantify the EE trade-off dynamics. We theoretically analyze how varying reduction rates influence decision quality, shedding light on the effects of "over-exploration" and "under-exploration." Empirically, we validate QCARE through experiments collecting behavioral data from human participants. QCARE not only captures critical behavioral patterns in the EE trade-off but also outperforms alternative models in predictive power. Our analysis reveals a behavioral tendency toward over-exploration.

2 - Sequential Experimental Design for Contextual Linear Optimization: a Prediction-Uncertainty-Based Approach

Beichen Wan, University of North Carolina-Chapel Hill, Chapel Hill, NC, United States, Mo Liu, Paul Grigas, Zuo-Jun Shen

We study the problem of data collection for training decision-focused predictive models, allowing for a wide range of loss functions beyond the standard squared loss. In our setting, the learner can sequentially design experiments—selecting which samples to label—with the goal of building a well performing prediction model using as few labeled data points as possible. However, the complexity of general loss functions makes computing optimal query strategies challenging. To overcome this, we introduce a new algorithm that leverages local prediction uncertainty within a confidence set of candidate predictors. This approach enables efficient, tractable decision-making during the data acquisition process. We establish theoretical guarantees by deriving an upper bound on the label complexity of our method, showing its advantage over conventional supervised learning approaches in contextual stochastic linear optimization (CSLO) settings.

3 - Selective Randomization Inference for Adaptive Designs

Zijun Gao, University of Southern California, Los Angeles, CA, United States

Many clinical trials are structured with multiple stages, where data analysis is conducted after each stage to inform subsequent participant recruitment and treatment allocation. This adaptive approach allows for early elimination of ineffective treatments or targeted recruitment of subpopulations showing potential benefits. Analyzing such trials presents challenges as the data is utilized twice: first for selecting the design and null hypothesis, and then for testing the chosen hypothesis using the data generated under the selected design. Classical statistical methods are inadequate as they require pre-specified data generating mechanisms and null hypotheses. Existing solutions are often limited in scope, tailored to specific designs. In this work, we propose a general framework capable of handling diverse designs and adaptive choices. Our approach leverages post-selection inference principles to develop a selective randomization p-value. Notably, it does not necessitate assumptions about the distribution of outcomes or covariates, or the dependency structure among participants. We demonstrate that our method enhances statistical power compared to other valid tests while maintaining control over the selective type-I error in simulated data and hypothetical clinical trials.

4 - Distributional Robust Experiment Design

Guangyan Gan, Nanyang Technological University, Singapore, Singapore, Tu Ni, Zhenzhen Yan, Jinglong Zhao

Data-driven experiment design has attracted significant attention in recent years. In this paper, we introduce, for the first time, a distributionally robust framework for experimental design. We investigate the relationships between optimal decisions under the minimax, sample average approximation (SAA), and distributionally robust optimization (DRO) paradigms. Furthermore, we characterize the conditions under which the DRO framework outperforms SAA under both Bernoulli design and completely randomized design. The performance of our proposed methods is evaluated through extensive numerical experiments.

1 - The Optimal Smoothing of Sublinear Functions and Convex Cones**Thabo Samakhoana, Johns Hopkins University, Baltimore, MD, United States, Benjamin Grimmer**

A nonsmooth objective function can be optimized at an improved rate by optimizing its smooth approximation at an accelerated rate. Given that better smoothings lead to improved convergence guarantees, it is natural to seek the best possible smoothing. In this work, we provide a theoretical study of optimal smoothings of functions and sets. In particular, we completely characterize the set of optimal smoothings of sublinear functions and cones. As an application of our sublinear smoothings, we obtain well-motivated smoothings for nonsmooth composite functions. Similarly, our conic smoothings provide well-motivated smoothings for conic programming constraints.

2 - Inexact Moreau Envelope Lagrangian Method for Non-Convex Constrained Optimization Under Local Error Bound Conditions on Constraint Functions**Yankun Huang, Arizona State University, Tempe, AZ, United States, Qihang Lin, Yangyang Xu**

In this paper, we study the inexact Moreau envelope Lagrangian (iMELA) method for solving smooth non-convex optimization problems over a simple polytope with additional convex inequality constraints. By incorporating a proximal term into the traditional Lagrangian function, the iMELA method approximately solves a convex optimization subproblem over the polyhedral set at each main iteration. Under the assumption of a local error bound condition for subsets of the feasible set defined by subsets of the constraints, we establish that the iMELA method can find an ϵ -Karush-Kuhn-Tucker point with $\tilde{O}(\epsilon^{-2})$ gradient oracle complexity.

1 - Stimulating Feedback Contributions Using Digital Nudges: a Field Experiment in a Real-Time Mobile Feedback Platform**Xue Guo, Georgia State University, Atlanta, GA, United States, Michael Rivera, Guohou Shan, Liangfei Qiu**

Organizations increasingly recognize the value of real-time feedback for employee performance, yet motivating employees to provide sufficient high-quality feedback remains challenging. Our study explores digital nudges as tools to enhance employee participation in feedback applications. Leveraging Cognitive Load Theory and Job Characteristics Theory, we focus on two critical dimensions: timing of nudges (morning vs. afternoon) and task significance messaging. We propose that morning nudges lower cognitive load, facilitating better processing, while task significance messaging emphasizes the meaningfulness of feedback, increasing motivation. Through a field experiment within a real-time feedback application, we assessed how these dimensions influence feedback quantity and quality individually and interactively. Our findings reveal that task significance nudges significantly increase both feedback contributions and feedback quality compared to generic prompts. Further interaction analysis shows timing amplifies task significance effects by reducing cognitive load, allowing greater resource allocation for message processing. Notably, timing alone was influential only when paired with task significance messaging. Additionally, through a randomized online experiment, we investigated underlying cognitive mechanisms. Results indicate that optimal timing reduces intrinsic and germane cognitive loads, whereas task significance primarily elevates germane load and external motivation. Thus, while task significance predominantly motivates feedback contributions, timing significantly enhances this effect. This research provides theoretical insights into the cognitive and motivational processes involved in digital nudging. Practically, it guides organizations in designing more effective digital feedback interventions by strategically combining timing and task significance messaging.

2 - Prompting Entrepreneurship Evaluation: Exploring Anchoring Bias with LLMs**Lauren Rhue, University of Maryland, College Park, MD, United States, Jessica Clark**

Using an experiment, the study explores whether large language models (LLMs), like OpenAI's GPT-4o, exhibit cognitive biases when evaluating project descriptions on the crowdfunding platform Kickstarter. We analyzed over 8,000 Kickstarter projects and simulated decisions made by human backers, incorporating prompt engineering to test the consistency and fairness of AI-generated donation rationales and amounts. We explore whether LLMs are subject to the anchoring bias, similar to human subjects, and whether they are more likely to rely on human or machine anchors.

Results showed that the output varied with the prompt structure, even when based on identical project information. This finding highlights the importance of careful prompt engineering to ensure reliable AI-supported decision-making. The study's findings raise concerns about whether LLMs are susceptible to the same cognitive biases as people are. The broader goal is to understand LLM behavior in order to mitigate cognitive biases for subjective tasks.

3 - Designing Rigorous Experiments with Generative AI: Opportunities, Threats, and Best Practices**Weifeng Li, University of Georgia, Athens, GA, United States, Carolina Alves de Lima Salge**

Generative AI (GenAI) is transforming experimental research by enabling rapid, scalable, and adaptive workflows across all stages of the research process—from stimulus design and pilot testing to follow-up and analysis. This paper outlines how GenAI can be leveraged to improve efficiency and rigor while identifying emerging threats across Shadish et al.'s (2002) validity framework. I draw on recent applications in information systems and experimental economics to show how GenAI facilitates standardization, uniform treatment delivery, synthetic pretesting, and AI-assisted data analysis. However, I also identify risks such as construct ambiguity, instrumentation drift, and AI-induced bias, particularly when model behavior is uncontrolled or unvalidated. To navigate this evolving landscape, I develop a structured framework of threats and mitigation strategies, as well as eleven normative best practices. These practices span the full experimental lifecycle, including guidance on pre-registration, disclosure, output validation, and AI-human equivalence testing. I also highlight the importance of transparency, model documentation, and ethical safeguards to address privacy, autonomy, and reproducibility concerns. By synthesizing technical capabilities with methodological rigor, this work offers both a roadmap and a caution for researchers integrating GenAI into experimental design. The contribution is twofold: (1) a validity-based evaluation of GenAI's impact on experimental methods, and (2) actionable recommendations for responsibly deploying GenAI in complex, information-rich domains such as information systems research. This guidance is particularly relevant for scholars seeking to enhance scalability, reduce costs, and preserve causal inference while using GenAI-powered tools.

Resource Allocation and Defender-attacker Problems

Job Market Showcase

Job Market Showcase

Chair: Samuel Affar, University of Tennessee, Knoxville, Knoxville, TN, United States

1 - Trustworthy Algorithmic Solutions: from Fair Division to Federated Learning**Aniket Murhekar, University of Illinois, Urbana-Champaign, Urbana, IL, United States**

In today's world, algorithmic decision-making plays a crucial role in shaping social and industrial outcomes. A fundamental challenge, however, is ensuring that these algorithmic solutions are trustworthy – that is, fair to the participants, economically efficient, and aligned with their incentives. A wealth of remarkable works address such

challenges in various settings, though they are largely focused on the distribution of rivalrous goods.

In this talk, I will present my work on designing trustworthy algorithms and solution concepts for non-traditional and modern settings such as task allocation and data collaboration. For the fair allocation of tasks, I will discuss our recent breakthrough showing the first constant-factor approximation of EFX, a compelling fairness criterion whose existence remains one of the most important open problems in fair division.

I will then turn to collaborative settings involving data such as federated learning and data exchange. I will present solution concepts that incentivize participation, discourage free-riding, and ensure fairness and welfare guarantees in these settings.

I will conclude with interesting avenues for future work in trustworthy resource allocation and data economics.

2 - Allocation and Pricing in Modern Settings: Submodularity, Online Arrivals and Data Markets

Pooja Kulkarni, UIUC, Urbana, IL, United States

The problem of allocating limited resources among competing agents arises across a range of operational contexts: assigning compute nodes to jobs, distributing bandwidth across network flows, allocating ad slots to bidders, or distributing aid among individuals. A central challenge in these settings is *fairness*—a criterion critical for ensuring system stability, social equity, and long-term participation.

My work addresses fair allocation under two non-standard but increasingly relevant settings:

- **Beyond-Additive Valuations:** Traditional models assume additive utilities, but real-world preferences often exhibit diminishing returns—captured by *submodular* and more general valuation functions. I will discuss challenges and results on fairness objectives such as **Maximin Share (MMS)** and **Nash Social Welfare (NSW)** under these richer valuation models.
- **Online Arrivals:** In many real-world systems, agents arrive over time and allocation decisions must be made without full information. These problems are notoriously hard with no previous positive results. I will talk about our new learning-augmented model for fair allocation in such *online* settings. Our model provides strong theoretical guarantees while still being able to capture real-world settings.

Closely related to allocation is the problem of *pricing*. Classical equilibrium models rely on the balance of supply and demand—a paradigm that breaks down for *data*, a replicable and non-rivalrous resource. In the second part of my talk, I will discuss our new notion of equilibrium for data markets and present its existence and other desirable properties for valuations arising naturally from *vertically partitioned datasets*.

3 - A Successive Refinement Algorithm for Tri-Level Stochastic Defender-Attacker Problem with Decision-Dependent Probabilities

Samuel Affar, University of Tennessee, Knoxville, Knoxville, TN, United States

Tri-level defender-attacker game models are a well-studied method for determining how best to protect a system (e.g., a transportation network) from attacks. Existing models assume that defender and attacker actions have a perfect effect, i.e., system components hardened by a defender cannot be destroyed by the attacker, and attacked components always fail. Because of these assumptions, these models produce solutions in which defended components are never attacked, which may not be realistic in some contexts. This study considers an imperfect defender-attacker problem in which defender decisions (e.g., hardening) and attacker decisions (e.g., interdiction) have an imperfect effect such that the probability distribution of a component's capacity depends on the amount of defense and attack resources allocated to the component. Thus, this problem is a stochastic optimization problem with decision-dependent probabilities and is challenging to solve because the deterministic equivalent formulation has many high-degree multilinear terms. To address the challenges in solving this problem, we propose a successive refinement algorithm that dynamically refines the support of the random variables as needed, leveraging the fact that a less-refined support has fewer scenarios and multilinear terms and is, therefore, easier to solve. A comparison of the successive refinement algorithm versus the deterministic equivalent formulation on a tri-level stochastic maximum flow problem indicates that the proposed method solves many more problem instances and is up to 66 times faster. These results indicate that it is now possible to solve tri-level problems with imperfect hardening and attacks.

4 - Defensive Resource Allocation Versus a Realistic Attacker in a Multi-Layer Security Game

Ian Unson, University at Buffalo, Buffalo, NY, United States, Jun Zhuang

Understanding how adversaries make decisions is essential for enhancing security and protecting public spaces. This project develops new tools to help security professionals allocate resources more effectively, minimizing vulnerabilities at soft targets such as schools, public venues, and places of worship. By combining insights from human-subject experiments and surveys with advanced mathematical modeling, this research provides practical strategies for making better defensive decisions. Unlike traditional, theoretical approaches, which assume adversaries act purely rationally, this project incorporates data from human decision-making experiments and surveys to create more realistic and actionable models. The outcomes of this research extend beyond improving security as they also offer valuable insights into adversarial behavior that can inform fields like marketing and risk management. By advancing our understanding of decision-making and optimizing resource allocation, this project promotes national safety and prosperity. This project develops a novel framework for studying adversarial decision-making by combining game-theoretic modeling with data from human-subject experiments and surveys. The primary objective is to model an attacker's best response function based on actual decisions made in attacker-defender scenarios, rather than assuming purely rational and theoretical strategies. The research investigates key variables, reward, cost, and probability of success and their influence on adversarial behavior. Using this data, the project derives closed-form Nash equilibria to optimize defensive resource allocation strategies across multi-layered security systems. The results contribute to actionable resource allocation strategies while offering a scalable framework for analyzing adversarial behavior in diverse applications, including security and risk management.

1 - Mutual Information Surprise: Rethinking Unexpectedness in Autonomous Systems

Yinsong Wang, Georgia Institute of Technology, Atlanta, GA, United States

Recent breakthroughs in autonomous experimentation have demonstrated remarkable physical capabilities, yet their cognitive control remains limited—often relying on static heuristics or classical optimization. A core limitation is the absence of a principled mechanism to detect and adapt to the unexpectedness. While traditional surprise measures—such as Shannon or Bayesian Surprise—offer momentary detection of deviation, they fail to capture whether a system is truly learning and adapting. In this work, we introduce Mutual Information Surprise (MIS), a new framework that redefines surprise not as anomaly detection, but as a signal of epistemic growth. MIS quantifies the impact of new observations on mutual information, enabling autonomous systems to reflect on their learning progression. We develop a statistical test sequence to detect meaningful shifts in estimated mutual information and propose a mutual information surprise reaction policy (MISRP) that dynamically governs system behavior through sampling adjustment and process forking. Empirical evaluations—on both synthetic domains and a dynamic pollution map estimation task—show that MISRP-governed strategies significantly outperform classical surprise-based approaches in stability, responsiveness, and predictive accuracy. By shifting surprise from reactive to reflective, MIS offers a path toward more self-aware and adaptive autonomous systems.

2 - Time-Series Analytics for Smart Manufacturing Systems

Mojtaba Farahani, University of South Carolina, Columbia, SC, United States, Thorsten Wuest

We are witnessing a transformation in manufacturing industries driven by the integration of Industry 4.0 infrastructure and smart manufacturing systems. Leveraging technologies like Machine Learning (ML), Artificial Intelligence (AI), and Digital Twins (DT) by manufacturers on the shop floor and using data-driven decision-making, leads to unlock efficiency gains, quality improvements, and cost savings. This work focuses on time-series analytics within smart manufacturing systems, aiming to bridge the existing research gap between theoretical advancements in computer science literature and their practical application in manufacturing with Time-Series Classification, and Time-Series Forecasting identified as the primary tasks. The main objective is to develop a comprehensive framework that will help to bridge the identified research gap, provide practical guidance for practitioners, advance smart manufacturing systems, and promote promising Research Avenues. This framework aims to advance the maturity of time-series analytics in manufacturing, providing valuable guidance for researchers and practitioners.

3 - Integrating AI and Simulation for Intelligent Material Handling Using Autonomous Mobile Robots

Sripavathi Shaji Bhattathiri, Rochester Institute of Tech., Rochester, NY, United States

This research tackles challenges in integrating autonomous mobile robots (AMRs) into material handling by addressing two interconnected problems using AI-driven solutions: intelligent dispatching and seamless human-robot interaction (HRI). Motivated by the need for safe, efficient automation, the work addresses dynamic task allocation and non-verbal communication in shared spaces.

First, a reinforcement learning (RL) framework optimizes dynamic task assignments, outperforming rule-based methods (e.g., shortest distance) under moderate deadline tightness by balancing travel distance and due dates. It matches rule-based efficiency under tight deadlines, adapts to various warehouse layouts, and scales in simulated environments.

Second, for HRI, experiments show that unidirectional intent signaling (e.g., digital avatars) improve coordination, but seamless HRI often requires bidirectional communication. A deep learning-based gesture recognition system using RGB cameras achieves $\geq 99\%$ accuracy, enabling AMRs to interpret human gestures without verbal cues. The robustness of the model is tested by synthetically altering the background as well. A gesture language framework and machine learning pipeline together contribute to robot perception paving way further to intuitive collaboration.

Together, these contributions advance AMR deployment in real-world dynamic environments: RL enhances task efficiency, while vision-based gesture recognition ensures safety. Results demonstrate AI's potential to harmonize productivity and safety in industrial automation, offering scalable solutions that combine theoretical advances with practical needs. This work paves the way for smarter, collaborative robotic systems in dynamic intralogistics environments.

Advances in Healthcare and Energy

Job Market Showcase

Job Market Showcase

Chair: Jaachinma Okafor, University of Tennessee, Knoxville, TN, 37920, United States

Co-Chair: Yusi Wei, Drexel University, Philadelphia, PA, United States

1 - Modeling Shared Ownership to Reduce Cost Barriers for Distributed Storage

Ogechi Vivian Nwadiaru, University of Massachusetts, Amherst, MA, United States

Energy storage, especially distributed energy storage, can provide key operational flexibility services and support the participation of diverse actors particularly low-income consumers in the energy transition. However, incentivising the adoption of energy storage behind-the-meter remains an open challenge. Whilst distributed energy storage can help provide affordable, reliable electricity access to economically marginalized communities, investment in residential storage is only economically viable with value stacking. The challenge with value stacking lies in the complexity of monetizing multiple revenue streams, such as energy arbitrage, demand charge management, and grid services, which often requires access to market mechanisms, regulatory support, and technological expertise that marginalized communities may lack. In this work, we evaluate the potential of novel equity-driven energy storage ownership structures combined with time-based demand response incentives in increasing the benefits marginalized communities derive from the energy transition. We investigate the value of shared energy storage systems (SES) and quantify the monetary savings derived from various aggregation sizes under three distinct time of use structures.

2 - Trade-Offs Between Privacy and Utility in Machine Learning

Yusi Wei, Drexel University, Philadelphia, PA, United States

The secondary use of healthcare data is vital for research and clinical innovation, but it raises concerns about patient privacy. This study investigates how to balance privacy preservation and data utility in healthcare data sharing, considering the perspectives of both data providers and data users. Using a dataset of adult patients hospitalized between 2013 and 2015, we predict whether sepsis was present at admission or developed during the hospital stay. We identify subpopulations—such as older adults, frequently hospitalized patients, and racial minorities—that are especially vulnerable to privacy attacks due to their unique combinations of demographic and healthcare utilization attributes. These groups are also critical for machine learning (ML) model performance. We evaluate three anonymization methods—k-anonymity, the technique by Zheng et al., and our proposed model, the MO-OBAM—based on their ability to reduce re-identification risk while maintaining ML utility. Results show that k-anonymity offers limited protection. The methods of Zheng et al. and MO-OBAM provide stronger privacy safeguards, with MO-OBAM yielding the best utility outcomes: only a 2% change in precision and recall compared to the original dataset. This work provides actionable insights for healthcare organizations on how to share data responsibly. It highlights the need for anonymization methods that protect vulnerable populations without sacrificing the performance of data-driven models.

3 - Sustainable Operations - Sustainable Supply Chains & Energy Servicing

Jaachinma Okafor, University of Tennessee, Knoxville, TN, United States

his talk presents two research streams that address key challenges in sustainable operations: expanding renewable energy access and reducing supply chain emissions.

The first study explores a *servicizing* model to improve residential energy access in developing countries. This model involves a firm installing and maintaining a solar array-battery system in households in exchange for usage-based payments. This removes upfront cost barriers and shifts ownership and maintenance responsibilities to the provider. We develop an analytical model to determine the optimal pricing, solar capacity, and battery size, incorporating cost, demand variability, and adoption dynamics. A numerical study using solar and demand data from Nigerian households validates the model and highlights the profitability and reliability of shared systems, especially in areas reliant on gasoline generators.

The second study examines how buyers can incentivize suppliers to voluntarily reduce greenhouse gas (GHG) emissions. Using a game-theoretic model and a behavioral experiment, We compare two mechanisms: a fixed bonus and a wholesale price premium. While the analytical model favors the price premium, the experiment reveals that a fixed bonus more effectively motivates emission reductions, emphasizing the role of behavioral factors in supply chain contracting.

Together, these studies offer practical insights for designing sustainable business models and incentive mechanisms that advance environmental and social goals across energy systems and supply chains.

Novel Problems in Estimation

Job Market Showcase

Job Market Showcase

Chair: Danielle Morey, University of Washington, Seattle, WA, United States

1 - Design-Based Weighted Regression Estimators for Conditional Spillover Effects**Fei Fang, Yale University, New Haven, CT, United States**, Edoardo Airoldi, Laura Forastiere

In a clustered interference setting, with networks collected within clusters and no interference between clusters, we introduce a general causal estimand for conditional spillover effects, offering flexible ways of integrating unit-to-unit spillover effects. In particular, we define spillover effects from the treatment received by one neighbor, averaged over the distribution of the cluster treatment, and conditional on the characteristics of the treated unit. Such definition enables to access the heterogeneity of a unit's spillover effect on their neighbors with respect to the unit's characteristics. Two weighted regression-based estimators are proposed: i) at the individual level, taking neighbors' averages either in the outcomes or in the treatments within weights; and ii) at the dyadic level, where the outcome of one unit is regressed on the treatment of each neighbor. When covariates driving the heterogeneity are categorical, we prove the equivalence of the two regression-based estimators to the non-parametric Hajek estimator. For continuous covariates, we demonstrate that both estimators consistently estimate the proposed estimands. Under a design-based perspective, we derive HAC variance estimators and establish the central limit theorem. Simulations are conducted to compare the performance of our estimators. Finally, we apply our methods to a randomized experiment conducted in Honduras to evaluate the spillover effect of a behavioral intervention.

2 - Degradation Signal Missing Data Imputation via Transformers**Madi Arabi, North Carolina State University, Raleigh, NC, United States**, Xiaolei Fang

Accurate prognostics for industrial assets rely heavily on the quality and completeness of degradation signals, yet real-world scenarios often suffer from sparse, fragmented, or missing condition-monitoring data due to sensor failures, cost constraints, or invasive measurement procedures. To address this challenge, we investigate transformer-based imputation techniques for multivariate degradation signals with the goal of improving time-to-failure (TTF) prediction. While traditional methods such as statistical approaches and matrix factorization often disregard temporal dependencies, transformer architectures are well-suited for capturing long-range relationships in sequential data through self-attention. We benchmark the performance of standard transformers and convolution-enhanced transformers for imputing missing values and predicting TTF, under varying degrees of signal sparsity. Our results highlight the strengths and limitations of each model, and ongoing work focuses on architectural modifications to optimize imputation quality for downstream prognostic tasks.

3 - Computationally Efficient Reductions Between Some Statistical Models**Mengqi Lou, Georgia Institute of Technology, Atlanta, GA, United States**, Guy Bresler, Ashwin Pananjady

We study the problem of approximately transforming a sample from a source statistical model to a sample from a target statistical model without knowing the parameters of the source model, and construct several computationally efficient such reductions between canonical statistical experiments. In particular, we provide computationally efficient procedures that approximately reduce uniform, Erlang, and Laplace location models to general target families. We illustrate our methodology by establishing nonasymptotic reductions between some canonical high-dimensional problems, spanning mixtures of experts, phase retrieval, and signal denoising. Notably, the reductions are structure-preserving and can accommodate missing data. We also point to a possible application in transforming one differentially private mechanism to another.

4 - Optimal Design in the Absence of Ground Truth: a Multi-Model Consistency Approach**Danielle Morey, University of Washington, Seattle, WA, United States**

There exist many real-world complex systems that can be represented via multiple models, but where no known ground truth exists. Traditional methods of multi-fidelity modeling and optimization often fall short in such cases. Motivated by applications in underwater communication networks and biomanufacturing, I propose a weighted comparison methodology that leverages consistency between models to optimize systems without relying on ground truth.

Drone-Assisted Delivery and Logistics Optimization

Contributed Session

Contributed

Chair: Bibek Yadav, Florida A & M university, 1001 Ocala Road, D328, Tallahassee, FL, 32304, United States

1 - The Drone Routing Problem with Mixed Fleet of Electric and Conventional Trucks**Cagri Koc, Hacettepe University, Ankara, Turkey**, Gulcin Bektur, Cihan Tugrul Cicek

We introduce a variant of the drone routing problem with a mixed fleet by considering both internal combustion and electric trucks. In the problem, both truck types are equipped with a single drone. A drone may either depart from the starting depot along with its vehicle or directly from the starting depot to serve a relevant customer. Customers must receive service either from a drone or a truck. However, due to the drone's limited carrying capacity, some customers may not be eligible for drone service. The drone can be launched either directly from the starting depot or from a node along the truck's route to serve a relevant customer. After serving a customer, the drone returns either directly to the ending depot or to the truck at a node along the vehicle's route. Once the truck picks up the drone at the meeting point, it can continue its route from the corresponding node. The objective is to minimize the maximum tour completion time. We formulate the problem as a mixed-integer linear programming model and introduce valid inequalities to strengthen the formulation. We develop a metaheuristic to effectively solve the problem. We conduct extensive computational experiments on a set of generated instances, based on several data sets from the literature, to provide insights into the problem's characteristics. Our metaheuristic proves to be highly effective in solving the problem for large-scale instances.

2 - Drone-Truck Arc Routing Problems**Sung Hoon Chung, Binghamton University, Binghamton, NY, United States**, saif al-nimer

We address a Drone-Truck Arc Routing Problem (DT-ARP), for which a clustering algorithm is proposed to improve computational efficiency. This problem extends the rural postman problem by incorporating an aerial vehicle (drone) in addition to the ground vehicle. We also investigate the optimal combination of drone launch and recovery nodes to minimize the makespan. Numerical examples are provided to demonstrate the effectiveness of the proposed model and heuristic for the DT-ARP.

3 - Drone Scheduling and Mobile Pantry Placement for Enhanced Campus Food Distribution**Tamanna Kamal, North Carolina State University, Raleigh, NC, United States**, Ameya Abhay Mulay, Syed Md Kashan Naiyer, Leila Hajibabai

Ensuring equitable food access on university campuses presents a growing logistical challenge, especially with the rising rates of food insecurity. Traditional fixed-location food distribution systems often fall short in meeting the spatially and temporally dynamic needs of campus communities. This study proposes a data-driven decision support framework that integrates a maximal covering location model with an approximate dynamic programming (ADP) algorithm to address these challenges. The framework optimizes mobile pantry placement and schedules real-time drone deliveries across campus. The location model determines optimal pantry sites using ZIP-

code-level food insecurity data to maximize geographic coverage and support distributional equity. The ADP algorithm dynamically coordinates drone routing and pantry pickups by incorporating practical constraints such as limited drone capacity, time windows, and urban mobility barriers. The model is informed by real-world inventory and demographic data from Feed the Pack, the food pantry at North Carolina State University. Preliminary results show that the integrated approach reduces unmet demand and improves operational responsiveness compared to static delivery strategies. Sensitivity analysis reveals key trade-offs between equity and efficiency, providing decision-makers with actionable insights for resource allocation and logistical planning. This work contributes an adaptive framework for campus food distribution that aligns operational efficiency with humanitarian objectives. The methods are generalizable to other institutional or urban contexts where mobility and equity are central concerns.

Keywords—Approximate dynamic programming, drone delivery, mobile pantry, food insecurity, humanitarian logistics, decision support.

Air Transportation Section

Co-Chair: Garrett Schueller, University of Texas at Austin, 3001 Cedar st, Austin, TX, 78705, United States

1 - Optimizing Multi-Team Agricultural Drone Deployment and Routing with Weather Aware Planning

Ethan Kolby, University of Michigan, Ann Arbor, MI, United States

Optimizing agricultural drone operations requires addressing unique complexities posed by dynamic weather conditions, particularly in multi-team deployments. Recent research on facility location problems (FLP), vehicle routing problems (VRP), and coverage VRP tailored to agricultural applications emphasizes how weather considerations impact drone utilization strategies. Key areas explored include wide-region survey drone deployments, where real-time weather dynamics, such as wind and precipitation, may temporarily restrict or diminish flight efficiency. Integrating weather-aware routing strategies enhances mission adaptability and robustness. Additionally, crop spraying operations illustrate how predictive weather modeling influences route selection and adjustments. Incorporating weather forecasts into optimization models has the potential to improve spray coverage efficacy. The importance of weather-informed optimization strategies in agricultural drone logistics is highlighted throughout.

2 - Last-Mile Delivery Optimization of Combining Public Transport and Drone Systems

Bipan Zou, Zhongnan University of Economics and Law, Wuhan, China, People's Republic of, Rui Zhang, Jiliu Li, Yuanqian Shi

This paper considers an innovative last-mile delivery system that combines public transport with drones. We study the problem of delivering a given set of parcels from warehouses to customers using the drones, in collaboration with several bus lines, with the objective of minimizing the sum of the completion time of all orders. We first formulate this problem in a decomposition framework with the master problem determines a schedule for each drone that consists of the routing and bus taking decisions, and the subproblem aims at identifying promising schedules to be added into the master problem. We design a state function driven branch-and-price-and-cut (BPC) algorithm that uses a novel dynamic programming (DP) approach to find the promising schedules. A dominance rule and three strategies are developed to speed up the DP those bring substantial improvements. We apply a variable fixing technique to eliminate unpromising schedules in advance and design a heuristic to help solving the pricing subproblem. Using both a random instance and a real dataset, we verify the efficiency of our algorithm by comparing with commercial solvers. Numerical results show that the drone service area can be significantly expanded, especially when the drone battery capacity is medium. Besides, introducing public buses can promote the sharing of drones among warehouses, that reduces the total delivery time by up to 15%. Finally, we analyze several select mechanisms of bus lines and show the potential benefits of slightly adjusting bus lines for warehouse proximity alignment.

3 - Performance Estimation of Aircraft Computer Vision Models Using Optimal Transport-Based Distributional Mismatch

Binshuai Wang, The George Washington University, Washington, DC, United States, Peng Wei

Ensuring the reliable deployment of deep learning models in real-world environments remains a fundamental challenge, particularly in safety-critical applications such as autonomous unmanned aerial system (UAS) landings. This paper investigates the relationship between model performance and distributional mismatch between training data and operational design domain (ODD) samples. We propose a framework that quantifies this mismatch using Wasserstein distances derived from optimal transport theory, applied to both raw image data and semantic embeddings from a pretrained CLIP (ViT-B/32) model. To address the scarcity of real ODD data collected by flight tests, we additionally leverage diffusion models to generate additional ODD scenarios, and evaluate their quality using Fréchet Inception Distance (FID) score. Experimental results demonstrate a strong correlation between the magnitude of distributional mismatch and model performance degradation. Moreover, our results demonstrate that models trained on datasets with lower distributional mismatch to the ODD domain, such as VisDrone, compared to COCO, achieve superior detection performance. These findings highlight the effectiveness of our framework as a practical and generalizable tool for estimating model reliability in complex real-world deployment scenarios, when trained on different training datasets.

4 - Flying Against the Wind: Smart Uav Stationing for Faster Disaster Relief

Sina Kazemdehbashi, Wayne State University, Detroit, MI, United States, Yanchao Liu, Boris Mordukhovich

Natural and human-made disasters can cause severe devastation and loss of life. In such situations, rapid collection of information about affected areas, damages, and victims is critical. However, in many disasters—such as earthquakes—communication infrastructure is often destroyed, limiting victims' ability to send distress signals and hampering rescue efforts.

Unmanned Aerial Vehicles (UAVs) can assist by collecting data and establishing temporary communication networks. However, real-world deployment is challenged by factors such as wind and heterogeneous UAV dynamics. To address this, we extend classical single-facility location problems by incorporating heterogeneous dynamic sets that represent varying UAV speeds. We generalize the Fermat-Torricelli and Sylvester problems to introduce the Sylvester-Fermat-Torricelli (SFT) problem, which captures complex factors such as wind influence, UAV heterogeneity, and back-and-forth motion within a unified framework. The SFT problem exhibits intrinsic nonsmoothness due to the min-max nature of its objective function. To overcome the resulting analytical complexities, we employ tools from convex analysis.

Experiments show that our approach can reduce operation time by up to 55%, improving the efficiency of UAV-based disaster response missions.

5 - Probabilistic Modeling of Lunar Terrain for Uncertainty-Aware Global Path Planning via Stochastic Programming

Garrett Schueller, University of Texas at Austin, Austin, TX, United States, John-Paul Clarke, Alessandro Pinto

Accurate global path planning is essential for the success of lunar rover missions, yet current methods are fundamentally constrained by uncertainty in orbital imagery. Remote sensing offers only partial, low-resolution views of the surface, rendering deterministic plans brittle in the face of unexpected hazards. To address this, we present a framework that integrates computer vision and stochastic programming to enable robust, uncertainty-aware path planning. A convolutional neural network is trained to predict traversability distributions from LROC imagery, generating probabilistic cost maps that model terrain risk. The model demonstrates strong performance across standard evaluation metrics. To improve realism, spatial correlations are incorporated into the map sampling process, yielding coherent terrain realizations. These samples serve as inputs to a two-stage stochastic branch-and-bound algorithm, which selects global paths that balance expected performance with downside risk. This framework offers a scalable and extensible solution for risk-aware autonomy, demonstrated on a lunar test case and applicable to long-range exploration of other planetary surfaces.

Optimizing Product Supply Reliability With Advanced Risk Models

Invited Session

The Practice Section of Informs

Co-Chair: Hanzhang Liu, Johnson & Johnson, Denville, NJ, United States

1 - Enhancing Supply Chain Resilience and Agility Through Advanced Planning Parameter Optimization

Nasim Arbabzadeh, Johnson & Johnson, Bellevue, WA, United States, VISHAL VARMA

The reliability provided by healthcare supply chains to their patients and customers is strongly contingent upon a reliable flow of input raw materials from their diverse supplier base. Any delays in receipt of critical raw materials can pose serious risks to an otherwise smoothly running supply chain. Predicting delays or volatility in raw material supply lead times is therefore an important component of managing today's highly inter-twined healthcare supply chains. This work presents an advanced time series-based modeling framework to predict supplier lead times, the applications of those lead times into various business workflows such as right-sizing inventories and raising critical supply alerts to material resource planners. We provide examples of specially designed hierarchical time series models, inspired by proportional-integral-derivative (PID) control principles, which can handle predictions at different levels of the material and supplier hierarchy and how we track their performance using multiple error metrics. Following successful pilot results, the solution is scalable for deployment across multiple global manufacturing sites and SAP platforms. Performance tracking using multiple error metrics shows how such models can be deployed at large scales and drive substantial improvements in supply reliability, resilience and operational efficiency.

2 - Designing Resilient Networks for Cellular Therapies with Mathematical Programming Based Heuristics

Aric Johnson, Johnson & Johnson, Raritan, NJ, United States

Advanced cellular therapies are increasingly offering the "new frontier" against several high mortality illnesses such as cancer. Delivery of these therapies at scale requires the underlying therapy supply chains to control cell processing lead times within tight limits. This in turn requires the availability of all supporting raw materials while ensuring adequate availability of cell/raw material production capacities, timeliness of raw material procurements and production runs, and minimal wastage of materials related to obsolescence. These are complex objectives to meet especially in a highly dynamic environment of rapidly growing demand for such therapies. In this talk we describe mathematical programming based heuristics designed for supporting advanced cell therapy supply chains and their implementations using latest sematic layer technologies.

3 - Optimizing Supplier Selection under Tiered Pricing and Resilience Constraints

Brijesh Jakhania, Johnson & Johnson, Allentown, PA, United States

Organizations that procure critical materials face a recurring trade-off between minimizing cost and maintaining resilience. Supplier quotes are commonly tiered—unit prices decline only after specific volume thresholds—while policies often mandate multiple suppliers or minimum/maximum share limits. These interacting rules, combined with shifting demand and evolving quotes, make manual allocation error-prone and expensive. This work presents a year-by-year mixed-integer optimization framework that selects suppliers, activates exactly one price tier per chosen supplier, and allocates volumes to meet requirements at the lowest total cost subject to resilience and share constraints. The approach uses tidy, auditable inputs (requirements by year, supplier tier tables, policy rules) and produces transparent outputs (selected suppliers, active tiers, volumes, and total cost) that can be reviewed by finance and procurement and rerun quickly as conditions change. We illustrate typical recommendation patterns—concentration on cost-effective tiers with measured diversification when policies require it—and quantify the incremental “price of resilience.” The framework is practical to implement, fast to execute, and straightforward to govern, enabling organizations to capture tier-based savings, make informed trade-offs, and institutionalize repeatable, defensible sourcing decisions.

4 - A Decomposition-Based Heuristic for Optimizing Inventories in A Multi-Echelon Inventory System

Sharmine Akther Liza, Lehigh University, Bethlehem, PA, United States, Lawrence Snyder

This study proposes a decomposition-based heuristic for determining order-up-to level at each stage within a general multi-echelon system, accounting for stochastic lead times resulting from random stock-outs throughout the system. In a multi-echelon inventory system, upstream stages (nodes) are responsible for supplying items to downstream stages, fulfilling their demands whenever sufficient inventory is available. Each downstream stage manages its own inventory while determining order quantities based on the inventory levels of the upstream stage. This interdependency emphasizes a critical relationship—shortages at the upstream stages can significantly impact the ordering decisions of downstream stages. This study explores both the theoretical and numerical aspects of how order quantities at downstream stages are influenced by upstream inventory levels and how these decisions evolve over a given time horizon. This understanding will provide an essential building block for developing the proposed heuristic.

AI, Data Science, and Optimization in Media: Methods and Applications

Invited Session

Practice Track

Chair: Xin Ma, Monks, Atlanta, GA, United States

1 - Reimagining Media Decisions: How AI and ML are Transforming Media Planning and Optimization

Xin Ma, Monks, Atlanta, GA, United States

AI and ML are revolutionizing media planning, testing, and optimization by delivering actionable insights, enhancing targeting precision, and boosting campaign performance. This ultimately enables advertisers and brands to achieve higher ROI and more effective advertising strategies. In media planning, we train models using historical media and performance data to understand how media investments influence business outcomes. By factoring in elements like channel interactions, adstock, and saturation effects, we can generate investment scenarios and optimize budget allocations and fighting across channels and tactics. In the realm of testing, we offer a data-driven geo-experimentation tool that enables clients to design and evaluate incrementality effectively. By leveraging first-party data, demographic, and socioeconomic data, and applying advanced AI and ML algorithms, the tool identifies key performance drivers. It then crafts well-balanced test/control splits and provides recommendations on budget and test windows to achieve statistical significance, tailored to the specific testing needs.

2 - Precision Planning: A Simulation Tool for Addressable TV Impact and Reach

Wes Chaar, Avant-Garde Strategy, Dallas, TX, United States

In an era of precision marketing and evolving viewer behaviors, Addressable TV offers a powerful alternative to traditional broadcast planning - but demonstrating its value at the planning stage remains a challenge. This session will introduce a next-generation simulation tool designed to model the reach and performance of Addressable TV campaigns under a wide range of “what-if” scenarios. Attendees will explore how the tool empowers advertisers, agencies, and media strategists to forecast audience reach, assess incremental value, and optimize campaign design based on key variables such as spend, targeting, and media mix. With features like dynamic scenario comparisons, saturation diagnostics, and budget-efficiency projections, the tool transforms complex planning into clear, data-driven decisions. This session will show how scenario simulation can accelerate Addressable TV adoption by delivering transparency, flexibility, and actionable insight at the moment decisions are made.

3 - AI Applications in Media Measurements: Audience, Content, and Revenue Optimization

Hanxi Bao, NBCUniversal, New York, NY, United States

The media and advertising industry is undergoing a fundamental transformation driven by AI technologies. This presentation explores a few examples on leveraging innovations to address critical challenges in audiences testing, content recognition, and revenue allocations.

With the help of LLM and cloud data platforms, audience profiling and segmentation can be performed using a mix of 1st party and 3rd party data. Machine learning algorithms analyze large datasets to identify audience patterns, predict future behavior, and create unified audience profiles for media planners. This enables highly targeted content strategies and personalized user experiences that drive higher engagements and better impacts.

AI can also help on upper funnel media measurements through reach and frequency measurements and optimizations. AI tools can be implemented in the workflow of audience deduplication process to help eliminating impression wastes and maximizing unique reach across different platforms.

AI-assisted A/B Testing moves beyond traditional experimentation by using machine learning to automatically generate test hypotheses, conduct dynamic multivariate testing, and provide predictive optimization. This enables publishers to optimize content performance faster and more effectively than manual testing approaches.

Implementation requires a phased approach from data engineering, modeling developments and deployments, to the result summary and product managements. This presentation summarizes the examples of AI-driven advanced analytics from a publisher perspective and suggest guidelines in media measurements.

Optimization Techniques for Contested Logistics

Invited Session

Military and Security

Chair: Robert Curry, University of Arkansas, Fayetteville, AR, United States

1 - Optimizing Unmanned Resupply to Marine Littoral Regiments

Gary Lazzaro, United States Naval Academy, Annapolis, MD, United States

The future of warfare in the littoral regions of the world presents a unique challenge of delivering supplies to forward deployed forces in contested areas. Unmanned Surface Vehicles (USVs) offer a contemporary approach to resupplying Marine Littoral Regiments (MLR) with the materials needed for sustained operations within the enemy's weapons engagement zone. We present an unclassified scenario where MLRs require resupply in an archipelago island chain that is defended by a number of enemy patrol craft. We utilize search and detection theory to create a user-friendly Excel interface. This tool provides warfare commanders with information regarding the probability of detection for a library of friendly USVs. It also analyzes specifications of friendly USV options to best evade enemy USV barrier patrols for different battlespace scenarios. It aids in deciding how to best employ the chosen friendly USVs to effectively resupply. We also present an integer program that chooses an optimal combination of friendly USVs to maximize survivability of craft while minimizing the cost of lost USVs. Our work enables future teams to use our tool in a classified environment for real-world scenarios.

2 - Tri-Level Optimization for Building Supply Chain Resilience with Safety Stock Against a Worst-Case Disruption

Dan Kosmas, University of Massachusetts Lowell, Lowell, MA, United States, Carson Grose, Ozlem Ergun

Engineering resilient supply chains is crucial to ensuring critical commodities such as fuel, pharmaceuticals, and emergency response supplies are available when needed. A resilient supply chain should function even in the event of a disruption, which can come in the form of natural disasters, equipment failures, or attacks by nefarious actors. One way to build resilience in a supply chain is through the pre-allocation of inventory, or safety stock to carefully chosen locations in the distribution network. We develop a tri-level minimum cost flow interdiction model to improve the resiliency of a distribution network by optimally pre-allocating safety stock while accounting for disruptions. We numerically demonstrate how different measures of supply chain resiliency – such as safety stock allocation, arc density, and production capacity – impact the total costs of operating the distribution network and the network service level.

3 - Optimizing Escort Strategies for Chokepoint and Littoral Maritime Lanes Using Mixed-Integer Programming

Shantonu Mitra, University of Arkansas, Fayetteville, AR, United States, Robert Curry, Kelly Sullivan

Over the years, the variety and sophistication of attacks on merchant ships in the littoral & chokepoint sea lanes – such as attacks using the explosive unmanned surface vessels (USVs), unmanned aerial vehicles (UAVs), modern anti-ship ballistic and cruise missiles have increased. So, the aim of this research is to allocate limited military resources to protect maritime shipping vessels such as oil tankers or aircraft carriers that need to traverse a shipping lane. To solve this problem, we have used the two-stage stochastic mixed-integer programming (MIP) approach where the first stage involves decisions such as assigning escort ships & allocating weapons and the second stage focuses on threat engagement & threat neutralization. The results suggest that the expected survival value of the vessels get decreased when the available weapon units of the escort ships aren't capable enough of neutralizing the threats as well as the late engagement of the threats by the escorts. The proposed model balances between the resource allocation versus threat neutralization and multi-scenario robustness versus resource consumption.

4 - Military Logistics Planning for Expeditionary Warfare

Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA, United States, Matthew Ford, Samuel Tan, Haden Boone, Peter Frazier, Yongjia Song, Huseyin Topaloglu

We consider the problem of designing military logistics operations in a contested environment. The objective is to route connectors to transport critical supplies (e.g., fuel, ammunition) from their stocking locations to demand locations by fixed deadlines set by a fire plan. We formulate this problem as a variant of the scheduled service network design problem developed for commercial logistics service providers. In our model, commodities may be sourced from various locations, and are transported by sea and air connectors with heterogeneous speeds and capacities. The resulting mixed-integer program determines a consolidation plan, i.e., paths for connectors and commodities on a time-space network, to minimize the delay in satisfying demands. To obtain good quality solutions, we design heuristics that exploit the problem's characteristics. We demonstrate our methodology on realistic training instances developed by the United States Marine Corps and provide military planners with insights regarding the design of logistics operations in contested environments.

Theoretical Frontiers in Causal Estimation

Invited Session

Applied Probability Society

Chair: Vasilis Syrgkanis, TBA, TBA, CA, United States

Co-Chair: Jikai Jin, Stanford University, Stanford, CA, United States

Co-Chair: Jiyan Tan

1 - Synthetic Survival Control

Devavrat Shah, Massachusetts Institute of Technology, Cambridge, MA, United States, Xinyi Han

In this talk, we shall present a natural generalization of causal inference method, synthetic control, with roots in traditional panel data to enable evaluation of counterfactual outcome where outcome corresponds to survival function.

2 - Stable Causal Estimation with Transport Maps

Yixin Wang, University of Michigan, Ann Arbor, MI, United States

This work proposes a causal estimation algorithm for observational studies using Optimal Transport (OT) maps. Traditional importance weighting based estimator often suffer from high estimation variance, especially when strong overlap is lacking, e.g. with high-dimensional covariates or small sample sizes. In contrast, OT maps offer a more stable approach to addressing distribution shift. To this end, we introduce an OT-based algorithm to estimate average treatment effects. To handle partially overlapping support, we further extend the algorithm using linear interpolation maps. Additionally, we develop a distributional sensitivity analysis framework using Wasserstein Distributionally Robust Optimization (WDRO). This approach relaxes the conditional exchangeability assumption and provides partial identification bounds for the causal estimand.

This is joint work with Yidan Xu and Long Nguyen.

3 - Consistency of Neural Causal Partial Identification

Jiyuan Tan, Stanford University, Stanford, CA, United States

Recent progress in Neural Causal Models (NCMs) showcased how identification and partial identification of causal effects can be automatically carried out via training of neural generative models that respect the constraints encoded in a given causal graph [Xia et al, Balazadeh et al]. However, formal consistency of these methods has only been proven for the case of discrete variables or only for linear causal models. In this work, we prove the consistency of partial identification via NCMs in a general setting with both continuous and categorical variables. Further, our results highlight the impact of the design of the underlying neural network architecture in terms of depth and connectivity as well as the importance of applying Lipschitz regularization in the training phase. In particular, we provide a counterexample showing that without Lipschitz regularization this method may not be asymptotically consistent. Our results are enabled by new results on the approximability of Structural Causal Models (SCMs) via neural generative models, together with an analysis of the sample complexity of the resulting architectures and how that translates into an error in the constrained optimization problem that defines the partial identification bounds.

4 - Structure-Agnostic Optimality of Doubly Robust Learning

Jikai Jin, Stanford University, Stanford, CA, United States, Vasilis Syrgkanis

The design of efficient non-parametric estimators has long been a central problem in statistics. However, optimal estimators designed under assumed structural properties crucially rely on the validity of these assumptions, so that they are often cumbersome to deploy in practice. In this paper, we consider non-parametric estimation problems for which the parameter of interest depends on an unknown nuisance function.

Motivated by the wide adoption of non-parametric adaptive estimators, we consider a structure-agnostic framework, where one does not impose structural assumptions on the model and only assumes access to black-box nuisance estimates. Within this framework, we first prove the minimax optimality of doubly robust learning for estimating the average treatment effect, arguably one of the central parameters of interest in the causal inference literature. We then generalize this result by establishing the optimality of the popular first-order debiasing estimators under general conditions that are satisfied by a broad range of parameter estimation problems. Notably, we differentiate between two regimes in which double robustness can and cannot be achieved and in which first-order debiasing yields different error rates. Our result implies that first-order debiasing is simultaneously optimal in both regimes. We instantiate our lower bound by deriving optimal error rates that recover existing results, as well as for new parameters that are of interest in the literature, including the weighted average derivative, average policy effect, counterfactual effect of distribution shift and the expected derivative of conditional quantile.

5 - Regression Adjustments for Experimental Designs in Two-Sided Marketplaces

Timothy Sudijono, Stanford University, Stanford, CA, United States

Multiple randomization designs (MRDs) are a class of experimental designs used to handle interference in two-sided marketplaces. We investigate regression adjustment strategies for estimating total, spillover, and direct effects in MRDs. We derive minimum asymptotic variance estimators among a broad class of linearly adjusted estimators. Surprisingly, the optimal regression adjustments are estimable from data and are generally different from regression adjustments in classical randomized experiments. For example, one such optimal estimator for the direct effect corresponds to a weighted regression with interacted two-way fixed effects. We establish model-robustness properties, central limit theorems, and inferential methods for our estimators; we also contribute to the theory of MRD experiments. These results provide the analog of the CUPED regression adjustment for marketplace experiments. Numerical simulations demonstrate a considerable increase in efficiency over simpler approaches, enabling better inference when running MRDs.

Transportation Network Optimization

Invited Session

Railway Applications

Chair: Krishna Jha, Optym, Coppell, TX, 75019, United States

1 - Train Movement Optimization

Krishna Jha, Optym, Coppell, TX, United States, Wei Huang, Sajeeb Kumar Kirtonia

Optimizing train movements is a complex decision problem due to physical movement constraints, cascading decision impacts, and conflicting operational objectives. We have developed a solution approach that leverages advanced optimization and machine learning techniques to address this problem effectively. Our approach is scalable for large railroad networks and has been applied across multiple use cases, including improvements in service quality, network throughput, and maintenance planning. In this talk, we will present the methodology and share numerical results that demonstrate its effectiveness.

2 - Rail-Centric Multi-Objective Network Optimization for Sustainable Logistics of Mineral Tailings in Construction Supply Chains

Claudio Cunha, University of Sao Paulo, Sao Paulo, Brazil

This study addresses the challenge of designing a sustainable logistics network for the large-scale distribution of iron ore tailings, as by-product of mining operations in Brazil. When stored in dams, these tailings pose serious environmental risks—but they also offer a valuable opportunity for reuse as substitutes for raw materials in civil construction. However, their economic viability is strongly dependent on an optimized logistics system due to their low commercial value and the extensive distances to potential markets. To address this, we develop a rail-centric, multi-objective linear optimization model that integrates economic, environmental, and social factors. The model allowed us to determine optimal multimodal flows—primarily via rail but including road and waterway segments—linking a single origin to over 100 mesoregions through a capacity-constrained hub network. Objectives include maximizing total profit, minimizing negative socio-environmental impacts and maximizing positive externalities (e.g., job creation, GDP contribution). Using a constraint- ϵ method, we generate Pareto-optimal tradeoffs that allow policymakers and logistics planners to assess how marginal profit reductions can yield significant environmental and social benefits. Results indicate that a partial substitution strategy, guided by targeted regional selection and mode choice, enables a feasible, profit-generating network configuration that significantly reduces externalities. The framework underscores the strategic role of rail infrastructure in decarbonizing bulk logistics and demonstrates how optimized multimodal transport can link mining residues to sustainable construction supply chains. By enabling the integration of industrial by-products into the circular economy, it contributes to the decarbonization of both the construction and mining sectors through network optimization.

3 - Optimizing Maintenance Intervals Using Monte Carlo Simulation

Masood Kang, TTX Company, Charlotte, NC, United States, David Cannon, Clayton Bartelt

Condition-Based Maintenance (CBM) is a proactive approach scheduling maintenance based on equipment conditions rather than fixed intervals. In the context of freight rail rolling stock, CBM leverages sensors and diagnostic data to predict and prevent failures, thereby enhancing fleet reliability and availability. This method contrasts with traditional maintenance practices, which often lead to either premature or delayed overhauls. A critical aspect of CBM is determining the optimal End-of-Life (EOL) thresholds for components such as bolsters. EOL thresholds are the points at which components are deemed no longer reliable and require replacement. Setting these thresholds accurately is crucial for minimizing maintenance costs and avoiding unexpected failures. To address this, we developed a Monte Carlo Simulation model to evaluate different maintenance practices and identify the optimal intervals for EOL thresholds. The simulation incorporates various factors, including component failure probabilities, maintenance costs, and fleet health metrics. By iterating over numerous scenarios, the model provides insights into the impact of different EOL thresholds on overall fleet performance. Our findings indicate that adjusting EOL thresholds can significantly reduce maintenance costs and improve fleet reliability. For instance, increasing the EOL mileage thresholds for bolsters can lead to substantial cost savings while maintaining acceptable levels of reliability. The simulation results also highlight the importance of balancing maintenance capacity and work order generation to manage backlog effectively. This project demonstrates the potential of Monte Carlo Simulation in optimizing maintenance strategies for freight rail rolling stock, offering a data-driven approach to enhance CBM practices and achieve better operational outcomes.

4 - A Backtracking-Based Heuristic for Train to Fuel Pad Assignments

Ashutosh Shukla, BNSF Railway, Fort Worth, TX, United States, Dasaradh Mallampati, Paul Kuhn

Belen, N.M. is BNSF Railway's largest fueling station, annually serving close to 50,000 trains with fuel worth more than a billion dollars. These trains can have different costs when it comes to delays. That is, the delay of certain kinds of trains is preferred over others. At the same time, to make an optimal assignment of trains to fuel pads, one must also account for the network topology, train's fueling, crew change, and inspection time. Up until now, these assignments have been done manually. To automate this assignment process, we present a backtracking-based heuristic that adheres to all the hard and soft constraints and generates valid assignments within seconds using the most up-to-date train arrival status.

Co-Chair: Kenan Zhang, EPFL, Lausanne, Switzerland

1 - A Markovian Traffic Equilibrium Model for Ride-Hailing

Song Gao, University of Massachusetts Amherst, Amherst, MA, United States, Chiwei Yan, Guocheng Jiang, Hanyu Cheng

We develop a Markovian traffic equilibrium model for ride-hailing, where ride-hailing vehicles make sequential link choices in a network, whether empty or hired, to maximize random utilities in an infinite-horizon semi-Markovian process. Competitions among empty vehicles for passengers are modeled at nodes, and traffic congestion due to road usage is modeled on links. We define the equilibrium as the solution to a fixed point problem, and prove the existence of the fixed point solution. We conduct computational experiments in networks with varying sizes to explore the convergence of the fixed point iteration, and derive policy and managerial insights. We contribute to the state of the art by developing a new equilibrium model that accounts for both traffic congestion and vehicle competition for passengers in a sequential decision making framework to account for drivers' forward looking capabilities.

2 - Mobility-as-a-Service (MaaS) System as a Multi-Leader-Multi-Follower Game: a Single-Level Variational Inequality (Vi) Formulation

Kenan Zhang, EPFL, Lausanne, Switzerland

This study models a Mobility-as-a-Service (MaaS) system as a multi-leader-multi-follower game that captures the complex interactions among the MaaS platform, service operators, and travelers. We consider a cooperative setting where the MaaS platform purchases service capacity from service operators and sells multi-modal trips to travelers following an origin-destination-based pricing scheme; meanwhile, service operators use their remaining capacities to serve single-modal trips. As followers, travelers make both mode choices, including whether to use MaaS, and route choices in the multi-modal transportation network subject to congestion. Inspired by dual formulation for traffic assignment problems, we propose a novel single-level variational inequality (VI) formulation by introducing a virtual traffic operator, along with the MaaS platform and multiple service operators. To decouple the decision-making process between the MaaS platform and service operators, we define additional variables, proposed capacity purchase price by the MaaS platform, and impose consensus constraints that also represent the negotiation process. A key advantage of the proposed VI formulation is that it supports parallel solution procedures and thus enables large-scale applications.

3 - Cooperation and the Design of Public Goods

Juan Martinez Mori, University of Colorado Denver, Denver, CO, United States, Alejandro Toriello

We consider the cooperative elements that arise in the design of public goods, such as transportation policies and infrastructure. These involve a variety of stakeholders: governments, businesses, advocates, and users. Their eventual deployment is critically dependent on the decision maker's ability to garner sufficient support from each of these groups; we formalize these strategic requirements from the perspective of cooperative game theory. Specifically, we introduce non-transferable utility, linear production (NTU LP) games, which combine the game-theoretic tensions inherent in public decision-making with the modeling flexibility of linear programming. We derive structural properties regarding the non-emptiness, representability, and complexity of the core, a solution concept that models the viability of cooperation. In particular, we provide fairly general sufficient conditions under which the core of an NTU LP game is guaranteed to be non-empty, prove that determining membership in the core is co-NP-complete, and develop a cutting plane algorithm to optimize various social welfare objectives subject to core membership. Lastly, we apply these results in a data-driven case study on service plan optimization for the Chicago bus system. We illustrate how, while cooperation is necessary for the successful deployment of transportation service plans, it may also have adverse and/or counterintuitive distributive implications.

4 - Data-Driven Facility Layout for Enhancing Walk Appeal in Walkable Neighborhoods

Haoran Guo, Tsinghua University, Beijing, China, People's Republic of, Sentao Miao, Wei Qi

In response to the challenges posed by car-centric urban development, there is growing global advocacy for walkable neighborhoods that promote public health and urban sustainability. To support the design of such neighborhoods, this paper studies the optimal layout of facilities (e.g., retail and service establishments) to enhance walk appeal. Unlike conventional designs that rely primarily on distance metrics, our approach focuses on pedestrian choices. We use a latent class logit model to estimate how facility layouts influence individuals' propensity to walk, accounting for heterogeneous travel purposes. This model is calibrated with a city-wide dataset from our industry collaborator, a leading Chinese map service provider. Building on this model, we develop a choice-based optimization framework to determine facility layouts that maximize the aggregate walking probability of residents. We first analyze its structural properties to derive analytical insights into optimal layout patterns. To find optimal layouts for this NP-hard problem, we reformulate it as an exponential cone program. To address the computational challenges this poses for large-scale applications, we further develop efficient greedy algorithms and establish their performance guarantees via submodularity ratio analysis. A case study in Beijing shows that our approach significantly improves walk appeal compared to traditional methods, with minimal impact on facility accessibility. Our results also reveal a "wisdom of crowds" effect in existing layouts and emphasize the importance of neighborhood context in shaping optimal design patterns. Specifically, we find that dispersed layouts are preferable in already walkable environments, while more challenging walking conditions benefit from spatially concentrated facilities.

Experimentation and Interference

Invited Session

Applied Probability Society

Chair: Andrew Zheng, University of British Columbia, Boston, MA, United States

Co-Chair: Anushka Murthy, Stanford University, Stanford, CA, United States

Co-Chair: Wenqian Xing, Stanford University, Stanford, CA, United States

1 - Differences-in-Neighbors for Network Interference in Experiments

Andrew Zheng, University of British Columbia, Boston, MA, United States, Tianyi Peng, Naimeng Ye

Experiments in online platforms frequently suffer from network interference, in which a treatment applied to a given unit affects outcomes for other units connected via the platform. This SUTVA violation biases naive approaches to experiment design and estimation. A common solution is to reduce interference by clustering connected units, and randomizing treatments at the cluster level, typically followed by estimation using one of two extremes: either a simple difference-in-means (DM) estimator, which ignores remaining interference; or an unbiased Horvitz-Thompson (HT) estimator, which eliminates interference at great cost in variance. Even combined with clustered designs, this presents a limited set of achievable bias variance tradeoffs. We propose a new estimator, dubbed Differences-in-Neighbors (DN), designed explicitly to mitigate network interference. Compared to DM estimators, DN achieves bias second order in the magnitude of the interference effect, while its variance is exponentially smaller than that of HT estimators. When combined with clustered designs, DN offers improved bias-variance tradeoffs not achievable by existing approaches. Empirical evaluations on a large-scale social network and a city-level ride-sharing simulator demonstrate the superior performance of DN in experiments at practical scale.

2 - Experimentation Under Non-Stationary Interference

Su Jia, Cornell, New York, NY, United States, Peter Frazier, Nathan Kallus, Christina Yu

We consider experimentation in the presence of non-stationarity, inter-unit (spatial) interference, and carry-over effects (temporal interference), where we wish to estimate the global average treatment effect (GATE), the difference between average outcomes having exposed all units at all times to treatment or to control. Most work in this area assume that the interference between units is encoded as a *static* graph. However, in many real world settings, this interference graph varies over time, for example, since the units are moving. We study the scenario where the interference graph changes in a deterministic fashion. As the main result, we show that a natural design and estimator achieves an MSE of $1/NT$ times a factor that measures the complexity of the system, where N and T are the number of units and time periods.

3 - Estimation of Treatment Effects Under Nonstationarity via Truncated Difference-in-Q&R's

Ramesh Johari, Stanford University, Stanford, CA, United States, Tianyi Peng, Wenqian Xing

Randomized controlled experiments ("A/B tests") are essential for evaluating interventions in dynamic data-driven systems, where actions affect both current and future states. Accurate estimation of the global average treatment effect (GATE) must consider nonstationarity in these temporal dynamics; unfortunately, existing estimators typically suffer from high bias, high variance, or both in nonstationary environments. We propose the truncated DQ estimator, extending difference-in-means to use truncated outcome trajectories. We prove it estimates a policy gradient approximating the GATE and derive bias and variance bounds. Simulations and empirically calibrated synthetic experiments demonstrate its low bias and variance under nonstationarity.

4 - Heterogeneous Treatment Effects in Matching Marketplaces Under Interference: from Estimation to Decision

Kleanthis Karakolios, Georgia Institute of Technology, Atlanta, GA, United States, Arthur Delarue

Marketplace platforms frequently employ randomized experiments to guide operational decisions, such as determining whether to implement a new intervention globally or for specific user groups. Understanding how treatment effects vary across subpopulations—known as heterogeneous treatment effect (HTE) analysis—is critical for these decisions. However, such experiments often involve interference: the treatment assigned to one user can influence the outcomes of others. We first show that under interference, HTEs may not be uniquely defined, posing a fundamental challenge to identification and estimation. When the HTE for a subgroup is uniquely defined, we demonstrate that an estimator derived from linear programming duality can systematically reduce bias compared to the standard estimator. In settings where HTEs are not uniquely identifiable, we reframe the problem: rather than estimating effects directly, we focus on determining whether to implement the intervention within each subgroup. We leverage the duality-based estimator to construct a robust decision rule that accounts for interference and yields improved performance over rules derived from standard estimators, offering a better balance between effectiveness and conservatism. Theoretical findings are supported by numerical experiments on synthetic data, validating the proposed methodology.

Applications of Simulation

Contributed Session

Contributed

Chair: Fatemeh Mahroo, Clemson University, 811 Issaqueena Trl, Clemson, 29630, United States

1 - Modeling Life Settlements

Joseph Bakhtiar, Georgia Tech, Atlanta, GA, United States, Dave Goldsman, John-Paul Clarke

We develop a comprehensive discrete-time framework for the valuation, risk management, and performance analysis of life settlement portfolios. After establishing a discrete-time mortality model employing various probability distributions calibrated with empirical data via maximum likelihood estimation, individual policy valuations incorporate analytical solutions, and Monte Carlo (MC) simulations are used to assess key financial metrics, including expected policy value over time, variance, and the probability of profitability. Additionally, we explore portfolio-level valuation by aggregating multiple life settlement contracts, explicitly accounting for correlated mortality risks. Through detailed MC simulations, we illustrate how mortality correlations impact portfolio diversification, expected returns, and risk measures such as Value-at-Risk (VaR) and Conditional Value-at-Risk (CVaR). Robustness analyses evaluate the effects of model misspecifications, particularly concerning mortality assumptions and interest rate environments. Our discrete-time framework provides critical insights for investment decisions, portfolio optimization, and regulatory capital planning in the growing life settlements market.

2 - Proposal of the Shaft Theory: Analyzing Corporate Distress Using Concepts from Mechanics of Materials

Kaneki Yamaguchi, Waseda University, Tokyo, Japan

In today's volatile business environment, firms constantly face dramatic shifts in external and competitive conditions. Even companies with strong financial performance can rapidly collapse, as exemplified by the 2023 case of Bigmotor company in Japan. In response to increasing scrutiny, Japan mandated the disclosure of non-financial information, including human capital data, starting in 2023. To ensure sustainable growth, companies must now accurately assess their own value while monitoring competitors.

Although several corporate evaluation models attempt to assess a firm's sustainability and bankruptcy risk using both financial and non-financial metrics, few have focused on managerial resources—particularly human capital. This research addresses this gap by proposing a new corporate evaluation framework based on a physical analogy from materials mechanics: the "Shaft Theory." Specifically, the study models the structure of a firm's human resources using the mechanical properties of a shaft, one of the most fundamental components in structural mechanics.

Using analytical techniques from strength of materials, the model quantifies the "strength" of a firm's human resource structure and tests its relationship to business resilience and likelihood of survival. By establishing a statistically significant correlation between mechanical strength indicators and real-world corporate durability, the

research aims to validate the conceptual and practical value of Shaft Theory. This interdisciplinary approach not only provides a novel lens to understand organizational stability but also contributes to a more holistic evaluation framework that integrates human capital as a core factor in long-term corporate viability.

3 - Modeling Airport Tnc EV Charging Demand and Charging Infrastructure Needs Using Discrete-Event Simulation

Yanbo Ge, National Renewable Energy Laboratory, Golden, CO, United States, Monte Lunacek, Yi He, Kenneth Kelly

Transportation Network Companies (TNCs), such as Uber and Lyft, have set ambitious goals for fleet electrification. Airports are well-positioned to support TNC electric vehicle (EV) charging due to high passenger volumes, longer average trip distances, and naturally extended vehicle dwell times while waiting for ride requests. Accurately understanding infrastructure needs and charging demand is critical for both airports and TNCs as they plan for this transition. However, there is a lack of insight within both industry and academia regarding the energy requirements needed to support large-scale TNC electrification. To address this gap, the Athena ZEV project—funded by the U.S. Department of Energy's Vehicle Technologies Office (VTO)—has developed a discrete-event simulation model to quantify TNC EV charging infrastructure needs and energy demand at airports. The model tracks vehicle status and ride request dynamics at each time step, enabling scenario analysis based on varying assumptions such as vehicle state-of-charge (SOC), charger type and quantity, and fleet composition. A case study of Dallas/Fort Worth International Airport demonstrates the model's capabilities, highlighting how SOC policies, solar and storage integration, and charger design affect power demand and service quality. The tool can be adapted to any airport given the appropriate input data, offering a flexible and practical solution for planning TNC electrification strategies.

4 - Inventory Management Under Disruptions Using Risk-Averse Deep Reinforcement Learning

Chiye Ma, Department of Mechanical Engineering, City University of Hong Kong, Hong Kong, China, People's Republic of, Wei Wang

Modern supply chains have become increasingly vulnerable and inefficient due to a range of disruptions, including trade wars, pandemics such as COVID-19, natural disasters, cyberattacks, and geopolitical conflicts. These challenges underscore the urgent need for effective inventory management strategies that can enhance supply chain resilience and ensure operational continuity. In this work, we propose a risk-averse multi-agent proximal policy optimization (MAPPO) framework to address inventory management problems under typical disruptive events. We focus on a two-echelon supply chain network consisting of one supplier and four retailers. The periodic review inventory control problem is formulated as a decentralized partially observable Markov decision process (Dec-POMDP), extended with a disruption context space to capture environmental uncertainties. To tackle the high-risk nature of such scenarios, we integrate MAPPO with the cross-entropy soft-risk (CeSoR) algorithm, enabling risk-aware policy optimization for the retailers. Numerical experiments demonstrate that our proposed method outperforms risk-neutral MAPPO under disrupted scenarios. The results highlight the effectiveness of our approach in improving inventory performance and enhancing supply chain resilience.

5 - Modeling EV Adoption Under Behavioral Heterogeneity: a Simulation Framework Using LLMs and Agent-Based Modeling

Xinyi Du, Singapore Management University, Singapore, Singapore, Junfeng Jiao

Achieving Singapore's Green Plan 2030 target for full electric vehicle (EV) adoption requires more than infrastructure; it depends on how residents respond to policy design. This study evaluates the behavioral impact of a default EV enrollment policy that automatically assigns new car buyers to electric vehicle pathways, combined with modest financial incentives. We develop a simulation framework that integrates large language models (LLMs) with behavioral economics to generate a heterogeneous synthetic population. LLM-guided narrative generation, grounded in microeconomic theory, enables us to move beyond fixed trait distributions by deriving agent-level characteristics, such as risk aversion, time discounting, and institutional trust, that reflect realistic behavioral biases and socio-demographic variation. These traits inform decision rules within an agent-based model (ABM) that simulates adoption behavior under the default-plus-incentive mechanism. We experiment with variations in default strength, opt-out friction, and incentive magnitude. Agent-level thresholds for adoption are shaped by behavioral parameters such as perceived risk and policy trust, allowing us to simulate differentiated response dynamics across population segments. The simulation also allows policymakers to test targeted scenarios, such as tailoring incentives to high-friction groups, to evaluate efficiency-equity trade-offs in a controlled setting. This study offers a virtual policy lab for testing and refining EV strategies prior to real-world implementation.

6 - A Simulation-Optimization Framework for Inference of Mixture Patience Distributions in Multi-Server Queues

Fatemeh Mahroo, Clemson University, Clemson, SC, United States, Tugce Isik

We present an iterative simulation-optimization framework for estimating customer patience in multi-server queueing systems with unobservable customer types and possible abandonment. Our goal is to accurately estimate patience parameters while minimizing server usage cost, customer abandonment cost, and costs associated with adding or removing servers. Our approach involves data generated by two parallel systems: the “real” system, where patience parameters are unknown, and a simulated “estimated” system, where these parameters are updated over time. The two systems operate under identical arrival rates, service rates, and service policies. At each iteration, the waiting times, abandonments, and service completions in the real system are observed, and the equivalent data is collected from the estimated system via simulation. We compare the waiting time distributions for served and abandoned customers using the Anderson–Darling two-sample test and the Wasserstein distance. The estimated system's parameters are updated using the Expectation-Maximization algorithm, and staffing levels are optimized to minimize operational costs. The algorithm terminates when the two statistical measures suggest that the two systems' patience behavior is indistinguishable. Computational experiments show that the method typically converges to the true patience parameters, with faster convergence observed when more abandonment occurs. The Wasserstein criterion is generally satisfied earlier than Anderson–Darling. By efficiently learning the underlying patience parameters, the method brings operational costs in line with those of a system with full information.

Freight Management

Invited Session

TSL: Freight Transportation

Chair: Justin Goodson, Saint Louis University, Saint Louis, MO, United States

1 - Data-Driven Freight Shipment Reservation Problem

Raviv Pichayavet, Georgia Institute of Technology, Atlanta, GA, United States, Haoyun Wang, Yunqin Zhu, Alan Erera, Yao Xie, Benoit Montreuil

This project addresses the challenges faced by companies that rely on outsourced carriers to ship goods to their customer: securing cost-effective, reliable capacity for on-time pickups. Without their own delivery fleets, these companies depend on contracted carriers to ensure competitive shipping rates for specific lanes. However, these contracts lack guaranteed capacity, as carriers serve multiple shippers and allocate capacity on a first-come, first-served basis. When capacity is fully utilized, shippers face two costly choices: sourcing higher-priced services from alternative carriers or the spot market, or risking delays that impact operational schedules and customer satisfaction. To reduce the likelihood of last-minute costly purchases, the shipper has to make advance capacity reservations. However, this strategy is complicated by demand uncertainty, as shippers must reserve space for orders that may not yet be finalized. This study develops a data-driven stochastic optimization model to establish an effective reservation decision, addressing uncertainties in carrier capacity and shipment demand. By leveraging historical data on demand patterns, carrier capacity, and rate fluctuations, the model prescribes daily reservation quantities based on available capacity. It is designed to adapt as new information on demand and capacity becomes available, allowing the reservation policy to dynamically respond to changing conditions. This approach minimizes expected shipping costs while reducing the risk of capacity shortages and delays in scheduled pickups, providing companies with a flexible and responsive framework for managing outsourced shipping effectively.

2 - Spatio-Temporal Pattern Mining and Optimization for Load Consolidation in Freight Transportation Networks

Sikai Cheng, AI4OPT - Georgia Tech, Atlanta, GA, United States, Amira Hijazi, Jeren Konak, Alan Erera, Pascal Van Hentenryck

Freight consolidation is important to reduce transportation costs and mitigate congestion and pollution. An effective load consolidation plan relies on carefully chosen consolidation points to ensure alignment with existing transportation management processes, such as driver scheduling, personnel planning, and terminal operations. This complexity represents a significant challenge when searching for optimal consolidation strategies. Traditional optimization-based methods provide exact solutions, but their computational complexity makes them impractical for large-scale instances and they fail to leverage historical data. Machine learning-based approaches address these issues but often ignore operational constraints, leading to infeasible consolidation plans. This work proposes SPOT, the first approach that integrates the benefits of machine learning (ML) and optimization for load consolidation. The ML module plays a key role in the planning phase by defining the consolidation points through spatiotemporal clustering and frequent itemset mining, while the optimization module selects the most cost-effective feasible consolidation routes for a given operational day. Extensive experiments conducted on industrial load data demonstrate that SPOT significantly reduces travel distance and transportation costs compared to the existing industry-standard load planning strategy and a strong neighborhood-based heuristic. In addition, the ML module provides valuable tactical-level insights by identifying frequently recurring consolidation opportunities that guide proactive planning. Notably, SPOT is computationally efficient and can be easily scaled to accommodate large transportation networks.

3 - Dynamic Truck Scheduling Using Estimated Times of Arrival

Justin Goodson, Saint Louis University, Saint Louis, MO, United States

The paper addresses the problem of dynamically scheduling inbound trucks at a warehouse. Real-time vehicle positioning technology facilitates rolling estimates of truck arrival times. By taking these estimates as noisy signals of uncertain arrival times, we formulate a partially-observed Markov decision process to minimize expected delay in the assignment of trucks to unloading docks. A lookahead policy posts strong performance relative to a dual bound, significantly improves on the extant literature, substantially outperforms current practice, and scales to an industrial setting. Notably, using information relaxations and an information penalty, our analysis shows how mixed integer programming can be used to establish a lower limit on the cost of an optimal policy. The paper makes practical and methodological contributions to an industry with thin margins and demanding lead time targets.

4 - Line Network Design with Handling TIMES

Gabriel Deza, Tel Aviv University, Tel Aviv, Israel, Michal Tzur, Tal Raviv

We study the design of line-based vehicle routes for urban parcel delivery systems that rely on service points (SPs) and fixed periodic vehicle routes. These Hyperconnected Networks (HCNs) support transshipment between SPs, allowing multi-leg routing to boost consolidation and vehicle utilization. However, a key operational feature often overlooked in existing models is the significant time couriers spend idle at SPs handling parcels. Empirical data show that the majority of a driver's operational cycle is spent curbside—locating, scanning, loading, and unloading parcels—yet most optimization models treat this time as negligible or exogenous.

We introduce the Line Network Design with Handling Times (LND-HT) problem, which jointly optimizes line selection, parcel routing, and vehicle scheduling while explicitly accounting for parcel handling operations. We propose several formulations based on multi-commodity flow models over an expanded, multi-line network representation. We leverage the combinatorial problem structure to devise a branch-and-price solution method and compare with off the shelf solvers. Through numerical experiments on synthetic and real-world instances, we quantify the role of handling times in line planning for urban parcel delivery.

Recent Advances in Ranking and Selection

Invited Session

Simulation

Chair: Eunhye Song, Georgia Tech

Co-Chair: Jaime Gonzalez-Hodar, Georgia Institute of Technology, Atlanta, GA, United States

1 - Data-Driven Ranking and Selection with Simultaneous Input Data Collection and Simulation

Enlu Zhou, Georgia Institute of Technology, Atlanta, GA, United States, Yuhao Wang

We propose a general and novel formulation of ranking and selection with the existence of streaming input data. The collection of multiple streams of such data may consume different types of resources, and hence can be conducted simultaneously. To utilize the streaming input data, we aggregate simulation outputs generated under heterogeneous input distributions over time to form a performance estimator. By characterizing the asymptotic behavior of the performance estimators, we formulate two optimization problems to optimally allocate budgets for collecting input data and running simulations. We then develop a multi-stage simultaneous budget allocation procedure and provide its statistical guarantees such as consistency and asymptotic normality. We conduct several numerical studies to demonstrate the competitive performance of the proposed procedure.

2 - Feature Misspecification in Sequential Learning Problems

Dongwook Shin, HKUST Business School, Clear Water Bay, Hong Kong, Dohyun Ahn, Assaf Zeevi

We consider a class of sequential learning problems where a decision maker must learn the unknown statistical characteristics of a finite set of alternatives (or systems) using sequential sampling to ultimately select a subset of “good” alternatives. A salient feature of our problem is that system performance is governed by a set of features. The decision maker postulates the dependence on these features to be linear, but this model may not precisely represent the true underlying system structure. We show that this mis-specification, if not managed properly, can lead to suboptimal performance because of a phenomenon identified as sample-selection endogeneity. We propose a prospective sampling principle—a new approach that eliminates the adverse effects of misspecification as the number of samples grows large. The proposed principle

applies across a very general class of widely used sampling policies, enjoys strong asymptotic performance guarantees, and exhibits effective finite-sample performance in numerical experiments.

3 - Ranking and Selection with Multiple Correct Answers

David Eckman, Texas A&M University, College Station, TX, United States, Raahim Hashmi, Taeho Kim

We consider ranking-and-selection problems in which the decision maker would be equally satisfied with selecting any of a subset of systems satisfying some generic definition of acceptability. Practical examples include epsilon-optimal or top-m systems in the single-objective setting or Pareto-optimal systems in the multi-objective setting. Problems of this kind have been studied by both the operations research and computer science communities under different assumptions and limiting regimes, which has resulted in fundamentally different algorithm designs. More specifically, operations researchers have at times adopted a large-deviations perspective that focuses on the rate at which the probability of making an incorrect selection approaches zero as the sampling budget increases. In contrast, computer scientists have more often focused on the worst-case sampling complexity needed to make a correct selection with some fixed confidence. We compare and contrast these paradigms in an effort to unify and deepen understanding about this important class of problems.

4 - General-Purpose Ranking and Selection for Stochastic Simulation with Streaming Input Data

Jaime Gonzalez-Hodar, Georgia Institute of Technology, Atlanta, GA, United States, Eunhye Song

We study ranking and selection (R&S) where the simulator's input models are increasingly more precisely estimated from the streaming data obtained from the system. The goal is to decide when to stop updating the model and return the estimated optimum with a probability of good selection (PGS) guarantee. We extend the general-purpose R&S procedure by Lee and Nelson by integrating a metamodel that represents the input uncertainty effect on the simulation output performance measure. The algorithm stops when the estimated PGS is no less than $1-\alpha$ accounting for both prediction error in the metamodel and input uncertainty. We then propose an alternative procedure that terminates significantly earlier while still providing the same (approximate) PGS guarantee by allowing the performance measures of inferior solutions to be estimated with lower precision than those of good solutions. Both algorithms can accommodate nonparametric input models and/or performance measures other than the means (e.g., quantiles).

GPU Acceleration of Optimization Algorithms II

Invited Session

Computing Society

Chair: Matthew Galati, Amazon, Glen Mills, PA, United States

1 - Accelerating Crossovers with GPUs

Samiran Kawtikwar, University of Illinois Urbana Champaign, Champaign, IL, United States, Rakesh Nagi

This project explores the GPU-accelerated implementation of a novel crossover algorithm for linear programming (LP). The algorithm leverages the spiral dynamics observed in the primal-dual hybrid gradient (PDHG) method to efficiently transition from an interior or non-vertex optimal solution to a vertex optimal solution without resorting to traditional simplex-based methods. Our approach capitalizes on the inherent Single Instruction Multi Data (SIMD) parallelism of the PDL solver, specifically employing simultaneous perturbations of cost coefficients to enable efficient primal and dual pushes. This parallel strategy significantly enhances the suitability of the crossover process for GPU acceleration. Initial analysis highlights the substantial parallel potential of this approach, promising significant computational performance improvements. Ongoing computational experiments aim to quantify these performance gains and provide concrete speedup metrics. This work thus demonstrates a promising new direction for enhancing crossover processes in LP through GPU optimization.

2 - Second-Order Gpu Power for Machine Learning and Stats Procedures

Yan Xu, SAS, Cary, NC, United States, Joshua Griffin, Riadh Omhenni

A first-order method like SGD and coordinate-descent are attractive algorithms in that they are easier to implement and tend to work well in practice with nominal tuning. By design, they operate using vector-based (as opposed to matrix-based) operations. It is well-known that GPUs offer the greatest advantages for deep learning models that rely on fast dense-matrix-matrix multiplies. A challenge for first-order methods is that dense-matrix-matrix products do not naturally occur, and something like excessive batch sizes must be artificially induced. A benefit of second-order methods is that they are globally convergent and have naturally occurring dense matrix-matrix operations that are both cache-efficient on modern CPUs and naturally benefit from GPU devices. We will show the results of second-order methods applied to support vector machines and quantile regression, showing the additional benefit of GPU devices that customers may have purchased initially for applications in deep learning.

3 - How to Leverage a Gpu to Improve Mip/Lp Performance?

Mitch McKay, SimpleRose, St. Louis, MO, United States

In this talk we will discuss how designing algorithms for CPU vs GPU affect performance. With CPUs hitting the limit of Moore's law, we need to look to other hardware and novel algorithms to solve the ever growing problem of complexity in optimization. Recent hardware advances from Nvidia buck this trend, and enable a paradigm shift in how MIPs and LPs are solved. We will provide a developer's perspective on what we have learned at SimpleRose from implementing MIP/LP algorithms on NVIDIA GPUs.

4 - Training from Structure, Not from Data: Dataless Neural Networks for Combinatorial Optimization

Alvaro Velasquez, University of Colorado Boulder, Boulder, CO, United States, Cunxi Yu, Ismail Alkhouri

Recent advancements in deep learning have fueled a surge in research on machine learning for combinatorial optimization. These methods are typically rooted in (un)supervised learning and reinforcement learning. However, these approaches rely on labeled datasets, exhibit weak generalization, and often depend on problem-specific heuristics. In this presentation, we make the argument for dataless neural networks that are trained based on the structure of the problem instance as opposed to being trained on a conventional dataset. In particular, we present ReLU-based and quadratic relaxations for the MIS problem. By employing a gradient-based optimization algorithm like ADAM and leveraging efficient off-the-shelf GPU implementation, our straightforward yet effective approaches demonstrate competitive or superior performance compared to state-of-the-art learning-based methods.

1 - On Iteratively Regularized First-Order Methods for Simple Bilevel Optimization

Sepideh Samadigharabalah, Rutgers university, Piscataway, NJ, United States, Daniel Burbano, Farzad Yousefian

We consider simple bilevel optimization problems where the goal is to compute among the optimal solutions of a composite convex optimization problem, one that minimizes a secondary objective function. Our main contribution is threefold. (i) When the upper-level objective is a composite strongly convex function, we propose an iteratively regularized proximal gradient method in that the regularization parameter is updated at each iteration under a prescribed rule. We establish the asymptotic convergence of the generated iterate to the unique optimal solution. Further, we derive simultaneous sublinear convergence rates for suitably defined infeasibility and suboptimality error metrics. When the optimal solution set of the lower-level problem admits a weak sharp minimality condition, utilizing a constant regularization parameter, we show that this method achieves simultaneous linear convergence rates. (ii) For addressing the setting in (i), we also propose a regularized accelerated proximal gradient method. We derive quadratically decaying sublinear convergence rates for both infeasibility and suboptimality error metrics. When weak sharp minimality holds, a linear convergence rate with an improved dependence on the condition number is achieved. (iii) When the upper-level objective is a smooth nonconvex function, we propose an inexact projected iteratively regularized gradient method. Under suitable assumptions, we derive new convergence rate statements for computing a stationary point of the simple bilevel problem. We present preliminary numerical experiments for resolving three instances of ill-posed linear inverse problems.

2 - An Incentive-Enabled Method with Complexity Guarantees for Federated Learning

Fateme Maleki, Rutgers University, Piscataway, NJ, United States, Farzad Yousefian

Federated learning enables distributed model training without sharing raw data. In this framework, keeping the clients engaged remains challenging since participants may receive uneven benefits from their contributions. We consider nonconvex and L -smooth local objective functions for the clients. We present an Incentive-enabled Federated Averaging method that rewards participants based on their level of participation in each round, through allowing clients to control the size of their training data dynamically in each round of communication. In each communication round, clients exchange both local parameters with the server and their updated training dataset sizes, which are dynamically adjusted using a Nash equilibrium seeking update rule. Subsequently, the server transmits updated global parameters back to clients to initiate the following round. We theoretically analyze the proposed method, obtaining explicit iteration and communication complexity guarantees. We plan to conduct numerical experiments on MNIST and CIFAR-10 datasets to evaluate the effectiveness of our approach, with a focus on examining the convergence behavior of the loss function.

3 - Iteratively Regularized Gradient Tracking Methods for Distributed Optimal Equilibrium Seeking

Farzad Yousefian, Rutgers University, Piscataway, NJ, United States

We consider a class of distributed constrained optimization problems where the constraint set is characterized by the solution set of a distributed monotone variational inequality problem. This problem is motivated by the need for estimation of the efficiency of equilibria in Nash games. First, we consider solving this problem over directed networks. We develop an iteratively regularized distributed gradient tracking method where the agents employ a push-pull protocol to communicate over the network. Second, we consider a stochastic variant of this problem over undirected networks and develop an iteratively regularized distributed stochastic gradient tracking method. For both algorithms, we establish the convergence of the generated iterates by the agents to the optimal equilibrium and derive new convergence rate statements. We validate the two proposed methods and present preliminary numerical results for computing the optimal equilibrium in a Cournot competition.

Advancing Hydrogen Integration in Energy Systems: Models and Analyses of Technical, Economic, and Legal Dimensions

Invited Session

ENRE: Energy

Chair: Chiara Lo Prete, The Pennsylvania State University John and Willie Leone Family Department of Energy and Mineral Engi, University Park, PA, United States

1 - Green Hydrogen Integration to Enhance Grid Reliability During Winter Emergencies

Jiaxing Wu, The Pennsylvania State University, State College, PA, United States, Chiara Lo Prete, Enzo Sauma

Increasing reliance on natural gas for electricity generation has heightened the power grid's vulnerability during extreme weather events, when gas demand spikes across both the electricity and heating sectors. This dependence on a single fuel source exposes the gas-fired generators to gas disruption risks and, consequently, challenges grid reliability. Green hydrogen, produced via water electrolysis powered by renewable energy, is emerging as a promising alternative, and could serve as a backup fuel during gas supply disruptions. This study investigates whether the integration of green hydrogen can improve power system reliability during winter emergencies by using electrolyzers to produce hydrogen when renewable energy is abundant, storing it on-site, and supplying it to gas-fired generators during natural gas shortages. This integration presents potential operational trade-offs: electrolyzers connected to the grid can increase electricity demand, potentially worsening transmission congestion—especially when they are located far from renewable energy sources and require power to be transmitted across already constrained parts of the grid. To assess potential benefits and challenges, this study couples a gas-electric optimization model with green hydrogen production and use. The integrated model quantifies the trade-off between enhanced reliability during natural gas disruptions due to scheduling reductions and increased grid congestion caused by the electricity demand of electrolyzers during non-critical periods. It captures the interactions among fuel availability, power system operations, and transmission constraints associated with green hydrogen integration.

2 - Unlocking the Value of Hydrogen Energy Storage: Modeling, Tools, and Assessment Insights

Di Wu, Pacific Northwest National Laboratory, Richland, WA, United States

Hydrogen is a promising solution for future energy systems. Understanding how to optimally utilize hydrogen energy storage (HES) to unlock stacked value streams is essential for advancing its market viability. This presentation introduces a techno-economic assessment framework for modeling hydrogen production, compression, storage, and utilization, capturing system interactions, and optimizing economic benefits across multiple value streams. We will also showcase the Hydrogen Energy Storage Evaluation Tool (HESET), a web-based application built on this framework. Finally, insights from real-world assessments of hydrogen and hybrid systems will be shared.

3 - Hydrogen in the Pipeline: Legal and Regulatory Challenges of Converting Natural Gas Pipelines for Hydrogen-Gas Blends

Chiara Lo Prete, Pennsylvania State University, University Park, PA, United States, Shahin Mirzaei

Hydrogen is the most abundant element in the universe, and its versatility and potential to lower emissions make it central for decarbonization purposes. As interest in hydrogen continues to grow in the United States, one proposed strategy for scaling up its use is blending small quantities hydrogen with natural gas in existing pipelines and, eventually, converting these pipelines to be able to carry higher hydrogen-natural gas ratios. However, the legal and regulatory frameworks governing the use of pipelines for hydrogen-gas blends remain underdeveloped. This presentation aims to examine the major legal challenges associated with pipeline repurposing for hydrogen-gas blends. Key topics include legal challenges associated with approving pipeline abandonment or conversion and addressing impacts on existing shippers' contracts. The goal of this presentation is to inform audience about the legal impediments to converting gas pipelines to carry gas-hydrogen blends and to shed light on the regulatory and legal barriers that must be addressed to enable the safe and reliable usage of hydrogen in the U.S. energy system.

4 - Co-Optimizing Freight and Hydrogen Logistics for Regional Decarbonization

Mohammad Reza Ghorbanali Zadegan, University of Texas at Austin, Austin, TX, United States, Zhaomiao Guo

Decarbonizing transportation and industrial operations has become a high priority as climate concerns intensify. Hydrogen plays a central role in national decarbonization plans and serves as a flexible alternative fuel in transport and industry, e.g., powering fuel-cell electric vehicles (FCEVs) or serving as feedstock for ammonia synthesis. However, large-scale hydrogen adoption requires coordinated planning of production and fueling infrastructure while addressing economic, technical, policy, and environmental challenges. This research develops a location-allocation optimization model to guide the deployment of hydrogen infrastructure for the heavy-duty

transportation sector and industrial applications. Decision variables cover station siting, electrolyzer sizing, hydrogen shipments, and freight refueling assignments, while the objective minimizes combined infrastructure, production, and transportation costs. This model provides insight into the evolution of infrastructure configurations and cost structures under different scenarios, and it serves as a guide to policymakers and industry in their quest for timely and economic decarbonization integrating hydrogen.

Decarbonizing Energy Systems under Various Sources of Uncertainties

Invited Session

ENRE: Electricity

Chair: Angela Flores, Universidad de Chile, Santiago, Chile

Co-Chair: Rodrigo Moreno, University of Chile, Santiago, Chile

1 - Transmission Expansion Planning Under Weather-Induced Uncertainties

Angela Flores, Universidad de Chile, Santiago, Chile

Power systems are increasingly exposed to weather-induced uncertainties, driven by climate change. In Chile, rising temperatures, prolonged droughts, and more frequent extreme weather events such as heatwaves and storms pose growing risks to the power system operation. In this study, we develop a comprehensive transmission expansion planning model that accounts for both short term and long term climate-related uncertainties through multi-scale stochastic programming. We also present a methodology to generate multistage scenario trees that represent future weather-driven variability, using historical meteorological data in combination with downscaled climate projections. The proposed framework is applied to the Chilean power system and provides insights into how climate uncertainty may influence future transmission investment needs.

2 - Tractable Formulations for Mixed-Integer Integrated Medium- and Low-Voltage Distribution Expansion Planning with Controllable Devices

Alfredo Oneto, ETH Zurich, Zurich, Switzerland, Blazhe Gjorgiev, Giovanni Sansavini

The global transition to net-zero societies transforms power distribution networks (DNs), driven by the widespread adoption of distributed energy resources (DERs). These resources include, but are not limited to, photovoltaic systems, battery energy storage systems, electric vehicles, and heat pumps. While these technologies introduce new flexibility capabilities, they also increase volatility and strain networks initially designed for passive demand. Ensuring reliable and cost-effective operation under these evolving conditions requires accurate modeling of DER behavior and flexibility, as well as appropriate planning of DNs. This work contributes to that effort by planning integrated medium- and low-voltage systems with controllable DERs and applying complexity reduction techniques to maintain tractability.

The distribution infrastructure of Switzerland is analyzed as a case study, focusing on 2030, 2040, and 2050. Given the significant computational burden of analyzing the entire system, spatial and temporal aggregation techniques are applied. Specifically, previous results on clustering DNs using distributional and vectorial features to identify representative systems are used to reduce model construction time. In addition, a temporal aggregation method describes weekly seasonal storage with a reduced set of operational days. Furthermore, the investment decisions involve many integer variables, resulting in a challenging combinatorial problem. Suitable solution techniques, incorporating additional cuts and binary expansions, are applied to solve the optimization problem.

3 - The GB and Australian Path to Net Zero: How Do Regulators Navigate Epistemic Uncertainty, Multiple Criteria, and Diverse Stakeholders?

Evangelia Spyrou, Imperial College London, London, United Kingdom

Majority of the countries have net zero targets for future energy systems. Among the countries with detailed decarbonization plans and accountability frameworks, Great Britain and Australia are the largest greenhouse gas emitters and they both have ambitious plans to reach deep decarbonization levels in the near future. To achieve their ambitious goals, they have already changed several of their power system operating practices. For every change, regulators have to consider multiple criteria, diverse perspectives from stakeholders, and potential evolution of technological uncertainty. This presentation will summarize findings from the review of hundreds of changes adopted by the GB and Australian regulators in the last decade. The findings will highlight what are common trade-offs among criteria, how epistemic uncertainty affects the transformation of the sector and its pace, and how stakeholder participation varies among initiatives and types of stakeholders.

4 - An EU-Wide Electricity Generation Capacity Expansion Problem Subject to Network Constraints

Anthony Papavasiliou, National Technical University of Athens, Kifisia, Greece, Daniel Felipe Avila, Marilena Zampara, Georg Thomassen, David Pozo

The European Union has set ambitious renewable energy integration targets over the following decades as part of its climate, environmental protection and sustainability policy. These targets translate into concrete minimum targets for the supply of renewable energy sources, in particular wind and solar energy. Our focus in this work is to formulate and solve an EU-wide power generation expansion problem with such renewable energy targets. The model that we formulate provides an optimal generation expansion plan while accounting for uncertainty in future European climate scenarios as well as constraints in the ability of the power network to transport electric power from locations of abundant renewable supply to locations of high electricity demand.

Chair: Stefano Galelli, Cornell University, Ithaca, NY, United States

1 - Priority List Heuristic for the Stochastic Unit Commitment Problem

Luis Rojas, Universidad Católica del Norte, Antofagasta, Chile, Carlos Olivares

The Unit Commitment Problem (UCP) is a fundamental optimization challenge in power systems operations, aiming to determine the optimal schedule of generating units to meet demand while minimizing costs. Incorporating renewable energy introduces stochastic generation patterns that significantly increase the computational burden. To address this, we propose a priority list heuristic for the Stochastic UCP, which generates an initial solution while ensuring that technical unit commitment constraints are met. This significantly reduces the computational time when searching for integer solutions. This starting point enables faster convergence of the full stochastic optimization procedure while preserving solution quality. Results from a case study using different power system instances and algorithmic details will be presented.

2 - Trends and Directions in Healthcare Supply Chain Research: a Data Mining Approach

Seunghye Ha, School of Business Administration, Kyungpook National University, Daegu, Korea, Republic of, Sungsu Kim

This study analyzes research trends in the field of healthcare supply chain management and suggests future research directions by applying topic modeling to approximately 500 international academic papers published between 2001 and 2024, retrieved from the Scopus and Web of Science databases. The analysis identified eight major research topics, including "Demand and Delivery Optimization," "Healthcare Logistics and Inventory Management," and "Crisis Response and Resource Allocation during Pandemics." In recent years, emerging topics such as "Supplier Selection and Risk Mitigation" and "Blockchain and Technology Applications" have gained increasing attention. The study also identifies central keywords such as Technology, Hospital, Procurement, Blockchain, and Supplier, which frequently appear in relation to major themes.

This study provides a systematic trend analysis based on international literature, offering insights into the thematic development and recent trajectories of research in the field of healthcare supply chains. By presenting representative papers for each topic, the study serves as a practical reference for researchers seeking to define actionable research questions and explore diverse applications. Furthermore, by identifying future research directions through quantitative analysis, the study aims to contribute to the academic accumulation and theoretical advancement of healthcare supply chain research.

3 - Optimizing Grid Planning Under Climate Uncertainty

Pin-Chun Cho, The University of Texas at Austin, Austin, TX, United States, Erhan Kutanoglu

Climate change is impacting the power grid in multiple ways compelling to rethink the processes and models used for grid planning. Rising temperatures, changing wind patterns, and evolving load profiles, and the variability of such factors across different locations are introducing new challenges to the spatial allocation of grid assets. In particular, identifying where to locate new renewable capacity and which existing plants to retire or reinforce has become more complex under climate uncertainty. We present a multi-objective optimization framework to support location-specific decisions for renewable generation siting, capacity replacement, and transmission reinforcement, incorporating high-resolution climate projections and operational constraints. The underlying model aims to identify infrastructure planning strategies that remain effective across a range of climate-shifted scenarios. We simulate weather-dependent load and renewable generation profiles using future projected climate data, capturing regional variation in future grid stress and resource availability. Using the optimization framework based on stochastic programming, we explore trade-offs among costs, emissions, and reliability in long-term planning. By explicitly modeling spatial and temporal correlations and climate-related uncertainty, we provide insights into how planning strategies should be optimized over time across multiple regions. A case study with a test grid on the footprint of Texas will show the potential benefits of optimization-based decision models linked to most up-to-date climate data to improve siting and retirement decisions, addressing a few of the challenges in energy transition under climate uncertainty.

4 - Assessing Temporal Aggregation Error in Capacity Expansion Models with Integrated Renewables, Grid, and Storage Constraints

Daniel Fontecha, KAUST, Jeddah, Saudi Arabia, Ricardo M. Lima, Omar Knio

Long-term investment decisions in the power sector require robust capacity expansion models (CEM) that minimize costs while meeting policy and reliability goals. Climate data, an essential input for CEM with renewables, is widely available, but its large size is cumbersome for linear optimization models with polynomial complexity. To address this, time aggregation techniques are used to reduce the dataset size, at the expense of accuracy. A well-designed aggregation method must therefore balance computational tractability and model fidelity.

A-priori clustering techniques, which define representative days before system design, are widely used but are inherently myopic, often leading to performance gaps when validated against the full dataset. More recent a-posteriori aggregation methods iteratively refine data selection using feedback from optimization results and have shown superior accuracy for models without spatial or temporal binding constraints. However, such constraints (like ramping limits, storage dynamics, and transmission flows) are fundamental to modern CEM and critical to capturing the operational flexibility of renewables.

This study evaluates the performance of two a-priori and one a-posteriori temporal aggregation techniques within a CEM with renewable and storage technologies, ramping limits, and inter-nodal transmission. We apply these methods to two case studies: a fully renewable system and a scenario with a fixed 2050 emission target. Using over 30 different climate datasets, we ensure statistical significance. The aggregation technique performance is assessed in terms of system cost, lost load, emissions, and computation time. Based on our findings, we offer practical recommendations and propose an enhanced aggregation approach informed by observed limitations.

5 - Coupled Modeling of Hydropower and Grid Operations in Regional Power Markets

Stefano Galelli, Cornell University, Ithaca, NY, United States, Hisham Eldardiry, Phumthep Bunnak

As wind and solar power increasingly shape electricity markets, hydropower is expected to play a more prominent role in maintaining grid flexibility and reliability. This shift underscores the need to understand how hydropower dispatch decisions respond to changing hydrological and demand conditions. Yet modeling these decisions remains difficult, as they depend simultaneously on the evolving states of both river basins and power systems. Traditional modeling soft-coupling approaches fall short, as they typically enforce one-way information flow, failing to capture dynamic feedbacks between water and energy systems.

Here, we present a tightly integrated modeling framework that hard-couples a reservoir system model (VIC-Res) with a large-scale power system simulator (PowNet). VIC-Res represents and optimizes hydropower operations, while PowNet performs unit commitment and economic dispatch. A dedicated coupler coordinates both models, synchronizing their time steps and ensuring convergence in simulated hydropower generation before advancing the system state.

We apply this framework to the Lao PDR–Thailand–Malaysia–Singapore Power Integration Project (LTMS-PIP), which depends heavily on hydropower from the Mekong and Chao Phraya basins. Our setup includes four PowNet instances (one per national grid) and two VIC-Res models (one per basin). Over a decade-long simulation, we demonstrate that integrating the hydrological and electrical system states into dispatch decisions improves overall system performance—lowering operational costs and reducing CO₂ emissions.

Navigating Deep Climate Uncertainty in Energy Modeling

Invited Session

ENRE: Energy-Climate

Chair: Martha Christino, University of Michigan, Ann Arbor, MI, 48109, United States

Co-Chair: Michael Craig, University of Michigan, Ann Arbor, MI, United States

1 - Hydrochips: Coupler-Ready High Performance Pliers for Integrating River-Reservoir and Power System Models in Hydropower Management

Sean Turner, Oak Ridge National Laboratory, Oak Ridge, TN, United States, Stefano Galelli, Quentin Ploussard, Matija Pavicevic, Phumthep Bunnak

Hydropower operators face a daily challenge of coordinating power generation across their assets while faced with uncertain inflow and electricity price conditions. Performing this task may involve first optimizing generation using Unit Commitment / Economic Dispatch tools, then testing the resulting schedule with river routing and reservoir models to ensure feasibility with respect to river and reservoir dynamics. This is often a manual, multi-departmental process that can be inefficient and suboptimal, potentially leading to spilled energy and missed generating opportunities. We introduce the concept of a Coupler-ready High-Performance Plier (CHiPP) for addressing water-energy problems of this nature. CHiPPs are fast, open architecture tools, able to address the key dynamics of power and river systems models applied in the hydropower industry while being amenable to external control via a coupler. Development of CHiPPs will allow for in-depth experimentation and exploration into the value of hard-coupled water-power models. Using the Cumberland River System as an example case, we will present “Powersheds”—a high performance CHiPP for hourly water operations simulation in multi-reservoir cascades. Powersheds converts a desired multi-asset generating schedule to a sequence of water releases, considering turbine efficiencies with varying pool and tailwater elevations, reservoir bathymetry, river routing and other nuances of the river system. By identifying infeasibilities in the desired generating schedule, Powersheds is primed for interacting with production cost models by providing automated feedback on river system constraints. This research advances operations research methodologies for hydropower management.

2 - Combining Synthetic Generators, Machine Learning, and Open-Source Dcopf Models for Current and Future Grid Stress-Testing

Jordan Kern, North Carolina State University, Raleigh, NC, United States, Duc-Huy Pham, Troy Wibowo

Compound extremes (i.e., simultaneous occurrence of extreme values across regions and/or variable types) may pose the greatest resource adequacy risks for power systems. Given the scales and the number of variables involved, for any assumed state (past, present, or future), available weather datasets inevitably fail to capture all events that could pose risks to system reliability. Trying to address this limitation by increasing the sample size risks selection of data from non-representative system (i.e., climate) states. To overcome this, synthetic weather generators can be trained on empirical data and then used to generate new time series of unlimited size. Here, we demonstrate a framework for creating synthetic weather time series for use in predictive machine learning models of electricity load, wind power production, and solar power production, aggregated to the balancing authority (BA) level. We apply a heuristic dimensionality reduction to gridded weather data and then train a synthetic weather generator on this reduced data. We create synthetic ensembles of weather data across spatial scales ranging from a single electrical balancing authority (BA) to the contiguous U.S., and then pass these data through ML models trained to predict hourly electricity load, wind, and solar capacity factors for every BA in the U.S. We show how the resultant synthetic datasets can be used to perform stress testing of bulk power systems using open-source nodal DCOPF models developed in house. The “full stack” (synthetic weather generator, ML models, and grid simulation models) is publicly available for the entire contiguous U.S.

3 - Understanding Climate Change Induced Risk for Investment Pathways in the Bulk Power System

Martha Christino, University of Michigan, Ann Arbor, MI, United States

The increasing frequency and intensity of severe weather events, driven by anthropogenic climate change, poses significant challenges to the reliability of energy systems. Existing research has focused on quantifying the threat to the electricity grid and exploring system operations and capacity expansion needs under multiple future climate realities but lacks analysis of the deep uncertainty created by climate change. Our study aims to explore this deep uncertainty to understand how the value of bulk power system investment pathways change across different future climate realities. We propose a transdisciplinary approach combining dynamically downscaled climate data, an open-source resource adequacy model, and a cross-model analysis framework. We introduce a novel methodology that uses a “risk score” to quantify the robustness of an investment pathway’s resource adequacy contribution under multiple potential future climate realities. We find certain pathways in wind, solar, and storage investments can consistently improve system resource adequacy across future climate realizations, making them robust to the deep uncertainty of future climate states. By developing a risk versus cost frontier, we identify the trade-offs between investment strategies, allowing for informed decision-making amid the complexities introduced by climate change.

4 - Evaluating the Impact of Climate Change and Its Influence on Water Systems on Electricity System Planning in the Western Interconnect

Julia Szinai, Lawrence Berkeley National Laboratory, Berkeley, CA, United States

In the Western US, rising temperatures and changing precipitation patterns from climate change impact the electricity system directly (such as through cooling loads), as well as indirectly through the interdependent water sector (such as through hydropower and energy demand related to water). However, electricity planning models typically ignore these climate and water interactions when considering future investment. We therefore couple detailed water resources and grid capacity expansion models to optimize how the Western Interconnection can both adapt to climate change and develop carbon-free generation by 2050, while accounting for uncertainties from the interactions and climate vulnerabilities of the water sector. We first quantify the range of plausible hydropower and energy demand changes under a large ensemble of future climate scenarios, and then compare the generation and transmission buildout, dispatch, and cost of each climate scenario against a baseline wherein the Western Interconnection reaches carbon-free generation but has a stationary climate. Our results show that cooling and water-related loads increase in all climate scenarios by 2050, which is compounded in most cases by decreases in hydropower generation. The added uncertainty from having to adapt to the worst case climate scenario could increase infrastructure investment costs by up to 7%, highlighting the substantial consequences for grid planning from climate and water interactions and uncertainties.

5 - A National Screening Assessment of Climate Risks to U.S. Hydropower Functions

Jacob Mardian, EPRI, Toronto, ON, Canada, Mark Christian

Hydropower is a unique form of power generation, providing renewable and dispatchable electricity and a range of other services critical to public safety, the economy, and the environment. As climate change alters precipitation patterns and water availability, it is important to consider the impacts on the diverse range of hydropower functions, including power generation, flood control, navigation, recreation, irrigation, municipal water supply, and environmental support. Effectively balancing these multiple, sometimes competing, priorities require effective coordination of available water resources and is dependent on the design of the hydropower facility. Hydropower plants were designed to effectively provide services under historical climate conditions. However, climate change continues to drive increasingly dynamic and non-stationary river conditions, so it is important to review the adequacy of current design and integrate future hydrological regimes into plant modernization. In this study, we develop a series of Hydrological Key Performance Indicators (HKPIs) to project future changes in the ability of ~1,000 hydropower plants in the U.S. to continue providing these critical functions over the near-term (2020 to 2059) and the long-term (2060 to 2099). An HKPI is developed for each function that quantifies projected changes in a relevant hydrological quantity against the plant characteristics describing its ability to cope with those changes. The results show significant variations across hydropower functions, regions, as well as models and scenarios, demonstrating the need for site-specific vulnerability assessments and robust decision-making frameworks under deep uncertainty.

Interpretable LLM/Deep Learning

Invited Session

Health Applications Society

Chair: Shixing Yu, Cornell University, New York, 14850, United States

Co-Chair: Kyra Gan, Cornell Tech, Cornell University, New York, NY, United States

1 - Tbd

Shixing Yu, Cornell/ Cornell Tech, Ithaca, NY, United States

Interpreting the behavior of large language models in critical domains like medical QA requires understanding how internal representations influence final outputs. We propose a framework that extends influence functions, a classical technique from statistics and model interpretability, to analyze how intermediate transformer representations and their compressed sparse autoencoder encodings affect an LLM’s outputs. By inserting a sparse, interpretable bottleneck representation $\$H\$$ (via an encoder $\$E\$$) between an intermediate layer representation $\$R_i\$$ and the model’s final output $\$O_i\$$, we can trace how changes in these hidden states propagate to outputs. This framework combines theoretical tools (Taylor expansions, gradients/Hessians) with practical strategies (autoencoder design for interpretability) to yield a comprehensive approach suitable for research on interpretability and causal analysis of LLMs.

We first recap classical influence functions and draw analogies to intermediate representations. We then develop an influence quantification between an intermediate representation $\$R_i\$$ and model output $\$O_i\$$ using gradient and Hessian-based analyses. Next, we extend this to the two-step path $\$R_i \rightarrow H \rightarrow O_i\$$, leveraging the deterministic SAE mapping $\$H = E(R_i)\$$. We discuss how to design the sparse hidden state $\$H\$$ for maximum interpretability (e.g. disentangled or semantically grounded features). Throughout, we integrate insights from recent work on topic-based influence functions using variational autoencoders

2 - Toward Universal Steering and Monitoring of AI Models

Adityanarayanan Radhakrishnan, MIT and Broad Institute of MIT and Harvard, Cambridge, MA, United States, Daniel Beaglehole, Enric Boix-Adsera, Mikhail Belkin

Modern AI models have learned much of human knowledge, yet understanding of their internal representation of this knowledge remains elusive. Characterizing the structure and properties of this representation will lead to improvements in model capabilities and development of effective safeguards. Building on recent advances in feature learning, we develop an effective, scalable approach for extracting linear representations (vectors and subspaces) of general concepts in large-scale AI models (language models, vision-language models, and reasoning models). We show these representations enable model steering, through which we expose vulnerabilities, mitigate misaligned behaviors, and improve model capabilities. Additionally, we demonstrate that concept representations are remarkably transferrable across human languages and combinable to enable multi-concept steering. Through quantitative analysis across hundreds of concepts, we find that newer, larger models are more steerable and steering can improve model capabilities beyond standard prompting. We show how concept representations are effective for monitoring misaligned content (hallucinations, toxic content). We demonstrate that predictive models built using concept representations are more accurate for monitoring misaligned content than using models that judge outputs directly. Together, our results illustrate the power of using internal representations to map the knowledge in AI models, advance AI safety, and improve model capabilities.

3 - Multimodal Representation Learning for Clinical Decision Support

Sana Tonekaboni, Broad institute of MIT and Harvard, Cambridge, MA, United States

As healthcare data becomes increasingly multimodal—spanning imaging, waveforms, text, and structured records—there is growing interest in methods that can learn from these diverse sources in a unified way. In this talk, I will discuss advances in multimodal representation learning, focusing on how they can help bridge the gap between heterogeneous clinical inputs and downstream decision-making. I'll outline key challenges in aligning and interpreting information across modalities, and highlight design choices that affect generalization and interpretability in clinical settings. To ground the discussion, I'll present our recent work integrating electrocardiogram (ECG) signals and cardiac MRI to learn joint representations that improve cardiovascular risk assessment. Our findings show how shared and modality-specific patterns can be disentangled to reveal clinically meaningful insights, such as structural-functional relationships in the heart.

4 - Representation Learning for Cell and Tissue Biology: from Multimodal Integration to Function

Xinyi Zhang, Broad Institute of MIT, Boston, MA, United States

Biological processes involve complex interactions across different scales, from intracellular changes in gene expression and chromatin organization to intercellular communication and tissue organization. Comprehensive understanding of cell and tissue states as well as disease mechanisms requires computational methods that can integrate diverse data types. First, we introduce a graph-based autoencoder that integrates gene expression, spatial coordinates, and cellular imaging into a joint representation. Applied to a mouse model of Alzheimer's disease, this approach reveals spatio-temporal disease patterns and associated nuclear and transcriptional changes. To address the lack of scalability in multimodal and sequencing-based assays, we develop unsupervised image autoencoder frameworks that extract cell state information from imaging data and enables the identification of cell state and tissue organization based on imaging. The proportions and spatial organization of these states predict diagnosis, phenotype, and mutation status, providing scalable biomarkers and insight into chromatin and microenvironmental involvement.

Building on the richness of cellular images, we developed PUPS (Predictions of Unseen Proteins' Subcellular localization), which combines protein language models with image inpainting to predict protein localization. PUPS overcomes experimental limitations in scalability and reveals associations between protein localization variability and biological function. Finally, we introduce APOLLO, which disentangles shared and modality-specific information in multimodal datasets. Applied to transcriptomic and imaging data, APOLLO identifies shared gene pathways and links localization variability to cellular compartment morphology. Together, these frameworks enable integration of diverse modalities, advancing our understanding of cell states, tissue organization, and disease.

1 - Boosting Kidney Transplant Access: Interpretable AI to Discover Opportunities for Xenografted and Cryopreserved Organs

Thomas Dailak, Massachusetts Institute of Technology, Cambridge, MA, United States, Ju Young Lee, Madeleine Pollack, Prateek Gautam, David Cron, Mehmet Toner, Korkut Uygun, Heidi Yeh, Swati Gupta

Recent breakthroughs in cryopreservation and xenotransplantation offer new possibilities for expanding the supply of viable donor kidneys. However, it remains unclear where in the current transplantation pipeline these innovations would have the maximum impact. In this work, we use interpretable AI methods to identify systemic inefficiencies and opportunities for placing either cryopreserved or xenografted organs. We focus on two key questions: (i) can we quantify the supply-demand gap across different patient groups and regions, using organ quality as a proxy? and (ii) can we develop predictive tools to identify regions where a given organ is most likely to be accepted, based on local clinical behavior? We will present our analysis of over 8 million donor-patient match-run offers from UNOS (2016–2019), using multimodal predictive models for three demographically diverse regions. We introduce a new metric for quantifying the supply demand gap in this complex pipeline, and show organ profiles that would be most useful targets for xenografting. We further identify areas of model uncertainty based on organ quality, data imbalance and the region of performance, and discuss the multi-criteria considerations for organ placement using cryopreservation. Our interpretable methods include an extension of SHAP analysis for multimodal models, which further reveals key donor, recipient, and text-feature interactions that are predictive of offer acceptance. This presentation is based on joint work with Ju Young Lee, Madeleine Pollack, Prateek Gautam, David Cron, Mehmet Toner, Korkut Uygun, Heidi Yeh, and Swati Gupta.

2 - AI Meets Peer Review: The Good, the Bad, and the Ugly

Nihar Shah, Carnegie Mellon University, Pittsburg, PA, United States

As AI becomes increasingly integrated into academic workflows, their influence on scientific peer review is both promising and concerning. This talk will explore three facets of this evolving intersection.

The Good: AI's ability to execute aspects of peer review that are challenging for human reviewers.

The Bad: Vulnerabilities in the review process to fraud such as collusion rings.

The Ugly: Reviewers using AI to generate reviews, and detection of such usage.

3 - Q-Learning with Posterior Sampling

Priyank Agrawal, Columbia University, New York, NY, United States, Shipra Agrawal

Bayesian posterior sampling techniques have demonstrated superior empirical performance in many exploration-exploitation settings. However, their theoretical analysis remains a challenge, especially in complex settings like reinforcement learning. In this talk, I will introduce Q-Learning with Posterior Sampling (PSQL), a simple Q-learning-based algorithm that uses Gaussian posteriors on Q-values for exploration, akin to the popular Thompson Sampling algorithm in the multi-armed bandit setting. I will show that in the tabular episodic MDP setting, PSQL achieves a regret bound of $\tilde{O}(\sqrt{SAT})$, closely matching the known lower bound of $\Omega(\sqrt{SAT})$. Here, S, A denote the number of states and actions in the underlying Markov Decision Process (MDP), and $T=KH$ with K being the number

of episodes and H being the planning horizon. This work provides several new technical insights into the core challenges in combining posterior sampling with dynamic programming and TD-learning-based RL algorithms, along with novel ideas for resolving those difficulties. I hope this will form a starting point for analyzing this efficient and important algorithmic technique in even more complex RL settings.

4 - Cost-Averse Learning with Mixed-Fidelity Bandit Feedback

Madeleine Pollack, Massachusetts Institute of Technology, Cambridge, MA, United States

In today's data-driven world, decision-makers face a complex landscape of diverse data sources. They must navigate a mosaic of high- and low-fidelity information, each with its own cost implications and impact on decision reliability. The quality of information directly affects operational performance, so care must be taken to de-bias, de-noise, and properly integrate data from these differing-fidelity sources. This challenge is particularly acute when faulty information can lead to significant adverse outcomes in systems such as human-AI pipelines in decision-making (e.g., content moderation, labeling, fact-checking), prescriptive medicine, supply chains, and other applications. We introduce a new bandit model to study the trade-off between quality of feedback and the cost of the feedback mechanism. We show that without distinguishing between the feedback mechanisms generating the observed rewards, algorithms like UCB can incur linear regret. We propose a new Combined-Learning UCB algorithm that can calibrate the initially unknown fidelities of different feedback mechanisms. We show that in certain settings, this algorithm outperforms a mechanism-conscious version of UCB1. We finally showcase the impact of our algorithms on a dataset from a call center, where experienced callers can convert a higher call volume into sales, compared to new callers by enabling cost-aware decision-making in dynamic environments. This approach contributes to more reliable and robust decision-making, particularly in settings where data quality varies widely.

5 - Practical Contextual Bandits for Large-Scale Structured Discrete Constrained Optimization Problems

Pavithra Harsha, IBM Research, Yorktown Heights, NY, United States, Chitra Subramanian, Naoki Abe, Shivaram Subramanian, Amadou Ba, Kevin Fernandez, Mauricio Longinos

We address the contextual bandit problem for high-dimensional combinatorial action spaces involving a class of structured discrete constrained optimization problems. In this setting, key quantities within the optimization formulation, such as performance indicators contributing to the objective or constraints, must be estimated from data during the trial sequence of optimized actions. These problems frequently arise in the many operations management domains including IT resource allocation and retail assortment price optimization. We propose a novel, practical, and transparent approach based on general-purpose regression oracles, leveraging Inverse Gap Weighting (IGW) for seamless integration within an optimization framework. IGW sampling is efficiently managed by: (a) a column generation reformulation of the underlying Mixed Integer Programming (MIP) model which allows for flexible lower-level predictors, causal coherence, and efficient representation of large action spaces; (b) a diverse solution pool generation to balance the exploration-exploitation trade-off in large action spaces. To address non-smoothness in the reward function due to optimization constraints, we incorporate a risk-averse phased learning strategy. We validate our approach on a real world auto-scaling problem in IT automation, achieving a significant reduction in cumulative regret through skillful exploration, with additional gains from risk-averse methods that effectively manage constraint violations.

1 - The Value of Incorporating Uncertainty in School District Design

Aysu Ozel, Kennesaw State University, Kennesaw, GA, United States, Karen Smilowitz

Long-term public school district design decisions, such as opening or closing schools, drawing attendance boundaries, and placing programs in schools, can significantly shape students' educational experiences. While such decisions aim to provide students with continuity, they are often made under uncertainty in student enrollment. We explore the value of incorporating uncertainty into school district design through a family of models that differ in their timing of long-term decisions and how they account for uncertain enrollment. We develop scenario-based models that support multi-year school district design under enrollment uncertainty, with decision structures ranging from fixed, one-time decisions to adaptive, scenario-dependent ones. To evaluate these models, we generate realistic enrollment scenarios using historical enrollment data and census-derived spatial distributions for representative simulated school districts. These scenarios reflect structured patterns in student progression and capture both aggregate trends and geographic variation in enrollment changes. Our analysis examines the trade-offs between model complexity and solution robustness. In particular, we assess when and how stochastic and dynamic models may provide meaningful advantages over simpler approaches, given the structured yet uncertain nature of enrollment shifts. This work contributes to the broader literature on decision-making under uncertainty by offering insights into the conditions under which uncertainty-aware models can enhance the effectiveness of school district design decisions.

2 - Perspectives on OR for Societal Good, a Review of the Last 10 Years, and a Call for a Research Agenda for the Next 10 Years

Matt Kammer-Kerwick, The University of Texas at Austin, Austin, TX, United States

This presentation will provide a high-level overview of 10 years of collaborative research in Operations Research (OR) for the Social Good and a call for a new or reaffirmed research agenda for the next decade.

As context, in 2017 National Science Foundation funded a workshop on promising research directions for applications of operations research and data analytics toward the disruption of illicit supply networks like human trafficking as a specific social good thematic focus. The workshop was funded by the NSF's Operations Engineering (ENG) and the Law & Social Sciences Program (SBE) under grant # CMMI-1726895. Participants addressed the opportunity to apply advances from the fields of operations research, management science, analytics, machine learning, and data science toward the development of disruptive interventions against illicit networks.

This presentation will briefly review the proposed research agenda from that workshop and some of the research streams that emerged. Discussion will be invited about an agenda for the next 10 years.

3 - Collaboration in Antitrafficking Efforts: a Network Interdiction Problem

Priscila de Azevedo Drummond, Northeastern University, Boston, MA, United States, Kayse Maass

Labor trafficking is a ubiquitous issue in the U.S. affecting various sectors from agricultural workers to the assessment of imported goods. combating labor trafficking has many different facets. The efforts to combat and prevent this crime involve numerous agencies, each with different areas of expertise and communities they serve. These agencies often have varying values and operational procedures, which can complicate collaboration. While teamwork has been shown to enhance the effectiveness of labor trafficking mitigation strategies, data supporting this effectiveness is scarce, and thorough evaluations are even rarer. Moreover, collaboration requires time and resources, and most anti-human trafficking operations run under strict budget constraints. The lack of data hinders our ability to develop responses based on historical evaluations. In these situations, analytical tools like Network Indicator Models can provide insights to help us understand how collaboration functions within this context.

4 - Developing a Systems-Focused Tool for Modeling Lung Cancer Screening Resource Needs in the Veteran's Affairs Health Service

Kira Woodhouse, Northeastern University, Boston, MA, United States

Within past decades, the medical field has experienced a rapid expansion in the number of available cancer screening interventions. While it is known that cancer screenings have many benefits on both a patient- and hospital-level, the question of how to implement them in these settings remains. In a partnership between the University of Michigan and the Veteran's Affairs (VA) Lung Precision Oncology Program, we examined the existing structures of Lung Cancer Screening (LCS) in the VA system through informational interviews and data collection. This was followed by collaborative system-mapping exercises with providers and the development of

calculation tools, both deterministic and stochastic. Such tools consider the patient volume, provider volume, provider tasks, and the cyclical nature of screening to produce estimations of the required staff hours for a scenario. Finally, we released these calculation tools to current staff of the LCS programs nationwide, aiding them in making informed decisions on both staffing levels and staff responsibilities.

5 - The Impact of Access to Food Retail Stores on Household Food Waste

Vijaya Chebolu-Subramanian, Drexel University, Philadelphia, PA, United States, Jennifer Quinlan

Food waste in the United States is estimated to be between 30–40% of the total food supply, with households responsible for the majority of waste along the downstream segment of the supply chain. This waste is valued at approximately \$240 billion annually, representing both economic and environmental loss. The objective of this study was to examine the impact of access to food retail on household food waste across income levels in the United States. According to the U.S. Department of Agriculture, two primary indicators of household retail access are distance to food stores and vehicle ownership. Prior research suggests that access to retail stores can influence shopping frequency, impulse purchases, and overbuying behavior—all of which are linked to food waste. We administered two nationwide surveys ($n=1,103$; $n=816$) during 2023–2024, capturing household food waste patterns and shopping behaviors. Using ordered probit regression models, we found that greater distance to stores was significantly associated with increased food waste among lower-income households. Additionally, lack of vehicle ownership correlated with higher food waste across all income groups. Importantly, for lower-income households, the combination of long distances and no car ownership had a compounding effect on food waste. This study contributes to a deeper understanding of access barriers to retail stores—specifically distance and transportation—as critical factors influencing household food waste, particularly among lower-income populations. The findings highlight the need for further research and targeted interventions to reduce these barriers and support food waste reduction efforts.

1 - Active Set Identification and Rapid Convergence for Primal-Dual Degenerate Problems

Mateo Diaz, Johns Hopkins University, Baltimore, MD, United States, Pedro Izquierdo Lehmann, Haihao Lu, Jinwen Yang

Primal-dual methods for solving optimization problems with functional constraints often exhibit a distinct two-stage behavior. Initially, they converge towards a solution at a sublinear rate. Then, after a certain point, all iterates accurately identify the set of active constraints, after which their convergence accelerates to a much faster linear rate. Theory characterizing this phenomenon spans more than three decades. However, most existing work only guarantees eventual active set identification and relies heavily on nondegeneracy conditions, such as strict complementarity, which frequently fail to hold in practice. We introduce mild conditions on the problem geometry and algorithm under which this phenomenon provably occurs. Our guarantees are entirely nonasymptotic and, importantly, do not require any nondegeneracy assumptions. We demonstrate that our framework encompasses several widely-used algorithms, including the proximal point method, primal-dual hybrid gradient method, alternating direction method of multipliers, extragradient method, and optimistic gradient method.

2 - A Hybrid Newton-CG-MR Method with Worst Case Complexity Guarantees for Nonconvex Optimization

Michael O'Neill, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Chengze Xie

Inexact Newton methods have a long history of popularity in large scale, nonlinear optimization. We propose a new Newton type algorithm which uses a combination of the conjugate gradient (CG) and minimum residual (MR) solvers for linear systems to generate search directions. The new method outperforms both Newton-CG and Newton-MR methods on a wide range of test problems while maintaining optimal worst-case complexity guarantees for nonconvex optimization.

3 - Solving Convex Quadratic Optimization with Indicators over Graphs with Small Treewidth

Aaresh Bhathena, University of Michigan, Ann Arbor, MI, United States, Salar Fattahi, Andres Gomez, Simge Kucukyavuz

This paper studies convex quadratic optimization problems where each continuous variable is coupled with an indicator variable. Our focus is on the structured case in which the matrix Q defining the quadratic term is positive definite and whose sparsity pattern corresponds to the adjacency matrix of a graph with small treewidth. We introduce a dynamic programming algorithm that solves this problem in linear time with respect to n , under the assumptions of a fixed condition number of Q , fixed treewidth, and linear volume growth of the underlying graph. Computational experiments on synthetic data demonstrate that our algorithm significantly outperforms state-of-the-art mixed-integer quadratic programming solvers on instances with over 20,000 indicator variables. To demonstrate the practical utility of the method, we develop a novel framework for joint forecasting and anomaly detection by extending exponential smoothing to handle time series data with outliers. This framework is applied to various real-world instances from the Numenta Anomaly Benchmark, which includes traffic and AWS CloudWatch datasets.

4 - Proximal Random Reshuffling Under Local Lipschitz Continuity

Xiaopeng Li, Columbia University, New York, NY, United States, Cedric Jozs, Lexiao Lai

We study proximal random reshuffling (PRR) for minimizing the sum of locally Lipschitz or locally smooth functions and a proper lower semicontinuous convex function without assuming coercivity or the existence of limit points. The algorithmic guarantees pertaining to near approximate stationarity rely on a new tracking lemma linking the iterates to trajectories of conservative fields. One of the novelties in the analysis consists in handling conservative fields with unbounded values. In the locally smooth case, it improves the known convergence rate from nearly $\mathcal{O}(k^{-1/4})$ to nearly $\mathcal{O}(k^{-1/2})$.

5 - Parameter-Free Second-Order Methods for Min-Max Optimization

Ali Kavis, University of Texas at Austin, Austin, TX, United States

I will talk about an adaptive, line-search-free second-order methods with optimal rate of convergence for solving convex-concave min-max problems. By means of an adaptive step size, our algorithms feature a simple update rule that requires solving only one linear system per iteration, eliminating the need for line-search or backtracking mechanisms. Specifically, we base our algorithms on the optimistic method and appropriately combine it with second-order information. Moreover, distinct from common adaptive schemes, we define the step size recursively as a function of the gradient norm and the prediction error in the optimistic update. We first analyze a variant where the step size requires knowledge of the Lipschitz constant of the Hessian. Under the additional assumption of Lipschitz continuous gradients, we further design a parameter-free version by tracking the Hessian Lipschitz constant locally and ensuring the iterates remain bounded. We also evaluate the practical performance of our algorithm by comparing it to existing second-order algorithms for minimax optimization. Inspired by the adaptive design of the step size, we propose a heuristic initialization rule that performs competitively across different problems and scenarios and eliminates the need to fine tune the step size.

Decision-Focused Learning: Methodology and Applications

Invited Session

OPT: Optimization Under Uncertainty

Chair: Tito Homem-de-Mello, Universidad Adolfo Ibañez, Santiago, Chile

1 - Neural Decision Rule for Constrained Contextual Stochastic Optimization

Rui Gao, The University of Texas at Austin, Austin, TX, United States

Contextual stochastic optimization is a powerful paradigm for data-driven decision-making under uncertainty, where decisions are tailored to contextual information revealed prior to decision making. Recent advances leverage neural networks to learn expressive decision rules mapping contexts to decisions. However, enforcing feasibility under complex constraints remains a core challenge, as neural architectures do not inherently satisfy constraints in general. Existing approaches often incur significant computational overhead and lack theoretical guarantees.

In this paper, we propose a principled framework for training neural decision rules under general constraints via a single-loop algorithm that solves the augmented Lagrangian minimax problem. Our method eliminates the need for iterative projection layers or nested optimization loops, and provides provable guarantees on generalization, constraint violation, and suboptimality. Empirical results on constrained contextual decision tasks demonstrate that our approach outperforms state-of-the-art baselines in both efficiency and solution quality.

2 - Pessimistic Bilevel Optimization Approach for Decision-Focused Learning

Bernardo Pagnoncelli, SKEMA Business School, Lille, France, Diego Jimenez, Hande Yaman

The recent interest in contextual optimization problems, where randomness is associated with side information, has led to two primary strategies for formulation and solution. The first, estimate-then-optimize, separates the estimation of the problem's parameters from the optimization process. The second, decision-focused optimization, integrates the optimization problem's structure directly into the prediction procedure. In this work, we propose a pessimistic bilevel approach for solving general decision-focused formulations of combinatorial optimization problems. Our method solves an approximation of the pessimistic bilevel problem using a specialized cut generation algorithm. We benchmark its performance on the 0-1 knapsack problem against estimate-then-optimize and decision-focused methods, including the popular SPO+ approach. Computational experiments highlight the proposed method's advantages, particularly in reducing out-of-sample regret.

3 - Predict and Optimize in Energy Markets

Pascal Van Hentenryck, ISyE Georgia Tech, Atlanta, GA, United States

This presentation reviews the fundamentals of Predict and Optimize for Energy markets applications. It discusses their benefits on practical applications, computational issues that arise in practice, and how they can be addressed. In particular, it reviews how primal and dual optimization proxies can be helpful in speeding up decision-focused learning with negligible loss in accuracy.

4 - A Fully First-Order Method for Decision-Focused Learning

Kai Wang, Georgia Institute of Technology, Atlanta, GA, United States

Decision-focused learning (DFL) aims to train predictive models by optimizing downstream decision quality rather than traditional predictive accuracy. While recent algorithms have integrated optimization directly into the training pipeline to achieve decision-focused learning, they often rely on second-order derivatives or surrogate losses, limiting their scalability and applicability in large-scale or constrained settings. In this talk, I will introduce a fully first-order method for DFL, grounded in recent advances in bilevel optimization algorithms. Our approach enables efficient end-to-end training using only first-order gradients by reformulating the decision problem with a smooth penalty, allowing gradients to backpropagate through the optimization layer without requiring differentiation through exact solvers. I will discuss both the theoretical convergence guarantees of our method and the empirical results demonstrating strong computation advantage and performance on large-scale problems. This work on fully first-order DFL advances the scalability and practicality of decision-focused learning by eliminating key computational bottlenecks.

5 - An Adaptive-Partition Method for Decision-Focused Learning

Tito Homem-de-Mello, Universidad Adolfo Ibáñez, Santiago, Chile

Data-driven optimization problems with contextual information have given rise to a number of new approaches that integrate the estimation and optimization steps. In this talk we consider one such approach, which formulates the problem of estimating the parameters for the learning method as a bilevel optimization model with multiple lower levels. While such a formulation is provably convergent to the optimal parameters, the model is computationally challenging. We discuss an approach based on the Adaptive Partition Method (APM) introduced in the literature for two-stage stochastic optimization. With the APM approach, the number of lower level problems can be reduced considerably. We illustrate the method with an application to the optimization of microgrids in power systems.

1 - Accelerating Low-Rank Factorization-Based Semidefinite Programming Algorithms on GPU

Qiushi Han, UNIVERSITY OF ILLINOIS AT URBANA - CHAMPAIGN, Urbana, IL, United States, Zhenwei Lin, Hanwen Liu, Caihua Chen, Qi Deng, Dongdong Ge, Yinyu Ye

In this paper, we address a long-standing challenge: how to achieve both efficiency and scalability in solving semidefinite programming problems. We propose acceleration techniques for a wide range of low-rank factorization-based first-order methods using GPUs, making the computation much more efficient and scalable. To illustrate the idea and effectiveness of our approach, we use the low-rank factorization-based SDP solver, LoRADS, as an example, which involves both the classic Burer-Monteiro method and a novel splitting scheme with a starting logarithmic rank. Our numerical results demonstrate that the accelerated GPU version of LoRADS, cuLoRADS, can solve huge-scale semidefinite programming problems with remarkable efficiency. By effectively leveraging GPU computational power, cuLoRADS exhibits outstanding performance. Specifically, it can solve a set of MaxCut problems with $10^7 \times 10^7$ matrix variables in 10 seconds to 1 minute each on an NVIDIA H100 GPU with 80GB memory, whereas previous solvers demonstrated the capability of handling problems of this scale, required at least dozens of hours per problem on CPUs. Additionally, cuLoRADS shows exceptional scalability by solving 1) a MaxCut problem with a 170 million $\times$ 170 million matrix variable and 2) a Matrix Completion problem with a 20 million $\times$ 20 million matrix variable and approximately 200 million constraints, both in a matter of minutes.

2 - Gpu-Based Mathematical Programming

Haihao Lu, MIT, Cambridge, MA, United States, Jinwen Yang

In this talk, I will provide an overview and recent updates on my group's research in GPU-based mathematical programming, with a focus on linear programming, convex quadratic programming, semidefinite programming, and potentially other related topics.

3 - Advances in Nvidia CuOpt : Open Source Optimization on GPUs

Alex Fender, NVIDIA, Santa Clara, CA, United States

cuOpt is NVIDIA's solver for decision optimization, built for accelerated architectures. This talk introduces its core capabilities and highlights recent advancements in both design and integration.

A major milestone this year is the first open-source release of cuOpt under the Apache 2.0 license, supported by an active ecosystem of researchers, solvers and modeling tools. We'll explore how cuOpt leverages recent hardware to push the boundaries of decision optimization performance. Attendees will gain a deeper understanding of how cuOpt bridges the gap between research on parallel algorithms and real-world systems.

4 - Distributed Hybrid Compute for Large-Scale MIP and LP Optimization

Mark Ostroot, Simpleroose, St. Louis, MO, United States

Recent advances in GPU computing have opened new possibilities for accelerating mixed-integer and linear programming. At SimpleRose, we've been exploring distributed CPU/GPU hybrid compute architectures that leverage NVIDIA's cloud-scale hardware to push the boundaries of what's solvable. We'll share early insights from our ongoing work, including integration efforts inspired by frameworks like cuOpt, and discuss the challenges and opportunities in scaling optimization solvers across heterogeneous compute environments.

5 - Latest Optimization Benchmark Results

Hans Mittelman, Arizona State University, Tempe, AZ, United States

A selection of our optimization software benchmarks will be presented.

1 - Cutting Planes for Mixed-Integer Semidefinite Programming

Jan Kronqvist, KTH Royal Institute of Technology, Stockholm, Sweden, Johanna Skåntorp

Here we focus on Mixed-Integer Semidefinite Programming (MISDP), and specifically solving MISDP by outer approximation techniques. We present an alternative interpretation of some known types of cutting planes, and some new techniques to derive cuts with more desirable properties. We also present a new primal heuristic that also builds on an outer approximation concept that can both find feasible solutions and produce cutting planes for the main algorithm.

2 - Revisiting Composite Relaxations from a Lifting Lens

Haisheng Zhu, Purdue University, West Lafayette, IN, United States, Taotao He, Mohit Tawarmalani

We develop a new relaxation for nonlinear expressions in factorable programming. This relaxation generalizes composite relaxation by using a better abstraction of the inner function, which is constructed by the perturbation of the inner function. In limiting case, our relaxation converges to the convex hull of the graph of $f_1(x_1) f_2(x_2)$ over $X_1 \times X_2$ when f_1 and f_2 are convex. Our relaxation can improve factorable programming by introducing few auxiliary variables.

3 - Minlp for Regularized Symbolic Regression

Dimitrios Fardis, Georgia Institute of Technology, Atlanta, GA, United States, Radhakrishna Tumbalam Gooty, Nikolaos Sahinidis

Over the past decade, symbolic regression has been approached through MINLP formulations. We investigate various regularization metrics in the context of symbolic regression. We present extensive computational experimentation with the different metrics as we evaluate them for solvability of the resulting MINLP and for their ability to produce symbolic regression models that are simple and accurate.

4 - Globally Solving Assortment Optimization Problems via Multilinear Optimization Methods

Yating Zhang, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Taotao He, Zhongqi Wu, Huan Zheng

In assortment planning, the goal is to select a subset of products that maximizes expected revenue, assuming that consumers' stochastic choice behavior has already been estimated. This leads to a deterministic nonlinear 0-1 programming problem. In this talk, we investigate two such problems through the lens of multilinear optimization. For the correlated choice model, we use convexification techniques from fractional and multilinear optimization to obtain bounds-free MIP formulations, which are tighter than those obtained using Big-M approaches. For the ranking-based choice model, we reformulate the problem as a 0-1 multilinear optimization problem, and leverage consumers' rankings to derive multiple classes of valid inequalities. We also provide numerical experiments to demonstrate the efficiency of our formulations.

5 - On Local Search in Bilevel Mixed-Integer Programming

Eneko Clemente, University of Zurich, Zurich, Switzerland, Oleg Prokopyev

We consider Bilevel Mixed-Integer Linear Programs (Bilevel MILPs) in which a leader makes a decision, anticipating that a follower subsequently solves an optimization problem that depends on the leader's decision. Local search in Bilevel MILPs encounters two main challenges: (i) similar to many combinatorial optimization problems, local search may require an exponential number of improving steps to converge in the worst case, and (ii) each evaluation of the leader's objective function value requires solving the follower's problem, which can be inherently difficult. We address these two challenges by exploring generalized notions of local optimality that leverage the structural properties of BMILPs.

6 - Simple Randomized Rounding for Max-Min Eigenvalue Augmentation

Haeseong Yang, University of Pittsburgh, Pittsburgh, PA, United States

We consider the max-min eigenvalue augmentation problem: given $n \times n$ symmetric positive semidefinite matrices $M, A_1, \dots, A_m$ and a positive integer $k < m$, the goal is to choose a subset $I \subset \{1, \dots, m\}$ of cardinality at most k that maximizes the minimum eigenvalue of the matrix $M + \sum_{i \in I} A_i$. The problem captures both the Bayesian E-optimal design and maximum algebraic connectivity augmentation problems. In contrast to the existing work, we do not assume that the augmentation matrices are rank-one matrices, and we focus on the setting in which $k < n$. We show that a simple randomized rounding method provides a constant-factor approximation if the optimal increase is sufficiently large, specifically, if $\text{OPT} - \lambda_{\min}(M) = \Omega(R \ln k)$, where OPT is the optimal value, and R is the maximum trace of an augmentation matrix. To establish the guarantee, we derive a matrix concentration inequality that is of independent interest. The inequality can be interpreted as an intrinsic dimension analog of the matrix Chernoff inequality for the minimum eigenvalue of a sum of independent random positive semidefinite matrices; such an inequality has already been established for the maximum eigenvalue, but not for the minimum eigenvalue.

1 - Using Sensor Technology to Evaluate the Effects of a Price Promotion on Store Arrival Times

Ignacio Inostroza-Quezada, Universidad de los Andes, Santiago, Chile, Leonardo Epstein, Ronald Goodstein

Store managers frequently conduct marketing actions (MAs) to boost store traffic. Thus, measuring this traffic is crucial for assessing the effectiveness of such initiatives. Recently, store managers have gained access to sensors that record data continuously, enabling a more in-depth analysis of how their actions affect consumer behavior. In this talk, we present a novel approach that uses shopper-specific arrival times from periods outside a MA to build a counterfactual baseline for store traffic during this MA.

This baseline (i) assumes that the MA has not taken place, and (ii) is essential because a store cannot operate simultaneously with and without the MA. Next, we compare observed traffic data with the counterfactual baseline during the MA to evaluate its effect on store traffic. Finally, we assess the uncertainty of this effect during the MA. We illustrate our approach with data from an actual two-week price promotion, which showed an increase of 2880 store arrivals attributed to the promotion. Additionally, we complement our results with visual plots that help managers (i) examine the evolving effects of the promotion and (ii) understand the influence of time-varying covariates on consumer behavior.

2 - Optimal Job Recommendation Policies in Online Platforms with No-Shows and Stochastic Arrivals

HEDIEH SAZVAR, Northwestern University, Evanston, IL, United States, Seyed Iravani, Sanjay Mehrotra

The increasing reliance on online platforms to match job opportunities with agents highlights the need for efficient job recommendation policies. This paper aims to optimize job recommendations to maximize platform revenue. Our model considers different preferences and commitment probabilities for each agent-job pair, as well as varying number of agents required for different jobs. We propose a job recommendation model for implementation on a matching platform, where agents arrive sequentially to the platform (i.e., log in one after another). The objective is to maximize the revenue earned when agents complete their jobs.

We develop a heuristic algorithm to generate near-optimal recommendation policies under stochastic agent arrivals, and introduce an efficient objective function evaluation method to support large-scale implementation. Moreover, for platforms that can control the arrival sequence of agents, we identify the optimal sequence and derive the corresponding optimal recommendation policy to further improve platform revenue.

3 - A Rolling Recruitment Process Under Applicant Stochastic Departures

Chenyin Gong, Hong Kong University of Science and Technology, Hong Kong, China, People's Republic of, Qing Li

We study a rolling recruitment process in which applicants leave the system stochastically. Applicants arrive randomly over time, and each applicant is available for a random amount of time after they arrive. In each period, the recruiter must decide whether to stop or to wait. If they stop, they need to determine how many offers to make and whom to make offers to, and the applicants who do not receive an offer will leave the system. If the recruiter waits, more applicants will be available in the next period, while some who arrived earlier will leave. We model the process as a large-scale optimal stopping problem and show how the applicant qualifications, measured by scores, affect the recruiter's optimal policy. We find that the optimal stopping rule for each applicant's score is a two-threshold policy. If the score exceeds the higher threshold, the recruiter stops and makes an offer to the applicant and possibly to others. If the score falls below the lower threshold, the recruiter also stops but makes no offer to the applicant. If the score is in between the two thresholds, the recruiter waits. We further explore the impact on an applicant's likelihood of receiving an offer if their competitors become more qualified. We show that an applicant may be disadvantaged when competing against stronger applicants; however, they may also benefit from such competition. These results can be extended to allow multiple scores to change simultaneously.

4 - Optimal Inventory Disclosure and Pricing when Consumers Experience Stock-Out Inconvenience

Ceren Gultekin, Baruch College, CUNY, Graduate Center, New York, NY, United States, Tolga Aydinliyim, Qiuyu Fan

Retailers employ various non-price tactics to discourage consumers' strategic purchase deferrals and stimulate full price demand ahead of markdowns. One such strategy is to use availability indicators, which may suggest future stock-outs. These scarcity signals are commonplace, but recent studies argue they may backfire as consumers avoid transacting with limited-availability products. While these studies make empirical observations regarding how inventory disclosure affects sales, they fall short of prescribing actionable insights. We fill this gap by modeling optimal inventory disclosure and pricing decisions for retailers facing forward-looking consumers. We find that selective inventory disclosure (share low & mask high stock levels) remains optimal even when consumers experience an inconvenience cost at stock-out events. However, this does not imply that retailers should employ more inventory masking. In contrast, we show that inventory sharing must be more robustly utilized, i.e., at even higher stock levels relative to when consumers do not incur a stock-out inconvenience cost.

5 - Joint Estimation of the Arrival Rate and Customer Taste Coefficients from Censored Transactional Data

Weikun Xu, Washington State University, Pullman, WA, United States, Xinchang Wang

This work aims to jointly estimate the arrival rate of customers to a market and the nested logit model that forecasts hierarchical customer choices from an assortment of products. The estimation is based on censored transactional data, where lost sales are not recorded. The goal is to determine the arrival rate, customer taste coefficients, and nest dissimilarity parameters that maximize the likelihood of the observed data. The problem is formulated as a maximum likelihood estimation model that addresses two prevailing challenges in the existing literature: Estimating demand from *data with unobservable lost sales* and capturing *customer taste heterogeneity arising from hierarchical choices*. However, the model is intractable to solve or analyze due to the nonconcavity of the likelihood function in both taste coefficients and dissimilarity parameters. We characterize conditions under which the model parameters are identifiable. Our results reveal that the parameter identification is influenced by the *diversity of products and nests*. We also develop a sequential minorization-maximization algorithm to solve the problem, by which the problem boils down to solving a series of convex optimization models with simple structures. Then, we show the convergence of the algorithm by leveraging the structural properties of these models. We evaluate the performance of the algorithm by comparing it with benchmarks, using both synthetic and real data. Our findings show that the algorithm consistently outperforms the benchmarks. Moreover, our algorithm is particularly effective in estimating nested logit models with low dissimilarity parameters, yielding higher profitability compared to the benchmarks.

6 - Temporal Decision Making in High-Demand Sales Events with Limited Inventory

Fatima Ulubayova, McMaster University, Hamilton, ON, Canada, Yun Zhou, Mahmut Parlar

In this paper, we explore a critical challenge in high-demand sales events for limited products, where the imbalance between product availability and consumer demand introduces complex strategic behavior. We introduce a general model for such sales events, where a finite number of product units q are allocated among n arriving customers, with $q < n$. Our analysis considers scenarios involving one, two, and n competing customers, under both identical and heterogeneous arrival time distributions. As the number of competitors increases, the complexity of the allocation dynamics escalates. Using order statistics, we frame the problem as a benefit maximization problem from the customer's perspective and characterize the optimal arrival time based on an optimality condition. We further analyze the problem through a game-theoretic setting. For the case of two strategic customers, we model the scenario as a static game with complete and incomplete information with discrete and continuous strategies. In this setting, each player's effort affects their random arrival times. These efforts reflect the cost and inconvenience of attempting to arrive early, which may include opportunity costs, travel expenses, and the inherent hassle of the process. We prove the existence and uniqueness of the Nash equilibrium under general conditions and derive the explicit equilibrium in the special case where effort costs are zero for all players. Our results provide insight into the strategic behavior of consumers in high-demand sales settings and highlight the role of timing and effort in securing limited products.

1 - Cost-Effectiveness of a Lethal Ovitrap Network for Dengue Fever Prevention and Control

Yvonne Huijun Zhu, National University of Singapore, Singapore, Singapore, Joel Aik, Shuzhen Sim, Joel Goh

We conduct a system-level analysis of the cost-effectiveness of lethal ovitraps for dengue fever prevention, assessing both epidemiological outcomes and operational costs. The health benefits are captured using a multiple-infection epidemiological model and quantified as reductions in disability-adjusted life years (DALYs). Labor costs are estimated by modeling the maintenance workload for the ovitrap network as a Vehicle Routing Problem (VRP). Initially applied in Singapore, our analytical

framework is further extended through a simulation study evaluating the prospective cost-effectiveness of implementing a city-wide ovitrap network in Bangkok, Thailand.

2 - Enhancing Mental Health Service Accessibility on University Campuses: the Impact of Tragic Events

Xiaoyan (Amber) Liu, Santa Clara University, Santa Clara, CA, United States, Wilson Lin, Hussein El Haj

Student mental health has emerged as a pressing concern in higher education in recent years. In this paper, we examine how universities can enhance the accessibility of mental health counseling services on campus in light of the potential occurrence of tragic events. Leveraging a comprehensive dataset from the Counseling and Psychological Service (CAPS) center of a US university, we address this issue by first rigorously estimating the impact of a tragic event on the demand for mental health counseling services. We find that demand increases significantly, with individuals being more likely to make an appointment in the immediate days after the tragic event. Second, we propose a multi-period optimization model to allocate mental health clinicians in a rolling-horizon approach given a budget constraint, strategically balancing the trade-off between meeting immediate demand and anticipating future demand. We further show that properly accounting for the demand surge in the optimization framework can yield substantial gains compared to less sophisticated benchmarks.

3 - Hospital-Physician Integration and Quality Outcomes: the Role of Financial Incentives Faced by U.S. Hospitals

Jingyun Su, University of Miami, Coral Gables, FL, United States, Jong Myeong Lim, Masoud Kamalahmadi

The healthcare industry has witnessed a growing trend toward vertical integration between hospitals and physicians. Existing research presents mixed evidence regarding its impact on costs and outcomes. This study fills in the gap of examining relationship between hospital-physician vertical integration and performance under financial incentive programs.

4 - Regression Modeling in Healthcare: Group Fairness and Maximizing the Good

Margret Bjarnadottir, University of Maryland, College Park, MD, United States, Courtney Paulson, Daniel Smolyak

In many healthcare settings, it is both critical to consider fairness when building analytical applications but also uniquely unacceptable to lower model performance for one group to match that of another (e.g. fairness cannot be achieved by lowering the diagnostic ability of a model for one group to match that of another and lose overall diagnostic power). We therefore suggest a new modeling framework, FAIR, to maximize performance across imbalanced groups. This efficient approach overcomes many of the limitations in current approaches and manages to balance learning from other groups with tailoring prediction to the small focal group(s). FAIR has an added advantage in that it still allows for model interpretability in research and clinical settings. We demonstrate its usefulness with numerical and health data experiments.

1 - The Impact of List Diving on Post-Transplant Outcomes

Jingyao Huang, University of Missouri-Kansas City, Overland Park, KS, United States

Transplant programs frequently turn down deceased-donor kidney offers for the top-ranked potential transplant recipients (PTRs) at their centers and utilize the kidneys for lower-ranked PTRs. This practice is known as list diving. In a retrospective study of 29,932 first-time kidney-only transplants from 18,956 adult donors performed during 2015-2018, we found 6,680 (22.32%) list-diving transplants. PTRs in the US are ranked based on an evidence- and consensus-based policy that reflects the collective judgment of stakeholders in the kidney transplant ecosystem. When transplant programs find it necessary to deviate from the national ranking (either because of PTR unavailability or match-specific reasons), it is expected that their decisions will benefit the recipients they select. However, upon accounting for treatment endogeneity, we find that list-diving recipients' 1-year survival neither worsens nor improves. However, list diving worsens the 1-year survival for transplants from relatively good quality donors (KDPI from 0.2 to 0.35). Conditional on survival, list-diving recipients' are more likely to achieve lower 1-year post-transplant estimated Glomerular Filtration Rate (eGFR-1), which is an indicator of kidney function. The latter is also associated with long-term transplant survival. Additionally, list diving worsens the eGFR-1 for transplants from good quality kidneys.

2 - Value Destruction and Recovery from Supply Chain Disruptions

Yue Tang, Emory University, Atlanta, GA, United States, Nikolay Osadchiy

We study the effect of disruptions in firms' supply chain and internal operations on their market value. We propose two novel empirically grounded metrics to characterize a firm's resiliency to disruptions in its own operations or operations of its supply chain partners: maximum value destruction (MVD) and time to recover market value (TMRV). Applying the event study framework to the disruption data from 2003 to 2019, we show that disrupted firms on average experience 2.1% MVD and need 53.5 days to recover market value. Furthermore, disruptions propagate along supply chains, with significant effects both upstream and downstream and with the downstream supply-disrupted side experiencing higher MVD and longer TTRMV. The effects are mitigated by longer buyer-supplier relationships and customer diversification, but not by multisourcing. A one-year increase in relationship length reduces TTRMV by 8.49% (4.54 days) for disrupted firms, 15.26% (8.13 days) for their customers, and 8.39% (4.01 days) for their suppliers. For suppliers, an additional customer within the same industry as the disrupted firm reduces TTRMV by 10% (6.96 days). In the process, we develop a replicable, shareable, and adjustable fine-tuned large language model-based approach to identifying supply chain disruptions from firm press releases.

3 - Evaluating the Impact of Novel Organ Preservation Technologies on Transplant Access

Ting-Tsen Lin, University of Minnesota, Minneapolis, MN, United States, Saumya Sinha

This project investigates the impact of technological advances on access to organ transplantation. Specifically, we consider novel technologies that preserve organ function for extended periods, enabling organs to be transported over longer distances, improving the quality of transplanted organs, and making certain marginal organs viable for transplantation. We study how such technologies can be efficiently implemented to maximize benefits for transplant recipients and, more broadly, enhance the overall transplant system. The system is modeled as a steady-state framework, formulated as a mixed-integer linear program (MILP). We present both analytical and numerical results.

4 - Targeted Priority Mechanisms in Organ Transplantation

Ruo Chen Wang, Virginia Tech, Blacksburg, VA, United States, Sait Tunc, Burhaneddin Sandikci, Bekir Tanriover, Mark Ellis

The persistent imbalance between organ supply and demand poses a significant challenge for the life-saving treatment of transplantation. This study introduces innovative targeted priority mechanisms inspired by the Eurotransplant Senior Program (ESP), designed to bridge the supply-demand gap while optimizing the matching between organs and recipients without mandating offer acceptance. These mechanisms diverge from traditional prioritization by offering voluntary participation and granting explicit priority to disadvantaged patients for a specified range of organs provided they restrict their offer acceptance to this set. Using a comprehensive queueing model, our study analyzes the strategic decisions of waitlisted candidates under targeted priority mechanisms in equilibrium, establishing the optimal program design. Our findings reveal the capacity of these mechanisms to separate organ allocation across different patient classes, improving overall system efficiency. Our evaluation of these mechanisms' impact on social welfare underscores their potential to improve overall welfare without adversely affecting any patient group. The practical applicability and impact of these mechanisms are demonstrated through a case study within the U.S. kidney allocation system using a clinically detailed simulation model, targeting elderly

patients aged 65 and above. Simulation outcomes reveal a significant participation rate even when the program offers priority over kidneys that are conventionally perceived as marginal. Furthermore, our findings highlight the mechanisms' potential to increase yearly transplants by 1,000 and prevent up to 200 waitlist deaths annually. Improvements in the outcomes of even nonelderly patients highlight the mechanisms' potential to comprehensively address organ underutilization and improve organ-recipient matching in a real-world context.

1 - Optimization of Cancer Screening Strategy Using Statistical Control Chart Techniques

Zheng Zhang, Zhejiang University, Hangzhou, China, People's Republic of

This study proposes a two-phase optimization strategy for cancer screening, accounting for binary latent states and random observations. We utilize an Exponentially Weighted Moving Average (EWMA) chart, a tool from statistical quality control, to predict cancer risk and decide whether to proceed with confirmatory testing based on the results of preliminary tests. The problem is formulated as a specialized simulation optimization model, employing decomposition and reformulation techniques to enhance tractability. Our analysis reveals that the model possesses several advantageous properties that significantly improve computational efficiency, facilitating practical implementation in clinical settings. This approach aims to refine decision-making in cancer screening, potentially leading to earlier detection and improved patient outcomes.

2 - The Impact of Physician Familiarity on Emergency Department Productivity

Yiran Zhang, The University of Hong Kong, Hong Kong, Hong Kong, Huiyin Ouyang, Zhankun Sun

Emergency departments (EDs) frequently face challenges with overcrowding, resource limitations, and inefficiencies. Extensive research aims to enhance ED operational performance by understanding physician practices, particularly focusing on physician productivity and patient handoffs. Our working paper examines the impact of physician familiarity on productivity, handoff practices, and patient outcomes, building on existing literature in worker familiarity and productivity. Pairwise physician familiarity is quantified by the number of shared shifts with active interactions. Physician productivity is measured by new patient pickups and instantaneous service rate. Using two years of data from a Canadian teaching hospital, we aim to provide insights for improving ED efficiency.

3 - Feature-Based Optimization of Resource Allocation in Healthcare

Ya-Tang Chuang, National Cheng Kung University, Tainan, Taiwan

Efficient resource allocation is a critical challenge in healthcare systems, particularly under conditions of limited capacity and increasing demand. This study proposes a feature-based optimization framework designed to enhance decision-making by leveraging patient-specific information to improve the allocation of healthcare resources. We model the problem as a Markov decision process (MDP), capturing patient heterogeneity through clinical and non-clinical characteristics. To address the computational challenges associated with high-dimensional state spaces, we propose a priority index (PI) that prioritizes patients based on a cost-benefit analysis between treat-or-wait decisions. A closed-form approximation of the index is derived to enhance computational efficiency, and a Lagrangian relaxation approach is introduced to establish a computable lower bound for performance benchmarking. Numerical experiments demonstrate that the proposed PI achieves near-optimal performance and consistently outperforms benchmark policies, particularly when accounting for patient readmissions. The results underscore the value of efficient resource allocation in enhancing patient flow, advancing equity, and mitigating capacity strain in constrained healthcare environments.

1 - Designing Doctor-Patient Shared Decision-Making Processes Under Bounded Rationality

Feray Tuncalp, Bilkent University, Ankara, Turkey, Rouba Ibrahim, Song-Hee Kim, Jordan Tong

Shared decision-making (SDM) processes, in which doctors and patients work together to choose among treatment options, have gained increasing support from clinicians and governments. Despite the recognized benefits and limitations of these processes, clear guidelines on when and how to implement them are lacking. We develop a stylized analytical model to derive a set of results characterizing when and how to personalize the treatment decision-making process between doctors and patients, taking into account the bounded rationality of doctors and patients. For example, we find that personalizing treatment to account for individual patient preferences is beneficial when treatments have a large expected medical difference across patient types relative to the degree of patient decision error. We also find that the benefits of personalizing treatment to account for individual medical prognoses depends on the degree of patient decision participation. With patient participation, prognosis personalization can even be detrimental when patients strongly prefer one treatment over the other. Challenging common medical belief that advocates for uniform increases in personalization, we show that limitations in medical prognoses accuracy and human cognition imply the existence of trade-offs between personalization and standardization on multiple dimensions within doctor-patient SDM processes. Our results prescribe whether and how to target personalization efforts based on environmental factors, doctor, and patient characteristics.

2 - Justice in Patient Routing

Galit Yom-Tov, Technion - Israel Institute of Technology, Haifa, Israel, Anat Rafaeli

Fairness is critical in the design of queuing and routing systems. We study how patient routing policies affect fairness perceptions and medical personnel behavior. In a field experiment, we examine a new routing policy implemented at a medium-sized hospital, designed to improve fairness in routing patients from the Emergency Department (ED) to three Internal Wards (IWs). This change represents a shift from a pooled queue system to dedicated queues. We assess its impact on fairness, operational performance, and quality-of-care metrics, including patient length of stay (LOS) in both the ED and the wards, as well as the likelihood of readmission.

We find that the new routing policy had positive effects on hospital operations. It reduced overall hospital LOS by approximately one day (14.7%) and decreased ED LOS for patients awaiting IW transfer by 2.2 hours (17%). Importantly, these reductions did not increase the probability of patient readmission, indicating that the policy is a safe and effective way to improve hospital efficiency.

To understand the underlying mechanisms, we conducted online experiments. These reveal that workload imbalance among staff affects fairness perceptions, motivation, and emotional responses such as anger. The dedicated queue policy is perceived as a fairer approach and helps mitigate workload imbalances between wards.

3 - Improving Provider Regionalization: Online Optimization for Patient-Physician Assignment

Angela Lin, Massachusetts Institute of Technology, Cambridge, MA, United States, Dessislava Pachamanova, Georgia Perakis

The practice of localizing physicians to a concentrated geographic region within a large hospital is known as provider regionalization and has been shown to result in a host of benefits.

In this work, we formulate a multi-period stochastic optimization model and design an online algorithm for assigning patients to physicians (after the patient has already been assigned to a unit in the hospital). Our approach accounts for uncertain patient arrivals by simulating future patient arrival sequences using past data distributions, and we propose a novel and realistic objective that is appropriate for the hospital's goals. To make our formulation tractable, we reformulate the problem to eliminate variables, simplify from a nested T-stage stochastic problem to a two-stage problem, relax the integrality of the second-stage variables, and use an enhanced sample average approximation. We also iteratively engage with hospital administrators and physicians to define objectives and incorporate constraints that reflect hospital priorities, and evaluate tradeoffs.

We have an ongoing pilot for our patient-physician assignment framework and have been coordinating with hospital leadership to help change existing practices and workflows. So far, in our pilot, we have seen a 300% decrease in daily physician travel time when using our assignment framework over manual assignment, and additionally, we have saved each assigning physician 3-4 hours of time per week.

Our framework not only saves physician travel time by improving the quality of the assignments, but also saves valuable physician time by eliminating the process of physicians making the assignments themselves.

4 - Advice Provision in the Pandemic: the Impact of Information Granularity on Social Protection

Jingjing Weng, Temple University, Philadelphia, PA, United States, Guangwen Kong, Yang Zhang

This paper investigates the strategies for providing public health advice during a pandemic, such as COVID-19 or a potential future disease, focusing on the granularity of information given by a social planner. We compare two main information provision strategies: aggregated and disaggregated information provision. Under an aggregated information provision strategy, the social planner announces a weighted average of the disease burden across the entire society. Under a disaggregated information provision strategy, the social planner specifies disease burdens for different social groups. We identify conditions where an aggregated information provision is more effective than a disaggregated one. We further extend the analysis of the granularity of information in multi-period scenarios with single- and multi-dimensional information. Our findings show that more granular information does not necessarily lead to better pandemic management and offer insights for designing effective public health information strategies.

5 - Data-Driven Queueing Simulation Using Simlq

Opher Baron, University of Toronto/ SiMLQ, Toronto, ON, Canada, Dmitry Krass, Arik Senderovich

We present a data-driven approach to queueing simulation using SiMLQ. Starting with typical data from queueing networks, we illustrate how such data can be structured as an event log. Leveraging techniques from queue mining and machine learning, we demonstrate how to transform these logs into actionable simulation models. The tale will include a live demonstration of SiMLQ's capabilities across descriptive, predictive, and comparative analytics. We will also discuss how SiMLQ can be applied to prescriptive analytics to support data-informed decision making.

1 - Regularized Aggregation of Point Predictions from Experts with Different Amounts of past Performance Data

Junnan Wang, INSEAD, Singapore, Singapore, Ville Satopaa

Aggregating point forecasts from multiple experts is a critical challenge, especially in the common context where those experts have contributed a varied number of predictions in the past. Consider the scenario where one expert has provided just two forecasts but with perfect accuracy, and another has offered a hundred predictions with lower accuracy. This situation presents a challenge in achieving accuracy while managing the risks associated with less data. To address this, our work introduces a novel aggregation method that balances these considerations. Specifically, our aggregator factors in their unique prediction histories, and appropriately shrinks each expert's weight toward equal weight, depending on the expert's skill and how reliably that skill can be estimated. In our empirical study, we apply our aggregator to the data from the European Central Bank's Survey of Professional Forecasters and observe that it not only outperforms traditional aggregation methods, such as the simple average methods, but also improves the accuracy of performance-weighted methods and performance-based crowd-selection methods.

2 - Diversified Learning: Bayesian Control with Multiple Biased Information Sources

Xinyuan Zhang, Sauder School of Business, University of British Columbia, Vancouver, BC, Canada, Jussi Keppo, Michael Jong Kim

We consider a decision-maker (DM) who can acquire signals from multiple biased information sources to learn about a hidden state before making an earning decision. Unbiased signals are also available but come at a higher acquisition cost. The DM jointly optimizes both learning (information acquisition) and earning decisions to minimize expected loss. This problem is motivated by applications such as medical diagnostics, revenue management and financial investments, where decisions often rely on multiple biased information sources. In contrast to existing literature that primarily focuses on stopping problems with unbiased information, we develop a Bayesian decision framework that accommodates general earning decisions, and models multi-source learning using a hierarchical Bayesian network, explicitly capturing intrinsic biases. We fully solve the model and explicitly characterize the optimal acquisition policy: For small budgets, cost-effectiveness dominates, prioritizing cheap biased sources. As budgets grow, diversification across all biased sources becomes optimal as it mitigates risks from biases. With large budgets, acquisition shifts to costly unbiased sources as biased signals offer diminishing value due to their limited accuracy. We also illustrate the model through two use cases: a disease nowcasting example using real data that shows how budget allocation shifts with bias, cost, and precision, and a demand forecasting example that demonstrates the performance advantage of the proposed policy (learning algorithm) over benchmarks in simulation

3 - Risk-Averse Decision-Making with Endogenous Regressors

Xinyu Hou, National University of Singapore, Singapore, Singapore, Jussi Keppo, Ian Zhu

Data-driven optimization often follows an estimate-then-optimize paradigm, but endogeneity introduces bias that can degrade decision quality. We propose a Bayesian framework that compares Bayesian linear regression (which is biased under endogeneity) with the corresponding Bayesian two-stage least squares (2SLS), which leverages instruments to correct the bias. While 2SLS addresses endogeneity, it also increases the posterior variance. This raises a critical question: Should risk-averse decision-makers always prefer unbiased estimators?

We examine this bias-variance tradeoff and show that unbiased estimators like 2SLS do not necessarily lead to better outcomes when both estimation uncertainty and downstream decision performance are considered. Our results guide estimation method selection by linking endogeneity correction not only to statistical consistency but also to prescriptive performance under risk, offering practical insights for robust decision-making under imperfect identification.

4 - Pasta: a Unified Framework for Offline Assortment Optimization

Juncheng Dong, Duke University, Chapel Hill, NC, United States, Weibin Mo, Zhengling Qi, Cong Shi, Ethan Fang, Vahid Tarokh

We study a broad class of assortment optimization problems in an offline and data-driven setting. In such problems, a firm lacks prior knowledge of the underlying choice model, and aims to determine an optimal assortment based on historical customer choice data. The combinatorial nature of assortment optimization often results in

insufficient data coverage, posing a significant challenge in designing provably effective solutions. To address this, we introduce a novel Pessimistic Assortment Optimization (PASTA) framework that leverages the principle of pessimism to achieve optimal expected revenue under general choice models. Notably, PASTA requires only that the offline data distribution contains an optimal assortment, rather than providing the full coverage of all feasible assortments. Theoretically, we establish the first finite-sample regret bounds for offline assortment optimization across several widely used choice models, including the multinomial logit and nested logit models. Additionally, we derive a minimax regret lower bound, proving that PASTA is minimax optimal in terms of sample and model complexity. Numerical experiments further demonstrate that our method outperforms existing baseline approaches.

Chair: Jack Zhang, Massachusetts Institute of Technology, Cambridge, MA, United States

1 - Integrated Offline and Online Learning to Solve a Large Class of Scheduling Problems

Anbang Liu, Tsinghua University, Beijing, China, People's Republic of, Zhi-Long Chen, Jinyang Jiang, Xi Chen

We propose a machine learning approach to efficiently generate high-quality solutions for single-machine scheduling problems with a non-decreasing min-sum objective function with or without release times. Our approach is novel in three major aspects. First, through exploiting the time-index formulation and Deep Neural Network (DNN) model, our approach provides a unified solution method for the entire class of the aforementioned problems. The second novel aspect lies in the training of our DNN model. In view of the NP-hard nature of the problems, labels (i.e., optimal solutions) are hard to generate for supervised training. To overcome this difficulty, we generate a set of special instances, for which optimal solutions can be found with little computational effort, to train the DNN model in a supervised manner offline. The third novel idea is that we develop an online single-instance learning approach to fine tune the offline trained parameters in the DNN for a given online instance, with the goal of generating an improved solution for the given instance. Computational results show that our approach can quickly generate near-optimal solutions for a variety of single-machine scheduling min-sum problems with up to 1000 jobs.

2 - Automatic Change-Point Detection Using Piecewise Support Vector Quantile Regression

Sheng-Yu Tsai, Department of Information Management, National Chi Nan University, Nantou, Taiwan, Jing-Rung Yu, Chun-Yen Tsai, Donald Lien

Pattern change detection (PCD) in time series data is essential for identifying structural shifts, enabling accurate forecasting and informed decision-making across domains such as finance, healthcare, IoT, and manufacturing. This study proposes a piecewise support vector quantile regression (PSVQR) model to achieve automatic change-point detection and accurate interval prediction. The PSVQR model combines four key components: it employs the quantile loss function to estimate conditional quantiles, generating prediction intervals that account for non-constant variance and data heterogeneity; it incorporates a piecewise structure formulated through multi-objective programming to capture structural changes by segmenting data into distinct regions; it enables automatic detection of multiple change-points by treating their number as an optimization objective; and it utilizes feature selection to refine input variable selection and improve model parsimony. Overall, the PSVQR framework offers a flexible, adaptive, and computationally efficient solution that outperforms conventional methods in handling complex datasets with structural shifts.

3 - Formulation and Regret Analysis of a Delivery Reward Maximization Problem Using Contextual Multi-Armed Bandits with Stochastic Costs

Shinnosuke Uba, The University of Osaka, Suita, Japan, Yutaro Yamaguchi

In food delivery, a courier moves across multiple locations, deciding whether to accept or reject delivery requests to maximize the cumulative reward within a limited time. Since each location offers different reward efficiencies and waiting times, efficient strategies must balance exploration and exploitation under uncertainty. We model this problem as a contextual multi-armed bandit problem with stochastic costs. Each location is associated with a set of actions: either accepting a request at the current location, or taking an action that moves to a (possibly the same) location to wait for the next request. In this model, the current location corresponds to the context. To solve this problem, we propose an UCB-based algorithm that leverages the structure of the problem. Under several technical assumptions, such as the destination of each request being drawn uniformly at random from all cities, we prove that the expected regret of this algorithm, compared to an optimal algorithm with full knowledge of the environment, increases at the best possible logarithmic rate with respect to the number of decisions. Due to the difference in the number of independent targets for exploration, our method achieves a better regret bound in terms of the constant factor compared to directly applying the previously proposed method for the contextual multi-armed bandit problem with stochastic costs, where both the context and the cost distribution are of a single type.

4 - Neural Approximate Optimization for Real-TIME Dispatching of Renewable Energy Sources with Battery Energy Storage

Minseo Kim, Yonsei University, Seoul, Korea, Republic of, Soongeol Kwon

We address the problem of real-time dispatching for renewable energy sources integrated with battery energy storage. Given day-ahead commitments, i.e., the amount of electricity committed for sale ahead of operations, real-time dispatching is designed to maximize profit by determining the amount of electricity to sell in the real-time market while using battery storage to compensate for generation mismatches due to uncertainty. This problem is formulated as a multi-stage stochastic program (MSSP), where non-anticipativity under evolving uncertainty in renewable energy generation and electricity prices makes it challenging to ensure feasibility with time-dependent constraints and achieve profit-maximizing optimality. To overcome these challenges, we propose a neural approximate optimization framework that approximates the decision-making process of the MSSP in a computationally efficient and scalable manner. The framework reduces the dimensionality of the decision space through variable reduction, resulting in a single net dispatch adjustment variable. Input sequences are constructed using only realized and available information up to the current period. A Transformer encoder is employed to capture temporal dependencies, with a feasibility-aware module embedded to enforce both equality and inequality constraints through variable reconstruction and bound-based projection. The model is trained using multi-step-ahead targets derived from optimal solutions, along with a profit-oriented loss function that directly aligns learning objectives with profit maximization. As a result, the proposed framework yields feasible and profitable dispatching decisions without requiring explicit optimization during real-time operation.

5 - Heatflow: a Non-Autoregressive Solution to the Workflow Scheduling Problem

Vivek Anand Rajopanth, University of Illinois Urbana-Champaign, Urbana, IL, United States, Rakesh Nagi, Asser Tantawi

Efficiently orchestrating large batches of data and compute-intensive workflows is a central challenge for modern cloud platforms. Existing production schedulers rely on hand crafted heuristics that trade solution quality for speed, whereas exact approaches such as Mixed-Integer Linear Programming (MILP) can deliver optimal schedules that are prohibitively slow for use in practice. We introduce HeatFlow, the first non-autoregressive Graph Neural Network (GNN) framework that is MILP-aided yet inference-time efficient for the workflow scheduling problem. HeatFlow consists of GNNs that predict an ordering of operations along with an efficient allocation of operations to resources. The resulting “heat maps” are decoded using a lightweight heuristic that guarantees feasibility. Training labels are harvested offline from a MILP that accounts for all relevant constraints in the cloud environment. Experiments on three diverse, real-world and simulated workload suites running on a simulated KWOK cluster controlled using Kubernetes demonstrate that HeatFlow produces solutions that outperform traditional baselines in terms of optimality gaps with minimal computational time. These results highlight the promise of learning-augmented optimization for production cloud schedulers and for other similar combinatorial optimization problems.

6 - Discovering Closed-Form Solutions to Quadratic Programs with Linear Constraints with Neural Networks

Fuat Can Beylunioglu, University of Waterloo, Waterloo, ON, Canada, P. Robert Duimering, Mehrdad Pirnia

Mathematical programming has primarily been a study of numerical optimization where the solution is obtained following a procedure recursively until convergence. Recent applications of Neural Networks (NN) as surrogate models have challenged this view by treating optimization problems as approximating unobserved functions that map input parameters to optimal solutions, similar to closed-form solutions. Drawing on insights from multiparametric programming (MP), which explores piecewise-linear (PWL) properties of quadratic programs with linear constraints (QP), we propose a closed-form NN (CF-NN) model and a learning via discovery algorithm that

learns an exact representation of the solution function without training, by applying algebraic operations to derive all model weights from problem coefficients without the need for training data. Our proposed learning algorithm begins with an optimal solution to initiate the NN model, then discovers each linear segment of the PWL solution function and expands the model parameters iteratively without using solvers. The proposed procedure yields a NN model that acts as the closed-form solution to QP with linear constraints, ensuring that optimal solutions for the discovered regions are both feasible and optimal. It is shown that the proposed CF-NN model offer significant advantages. The model takes seconds to learn the solution function and can seamlessly generalize outside the training distribution. Results on IEEE DC-OPF test cases significantly outperforms traditional deep NN training methods and a commercial solver, achieving optimal solutions with around $1E-16$ KKT optimality violations in all discovered critical regions.

7 - Using Deep Learning to Approximate Feasible Solutions for General Scheduling Assignment Problems

Constanza Lorca, University of Virginia, Charlottesville, VA, United States, Robert Riggs

In some real-world scheduling environments, the availability of resources can vary unpredictably, requiring schedulers to make quick decisions that are not always optimal. Solving these problems dynamically frequently limits the ability to guarantee optimality, showing the need for fast approximation methods.

To tackle the challenge of creating feasible solutions in a timely manner, we propose a neural network framework that learns to approximate feasible near optimal solutions for an assignment decision problem. This approach implicitly incorporates constraints during the learning process, to enable fast and valid assignment predictions, based on optimal solutions generated by a mathematical programming solver.

Our model learns to predict assignment probabilities, by incorporating a masked SoftMax layer into the neural network model, that enforces constraints and only allows for valid assignments. It is trained on the solutions generated by a MILP solver across diverse generated instances, with varying problem sizes and constraints, which ensures generalization and scalability.

This work aims to integrate operations research and deep learning, by demonstrating how neural network models can be used to approximate combinatorial problem solutions while ensuring feasibility and reducing computation time. This framework provides an efficient decision-support tool to generate solutions to reallocate tasks in dynamic scheduling environments.

8 - Approximate Solution of Infinite-Horizon Risk-Sensitive Markov Decision Processes

Jack Zhang, Massachusetts Institute of Technology, Cambridge, MA, United States, M. Soheil Hemmati, Saumya Sinha

Infinite horizon risk-sensitive Markov decision processes (MDPs) with the discounted cost criterion are challenging to solve because the optimal policy may be non-stationary. Existing solution methods reformulate the problem as a continuous-state (risk-neutral) MDP and solve it using state-discretization or value function approximation. In this paper, we present approximate variants of value iteration, policy iteration, and linear programming approaches that can directly solve the risk-sensitive MDP without the need for reformulation. We show that the approximate value functions obtained by value iteration and linear programming converge to the optimal value function, and the policies generated by the policy iteration algorithm converge in value to the optimal policy. Importantly, in addition to proving asymptotic convergence, we provide explicit stopping conditions to achieve arbitrarily close approximations to the optimal value function.

Advances in Decision Making: Theory and Applications

Invited Session

Decision Analysis Society

Chair: Hao Wang, University of Science and Technology of China, Hefei, N/A

Co-Chair: Guangyan Gan, NTU, Singapore, Singapore

1 - Online Emergency Resource Allocation in Humanitarian and Health Logistics

Hao Wang, University of Science and Technology of China, Hefei, China, People's Republic of

Resource allocation is a critical challenge in humanitarian and health logistics (HHL) such as allocating scarce resources to patients or disaster-affected populations. Given the dynamic and uncertain nature of such systems, where decisions must be made with limited information about future supply or demand and without the possibility of recourse, these problems in HHL are referred to as online emergency resource allocation. To address this challenge, we propose an online resource allocation model for emergency management and an adaptive algorithm designed to minimize the performance gap relative to static offline benchmarks. We prove that our algorithm achieves a competitive ratio of $1/8$ and establish a hardness result demonstrating that no algorithm can attain a ratio better than $1/2$. To validate our approach, we conduct a case study using data of in-kind donations following the 2023 Jishishan earthquake. The results confirm the feasibility of our model, demonstrate the effectiveness of our solution, and illustrate how our algorithm can be applied in practice.

2 - Fostering OR Hindering Sales? Overlapping Influencer Followers in Live Streaming E-Commerce

Jingyun Hu, Clemson University, Pendleton, SC, United States

In social media, consumers often follow multiple influencers and may encounter advertising messages for the same product from different influencers. When firms switch influencers to promote their products, an overlap in followers between the previous and current influencers may diminish the returns from the promotion but can also provide additional opportunities to sell to followers of the first influencer who have not yet purchased. This study develops a formal model to examine the impact of overlapping followers on a firm's incremental sales when engaging a new influencer. We generate and empirically test predictions using live streaming e-commerce data from Douyin (the Chinese sister app of TikTok). By utilizing Natural Language Processing (NLP) to estimate the follower overlap between influencers and their respective product demands, we find that more follower overlap often reduces profits but can increase profits if these overlapping followers have a disproportionately high demand for the firm's product. For example, overlap can be beneficial in cases where the firm did not advertise too heavily through the first influencer and can still generate significant sales by re-engaging these consumers through the second influencer. Heterogeneity analysis suggests that the effects of follower overlap vary substantially across different product categories.

3 - Dynamic Pricing and Resource Relocation in a Large Closed Network

Shubo Sun, Miami Herbert Business School, Miami, FL, United States, Ganggang Xu, Xu Sun

We study dynamic pricing and resource relocation in a closed service network with stochastic customer arrivals and travel times. Motivated by shared mobility and micromobility platforms, we consider a system with $n + n_0$ supply units distributed across multiple locations, where n represents the ideal server size under instantaneous relocation and n_0 provides safety staffing to buffer against supply unavailability caused by relocation delays. We propose a state-dependent policy that integrates real-time pricing with adaptive relocation and prove that it achieves a per-edge revenue loss of $O(n^{-(2/3)} \log(n))$ relative to a fluid model benchmark for a given network

structure. Our analysis reveals that this optimality gap is attainable with the additional safety staffing n_0 , whose magnitude depends on the network topology and relocation speeds. This quantifies the operational cost of travel-time stochasticity and demonstrates that pricing alone cannot ensure efficiency in large-scale stochastic networks. Our framework offers a tractable and provably effective approach for demand-supply coordination in modern service networks.

4 - Modeling the Epidemiology Dynamics of Respiratory Syncytial Virus Infections in the United States Under Novel Pharmaceutical-Based Interventions

Xinmeng Zhao, Centers for Disease Control and Prevention, Atlanta, GA, United States, Brian Gurbaxani, Michael Melgar, Ismael Ortega-Sanchez, Ian Plumb, Ryan Wiegand, Phillip Salvatore

Respiratory syncytial virus (RSV) is the leading cause of hospitalization among infants and is associated with 100,000–150,000 admissions annually in U.S. adults aged ≥ 60 years. The recent implementation of novel immunizations—including maternal vaccines, long-acting monoclonal antibodies for infants, and vaccines for pregnant women and other adults—demands a framework capable of quantifying their population-level impact, including both direct protection and indirect effects. While previous mathematical models have described RSV transmission, few have evaluated the impacts of interventions using economic and morbidity metrics, and none have evaluated multiple simultaneous interventions. For the first time, we report the development process of a novel, multi-intervention model for rapid estimation of disease burden to evaluate intervention guidelines. We developed a deterministic susceptible-exposed-infected-recovered (SEIR) model stratified by four RSV infection histories (maternal, primary, secondary, repeat), 32 age classes (monthly intervals through 24 months; broader bands thereafter), and two clinical-risk groups. Each history tier comprises asymptomatic, symptomatic, hospitalized, and recovered compartments, with births, ageing, natural mortality, and waning immunity explicitly represented. Implementation of this model is customizable to end-user localities, burden, and seasonality through adjustment of calibration targets to population demographics. This age- and risk-resolved platform provides a tool for assessing current and future RSV intervention guidelines across diverse subpopulations.

Chair: Alp Sungu, Wharton, Philadelphia, PA, United States

1 - Performance Gains, Motivational Pains: Evidence from AI Adoption in Turkish Schools

Benjamin Lira Luttgies, University of Pennsylvania, Philadelphia, PA, United States, Alp Sungu, Angela Duckworth

While educators express growing concern over generative AI's role in teaching, empirical evidence of its classroom impact remains scarce. We conducted a large-scale randomized field experiment in Turkish private schools to evaluate whether access to an AI-based teaching assistant—and behavioral nudges to encourage its use—could enhance educational outcomes. Teachers were randomly assigned at the school-department level to three conditions: (1) control group receiving standard professional development, (2) AI-access group trained on a custom teaching tool, and (3) AI-exposure group receiving the same training plus weekly engagement reminders.

Both AI conditions significantly improved student performance, with the AI-access group showing the largest gains. However, this academic success came at a cost: the AI-access group experienced marginal declines in both teacher and student motivation, alongside more negative attitudes toward AI. In contrast, the AI-exposure group—encouraged to engage more consistently with the tool—achieved smaller student gains but no motivational penalties.

We explore treatment heterogeneity and conduct exploratory language analysis of chatbot logs to better understand usage patterns.

Our findings highlight a critical tension in educational AI adoption: the conditions producing the strongest immediate academic improvements may simultaneously erode the motivational foundations necessary for sustained success. These results suggest that successful AI integration requires not merely access but carefully structured implementation that balances performance gains with the preservation of teacher autonomy and student engagement.

2 - Spatial Matching Under Multihoming

Alireza Amaniamedani, London Business School, London, United Kingdom, Ali Aouad, Daniel Freund

Motivated by spatial matching platforms such as ride-hailing, we present a model of two-sided matching platforms in a duopoly market with spatial frictions. The two platforms face disjoint streams of rider requests, but they share the same suppliers, i.e., the suppliers multi-home. Spatial frictions create a need for admission control policies that maintain a buffer of available suppliers to balance matching distances against other costs. We find that a duopoly equilibrium entails at least one platform undercutting, by accepting all requests, to gain market share. When both platforms undercut, the supply buffer is not maintained and inefficiencies ensue. We provide a classifier of market conditions that delineates the two regimes and allows us to characterize the prices of anarchy and stability in these settings.

3 - Large-Scale Optimal Contextual Pricing for Demand Response

Mohammad Mehrabi, Stanford University, Stanford, CA, United States, Omer Karaduman, Stefan Wager

The time at which renewable (e.g., solar or wind) energy resources produce electricity cannot generally be controlled. In many settings, consumers have some flexibility in their energy consumption needs, and there is growing interest in demand-response programs that leverage this flexibility to shift energy consumption to better match renewable production—thus enabling more efficient utilization of these resources.

We study optimal demand response in a model where consumers operate home energy management systems (HEMS) that can compute the “indifference set” of energy-consumption profiles meeting pre-specified consumer objectives, receive demand-response signals from the grid, and control consumer devices within the indifference set. For example, if a consumer asks for the indoor temperature to remain between certain upper and lower bounds, a HEMS could time the use of air conditioning or heating to align with high renewable production when possible.

Here, we show that while price-based mechanisms do not generally achieve optimal demand response—i.e., dynamic pricing cannot induce HEMS to choose optimal demand-consumption profiles within the available indifference sets—pricing is asymptotically optimal in a mean-field limit with a growing number of consumers. Furthermore, we show that large-sample optimal prices can be efficiently derived via an algorithm that only requires querying HEMS about their planned consumption schedules under different prices. Finally, we study learning the optimal price passively (when frequent queries to HEMS are not possible) as an online learning problem over a series of days, using only the day's forecasts—i.e., weather, temperature, and weekday conditions—as context, and by observing only consumer consumption profiles.

1 - Working with AI vs Humans: The Impact on Wellbeing

Shawn Mankad, North Carolina State University, Raleigh, NC, United States, Tim Kraft, Eirini Spiliotopoulou, Yanchong Zheng

The use of AI decision-support tools can benefit operational efficiency. However, it can also impact employee wellbeing. In this paper, we utilize human-subject lab experiments to examine how collaborating with an AI tool (versus a human co-worker) impacts both worker performance and wellbeing.

2 - Sequential Selection of Candidates: An Experimental Investigation

Morvarid Rahmani, Georgia Institute of Technology, Atlanta, GA, United States, Karthik Ramachandran, Chris Green

In many settings, managers face sequential selection decisions, constrained by both the number of selections they can make and the uncertainty about forthcoming candidates. This "sequential selection" problem is exemplified in the United States Army's officer evaluation process, where supervising officers assess subordinates' performance and decide whether to award a "high" rating. Critically, these decisions are further restricted by strict limits on the proportion of evaluated officers who can receive high ratings. This paper employs a theoretical model and develops an experimental framework to study how effectively human subjects select candidates and to explore the factors influencing their decisions.

3 - Measuring the Impact of Solar Lighting on the Lives of the Poor: Implications for Donor Organizations and off-Grid Solar Firms

Bhavani Shanker Uppari, Singapore Management University, Singapore, Singapore, Serguei Netessine, Michael Sakellakis

We randomly assigned solar-lighting kits with varying configurations to a large number of households in Ghanaian villages. We document the impact of these kits on the treatment households, in terms of economic improvement as well as improvements in the education of children and the overall well-being of the household members, vis-à-vis the control households that were not given solar kits. We find that the treatment households decreased the purchase and usage of inefficient and unsustainable energy solutions, they recharged mobile phones at home, and the overall expenditure on medicines decreased. These contribute to increased savings: a treatment household (on avg.) saved 83 GHS per month more than a control household, which amounts to 20% of their earnings. The treated children spent (on avg.) 20 minutes longer studying and scored 13 percentage points higher than the children in the control group. Interestingly, the impact magnitudes were similar across different solar-kit configurations in our experiment. This is because the households that received less and/or dimmer bulbs compensated for their lack of sufficient (brighter) light by purchasing additional USB-compatible light sources that could be recharged at home using their short-term savings. We discuss the implications of this reactionary behavior of consumers for the donor organizations (in terms of how they can optimize their donation resources) and the off-grid solar firms (in terms of designing better payment models).

4 - Retailer's Informational Role in the Durability of Goods in An Informal Circular Economy

Amrita Kundu, McDonough School of Business, Georgetown University, Washington, DC, United States, Erica Plambeck, Qiong Wang

This paper reveals the strategic behaviour of small retailers in providing (mis)information to heterogeneous customers about the durability of goods from competing brands in an informal circular economy. These retailers sell lead-acid batteries for electric three-wheeled vehicles, buy-back batteries at end of life, and thus directly observe the life of batteries of various brands. Most batteries have inefficiently short life, whereas customers want long life. A retailer could guide customers to the longest-lasting brand for which the marginal cost is well justified, to build reputation and attract a stream of repeat customers. To observe how retailers actually behave, we covertly audit 261 retail shop owners. Posing as five different types of customer across 1,122 visits, we learn that retailers provide inconsistent information about battery life and which brand is longest-lasting. For poor customers, a retailer exaggerates the life and sets a higher price (net of used battery trade-in value) for a given brand of battery. More frequently with poor customers, a retailer promotes as longest-lasting the brand that offers him the best incentive. This puts poor customers (the predominant types of customer in the market) at an informational and economic disadvantage. For wealthy customers with multiple vehicles, a retailer sets the lowest prices for a given brand of battery. Manufacturers of long-lasting batteries or policy-makers should establish systems to provide reliable information to customers about battery life. Adoption of long-lasting batteries would reduce the rate of lead emissions from battery recycling and manufacturing, which is crucial for public health.

5 - The Impact of Racial Matching on Foster Care Outcomes

Wani Zhang, London Business School, London, United Kingdom

We investigate the impact of racial matching of foster children and caregivers on placement stability and permanency outcomes using data from the Adoption and Foster Care Analysis and Reporting System (AFCARS) from 2008 to 2021. Utilizing hazard models, we find strong evidence that racial matching significantly reduces the risk of placement transfers, indicating enhanced placement stability. Additionally, racial matching affects permanency outcomes, increasing the hazards of adoption and guardianship while decreasing the hazard of reunification with biological families. Our results are robust to several alternative specifications that account for sources of endogeneity. Our findings highlight the complex and crucial role racial matching plays within the foster care system, suggesting that placement practices promoting racial similarity could substantially improve children's long-term stability and well-being.

1 - Recommendations in High-Stakes Settings

Nikhil Garg, Cornell Tech, New York, NY, United States

Recommendation systems are now used in high-stakes settings, including to help find jobs, schools, and partners. Building public interest recommender systems in such settings bring both individual-level (enabling exploration, diversity, data quality) and societal (fairness, capacity constraints, algorithmic monoculture) challenges. In this talk, I'll discuss our theoretical, empirical, and deployment work in tackling these challenges, including ongoing work on (a) applicant behavior and recommendations for the NYC HS match, (b) a platform to help discharge patients to long-term care facilities, (c) feed ranking algorithms on Bluesky for research paper recommendations.

2 - The Disparate Effect of Disasters on American Supply Chains

Mark Brennan, Rutgers University, Camden, NJ, United States, Jonas Jonasson

Recent disasters across the United States highlight the devastating effect of climate-change. How these disasters impact business continuity is a pressing issue of social equity and public policy. In this work, we investigate the impact of disasters on supply chains. We first estimate the impact—as well as the subsequent rate-of-recovery—of severe floods on different tiers of the supply chain. We then investigate the level of heterogeneity of those effects by sector and along socioeconomic lines. Finally, we explore whether recovery at the retail tier of the supply chain is driven by local recovery at the wholesale tier. This has implications for disaster relief policies and resource allocation.

3 - Exploring Classical Heuristics and Biases in LLM-Assisted Decision Making

Jessica Shi, New York University, New York, NY, United States

As large language models (LLMs) become increasingly embedded in data-centric workflows, their impact on human judgment and decision-making warrants careful scrutiny. This study examines how cognitive biases manifest when individuals use LLM-generated summaries to make decisions in data science contexts. Through a series of controlled experiments grounded in realistic data evaluation tasks, we explore how variations in the presentation of information from LLM-generated summaries influence user decisions. Our results reveal systematic patterns of bias, including framing effects, negativity bias, anchoring, and narrative bias, all of which collectively diminish critical engagement with underlying statistical evidence. Moreover, we find that users' follow-up queries to the LLM often reinforce their initial biases, creating a

feedback loop that exacerbates miscalibrated decision-making. To address this, we design interventions that nudge users toward more reflective questioning strategies, improving deliberative reasoning. These findings underscore the importance of bias-aware LLM interfaces and explanation strategies to foster more calibrated and responsible human-AI collaboration.

4 - A Data-Driven Approach to Improve Artisans Productivity in Distributed Supply Chains: Evidence from Field Implementation

Xinyu Zhang, New York University Stern School of Business, New York, NY, United States, Divya Singhvi, Somya Singhvi

Despite their vital role in rural economy, artisanal supply chains continue to be plagued by low productivity and the highly fragmented nature of their upstream. This study presents research conducted in close collaboration with a leading exporter of handmade rugs in India, aimed at improving artisans' productivity in distributed supply chains. Inspired by the robust empirical evidence that frequent supervisor visits can play a crucial role in improving artisans' productivity, we implement a novel predict-then-optimize framework for optimizing supervisor visits in the supply chain for a set of treatment looms for 25 consecutive weeks. A difference-in-differences (DID) analysis using data from more than 5,700 supervisor visits across 200 looms during the implementation suggests that the implementation is associated with a statistically significant 16.5% increase in weaving rate for treatment looms, highlighting the practical relevance of the work.

5 - To Pivot or Persevere? An Examination of Venture Founder Solution Choice Strategies

Stylianos Kavadias, University of Cambridge, Cambridge, United Kingdom

A recent surge in the strategy and entrepreneurship literature has reopened search and dynamic choice models as a way to capture pivots in entrepreneurial ventures. Motivated by several examples of pivots we have studied in a European business school accelerator, in this study we are introducing a model of venture founder decision making that reflects both the bounded rationality and the imperfect information they are facing when making choices about pivoting or persevering. Within that context, we delineate some of the key parameters that describe the solution landscape and we develop a framework that showcases that in certain circumstances persevering (also viewed as a less flexible choice strategy) ends up being the best choice strategy for the founder.

Invited Session

Revenue Management

Chair: Aydin Alptekinoglu, Penn State, University Park, PA, United States

1 - Designing Size Inclusive Fashion Assortments

Alireza Alavi, McGill University, Montreal, QC, Canada, Mehmet Gumus, Javad Nasiry

Size unavailability—the absence of apparel in certain sizes—damages both profit and brand image. Plus-size customers face this unavailability far more frequently than others, creating a disparity that has been called "a subtle form of social discrimination." In this research, we address this problem in a static setting. We incorporate customers' reactions to size unavailability into our choice model and develop algorithms to create fashion assortments that are both profitable and size-inclusive.

2 - Dynamic Assortment in Service Systems

Chen-An Lin, Purdue University, West Lafayette, IN, United States, Yuan Guo

This paper examines dynamic assortment optimization in service systems where customer purchasing decisions are influenced by real-time congestion, as seen in food delivery platforms. We address two key questions: (1) How should firms adjust product or service variety when customer choices depend on evolving congestion levels? and (2) How do product features, such as profit margins and service times, shape optimal assortment strategies? We model the system as an M/G/1 queue and develop a dynamic control framework under a general discrete choice model with impatient customers, where the system state reflects congestion and the decision variable is the assortment offered. Each product is characterized by its selling price, production cost, and ex ante service time distribution. We first establish the existence of a concave solution function under a general choice model. For the MNL choice model, we show that the optimal policy follows an adjusted-margin-ordered structure, where product adjusted margins depend on product features and congestion. We find that when product margins increase linearly with service time, the optimal assortment expands in size as congestion rises. For more general relationships between product margins and service times, we find that optimal assortments in service systems can be non-monotonic, reflecting richer trade-offs than those captured by traditional revenue-ordered policies. In a special two-product setting, we provide sufficient conditions for this non-monotonicity. Our results reveal a novel tradeoff consisting of two counteracting forces: while higher congestion may lead to smaller assortments to improve service efficiency, firms may also expand offerings to sustain demand.

3 - Optimal Search for Tiered Product Information

Zhen Liu, Benedictine University Goodwin College of Business, Lisle, IL, United States

In this study, we assume the various ways a consumer can gather information about a product, including paying search costs before purchase, obtaining information through ownership, and participating in trials (free or paid) before making a purchase. Our model incorporates all three methods of information gathering and analyzes the consumer's decision-making process, including the decision to initiate trials without incurring further search costs, the duration of the trial period, and the ultimate decision to purchase the product.

In this study, we model the customer's expected valuation as a continuous-time Brownian motion and formulate the customer's decision-making process as a multiple optimal stopping problem, following the approach of Branco et al. (2012). Our research characterizes the optimal stopping rules for either starting a trial or not, as well as the optimal stopping rules for either purchasing the product or not, taking into account factors such as search costs, attribute informativeness, discount factor, and trial and sales prices. Our findings indicate that the optimal trial period depends on discount factor, trial and sales prices, but is independent of search costs and informativeness. We

also examine the seller's optimal pricing strategies, considering factors such as discount factors, switching costs, and freemium pricing strategies (limited access to attributes with longer trial periods). Our results support the widespread use of fixed-time trial periods in the SaaS industry and provide a basis for marketing managers to make informed pricing decisions.

4 - Shaping Choices in Sequential Search

Aydin Alptekinoglu, Penn State, University Park, PA, United States, Victor Martinez-de-Albeniz

We study how a retailer can shape the consumers' sequential search outcomes by setting product-specific search costs and choosing an assortment. Building on Weitzman (1979) we first characterize when it is optimal for the retailer to induce a search sequence that is "revenue-ordered" (in decreasing order of prices or, equivalently, margins). Then, we explore how much additional expected revenue (or, equivalently, profit) the optimal sequential-search solution brings over the traditional assortment planning solution. In essence, the goal of this analysis is to compare two fundamental ways of framing assortment optimization: One assuming that consumers search and consider products one at a time (sequentially, à la Weitzman, 1979); and the other assuming that consumers consider all available products at once (in parallel), which is more traditional and in line with most models of assortment optimization in the extant literature.

Frontiers of Revenue Management: Theory and Practice

Invited Session

Revenue Management

Chair: Ming Hu, Rotman School of Management, University of Toronto, Toronto, ON, Canada

Co-Chair: Ali Daei Naby, Rotman School of Management, University of Toronto, 468 Roxton Rd., Toronto, ON, M6G 3R4, Canada

1 - Walled Garden or Cash Cow? Strategizing with Supporting Services

Bin Hu, University of Texas at Dallas, Richardson, TX, United States, Yulin Hu, Mingliu Chen

We investigate when a firm that possesses a proprietary, value-adding "supporting service" (e.g., Tesla's Supercharger network) should keep that service exclusive to its own products ("walled-garden" strategy) versus open it to rival products and monetize it directly ("cash-cow" strategy). We model a duopoly in which the service-advantaged firm and its competitor sell substitutable products over two market stages. Early-stage customers form beliefs on the service-openness decision, which then changes the firm's decision-making environment. Using a game-theoretical model and rational expectation equilibrium concept, we explicitly characterize the equilibrium prices and service-openness decisions. We show that, even with unchanged market fundamentals, the service-advantaged firm may optimally switch from exclusivity in the early stage—using the service to boost product demand—to openness in the mature stage to harvest service revenue. We then endogenize the service-advantaged firm's investment in enhancing service quality and study government mandates that force openness either immediately or with a delay. Mandates can crowd out investment when the service is only mildly lucrative, but can stimulate higher investment and raise social welfare when service revenues are substantial; the welfare-maximizing mandate (none, immediate, or delayed) varies systematically with the service charge, the intrinsic service advantage, and the cost of investment. We also show that allowing the firm to commit credibly to future openness has a negligible policy impact.

2 - Optimality of Lower-Censorship in Information Design

Yunzong Xu, University of Illinois, Champaign, IL, United States, Zhangyi Liu, Yunbei Xu

We examine the surprisingly broad optimality of "lower-censorship" rules in information design, offering a unified framework that extends and connects prior results in rating, delegation, and persuasion.

3 - Non-Exclusive Notifications: From Theory to Practice

Farbod Ekbatani, Chicago Booth School of Business, Chicago, IL, United States, Rad Niazadeh

Ride-hailing platforms face increasing uncertainty in driver compliance, with growing rates of ignored or rejected ride assignments. To address this, platforms are shifting from traditional one-to-one matching toward non-exclusive notifications, where the same ride request is sent to multiple drivers simultaneously. This paper introduces a formal framework for analyzing such notifications, capturing the trade-offs between quality and speed of the matches. With many-to-one matching, a new challenge arises: contention resolution among drivers who accept the same ride. We study two contention-resolution strategies—First Accept, which prioritizes speed by assigning the ride to the first responder, and Best Accept, which prioritizes quality by waiting to select the best available driver. We develop algorithms for selective notifications, including optimal formulations, greedy approximations, and heuristic approaches, and analyze their performance through fluid and batching models. Our results reveal a Pareto frontier between match quality and waiting time, showing when non-exclusive notification improves reliability and when it creates inefficiencies. By bridging centralized matching models with the realities of voluntary participation and driver lapses, this work provides theoretical and practical guidance for designing robust assignment protocols in ride-hailing platforms.

4 - Online Strategic Decision Making with Instruments

Rui Ai, MIT, Cambridge, MA, United States, David Simchi-Levi

This talk explores algorithmic approaches to learning and decision-making in strategic environments characterized by confounding, information asymmetry, and knowledge transfer challenges. In many economic systems, such as service fee pricing, we only observe equilibrium outcomes rather than the full demand curve, making OLS-based inference unreliable. We address this by leveraging proactive actions as instrumental variables and reveal how market randomness can aid identification, uncovering a phase transition phenomenon. When agents are forward-looking and strategic, we design a low-switching algorithm that achieves optimal regret bounds across several settings. The second part of the talk focuses on online reinforcement learning under information asymmetry, where agents act based on private signals. We examine the interplay between confounded observations and the difficulty of transferring knowledge across environments. We introduce a sample-efficient algorithm that not only identifies hidden system dynamics but also learns an ϵ -optimal policy under strategic interaction and non-i.i.d. actions. Our approach achieves near-optimal sample complexity and contributes to a broader understanding of learning in dynamic, multi-agent systems. Together, these works offer insights into how proactive experimentation and carefully designed algorithms can overcome deep structural challenges in learning and inference within strategic marketplaces.

5 - Online Mechanism Design for Crowdsourcing Systems

Renfei Tan, Massachusetts Institute of Technology, Cambridge, MA, United States

In the era of artificial intelligence, the need for high-quality labeled data has become more pressing than ever, and crowdsourcing platforms are a key source of such data. Yet these crowdsourced annotations can be vulnerable to data poisoning attacks and varying levels of worker reliability. In this talk, we introduce an online mechanism design framework that models this problem through a label-efficient and stochastic version of the prediction with expert advice paradigm. By selectively querying true labels while minimizing costs, our approach aims to maintain robust learning guarantees in the presence of adversarial or erroneous annotators. We discuss theoretical bounds, algorithmic insights, and the practical implications of applying these methods to modern crowdsourcing platforms.

Revenue Management

Chair: Bradley Sturt, University of Illinois Chicago, Chicago, IL, United States

1 - Approximation Schemes for Dynamic Pricing with Menu Costs**Jacob Feldman, Washington University, Clayton, MO, United States, Danny Segev**

We study a multiperiod, multiproduct, dynamic pricing problem with price adjustment costs known as “menu costs.” In this setting, decision makers, such as retailers or online platforms, incur a fixed menu cost whenever prices are updated between periods as well as a variable menu cost that linearly scales with the number of between-period price changes. Our first main contribution consists of establishing fundamental hardness results for the dynamic pricing problem of interest, unveiling inherent computational hurdles even when stripped down to its simplest form. On the positive side, we identify grocery retail as a particular application domain whose distinguishing features allow us to develop a fully polynomial time approximation scheme (FPTAS), through which optimal expected revenues are shown to be approachable within any degree of accuracy. Finally, we present two extensive numerical experiments aimed at studying the impacts of menu costs, albeit from distinct vantage points. Both studies make use of a large and diverse test bed of problem instances that we painstakingly construct from a NielsenIQ scanner grocery data set. Given the novelty of incorporating menu costs within dynamic pricing environments, we use the first set of numerical experiments to present what constitutes one of the first close looks at how these price adjustment costs shape pricing patterns and influence optimal gross margins in a multiproduct setting. The second set of experiments is used to evaluate the efficacy of our FPTAS, ultimately showing its mean revenue performance to be within 1%–2% of optimal.

2 - Assortment Optimization and the Sample Average Approximation**Bradley Sturt, University of Illinois Chicago, Chicago, IL, United States**

We study a simple approach to solving assortment optimization problems under general choice models. The approach uses samples to construct a ranking-based choice model that serves as a proxy for the true choice model, followed by finding an assortment that is optimal with respect to that proxy. In this talk, we make that approach more practically viable by developing faster algorithms for finding assortments that are optimal under ranking-based choice models. We show using real-world data that our algorithms—without any warm starts or parameter tuning—can offer more than a 30x speedup over the previous state-of-the-art. Equipped with these algorithms, we will discuss the viability of using the sample average approximation to solve assortment optimization problems in various settings of practical importance for which no polynomial time algorithms exist.

3 - Dynamic Resource Allocation with Recovering Rewards**Mika Sumida, University of Southern California, Los Angeles, CA, United States**

In many resource allocation settings, the value derived from resources depends on their usage history, with resources that have sufficient recovery or idle periods between allocations often providing greater utility or reward. This paper studies a resource allocation problem in which resource rewards recover over time following each use. Motivated by settings such as content recommendation, service platforms, and renewable energy management, we consider a dynamic matching problem with non-stationary arrivals, where customer types and matching preferences vary over time. Each arriving customer must be immediately and irrevocably matched to a resource or lost. The reward from matching a resource is non-decreasing in the time since its previous use. The goal is to maximize the expected reward collected from all arrivals over a finite time horizon.

Computing the optimal policy for this problem is computationally intractable as the number of resources grows. While the greedy policy achieves at least 1/2 of the optimal expected revenue for subadditive reward functions, it performs arbitrarily poorly for general non-decreasing reward functions. To address this, we propose an approximate policy based on a novel value function approximation that achieves a 1/3 performance guarantee for general non-decreasing reward functions. We show that for the special case of concave reward functions as well as the special case where all resources are reusable, the approximate policy's guarantee improves to 1/2. Our approximation leverages resource-specific dynamic programs that incorporate each resource's recovery level as a state, a framework that we believe to be new to the literature.

4 - Driving Efficiency: Optimizing Workforce for Last-Mile Deliveries**Tamar Cohen-Hillel, UBC Sauder School of Business, Vancouver, BC, Canada, Liron Yedidsion, Tolga Cezik**

Last-mile delivery labor planning is a critical challenge for logistics providers like Amazon, where timely delivery and cost efficiency are essential. In this work, we address the problem of determining the optimal number of drivers required each week over a given planning horizon, accounting for uncertain demand and cross-time constraints. We formulate this as a stochastic dynamic program, capturing both fixed hiring costs and variable operational costs.

To address the computational challenges of this NP-hard problem, we propose a dynamic programming-based approximation algorithm. Our approach effectively balances the trade-off between cost efficiency and service reliability, minimizing the total expected cost while ensuring all shipments are delivered on time. The cost model accounts for the fixed expenses of onboarding new drivers and the operational costs of dedicated vans and flex drivers, providing a realistic representation of the cost structure.

We validate our approach with both theoretical bounds and extensive computational experiments, demonstrating that our algorithm achieves a tight optimality gap and performs near-optimally in practice. These results highlight the potential for significant cost savings in last-mile delivery operations through intelligent labor planning, offering valuable insights for both practitioners and researchers.

Optimization and Strategy Issue in Matching Markets

Invited Session

Auctions and Market Design

Chair: Chengyue He, Columbia University, Jersey City, NJ, 10027, United States

1 - Minimum Cut Representability of Stable Matching Problems**Chengyue He, Columbia University, New York, NY, United States**

We introduce and study Minimum Cut Representability, a framework to solve optimization and feasibility problems over stable matchings by representing them as minimum s-t cut problems on digraphs over rotations. We provide necessary and sufficient conditions on objective functions and feasibility sets for problems to be minimum cut representable. In particular, we define the concepts of first and second order differentials of a function over stable matchings and show that a problem is minimum cut representable if and only if, roughly speaking, the objective function can be expressed solely using these differentials, and the feasibility set is a sublattice of the stable matching lattice. To demonstrate the practical relevance of our framework, we study a range of real-world applications, including problems involving school choice with siblings and a two-stage stochastic stable matching problem. We show how our framework can be used to help solving these problems.

2 - Adding Private Information into Centralized Algorithms: A Field Experiment at A Ride-Sharing Platform**Yingzhi Liang, Naveen Jindal School of Management, University of Texas at Dallas, Dallas, TX, United States**

Many have seen the gig economy as the “future of work”. Despite having a boss-free working environment and a flexible working schedule, gig workers have little power over the algorithm that assigns them tasks. Take ride-sharing drivers for example, the platform assigns drivers trips without considering driver preferences for locations. As a result, drivers might suffer from a lack of working location flexibility. Through a field experiment on the largest ride-sharing platform in China, I examine the effect

of incorporating location preferences into the centralized matching. I find that allowing drivers to self-define working regions increases their working hours and income by more than 4%, without lowering their productivity. Drivers use this feature both for necessity constraints and strategy concerns.

3 - Managing Self-Interested Behavior in Failure-Aware Kidney Exchange

Itai Feigenbaum, City University of New York, New York, NY, United States

Patients requiring kidney transplant may have proxy donors, who wish to donate a kidney to the patient- but are incompatible. However, patients can swap their proxy donors for a compatible one. Transplants often get canceled, so planned swaps should maximize the expected number of non-canceled transplants. Exact maximization is neither strategyproof nor core-stable: patients can increase their probability of receiving a kidney via hiding proxy donors, or via side-arrangements. We introduce a group-strategyproof and core-stable mechanism called SuperGreedy. On uniform markets, where cancellation probabilities are equal across transplants, SuperGreedy is worst-case 2.03-approximate for realistically large cancellation probabilities, and empirically average-case 1.142-approximate in simulation. Our results extend beyond current practice, to when patients can swap multiple proxy donors, with weaker theoretical approximation guarantees but even stronger empirical performance. SuperGreedy is efficiently computable when restricted to size-2 cycles; without this restriction SuperGreedy is NP-hard, but still practically computable on uniform markets.

Learning in Auctions and Games

Invited Session

Auctions and Market Design

Chair: Gabriele Farina, MIT, Cambridge, MA, United States

Co-Chair: Giannis Fikioris, Cornell University, Ithaca, NY, United States

1 - Learning in Budgeted Auctions with Spacing Objectives

Giannis Fikioris, Cornell University, Ithaca, NY, United States

In many repeated auction settings, participants care not only about how frequently they win but also how their winnings are distributed over time. This problem arises in various practical domains where avoiding congested demand is crucial, such as advertising campaigns that require sustained visibility over time. We introduce a simple model of this phenomenon, modeling it as a budgeted auction where the value of a win is a concave function of the time since the last win. This implies that for a given number of wins, even spacing over time is optimal. We also extend our model and results to the case when not all wins result in "conversions" (realization of actual gains), and the probability of conversion depends on a context. The goal is to maximize and evenly space conversions rather than just wins.

We study the optimal policies for this setting in second-price auctions and offer learning algorithms for the bidders that achieve low regret against the optimal bidding policy in a Bayesian online setting. Our main result is a computationally efficient online learning algorithm that achieves $O(\sqrt{T})$ regret. We achieve this by showing that an infinite-horizon Markov decision process (MDP) with the budget constraint in expectation is essentially equivalent to our problem, even when limiting that MDP to a very small number of states. The algorithm achieves low regret by learning a bidding policy that chooses bids as a function of the context and the system's state, which will be the time elapsed since the last conversion.

2 - Robust Online Fair Allocation with a Single Sample

Zongjun Yang, Columbia University, New York, NY, United States, Christian Kroer, Rachitesh Kumar

We consider the online fair allocation problem with T sequentially arriving items and n agents with linear, additive utilities. Given potentially non-stationary or adversarial arrivals over time, prior works either focuses on worst-case approximation ratio results, or assumes a bounded extent of non-stationarity. We investigate the question of using a minimum number of historical sample traces to enable no-regret guarantees for the Eisenberg-Gale objective, with arbitrarily non-stationary input. We show that a single sample per distribution is sufficient for the resolving algorithm to achieve $O(\log T/\sqrt{T})$ regret, while being robust to potential errors in the sampling distribution.

3 - Equilibria in Uniform Price Auctions: Theory, Computation, and Market Insights

Qinzheng Li, National University of Singapore, Singapore, Singapore, Yifan Feng, Negin Golrezaei

We study pure-strategy Nash equilibrium outcomes of multi-unit auctions under the $\$K\$$ -th price payment rule. Despite their widespread use in resource allocation markets such as treasury bond sales, electricity markets, and carbon credit trading, these auctions remain poorly understood due to their combinatorial complexity and bidders' strategic incentives for bid shading. In this paper, we provide a complete characterization of the set of allocation and clearing price outcomes at equilibrium. This enables us to develop a mixed-integer programming formulation to compute Nash equilibrium outcomes and select those with desirable properties, such as maximum welfare or revenue. We further extend our analysis to incorporate reserve prices. We then leverage our characterization to study market stability through numerical experiments, which show that markets with fewer bidders and coarser bid grids are more prone to tacit collusion. These inefficiencies can be mitigated by increasing the number of bidders to enhance competition or by using reserve prices to curb revenue loss. We also examine repeated multi-unit auctions and find that adaptive bidding algorithms often converge to stable equilibria and exhibit inertia when initialized at an equilibrium—suggesting that initial bids can serve as a practical lever to avoid undesirable outcomes.

4 - Learning to Play Against Unknown Opponents

Jon Schneider, Google, Columbia, NY, United States

We consider the problem of a learning agent who has to repeatedly play a general sum game against a strategic opponent who acts to maximize their own payoff by optimally responding against the learner's algorithm. The learning agent knows their own payoff function, but is uncertain about the payoff of their opponent (knowing only that it is drawn from some distribution D). What learning algorithm should the agent run in order to maximize their own total utility, either in expectation or in the worst-case over D ? When the learning algorithm is constrained to be a no-regret algorithm, we demonstrate how to efficiently construct an optimal learning algorithm (asymptotically achieving the optimal utility) in polynomial time for both the in-expectation and worst-case problems, independent of any other assumptions. When the learning algorithm is not constrained to no-regret, we show how to construct an ϵ -optimal learning algorithm (obtaining average utility within ϵ of the optimal utility) for both the in-expectation and worst-case problems in time polynomial in the size of the input and $1/\epsilon$, when either the size of the game or the support of D is constant. Finally, where the learner wishes to maximize their minimum payoff over all possible optimizer types, we construct a learner algorithm that runs in polynomial time in each step and guarantees convergence to the optimal learner payoff. All of these results make use of recently developed machinery that converts the analysis of learning algorithms to the study of the class of corresponding geometric objects known as menus.

Chair: Xiao Xiao, California State University, Stanislaus, Turlock, CA, United States

1 - Spillover Effect of Supply Chain Credit Risk :Empirical Evidence from Chinese a-Share Listed Enterprises

Yu Liu, Shanghai Jiaotong University, Shanghai, China, People's Republic of

Based on the data of Chinese A-share listed enterprises from 2013 to 2022, this paper selected core enterprises and small and medium-sized enterprises (SMEs) with supply relationship as the research samples. calculated the credit risk level by using the KMV model, researched the spillover effect of credit risk from core enterprises to SMEs in the supply chain, explored the transmission path of supply chain credit risk, and analyzed the heterogeneity of the spillover effect of credit risk in the supply chain. The research results show that there is a spillover effect of credit risk from core enterprises to associated SMEs in the supply chain. Further, the good credit performance of core enterprises can significantly improve the profitability, operating ability, and debt-servicing ability of associated SMEs, and thus mitigate the spillover effect of supply chain credit risk; The spillover effect of credit risk in supply chain is more obvious under high financing constraints, and high supply chain concentration exacerbates the spillover effect of credit risk in supply chain. The findings offers empirical evidence for related enterprises to develop prevention and control strategies for supply chain credit risk and provides practical insights for government agencies to strengthen credit supervision and improve the financing environment.

2 - Tracing the Paths of Cascading Disruptions in Multi-Tier Supply Networks

Phu Nguyen, Berlin School of Economics and Law, Berlin, Germany, Dmitry Ivanov

Modern supply chains have grown increasingly complex and fragile, exposing firms to cascading disruptions, also known as ripple effects. While prior research has focused on identifying critical suppliers and materials to enhance resilience, little research has been done to understand the structure and characteristics of disruption propagation paths. Our study addresses this gap by proposing an approach to analyze the critical disruption paths in a deep-tier supply network. We model the supply chain as a random network and employ a simulation framework based on the Susceptible–Infected–Recovered paradigm to capture the supply chain emergence over time. To systematically examine the properties of critical disruption paths, we conduct a structured experiment design using three distinct disruption scenarios, each representing different levels of impact severity. Our approach is further validated through an empirical case study involving a leading European manufacturing firm. The supply network comprises a focal firm, 130 customers, 251 direct suppliers, and 1,479 Tier-2 suppliers. The results reveal key structural attributes of critical disruption paths significantly influencing the focal firm's exposure. Our findings inform the development of a minimum viable supply chain stress-testing model in research. Supply chain managers can leverage the results to safeguard critical paths and ensure more efficient allocations of resilience resources.

3 - Mitigating Supply Chain Risks Under Multi-Level Geopolitical Tensions: the Impact of Digital Network Capability on Supply Chain Resilience

AI-Hsuan Chiang, Ming Chuan University, Taipei, Taiwan

Amid rising geopolitical tensions, natural disasters, and regional conflicts, global market uncertainty continues to grow, significantly heightening the risk of supply chain disruptions. Under multilayered geopolitical risks, firms encounter complex challenges at multiple levels. Firm-level risks, such as regulatory interference or trade restrictions, directly affect operations. In contrast, regional or national-level risks, including cross-border sanctions or abrupt policy shifts (e.g., trade wars), disrupt broader supply chain environments. To enhance responsiveness and resilience, firms are increasingly adopting advanced technologies such as Industry 4.0 and the Internet of Things (IoT). These innovations are enabling the transformation of traditional supply chains into digital ones, thereby strengthening digital network capabilities to absorb external shocks.

Grounded in the dynamic capabilities perspective, this study investigates how digital network capability contributes to supply chain resilience, helping firms mitigate the effects of multilayered geopolitical risks. The study also identifies key antecedents that shape digital network capability. Data were collected from firms across multiple countries and analyzed using structural equation modeling. The results indicate that digital network capability significantly enhances supply chain resilience, which in turn improves both operational and environmental performance. Moreover, resilience acts as a key mediator between digital network capability and performance outcomes. Notably, while resilience buffers firm-level geopolitical risks, it remains susceptible to erosion under regional-level geopolitical pressure. These findings underscore the dual role of digital network capability—serving both as a product of strategic enablers and as a foundation for organizational resilience in volatile geopolitical contexts.

4 - Who Rules the Battery? Technology Control, Supply Chain Synergy, and Cost Structure Dynamics in Vehicle-Battery Separation Models

Bo Liu, Southeast University, Nanjing, China, People's Republic of, Yi Ding

The vehicle-battery separation (VBS) model represents a crucial innovation in the new energy vehicle industry, where its supply chain structure and operational strategies systematically influence battery leasing prices, technical performance, and corporate profits. This study conducts a comparative analysis of three business models: Manufacturer-Integration (MI), Supplier-Integration (SI), and Manufacturer-Cooperation (MC), revealing the dynamic equilibrium between synergistic effects, technological control, and economies of scale across different operational approaches. The research demonstrates that in terms of pricing mechanisms, the SI model establishes distinct leasing price advantages by capitalizing on suppliers' specialized expertise and automakers' cross-subsidization strategies. Regarding technical performance, the MI strategy delivers optimal results in high-efficiency environments through fully integrated industrial chains, while the MC strategy shows greater adaptability in low-efficiency or high revenue-sharing ratio scenarios. Profit distribution exhibits threshold effects related to technological control and economies of scale: MI generates maximum profits in high-efficiency phases, SI prevails in low-efficiency stages, and MC proves most competitive during moderate efficiency periods or when vehicle body revenues are substantial. The study also identifies how consumer risk preferences asymmetrically influence market equilibrium: under low R&D costs, risk aversion paradoxically elevates market prices and profit margins, whereas high-cost conditions may trigger market failures characterized by "performance degradation-price escalation". This research establishes a strategic decision framework for VBS model adoption: technology-leading enterprises should implement MI models for value capture; while cost-sensitive operators should optimize efficiency via either SI or MC approaches.

5 - A Multi-Agent Based Digital Twin Framework for the Digitalization of Assembly Environments

Michail Katsigiannis, Auburn University, Auburn, AL, United States, Konstantinos Mykoniatis

This work introduces a scalable Multi-Agent-Based Digital Twin (MABDT) framework designed to create Digital Twin models that can monitor complex production systems. The framework architecture is structured into three interoperable layers: the Physical Layer, the Digital Twin Layer, and the Application Layer. The Physical Layer captures live data from sensors, automation systems, and Internet of Things devices. Next, the Digital Twin Layer comprises autonomous agents that maintain state charts, process incoming messages, and simulate future scenarios. Finally, the Application Layer delivers analytics, visualization, and decision-support tools. Communication Agents orchestrate bi-directional data flows, translating raw inputs into structured events for Digital Twin Agents, which can issue control commands back to the physical environment. Digital Twin Agents leverage state-chart-based models to represent entities, such as workstations, products, and handling resources, defining clear state transitions, communication interfaces, and action routines. The proposed MABDT framework advances the Digital Twin paradigm toward highly adaptive, autonomous, and interoperable simulation ecosystems by focusing on modular agent definitions and flexible communication patterns. A case study at the Tiger Motors educational assembly line at Auburn University illustrates the framework's use in modeling a 15-workstation mixed-model assembly line. Car, Workstation, and Inspection Station Agents provide real-time tracking of vehicle progression, workstation utilization, and fault events, delivering dynamic performance metrics and interactive visualizations for teaching and prototyping digital manufacturing processes.

6 - Risk Sharing in a Two-Level Supply Chain with Variable Capacity and Random Yield

Xiao Xiao, California State University, Stanislaus, Turlock, CA, United States

Research on production uncertainty is crucial in today's complex and interconnected business environment, as supply chains contend with numerous uncertainties, including demand fluctuations and supplier disruptions, significantly affecting their operations. This study is based on three centralized supply chains and three decentralized supply chains, and investigates two types of production uncertainty: Variable Capacity (VC) and Random Yield (RY), examining their impacts on supply capability, relationships among supply chain members, decision-making behaviors, and overall performance. RY, often resulting from imperfect processes, is predictable and measurable, unlike VC, which is triggered by entirely random factors such as unforeseen interruptions and unplanned maintenance, rendering it uncontrollable. Our findings reveal that centralized models are predominantly influenced by RY due to its predictability, enabling manufacturers to adjust their production strategies accordingly. In contrast, the unpredictable nature of VC, stemming from external shocks, is frequently disregarded in decision-making. In the absence of risk-sharing, RY primarily affects manufacturers, with VC having a minimal impact. However, RY influences manufacturers' production decisions, while retailers' ordering strategies consider both types of uncertainty. In response to production uncertainties, manufacturers adapt to RY's predictability within supply chains, whereas retailers modify their ordering practices to mitigate risks arising from both supply and demand uncertainties. These insights underscore the distinct impacts of production uncertainties on supply chain entities and highlight management practices for addressing these challenges.

Learning and Optimization in Healthcare Operations

Contributed Session

Contributed

Chair: Marco Patino, North Dakota State University, Fargo, ND, United States

1 - Multi-Item Inventory Optimization with Correlated Demands

Zhaleh Rahimi, McMaster University, Hamilton, ON, Canada, Douglas Down, Na Li

We study optimal ordering policies for a multi-item periodic-review inventory system, considering demand correlations and historical data for the products involved. While previous studies have considered demand correlation, the effects of different correlation types, such as autocorrelation, cross-correlation and time-lagged dependencies, is underexplored. To address this, we model the demand process using a VARMA (vector autoregressive moving average) framework. VARMA can effectively capture these correlations and enable the exact computation of optimal policies under separable cost functions. We also investigate whether a VARMA process can be effectively fitted to operational data through numerical experiments using both synthetic data and real-world demand for immunoglobulin blood products including intravenous (IVIg) and subcutaneous (SCIg).

2 - Multi-Objective Evolutionary Optimization for Healthcare Districting: a Customized Nsga-Ii Approach

Huijae Kim, KAIST, Daejeon, Korea, Republic of, Taesik Lee

Properly districting a large service region—such as a country—into sub-regions is essential for the efficient and equitable delivery of healthcare services. Healthcare districting inherently involves trade-offs between two critical objectives: *self-containment* (i.e., the proportion of patients treated within their own district) and *accessibility*. This study proposes a bi-objective optimization model that aims to maximize the average self-containment rate while minimizing the maximum intra-district travel distance, under constraints on population size, healthcare facility capacity, and geographic contiguity. To solve this model, we design a tailored NSGA-II algorithm that incorporates an efficient encoding structure inspired by graph-partitioning problem and domain-specific genetic operators to enhance both search efficiency and solution quality. Using Korean National Health Insurance claims data, we conduct extensive experiments. For small-scale instances, we validate our approach against exact optimization methods to ensure solution accuracy. For larger-scale problems, we benchmark our method against two established NSGA-II variants, demonstrating the superior quality of Pareto front and faster convergence. The results highlight the practical utility of multi-objective evolutionary optimization for addressing real-world healthcare districting problems.

3 - Early Breast Cancer Detection in Rural North Dakota: Strategic Resource Allocation

Marco Patino, North Dakota State University, Fargo, ND, United States, Diana Lopez-Soto, Ph.D.

Cancer remains one of the most significant public health concerns in the United States, with approximately half of the men and one-third of women expected to develop the disease in their lifetime. Among all types, breast cancer in particular stands out due to its high prevalence in new cases and cost. In the U.S., over 300,000 new cases are projected in 2025, with treatment expenses reaching nearly 30 billion in 2020. While early detection can significantly improve survival rates and reduce costs by up to one-third, many individuals face barriers to timely screening.

Out-of-pocket expenses and limited access to healthcare services contribute to delayed diagnoses. In some cases, treatment costs for breast cancer can exceed \$120,000. These challenges are especially pronounced in North Dakota, where breast cancer incidence rates among women are above the national average, and rural populations often lack access to preventive care.

This study proposes the use of mathematical programming to strategically deploy mobile health units across North Dakota. The goal is to improve early detection rates and reduce both mortality and the economic burden on underserved populations. The proposed model could serve as a blueprint for other rural states facing similar disparities in cancer outcomes.

LLM Applications in Decision Support

Contributed Session

Contributed

Chair: Behrooz Davazdahemami, University of Wisconsin-Whitewater, Whitewater, WI, United States

1 - Which LLM Builds the Best Optimization Model?

Brian Schaefer, SimpleRose, St. Louis, MO, United States

This talk compares leading large language models (LLMs)—including ChatGPT, Claude, and Gemini—for their ability to formulate, debug, and explain optimization models. Through a series of structured prompts and real-world modeling tasks, I'll highlight where each model excels or struggles, from translating problem statements to generating clean code or catching feasibility issues. The session will include practical tips for better prompting and model verification, and end with guidance on which LLM to use for which optimization task.

2 - Automatic Validation of Optimization Models Using LLMs

Alexander Zadorojniy, IBM Research, Haifa, Israel, Segev Wasserkrug, Eitan Farchi

Recently, using Large Language Models (LLMs) to generate optimization models has become increasingly popular. However, despite the potential benefits of such generation, a major open question is how to validate the correctness of the generated models. In our work, we propose a novel method for automatic validation of such LLM generated optimization models. Our approach builds upon best practices in software testing and using the natural language description of the problem to be modelled, consists of several LLM based agents: an agent that uses an LLM to create a problem level, rather than an optimization model level, testing interface; an LLM agent to create unit tests; and an LLM agent to generate mutations with the goal of helping the unit test creator cover corner cases based on the problem description. In our context mutations are applied to the constraints of a given problem in the benchmark. For example, a constraint of a given problem in the benchmark may state that $x+y \leq 8$ and its mutant may be $x+y \leq 7$. We show empirically that our approach results in higher coverage of the generated optimization models with respect to standard methods such as objective function value comparison.

3 - AI Decision Support: Alignment of Risk Attitudes

Elisabeth Paté-Cornell, Stanford University, Stanford, CA, United States

AI decision support includes both the relevant information and a suggestion (or implementation) of an optimal decision option. Information can be checked against facts and beliefs. The choice of an option, however, has to be based on relevant preferences. This talk will discuss the need and the implementation in AI decisions of a risk attitude that fits that of the decision maker, and will present model of examples to do so.

4 - E2r2: a Hybrid Explainable Framework for Case-Based Reasoning and Generative Decision Support

Behrooz Davazdahemami, University of Wisconsin-Whitewater, Whitewater, WI, United States, Hamed Zolbanin, Dursun Delen

The rapid evolution of artificial intelligence has introduced new methodological possibilities for Information Systems Research (ISR), particularly in decision support. This paper presents E2R2—an Explain, Embed, Retrieve, and Reason framework—that integrates explainable AI, semantic similarity matching, and generative reasoning to support interpretable, example-driven classification. E2R2 was applied to the task of predicting second-year college attrition using a real-world student dataset and demonstrated strong predictive accuracy (84%), session-level consistency (92%), and robustness under partial data conditions (88% agreement).

The framework operates in three stages: (1) model prediction and SHAP-based feature attribution, (2) generation of natural language rationales via a fine-tuned generative model (o3-mini), and (3) classification and explanation of new instances based on semantic proximity to precedent cases. Unlike traditional black-box classifiers or basic CBR systems, E2R2 provides personalized, SHAP-informed explanations grounded in contextual case analogies, enabling transparent, cognitively aligned decision support.

Experimental results confirm that E2R2 not only performs reliably across different execution contexts but also delivers actionable, domain-relevant insights in natural language. The system balances computational precision with interpretive relevance—offering a pragmatic approach to the “precision vs. relevance” tradeoff outlined by Zadeh. The study advances ISR by operationalizing a flexible and reusable methodology suitable for digital coaching, algorithmic decision support, and adaptive information systems. It also lays the groundwork for future enhancements, including user-in-the-loop refinement and domain adaptation.

This work contributes to the design and evaluation of AI-driven decision methodologies that are interpretable, resilient, and grounded in human-centered reasoning.

Recent Advances in High-Dimensional Change Detection and Gaussian Processes

Invited Session

Quality, Statistics and Reliability

Chair: Ruizhi Zhang, University of Georgia, Athens, GA, 30542, United States

Co-Chair: Liyan Xie, University of Minnesota, 1400 Park Avenue, MINNEAPOLIS, 55404, United States

1 - High-Dimensional Dynamic Process Monitoring by Pca-Based Sequential Learning

Xiulin Xie, Florida State University, Tallahassee, FL, United States

Air pollution surveillance is critically important for public health. To monitor a sequential process online, a major statistical tool is statistical process control (SPC) chart. However, traditional SPC charts are developed mainly for monitoring production lines in the manufacturing industry under the assumptions that process observations at different observation times are independent and identically distributed with a parametric (e.g., normal) distribution when the process is stable. Nevertheless, the air pollution and meteorological data would not satisfy these conditions due to serial correlation, seasonality, and other complex data structure. In this talk, we present our latest research on sequential monitoring of air quality over time. In particular, we propose a flexible method for sequential monitoring of high-dimensional dynamic processes with serially correlated data. The new method is based on nonparametric longitudinal modeling for describing the longitudinal pattern of the process under monitoring, principal component analysis for dimension reduction, and a sequential learning algorithm for developing an effective decision rule. Numerical studies and real data applications show that the proposed method works well.

2 - Adaptive Block-Based Change-Point Detection for Sparse Spatially Clustered Data with Applications in Remote Sensing Imaging

Lynna Chu, Iowa State University, Ames, IA, United States, Alan Moore, Zhengyuan Zhu

We present a non-parametric change-point detection approach to detect potentially sparse changes in a time series of high-dimensional observations or non-Euclidean data objects. We target a change in distribution that occurs in a small, unknown subset of dimensions, where these dimensions may be correlated. Our work is motivated by a remote sensing application, where changes occur in small, spatially clustered regions over time. An adaptive block-based change-point detection framework is proposed that accounts for spatial dependencies across dimensions and leverages these dependencies to boost detection power and improve estimation accuracy. Through simulation studies, we demonstrate that our approach has superior performance in detecting sparse changes in datasets with spatial or local group structures. An application of the proposed method detect activity, such as new construction, in remote sensing imagery of the Natanz Nuclear facility in Iran is explored.

3 - Change Point Detection for Multiple Dynamic Processes with Exogenous Covariates

Zibo Tian, University of Florida, Gainesville, FL, United States, Peihua Qiu

Detecting structural changes in dynamic processes is important in fields like finance, genomics, and manufacturing, where abrupt changes in system dynamics can signal regime changes, faults, or external influences. Traditional change point detection methods focus on identifying transitions in univariate or multivariate processes but often overlook the role of exogenous covariates, which can drive underlying structural changes. To address this gap, this paper develops a change point detection method for piecewise stationary vector autoregressive models with exogenous covariates (VARX) to address structural changes in the observed multivariate time series influenced by exogenous variables. Unlike existing methods focusing on single-process settings, our approach can detect change points shared across multiple processes with heterogeneous exogenous effects. By reformulating change point detection as a variable selection problem, a sparse group Lasso-based approach is employed in our method to identify candidate change points, refined subsequently by a backward elimination procedure. This enables simultaneous estimation of the number, locations, and other parameters of the structural changes in high-dimensional settings. Numerical studies show that the proposed method performs well in various scenarios considered.

4 - Sequential Change Point Detection via Denoising Score Matching

Liyan Xie, University of Minnesota, MINNEAPOLIS, MN, United States

Sequential change-point detection plays a critical role in numerous real-world applications, where timely identification of distributional shifts can greatly mitigate adverse outcomes. Classical methods commonly rely on parametric density assumptions of pre- and post-change distributions, limiting their effectiveness for high-dimensional, complex data streams. This paper proposes a score-based CUSUM change-point detection, in which the score functions of the data distribution are estimated by injecting noise and applying denoising score matching. We consider both offline and online versions of score estimation. Through theoretical analysis, we demonstrate that denoising score matching can enhance detection power by effectively controlling the injected noise scale. Finally, we validate the practical efficacy of our method through numerical experiments on two synthetic datasets and a real-world earthquake precursor detection task, demonstrating its effectiveness in real scenarios.

5 - Scalable Gaussian Processes with Low-Rank Deep Kernel Decomposition

Yunqin Zhu, Georgia Institute of Technology, Atlanta, GA, United States, Henry Yuchi, Yao Xie

Kernels are key to encoding prior beliefs and data structures in Gaussian process (GP) models. The design of expressive and scalable kernels has garnered significant research attention. Deep kernel learning enhances kernel flexibility by feeding inputs through a neural network before applying a standard parametric form. However, this approach remains limited by the choice of base kernels, inherits high inference costs, and often demands sparse approximations. Drawing on Mercer's theorem, we introduce a fully data-driven, scalable deep kernel representation where a neural network directly represents a low-rank kernel through a small set of basis functions. This construction enables highly efficient exact GP inference in linear time and memory without invoking inducing points. It also supports scalable mini-batch training based on a principled variational inference framework. We further propose a simple variance correction procedure to guard against overconfidence in uncertainty estimates. Experiments on synthetic and real-world data demonstrate the advantages of our deep kernel GP in terms of predictive accuracy, uncertainty quantification, and computational efficiency.

Recent Advances in Experimental Design and Variable Selection Techniques

Invited Session

Quality, Statistics and Reliability

Chair: William Fisher, JMP Statistical Discovery LLC, Raleigh, NC, United States

Co-Chair: Qiong Zhang, Clemson University, Clemson, SC, United States

1 - Combinatorial Testing of Engineered Systems with Hard-to-Change Factors**William Fisher, JMP, Cary, NC, United States**

The testing of engineered systems is a complex task which often requires a test engineer to select a suite of test cases to investigate in order to detect and correct errors. Test engineers often must strategically select their suite of test cases due to budgets on time and other operational constraints. When the test cases are defined by a set of parameters or factors, one method which is often used to guide the selection of a test suite is combinatorial testing, and the construct which is typically used to facilitate this is known as a covering array. In some instances of a combinatorial testing problem, there may be a subset of factors that are expensive or hard to change. In design of experiments, split-plot designs are used when hard-to-change factors are present. Borrowing the concept of split-plot designs from design of experiments, we extend the methodology of combinatorial testing by showing a method for constructing covering arrays with split-plot structure. We then demonstrate the efficiency of our method in a case study involving the testing of an implementation of XGBoost.

2 - Robust Models for Experiments with Quantitative and Qualitative Responses**Yu Wang, University of Massachusetts Amherst, Amherst, MA, United States, Lulu Kang**

In supervised learning, datasets often contain both qualitative and quantitative response variables. Existing literature demonstrates that jointly modeling these mixed-type responses leads to superior prediction accuracy compared to separate modeling approaches. However, challenges such as high-dimensionality and outliers further complicate the analysis. In this talk, we introduce a novel framework for robust regression and classification that addresses these issues. Our approach formulates a loss function based on density power divergence, ensuring robustness against outliers and model misspecification. By integrating this divergence-based loss with L1 regularization, our method enables accurate prediction of both qualitative and quantitative responses in high-dimensional settings. To solve the resulting nonconvex optimization problem, we employ a proximal gradient algorithm enhanced by the Barzilai-Borwein spectral stepsize. Finally, we validate the proposed framework through numerical simulations and real-world examples.

3 - Optimal Sparse Projection Design for Experiments with Treatment Cardinality Constraints**Kexin Xie, Virginia Tech, Blacksburg, VA, United States, Ryan Lekivetz, Xinwei Deng**

Modern experimental designs often face the so-called treatment cardinality constraint, which is the constraint on the number of included factors in each treatment. Experiments with such constraints are commonly encountered in engineering simulation, AI system tuning, and large-scale system verification. This calls for the development of adequate designs to enable statistical efficiency for modeling and analysis within feasible constraints. In this work, we propose an optimal sparse projection (OSP) design for systems with treatment cardinality constraints. We introduce a tailored optimal projection (TOP) criterion that ensures a good space-filling property in subspaces and promotes orthogonality or near-orthogonality among factors. To construct the proposed OSP design, we develop an efficient two-stage Allocation-Assignment Algorithm (AAA) based on genetic algorithm (GA) to efficiently explore the design space with treatment cardinality constraints. Numerical examples demonstrate the merits of the proposed method.

4 - Screening Designs for Continuous and Categorical Factors**Ryan Lekivetz, JMP Statistical Discovery LLC, Cary, NC, United States**

In this talk, we discuss a new class of saturated designs containing m three-level continuous factors and $m-1$ two-level categorical or continuous factors in $n=2m$ runs, where $m \geq 4$. A key advantage is that these designs are available for any even $n \geq 8$. With effect sparsity or by not making use of all of the two-level columns of the design, we demonstrate via simulation that it is possible to identify up to three active quadratic effects. When n is a multiple of 8, the designs are orthogonal. When n is a multiple of four and not a multiple of 8, the three-level factors are orthogonal to each other and to the two-level factors, and the two-level factors are nearly orthogonal to each other. Finally, when n is a multiple of two, and not a multiple of four or 8, the three-level and two-level factors are nearly orthogonal within those groupings, and orthogonal to each other.

5 - Bayesian Variable Selection for Gaussian Process Models in Computer Experiments: Joint Credible Region and Indicator-Based Approaches**fan zhang, Clemson University, Clemson, SC, United States**

Gaussian process (GP) models are commonly used in the analysis of computer experiments. Variable selection in GP models is of significant scientific interest, but existing solutions remain unsatisfactory. For each variable in a GP model, there are two potential effects with different implications: one is on the mean function, and the other is on the covariance function. However, most existing research on variable selection for GP models has focused only on one of these effects. In this talk, we introduce two Bayesian approaches for variable selection in GP models, each addressing the challenge of considering both the mean and covariance functions.

Joint credible region method for variable selection in universal kriging introduces an inert variable and constructs a joint credible region based on the posterior samples of both regression coefficients and correlation parameters of the inert variable. The method determines variable activity by examining the location of each variable's posterior samples relative to the joint credible region. Indicator-based Bayesian variable selection procedure for GP models introduces an indicator variable to simultaneously consider variable effects in the mean and covariance functions. A variable is defined to be inactive if both effects are not significant, and an indicator is used to represent whether the variable is active or not. The proposed methods provide flexible and effective tools for variable selection in GP models for computer experiments. Simulation studies and real-data applications confirm the accuracy and robustness of both approaches.

Chair: Kaige Gao, Cleveland, OH, United States

1 - Unveiling Shadow AI use in the Workplace: Psychological Ownership as a Driver of Employee Knowledge Hoarding and the Moderating Role of Job Autonomy**Xiao Han, Xi'an Jiaotong University, Xi' an, China, People's Republic of**

With the rapid spread of generative AI tools and the distinct increase in their ease of use, employees can easily access AI tools and use them to support their work. At the same time, many organizations have yet to develop specific guidelines or management processes regarding the use of AI tools, resulting in a lack of organizational-level control and surveillance of the work process using AI tools. In this context, shadow AI use refers to the behavior of employees using AI tools without the approval of the technology department of the organization. Existing research around shadow AI use is confined to the perspective of viewing AI as an information technology, mainly defining shadow AI use as an unethical behavior of employees, focusing on its impact on organizational knowledge leakage, and ignoring the impact of shadow AI use on employees' knowledge behavior at the individual level. From the perspective of psychological ownership theory, this study argues that employees' AI shadow use causes employees' knowledge hoarding behavior by increasing knowledge-based psychological ownership. Based on the above mediating mechanism, we further explored the positive moderating role of a specific job characteristic-job autonomy on this process from the perspective of self-determination theory. The results of a multi-stage questionnaire study from employees in China confirm the proposed research hypotheses and provide useful insights into how organizations can maintain employees' knowledge-based initiatives in the context of the increasing prevalence of AI tools at the individual employee level.

2 - Prior Knowledge Does Help: Generating Adversarial Samples with Prior-Guided Multi-Objective Optimization

Yilun Jin, Southeast University, Nanjing, China, People's Republic of

Generating adversarial text samples in the black-box and hard label setup is a challenging task, as the data space is inherently discrete and non-differentiable, and only the predicted label is accessible. Research on this problem is still in the embryonic stage and only a few methods are available. Meanwhile, current methods often encounter difficulties in simultaneously achieving low perturbation rate and high semantic similarity, and they often require a large number of queries.

To address these limitations, we propose a novel prior-guided attack (PGAttack) to generate adversarial text samples satisfying multi-objectives in a query-efficient manner. Specifically, PGAttack includes a new word importance-aware method to identify critical words within the text. Then, a new multi-objective optimization algorithm is proposed to generate adversarial text based on this prior knowledge. This algorithm draws inspiration from evolutionary computation and incorporates two customized prior-guided operators and a new selection criterion. Extensive experimental results on four classical text classification datasets and across three widely-used text models, demonstrate the superiority of PGAttack. Furthermore, evaluations on two real-world APIs demonstrate that PGAttack can generate better adversarial samples while reducing query costs by more than 50% compared to baseline attack methods.

3 - Does AI Complement R and D Investments in Driving Innovation?

Patricia Angle, University of Oklahoma, Norman, OK, United States, Lubomir Litov

In 2024, U.S. private equity and venture capital investment in generative AI soared to \$56 billion, nearly doubling investments of the previous year, with organizations reporting significant revenue gains associated with generative AI use (S&P Global, 2025). However, the rapid integration of AI raises challenges, particularly for R&D-intensive firms, as AI's opaque algorithms complicate decision-making transparency. This paper investigates the impact of AI adoption on firm innovation, focusing on the role of R&D investment as a moderating factor. Utilizing data from the Aberdeen Ci Technology Database (2013–2017) and the USPTO (2013–2020), the study examines the relationship between AI-related software adoption and firm-level innovation outcomes, measured through patent grants. Fixed-effects Poisson panel regressions reveal a significant positive relationship between business intelligence (BI) intensity and patents, especially with a two- to three-year lag. However, the effect diminishes after winsorization, indicating that the positive relationship is driven by a small subset of firms with high BI intensity. Further analysis highlights robust complementarity between BI intensity and R&D intensity, suggesting that AI's positive innovation impact emerges primarily when paired with substantial R&D investment. Additionally, capital expenditures significantly enhance patenting outcomes, reinforcing the need for complementary resources. The findings indicate that AI adoption alone does not guarantee innovation; instead, its effectiveness relies on integrating advanced technologies with robust R&D infrastructure and capital investment. This study contributes to the discourse on AI-driven innovation by demonstrating the contingent nature of AI's impact, emphasizing the importance of aligning AI adoption with strategic R&D and capital investments.

4 - Using Embeddings to Understand in AI Decision Making

Yidan Zhang, Cornell University, Ithaca, NY, United States, X.Y. Han

While recent work in OR/OM increasingly explores /how/ to better train AI algorithms for decision-making, less attention has been given to a complementary question: once AI predictors are successfully trained, what rules has the AI actually learned? This talk demonstrates how the geometry of a network's learned embeddings can shed light on this issue. Using representative OR decision-making problems, such as multi-class scheduling, we show that after an AI learns to solve these problems, its internal vector representations can be mapped to classically understood models. This mapping allows for interpretability in the AI's decision-making procedure.

5 - AI-Assisted Triage of Patient Messages: A Clinically Calibrated Human AI Framework for Healthcare Operations

Mohamed Megahed, The Ohio State University, Columbus, OH, United States, Nathan Craig, Aravind Chandrasekaran

This study addresses clinician burnout from increased asynchronous patient messaging by developing and evaluating an AI-assisted triage system. Leveraging natural language processing and clinician-calibrated severity scoring, the system prioritizes messages for faster, more effective responses. Using data from 3.2 million messages, the research compares four triage workflows, linking severity flags to adverse clinical events. Results show AI-human collaboration improves response time and outcomes while maintaining alignment with clinician judgment. This integrated framework offers a scalable approach to enhancing healthcare operations and advancing human-AI interaction theory.

6 - Resolving AI Value Paradox: Unlocking AI's Value Through Strategic Knowledge Integration

Kaige Gao, Case Western Reserve University, Cleveland, OH, United States

Artificial Intelligence (AI) has transformed industries, yet firms often struggle to extract value from it. To address this AI value paradox, we examine how cross-boundary AI knowledge—AI expertise applied within specific industries—influences a firm value. Using a longitudinal dataset of patents, academic papers, and firm data, we find that how firms integrate cross-boundary AI knowledge with complementary assets significantly impacts their value. Specifically, firms leveraging cross-boundary AI knowledge in exploration strategies are more likely to see higher market returns, while those focusing on exploitation face greater challenges. This study extends the literature on knowledge transfer and exploration-exploitation strategies in the AI era, offering insights into AI's application in the industry and providing practical strategies for firms to maximize AI's value in innovation efforts.

Bridging Theory and Human Behavior in Operations

Invited Session

Behavioral Operations Management

Chair: Arturo Estrada Rodriguez, Católica-Lisbon School of Business and Economics, Lisboa, N/A, Portugal

Co-Chair: Siddharth Singh, University College London, London, E14 5AA, United Kingdom

1 - Non-Truthful Mechanism Design for Revenue Management in Queueing Systems

Arturo Estrada Rodriguez, Católica-Lisbon School of Business and Economics, London, United Kingdom, Siddharth Singh

We investigate how a capacity-constrained firm should define a price/lead-time menu and a scheduling policy in order to maximize revenues subject to the choices of heterogeneous customers with private types (service valuation and delay sensitivity). Traditionally, menu design in such settings has been focused on truthful incentive-compatible (IC) mechanisms, under which rational customers have the incentive to truthfully reveal their private types. In such settings, the need to ensure truthful revelation may incentivize providers to artificially inflate wait times by introducing strategic delay. Motivated by the existence of robust behavioural factors such as lying aversion or strategic naivety, we depart from the canonical model by allowing some proportion of customers to be unconditionally honest - unable/unwilling to misrepresent their private information. We find that the presence of such unconditionally honest customers may give rise to optimal non-truthful (NT) direct mechanisms - where it is optimal to allow some lying to occur in equilibrium - that yield revenue rates higher than any IC mechanism. Moreover, we find that optimal NT mechanisms, in contrast to IC ones, do not resort to delay tactics. We characterize such NT mechanisms, identify when they are optimal, and study their social welfare implications.

2 - Wait-Time Targets and Human Task Scheduling in Queues

Tomas Momesso, UCL School of Management, London, United Kingdom, Rouba Ibrahim, Bilal Gokpinar, Mirko Kremer

How do performance targets influence human scheduling behaviour in service operations? We investigate how wait-time targets (deadlines) can improve task scheduling in high-workload queueing systems. We design a controlled experiment where participants manage a queue with two task types (long and short) and aim to minimise linear delay costs. Tasks arrive dynamically and vary in their delay cost and (exogenously specified) service times. Our results enhance the understanding of how human servers schedule tasks under high workload and how performance targets affect discretionary task ordering.

3 - Transshipment with Overconfidence

Xuan Zhao, Wilfrid Laurier University, Waterloo, ON, Canada, jialu Li

This paper investigates how overconfidence affects the equilibrium of lateral transshipment systems. We find that overconfidence bias can exert a positive force on the decentralized transshipment system, in contrast to its consistent negative effect on a centralized system. Thus, contrary to intuition, overconfident newsvendors can be better off with a decentralized transshipment practice than a centralized one. Additionally, while conventional wisdom holds that coordinating transshipment prices exist to allow the decentralized system to achieve full coordination (first-best outcome), our analysis reveals that such coordination prices fail to exist when overconfidence bias is high. If this is the case, we show that newsvendors with a high (low) net profit margin benefit more from increased (decreased) transshipment prices. Our findings provide actionable insights on how overconfident newsvendors can design transshipment prices more effectively and suggest when to leverage decentralized transshipment practice depending on the newsvendors' overconfidence bias.

4 - Innovation and Information Free-Riding: An Experimental Investigation of Collective Experimentation

Yaroslav Rosokha, Purdue University, West Lafayette, IN, United States, Timothy Cason, Stanton Hudja

We study information free-riding in a dynamic collective experimentation setting. In theory, a social planner can reduce the benefit to free-riding by limiting future access to the innovation. To encourage more experimentation, the optimal amount of access balances the trade-off between too much access that leads to information free-riding and too little access that limits learning. We report a controlled lab experiment that varies future access to the innovation to test several theoretical predictions. Results show that human subjects respond to variation in the future access as predicted; however, the magnitude of their response is insufficient to generate the overall benefit of the intervention. We explore how individual characteristics such as risk aversion, loss aversion, cognitive ability, and ability to update beliefs optimally impact individuals' decisions to information free-ride.

5 - Solver Capacity Utilization and Allocation on Crowdsourcing Platforms: An Experimental Study

Ramazan Kizilyildirim, UCL, LONDON, United Kingdom

We employ a game-theoretic model combined with laboratory experiments to examine how solvers allocate and utilize their capacity across multiple contests as a crowdsourcing platform expands. Our experimental findings reveal that platform growth does not inherently diminish the profit per contest. To further understand these results, we utilize a structural model to analyze the observed data, uncovering the underlying behavioral mechanisms that drive these outcomes.

1 - Humanizing the Stay: Impact of Promoting Suppliers in Peer-to-Peer Markets

Yinan Yu, University of Oklahoma, Norman, OK, United States

Peer-to-peer (P2P) markets consist of a wide variety of individual suppliers who often take a back seat to their products. There is an ongoing debate about whether P2P platforms should place suppliers in a more prominent role in their online presence. We study a program promoting hosts in addition to their property offerings on Airbnb, the largest P2P home-sharing platform. In line with the Elaboration Likelihood Model of persuasion, we find that featuring host images on top of their property listings can boost property bookings by 4.2%. Drawing upon a theoretical framework of Stimulus-Organism-Response (S-O-R), we further unveil the mechanism by examining how image attributes (S) and image perception (O) each influence property bookings (R). We leverage a Generative AI approach to extract the objective attributes together with the perception conveyed in the host images. The results show a significant role of image attributes and perception. For example, properties with host images that feature a single person, depict a younger host, have higher resolution and a larger face-to-image ratio, or show a host perceived as friendly are more likely to receive bookings. The impact of host images, however, varies by host and property types. Our findings add to the debate about the online marketing strategy of P2P markets, which are largely driven by individual suppliers and provide novel evidence from Generative AI analytics that informs platform design and supplier management.

2 - Chatgpt vs. Google: a Comparative Study of Search Performance and User Experience

Ruiyun Xu, Miami University, Oxford, OH, United States

The emergence of ChatGPT, a large language model-powered chatbot, has the potential to revolutionize the way users search for information by shifting from keyword-based queries to natural language interactions. This study investigates user behavior differences when using search engines and chatbot tools for various information retrieval tasks and explores the combined use of both tools. We conduct two randomized online experiments to achieve this goal. Our findings reveal that ChatGPT users consistently spend less time on all tasks, with no significant difference in overall task performance between the ChatGPT and Google Search groups. Notably, ChatGPT excels at addressing common information look-ups and providing summarized solutions, but struggles with fact-checking tasks which require users to take extensive exploration to resolve conflicting information. The impact of cognitive fit between task requirements and search tools' design features on performance is task-dependent. Our results also indicate that a strong belief in search result accuracy can diminish the effectiveness of using ChatGPT. When both tools are accessible, the outcomes lie between the results of using each tool individually. Participants strategically employ both tools, often selecting the most suitable one for a specific task. Our study offers valuable insights for future development and integration of chatbot tools with search engines, suggesting potential improvements to enhance user experience and information-seeking efficiency.

3 - Why Do Some Moocs Attract More Subscribers than Others? A Social Presence Theory Perspective

Bo Wen, Northern Arizona University, Flagstaff, AZ, United States, Mandy Dang, Sophie Friedman

As MOOCs (Massive Open Online Courses) continue to transform how people learn new knowledge, an important question arises: why do some courses attract more subscribers than others? Draw on social presence theory, this study investigates two main design features that may drive learners to subscribe to MOOCs: instructor presence in the course cover image and the use of learner-focused course description. Analyzing data from over 3,000 Udemy courses, we find that courses featuring the instructor in the cover image attract more subscribers, even when controlling for other key variables. Additionally, course descriptions that use second-person pronouns (e.g., "you will learn") are more effective in attracting subscribers than those focused on the instructor (e.g., "I will teach"). These effects are robust across different course categories and model estimations. Post-hoc analyses further reveal that the positive effects of both instructor presence and learner-focused descriptions are amplified in more advanced courses. In addition, we find evidence that these two design features could interact positively to increase the number of subscribers. Together, these findings offer new insights into the subscription-based revenue model in MOOCs and suggest AI-driven strategies to enhance learner engagement, such as detecting missing instructor presence and optimizing course descriptions to be more learner-centric.

4 - Modeling Individual Credit Card Consumption Behavior and Delinquency with An LLM-Based Agent

Yu Zhu, University of Delaware, Newark, DE, United States, Bowen Yin, Minjia Mao, Xiao Fang

We propose an agent-based simulation framework that leverages large language models (LLMs) to emulate credit card user behavior, focusing on spending and repayment actions. To realistically model user dynamics, we introduce a novel memory architecture that integrates both user profiles (expressed in natural language) and transaction histories (encoded as graphs), enabling the agent to reason over static traits and behavioral patterns. This architecture features three key innovations. First, we construct two complementary graph representations of transaction history: one that captures individual behavioral patterns, and another that reflects aggregate transaction patterns across the full user population. These graph-based representations better capture interdependencies among transactions compared to traditional sequential formats. Second, we design an adaptor module to align the graph representations with the LLM's embedding space, facilitating seamless integration of structured financial data with natural language understanding. Third, we introduce a reflection mechanism that enables the LLM to dynamically retrieve relevant portions of the transaction graphs during

simulation. This approach allows the foundation LLM's parameters to remain frozen, requiring training only the lightweight reflection module. We demonstrate the utility of our framework in two key applications: delinquency prediction and intervention evaluation. Our experiments show that the LLM-based agent achieves predictive accuracy on par with conventional models in delinquency forecasting. Moreover, the simulated spending and repayment behaviors align closely with expected trends under varying macroeconomic scenarios, underscoring the framework's capacity to generalize under out-of-distribution conditions.

1 - The Pivot Summation Method: A Geometric Reimagination of Simple Linear Regression

Om Agrawal, Columbia University, New York City, NY, United States

In this paper, we will present a geometric re-interpretation of OLS regression for calculating the line of best fit in simple linear regression. This approach is using a novel pivot-based vector summation approach. Instead of creating the line of best fit using algebra by solving normal equations simultaneously, this paper aims to present a idea to consider each data point in the dataset as a pivot point, then construct the directional vector from that pivot point by iterative vector summation which then defines the slope of the line. We then iteratively choose the line that minimizes the root-mean squared error, where the algorithm uncovers the optimal direction. We mathematically prove that under conditions where the data is symmetrical, this approach converges with the classical OLS least squared result. We do this using the first order Taylor expansion around the data centroid. Additionally, we explore how the data asymmetry influences the slope and thus giving insights on a geometric intuition into leverage and influential points. While this paper doesn't propose a computational improvement over the OLS, this framework provides a conceptually rich, mathematically backed and a visually intuitive pathway to understanding regression. This approach can have potential value in statistics education and enhance the interpretability of the fundamental mathematical method to model data. Empirical results on the synthetic dataset supports the theoretical convergence, and visualizations reinforce the method's explanatory power.

2 - Improving Decision Analytics Education Using Team-Based Learning and Group Development

William Millhiser, Zicklin School of Business, Baruch College, CUNY, New York, NY, United States

We redesigned an undergraduate course in decision analytics around two related literatures: team-based learning (TBL) and group development. To our knowledge, this is the first to fully integrate best pedagogical practices in TBL into an entire decision analytics course, with adherence to the science of group development and behavioral anchors in the peer review process. Specifically, classroom time is restructured around team-based problem solving via 25 mini cases written by the author and sequenced to deliver the class learning goals. The students work in teams during class time, with a required team deliverable. Before each mini case, students prepare by watching a 10- to 15-minute "prep" video with accompanying materials; similarly, after submitting each deliverable, students "unlock" a debriefing video and corresponding materials. New theory, tools, and techniques are presented in the prep or in the debriefing, not a textbook. Materials are made available to students for free, part of the university's zero-textbook cost and open educational resources (OER) initiatives. Effective strategies in team-based learning are employed throughout the course: group formation and management, accountability for individual and team work (a team charter, 360-degree peer feedback), team exams, and promoting team learning and team development. We will present the course redesign and its objectives, connect the design to literature and evidence on the effectiveness of team-based learning and group development, and conclude with suggestions for further research.

3 - Rethinking CLV: Organizational Barriers to Adoption and the Future of Customer Value Metrics

Utkarsh Gupta, Birla Institute of Technology, Mesra, India, Satyajit Mahato, Satish Chander

Customer Lifetime Value (CLV) is widely recognized as a key metric in marketing analytics, offering a long-term view of customer profitability. Yet, in practice, its adoption often lags behind to short term KPIs or campaign level metrics. This disconnect between academic consensus and business implementation reveals a niche but critical challenge: why does a theoretically robust metric like CLV struggle to gain traction in business decision making?

This study examines the organizational dynamics influencing CLV adoption, focusing on subscription-based firms where customer value insights are especially relevant. Using semi-structured interviews with analytics and marketing leaders, we examine select enablers and barriers such as model interpretability, incentive alignment, and executive sponsorship, that influence whether CLV becomes embedded in strategic workflows.

Building on these insights, we propose the CLV Adoption Framework (CAF), a diagnostic tool designed to assess business readiness across three dimensions: analytical maturity, decision integration, and strategic alignment. While technical advancements in CLV modeling are well documented, few studies offer a structured, practitioner-focused lens on adoption challenges. The CAF addresses this gap by translating qualitative findings into an actionable roadmap for organizations.

Finally, we raise a forward-looking question: Has CLV, in its current form, reached its practical limit and should firms begin exploring more interpretable, action-oriented customer value metrics? This research contributes both conceptually and practically to marketing analytics and is especially relevant for data scientists, marketing strategists, and business leaders working to bridge the gap between predictive models and real-world impact.

4 - Increased Engagement and Learning Outcomes from the Production Planning Game

Melissa Tilashalski, Johns Hopkins, Baltimore, MD, United States, Kimberly Ellis, Natalie Cherbaka

The Production Planning Game is a web-based, experiential learning, manufacturing game. Teams of students prepare production plans by creating the aggregate plan, master production schedule, and material requirements plan for a set of products and then face off with other teams through simulated demand across nine time periods to earn the most profit in order to win the game. Effective experiential learning activities increase student engagement, which is considered a strong predictor of student learning. With the recent increase in distance learning, instructors are interested in experiential learning activities that are effective for multiple modalities. This research had teams of students play a web-based educational game, The Production Planning Game, either in-person or remotely, as a culminating learning experience in a required junior level course in industrial and systems engineering. Student engagement and learning outcomes were evaluated across the two modes of delivery, in-person and remote. The online experiential learning activity is found to be effective at improving student engagement in three ways - cognitively, emotionally, and physically - and at improving student learning outcomes, regardless of modality. This talk will present the results of the study as well as explain how to implement the experiential learning activity - The Production Planning Game - in your course.

5 - Sequential University Admission Optimization with ML-Based Enrollment Forecasts

Meiling Wu, University of California, Irvine, Irvine, CA, United States

University admission decisions are made across multiple rounds under uncertainty about applicants' future enrollment behavior. In this work, we develop a sequential admission optimization framework that integrates machine learning-based enrollment probability predictions with a dynamic optimization model inspired by the newsvendor problem. Our objective is to help universities meet enrollment targets while balancing trade-offs among class size, academic quality, and scholarship budget usage.

We first apply supervised learning models to estimate applicant-level enrollment probabilities using historical admission and enrollment data. These individualized forecasts are then used as inputs to a sequential decision model that determines whom to admit or waitlist in each round of the admission cycle. The optimization

framework extends the classical newsvendor logic by incorporating asymmetric costs of over- and under-enrollment, and it is solved via dynamic programming to account for future rounds and applicant pools.

Unlike traditional models that optimize admissions in a static, single-shot setting, our approach explicitly handles the dynamic nature of admissions and the delayed realization of enrollment outcomes. The final enrollment outcome is only observed at the end of the admission cycle, making the problem resemble a delayed-reward optimization. We show that our model improves decision quality over myopic or deterministic heuristics by anticipating future applicant inflows and reacting to stochastic applicant behavior.

6 - Adaptive Convoy Logistics: A DDDA Framework with Dynamic Bayesian Belief Networks

Elnaz Alinezhad, Wayne State University, Detroit, MI, United States

This work presents a Dynamic Data-Driven Applications System (DDDAS) for adaptive fidelity management in digital twins, with a focus on convoy logistics in contested environments. A Dynamic Bayesian Belief Network (DBBN) is developed to estimate latent system states using multimodal sensor observations, enabling real-time probabilistic reasoning under uncertainty. The latent variables modeled include Environment, Vehicle, Convoy, Operation, Human, and Enemy states, each inferred from heterogeneous inputs such as terrain, visibility, fuel, maintenance, health, and risk indicators. The system adaptively adjusts sensor fidelity levels and model update rates based on Bayesian posterior probabilities, minimizing computational load while preserving decision-relevant accuracy. A momentum-based prior update mechanism, controlled by a smoothing parameter α , is incorporated to balance responsiveness and belief stability. Through sensitivity analysis across varying α -values, we demonstrate how fidelity dynamics respond to memory-depth trade-offs. Simulation results show that environmental and vehicle subsystems exhibit sustained high-fidelity periods, while human and adversarial nodes trigger more transient responses. This framework enables scalable, resource-efficient digital twins that remain operationally responsive, particularly when integrating computationally expensive human-system components.

7 - Modeling the Evolution of Driver Trust in Conditionally Automated Vehicles Using a Bdi-Based Dynamic Bayesian Framework

Roohollah Jahanmahin, Wayne State University, Detroit, MI, United States, Sara Masoud

This research presents a cognitively inspired framework for modeling how driver trust evolves in conditionally automated vehicles. Using the Belief–Desire–Intention (BDI) model embedded in a Dynamic Bayesian Network (DBN), trust is represented as a latent state influenced by system performance, driver goals, and emotional context. Belief reflects the driver's perceived AV reliability, desire captures motivation to delegate control, and intention models the resulting behavioral decision. The model combines subjective trust ratings with observable behavior (e.g., gaze, AV outcomes) to infer and predict trust over time. A utility-based probabilistic function is trained to estimate intention decisions, enabling real-time trust monitoring. This framework supports the development of adaptive, trust-aware AV systems that can respond to individual cognitive states and behavioral changes.

8 - How Digitization Shapes Scientific Collaboration? Evidence from Electronic Health Records

Max Wang, Columbia Business School, New York, NY, United States

Digitization transforms knowledge production in teams by improving data interpretability and shareability. This paper validates this claim by estimating the effect of adopting Electronic Health Records (EHR) on scientists working at US hospitals. EHR is a digitization technology that standardizes and centralizes patient record data. It is designed to improve care delivery, and its adoption has been regulated since 2009. Using a panel of scientists from 148 teaching hospitals, I show that EHR adoption increases collaboration by 6.1% and broadens intellectual diversity by 1.1%. These effects surpass those of adopting conventional health information technologies without data standards and intensify when collaborators share a common EHR system. I then show that EHR adoption compromises research outcomes in citations and novelty, likely due to adjustment costs. Senior scientists, whose experience attenuates adjustment costs, benefit more from working with EHR. I corroborate my analyses using interviews with real-life hospital scientists.

9 - Optimizing Speed and Carbon in Omnichannel Fulfillment: AI-Powered Next-Day Delivery & Same-Day Pickup

Nixalkumar Patel, LG Electronics, Lake Hiawatha, NJ, United States

In the face of rising customer expectations and sustainability mandates, a large omnichannel enterprise reimagined fulfillment with advanced AI and analytics. In this session, we will demonstrate how to build ZIP-level demand-forecasting models and deployed intelligent allocation algorithms to optimize both next-day home delivery and same-day in-store pickup. Attendees will see how these techniques increased conversion and fulfillment reliability, while delivering measurable reductions in last-mile carbon emissions. We will examine key AI and machine-learning methods, explore the environmental trade-offs of AI-driven routing and delivery-window management, and present a scalable framework applicable across industries. You will leave with a practical blueprint for designing and implementing smarter, greener fulfillment strategies at scale.

Data Mining for Inference and Mathematical Conjecturing

Invited Session

Data Mining

Chair: Yanjun Qian, Virginia Commonwealth University, Richmond, VA, United States

1 - Predictive Inference for Ion Concentration Using Ensemble Models

Yanjun Qian, Virginia Commonwealth University, Richmond, VA, United States

Accurately measuring trace amounts of Nickel (Ni) and Cobalt (Co) is crucial for environmental monitoring, assessing toxicological risks, and ensuring quality control in industrial processes. While UV-Vis spectroscopy offers a rapid and non-destructive alternative to traditional chemical assays, it presents its own statistical challenges, including high dimensionality, significant multicollinearity, nonlinear signal-response relationships, and often limited sample sizes. We propose utilizing a stacked ensemble approach for spectral regression tasks, which consistently delivers stronger predictive accuracy compared to its individual components. Additionally, we incorporate uncertainty quantification methods to provide well-calibrated and interpretable confidence intervals, making this framework suitable for regulatory and decision-making contexts. Overall, this work presents a robust and principled pipeline for predicting ion concentrations, leveraging insights from uncertainty quantification.

2 - Spatiotemporal Machine Learning Framework for Predicting Dengue Incidence in the Dominican Republic

Sahil Chindal, Virginia Commonwealth University, Richmond, VA, United States, Demian Herrera, Manuel Colome-Hidalgo, Helena Sofia Rodrigues, Yanjun Qian, Michael Robert

Dengue is a mosquito-borne disease endemic to many tropical and subtropical regions around the world, including the Dominican Republic. Temperature, precipitation, humidity, and other climate variables play a crucial role in dengue spread due to their association with mosquito growth and proliferation. Using climate and dengue case data, we develop models for spatiotemporal analysis of dengue transmission between various provinces of the Dominican Republic. We estimate the reproduction number (R_0) and effective reproduction number (R_t) for each province using traditional statistical methods as well as various ensemble learning and deep learning models. We train our model for multiple years of data, and compare the accuracy of our methods to the expected values of R_0 and R_t for dengue in the region. We investigate graph neural networks (GNNs) to explore the relationship of dengue case transmission between provinces. We aim to construct a model that can help determine the flow of dengue transmission between provinces. Our model can be integrated with geographic, sociodemographic, and other types of information as part of a comprehensive early warning system that predicts outbreaks and informs public health and mosquito control policies.

3 - Reinforcement Learning for Mathematical Conjecturing

Samuel Paul Gyamfi, Virginia Commonwealth University, Henrico, VA, United States

Mathematical conjecturing plays a foundational role in scientific discovery, offer-

ing interpretable expressions that describe or bound relationships between variables.

Existing tools like the CONJECTURING framework, developed by Brooks et al., automate this process using the Dalmatian heuristic—a deterministic approach that generates symbolic expressions as trees and selects those that are valid across all data and not outperformed by others. While powerful, this heuristic is static: it does not learn from past experience, struggles with noisy or incomplete data, and lacks flexibility in balancing complexity and accuracy.

This project proposes a new direction: replacing the Dalmatian heuristic with a Reinforcement Learning (RL) framework. Rather than relying on fixed rules, an RL agent would learn to evaluate and filter expressions based on reward signals that account for both approximation error and structural simplicity. Each candidate expression becomes a decision point—should the agent keep or discard it? Over time, the agent would learn a generalizable policy for selecting high-quality, interpretable expressions tailored to the data.

4 - Data-Driven Analysis of Arctic Vessel Navigation: Mining Historical Shipping Patterns for Navigational Behavior Inference and Risk Assessment **Mauli Pant, Virginia Commonwealth University, Richmond, VA, United States, Linda Fernandez**

The Arctic Northwest Passage (NWP) offers emerging maritime opportunities, but also considerable risks due to shifting environmental and ecological conditions. This study analyzes Automatic Identification System (AIS) data from 2010 to 2019 to evaluate vessel speed as a proxy for backcasting navigational decisions under varying Arctic conditions. Key environmental drivers—sea ice concentration, wind speed, bathymetry, and whale distribution—are examined for their impact on vessel behavior and navigational risk.

Missing data on sea ice, wind, and bathymetry are interpolated using spatio-temporal kriging. Generalized Linear Mixed Models (GLMMs) with a Gamma distribution and log link are used to model Speed Over Ground (SOG), addressing zero-inflation and heteroscedasticity. The models incorporate spatial and temporal random effects to account for geographic and seasonal variability in vessel behavior.

The overlap between vessel tracks and environmental data enabled assessment of ice-related risks using Arctic Climate Change Economy Society (ACCESS 2015) safe speed thresholds. Findings show that cargo and tanker vessels frequently exceed these thresholds, with approximately 40% of vessels from 2010 to 2019 exposed to ice-related risks. GLMMs explain 67% of SOG variability compared to the null model, with spatial effects alone accounting for 31% of the variance. Interactions between vessel group and ice concentration reveal how vessels adjust speed in response to ice. Similarly, interactions between vessel status and bathymetry highlight how navigation decisions are influenced by ocean depth.

Future work will incorporate whale distribution data to evaluate ship strike risks, contributing to a risk optimization framework for sustainable Arctic maritime operations.

5 - Genotype Classification Using High-Resolution Melt Curves and Machine Learning Approaches **Parastoo Bybordi, Virginia Commonwealth University, Richmond, VA, United States, Indranil Sahoo**

In forensic science, high-resolution melt (HRM) curve analysis, a method for DNA sample analysis, plays an important role in criminal cases. High-resolution melt (HRM) curves provide valuable insights that help investigators identify people based on their DNA profiles at crime scenes. This is critical in situations where the DNA samples are degraded or exist in low amounts, which makes the analysis more challenging. Moreover, High-resolution melt (HRM) analysis is a cost-effective and rapid technique to confirm or rule out individuals from investigations by comparing the genotypes of DNA samples found at the scenes. HRM curves provide predictions about genotypes with accurate results even with degraded DNA samples. Machine learning methods are valuable tools for accurately analyzing HRM curves and improving the prediction and classification of genotypes from DNA samples. Machine learning algorithms precisely extract features from high-resolution melt (HRM) curves to identify and categorize the genotypes. Using these advanced methods in the initial stage of DNA analysis before the sample becomes degraded can increase the accuracy of identifying contributors' genotypes. This investigation aims to develop machine learning techniques that enhance the accuracy and reliability of genotype classification in scenarios where other DNA analyses, like STR profiling, may be less effective due to a limited amount of DNA sample data.

6 - Spatiotemporal ML Prediction of Egg Counts of the Dengue Vector *Aedes Aegypti* in Cordoba, Argentina **Sushyanth Sridhar, Virginia Tech, Blacksburg, VA, United States, Robert Michael, Esra Toy**

Abstract:

Dengue fever has escalated to critical levels across Latin America, with over 13 million cases and 8,000 deaths reported in 2024 alone. Accurate forecasting of *Aedes aegypti* populations is essential for proactive vector control. This study proposes a spatio-temporal modeling framework to predict weekly egg counts using ovitrap surveillance data in Córdoba, Argentina. We evaluate machine learning (ML) models—Random Forest, Gradient Boosting, XGBoost—and LSTM over a 28-week breeding season (November–May). Historical data from 178 traps (2009–2013) and recent records from 33 traps (2023–2024) form the observational basis. To address limited recent surveillance, we introduce a novel data augmentation method using K-means clustering and random resampling, validated via Fourier analysis to preserve temporal frequency characteristics. ML models trained on real ovitrap data achieved R^2 scores above 0.95, with Random Forest consistently outperforming other ML methods. An LSTM model trained solely on synthetic data also demonstrated high predictive fidelity. Environmental features, including LANDSAT-7 land cover indices and NASA POWER weather data, served as critical inputs. Our results reveal strong associations between mosquito incidence and urbanization, surface moisture, and small water bodies, with reduced presence in arboreal zones. Peak egg counts consistently occurred after week 16. This framework offers scalable, data-efficient strategies for guiding vector control in resource-constrained environments.

Machine Learning and Optimization for Decision-Making Under Uncertainty

Invited Session

Data Mining

Chair: Dervis Ozay, The University of Texas at Arlington, Arlington, TX, United States

Co-Chair: Shouyi Wang, The University of Texas at Arlington, Arlington, TX, United States

1 - Design Optimization Techniques Under Uncertainty, Incorporating Online Learning and Calibration to Account for Evolving Market Conditions

Shouyi Wang, The University of Texas at Arlington, Arlington, TX, United States

Dynamic pricing under uncertainty is critical for small and medium-sized sellers operating in competitive e-commerce markets. Existing platform tools, such as those offered by Amazon, often provide only basic rule-based adjustments—setting minimum and maximum thresholds or staying below competitors' prices—without accounting for seasonality, customer behavior, or broader competitive dynamics. This study develops an adaptive optimization framework that combines probabilistic demand forecasts with techniques such as Bayesian optimization, grid search, and random search to determine optimal pricing and advertising expenditure. By integrating online learning and calibration, the framework adapts to evolving market conditions while remaining computationally efficient and accessible for smaller sellers. Validation in simulated market environments shows that the approach improves pricing precision, captures demand fluctuations, and supports practical, affordable dynamic pricing strategies beyond the limitations of current platform tools.

2 - Enhancing Healthcare Access in Rural Appalachia via a Hybrid Truck&Ndash;Drone Delivery System Powered by Deep Reinforcement Learning

Sabrullah Deniz, The University of Tennessee Knoxville, Knoxville, TN, United States

Timely delivery of critical medical supplies in rural and mountainous regions is hindered by poor infrastructure, long travel distances, and unpredictable conditions. This work proposes and evaluates a hybrid truck–drone delivery framework optimized using multi-agent deep reinforcement learning (MADRL) to improve healthcare logistics in such challenging environments. Trucks act as mobile depots transporting bulk supplies to strategically chosen stops, from which drones execute agile last-mile deliveries. The operational decision-making problem is modeled as a Decentralized Partially Observable Markov Decision Process (Dec-POMDP) and solved using a centralized-training, decentralized-execution (CTDE) MADDPG architecture with an aggregator-based critic, enabling scalable coordination under partial observability. We develop a custom simulation environment for East Tennessee's rural topology, incorporating realistic fuel, battery, traffic, and weather constraints. Experiments compare single-truck and multi-truck fleet configurations, each paired with varying drone fleet sizes. Results demonstrate that (i) integrating drones significantly reduces last-mile delivery times and truck mileage, (ii) increasing the number of trucks enables workload partitioning that lowers both delivery time and operational cost, and (iii) an optimal fleet balance exists where the marginal benefit of additional drones diminishes. The proposed DRL-driven hybrid system achieves up to 30–40% reduction in total delivery time and 20% cost savings compared to traditional truck-only logistics. This framework is adaptable to other rural and underserved regions, providing a scalable, data-driven approach to improving healthcare accessibility.

Keywords: rural healthcare logistics, hybrid truck–drone delivery, deep reinforcement learning, multi-agent systems, last-mile delivery optimization

3 - Energy Infrastructure Planning Under Extreme Weather Uncertainties

Thushara Gunda, Sandia National Laboratories, Livermore, CA, United States

Extreme weather poses significant risks to critical infrastructure operations. However, the uncertainties associated with these events pose even more challenges to energy planning activities that are looking out 5 to 50 years into the future. This talk will summarize multiple efforts that are aiming to leverage machine learning and advance data analytics to support characterization of current impacts at both the generator and at grid scales. We will also describe how these impacts are being projected into the future to support identification of optimal investment decisions.

4 - How Uncertain are Your Confidence Intervals: An Investigation on Molecular Properties Prediction

Priscilla Avegliano, IBM Research, São Paulo, Brazil, Emilio Vital Brazil, Eduardo Soares, Victor Shirasuna

Uncertainty is an inescapable part of any decision-making process that takes place in the real world. Even state-of-the-art Machine Learning Models are susceptible to errors that can stem from a myriad of uncertainty sources, ranging from measurement errors to model bias. To tackle this issue, confidence intervals are often used to express how certain a model is about its predictions, but these intervals are themselves error-prone, and if they are over or underestimated they can lead to poor decisions. Hence, the calculation of confidence intervals must be subject to a careful analysis to maximize its contributions. Conformal Prediction is a promising method for generating confidence intervals. It works well with small datasets and makes minimal assumptions about the data or model. A key idea in this method is to estimate how different a new input is from previously seen data. This difference, expressed by a “distance” measure, helps determine how wide the confidence interval should be—the more unfamiliar the input, the wider the interval. In this work, we investigate whether measuring distance in an embedding space, where data is represented in a compressed and more structured form, can improve the confidence interval calculation. We conduct experiments using an open-source deep-learning model for molecular properties prediction. Our results compare embedding-based distances to the traditional Tanimoto distance, a common similarity measure in chemistry. We evaluate which approach produces more reliable confidence intervals for decision-making associated with molecular property prediction tasks.

Technology, Innovation Management and Entrepreneurship

Chair: Zhili Tian, Univ. of Houston, Houston, TX, United States

1 - Toward Fair and Informed Vaccine Allocation: Data-Driven Prioritization of Vaccine Proposals Using Multi-Modal Fusion, Temporal Processing, and Multi-Criteria Decision Optimization

Ashutosh Kumar, Rochester Institute of Technology, Rochester, NY, United States, Ruben Proano

Equitable vaccine distribution in low- and middle-income countries (LMICs) remains a persistent challenge amid financial, logistical, and data limitations. Each year, the Global Alliance for Vaccines and Immunization (GAVI) must allocate a limited budget across diverse country proposals to maintain routine immunization, introduce new vaccines, or respond to outbreaks. Existing decision frameworks often struggle to account for heterogeneous, incomplete data spanning epidemiological, socio-economic, and political domains, resulting in suboptimal and inequitable outcomes.

We propose an AI-driven decision-support system to enhance transparency and contextual relevance in GAVI's annual vaccine funding decisions. The system integrates: (1) a **data imputation module** for reconstructing missing epidemiological data using static, temporal, and latent variables; (2) an **interpretable multimodal fusion pipeline** that learns joint representations across health, infrastructure, and economic indicators; and (3) a **multi-objective optimization model** that prioritizes proposals by balancing health impact, equity, and feasibility under real-world constraints (e.g., cold-chain capacity, limited supply).

We hypothesize that integrating robust imputation and multimodal learning will yield more accurate, context-aware funding recommendations, and that a multi-objective optimization framework will outperform existing rule-based or single-objective methods. Validation will use public (WHO, UNICEF, GAVI) and simulated datasets to assess imputation accuracy, representation quality, and allocation performance, measured via Pareto efficiency, DALYs averted, and equity indices. This work contributes the first unified AI pipeline for vaccine budget allocation, potentially supporting more equitable and effective global immunization strategies.

2 - Using Children's Games to Illustrate Lean Principles in Healthcare Process Improvement

Murray Côté, Texas A&M University, College Station, TX, United States

Lean management has become a widely adopted framework for healthcare quality improvement due to its emphasis on waste reduction, standardization, and continuous process improvement. Despite its benefits, widespread and sustained implementation in healthcare settings can be perennially difficult, often due to limited stakeholder engagement and the complexity of fostering a lean mindset. This presentation uses children's games as an educational and validation tool to enhance stakeholder

understanding and application of lean principles in healthcare process improvement. The games *Cootie* and *Hi Ho! Cherry-O* serve as an analog for healthcare processes as the simplicity of the games, combined with the intuitive underlying Markov structure, allows stakeholders to visualize process variability, understand performance metrics such as cycle time, and identify areas for process improvement. Four scenarios are compared to demonstrate how baseline conditions and probability distributions affect overall performance. This approach provides a user-friendly approach that encourages stakeholder engagement and demystify lean methodologies. In turn, our approach contributes a novel, accessible tool for lean education in healthcare, reinforcing the need for stakeholder-driven, experiential learning to ultimately achieve sustainable quality improvement.

3 - Port Congestion and Resilience Effects on Supply Chains

Elham Zafarani, Arizona State University, Tempe, AZ, United States

We examine US port congestion and resilience, focusing on the impact of external shocks, such as weather events, on supply chain flows. We examine these flows over time and across industries, aiming to inform policy on infrastructure investment to alleviate port congestion and improve resilience.

Plenary Keynote

Plenary

1 - Delta at 100: Harnessing a Century of Insight to Power the Future of Travel with AI

Eric Phillips, Delta Airlines, Atlanta, GA, United States

As Delta Air Lines celebrates its centennial year, we reflect on a century of transformation fueled by data, innovation, and a deep commitment to customer experience. From early operational metrics to today's real-time, AI-powered decision-making, Delta's journey highlights how data and insights have continually shaped our strategy and elevated our brand.

This session explores how Delta's digital and AI evolution is not a recent shift, but a natural extension of our longstanding focus on operational excellence and customer-centricity. AI is now embedded across our enterprise—from optimizing crew and aircraft scheduling to delivering personalized, real-time support through the Fly Delta app and emerging tools like Delta Concierge.

These capabilities are redefining how employees embody Delta's values, how we manage global operations with precision, and how we create seamless, tailored experiences for over 200 million customers annually.

Attendees will gain insight into how Delta is leveraging AI to:

Enhance operational reliability through predictive analytics.

Empower employees with intelligent tools that streamline service.

Drive loyalty through hyper-personalized engagement strategies.

Build a scalable digital platform that connects data, people, and purpose.

Join us to discover how Delta's century of experience is powering the next era of intelligent, human-centered air travel.

1 - AI-Augmented Monte Carlo Simulation for Capital Investment Decisions in Innovation Project Portfolios

Gustavo Vinueza, Ferryfield, Ithaca, NY, United States

Capital investment decisions in innovation project portfolios are characterized by high uncertainty—ranging from technical feasibility and development timelines to market adoption and regulatory approval. Traditional deterministic models often fail to capture these uncertainties, leading to suboptimal capital allocation and increased risk exposure. This paper introduces a decision-support framework that combines Monte Carlo Simulation (MCS) with artificial intelligence (AI) to support more robust, data-informed investment strategies. Monte Carlo Simulation is used to model uncertainty across financial and scheduling dimensions, producing probabilistic estimates for key metrics such as Net Present Value (NPV), Internal Rate of Return (IRR), and the likelihood of cost and time overruns. To improve simulation fidelity, AI techniques—particularly machine learning—are applied to historical and contextual project data. These models help refine input distributions, detect interdependencies between projects, and dynamically adjust assumptions in response to new evidence. Beyond input calibration, AI is used to support optimization efforts by analyzing simulated outcomes and identifying portfolio strategies that maximize expected value under defined risk constraints. This enables decision-makers to explore trade-offs between risk and return, better allocate limited capital, and gain visibility into the impact of uncertainty drivers. The proposed framework is demonstrated through a fictitious innovation portfolio composed of diverse early-stage projects. Results show improved transparency, better risk-adjusted returns, and actionable insights for capital allocation under uncertainty. The methodology is applicable to industries where innovation drives value, such as pharmaceuticals, energy, and technology.

2 - From Classroom to Industry: Modern Optimization with AMPL for Energy, Finance, Supply Chain, and Beyond

Gleb Belov, AMPL Optimization Inc., Melbourne, Australia, Marcos Dominguez Velad

Optimization has never been more critical – or more accessible. This talk will show how students and applied researchers can bridge the gap between academic learning and real-world impact using AMPL in modern workflows. With free academic licenses now including commercial-grade access to leading linear solvers (Gurobi, CPLEX, Xpress, Mosek, COPT, HiGHS and more), AMPL offers an unmatched opportunity to develop and apply optimization skills directly in industry contexts. We will explore how AMPL integrates seamlessly with the tools you already know – Python, R, Jupyter, Colab, VS Code, cloud platforms, and modern data pipelines – making it a “set it and forget it” system for building models that stay faithful to the real problems you're solving. Attendees will see how AMPL powers large-scale, mission-critical applications in energy, finance, transportation, and supply chain, enabling companies to save costs, increase efficiency, and improve decision-making. By combining intuitive modeling with cutting-edge solver technology, AMPL empowers students and researchers not just to learn optimization, but to contribute immediately to high-impact, industry-grade projects. Join us to discover how AMPL can position you, or your students, at the forefront of applied optimization.

Chair: Aparna Gupta, Rensselaer Polytechnic Institute, Troy, NY, United States

1 - Estimating GHG Emissions Using Advanced Industrial Classification Systems**Rei Yamamoto, Keio University, Kohoku-ku, Japan, Akifumi Isogai, Masatoshi Nozaki, Kosuke Ishikawa**

This study proposes a novel methodology for estimating corporate greenhouse gas (GHG) emissions using a highly detailed industry classification system. Conventional estimation models often rely on coarse, single-segment industry classifications, which fail to capture the complexity of modern business structures—particularly when estimating Scope 3 emissions. In contrast, we utilize the FactSet Revere Business Industry Classification System (RBICS), which categorizes companies into over 1,800 detailed business segments based on revenue composition. By combining RBICS data with company financials and disclosed emissions data, we construct an Ordinary Least Squares (OLS) regression model that incorporates multi-segment business structures. Our empirical analysis of 4,000 global companies demonstrates that more granular classifications (L6 level) significantly improve the explanatory power of the model compared to traditional methods. Additionally, companies with diversified business portfolios show lower estimation errors, indicating the model's robustness. Unlike machine learning approaches, our method maintains high interpretability, allowing stakeholders to identify which business activities drive emissions. This transparency is particularly valuable for financial institutions aiming to manage climate-related risks and engage with investee companies. Our findings suggest that advanced product-based classification systems, combined with transparent modeling, can meaningfully enhance the accuracy and usability of GHG emissions estimates in sustainable finance.

2 - When the Weather Hits the Market: the Financial Impact of Climate Extremes on Firms in the Energy Sector**Thomas Purchas, University of Washington, Bothell School of Business, Bothell, WA, United States, Xiahua Wei**

This study investigates the potential causal relationship between extreme weather events and the financial performance of U.S. energy sector firms. We focus on the growing occurrence of climate-related disruptions, including hotter summers, colder winters, and a rising frequency and intensity of hurricanes, and analyze their impact on firm's financial outcomes, such as revenues and stock prices. Analyzing historical weather and financial data, we identify patterns of abnormal returns associated with these events. Our findings provide insights to inform investor strategies and enhance understanding of climate-related financial risk in the energy sector.

3 - Disaster Risks and Intergenerational Equity**Heqing Huang, National University of Singapore, Singapore, Singapore, Harrison Hong, Neng Wang**

Disasters, especially ones worsened by climate change, pose a threat to intergenerational equity. As society learns about these disaster risks with unfolding extreme events, we model how to optimally ensure intergenerational equity, which is captured by a constraint that the welfare of future generations be in expectation non-decreasing over time. The planner's solution under this sustainability criterion can be decentralized by disaster-risk state-contingent fiscal policies. When disaster risk is high, the sustainability constraint binds and consumption taxes are then needed to subsidize investments for future generations. Calibrating to the US data, we solve for the optimal fiscal policies and show how intergenerational equity differs with and without the sustainability considerations.

4 - Investment Decision Support for Circular Economy Portfolio Allocation by Firm and Industry**Aparna Gupta, Rensselaer Polytechnic Institute, Troy, NY, United States**

There is an increasing emphasis the world over for reducing waste and making the industrial economy more circular and geared towards sustainability. However, the appropriate advisory for making investment allocation decision to support this development and advancement is significantly missing. In this paper, we develop an

investment analysis framework to support investors' assessment of industries and firms to make their investment allocation decision.

1 - How Not to Overpackage: AI for Sustainability in Hellofresh's Service Supply Chains

Evelyn Xiao-Yue Gong, Carnegie Mellon University, Pittsburgh, PA, United States, Michael Johnson

Packaging waste is a common challenge faced by meal kit subscription services. Before shipping each meal kit box, providers must decide the grade of liners and the number of freezer packs to include. While these materials are essential for preserving the quality and safety of meal kits in transit to customers, excessive use leaves a larger carbon footprint. As the leader of the meal kit industry, HelloFresh is committed to furthering the sustainability of its supply chain and decreasing its environmental footprint. This paper formulates the contextual packaging problem as an online learning problem, and develops a contextual bandit-based AI method to mitigate overpackaging efficiently. Our algorithm, Contextual One-Sided Arm Elimination, takes into account weather, conditions of transit, box contents and other information to adaptively make the packaging decision for each box. We extract structural information from offline delivery data to accelerate online learning. Our algorithm achieves theoretically optimal performance with an $\sim O(T^{1/2})$ regret bound where T is the horizon length. We test our algorithm on real delivery data from HelloFresh and identify points of overpackaging in the current guidelines. In comparison with the current practice of conducting physical chamber experiments to build packaging guidelines, our algorithm refines the packaging guidelines more swiftly, with higher granularity and lower cost. Our method is effective in identifying overpackaging in existing guidelines, and could smoothen the transition process to new packaging options that are more environmentally friendly in the future.

2 - Achieving Rawlsian Justice in Food Rescue

Aydin Alptekinoglu, Penn State, University Park, PA, United States, Gerdus Benade

We study a problem faced by a national food rescue platform that matches each donation to the first recipient who claims it. Recipients have very different response rates, leading to a few highly responsive recipients claiming the bulk of the donations. We ask whether priority lists, which control when the donation is announced to each recipient, are a remedy for such inequitable outcomes. We show that an n -stage priority list, with an individual notification time specific to each eligible recipient, can achieve any desired expected allocation, hence any fairness target, if the donation is non-perishable. Two-stage or binary priority lists, which notify eligible recipients in only two waves, are simpler to implement and administer but offer less fine-grained control over fairness outcomes. For both perishable and non-perishable donations, we give polynomial-time algorithms to find the n -stage and binary priority lists that optimize a class of Rawlsian objective functions-maximize the minimum value-representing a notion of fairness that focuses on the worst-off. The key insight that animates optimal priority list design throughout is to give higher priority (and thus more time to claim a donation) to recipients who have received less in the past and to those who were slower in responding to notifications. We prove that this idea can be codified into a simple index by which to rank order eligible recipients. Computational experiments calibrated by real data confirm that even simple, binary priority lists lead to significantly more fair allocations than the existing first-come-first-serve allocation system.

3 - Improving Access to Essential Medicines in Sierra Leone via Machine Learning

Angel Tsai-Hsuan Chung, The Wharton School, UPenn, Philadelphia, PA, United States, Jatu Abdulai, Patrick Bayoh, Lawrence Sandi, Francis Smart, Hamsa Bastani, Osbert Bastani

A critical challenge in healthcare systems in Low- and Middle-Income Countries (LMICs) is the efficient and equitable allocation of scarce resources, particularly essential medicines. This problem is complicated by limited high-quality data, which restricts the applicability of traditional data-driven techniques. We propose a novel machine learning framework for essential medicines allocation, which leverages a combination of multi-task learning and decision-aware learning to improve sample efficiency and ensure equitable allocation. In collaboration with the Sierra Leone national government, our framework has been deployed nationwide as a decision support tool to help reduce waste and improve essential medicines allocation. Our evaluation using synthetic difference-in-differences analysis demonstrates a 19% increase in medicine consumption, with no changes to the supply, improving access for approximately 3.7 million women and children under five. Through experimental validation, we demonstrate that our approach also significantly outperforms baseline approaches. Our work demonstrates the tangible impact of machine learning in optimizing high-stakes decisions in resource-constrained settings, improving efficiency while ensuring equity and cost-effectiveness.

4 - Unveiling Operational Processes: the Impact of Real-Time Videos on Operational Outcomes

Zhanzhi Zheng, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Yuqian Xu, Bradley Staats

In the digital age, merchants are presented with an expanding range of resources to enhance operational transparency for customers. Moreover, the digital marketplace increasingly demands improved transparency due to the physical separation between merchants and customers. This paper explores a new method to enhance operational transparency for merchants on digital platforms: displaying real-time videos of their operational processes. Using a unique dataset about chain restaurants on a leading food delivery platform, we employ the difference-in-differences method with matching techniques for empirical analyses. Our results show that the display of real-time videos indeed improves restaurants' operational performance on the platform, including demand, customer average spending per order, and revenue. Furthermore, we find that reducing information asymmetry could be a key mechanism driving the positive effects of real-time videos. Specifically, these benefits are more pronounced for restaurants with less available information on the platform, such as those with fewer online reviews or lacking the premier label. Additionally, by leveraging advanced computer vision algorithms, we analyze the performance impact of key features in real-time videos through image mining, focusing on both the quality and content of the visual information that customers observe. Our findings indicate that both image quality and region of interest coverage play a crucial role in enhancing the benefits of operational transparency. Overall, our study highlights the importance of sharing visual information on operational processes to enhance performance in the digital marketplace, offering actionable insights for platform managers and service providers aiming to optimize their video content for improved outcomes.

1 - The Toll of Driver Moral Hazard in Ride-Hailing Platforms

Mengwei Qu, University of Connecticut, Storrs, CT, United States, Chen Liang, Chunxiao Li, Shuliu Yuan, Bin Gu

This paper investigates the prevalence of moral hazard behaviors among ride-hailing drivers and evaluates the impact of different forms of platform control on their engagement in such behaviors. By examining the differences in incentive structures across product lines within a prominent ride-hailing platform in China, we utilize rides where driver compensation is fixed as a benchmark to measure moral hazard in similar rides with variable compensation. Leveraging the quasi-random variation in trip characteristics arising from the platform's order dispatch algorithm, we find that (1) Ride-hailing drivers indeed engage in moral hazard behaviors, including taking detours and exceeding estimated payment. (2) During trips with higher compensation, e.g., long trips or those with a higher driver compensation ratio, drivers tend to exhibit increased, rather than decreased, engagement in moral hazard behaviors. (3) Drivers on the hook for a car lease contract exhibit significantly lower levels of moral hazard behavior than independent drivers.

2 - Policing the Platform: Uncovering the Impact of Police Involvement in Online Platforms on Users' Voluntary Contributions

Jingyan Dai, University of Florida, Gainesville, FL, United States, Qili Wang, Shu He, Liangfei Qiu

Government organizations are increasingly using social media to engage with the public, with police departments serving as a prominent example. However, the effects of government presence on online platforms, particularly on users' voluntary contributions, remain unclear. In this study, we address the gap and examine how police involvement influences users' voluntary contributions on a leading online neighborhood platform. Using a difference-in-differences approach, we find that police involvement leads to a decline in voluntary user posts. This reduction is primarily concentrated in posts concerning less severe and more ambiguous safety incidents, suggesting that users may engage in increased caution and self-censorship in response to perceived police monitoring. To better understand the underlying mechanisms, we conduct additional analyses by introducing moderators such as the percentage of visual evidence (e.g., photos and videos in posts) and the number of police-generated posts. Furthermore, we evaluate the effects of police involvement on the quality of user posts. Our findings show that the length and uniqueness of safety-related posts increase, indicating potential community safety benefits linked to police involvement. Overall, our study offers valuable insights for online platforms aiming to collaborate with government agencies in ways that enhance platform content quality while preserving user engagement. It also provides practical guidance for government agencies on leveraging social media to foster more effective community engagement.

3 - Multi-Homing Across Social Media: Influencer Behavior and Its Impact on Content Creation

Kinzhi Rao, University of Florida, Gainesville, FL, United States, Jingyan Dai, Yulin Hao, Liangfei Qiu

This study examines the strategies and impacts of multi-homing behavior among social media influencers. Using data from TikTok and RedNote, we provide empirical evidence on the current landscape of multi-homing: only a minority of influencers engage in multi-homing, typically doing so when follower growth on their original platform stagnates, and they choose to cross-post only a subset of their content to the other platform. To identify the causal effects of multi-homing on content creation and performance, we employ a Difference-in-Differences (DiD) approach. Our results show that multi-homing leads to significant increases in follower count, content quantity, user engagement, and sponsorship activity. Furthermore, multi-homing promotes content diversification and generates positive spillover effects on exclusive (non-multihomed) posts. These findings offer valuable insights into influencer strategies and platform competition, highlighting multi-homing as a powerful tool for audience expansion and monetization.

4 - Nudging for Re-Engaging Multi-Homing Consumers: Evidence from a Randomized Field Experiment

Xi Jing, Boston University, Boston, MA, United States, Tong Shen, Chen Liang, Chunxiao Li, Bin Gu

Multi-homing poses an increasing challenge for digital platforms, particularly in industries where aggregator apps enable users to submit multi-homing requests, allowing simultaneous product or service searches across multiple distinct platforms. To counteract multi-homing, platforms can deploy nudging strategies to encourage users to conduct product or service searches directly within the platform's native channel. To assess this strategy in a ride-hailing context, we leverage archival data from a randomized field experiment on a leading ride-hailing platform in China. The experiment involves 49,902 multi-homing users who had initiated at least one multi-homing request during the one-week experiment period. Among them, those randomly assigned to the treatment group received a message nudging them to use the focal platform's native channel upon their multi-homing request, while those in the control group received no intervention. We find interesting results. First, nudging significantly increases consumption on the platform through its native channel usage without cannibalizing rides booked via the aggregator. Second, nudging is more effective among users with a stronger brand attachment. However, it is not effective in bringing back disengaged multi-homing users to the platform's native channel. Third, the effect of nudging is contingent on cross-channel promotion comparisons. Nudging is only effective when the platform's native channel offers a larger discount than the aggregator. Fourth, the effect of nudging intensifies as the coupon validity period shortens. Our findings offer important practical insights for optimizing nudging strategies to re-engage multi-homing users and offer broader implications for platform competition dynamics.

Job Market Showcase

Chair: Amirhossein Moosavi, University of Michigan, Ann Arbor, United States

1 - A Model-Based Approach to Vacant Vehicle Routing of A Ride-Sourcing Fleet in Transportation Networks

Guocheng Jiang, University of Massachusetts Amherst, Amherst, MA, United States, Song Gao

A model-based approach to the optimal routing of vacant ride-sourcing vehicles is developed for scalability with respect to the fleet size in metropolitan scale transportation networks. The routing is formulated as an average-reward maximizing, infinite-horizon semi-Markov Decision Process problem in a physical transportation network with each node as a state and outgoing links as actions. All taxis are assumed to follow a uniform, parameterized, probabilistic policy to reduce the state and action space dimensions and balance out crowding. State transition probabilities are endogenous due to the competition among vehicles for passengers, and theoretical analyses are provided regarding the existence and uniqueness of the stationary distribution of the embedded Markov chain for a given policy.

A proof-of-concept two-node network case study shows that the optimal policy makes trade-off between moving to a high-demand area and the cost of relocation, while heuristics relying purely on demand distributions do not perform as well. A case study in a large network with around 30k links is conducted. The vacant taxi spatial distribution of the optimal policy indicates that vacant taxis tend to stay in and move towards areas with high demand such as the city center and transportation hubs, consistent with intuition. As the fleet size increases, the optimal policy dictates more widely spread vacant taxis and the optimal unit profit decreases, suggesting that competition leads to certain loss of profit.

2 - Distributed Load Balancing with Workload-Dependent Service Rates

Wenxin Zhang, Columbia University, New York, NY, United States, Santiago Balseiro, Robert Kleinberg, Vahab Mirrokni, Balasubramanian Sivan, Bartek Wydworski

We study distributed load balancing in bipartite queueing systems where frontends route jobs to heterogeneous backends with workload-dependent service rates. The system's connectivity---governed by compatibility constraints like data residency or resource requirements---is represented by an arbitrary bipartite graph. Each frontend operates independently without any communication with the other frontends, and the goal is to minimize the expectation of the average latency of all jobs. We propose a closed-loop policy called the Greatest Marginal Service Rate policy (GMSR) that achieves effective coordination without requiring arrival rates knowledge.

In a discrete-time stochastic model, we show that the behavior of our routing policy converges (almost surely) to the behavior of a fluid model, in the limit as job sizes tend to zero and job arrival rates are scaled so that the expected total volume of jobs arriving per unit time remains fixed. Then, in the fluid regime, we demonstrate that the policy attains an ϵ -suboptimal solution in $O(\delta \log(1/\epsilon))$ time from δ -suboptimal initial workloads, which implies global convergence to the centrally coordinated optimal routing.

Finally, we analyze the fluid model when the system is overloaded. We show that GMSR lexicographically maximizes throughput, maximizes the number of stable backends, and minimizes their collective workload.

3 - Rerouting During Shipping Lane Disruption

Yaniv Ravid, University of Toronto, Toronto, ON, Canada, Ming Hu

Major disruptions to global supply chains in recent years have imposed billions of dollars of additional costs onto consumers, retailers, shippers and manufacturers all around the world. In many instances, these disruptions reduce the capacity of major shipping lanes for unknown periods of time. These short-term disruptions, often driven by extreme weather, political forces, and chance events, have long-term implications on suppliers' decision-making. We study the implications of these disruptions on

shippers and the global supply chain using a transient queuing model. We derive the optimal self-interested routing policy under uncertain disruption length, and show that myopically dealing with this uncertainty results in unnecessarily long lines of ships awaiting travel in the disruption channel. We use real container-ship traffic data to show how our findings can mitigate the impact of such disruptions. We fit our model to the blockage of the Suez Canal in 2021, and analyze the sentiment of over 4,000 news articles to measure shippers' uncertainty in the disruption length, showing how hundreds of ships could have avoided unnecessary delays by choosing alternative routes, saving billions of dollars in delay costs imposed onto consumers as a result.

4 - Learning-Based Distributed Ambulatory Care Scheduling

Amirhossein Moosavi, University of Michigan, Ann Arbor, MI, United States

This work studies an ambulatory care scheduling problem for a geographically distributed healthcare center offering multi-appointment, multi-class, and multi-priority treatments. The problem is considered in a dynamic environment characterized by uncertain patient arrivals and emergency department utilization, formulated as an infinite-horizon Markov decision process. Given the limitations of conventional methods in solving large-scale instances, a neural network is integrated within the Markov decision process model to simplify feasibility constraints while ensuring adherence to the problem's assumptions. To mitigate the curse of dimensionality inherent in the Markov decision process formulation, an affine approximation architecture is employed to estimate the value function. Subsequently, an equivalent linear programming model is developed and solved using column generation, enabling computation of approximate optimal policies. Additionally, two straightforward, easy-to-implement scheduling policies are derived from this approach. Simulation results indicate that the approximate optimal policy and derived heuristic rules significantly outperform alternative scheduling methods. Specifically, the proposed approach enhances performance metrics within a large Canadian ambulatory care center context. In contrast, the traditional template-based scheduling rule currently used at the center results in high resource utilization but often leads to suboptimal scheduling decisions. Providing booking clerks with efficient, data-driven scheduling rules demonstrates substantial improvements over scheduling templates.

Generative AI in Business Analytics: Innovations, Applications, and Implications

Invited Session

Information Systems

Chair: Houping Xiao, Robinson College of Business, GSU, Atlanta, GA, United States

1 - Rewiring Deep Engagement: How Generative AI Transforms Knowledge Exchange in Online Q&a Communities

Xinyuan Wei, Georgia State University, Atlanta, GA, United States, Xinfu Fu, Arun Rai, Yusen Xia

This research examines how the emergence of generative AI (GenAI), specifically ChatGPT, impacts user engagement within online Question & Answer (Q&A) communities like Stack Exchange. Drawing on a collective information foraging perspective, the study analyzes user behavior before and after ChatGPT's release, treating it as an exogenous technological shock. Utilizing a difference-in-differences approach, the research focuses on shifts in answer elaboration and evaluation, key aspects of collective knowledge foraging. Findings indicate that GenAI increases deep engagement by broadening both answer elaboration and total evaluation breadth, partially mediated by changes in question evaluation. This suggests GenAI not only serves as a substitute for user-generated content but also stimulates wider distribution of user attention and engagement across diverse answers, enhancing the collective foraging process. The study introduces the concept of cognitive discrepancy between AI- and peer-generated content as a driver for deeper engagement in this foraging ecosystem and offers insights for platform design in an AI-mediated environment, adapting to evolving social information foraging dynamics.

2 - A Self-Instantiated Multi-Agent System for Simulating Field Experiments

Yaoyu Chen, University of Illinois Chicago, Chicago, IL, United States, Yingda Lu, Yuheng Hu

Field experiments are a gold standard in social science research for establishing causal claims in naturalistic settings. However, they are notoriously costly, time-consuming, ethically sensitive, and difficult to replicate. To address these challenges, this paper proposes a novel framework that uses Large Language Models (LLMs) to simulate field experiments through a Self-Instantiated Multi-Agent System (SIMAS). LLM-driven agentic models are well-suited for simulating individual decision-making, as they instantiate autonomous entities with distinct goals and internal states. Building on this capacity, recent studies have demonstrated the feasibility of replicating laboratory experiments using LLMs. Extending this line of research, our work targets the more complex and underexplored domain of field experimentation by offering a fine-grained simulation of naturalistic decision-making processes. In contrast to prior lab-based simulations—often constrained by limited generalizability and lacking coordinated multi-agent dynamics—the proposed SIMAS is adaptive to universal field experiment scenarios, capable of determining treatments, automatically generating synthetic participants, collecting responses, and drawing experimental conclusions through a reflective, iterative process. Notably, its self-instantiation mechanism enables the large-scale generation of synthetic agents, fulfilling the scale requirements of various kinds of experiments. Our artifact is to be evaluated against a diverse set of field experiments across domains such as finance, marketing, and organizational behavior. This study contributes both a theoretical advancement—demonstrating emergent capabilities of LLMs in simulating human-like interactions at scale—and a methodological innovation in designing domain-adaptive multi-agent architectures for experimental research.

3 - Evaluating Generative AI for Medical Reporting: a Comparative Study of Clinician and LLM-Based Diagnoses for Mild Cognitive Impairment

Houping Xiao, Robinson College of Business/GSU, Atlanta, GA, United States

Generative Artificial Intelligence (AI), such as ChatGPT, holds significant promise in healthcare, particularly in automating the generation of medical reports and clinical recommendations. This capability raises important questions about its potential to complement or even replace traditional diagnostic processes, such as those used for Alzheimer's Disease (AD). Clinician-generated medical reports based on functional MRI (fMRI) images have long served as a gold standard in cognitive assessments. However, it remains unclear how patients and healthcare professionals perceive and evaluate reports produced by large language models (LLMs) compared to those authored by clinicians. This study investigates the effectiveness of LLM-generated medical reports in the context of predicting Mild Cognitive Impairment (MCI). By comparing medical reports written by clinicians and LLMs, and incorporating analysis of impaired shallow spatial features derived from deep learning models, we aim to assess the diagnostic reliability and user appraisal of AI-generated content. The findings will offer critical insights into the role of generative AI in clinical decision-making and its broader implications for the future of healthcare delivery.

4 - An Integrative ML and Rag Pipeline for Health Data-Based Hypothesis Generation

mouayed lajnef, Georgia State University, Atlanta, GA, United States, Aaron Baird, Yusen Xia, Arun Rai

Hypothesis generation in scientific research has traditionally relied on researcher intuition, gap spotting, and theory-driven inquiry. Recent advances in machine learning (ML) and large language models (LLMs) offer new opportunities for data-driven discovery by surfacing complex patterns in observational data. However, two major challenges persist: (1) ML-generated insights often lack interpretability and standardization, and (2) verifying the novelty of these hypotheses typically requires extensive manual literature reviews, which are time-consuming and difficult to scale. To address these issues, we propose an integrated hypothesis generation and verification pipeline that combines interpretable ML methods, Retrieval-Augmented Generation (RAG), and a structured conceptual framework. Our pipeline includes a five-step ML discovery module that uncovers statistically robust higher-order interactions, followed by a RAG-powered literature agent that retrieves and synthesizes relevant studies from PubMed to assess novelty. To better align machine-generated hypotheses with existing scientific knowledge, we extend the widely-used PICO framework (Population, Intervention, Comparison, Outcome) into PICO-CMV by introducing three additional dimensions: *Conditions*, *Modifiers*, and *Validation*. This enhancement allows for a more granular organization of evidence and supports structured comparison with existing literature. A Human-in-the-loop design is implemented at multiple stages, including hypothesis refinement, model interpretation, and literature verification, ensuring that domain expertise shapes and validates machine-driven insights. We illustrate the utility of this pipeline through an application in the substance use disorder (SUD) context, showing how novel, testable hypotheses can be efficiently surfaced and contextualized within the existing body of evidence.

1 - Incoherence of Business Model Innovation During Digital Transformation**Chen Ye, University of Cambridge, CAMBRIDGE, United Kingdom**

This research investigates business model incoherence during digital transformation, a critical challenge for innovating firms. Initial foundational work, based on 50 interviews and workshops, classified six types of incoherence—strategic, organizational, operational, partner-driven, market-driven, and regulation-driven—stemming from four primary sources: changes in decision rights, incentives, information flow, and material flow, alongside potential solutions. Furthermore, focused longitudinal single-case studies with firms examined the mechanisms of incoherence through the paradox lens, highlighting how firms navigate contradictory demands like efficiency versus flexibility by managing different business models. Building on this, multi-case studies with the firms further explored the deep mechanisms of how incoherence occurs and is managed within different value configuration models. This demonstrated how "disciplined incoherence"—loose coupling and organized contestation—is used to manage these tensions, revealing alternative effects on creating versus sustaining competitive advantage. Additionally, industry-specific multi-case studies also explored incoherence mechanisms, such as in Large Language Model ecosystems (LLM), where firms manage strategic tensions, and in predictive maintenance in manufacturing, where institutional constraints drive incoherence during servitization.

Moreover, the study expanded by using system dynamics modeling on firms to reveal how misalignments initiate incoherence, identifying balancing feedback loops and reinforcing loops in contexts. Additionally, a crisp-set qualitative comparative analysis (csQCA) of cases identified specific configurations of sources leading to internal incoherence versus external incoherence. Collectively, these studies deepen the understanding of incoherence, extending strategic contradiction theory and the Business Model Cohesiveness Scorecard (BMCS) by detailing dynamic pathways and offering actionable solutions for managers to anticipate and resolve the incoherence.

2 - Incorporating Sustainability into Portfolio Choices: a Rational Investor Approach**Giulia Crippa, Princeton University, Princeton, NJ, United States**

Traditional mean-variance portfolio frameworks often impose constraints—such as minimum sustainability thresholds—as proxies for investor preferences, implicitly assuming that constrained and preference-based approaches yield equivalent solutions. However, this assumption may misrepresent rational investor behavior or fail to capture investor heterogeneity.

In this paper, we extend the classical mean-variance framework by incorporating a sustainability attribute directly into the investor's utility function. We formally characterize the conditions under which constrained and preference-based formulations are equivalent, building on prior results from the dynamic portfolio choice literature. In a complete market setting, we derive closed-form equilibrium strategies that generalize the classical solution to account for sustainability preferences.

We validate our theoretical findings through simulations and an empirical application using U.S. equity data. By endogenously recovering investor trade-offs across return, risk, and sustainability, we construct a three-dimensional mean-variance-sustainability (MVS) efficient frontier that yields Pareto-optimal portfolios. Our framework establishes a coherent and flexible foundation for sustainable investment design, with direct implications for asset managers and policymakers seeking to align portfolio performance with sustainability objectives.

3 - Contingent Performance Impact of Digital Transformation Orientation: An Organizational Change Perspective**Hongyu DUAN, Hong Kong Baptist University, Hong Kong, Hong Kong**

Despite growing global emphasis on the potential of digital transformation as a strategic orientation, firms often struggle to realize its anticipated benefits. To clarify the intricate relationship between digital transformation orientation (DTO) and firm performance, this study proposes that organizational changes exert powerful influences. A longitudinal data set pertaining to 2,766 Chinese public firms, for the years 2010–2022, reveals that on average, DTO diminishes firm performance (return on assets), but this negative impact also is moderated by specific organizational changes, both asset-centric (e.g., asset divestiture, expansion) and human-centric (e.g., executive and employee turnover). Asset divestitures and expansion mitigate the negative impacts of DTO by optimizing resource allocations; employee turnover introduces new skills that can alleviate these adverse performance impacts. However, frequent IT executive turnover exacerbates the negative performance impacts by disrupting strategic persistence and leadership stability. The combined results thus help address prior mixed findings regarding the performance implications of DTO and highlight contingencies stemming from organizational changes. In underscoring the importance of aligning organizational change initiatives with DTO, the current study offers actionable recommendations for firms navigating their own digital transformation journeys.

4 - How Developers' Social Interaction on External Platforms Shapes Firms' Strategy Orientations in Digital Innovation**Sidi Zhao, Auburn University, Auburn, AL, United States, Pei Xu, Uzma Raja**

Digital innovation is essential for firms aiming to enhance competitiveness, improve operations, and drive value creation. A firm's strategic orientation toward digital innovation shapes how it engages with emerging technologies and determines its long-term success. While existing research emphasizes top management as the primary driver of this orientation, the role of developers, especially through external social interactions, remains underexplored. Drawing on the absorptive capacity theory and heterogeneous diffusion model, we propose that developers play a critical role in steering their firms' digital innovation strategies. Collaborative development platforms with social media features serve as key conduits for knowledge transfer beyond firm boundaries, allowing developers to absorb external expertise and inform strategic direction from the bottom up. Leveraging longitudinal data from 2010 to 2022 on USPTO patents and GitHub developer networks, we identify four distinct innovation strategies firms may pursue: No Engagement, Comprehensiveness-Only, Efficiency-Only, and Fully-Engaged. We then examine how developer network characteristics, social proximity (cohesion and role equivalence), infectiousness, and susceptibility, shape firms' strategic choices. Our results show that while social cohesion and susceptibility have mixed effects, role equivalence and infectiousness consistently exert positive influences. Moreover, susceptibility moderates these effects, dampening the influence of cohesion but strengthening that of role equivalence. This study contributes a novel typology of digital innovation strategies and advances a developer-driven view of innovation. By highlighting how micro-level developer interactions drive macro-level strategic outcomes, we complement traditional top-down accounts and offer new insights into how firms can leverage developer communities for sustained innovation and competitive advantage.

Chair: Ali Akhavan, MIT, Boston, MA, United States

1 - Efficiently Solving Variational Inequalities Under the Minty Condition, and Game-Theoretic Applications**Brian Zhang, Carnegie Mellon University, Pittsburgh, PA, United States**

Solving (Stampacchia) variational inequalities (VIs) is a foundational problem at the heart of optimization, with a host of critical applications ranging from engineering to economics. However, this expressivity comes at the cost of computational hardness. As a result, most research has focused on carving out specific subclasses that elude those intractability barriers. A classical property that goes back to the 1960s is the Minty condition. We will establish the first $\text{poly}(d, \log(1/\epsilon))$ -time algorithm for solving SVI problems under the Minty condition. Prior approaches either incurred an exponentially worse dependence on (and other natural parameters of the problem) or made overly restrictive assumptions – such as strong monotonicity. To do so, we introduce a new variant of the ellipsoid algorithm wherein separating hyperplanes are obtained after taking a gradient descent step from the center of the ellipsoid. It succeeds even though the set of SVIs can be nonconvex and not fully dimensional. Moreover, when our algorithm is applied to an instance with no MVI solution and fails to identify an SVI solution, it produces a succinct certificate of MVI infeasibility. Finally, we will discuss the numerous relationships and implications of our framework for learning in games and computational game theory more broadly, including the best algorithms for computing and learning certain kinds of correlated equilibrium in concave games.

This talk will cover joint works with Ioannis Anagnostides, Emanuel Tewolde, Ratip Emin Berker, Gabriele Farina, Vincent Conitzer, and Tuomas Sandholm.

2 - Online Learning for Dynamic Vickrey-Clarke-Groves Mechanism in Sequential Auctions Under Unknown Environments

Vincent Leon, University of Illinois Urbana-Champaign, Urbana, IL, United States, Rasoul Etesami

We consider the problem of online mechanism design for sequential auctions in unknown environments, where the underlying market and the values vary over time as the auctions progress. We model the sequential auctions as an infinite-horizon Markov decision process (MDP), where the transition kernel and reward functions are unknown to the seller. In each round, the seller determines an allocation and a payment for each bidder. Each bidder receives a private reward and submits a sealed bid to the seller. The state, which represents the underlying market, evolves according to an unknown transition kernel and the seller's allocation. Unlike existing works that formulate the problem as a multi-armed bandit model or as an episodic MDP, where the environment resets to an initial state after each episode, our paper considers a more realistic and sophisticated setting in which the market continues to evolve without restarting. We first extend the Vickrey-Clarke-Groves (VCG) mechanism, which is known to be efficient, truthful, and individually rational for static auctions, to sequential auctions, thereby obtaining a dynamic VCG mechanism counterpart that preserves these desired properties. We then focus on the online setting and develop a reinforcement learning algorithm for the seller to learn the underlying MDP model and implement a mechanism that closely resembles the dynamic VCG mechanism. We show that the learned online mechanism asymptotically converges to a dynamic mechanism that approximately satisfies efficiency, truthfulness, and individual rationality with arbitrarily high probability and achieves guaranteed performance in terms of various notions of regret.

3 - An I-Mobility" Framework for Studying Social Mobility: Individualized Inference via Generative Analysis of Discrete Data

Jiawei Huang, University of Cincinnati, Cincinnati, OH, United States, Dungang Liu, Yuan Jiang

Social mobility refers to the ability of individuals or groups to move within a social hierarchy. Interest in social mobility has grown over the past decades due to rising concerns over educational disparities and the intergenerational persistence of poverty. Existing literature primarily investigates this issue by focusing on broad demographic groups (e.g., race, gender, or country), which may overlook important nuances between individuals. In this work, we establish an 'i-Mobility' framework that allows us to study social mobility at the individual level. Specifically, given a predefined profile with a combination of individual characteristics, our framework can provide a measure that reflects the mobility of this 'individual.' Analysis of the well-regarded General Social Survey (GSS) shows that our framework is more robust than traditional group-focused methods for studying social mobility. Moreover, our framework can capture heterogeneity at the individual level and distinguish between different profiles by considering more nuanced personal characteristics.

4 - Benchmarking Estimation of Dynamic Models in Social and Behavioral Sciences

Ali Akhavan, MIT & MGH, Cambridge, MA, United States, Jimmy Cabot, Hazhir Rahmandad

Reliable parameter estimation is critical for dynamic simulation models across various fields, such as economics, epidemiology, ecology, marketing, management, and sustainability. We present a benchmarking framework that systematically assesses the inference quality of diverse estimation methods for such models. The framework provides various performance metrics, such as RMSE, posterior contraction, interval score, z-score, and simulation-based calibration tests. In addition, we offer a testbed of canonical dynamic models with different scales (e.g., number of parameters) and dynamic complexity levels (e.g., different modes of behavior). The testbed includes representative models such as Bass Diffusion, SEIRb, Market Growth, and Lotka-Volterra, selected through a literature review and a survey of modeling experts. We use the benchmarking framework to assess Neural Posterior Estimation (NPE) as an illustrative example of emerging likelihood-free approaches and report the inference quality as a function of various training data sizes. The method-agnostic testbed models and performance metrics will allow researchers to assess and compare alternative estimation methods, ranging from classical maximum-likelihood estimators to various simulation-based inference algorithms such as Neural Ratio Estimation (NRE) or Sequential Neural Posterior Estimation (SNPE). The benchmark can also be expanded with new testbed models that may incorporate more complex estimation problems. We hope our research promotes a transparent, scalable, and replicable way of quantitative evaluation of inference quality across the existing and emerging estimation methods for dynamic simulation models.

1 - Metadata-Aware Multimodal Object Detection with Feature-Level Fusion for Unpaired Rgb-Thermal Datasets

Nicolas Bustos, University of South Florida, Tampa, FL, United States, Susana Lai-Yuen, Tapas Das

Unpaired multimodal datasets pose challenges to fusing information in multimodal object detection algorithms. Unpaired datasets either lack spatial alignment between image modalities or have missing images for some scenes. Traditional solutions rely on image registration (e.g., SIFT, Fourier-Mellin Transform) and domain translation methods (e.g., CycleGAN). However, these techniques are often sensitive to environmental conditions—especially when using RGB images—and are not optimized for detection tasks. Instead, they produce pseudo-realistic aligned pairs that are not often suitable representations to enhance object detection. Moreover, metadata such as weather or time-of-day labels remains underutilized despite its potential to improve object detection.

We propose a novel multimodal object detection framework capable of leveraging all image modalities from datasets that are unpaired. A thermal-to-RGB generator is trained to produce synthetic RGB features optimized for object detection, which uses a YOLOv10 model pre-trained on RGB images. These RGB features are fused in another YOLOv10 model during its training with original thermal images. At this step, we also fuse metadata features extracted from ResNet50 models pre-trained to classify weather and time of the day on the thermal images.

The Teledyne FLIR dataset is used to train and test the models in our framework. This dataset contains unpaired RGB and thermal images, partially labeled with weather and time of day. We train the algorithms with only annotations for cars and people, as these are the most critical categories in the fields where multimodal object detection is applied, such as surveillance and autonomous driving.

2 - Human-Centric Xr Design to Support Dimensions of Wellness: Applications Across Domains and Age Groups

Emre Eraslan, University of Illinois Urbana-Champaign, Urbana, IL, United States, Qiyuan Cheng, George Mois, Wendy Rogers, Avinash Gupta

Extended reality (XR), which includes virtual reality (VR), augmented reality (AR), and mixed reality (MR), presents new opportunities for enhancing human well-being across different life stages. Although XR technologies are increasingly applied in health, education, and social domains, there is limited understanding of how specific XR modalities correspond to the diverse and interconnected Dimensions of Wellness (DoW), especially when considering differences among young, middle-aged, and older adults. The DoW framework includes emotional, physical, intellectual, social, occupational, environmental, financial, and spiritual aspects, each contributing to overall quality of life. This study offers a systematic mapping review that classifies XR interventions by DoW, age group, and study context. Following the PRISMA-ScR methodology, 145 peer-reviewed studies published between 2016 and 2024 were identified through searches in PubMed, Scopus, and Web of Science. The analysis shows that fully immersive VR is the most frequently used modality, while non-immersive VR, AR, and MR show more variable patterns of use. Emotional, physical, intellectual, and social DoWs are consistently addressed across age groups, and occupational DoW appears primarily in studies involving young adults. In contrast, environmental, financial, and spiritual DoWs remain largely unaddressed. These findings highlight critical gaps in current XR research and suggest opportunities for more inclusive, age-responsive design. By mapping DoW priorities to XR capabilities, this study paves the way for designing targeted VR applications that address population-specific needs, bridging the gap between research insights and real-world interventions.

3 - Optimization and Learning Methods Applied to Automated Vision-Based Body-in-White Dimensional Inspections

Yifei Zhang, Ohio State University, UPPER ARLINGTON, OH, United States, Theodore Allen

Traditional measurement of gaps and flush in automotive Body-in-White (BIW) assembly relies on manual instruments such as feeler gauges or dial gauges, which are labor-intensive, time-consuming, and unable to provide continuous data. This work develops a vision-based inspection system capable of automatically and non-invasively measuring BIW dimensions under dynamic production conditions.

Due to challenges such as limited supervised dimensional data, scarce target detection images, moving targets, and the requirement for prediction errors below 0.5 mm, this work proposes a framework that integrates Optimal Transport (OT) theory, Markov Decision Process (MDP) formulations, and regression-based modeling. OT-based image matching with Procrustes Analysis ensures precise alignment of edge points, enabling robust geometric transformation learning. The MDP formulation allows Reinforcement Learning (RL) agents to autonomously learn optimal tracking strategies in dynamic environments, while polynomial regression provides accurate dimensional prediction with limited supervision.

Experimental results show that the system achieves over 93% detection accuracy and reduces computation time by more than two orders of magnitude compared with grid search baselines. These findings demonstrate that combining OT-based matching, RL-driven tracking, and regression modeling yields a scalable, low-cost solution for high-precision visual inspection.

4 - Advancing Admixture Genetic Analysis with Large Language Model (AdmixAI)

Nahian Tahmin, The University of Tennessee Knoxville, Knoxville, TN, United States, Lokesh Chinthala, Franco Marsico, Akram Mohammed, Silvia Buonaiuto, Vincenza Colonna, Tesfaye Mersha, Robert L Davis, Anahita Khojandi

Recent advancements in artificial intelligence have significantly enhanced genomic research. LLMs facilitate the integration of contextual information into predictive models, thereby improving our understanding of ancestry-informed genetic influences on disease predictions.

Despite these advancements, genomic studies have predominantly focused on populations of European ancestry, leading to a limited understanding of complex diseases in admixed populations, such as self-reported African-American (AA) individuals. This leads to limitations of the generalizability of risk prediction models, exacerbating disparities in disease diagnosis and treatment. Additionally, most previous studies have primarily relied on global ancestry estimates and linear associations between genetic variation and ancestry. This approach often overlooks the complex, nonlinear interactions that can occur at more granular levels, such as local ancestry (LA). Incorporating local ancestry (LA) can offer deeper insight into genetic disease risk, especially in admixed individuals. Notably, conditions like asthma exhibit significant prevalence variations across diverse populations, underscoring the necessity for ancestry-informed methodologies in genomic risk assessment.

To address these challenges, we propose AdmixAI, an innovative LLM-based pipeline that integrates genotype data, LA ancestry data and clinical data to enhance disease risk prediction in self-reported AA populations. AdmixAI explicitly models interactions between ancestry and genetic variants to enhance predictive accuracy and support precision medicine in admixed populations. To our knowledge, it is among the first applications of LLMs for ancestry-informed genomic risk prediction, specifically targeting asthma. By integrating ancestry and genotype data into LLM-based pipelines, AdmixAI aims to refine polygenic risk scoring and promote more equitable precision genomics.

Applications of Vehicle Routing in Modern Logistics

Contributed Session

Contributed

Chair: Nikhil Eti, Clemson University

1 - A Practical Algorithm for Multi-Vehicle Residential Waste Collection Problem

Seungyeop Lee, Pohang University of Science and Technology (POSTECH), Pohang, Korea, Republic of, Sangil Han, Byung-In Kim

The residential waste collection problem is a variant of the arc routing problem. It seeks an arc sequence that minimizes the total route cost of a fleet of heterogeneous vehicles servicing all required arcs and edges on a mixed graph, which includes both directed arcs and undirected edges. Each vehicle must visit landfills multiple times during its route to dump collected waste due to capacity constraints. It must also comply with a maximum work time from departure to return at the depot. However, solutions that focus solely on minimizing total route cost are often unacceptable to practitioners for the following reasons. First, they neglect turn penalties associated with heavy vehicles, leading to inaccurate calculations of work time. Second, unbalanced workloads among drivers are problematic due to disparities in work intensity. Third, excessive overlap in service areas and repeated visits to the same roads are undesirable for both drivers and residents. To address these issues, we propose a graph partitioning-based matheuristic. Specifically, we introduce a clustering algorithm that leverages both the graph structure and coordinate data of the road network to generate visually attractive clusters. Using this algorithm, we adopt a sequential clustering approach, where balanced clustering is first used to assign required arcs and edges to each vehicle. Then, capacitated clustering is applied within each vehicle's cluster to assign the required arcs and edges to feasible subtrips. For each decomposed single-trip problem, we minimize turn-penalized route cost. Consequently, our method yields solutions that are cost-efficient, workload-balanced, and visually attractive.

2 - Joint Optimization of Driver Shift Assignment and Vehicle Routing in Ada Paratransit

Shijie Chen, Florida State University, Tallahassee, FL, United States, Hishamur Rahman, Nikola Markovic, Yanshuo Sun

Paratransit services mandated by the Americans with Disabilities Act (ADA) play a vital role in providing accessible transportation for individuals with disabilities. Traditional scheduling methods, however, often fail to account for drivers' shift preferences and the financial impacts of shift reassignments. To address this gap, we develop an integrated optimization framework that jointly determines vehicle routes and driver shift assignments for ADA paratransit. The problem is formulated as a route-based integer program, which requires a large number of routes and causes an infeasibility issue. Therefore, we propose a two-phase relaxation-decomposition algorithm that combines Lagrangian relaxation with column generation to address the challenges. Comprehensive numerical experiments using synthetic and real-world data reveal that our model achieves up to 42.8% cost reduction by optimizing shift reassignments and reducing reliance on extra board drivers. Additionally, the model adapts effectively to various operational scenarios, including cases with skewed shift preferences and rising shift differential costs.

3 - Last-Mile Delivery Assignment Across a Traditional Route and a Crowdsourcing Platforms

Raghavan Srinivasan, Metro State University, St.Paul, MN, United States, Joseph Szmerkovsky

In this study we aim to determine the assignment of packages to be delivered between traditional routes and crowdsourcing services using a contemporary Machine Learning (ML) approach. The objective is to achieve the lowest possible operational costs using a combination of the two delivery options given capacity constraints. To achieve this, a ML model is first used to determine the packages to be assigned to a crowdsourcing platform with the remainder being delivered using a traditional delivery route. The packages are to be delivered in a definite geographic region, and a Geographic Information System (GIS) is used to determine the optimal traditional route.

4 - Incentive-Based Consolidation In Last Mile Parcel Delivery

Semih Boz, University of Massachusetts Amherst, Amherst, MA, United States, Ahmed Ghoniem, Amro El-Adle

We study incentive-based parcel consolidation within the context of last-mile delivery by a single vehicle over multiple time periods. We propose a mixed-integer program enhanced with RLT cuts. The efficacy of our methodology is assessed through computational experiments on realistic networks.

5 - The Vehicle Routing Problem with Transfers

Maichel M. Aguayo Bustos, Universidad San Sebastián, Concepcion, Chile

In the vehicle routing problem (VRP), a fleet of capacitated vehicles serves a set of customers with known demands at minimum cost. We study the VRP with transfers (VRP-T), where customers can be visited by multiple vehicles. Additionally, customer locations can be used as transfer points to exchange loads among vehicles. We find that routing costs can potentially be reduced by up to 50% by allowing such transfers in the VRP. We develop a two-index mixed-integer programming (MIP) model and a heuristic algorithm based on multi-start local search (MSLS). The solutions obtained by MSLS are used as a warm start for the MIP, and the corresponding approach is tested. Computational results indicate substantial savings in costs incurred and a reduction in the number of vehicles required when transfers are allowed.

6 - Multi Depot Multi Trip Vehicle Routing Problem with TIME Windows

Daniel Neira, Virginia Tech, Blacksburg, VA, United States

The multi-depot multi-trip vehicle routing problem with time windows (MDMTVRPTW) is a complex optimization problem that extends traditional vehicle routing problems by incorporating multiple depots, multiple trips per vehicle, service-dependent loading times, and fixed destinations. The objective is to minimize the total distance traveled while ensuring customer visits within specified time windows and operational constraints.

This study presents new mathematical formulations for the MDMTVRPTW, including a compact two-index formulation based on depot node insertion and a three-index formulation using arc replenishment. These models efficiently handle vehicle capacity, trip duration limits, and service times. Additionally, we propose a heuristic method based on a secondary graph in a dynamic programming algorithm to improve computational efficiency. The heuristic is compared against the exact formulations to evaluate solution quality and computational performance.

We validate our approaches using well-known VRP benchmark instances, including Solomon's datasets and others, to ensure robustness and applicability. The results demonstrate that the heuristic achieves near-optimal solutions with significantly reduced computational time, making it suitable for large-scale instances. The comparison highlights the trade-off between exact optimization and heuristic efficiency.

Our findings contribute to vehicle routing research by introducing novel formulations and a practical heuristic for solving real-world logistics challenges. Future work will explore hybrid metaheuristic techniques to further enhance solution quality and scalability.

7 - Online Mapping Errors and Their Impact On Last-Mile Delivery Operations

YUQING CHENG, Arizona State University, Tempe, AZ, United States, Elliot Rabinovich, Stanley Lim

We investigate the magnitude of online mapping errors and their impact on last-mile delivery operations in urban environments. These errors are reflected in the distances that exist between the actual geographical coordinates for delivery addresses and the coordinates for these addresses in the online navigation maps used by last-mile delivery agents. We report on the magnitude of these errors. Moreover, we estimate these errors' effects on delays incurred by agents performing these deliveries as well as on the likelihood of missed deliveries. We close with policy implications for last-mile delivery services based on these findings.

8 - Multi-Stage Stochastic Multi-Door Cross-Dock Scheduling Under Uncertain Arrivals

Nikhil Eti, Clemson University, Greenville, SC, United States, Bill Ferrell, Nathan Huynh

Cross-docks are facilities in a logistics network that are used to consolidate shipments so that truck utilization is improved. Products requiring delivery to different destinations arrive at a cross-dock from multiple sources. They are then consolidated by destination and shipped on trucks that are full or nearly full. This has many benefits including lower costs and fewer trucks required for deliveries which reduces road congestion and emissions. This research focuses on cross-dock operations under disruptions; specifically, disruptions that delay arrival times of inbound trucks. This is important because outbound trucks have departure deadlines designed for on-time delivery to customers. Delays to inbound freight can delay the outbound truck awaiting these items but they can also cause a dock door to be occupied that is needed to load subsequent outbound trucks. A Multi-Stage Stochastic Programming (CD-MSSP) model of cross-dock operations has been developed to schedule outbound trucks so that delays to outbound departures are minimized. The model is used to solve a number of scenarios which involve disruptions to inbound trucks causing them to arrive late at the cross-dock. To solve the resulting large mixed integer models, a Progressive Hedging (PH) algorithm is used to find good feasible solutions. The PH algorithm relaxes the complicating constraints in CD-MSSP to enable scenario-based decomposition which promotes faster solution times. The PH algorithm is compared with direct branch and bound algorithm for various numerical test instances, and the PH algorithm is found to be up to 42 times faster.

1 - Backwards Planning with Generative AI**Samantha Keppler, University of Michigan, Ann Arbor, MI, United States, Park Sinchaisri, Clare Snyder**

Generative AI technologies can help workers do tasks faster and better. However, workers often must plan their tasks in addition to completing them, and this planning can be difficult. K12 teachers plan tasks (i.e., activities, quizzes, projects) by working backwards from end-of-year goals defined by state standards. In this paper, we ask: How are teachers, who must both plan and do tasks, beginning to use generative AI? We conduct a longitudinal case study of 24 US public school teachers. During the 2023--2024 school year, we gather from these teachers 360 minutes of recorded observation of generative AI use for their own work involving over 200 inputted prompts and responses, together with 29 in-depth interviews and 34 generative AI use surveys. Analyzing this data corpus, we find teachers separate into three groups: (1) those who seek generative AI input (i.e., thoughts or ideas about learning plans) and output (i.e., quizzes, worksheets), (2) those who only seek generative AI outputs, and (3) those not using generative AI. The teachers in the first group—but not the second group—report productivity gains in terms of workload and work quality. In sum, workers can use generative AI for known tasks (task-level) or for deciding which tasks to do (workflow-level). Task-level use may save time completing tasks and increase the number of tasks done, but workflow-level use can save time deliberating about which tasks to do and nudge people toward the "right" tasks.

2 - Algorithm Reliance and the Value of Information in Recommendation Systems**Ruth Beer, Baruch College, CUNY, New York, NY, United States, Daniela Saban**

We study individuals' preferences for delegating managerial decisions to a matching algorithm, after a large set of alternatives have been screened and the best candidates have been identified. Two behavioral considerations are central to our setting: algorithm reliance (i.e., individuals' willingness to delegate decision rights) and preferences for information (i.e., individuals' preferences for making a more informed decision and learning). Our experimental results show that most subjects significantly overpay for the option to gather more information and select the candidate themselves. In addition, their beliefs about the probability that the algorithm selects the worst candidate, and the expected difference in benefit between the candidates conditional on the algorithm selecting the worst candidate, are significantly higher than what the normative theory prescribes, suggesting that cognitive biases are a salient driver of behavior.

3 - Privacy, Risk and Fatalism**Cagla Ergul, University of Michigan, Ann Arbor, MI, United States, Stephen Leider, Ruslan Momot**

Firms collect and analyze users' data to personalize and improve their service. However, the risk of data breaches exposing a user's personal data imposes privacy costs on the user. In this paper, we experimentally study how users engage with the firms' services under different levels of data breach risk. To motivate our experiment, we first develop a theoretical model to characterize how the users' behavior changes as the background breach risk from previous service use increases. We find that privacy-conscious users decrease their service usage as the firm collects more data when the background breach risk is higher. However, if the users have fatalistic beliefs (i.e. they believe they will eventually face a breach, and become less sensitive to further breach risks), they do not protect their privacy as the background breach risk increases. We conduct a laboratory experiment, examining both the low and high background breach risk cases. We find that the majority of the users are fatalistic and are unresponsive to the Firm's increasing data collection. Users primarily choose the action that maximizes payoffs conditional on a breach happening. The share of fatalistic users is similar for both levels of background breach risk. Our results align with the fatalism predictions of the model; users are not sensitive to further data collection regardless of the background risk. Our results still hold when breach risk is communicated in a disaggregated format: most users are fatalistic, with similar proportions across different background risk levels and risk communication formats.

1 - Air Cargo Tail Assignment and Shipment Routing Under Flight Time Uncertainty**Felipe Delgado, Pontificia Universidad Católica de Chile, Santiago, Chile, Shurui Zhu, Alessandro Bombelli**

Efficient and reliable air cargo transportation is critical for time-sensitive and high-value goods. However, disruptions caused by uncertain flight times present significant challenges, particularly when cargo requires tight connections. This paper presents a two-stage stochastic programming model that jointly optimizes aircraft tail assignment, flight schedule adjustments, and shipment routing under flight time uncertainty. The model accounts for heterogeneous cargo characteristics, including varying delay sensitivities and routing constraints, and incorporates operational penalties for delayed deliveries and flight rescheduling. To manage computational complexity, we introduce a tailored itinerary generation method and a scenario aggregation algorithm that preserves probabilistic characteristics while reducing solution time. The model is tested in an instance inspired by a major integrated logistics provider, including a night-time network of 86 flights among 35 Chinese airports. Computational experiments demonstrate that the proposed approach outperforms benchmark deterministic strategies based on expected and optimistic flight durations. The stochastic model achieves a 7.3% increase in average profit while enhancing load factors and reducing schedule disruptions. The results underscore the importance of integrating tactical and operational planning stages and accounting for uncertainty in air cargo logistics.

2 - Optimizing Baggage and Cargo Transport for the Aircraft Turnaround Process**Marcus Koh, Singapore University of Technology and Design, Singapore, Singapore, Rakesh Nagi, Nuno Ribeiro**

The aircraft turnaround process comprises a series of operations carried out between an aircraft's arrival at the gate and its subsequent departure. Given the involvement of multiple service vehicles performing diverse tasks, the Vehicle Routing Problem (VRP) provides a natural framework for modelling the process.

This research aims to develop a comprehensive model of turnaround operations to optimise resource planning across the airport. To generate a model that capture critical elements within the turnaround operations, a decomposition of the model into smaller VRP models for each separate GSE is considered. The first of the vehicle models in

focus is the baggage tractor vehicle that has several unique constraints that forces the consideration of multi-service, multi-trip, split delivery, heterogeneity, and intra-service precedence.

3 - Enhancing Airport Passenger Experience Through Large Language Models: Insights from Skytrax Data and Real-TIME Review Analytics

Burak Cankaya, Embry-Riddle Aeronautical University, Daytona Beach, FL, United States, Inci Polat Sesliokuyucu, Maria Petrescu, Unal Hayta, Scott Ambrose

Airports are working hard to provide better experiences for passengers, but it can be difficult to understand and respond to all the different needs and complaints travelers have. This study explores how Large Language Models (LLMs) and Knowledge Graphs, can help airports improve the way they serve passengers. By using data from Skytrax ratings and real-time Google reviews, we show how LLMs can quickly analyze large amounts of feedback to find common issues—such as confusing signs, long wait times, or unhelpful staff. We also developed a demo tool that creates visual maps of these insights, helping airports see where improvements are needed. We found that LLMs can make airport operations more efficient and help passengers feel more supported. We also provide a step-by-step guide for airports that want to start using AI in this way, along with ideas for future research.

4 - A Study of Scheduling and Fleet Routing for Urban Air Mobility Service

Adler Edsel, Purdue University, West Lafayette, IN, United States, William Crossley, Daniel DeLaurentis

Urban air mobility (UAM) is an emerging transportation system involving electric vertical-takeoff-and-landing (eVTOL) aircraft that operate with compatible infrastructure such as airports and heliports, collectively referred to as aerodromes. These aircraft carry passengers in and around metropolitan areas, with the intent of reducing travel times for these passengers compared to other modes of transport.

An on-demand UAM service would likely manifest as an aerial extension of current ground ride-hailing services (e.g., Uber and Lyft), whereas a scheduled UAM service would be modeled similarly to commercial airlines, involving a fixed timetable of flights and less dynamic pricing. Most existing UAM literature focuses on on-demand service; however, timetable-bound UAM operations may be a feasible alternative for a profit-seeking UAM operator if the schedule meets sufficient passenger demand. Implementing UAM operations bound to a fixed schedule may reduce the number of unprofitable deadhead flights required to satisfy demand for UAM services relative to an on-demand service model.

This study adapts airline scheduling and aircraft fleet routing methods to scheduled UAM operations and then uses these adapted methods to investigate a hypothetical UAM operator providing scheduled UAM services in a small three-aerodrome network serving the Chicago metropolitan area. A schedule design problem will determine a timetable of UAM flights informed by potential daily demand for UAM services, followed by a tail number assignment problem to assign aircraft throughout the network to meet this demand.

The Practice Section of Informs

Chair: Liron Yedidsion, Amazon, Redmond, WA, United States

1 - Fleet Allocation and Balancing of Branded Vehicles, Electric Vehicles and Rentals

Ram Thiruveedhi, Amazon, Austin, TX, United States, Abhilasha Katariya, Xiaodong Lan, Hugh Medal, Animesh Biyani

We present an optimization model for allocation and balancing of vehicle fleets to delivery stations. The Fleet Allocation and Balancing (FAB) model integrates heterogeneous fleet management across networks while accounting for operational constraints, costs, and sustainability requirements. Our approach unifies traditionally separate aspects of fleet management into a single optimization model. The FAB model optimizes multi-period planning horizons with weekly granularity, incorporating spatial distribution across stations and service partners, electric vehicle integration with charging infrastructure constraints, dynamic fleet composition through rental management and redeployments, and service partner requirements. The mathematical formulation captures the relationships between fleet availability, operational demands, and infrastructure limitations while maintaining computational tractability. We demonstrate the model's effectiveness using computational results showing cost reductions and efficiency improvements.

2 - Multi-Period Newsvendor for Capacity Planning

Liron Yedidsion, Amazon, Redmond, WA, United States, Chinmoy Mohapatra

Efficiently solving multi-period newsvendor problems is challenging due to the curse of dimensionality. We present a novel approach that combines the advantages of dynamic programming and reinforcement learning. By leveraging the discrete nature of the problem and using a neural network to approximate the value function, our method can handle high-dimensional state spaces without requiring a full simulation engine.

AI and Optimization for Smarter Healthcare Systems

Panel Session

Practice Track

Co-Chair: Priya Sarathy, Wheel Data Strategies, 1171 Cumberland Road NE, Atlanta, 30306, United States

1 - Moderator Panelist

Priya Sarathy, Wheel Data Strategies, Atlanta, GA, United States

Healthcare systems around the world are under relentless pressure — grappling with rising costs, workforce shortages, care disparities, and increasingly complex patient needs. At the same time, advances in artificial intelligence (AI) and operations research (OR) offer the promise of smarter, faster, and more equitable solutions. But translating these tools from theoretical models to real-world impact remains a complex, unfinished journey.

This panel brings together cross-disciplinary leaders from healthcare, AI, and optimization to explore how data-driven decision-making can transform clinical operations, resource allocation, diagnostics, and care delivery. We will examine the hard questions: Why have intelligent scheduling systems failed to gain adoption despite clinician burnout? Can AI triage models be both efficient and ethical during crisis response? How do we optimize care pathways when data remains fragmented and biased? Panelists will share grounded perspectives from hospitals, research labs, startups, and policy circles. Topics will span predictive analytics for patient risk, prescriptive models for workforce planning, and the governance frameworks needed to build trust in AI at scale.

Rather than showcasing only success stories, this session will focus on real-world tension points—where theory meets resistance, and where opportunities for transformation lie just beyond the next iteration. Attendees will walk away with sharper insight into what it takes to operationalize intelligence in healthcare settings, along with key questions they should be asking as both practitioners and innovators.

Strategic Defense and Adversarial Decision-Making under Uncertainty

Invited Session

Military and Security

Chair: Isabella Sanders, Arizona State University, Newburgh, NY, United States

Co-Chair: Quanyan Zhu, New York University, New York, NY, United States

1 - The Location Set Covering Disruption Problem**Brian Lunday, Air Force Institute of Technology, WPAFB, OH, United States**, Andrew Sheldon, William Caballero

This research proposes a new, relevant competitive location problem and examines variants that relax complete and perfect game theoretic assumptions. The *location set covering disruption problem* (LSCDP) represents a Stackelberg game wherein the leader disrupts access to at most q out of n possible facility locations, after which the follower solves a perturbed location set covering problem (LSCP). Acknowledging the perturbed LSCP may not be feasible, the proposed LSCDP model represents a leader seeking to lexicographically maximize the value-weighted demands that cannot be covered and the follower's minimal cost of facilities required to cover remaining demands. Whereas the LSCDP adopts a complete and perfect game theoretic framework, two problem variants respectively account for incomplete and imperfect information: $q^c \leq q$ of the leader's disruptions are unknown to the follower, and a follower may be aware of the possibility of such covert disruptions but not their number. This research identifies appropriate solution methodologies for each of these variants and empirically demonstrates selected methods to derive relevant insights.

2 - Search for An Immobile Hider on a Binary Tree with Unreliable Locational Information**Thomas Lidbetter, Rutgers Business School, Newark, NJ, United States**, Steve Alpern

Adversarial search of a network for an immobile Hider (or target) was introduced and solved for rooted trees by Shmuel Gal in 1979. In this zero-sum game, a Hider picks a point to hide on the tree and a Searcher picks a unit speed trajectory starting at the root. The payoff (to the Hider) is the search time. In Gal's model (and subsequent investigations), the Searcher receives no additional information after the Hider chooses his location. In reality, the Searcher will often receive such locational information. For homeland security, mobile sensors on vehicles have been used to locate radioactive material stashed in an urban environment. In a military setting, mobile sensors can detect chemical signatures from land mines. In predator-prey search, the predator often has specially attuned senses that may help it locate the prey. How can such noisy locational information be used by the Searcher? We model such information as signals which indicate which of two branches of a binary tree should be searched first, where all signals have a known accuracy $p < 1$. Our solution calculates which branch (at every branch node) is favored, meaning it should always be searched first when the signal is in that direction. When the signal is in the other direction, we calculate the probability the signal should be followed. Compared with the optimal Hider strategy in the classic search game of Gal, the Hider's optimal distribution for this model is more skewed toward leaf nodes that are further from the root.

3 - Scheduling Cybersecurity Mitigations to Delay Attacker Projects**Ashley Peper, University of Wisconsin - Madison, Madison, WI, United States**, Laura Albert, Jim Luedtke

We study the problem of deploying cybersecurity mitigations to delay the completion times of a set of attacker projects. Existing literature studies how to select a portfolio of mitigations subject to a budget constraint to optimally delay such attack projects, but lacks consideration of the time it takes to implement the mitigations. We assume attackers are working on their projects at the same time the defender is working to complete mitigations to delay those attacks. Our proposed model captures the importance of scheduling mitigations, since to be useful they must be completed before an attacker exploits a vulnerability. This paper introduces an integer programming model of this problem that combines a defender's mitigation scheduling problem with the adversaries' project completion problem. We consider alternative solution methods and examine the benefit of the proposed model.

4 - Smart Tracking: How Hybrid UAV Scheduling and Kriging Enhance Fleet Surveillance**Esther Jose, University at Buffalo, Buffalo, NY, United States**, Moises Sudit, Rajan Batta

Tracking a fleet of targets is not the same as tracking multiple individual targets. This paper demonstrates how using surface resources to track a few vessels in a fleet can give us highly accurate probability heatmaps for the rest of the vessels in the fleet. This paper does so using a novel two-step framework that integrates a stochastic mixed-integer programming (MIP) model with spatio-temporal indicator Kriging (STIK) to optimize UAV assignments and dynamically update probabilistic heatmaps reflecting the locations of the rest of the fleet. First, the model schedules heterogeneous UAVs of two types: Synthetic Aperture Radar (SAR) to find the vicinity of a vessel, and Image Intelligence (IMINT) for precise identification, mimicking a tip-and-cue process. This is done to provide information to heatmaps that track the entire fleet.

The second stage employs STIK to assimilate these real-time sensor observations from the UAVs into dynamic heatmaps, capturing spatial and temporal autocorrelation among targets. Computational experiments, including detailed single-scenario analyses and larger randomized trials, demonstrate the robustness of our modeling framework, and show that piecewise-linear approximations optimally balance computational efficiency and solution accuracy. Although illustrated in maritime fleet tracking scenarios, our methodological contributions offer broad applicability to general fleet-based or group-target tracking problems prevalent in defense, search-and-rescue, and resource management operations.

Building A Level 4 A405

Decision Making with Limited Information: Optimization, Recommendations, Queues, and Matching

Invited Session

Applied Probability Society

Chair: Sushil Mahavir Varma, N/A

1 - Markov Decision Processing Networks**Neil Walton, Durham University, Durham, United Kingdom**

We introduce Markov Decision Processing Networks (MDPNs) as a multiclass queueing network model where service is a controlled, finite-state Markov process. The model exhibits a decision-dependent service process where actions taken influence future service availability. Viewed as a two-sided queueing model, this captures settings such as assemble-to-order systems, ride-hailing platforms, cross-skilled call centers, and quantum switches.

We first characterize the capacity region of MDPNs. Unlike classical switched networks, the MDPN capacity region depends on the long-run mix of service states induced by the control of the underlying service process. We show, via a counterexample, that MaxWeight is not throughput-optimal in this class, demonstrating the distinction

between MDPNs and classical queueing models.

To bridge this gap, we design a weighted average reward policy, a multiobjective MDP that leverages a two-timescale separation at the fluid scale. We prove throughput-optimality of the resulting policy. The techniques yield a clear capacity region description and apply to a broad family of two-sided matching systems.

2 - Impact of Rankings and Personalized Recommendations in Marketplaces

Akshit Kumar, Columbia Business School, New York, NY, United States, Omar Besbes, Yash Kanoria

Individuals frequently face a large set of alternatives while lacking a clear understanding of their own preferences. To facilitate choice, platforms deploy two ubiquitous information tools—public rankings and personalized recommendations—yet their comparative value across marketplace environments remains poorly understood. We develop a stylized model that spans two canonical settings: (i) uncapacitated supply, where any number of agents may select the same item, and (ii) capacitated supply, where each item can be matched to at most one agent. An agent's utility combines a common component that reflects population-level item quality with an idiosyncratic component that captures personal tastes; public rankings disclose only the common component, whereas personalized recommendations reveal both.

When supply is uncapacitated, either tool improves welfare relative to no disclosure. Public rankings are near-optimal when tastes are homogeneous, but personalized recommendations become increasingly valuable as heterogeneity grows because they exploit taste diversity. Under capacity constraints, revealing just the common component yields limited benefit: once an item's restricted common value is claimed, additional agents cannot share it. Personalized recommendations, by directing each agent to an item they idiosyncratically value highly, alleviate congestion and generate substantial welfare gains. The results demonstrate that the effectiveness of information provision is jointly governed by preference heterogeneity and supply constraints.

3 - Heavy-Traffic Analysis of Markov-Modulated Queues

Daniela Hurtado Lange, Northwestern University, Evanston, IL, United States, Izzy Grosof

In general, analyzing the delay distribution in queueing systems is intractable. However, key performance measures require knowledge of the distribution. For example, the service level requires computing the tail probabilities. To reduce this gap, a common practice in queueing theory is to analyze the system in an asymptotic regime, such as heavy traffic (where one loads the system close to its maximum capacity). Heavy traffic analysis has gained special attention in the last decade, when 'direct methods' have been developed. Here, one analyzes the steady state of the scaled queue lengths instead of a reflected Brownian motion. The Transform Method is one of them, and it focuses on studying the drift of an exponential transform of the scaled queue lengths (the test function) to show convergence in Moment Generating Function. A key step in this method is carefully designing a test function that yields a meaningful result. This method has been successfully used in systems where the inter-arrival and service times are i.i.d., and generalized to an input-queued switch with Markov-modulated arrivals. We propose using the Poisson equation to design the test function in this work. Specifically, we show that using the Poisson equation immediately yields the correct test function to study systems where the inter-arrival and service times depend on the queue lengths. Specifically, we study queueing systems with control in the arrival or the service process using the same essential steps. In this talk, I will present the methodology and examples of its use.

4 - Achieving Constant Regret for Dynamic Matching via State-Independent Policies

Mingwei Yang, Stanford University, Stanford, CA, United States, Süleyman Kerimov, Sophie Yu

We study a centralized discrete-time dynamic two-way matching model with finitely many agent types. Agents arrive stochastically over time and join their type-dedicated queues waiting to be matched. We focus on state-independent greedy policies that achieve constant regret at all times by making matching decisions based solely on agent availability across types, rather than requiring complete queue-length information. Such policies are particularly appealing for life-saving applications such as kidney exchange, as they require less information and provide more transparency compared to state-dependent policies.

First, for acyclic matching networks, we analyze a deterministic priority policy proposed by Kerimov et al. [2023] that follows a static priority order over matches. We derive the first explicit regret bound in terms of the general position gap (GPG) parameter ε —which measures the distance of the fluid relaxation from degeneracy.

Second, for general two-way matching networks, we design a randomized state-independent greedy policy that achieves constant regret with optimal scaling $O(\varepsilon^{-1})$, matching the existing lower bound established by Kerimov et al. [2024].

1 - Optimizing Railroad Flat Yard Switching with Reward-Driven Integer Programming: a Sequential Decision Framework Using Branch-and-Bound and Remember Algorithm

Peiran Han, Beijing Jiaotong University, Beijing, China, People's Republic of, Lingyun Meng, Xiaojie Luan, Jianrui Miao, Zhengwen Liao, Nikola Bešinović

The Flat Yard Switching Optimization (FYSO) problem is a complex yet relatively underexplored challenge in railway freight operations. We introduce a Shunting Action Network (SAN) model, where each railcar is represented as a node and each shunting operation as a directed arc. To improve computational efficiency, we incorporate symmetry-breaking techniques and implement lazy constraints. Furthermore, we develop a sequential decision-making framework with a reward-driven structure to guide the optimization process. To enhance solution quality, we embed a memorization mechanism within a branching tree, leveraging state-based dominance and pruning strategies. Our approach supports various search strategies, including depth-first, breadth-first, best-first, and cyclic best-first search. The proposed method has been validated on a variety of case studies and demonstrates strong potential for extension to switching problems in broader operational contexts.

2 - Optimize Data-Driven and TIME-Varying Predictive Maintenance in Railway Networks

Yili Tang, University of Western Ontario, London, ON, Canada, Tangjian Wei

Accurate railway track gauge measurement is crucial for rail safety and efficiency. However, environmental exposure and complex track components in special areas such as turnouts and level crossings, introduce intrusions and noise interference, making precise measurement challenging. This paper presents a novel automated gauge measurement model based on the Spatial Density Clustering and Spatial Connection Constraint-Based Gauge Measurement (SDC-SCC-GM) Algorithm, utilizing LiDAR sensor data. The proposed SDC-SCC-GM algorithm integrates Spatial Density Clustering (SDC) and Spatial Connection Constraint (SCC) strategies to enhance measurement accuracy in complex railway environments. The SDC strategy employs Density-Based Spatial Clustering of Applications with Noise (DBSCAN) to identify key points for gauge measurement, mitigating interference from noise points. Meanwhile, the SCC strategy expands the search space by placing potential key points into a candidate set and introducing spatial connection constraints to identify the most suitable key points for gauge measurement, effectively addressing track component interferences, particularly in turnouts and level crossings. To evaluate the effectiveness of SDC-SCC-GM algorithm, we conducted real-world field tests and compared our method with four baseline approaches. Experimental results demonstrate that SDC-SCC-GM outperforms all other methods, achieving the lowest error metrics across all rail conditions. The proposed method provides applicability and effectiveness of rail track gauge detection in complex railway environments.

3 - Railcar Shunting Optimization via An Adaptive Railcar Grouping Dynamic Programming Heuristic

Ruonan Zhao, Texas A&M University, College Station, TX, United States, Joseph Geunes, Xiaofeng Nie

Freight railyards commonly contain multiple tracks that require first-in-last-out (FILO) access for the classification and departure of railcars. Railcar Shunting Problems (RSPs) in such yards pose significant challenges because railcars with different destinations are mixed among different tracks, complicating retrieval and reassembly processes for outbound trains. This complexity is further intensified by the combinatorial explosion of possible railcar arrangements. To address these challenges, we propose an adaptive railcar grouping dynamic programming (ARG-DP) heuristic to solve the RSPs. Consecutive railcars sharing the same destination are merged into unified groups, ensuring that these groups move together without splitting. Additionally, ARG-DP adaptively groups railcars with common destinations at each shunting movement and employs a reduced distance-to-go function to construct the dynamic programming graph, significantly reducing the size of the network. Computational experiments demonstrate the effectiveness of ARG-DP in simulated and real-world railyards. On average, across 60 test cases of simulated yards, ARG-DP achieves solutions 355 times faster than an exact mixed-integer programming model, maintaining an average optimality gap of 6.65%. Moreover, in 10 test cases based on the Gaia yard in Portugal, ARG-DP obtains solutions 229 times faster on average, with an optimality gap of 6.90%.

4 - Strategic Planning of Classification Yard Operations Under Infrastructure and Service Constraints

Daniel Haalboom, Dresden University of Technology, Dresden, Germany

Classification yards are essential components of Single Wagonload (SWL) rail networks, enabling efficient transitions between inbound and outbound railcars. However, increasing competition from other transport modes and structural changes in the European industrial landscape necessitate a strategic redesign of these networks. The absence of historical operational data complicates long-term planning, while the high capital cost of yard infrastructure demands efficient use. Simultaneously, certain customer requirements necessitate rapid railcar interchange on specific routes. These competing demands require careful selection of which direct transitions to support, as not all can be accommodated. Railcars not assigned a direct transition must either traverse mixed tracks with subsequent rehumping, or bypass the hump entirely, requiring additional shunting operations. To address this trade-off, we propose a mixed-integer linear programming (MILP) model for the strategic scheduling of operations within classification yards. The model focuses on optimizing railcar transitions, prioritizing time-sensitive cars while minimizing the use of mixed tracks and re-humping operations. It explicitly incorporates infrastructure constraints and internal yard connections to ensure operational feasibility and avoid conflicts. We evaluate the proposed model using real-life-scale instances of classification yards. The results yield detailed, car-specific movement patterns and provide actionable insights to support strategic decision-making in SWL network design.

1 - Information Design for Strategic Driver Reposition on Ride-Hailing Platforms

Manxi Wu, University of California, Berkeley, Berkeley, CA, United States, Ozan Candogan

In this paper, we study how ride-hailing platforms like Uber and Lyft can strategically share information about the demand distribution with drivers to influence repositioning behavior. On these platforms, drivers have the flexibility to move strategically to different locations for better payoffs, and the spatial distribution of service requests and drivers is crucial for platform efficiency and revenue. We model drivers' strategic repositioning decisions as a game. Using a Bayesian persuasion framework, we show that in many practically relevant cases, the optimal mechanism takes a simple threshold form: the demand realization is fully revealed when it is below or above certain thresholds, and not revealed in the intermediate region. We also develop a computational method to solve for optimal information mechanisms in general settings, and extend the framework to the joint design of information and pricing.

2 - Integrated Equilibrium Model for Electrified Logistics and Power Systems

Rui Yao, EPFL, Lausanne, Switzerland, Xuhang Liu, Anna Scaglione, Shlomo Bekhor, Kenan Zhang

This paper proposes an integrated equilibrium model to characterize the complex interactions between electrified logistics systems and electric power delivery systems. The model consists of two major players: an electrified logistics operator (ELO) and a power system operator (PSO). The ELO aims to maximize its profit by strategically scheduling and routing its electric delivery vehicles (e-trucks) for deliveries and charging, in response to the locational marginal price (LMP) set by the PSO. The routing, delivery, and charging behaviors of e-trucks are modeled by a perturbed utility Markov decision process (PU-MDP) while their collective operations are optimized to achieve the ELO's objective by designing rewards in the PU-MDP. On the other hand, PSO optimizes the energy price by considering both the spatiotemporal e-truck charging demand and the base electricity load. The equilibrium of the integrated system is formulated as a fixed point, proved to exist under mild assumptions, and solved for a case study on the Hawaii network via Anderson's fixed-point acceleration algorithm. Along with these numerical results, this paper provides both theoretical insights and practical guidelines to achieve sustainable and efficient operations in modern electrified logistics and power systems.

3 - Congestion Pricing Revisited: Balancing Efficiency and Equity in Urban Transportation

Qianni Wang, Northwestern University, Evanston, IL, United States, Xinlei Zhou, Jun Xie, Marco Nie

Congestion pricing is a popular tool for travel demand management. However, it is often criticized for being regressive, i.e., benefiting the wealthy at the expense of the poor. Here, we attempt to address this concern for fairness through mechanism design. Building on recent advances in inequality-aware market design, we analyze a stylized network model to characterize inequality-aware congestion pricing mechanisms. We show that an optimal mechanism can take one of three forms: (i) a deterministic posted-price scheme, (ii) a lottery-based rationing scheme, or (iii) a hybrid mechanism combining a higher deterministic price with a lower lottery price granting access with limited probability. Leveraging the structural properties of these optimal mechanisms, we develop a numerical algorithm to facilitate their design and examine their efficiency (e.g., the price of anarchy) and welfare effects (e.g., Gini coefficient). We also discuss the potential extension to general transportation networks.

4 - A Game Between Ridehailing Operator and Government Under the Incentive Bundle Program

Jason Lu, University of Michigan, Ann Arbor, MI, United States, Neda Masoud

Multimodal transportation addresses the first-last mile problem by integrating fixed-route transit services with flexible or on-demand travel modes to support complete user journeys. However, compared to direct car trips, multimodal journeys can be more time-consuming or costly, discouraging users from adopting the system. In this paper, we consider a setting where travelers rely on public transit as the primary mode of transportation, using ridesourcing or walking to bridge the first and last miles of their journeys. To support and encourage the adoption of multimodal transportation, we propose an Incentive Bundle Program (IBP), administered by the government, which allocates subsidies to participating users to help offset ridesourcing costs. We develop a game-theoretic approach to capture the interactions among three key stakeholders in the IBP: the government, the ridehailing operator, and users. The government determines the subsidy distribution, the ridesourcing operator sets pricing, and users choose their preferred modes of transportation based on their individual utilities. We propose a tri-level optimization framework to model these interactions and transform the problem into a single-level convex program. For large-scale instances, we design a solution methodology that achieves strong solution quality while maintaining computational efficiency. Using real-world data, we conduct numerical studies to analyze how government subsidy allocation and ridehailing pricing decisions impact user behavior in the multimodal transportation system.

1 - Speculative Actions: a Lossless Framework for Faster AI Agents

Naimeng Ye, Columbia University, New York, NY, United States

Despite growing interest in AI agents across industry and academia, their execution in an environment is often slow, hampering training, evaluation, and deployment. For example, letting two state-of-the-art agents play a game of chess may take hours. A key bottleneck is that agent behavior unfolds sequentially: each action requires an API call, and these calls can be time-consuming. Inspired by speculative execution in microprocessors and speculative decoding in LLM inference, we propose Speculative Actions, a lossless framework that predicts likely actions using faster models, enabling multiple steps to be executed in parallel. We evaluate this framework across four agentic environments: gaming, e-commerce, web search, and operating systems. In all cases, speculative actions yield substantial acceleration, with potential speedups of up to 30%. Moreover, performance can be further improved through stronger guessing models, top-\$K\$ action prediction, multi-step speculation, and uncertainty-aware optimization, opening a promising path toward real-world, efficient deployment of AI agents.

2 - Optimizing LLM Inference: Fluid-Guided Online Scheduling with Memory Constraints

Gan Luo, Peking University, Beijing, China, People's Republic of, Ruicheng Ao, David Simchi-Levi, Xinshang Wang

Large Language Models (LLMs) is indispensable in today's applications, but their inference procedure—generating responses by breaking text into smaller pieces and processing them using a memory-heavy element named Key-Value (KV) cache—requires a lot of computational resources, especially when memory is limited. This paper treats LLM inference optimization as a multi-stage online scheduling problem, where prompts arrive sequentially and the incremental expansion of the KV cache during inference renders conventional scheduling algorithms ineffective. To address this challenge, we develop fluid dynamics approximation to establish a tractable benchmark, providing insights for devising effective scheduling algorithms. Building upon this foundation, we introduce the Waiting for Accumulated Inference Threshold (WAIT) algorithm as a warm-up. This method maintains multiple thresholds to determine the scheduling order of incoming prompts, optimizing resource utilization when output lengths are known at the time of arrival. In practical applications where output lengths are not known at the time of prompt arrival, we extend our method by introducing the Nested WAIT algorithm. This algorithm constructs a hierarchical framework comprising multiple segments, each defined by distinct thresholds, to effectively manage the random prompt arrivals with unknown output lengths. Theoretical analysis shows both algorithms have near-optimal performance compared with the fluid benchmark under heavy traffic limit, balancing throughput, latency, and Time to First Token (TTFT). Numerical experiments conducted with the Llama-7B model on an A100 GPU, utilizing both synthetic and real-world datasets, demonstrate that our approach achieves superior throughput and reduced latency compared to widely adopted baseline methods such as vLLM and Sarathi.

3 - Llm Inference Optimization via Operations Research

Jim Dai, Cornell University, Ithaca, NY, United States, Tianze Deng, Yueying LI, Tianyi Peng

As demand for Large Language Models (LLMs) and AI agents rapidly grows, optimizing systems for efficient LLM inference becomes critical. While significant efforts have targeted system-level engineering, little is explored through a mathematical modeling and queueing perspective. In this paper, we aim to develop the queueing fundamentals for LLM inference, bridging the gap between queueing and LLM system communities. In particular, we study the throughput aspect of LLM inference systems. We prove that a large class of 'work-conserving' scheduling algorithms can achieve maximum throughput for both individual requests and AI-agent workloads, highlighting 'work-conserving' as a key design principle in practice. Evaluations of real-world systems show that Orca and Sarathi-serve are throughput-optimal, reassuring practitioners, while FasterTransformer and vanilla vLLM are not maximally stable and should be used with caution. Moreover, under memory constraints, we identify a non-trivial necessary condition for stability, yielding practical insights into hyperparameter selection for Sarathi-serve. Our results highlight the substantial benefits queueing community can offer in analyzing and improving LLM inference systems and call for more interdisciplinary developments.

4 - What is Your AI Agent Buying? Evaluation, Implications, and Emerging Questions for Agentic E-Commerce

Amine Allouah, MyCustomAI, Santa Clara, CA, United States, Omar Besbes, Josué D Figueroa, Yash Kanoria, Akshit Kumar

Online marketplaces will be transformed by autonomous AI agents acting on behalf of consumers. Rather than humans browsing and clicking, vision-language-model (VLM) agents can parse webpages, evaluate products, and transact. This raises a fundamental question: what do AI agents buy—and why? We develop ACES, a sandbox environment that pairs a platform-agnostic VLM agent with a fully programmable mock marketplace to study this question. We first conduct basic rationality checks in the context of simple tasks, and then, by randomizing product positions, prices, ratings, reviews, sponsored tags and platform endorsements, we obtain causal estimates of how frontier VLMs actually shop. Models show strong but heterogeneous position effects: all favor the top row, yet different models prefer different columns, undermining the assumption of a universal "top" rank. They penalize sponsored tags and reward endorsements. Sensitivities to price, ratings, and reviews are directionally human-like but vary sharply in magnitude across models. Motivated by scenarios where sellers themselves use AI agents to optimize product listings, we show that a seller-side agent that makes minor tweaks to product descriptions—targeting AI buyer preferences—can deliver substantial market-share gains if AI-mediated shopping dominates. We also find that modal product choices can differ across models and, in some cases, demand may concentrate on a few select products, raising competition questions. Together, our results illuminate how AI agents may behave in e-commerce settings, and surface concrete seller strategy, platform design, and regulatory questions in an AI-mediated ecosystem.

1 - Rate-Optimal Strategy for Best Policy Identification in Reinforcement Learning

Mingjie Hu, Fudan University School of Management, Shanghai, China, People's Republic of, Edward Huang, Jie Xu, Jianqiang Hu, Chun-Hung Chen

Best policy identification (BPI), which seeks to identify the policy with the highest expected cumulative reward, has recently gained considerable attention in reinforcement learning (RL). This paper formulates a BPI problem for finite-horizon, time-inhomogeneous, tabular Markov decision processes (MDPs) within a fixed-budget ranking and selection (R&S) framework, with the goal of maximizing the probability of identifying the best policy. To tackle this problem, we first derive a rate-optimal sampling ratio using large deviation theory, incorporating the dynamics and rewards of MDPs into the rate function. We then quantify the benefits of incorporating MDP structural information and show that the optimal sampling ratio balances variance, optimality gap, and visitation probabilities. Motivated by abundant covariate information in practical decision-making, we propose a contextual BPI framework with linear reward functions and extend the optimal sampling ratio to this setting. In addition, we introduce an asymptotically rate-optimal strategy and an efficient approximate strategy based on a closed-form sampling ratio. Numerical experiments demonstrate that our proposed algorithm outperforms existing R&S and RL methods. Furthermore, we illustrate its practical applicability through a complex diffusion furnace scheduling problem. These results highlight the potential of R&S techniques for solving BPI problems.

2 - The Price of Streaming

Franco Berbeglia, Purdue University, West Lafayette, IN, United States, Timothy Derdenger, Sridhar Tayur

We study the price of streaming strategies on total movie revenues. Using panel data from 2014–2021 on US box office ticket sales, transactional video-on-demand (TVOD) rentals, digital sales, DVD/Blu-ray sales, and rentals, as well as streaming video-on-demand (SVOD) availability information, we estimate a dynamic structural model of demand across channels. We first analyze a direct-to-streaming strategy implemented by Warner Bros. (WB) and HBO Max: Project Popcorn. We determine that WB was not incorrect with its streaming strategy. We provide quantitative support and qualitative insights on the performance of hybrid strategies: simultaneous release in theaters and streaming, and delayed streaming within the theatrical window. Through "what-if" analyses our structural model can aid studio executives in crafting their streaming strategy by analyzing the pertinent trade-offs.

3 - Unifying CGE and Network Equilibrium Models of Commodity Demand by Industrial Sector

Patrick O'Reilly, Demand Scientific, Golden, CO, United States

Estimating commodity demand within specific economic sectors requires capturing both economy-wide market interdependencies and sector-specific network dynamics. This paper proposes a novel integration of Computable General Equilibrium (CGE) models, formulated as Mixed Complementarity Problems (MCPs), with Network Equilibrium (NE) models, expressed as Variational Inequalities (VIs), to forecast demand for a commodity in a targeted sector. By exploiting the mathematical equivalence of VIs and MCPs, I unify the CGE's market-clearing conditions with the NE's network flow constraints into a single MCP. Alternatively, the model can be formulated as a VI, preserving the NE's structure while appending CGE equations as constraints. A simplified example model demonstrates the approach, modeling commodity demand driven by sector-specific network interactions. The unified model captures substitution effects, price-quantity dynamics, and network feedbacks, offering richer insights than unlinked CGE and NE models that otherwise speak to the same context. Computational experiments, implemented in Julia/JuMP, demonstrate the model's scalability and convergence for monotone problems. Sensitivity analyses begin with exploring demand responses to price variation, offering implications for relative scarcity. This work extends prior CGE-NE integrations by focusing on commodity-specific demand, addressing a gap in sector-targeted applications. Presented results aim to motivate development into dynamic, multi-commodity settings.

4 - Efficient Bayesian Sampling Policies for Fixed-Budget Ranking and Selection

Xin Fei, University of Edinburgh, Edinburgh, United Kingdom, Juergen Branke

We study the fixed-budget ranking and selection problem, in which a decision maker must identify the best design from a finite set using a limited number of samples. The challenge lies in balancing exploration - allocating samples to designs not currently identified as best but characterised by significant uncertainty or the potential to outperform the current leader - and exploitation, focusing sampling efforts on designs presently estimated as best. This paper introduces a novel allocation policy designed to minimize either the probability of incorrect selection or the expected opportunity cost. Grounded in large deviation theory, the policy sequentially allocates samples to the design that potentially provides the largest value of sample information. We provide a theoretical analysis and conduct comparative empirical evaluations against selected state-of-the-art methods.

Modeling with Attack Graphs for Securing Cyber-physical Systems

Tutorial session

Tutorials

Chair: Brian Denton, University of Michigan, Ann Arbor, MI, United States

1 - Modeling with Attack Graphs for Securing Cyber-physical Systems

Laura Albert, University of Wisconsin-Madison, Madison, WI, United States, Carmen Haseltine

Modern critical infrastructures consist of increasingly complex and interdependent cyber-physical systems (CPS). Securing cyber-physical infrastructure requires understanding how components interact with one another across physical, cyber, and human dimensions, as well as how threat modeling affects system components and operations. This tutorial reviews modeling techniques for CPS security, focusing on network models, threat modeling techniques, and prescriptive decision-making. Attack graphs offer a structured and systematic approach to modeling threats to a system and are crucial in cybersecurity risk management. We review three applications of operations research modeling techniques that leverage attack graphs for CPS security: allocating a security budget for cybersecurity planning, developing vulnerability metrics for securing cyber-physical energy systems, and performing risk assessments for administering election systems. Through these applications, we demonstrate the potential for using attack graphs for prescriptive decision-making and proactive planning to secure CPS.

Integration of Learning and Routing

Invited Session

TSL: Freight Transportation

Chair: Dan Liu, Kean University, Union, NJ, United States

1 - CombFormer: Learn to Separate Strengthened Comb Inequalities for Cvrp

Merve Doganbas, KAIST, Daejeon, Korea, Republic of, Hayong Shin, Changhyun Kwon

The Capacitated Vehicle Routing Problem (CVRP) is a fundamental NP-hard problem in logistics and transportation. A key exact method for solving CVRPs is the branch-and-cut algorithm, which depends on the separation of strong cutting planes to tighten linear programming (LP) relaxations. Among these, Strengthened Comb Inequalities (SCIs) form a class of facet-defining cuts that incorporate vehicle capacity constraints into comb inequalities for the Traveling Salesman Problem. We propose CombFormer, a hybrid heuristic for separating SCIs using a learning-based approach. It formulates the SCI handle construction as a sequential decision-making problem over the LP solution. A transformer-based graph neural network encodes the fractional solution, and an attention-based decoder autoregressively selects handle nodes. Once the handle is formed, a greedy teeth-construction subroutine completes the SCI. The policy is trained with REINFORCE to maximize the violation of the generated cut. Training is conducted on instances with 50–100 nodes, and the model is fine-tuned on larger ones (150–300 nodes). In experiments, we compare our method to SCI separation heuristic of CVRPSEP, a cut separation algorithm package that is widely used for solving VRPs exactly. CombFormer performs comparably to CVRPSEP on small instances and significantly outperforms it on larger problems (up to 500 nodes), identifying SCIs with higher violations. These results suggest that structurally complex inequalities like SCIs can be effectively separated using learning-based techniques trained to recognize polyhedral structures. CombFormer complements classical heuristics by demonstrating the feasibility of learning-guided cut generation for complex inequalities.

2 - Test-TIME Search in Neural Graph Coarsening Procedures for the Capacitated Vehicle Routing Problems

Yoonju Sim, KAIST, Daejeon, Korea, Republic of, Hyeonah Kim, Changhyun Kwon

Recent advances in deep learning have motivated various efforts to enhance cutting-plane methods by integrating learned models. Kim et al. (2024) introduced a neural separation (NeuralSEP) framework that utilizes graph neural networks to generate rounded capacity inequalities (RCIs) for capacitated vehicle routing problems (CVRP). In this paper, we refine and extend NeuralSEP in two key directions: (1) by advancing its implementation and (2) by extending it to produce framed capacity inequalities (FCIs) without further training. Through our analysis of NeuralSEP, we identify a critical limitation: small input variations lead to poor cut diversity, reducing the effectiveness of the separation approach. To address this, we introduce stochastic edge selection by adding small random perturbations to edge contraction probabilities, enabling the generation of more diverse cuts. Also, we migrate the implementation from DGL to PyTorch Geometric, reducing computational overhead during graph coarsening operations. Furthermore, we leverage insights from the coarsening steps in NeuralSEP to generate FCIs at test time by examining the mapping history to identify promising candidate partitions. Experiments on randomly generated instances of CVRP show that our enhanced NeuralSEP scales more effectively than the original NeuralSEP and CVRPSEP, reducing computational time while achieving optimality gap reductions of 1-2% on average for instances with more than 300 nodes.

3 - A Contextual Online Prize-Collecting Vehicle Routing Problem

Amirmohammad Paksaz, University of Iowa, Iowa City, IA, United States

We consider a setting in which the decision maker coordinates a vehicle fleet to serve customers but has limited or no initial data on each customer's value. In each period, the decision maker (i) observes related contextual information, (ii) leverages this information in the form of feature variables to infer information about the stochastic customer prizes, (iii) determines a set of routes that visit a subset of the customers, (iv) collects the observed prizes, and (v) updates the prize-learning model. Thus, the decision-maker faces the well-known "exploration-exploitation" trade-off to efficiently allocate limited delivery resources across a spatially distributed customer base with an unknown context-dependent demand distribution that must be learned incrementally. We represent our contextual online prize-collecting vehicle routing problem as a combinatorial multiarmed bandit in which each arm corresponds to a customer. At each round, the decision maker selects a subset of arms (customers) that can be feasibly served by a given fleet of vehicles. We study a semibandit setting where we observe the prizes associated with each arm in the selected subset but do not observe the prizes associated with unselected arms. We seek a learning algorithm that minimizes the time-average pseudoregret. We present preliminary results obtained by modifying existing multiarmed bandit algorithms to our setting.

4 - Metaroutenet: a Meta-Reinforcement Learning Framework for Adaptive Electric Vehicle Routing with TIME Windows

Mertcan Daysalilar, University of Miami, Miami, FL, United States, Fuat Uyguroglu, Ramiro Valdes Jara, Gabriel Nicolosi, Adam Meyers

The Electric Vehicle Routing Problem with Time Windows (EVRPTW) introduces routing complexities due to energy constraints, charging infrastructure, and delivery time windows. Traditional optimization methods often lack flexibility in adapting to new problem variations, requiring manual redesign or tuning, while current reinforcement learning approaches typically struggle to generalize and must be retrained for each new scenario—making both approaches less suitable for dynamic logistics environment. This work proposes MetaRouteNet, a meta-reinforcement learning framework that combines Model-Agnostic Meta-Learning (MAML) and Proximal Policy Optimization (PPO) for fast adaptation across EV routing tasks. Each routing instance is modeled as a separate task, allowing MetaRouteNet to learn generalizable knowledge through meta-training. A graph-attention encoder and joint vehicle-node attention mechanism model spatiotemporal interactions between customers, charging stations, and vehicle states. To improve policy robustness, we employ curriculum learning, gradually exposing the model to increasingly complex customer scenarios (e.g., 5-, 10-, and 15-node problem instances). We are currently evaluating MetaRouteNet on the Schneider EVRPTW dataset, which includes instances across multiple complexity levels. Preliminary results indicate that MetaRouteNet may offer advantages over baseline PPO and static policy models in metrics such as adaptation time, route feasibility, and total distance. We anticipate that its meta-learning architecture will generalize effectively to unseen instances with varying customer demands and time constraints. These early findings suggest that MetaRouteNet is a promising solution for EV fleet management in dynamic, real-world environments. By bridging reinforcement learning and combinatorial optimization, this research contributes to adaptive, energy-efficient routing systems.

5 - Optimizing Urban Grocery Delivery: a Deep RL Framework with Linformer Attention and a Joint Decoder for Heterogeneous Fleet Routing

Dan Liu, Kean University, Union, NJ, United States

The Heterogeneous Capacitated Vehicle Routing Problem (HCVRP) represents a pivotal challenge in urban grocery delivery. This is due to the need to optimize routes for a diverse fleet with varying capacities, speeds, and cost structures. This heterogeneity adds layers of complexity that go beyond the traditional CVRP. Moreover, as the size of the problem increases (i.e., more nodes and vehicles), traditional optimization methods—whether exact algorithms or heuristics—often face exponential increases in computational demands. To address these challenges, this study introduces a novel neural network architecture that incorporates advanced attention mechanisms tailored specifically for HCVRP with backhaul considerations. Our approach features two key innovations. First, we integrate the Linformer, which employs a low-rank approximation attention mechanism to significantly reduce the computational demands of conventional Transformer models, thereby improving efficiency on large datasets. Second, we develop a Multi-Relational Joint Selection Decoder that dynamically updates node representations in real time, enabling more precise routing decisions based on current vehicle positions, previously traveled paths, and inbound backhaul requirements. Extensive experiments reveal that our deep reinforcement learning (DRL) framework consistently outperforms traditional heuristics and existing DRL methods in terms of solution quality, convergence speed, and computational efficiency across diverse problem scales and objectives. This research underscores the transformative potential of integrating state-of-the-art machine learning techniques with classical operations research methodologies, paving the way for more resilient, efficient, and sustainable transportation and logistics solutions in complex urban environments.

Simulation as a Digital Twin

Invited Session

Simulation

Chair: Canan Gunes Corlu, Boston University, Boston, MA, United States

1 - Digital Twins: Applications and Future Directions

Canan Gunes Corlu, Boston University, Boston, MA, United States, Bahar Biller, Stephan Biller

Digital twins are an essential concept for organizations pursuing digital transformation. In this talk, we explore the benefits of digital twin technology for supply chains, including improved supply chain resilience. We also examine the challenges associated with implementing digital twins and highlight opportunities for future research.

2 - Real-Time Digital Twin Approach for Personalized Medical Decision Making

Yangyuechen Zhao, Boston University, Boston, MA, United States, John Maleyeff, Fangzhou Xie

Digital twin approaches are a relatively new concept in healthcare. To support shared decision making, we utilize the digital twin model to create a virtual representation of a patient who needs to choose among a candidate list of treatment options. The digital twin exists within a real-time decision support system (DSS) that integrates electronic health records (EHR) and patient-reported outcomes (PRO). The DSS includes a decision aid that visualizes treatment benefits and side effects with their corresponding probabilities. Using a Bayesian framework, the digital twin continuously updates likelihood predictions for each individual patient based on their personal characteristics, medical histories, and health conditions. Unlike traditional digital twins used in supply chain or engineering domains that tend to be simulations. Here, a healthcare-focused digital twin consists of a prediction model that creates a prior prediction distribution. Bayesian updating is done using data from the EHR and PRO to create the posterior prediction distribution. In these cases, sample sizes are often small. An example is presented concerning carotid endarterectomy surgery with the possibility of stroke as a side effect. Medicare data is used to create a prediction model that serves as the prior prediction model, where the prediction is assumed to follow a beta distribution. Two clinical scenarios illustrate how the digital twin logic either creates the posterior prediction model or alerts the medical staff when PRO data differ significantly from predictions.

3 - Bridging the Physical and Virtual: Real-Time Simulation Modeling for Next-Generation Digital Twins

Ghaith Rabadi, University of Central Florida, Orlando, FL, United States, Bulent Soykan

Digital Twins (DTs) are rapidly transforming how complex systems are designed, monitored, and managed. A critical enabler for realizing the full potential of DTs, particularly in dynamic operational environments, is the integration of real-time simulation modeling. This presentation explores novel methodologies and frameworks for embedding high-fidelity, real-time simulation capabilities within DT architectures. We discuss how operations research techniques, including dynamic data assimilation, adaptive model calibration, and distributed simulation, can address the challenges of synchronizing virtual models with their physical counterparts in real-time. The talk will also address computational considerations and future research directions in this burgeoning field at the intersection of simulation, AI, and management science.

4 - Simulation Digital Twin Validation with Multi-Epoch Key Performance Indicators

Linyun He, Georgia Institute of Technology, Atlanta, GA, United States, Luke Rhodes-Leader, Eunhye Song

We propose a validation framework to verify whether the distributions of the simulated and system-observed key performance indicators (KPIs) are identically distributed across multiple epochs. The KPIs are transient and non-identically distributed across the epochs, which makes the validation challenging as we do not have repeated measurements of the system KPIs. To tackle this problem, we propose a hypothesis testing framework that consists of a set of marginal tests and one joint inter-correlation

test. Each marginal test corresponds to each KPI and examines if the marginal distribution of the Digital Twin (DT) and system KPI within each epoch align in all observed epochs. For each epoch, the system KPI is converted via probability integral transform using the empirical marginal cumulative distribution function of the simulated KPIs. The converted marginal KPIs from all epochs are then tested against a standard uniform distribution. If the marginal tests fail to reject, the joint test determines whether the inter-correlation of the DT and system KPIs, measured by their respective copula functions, match. Assuming that the copula structure remains unchanged across the epochs, we pool the multi-epoch data and apply nonparametric copula estimates based on the transformation used in the marginal tests. A copula hypothesis testing is then performed to compare the DT and system KPIs. We establish asymptotic analyses to ensure that the tests deliver a valid Type-I error. To further improve the finite-sample performance, we adopt a stepdown multiple hypothesis testing framework where a set of critical values are calculated using bootstrap.

1 - Transformers Provably Learn Chain-of-Thought Reasoning with Length Generalization

Yu Huang, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States, Zixin Wen, Aarti Singh, Yuejie Chi, Yuxin Chen

The ability to reason lies at the core of artificial intelligence, and tough problems usually call for deeper, more extended reasoning to tackle. A crucial question about AI reasoning is whether models can extrapolate from learned reasoning patterns to solve harder tasks that require longer chain-of-thoughts (CoT). In this work, we present a theoretical analysis of transformers trained via gradient descent on synthetic data for various state tracking tasks, revealing how length-generalizable reasoning can emerge. Specifically, we prove that 1) for tasks with simple algebraic structure, e.g., composition in a cyclic group, transformers learn a solution pattern that generalizes to polynomial-length CoT; 2) for more complex tasks like composition in a symmetric group, a recursive self-training curriculum enables transformers to bootstrap longer reasoning and achieve polynomial generalization. Intuitively, our results demonstrate that transformers can learn sequential reasoning skills that scale with problem complexity. Moreover, we provide the first provable optimization-based guarantee for constant-depth transformers on the state tracking problems beyond circuit complexity class TC^0 : we prove that they can learn problems in NC^1 , which goes beyond prior results that consider problems within TC^0 , unless the famous conjecture $\mathsf{TC}^0 \neq \mathsf{NC}^1$ is false.

2 - Causal Invariance Learning via Efficient Optimization of a Nonconvex Objective

Zhenyu Wang, Rutgers University, New Brunswick, NJ, United States, Yifan Hu, Peter Bulhmann, Zijian Guo

Identifying causal relationships among variables from observational data is important yet challenging. Data from multiple environments provide opportunities to uncover causality by exploiting the invariance principle that the causal outcome model should remain the same across heterogeneous environments. In this paper, we consider the problem of identifying the direct parents of the outcome from a set of covariates and learning their effects, i.e., to learn the causal outcome model. We first propose a novel Negative Weighted Distributionally Robust Optimization (NegDRO) to learn an invariant prediction model. Under the additive interventions regime, we establish three major contributions. 1) On the statistics side, we provide nearly necessary and sufficient identification conditions under which the invariant prediction model coincides with the causal outcome model. 2) On the optimization side, despite nonconvexity of NegDRO, under these identification conditions, we establish the benign nonconvex landscape of NegDRO, i.e., any stationary points are globally optimal, paving the path for computation. 3) On the computational side, we further develop a gradient descent maximization method that provably converges to the causal outcome model, and establish the convergence rate with respect to the sample size and iteration times. Our method avoids exhaustive combinatorial search over all possible (exponential many) subsets of covariates or integer programming used in the invariance learning literature, ensuring scalability when the number of covariates is large. To our knowledge, this is the first causal invariance method that guarantees global optimality of a nonconvex objective. Numerical results further validate the efficiency of the proposed method.

3 - Robustness and Regret Tolerance

Yilin Xue, National University of Singapore, Singapore, Singapore, Napat Rujeerapaiboon

This paper shifts focus from the typical approach of maximizing expected reward to minimizing expected regret, aiming to find a solution whose expected reward is close to the oracle. While these two approaches are equivalent when the uncertainty distribution is given, they diverge when accounting for distributional ambiguity, which is characterized by the Wasserstein distance, for enhanced robustness. This can be achieved by requiring the decision maker to specify their tolerance for expected regret under the nominal distribution and minimize the excess regret beyond this threshold across any other distribution. By exploring the entire range of this threshold parameter, our regret-based model encompasses both empirical optimization and worst-case regret minimization, the latter of which is NP-hard. When the reward function is represented by a linear program (possibly involving recourse decisions, a random technology matrix, and a random right-hand side), we propose two tractable safe approximations that preserve feasibility and empirical consistency of the original problem. The first approximation is formulated as a robust linear program with convex uncertainty sets, while the second tightens and improves upon the first using positive semidefinite constraints. Finally, we demonstrate the advantages of our tolerance-oriented regret-based model over a similar target-oriented reward-based model and empirical optimization in the context of supply chain procurement and portfolio selection.

4 - Preconditioning for Overparameterized and Ill-Conditioned Composite Optimization

Abdel Ghani Labassi, Johns Hopkins University, Baltimore, MD, United States, Mateo Diaz, Liwei Jiang

Composite optimization problems involve minimizing the composition of a smooth map with a convex function. Such objectives arise in numerous data science and signal processing applications, including phase retrieval and blind deconvolution. The subgradient method achieves local linear convergence when the composite loss is well-conditioned. However, if the smooth map is, in a certain sense, ill-conditioned or overparameterized, the subgradient method exhibits much slower sublinear convergence even when the convex function is well-conditioned. To overcome this limitation, we introduce a novel Levenberg-Marquardt subgradient method that converges linearly under mild regularity assumptions at a rate determined solely by the conditioning of the convex function. Further, we demonstrate that these regularity assumptions hold for several problems of practical interest, including square-variable formulations, low-rank matrix, and tensor recovery problems. Numerical experiments illustrate the benefits of our method.

5 - Doubly Fair Policy Learning

Zeyu Bian, Florida State University, Tallahassee, FL, United States

Fairness and trustworthiness have recently received significant attention in machine learning, particularly in supervised learning, driven by ethical concerns surrounding algorithmic applications. However, fairness in policy learning--where the goal is to make fair decisions (actions) while simultaneously maximizing expected rewards (value) has been seldomly explored. Most existing works in fairness for policy learning focus primarily on action fairness. Yet, in many applications, ensuring fairness in both actions and value is critical. This paper tackles the challenge of double fairness in policy learning by addressing three objectives simultaneously: action fairness, value fairness, and maximizing the value function. We propose a novel framework that integrates fairness constraints directly into the multi-objective optimization problem for policy learning. Our framework is flexible and accommodates various fairness notions. To the best of our knowledge, this is the first work to address double fairness in policy learning. We establish theoretical guarantees for the proposed method and demonstrate its empirical superiority over competing approaches.

1 - Differentially Private Federated Averaging with James-Stein Estimator

Minseok Ryu, Arizona State University, Tempe, AZ, United States, Geunyeong Byeon, Xinran Zhao

Differentially private federated learning (DPFL) enables collaborative model training without centralizing sensitive data, ensuring privacy via formal differential privacy mechanisms. A key challenge in DPFL is improving model utility under strong privacy constraints. To address this, we propose DP-FedStein, a variant of the differentially private federated averaging (DP-FedAvg), which incorporates the James-Stein estimator (JSE) at the server to more accurately estimate true pseudo-gradients from their noisy, differentially private versions. We provide a convergence analysis showing that, by leveraging the superior performance of JSE in high-dimensional settings, DP-FedStein achieves a better utility-privacy trade-off than DP-FedAvg. Empirical results on public and private image classification datasets confirm its effectiveness, demonstrating substantial accuracy gains under high noise conditions.

2 - Scaling Federated Learning to HPC: A Cross-Silo Framework for Real-World Large-Scale Model Training

Yijiang Li, Argonne National Laboratory, Lemont, IL, United States, Kibaek Kim

High-performance computing (HPC) systems offer unprecedented computational resources for federated learning (FL), yet deploying FL across heterogeneous HPC environments presents unique infrastructure and implementation challenges. This work presents a comprehensive framework for conducting real-world cross-silo federated learning experiments across diverse supercomputing facilities including Polaris, Aurora, Perlmutter, and Frontier. Our framework addresses these deployment challenges by extending the APPFL package: Globus Compute Endpoints for distributed task orchestration across heterogeneous architectures, Proxystore and Globus Transfer for efficient model synchronization and data movement, and DeepSpeed integration for multi-node parallel training. This enables training of large-scale applications including large language models, computer vision tasks, and time series forecasting. We demonstrate the framework's effectiveness through comprehensive benchmarks of various FL algorithms, providing practical insights into scalability, convergence behavior, and deployment considerations. Our results advance large-scale federated learning by enabling realistic experiments that mirror real-world collaborative machine learning scenarios across the HPC ecosystem while maintaining data sovereignty.

3 - Adding and Removing Clients on the Fly: A Federated Learning Approach

Krishnan Raghavan, Argonne National Laboratory, Lemont, IL, United States, Kibaek Kim, Todd Munson

Federated learning (FL) is one of the most common distributed learning paradigms that allow the flexibility of training large scale models with a multitude of clients with heterogeneous data. However, typical FL does not fully support dynamic addition and removal of clients. In this talk, we seek to illuminate the difficulties introduced due to on the fly addition/removal of clients and provides potential solutions to this problem. In particular, we will discuss a probabilistic viewpoint of FL that is naturally poised to address this challenge. We will demonstrate theoretically and practically the viability of this approach and develop experimental results supporting our claims.

4 - A Randomized Zeroth-Order Hierarchical Framework for Heterogeneous Federated Learning

Yuyang Qiu, Rutgers University, Piscataway, NJ, United States, Kibaek Kim, Farzad Yousefian

Heterogeneity in federated learning (FL) is a critical and challenging aspect that significantly impacts model performance and convergence. In this talk, we propose a novel framework by formulating heterogeneous FL as a hierarchical optimization problem. This new framework captures both local and global training process through a bilevel formulation and is capable of the following: (i) addressing client heterogeneity through a personalized learning framework; (ii) capturing pre-training process on server's side; (iii) updating global model through nonstandard aggregation; (iv) allowing for nonidentical local steps; and (v) capturing clients' local constraints. We design and analyze an implicit zeroth-order FL method (ZO-HFL), provided with nonasymptotic convergence guarantees for both the server-agent and the individual client-agents, and asymptotic guarantees for both the server-agent and client-agents in an almost sure sense. Notably, our method does not rely on standard assumptions in heterogeneous FL, such as the bounded gradient dissimilarity condition. We implement our method on image classification tasks and compare with other methods under different heterogeneous settings.

5 - Adaptive Federated Learning Across Heterogeneous High-Performance Computing Systems

Kibaek Kim, Argonne National Laboratory, Lemont, IL, United States, Yijiang Li

High-performance computing (HPC) systems commonly rely on job schedulers to manage resource allocation by queuing and executing jobs based on requested computing time and capacity. When conducting federated learning (FL) experiments across multiple, heterogeneous HPC systems, additional challenges arise due to the variability in system architectures, job scheduling policies, and resource availability. In this work, we identify and discuss these challenges, emphasizing their impact on performance and scalability in cross-system FL training. To address these issues, we propose a novel FL algorithm that actively monitors local system status and adaptively adjusts resource usage at each client. This adaptive strategy enables more efficient and robust training under the constraints imposed by diverse HPC environments. We demonstrate preliminary results from applying our method on U.S. Department of Energy (DOE) supercomputers, showing promising improvements in resource utilization and training efficiency.

1 - Imitation Learning for Distribution and Microgrid Intelligence: from Self-Healing Grid to Performance Guaranteed Control

Yichen Zhang, University of Texas at Arlington, Arlington, TX, United States

Modern deep learning has been strengthening the capability of automatic decision-making and intelligent control under complex scenarios and has become an essential piece of the blueprint for distribution intelligence and smart grids. Because of the strong representation power, a deep neural network (DNN) can make better and faster decisions to reroute power flow through network reconfiguration, especially under multiple outage scenarios, to facilitate self-healing distribution systems. DNN-based dynamic controllers can encode disturbance estimation, state and input constraint satisfaction, and expert knowledge into an end-to-end policy. All these advances rely on the construction of intelligent agents, and the reinforcement learning framework is naturally suitable for this task. However, there are currently two major limitations. First, traditional reinforcement learning algorithms are exploration dominant and exhibit low training efficiency, especially under random disturbances. Secondly, for dynamic control tasks, current training paradigms cannot ensure closed-loop stability. In this presentation, we will demonstrate a new training paradigm, a synergy between imitation learning, mathematical programming, and control theory, to improve the training efficiency and ensure system stability under random disturbances. The presentation investigates two problems: automatic network reconfiguration with reactive power dispatch for service restoration of distribution systems and frequency control with stability and safety guarantees in islanded microgrids. The successful results indicate that the imitation learning framework provides an opportunity to leverage well-established mixed-integer programming solvers and control theories for learning-based automations.

2 - Physics-Informed Online Learning for Dynamic State Estimation in Multimachine Power Systems

Guanyu Tian, Texas A&M University, Galveston, TX, United States

With the increasing penetration of distributed generators in the smart grids, having knowledge of rapid real time electromechanical dynamic states has become crucial to system stability control. Conventional Supervisory Control and Data Acquisition (SCADA)-based dynamic state estimation (DSE) techniques are limited by the slow sampling rates, while the emerging phasor measurement units (PMUs) technology enables rapid real-time measurements at network nodes. Using generator bus terminal voltages, we propose a hybrid-learning DSE (HL-DSE) algorithm to estimate the synchronous machine rotor angle and speed in real time. The HL-DSE takes the power system model into account and trains neuro-estimators with real-time data in an online manner. Compared with traditional DSE methods, the HL-DSE overcomes limitations by using a data-driven approach in conjunction with the physical power system model. The time efficiency, accuracy, convergence, and robustness of the proposed algorithm are tested under noise and fault conditions in both small- and large-scale test systems. Simulation results show that the proposed HL-DSE is much more computationally efficient than widely used Kalman filter (KF)-based methods while maintaining comparable accuracy and robustness. In particular, HL-DSE is over 100 times faster than square-root unscented KF (SR-UKF) and 80 times faster than extended KF (EKF). The advantages and challenges of the HL-DSE are also discussed.

3 - Repower: Enabling Autonomous Research in Power Systems with Large Language Models

Yongxin Zhang, University of Tennessee, Knoxville, TX, United States

Large Language Models (LLMs) have shown strong potential across various scientific fields, yet their application in power systems remains limited. In this talk, I will present Revive Power Systems (RePower), an autonomous research platform that employs a reflection-evolution strategy to independently address complex power system challenges. RePower autonomously controls devices, gathers data, designs methods, and evolves algorithms, achieving consistent improvements across tasks such as parameter prediction, power optimization, and state estimation. This work demonstrates a new direction for autonomous innovation in power systems research.

4 - Efficient and Effective Contrastive Self-Supervised Learning Framework for Power Time Series Data

Yifeng Gao, University of Texas Rio Grande Valley, Edinburg, TX, United States

Contrastive Self-Supervised Learning (CSSL) based training framework is widely used to train deep neural networks. By leveraging the ability to learn meaningful representations through view augmentation instead of task-specific labels, the CSSL framework trains a pre-training encoder model that can capture general data properties and is suitable for diverse downstream tasks. In the field of smart energy, CSSL framework is especially beneficial given the existence of diverse sensor signals and the challenge of accessing detailed human annotations. However, due to the rich information entangled within sensor signals, existing CSSL frameworks often train models that store an enormous amount of information in the embedding space, which significantly reduces model efficiency. In this talk, we will discuss the rationale and recent advancement on effective CSSL training framework for power time series. We will also discuss and introduce methods to enhance the inference efficiency.

5 - Physics-Informed Machine Learning Towards Cyber-Resilient Distribution Grid Situational Awareness

Ying Zhang, Oklahoma State University, Stillwater, OK, United States

Modern power systems are confronted with degraded and even stranded operational performances subject to growing complexity, uncertainty, and volatility from large-scale integration of distributed energy resources (DERs). Real-time distribution grid situational awareness must be obtained from data of heterogeneous sensors to support intelligent control and decision-making. This talk will present a new technique for AI-aided grid operation by developing physics-informed trustworthy learning for fast yet accurate state estimation in electric distribution systems with massive DERs—combining power engineering knowledge with a data-aided regression technique. Unlike black-box data-intensive machine learning that has limited creditability in real-world grids, the proposed method achieves significant performance synergy in terms of accuracy, efficiency, and robustness against outliers or cyber-attacked measurements. As system-wide voltage and power flow visibility is of fundamental importance, the proposed framework has the potential as a building block to accelerate and advance various system-wide optimization tasks, such as voltage control, thereby digitally twinning the physical grid.

Advancements in Generation and Transmission Expansion Planning

Invited Session

ENRE: Electricity

Chair: Todd Levin, Argonne National Laboratory, Lemont, IL, 60439, United States

1 - Deployment Pathways for Long Duration Energy Storage

Todd Levin, Argonne National Laboratory, Lemont, IL, United States, W. Neal Mann, Jonghwan Kwon, Zhi Zhou, Bo Cheng, Audun Botterud

We apply a least-cost generation expansion model of the continental United States to assess how optimal investments in long-duration energy storage (LDES) technologies are impacted by changes in system generation portfolios and technology costs, assessing 180 capacity expansion scenarios in total. The expansion model considers 8,760 hours of chronological operations for the entire target year, 2040. We find that low-cost LDES technologies can reduce generation investments and system costs. Specifically, once costs for 24-hour and 100-hour storage reach \$38/kWh and \$14/kWh, respectively, substantial deployments are observed. The distribution of storage investments across durations is strongly influenced by the system generation portfolio. We also demonstrate that a high-fidelity temporal representation is required to capture the value of LDES in generation expansion. Finally, we find that LDES deployments in the generation expansion are positively correlated with the combined wind and solar capacity share and negatively correlated with peaking and baseload shares.

2 - Regional Household-Level Impacts of Long-Term Transmission Strategies

Charalampos Avraam, National Renewable Energy Laboratory, Golden, CO, United States, Maxwell Brown, Yasser El Masri, Sarah Awara

Transmission infrastructure can allow consumers in remote regions to access the electricity generation of regions with more abundant resources, reducing the system-level cost and enhancing regional and system-level affordability and reliability. However, the costs and benefits of transmission expansion and resource availability can differ based on the type of household. The existing literature explores transmission and resource availability conditions for diverse households by assessing the operational implications of electricity disruptions. However, there is little emphasis on the role of long-term transmission expansion strategies and resource availability when accounting for the response across diverse households. Moreover, collection and processing of household-level data across the U.S. is extremely resource-intensive. Besides, large-scale national studies integrating the behavioral response of consumers by household type at the sub-state level can be computationally intensive. In this study, we leverage and process building-level electricity consumption data from ResStock across all U.S. households to generate inverse demand curves for five different household types at the sub-state level. Then, we integrate the inverse demand curves into the Regional Energy Deployment System (ReEDS), a large-scale capacity expansion model of the electric power sector of the contiguous U.S., to explore the impact of transmission expansion and regional resource availability to diverse U.S. consumers. By identifying critically affected regional households, this work aims to inform policymakers and regional stakeholders engaged in long-term transmission infrastructure design towards ensuring affordable, reliable, and abundant energy for all through the mid-century.

3 - Transmission System Approximations for Nodal Transmission and Generation Co-Expansion

Alyssa Kody, National Renewable Energy Laboratory, Golden, CO, United States, Bernard Knueven, Elizabeth Glista, Jean-Paul Watson

To support increasing and shifting customer loads and to uphold federal and state energy policy, the co-expansion problem jointly selects new generation and new transmission over a multi-decade planning horizon. System planners rely on various simplifications of the co-expansion problem for computational tractability. Examples of these simplifications include: (1) collapsing a network into zones or using a copper-plate model, (2) ignoring transmission physics using a “pipe-and-bubble” power flow approximation, and (3) the use of representative days or load flow cases as a proxy for a decades-long time horizon. Although these types of simplifications are widely used, little work has been performed to evaluate how closely these simplifications reflect the more detailed models that are used in operation. The focus of this paper is to evaluate example (2) and explore the quality of investment decisions when using simplified transmission models, like “pipe-and-bubble”, for nodal representations of realistically sized networks.

4 - Large-Scale Robust and Adaptive Planning for Generation and Transmission Expansion: California Case Study

Gabe Mantegna, Princeton University, Princeton, NJ, United States

Electric utility planners and regulators must frequently make decisions about long-lived infrastructure under deep uncertainty surrounding cost, demand, and technology availability. However, most planning practitioners use scenario analysis alone for considering uncertainty, a planning process which can frequently miss out on infrastructure decisions that offer much greater flexibility and robustness to uncertainty. Methods exist for identifying robust and adaptive decisions in an optimization framework, but they have not yet been applied to the specific context of realistic-scale generation and transmission expansion planning. In this study we develop a method for applying two-stage adaptive robust optimization to realistic-scale generation and transmission expansion planning for the state of California, and demonstrate its advantages relative to today's deterministic planning practices.

5 - Long-Term Capacity Planning Under Operational Uncertainty

KE XIN ZUO, Cornell University, ITHACA, NY, United States, Jacob Mays

This paper investigates how operational policies for managing uncertainty in power systems affect long-term capacity investment decisions in wholesale electricity markets. Traditional capacity expansion models (CEMs) typically assume perfect foresight and static representations of system dynamics, failing to capture the variability, forecast uncertainty, and intertemporal constraints present in real-world operations. Such simplifications result in the systematic mis-valuation of flexible resources (e.g. battery storage.) While theoretically, socially-optimal prices can be determined from extreme-scale stochastic programs with extensive scenario trees, such approaches remain computationally infeasible for practical implementation. In reality, system operators face a sequential decision-making problem where market-clearing prices from the operational stage coordinate capacity investments through a zero-profit condition in equilibrium. Consequently, market prices become dependent on the specific formulation and parameterization of the algorithms implemented to manage operations. Using a fixed-point iteration algorithm, we simulate operations under various policy assumptions—including Stochastic Lookahead Unit Commitment (SLAC) and Deterministic Lookahead Unit Commitment (DLAC) variants—and iteratively update capacity investments until convergence to the zero-profit equilibrium. Our results demonstrate that different operational policies yield fundamentally different price formations and capacity equilibria, despite identical underlying market structures. This algorithmic dependency of prices introduces critical inefficiencies in current market designs, distorting investment incentives and potentially leading to a long-run resource mix that diverges from the theoretical ideal. We conclude with recommendations for aligning operational uncertainty management with efficient long-term investment signals to improve resource adequacy.

Renewable Integration and Storage Systems

Contributed Session

Contributed

Chair: luce brotcorne, INRIA, Lille, France

1 - Shifting Renewable Energy Generation Under Climate Change

Renee Obringer, Pennsylvania State University, University Park, PA, United States

As the climate crisis intensifies, switching to renewable energy remains a critical piece of the solution to ensure rapid decarbonization. However, renewable energy generation is highly reliant on the ambient environmental conditions, making it difficult to estimate the long-term generation—a task that is likely to get more difficult under climate change. Accounting for the impact of climate change is particularly difficult, as there remains uncertainty related to the magnitude of climate change within the mid- and long-term in addition to the relatively unknown impacts of climate change on generation of renewable energy technologies. In this work, we aim to fill this gap by leveraging machine learning to investigate the impact of climate change on state-level renewable energy generation across the US. Using data from the Energy Information Administration (EIA), we project the solar, wind, and hydropower generation across multiple US states under two key climate change scenarios. Our goal is to answer two key questions: (1) How will climate change impact renewable energy generation; and (2) Do these impacts differ across states? To answer these questions, we leveraged several machine learning techniques, as well as an ensemble of models, to first model the observed relationship between renewable energy generation and the surrounding weather and climate. Then, we used those same models to project the changes to the system, given the most recent IPCC climate change scenarios.

2 - Optimized Co-Production of Cement and Methanol for Cost-Efficient Decarbonization

Yuezhang He, Tsinghua University, Beijing, China, People's Republic of, Jesse Jenkins

Cement and methanol production together contribute approximately 7.3% of global energy-related CO₂ emissions, underscoring their significance in achieving deep decarbonization. Given the substantial technical and economic barriers to separately decarbonizing these hard-to-abate sectors, we propose a renewable-powered co-production system that utilizes molecule exchange—captured CO₂ and by-product O₂—to reduce emissions more cost-effectively. We develop an hourly-resolved, process-based optimization model that incorporates operational flexibility and applies it to plant-level deployment strategies and CO₂ source-sink matching across China. Our results show that co-production can lower CO₂ abatement costs to \$41–53 per tonne by 2035, compared to around \$75 for standalone cement CCUS and over \$120 for renewable-based methanol. Introducing flexible methanol synthesis further reduces costs by 2.9%–16.6% through improved load balancing and storage integration. The co-production system also facilitates CCUS adoption in cement plants located in regions with abundant renewable energy, indicating a strategic opportunity to reshape national CO₂ transport and storage infrastructure. This study offers a system-level framework for jointly decarbonizing the cement and methanol industries, leveraging technological synergies and spatial heterogeneity to enhance cost-effectiveness and deployment feasibility.

3 - Resilient Renewable-Powered Multi-Functional Charging Station for Freight Transport at Maritime Ports

Jeremiah Gbadegoye, University of Tennessee, Knoxville, TN, United States, Yang Chen, Olufemi Omitaomu, Xueping Li

As freight transportation undergoes a paradigm shift toward decarbonization, ports emerge as strategic nodes for integrating clean energy infrastructure into intermodal logistics systems. This study proposes a simulation-based framework for optimizing and evaluating the operations of a Multifunctional Charging Station (MFCS) at a maritime port, capable of serving electric and hydrogen-powered freight vehicles including trucks, trains, and ships. The MFCS integrates renewable generation (solar photovoltaics and wind turbines) alongside hydrogen production via electrolysis and grid interaction to enable flexible, low-emission freight operations. We explore infrastructure capacity planning under uncertainty, focusing on capacity sizing for battery storage, hydrogen storage, and electrolyzers, using both historical freight data and forward looking scenarios based on Freight Analysis Framework (FAF) projections. The model incorporates real-world developments in battery-electric ships and inland waterway freight to ground technology adoption trends. Importantly, we examine system resilience by evaluating performance under grid outages, renewable variability, and evolving transport demands, comparing trade-offs between hydrogen and battery storage expansion. By simulating adoption trajectories of clean freight fleets through 2050, we offer a dynamic view of energy and logistics interdependencies at ports. The results inform investment strategies that balance operational costs, carbon impact, and infrastructure robustness. This research provides a reproducible approach to support planners and policymakers in scaling MFCS deployment at port facilities, emphasizing the critical role of renewable-integrated, resilient charging infrastructure in enabling the future of sustainable freight.

4 - Cloud Sharing for Energy Efficiency

luce brotcorne, INRIA, Lille, France, Nathalia Wolf

Cloud computing has revolutionized IT infrastructure by providing scalable and cost-efficient solutions. However, the rising demand for cloud services has intensified concerns around resource inefficiency and energy consumption. In this talk we propose a dynamic pricing and resource-sharing model designed to optimize virtual machine (VM) utilization. By reallocating idle VMs from long-term users to short-term consumers, this approach significantly improves resource efficiency while lowering energy costs.

Computational experiments demonstrate the effectiveness of this model in enhancing VM utilization and reducing energy consumption. Our results highlight the importance of incentivizing lender participation for maximizing efficiency and maintaining profitability in cloud services.

Power Grid Resilience Against Extreme Events

Invited Session

ENRE: Energy-Climate

Chair: Matthew Brun, Operations Research Center, MIT, Cambridge, MA, United States

Co-Chair: Xu Sun, Massachusetts Institute of Technology, Cambridge, MA, United States

1 - Quantifying Cascading Power Outages During Climate Extremes Considering Renewable Energy Integration**Luo Xu, Princeton University, Princeton, NJ, United States**

Climate extremes, such as hurricanes, combined with large-scale integration of environment-sensitive renewables, could exacerbate the risk of widespread power outages. We introduce a coupled climate-energy model for cascading power outages, which incorporates grid operations and comprehensively captures the impacts of climate extremes on renewable generation, and transmission and distribution networks. The model is validated with the 2022 Puerto Rico catastrophic blackout during Hurricane Fiona – a unique system-wide blackout event with complete records of weather-induced outages. The model reveals a resilience pattern that was not captured by the previous models: early failure of certain critical components enhances overall system resilience. Sensitivity analysis on various scenarios of behind-the-meter solar integration demonstrates that lower integration levels (below 45%, including the current level) exhibit minimal impact on system resilience in this event. However, surpassing this critical level without pairing it with energy storage can exacerbate the probability of catastrophic blackouts.

2 - Optimizing Battery and Line Undergrounding Investments for Transmission Systems Under Wildfire Risk Scenarios: a Benders Decomposition Approach**Ryan Piansky, Georgia Institute of Technology, Atlanta, GA, United States, Daniel Molzahn, Rahul Gupta**

With electric power infrastructure posing an increasing risk of igniting wildfires under continuing climate change, utilities are frequently de-energizing power lines to mitigate wildfire ignition risk, which can cause load shedding. Recent research advocates for installing battery energy storage systems as well as undergrounding risky overhead lines to reduce the load shedding during such de-energizations. Since wildfire ignition risk can exhibit substantial geographic and temporal variations, it is important to plan battery installation and line undergrounding investments while considering multiple possible scenarios. This paper presents a scenario-based framework for optimizing battery installation and line undergrounding investments while considering many scenarios, each consisting of a day-long time series of uncertain parameters for the load demand, renewable generation, and wildfire ignition risks. This problem is difficult to solve due to a large number of scenarios and binary variables associated with the battery placements as well as the lines to be undergrounded. To address the computational challenges, we decompose the problem in a two-stage scheme via a Benders decomposition approach. The first stage is a master problem formulated as a mixed-integer linear programming (MILP) model that makes decisions on the locations and sizes of batteries as well as the lines to be undergrounded. The second stage consists of a linear programming model that assesses these battery and line undergrounding decisions as modeled by a DC optimal power flow formulation. We demonstrate the effectiveness of the proposed scheme on a large transmission network with actual data on wildfire ignition risks, load, and renewable generation.

3 - Designing Wildfires for Adversarial Power Grid Outages**Matthew Brun, Operations Research Center, MIT, Cambridge, MA, United States, Xu Sun, Jean-Paul Watson**

Electric power infrastructure faces increasing risks of damage and disruption due to wildfires. The planning and operation of electric grids in wildfire-prone regions must consider the potential impact of unpredictable fires. However, traditional wildfire models do not easily answer how and when wildfires may disable some set of power grid elements. To address these questions, we propose an optimization model that designs an adversarial wildfire to target specific infrastructure while respecting physical fire spread dynamics. We identify a convex set for wildfire spread and formulate the adversarial model as a mixed-integer nonconvex program. We apply a novel convexification and dual reformulation that yield an infinite-dimensional mixed-integer conic program, which is solved via variable and constraint generation. We apply our approach to produce worst-case counterfactual fires that disable power grid elements near the recent Park and Eaton fires in California.

4 - An (Extreme) Probabilistic Perspective into Battery Trilemma: to Charge, to Charge, OR to Wait?**Tomas Tapia, Johns Hopkins University, Baltimore, MD, United States, Yury Dvorkin**

This presentation develops a risk-aware framework for positioning energy-limited battery storage under wholesale electricity market uncertainty. We first consider multi-interval battery dispatch using a finite-horizon stochastic dynamic formulation with a probabilistic end-of-horizon state-of-charge (SoC) constraint, ensuring with a given confidence level that the SoC remains within a target value. Building on this formulation, we derive explicit buy/sell thresholds using the k-search approach, with provable worst-case competitive ratios, and compute corresponding action probabilities across the finite horizon. To accelerate computations, we introduce two pruning techniques, probability redistribution and path pruning, and leverage them to quantify the likelihood of satisfying the end-of-horizon SoC target. Finally, we benchmark our results against a tractable robust optimization counterpart that incorporates budgeted uncertainty sets and propagation methods to estimate worst-case stopping times. Computational experiments using historical market prices show that the proposed framework significantly improves arbitrage revenues while maintaining system reliability and safety.

5 - Decision-Dependent Uncertainty-Aware Distribution System Planning Under Wildfire Risk**Alexandre Moreira, Lawrence Berkeley National Laboratory, Berkeley, CA, United States, Felipe Pianco, Bruno Fanzeres, Ruiwei Jiang, Chaoyue Zhao, Miguel Heleno**

The interaction between power systems and wildfires can be dangerous and costly. Distribution grids can be liable for the outbreak of wildfires during extreme weather. In wildfire-prone areas, investment planning should consider the impact of operational actions on wildfire-related uncertainties affecting line failure likelihood. In this case, endogenous-based uncertainty modeling should comprise the backbone of the investment planning model viz-a-viz the inability of standard exogenous-based uncertainty modeling. Therefore, we propose a decision-dependent uncertainty (DDU) aware methodology to optimize investment portfolios for distribution systems, considering that high power-flow levels in high-threat areas can ignite wildfires and increase line failure probability. The methodology identifies the best combination of upgrades (new lines, hardening existing lines, and placing switching devices). Methodologically, we propose a two-stage distributionally robust planning optimization problem with DDU that considers the distribution system's multiperiod operation. The first stage determines optimal switching actions and line investments, and the second stage evaluates the worst-case expected operational cost under a DDU framework designed to account for the endogenous impact of power-flow levels and hardening investment decisions in the line failure probabilities. An iterative method is tailored to handle the problem and numerical experiments demonstrate a more prepared grid to deal with wildfire risk.

Analytical Models in Healthcare

Invited Session

Health Applications Society

Chair: Hossein Piri, Haskayen School of Business-University of Calgary, Calgary, AB, Canada

1 - MI Compass: Pareto Frontier-Based Navigation of MI Model Trade-Offs**Vasileios Digalakis, Boston University, Boston, MA, United States, Ramayya Krishnan, Agni Orfanoudaki**

We propose a structured framework for ML model selection that systematically balances internal performance metrics (e.g., accuracy, interpretability, fairness) with external evaluation criteria (e.g., adoption and regulatory compliance). The framework formalizes the roles of modelers, users, and regulators, embedding their objectives within an optimization problem that maximizes the decision-maker utility under real-world constraints.

2 - Cost-Effective Surveillance Strategies for Early Detection of Cancer Recurrence: Optimal Integration of Imaging and ctDNA Testing

Reza Skandari, Imperial College Business School, London, United Kingdom, Narges Mohammadi, Alexander Pearson

Patients with cancer remain at risk of recurrence, either locoregionally or via distant metastasis, following completion of primary treatment. Timely identification of recurrence is essential for initiating treatment early and improving survival outcomes. Current surveillance strategies primarily rely on imaging, which are costly and associated with high false-positive rates leading to unnecessary biopsies and impose significant psychological and physical burdens on patients.

Circulating tumor DNA (ctDNA) testing offers a promising blood-based alternative that is more cost-effective and demonstrates higher accuracy. However, it lacks the ability to localize the site of recurrence. To address this limitation, we propose a cost-effective surveillance strategy that integrates both imaging and ctDNA testing.

We develop a constrained partially observable Markov decision process (CPOMDP) model to optimize surveillance costs under different target detection delays. Our framework introduces a Bayesian aggregation approach to personalize surveillance strategies across six patient subgroups, stratified by cancer stage and smoking habit.

Our findings indicate that the integrated strategy achieves detection delays comparable to current guidelines while significantly reducing overall costs—resulting in an estimated \$300 million in annual savings—and lowering false-positive rates from 56.5% to 6.5%. This work presents a scalable, data-driven framework for optimizing post-treatment surveillance in head and neck cancer, with potential applicability to other cancer types and future non-invasive diagnostic innovations.

3 - Convexity in Transient Queues with Appointment-Driven Arrivals and Implications on Dynamic Scheduling

Christos Zacharias, Miami Herbert, Miami, FL, United States, Alex Kuiper

We propose a unified platform to assess stochastic convexity in appointment scheduling. This paper relates to both intra-day and inter-day scheduling. In continuous intra-day scheduling, stochastic convexity is crucial in ensuring that minimization routines reach a global minimum - the optimal static schedule for a single day. We introduce to the scheduling literature the concept of strong stochastic convexity, which facilitates the assessment of convexity of performance measures of interest across a diverse range of stochastic settings. Moreover, our novel dynamic programming model encompasses inter-day scheduling, allowing us to jointly consider the assignment of both times and days for patients' appointments. This integration of intra-day and inter-day scheduling enables us to account for indirect delays and waitlist considerations when making appointment decisions.

4 - Pooling Uncommon Incidences Among Hospital Monitoring Locations for Decision-Making or Among Research Studies for Meta-Analyses

Franklin Dexter, University of Iowa, Iowa City, IA, United States, Rakesh Sondekoppam, Emine Bayman

Hospital engineering quality monitoring involves rare events (e.g., postoperative infections). Also, anesthesia procedural complications, such as neurological injury from peripheral nerve blocks, are rare. Consider combining postoperative infection data among adjacent operating rooms (e.g., for consideration of a common daily intervention such as ultraviolet-C disinfection). The economically important endpoint is the overall infection incidence (i.e., marginal estimate [e.g., 2%]). There is complete data, with room, numerator of infections, and denominator of cases. Several earlier Monte-Carlo simulation studies examined the accuracy of confidence interval coverage and bias when combining such incidences, guiding suitable analyses. However, these assume that the logit or probit of the incidence or rate follows normal distributions, which is not true in practice. Our simulation studies show marked impacts on results. Software produces nice-looking control charts, but inaccurate. Consider, similarly, meta-analyses for incidences of anesthesia complications. Investigators textually look at calculated confidence intervals and make statements about differences among methods and changes over time. For example, "the incidence of neurological dysfunction was approximately 0.9% (95% CI 0.8% to 1.1%) at <2 weeks' follow-up to approximately 0.03% (95% CI 0.01% to 0.05%) at 1 year." There is inherently complete data for meta-regression of incidences because each study provides a numerator, a denominator, and a study characteristic (e.g., follow-up period). Using generalized linear models with probit or logit link and single fixed effects variables (e.g., year), or generalized estimating equations, we again find highly inaccurate confidence interval coverage. The statistics packages converge, giving answers, but often highly unreliable.

Advances in Machine Learning

Invited Session

OPT: Machine Learning

Chair: Brian Liu, MIT, Cambridge, MA, 02139, United States

1 - Foundations and Applications in Explainable AI

Brian Liu, MIT, Cambridge, MA, United States

Tree ensembles, such as random forests and gradient boosting, remain among the most effective algorithms for structured, tabular data, and consistently outperform deep learning methods in these settings. However, their opacity make them challenging to use in high-stakes domains such as healthcare and public policy, where model explainability is crucial. In this talk, I will present a general optimization-based framework to extract explainable models from black-box tree ensembles. Our framework is flexible and allows practitioners to balance predictive accuracy with criteria such as sparsity, interaction depth, transparency, and stability. The extracted models are accurate and trustworthy, and can be examined to reveal useful relationships in the data.

2 - Benign Overfitting Beyond Prediction

Dennis Shen, USC, Los Angeles, CA, United States

Deep learning research has uncovered the benign overfitting phenomenon for overparameterized statistical models, which has drawn significant interest in recent years. Given its simplicity and practicality, the ordinary least squares (OLS) interpolator has become essential to gain foundational insights into this phenomenon. While the properties of OLS are well established in underparameterized settings, its behavior in overparameterized regimes is less explored (unlike for ridge or lasso). However, significant progress has been made of late. We contribute to this literature by providing fundamental algebraic and statistical results for the minimum ℓ_2 -norm OLS interpolator. Whereas recent research primarily focuses on the OLS interpolator's prediction accuracy, our results primarily focus on parameter estimation, which is often the central object in statistics, especially in causal inference, as these parameters are endowed with causal meanings. In particular, we provide algebraic equivalents of (i) the leave-k-out formula, (ii) the omitted variable bias formula, and (iii) the Frisch-Waugh-Lovell theorem in the overparameterized regime. Under the Gauss-Markov model, we present statistical results such as an extension of the Gauss-Markov theorem and an analysis of variance estimation under homoskedasticity for the overparameterized regime.

3 - Towards a New Frontier of Trustworthy AI: Interpretable Machine Learning Algorithms that Produce All Good Models

Chudi Zhong, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Machine learning has been increasingly deployed for high-stakes decisions that deeply impact people's lives. It's crucial to ensure the safe and efficient utilization of machine learning models in the decision-making process. In this talk, I will introduce a new paradigm, called learning the Rashomon set, which finds and stores all models within epsilon of the optimal loss. I will present algorithms for finding optimal models and Rashomon sets, discuss how this new paradigm can break the interaction bottleneck between users and ML algorithms, and provide examples of its applications.

4 - Generalized Additive Modeling for Survival Analysis

Madeleine Udell, Stanford University, Stanford, CA, United States, Mike Van Ness, Ziran Zhou

Additive models offer accurate and interpretable predictions for tabular data, a critical tool for statistical modeling. Recent advances in Neural Additive Models (NAMs) allow these models to handle complex machine learning tasks, including feature selection and survival analysis, on large-scale data. This talk introduces dnamite, a Python package that implements NAMs for these advanced applications. dnamite provides a simple scikit-learn style interface to train regression, classification, and survival analysis NAMs, with built-in support for feature selection. We describe the methodology underlying dnamite, its design principles, and its implementation. Through an application to the MIMIC III clinical dataset, we demonstrate the utility of dnamite in a real-world setting where feature selection and survival analysis are both important.

5 - Mixed-Integer Quadratic Optimization with Switching Constraints

Andres Gomez, University of Southern California, Los Angeles, CA, United States, Shaoning Han, Soobin Choi, Valentina Cepeda

We investigate convexification in convex quadratic optimization with step function penalties. Such problems can be cast as mixed-integer quadratic optimization problems, where binary variables are used to encode the non-convex step function. First, we derive the convex hull for the epigraph of a quadratic function defined by a rank-one matrix. Using this rank-one convexification, we develop copositive and semi-definite relaxations for general convex quadratic functions. Leveraging these findings, we construct convex formulations to the support vector machine problem with 0-1 loss and show that they yield robust estimators in settings with anomalies and outliers.

1 - Inventory Prepositioning as a Resilience Strategy Under Disruption

Alican Yilmaz, Northeastern University, Boston, MA, United States

The resilience of supply chain networks has become increasingly critical due to rising disruptions from natural disasters, trade conflicts, and terrorist activities. The severity of these disruptions highlights the need for effective resilience measures. In this study, we propose a tri-level defender-attacker-defender (DAD) model to enhance supply chain resilience through inventory prepositioning. The DAD problem is known for its high computational complexity, with exact algorithms in the literature often facing significant scalability challenges as problem sizes increase. To mitigate this issue, we adopt a network science based approach to identify candidate critical components, thereby reducing problem size and computational overhead. Specifically, we introduce a novel node criticality measure based on betweenness centrality to identify high-impact disruption targets. This measure is evaluated across various supply chain network configurations to assess its effectiveness. Next, we integrate this criticality information into the Column-and-Constraint Generation (C&CG) framework, reducing the number of iterations required for global optimality and thereby improving the runtime performance. Finally, we validate the proposed measure through a case study on the Alaska fuel supply chain network, offering insights into its effectiveness and identifying scenarios where it may be less effective.

2 - Multistage Chance-Constrained Programming

Soumya Ranjan Pathy, Clemson University, Clemson, SC, United States, Hamed Rahimian

In this talk, we explore multistage chance-constrained programming, a framework for sequential decision-making under uncertainty. This work introduces novel decomposition-based cutting-plane methodologies, specifically tailored to efficiently address these challenging optimization problems. Utilizing a ventilator allocation problem, we provide preliminary computational results that demonstrate the effectiveness and practical viability of the proposed approaches. Additionally, we offer managerial insights derived from evaluating multistage policies with varying decision frequencies over a fixed planning horizon. Our discussion underscores the critical impact of decision timing within a multistage optimization framework, emphasizing its relevance and potential strategic advantages in real-world decision-making contexts.

3 - Hurricane Shelter Networks Under Evacuation Behavior: Insights from Large-Scale Smartphone Data

Yu Lu, Tsinghua University, Beijing, China, People's Republic of, Fernanda Bravo, Elisa Long

Widespread natural disasters such as hurricanes and wildfires pose critical challenges for spatial resource allocation, including shelter site selection to support mass evacuations. Decision-makers must balance accessibility, coverage, and equity to ensure effective disaster response. We develop a 2-stage estimate-then-optimize model that integrates individual-level evacuation behavior into a shelter location optimization model. Using smartphone geolocation data from 1.57 million individuals during Hurricane Irma, we estimate a multinomial logit model (MNL) of evacuation choices---to a shelter, hotel, other location, or to stay home---accounting for demographics, shelter proximity, and evacuation orders.

An estimated 29% of Florida residents evacuated during Hurricane Irma, with most evacuees (87%) traveling to other locations, followed by shelters (8%) and hotels (6%). Evacuees are highly sensitive to distance, with stronger preferences for nearby shelters than hotels, and residents from mobile home communities and rural regions more frequently evacuate to shelters. Counterfactual analyses demonstrate that an Optimal-MNL policy increases predicted shelter evacuations by 28% and reduces the average shelter evacuation distance by 16%, relative to the status quo (445 shelters in operation in Florida). Compared to other benchmark policies, the Optimal-MNL policy delivers more equitable shelter access, particularly for suburban, rural, and mobile-home communities. This research offers actionable insights for disaster management, demonstrating that strategic shelter placement can achieve better outcomes with fewer facilities. Model robustness is validated through application to Hurricane Milton.

4 - Integrated Planning of Drone-Based Disaster Relief: Facility Location, Inventory Prepositioning, and Fleet Operations Under Uncertainty

Yuyang Ma, University of Southern California, Los Angeles, CA, United States, Karmel Shehadeh, Man Yiu Tsang

We introduce a two-stage robust optimization (RO) framework for the integrated planning of a drone-based disaster relief operations problem (DDROP). In the first stage, the model decides the number and locations of drone and relief items storage facilities, drone fleet size, drone assignment to demand nodes, and the amount of relief items to procure. In the second stage, the model decides drone reassignment and relief item distributions. We equip the RO model with a decision-dependent uncertainty set, which captures correlations between facility and drone disruptions and between demands and facility disruptions. We adopt the K -adaptability approximation scheme to address the combined challenges of integer recourse and decision-dependent uncertainty. We develop a new hybrid constraint-and-column generation (h-C&CG) algorithm to solve the K -adaptability approximation. Additionally, we derive new symmetry-breaking constraints and valid inequalities that improve the solvability of the model. We conduct extensive numerical experiments to demonstrate the computational efficiency of the proposed h-C&CG algorithm. Our results also show the superior operational performance of our proposed approach over traditional methods and illustrate the value of incorporating drone reassignments into disaster response planning.

5 - Improving Supply Chain Network Resilience: a Framework for Diagnosing Vulnerabilities in E-Commerce Distribution Networks

Jarrod Goentzel, Massachusetts Institute of Technology, Cambridge, MA, United States, Chelsey Graham, Ozlem Ergun

Supply chains have become more complex with interconnections and extended reach as customer expectations have risen. Simultaneously, supply chains designed for efficiency have increasingly had to adapt to disruptions such as extreme weather events, cyber security attacks, and a global pandemic. Therefore, companies now seek to consider resilience as part of their supply chain network design in order to remain competitive. In this paper, we investigate the vulnerability of e-commerce distribution networks through a three-step methodological approach: 1) network generation using optimization-based design principles, 2) network disruption, and 3) network evaluation. By studying many instances of regional networks in the U.S. and thousands of disruption scenarios, we explore which network structures best facilitate resilience and develop guidance for adaptation strategies.

Recent Advances in Stochastic and Nonlinear Optimization

Invited Session

OPT: Nonlinear Optimization

Chair: Sanyou Mei, The Hong Kong University of Science and Technology, Hong Kong, N/A

1 - Revisiting Smoothing-Enabled Stochastic Gradient-Type Schemes**Uday Shanbhag, University of Michigan, Ann Arbor, University Park, PA, United States**

We revisit the classical randomized smoothing techniques employed with stochastic gradient-type schemes. Recent progress is discussed in a broad range of settings afflicted by nonconvexity and hierarchy.

2 - Developing Lagrangian-Based Methods for Nonsmooth Nonconvex Optimization**Kuangyu Ding, Purdue University, West Lafayette, IN, United States, Nachuan Xiao, Xiaoyin Hu, Kim-Chuan Toh**

In this paper, we consider the minimization of a nonsmooth nonconvex objective function $f(x)$ over a closed convex subset $\mathcal{X}$ of $\mathbb{R}^n$, with additional nonsmooth nonconvex constraints $c(x) = 0$. We develop a unified framework for developing Lagrangian-based methods, which takes a single-step update to the primal variables by some subgradient methods in each iteration. These subgradient methods are “embedded” into our framework, in the sense that they are incorporated as black-box updates to the primal variables. We prove that our proposed framework inherits the global convergence guarantees from these embedded subgradient methods under mild conditions. In addition, we show that our framework can be extended to solve constrained optimization problems with expectation constraints. Based on the proposed framework, we show that a wide range of existing stochastic subgradient methods, including the proximal SGD, proximal momentum SGD, and proximal ADAM, can be embedded into Lagrangian-based methods. Preliminary numerical experiments on deep learning tasks illustrate that our proposed framework yields efficient variants of Lagrangian-based methods with convergence guarantees for nonconvex nonsmooth constrained optimization problems.

3 - Accelerated Stochastic Approximation with State-Dependent Noise**Tianjiao Li, Georgia Institute of Technology, Atlanta, GA, United States, Sasila Ilandarideva, Anatoli Juditsky, Guanghui Lan**

We consider a class of stochastic smooth convex optimization problems under rather general assumptions on the noise in the stochastic gradient observation. As opposed to the classical problem setting in which the variance of noise is assumed to be uniformly bounded, herein we assume that the variance of stochastic gradients is related to the “sub-optimality” of the approximate solutions delivered by the algorithm. Such problems naturally arise in a variety of applications, in particular, in the well-known generalized linear regression problem in statistics. However, to the best of our knowledge, none of the existing stochastic approximation algorithms for solving this class of problems attain optimality in terms of the dependence on accuracy, problem parameters, and mini-batch size.

We discuss two non-Euclidean accelerated stochastic approximation routines—stochastic accelerated gradient descent (SAGD) and stochastic gradient extrapolation (SGE)—which carry a particular duality relationship. We show that both SAGD and SGE, under appropriate conditions, achieve the optimal convergence rate, attaining the optimal iteration and sample complexities simultaneously. However, corresponding assumptions for the SGE algorithm are more general; they allow, for instance, for efficient application of the SGE to statistical estimation problems under heavy tail noises and discontinuous score functions. We also discuss the application of the SGE to problems satisfying quadratic growth conditions, and show how it can be used to recover sparse solutions. Finally, we report on some simulation experiments to illustrate numerical performance of our proposed algorithms in high-dimensional settings.

4 - Asgo: Adaptive Structured Gradient Optimization**Kang An, Rice University, Houston, TX, United States**

Optimizing deep neural networks presents a unique challenge: their parameters are inherently structured as matrices and tensors, departing from traditional vector representations. This structure gives rise to critical, yet often underutilized, properties such as low-rank gradients and approximately block-wise diagonal Hessians. While these properties are key to developing efficient optimization algorithms, many widely used optimizers, including Adam, do not fully leverage them. I will introduce ASGO (Adaptive Structured Gradient Optimizer), a new algorithm that explicitly incorporates these structural insights. We achieve this by employing an adaptive preconditioner that responds directly to the structured gradients. I will present our fine-grained theoretical analysis demonstrating ASGO's superior convergence rates over existing structured gradient methods, and discuss how ASGO directly benefits from low-rank and block-wise diagonal properties. Finally, I will showcase ASGO's practical effectiveness with empirical results on challenging language model tasks.

5 - Nonasymptotic Analysis of Accelerated Methods with Inexact Oracle Under Absolute Error Bound**Yin Liu, Peking University, Beijing, China, People's Republic of, Sam Davanloo**

In many emerging applications, access to exact gradient information is either computationally expensive or impractical, giving rise to the need for optimization algorithms that are robust to inexact oracles. While accelerated first-order methods offer faster convergence in the exact setting, they tend to be more sensitive to gradient errors compared to their non-accelerated counterparts.

This work presents a nonasymptotic convergence analysis for two accelerated methods—Inexact Fast Gradient Method (FGM) and Inexact Optimized Gradient Method (OGM)—for solving deterministic smooth convex optimization problems under inexact gradient information. Our analysis employs the Performance Estimation Problem (PEP) framework to derive analytical convergence bounds for these algorithms when the gradient approximation errors vary over iterations.

Under an absolute error model, we obtain the bounds where the cumulative error term is shown to be independent of initial conditions. We further investigate the trade-off between convergence rate and error accumulation, leading to insights on selecting optimal step sizes. In addition, we characterize the optimal scheduling of gradient inexactness across iterations to ensure that error accumulation remains subordinate to the convergence rate, thereby preserving the fast convergence of the algorithm.

Recent Advances in Data-Driven Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Soroosh Shafiee, Cornell University, Ithaca, NY, United States

Co-Chair: Sloan Nietert, Cornell University, Ithaca, NY, United States

1 - Estimation of Stochastic Optimal Transport Maps**Sloan Nietert, Cornell University, Ithaca, NY, United States**

The optimal transport (OT) map is a geometry-driven transformation between high-dimensional probability distributions which underpins a wide range of tasks in statistics, applied probability, and machine learning. However, existing statistical theory for OT map estimation is quite restricted, hinging on Brenier's theorem (quadratic cost, absolutely continuous source) to guarantee existence and uniqueness of a deterministic OT map, on which various additional regularity assumptions are imposed to obtain quantitative error bounds. In many real-world problems these conditions fail or cannot be certified, in which case optimal transportation is possible only via

stochastic maps that can split mass. To broaden the scope of map estimation theory to such settings, this work introduces a novel metric for evaluating the transportation quality of stochastic maps. Under this metric, we develop computationally efficient map estimators with near-optimal finite-sample risk bounds, subject to easy-to-verify minimal assumptions. Our analysis further accommodates common forms of adversarial sample contamination, yielding estimators with robust estimation guarantees. Empirical experiments are provided which validate our theory and demonstrate the utility of the proposed framework in settings where existing theory fails. These contributions constitute the first general-purpose theory for map estimation, compatible with a wide spectrum of real-world applications where optimal transport may be intrinsically stochastic.

2 - Data-Driven Robust Inventory Planning and Advertising Under Product Return

Qinshen Tang, Nanyang Technological University, Singapore, Singapore, Hongyan Zhang, Yugang Yu, Ye Shi, Li Chen

Retailers increasingly use online pay-per-click (PPC) ads on platforms like Amazon to boost sales, but these ads also influence product returns—an effect largely overlooked in prior research. Motivated by a real-world case, we study a multi-product setting where online ads impact both sales and returns, complicating inventory and advertising planning. We conduct predictive analysis on historical data and identify both direct effects (a product's ads influencing its own sales and returns) and spillover effects (ads affecting other products). Based on this, we develop linear models to estimate net demand and returns. To address data limitations and distributional uncertainty, we propose a robust satisficing framework that allows the retailer to set a desired profit level and make data-driven ad and inventory decisions accordingly. A case study demonstrates the practical scalability and improved performance of our Linear Approximation Robust Satisficing (LARS) model over the traditional Predict-then-Optimize (PO) approach. The LARS model achieves superior results, especially when spillover effects are present, outperforming PO by an average of 3.82%.

3 - Scaling the Cvar Approximation for Solving Chance Constrained Programs

Nan Jiang, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Rui Chen

In a chance constrained program (CCP), the decision maker aims to find an optimal solution that ensures the probability of violating uncertainty constraints remains within a specified risk level. However, the nonconvex nature of the CCP poses significant challenges in computing an optimal solution. To address this, convex approximations have been developed, with Conditional Value-at-Risk (CVaR) recognized as one of the best practical methods. Despite its strengths, CVaR approximation can be overly conservative. In this paper, we propose a scaling approach that enhances the CVaR approximation. We identify sufficient conditions under which the scaled CVaR approximation preserves optimality and demonstrate its applicability to both single and joint chance constrained programs. Since solving the scaled CVaR approximation to optimality is NP-hard, we develop efficient algorithms to iteratively refine the scaling factors and approximately solve the scaled CVaR approximation. Numerical experiments validate the proposed methods, confirming improvements over the CVaR approximation.

4 - Distributionally Robust Optimization via Iterative Algorithms in Continuous Probability Spaces

Linglingzhi Zhu, Georgia Institute of Technology, Atlanta, GA, United States, Yunqin Zhu, Yao Xie

We consider a minimax problem motivated by distributionally robust optimization (DRO) when the worst-case distribution is continuous, leading to significant computational challenges due to the infinite-dimensional nature of the optimization problem. Recent research has explored learning the worst-case distribution using neural network-based generative models to address these computational challenges but lacks algorithmic convergence guarantees. This paper bridges this theoretical gap by presenting an iterative algorithm to solve such a minimax problem, achieving global convergence under mild assumptions. In particular, we reformulate the discrepancy-based DRO as a minimax problem in the Wasserstein space and, by applying Brenier's theorem, represent the worst-case distribution as a transport map from a continuous reference measure for computation. Furthermore, we demonstrate that the worst-case distribution can be efficiently computed using the Jordan-Kinderlehrer-Otto (JKO) scheme with sufficiently large regularization parameters for commonly used discrepancy functions, linked to the radius of the ambiguity set. Additionally, we derive the global convergence rate and quantify the total number of subgradients and inexact JKO iterations required to obtain approximate stationary points. Numerical results on an illustrative robust classification example demonstrate the effectiveness of our DRO framework. Compared to existing point-to-point robust training methods, the solution derived from the proposed algorithm serves as an efficient adversarial attack generator thanks to the continuous probability space formulation.

5 - Learning Optimal Inventory Control Policies with Deep Neural Nets

Zhen Yang, University of Texas at Austin, Austin, TX, United States, Yizhe Huang, Rui Gao, Shuang Li

The inventory management problem is crucial for many businesses and has been extensively studied in previous works. Despite these efforts, some models remain challenging due to the unknown structure of the optimal inventory policy. We aim to approximate the policy at each stage by a neural network which is a universal approximator, and establish the statistical and global optimality guarantees.

Recent Progress in Optimization Software II

Invited Session

OPT: Computational Optimization and Software

Chair: Hans Mittelmann, Arizona State University, Tempe, AZ, United States

1 - Recent Developments in Optverse Optimization Solver

Zirui Zhou, Huawei Technologies Canada, Burnaby, BC, Canada

In this talk, we present latest development of Optverse optimization solver and some of its successful applications. We will introduce new features, new solvers, and discuss some techniques that are key to performance improvement.

2 - What's New in FICO Xpress Solver

Michael Perregaard, FICO, Birmingham, United Kingdom

We will give an overview of the latest enhancements, the newest features, and the most recent performance improvements in the FICO Xpress Solver for mixed-integer linear and nonlinear optimization problems. These include advances in MIP techniques such as heuristics, cutting, branching and presolving.

3 - Highs: Latest Updates

Benjamin Champion, University of Edinburgh, Edinburgh, United Kingdom

HiGHS is the world's leading open-source linear optimization solver. It supports Linux, macOS, and Windows, and interfaces with many popular programming languages. This talk examines recent developments and future prospects, primarily focusing on technical and algorithmic aspects. However, this talk also discusses other important parts of the HiGHS project. Fundamentally, a thriving software ecosystem stimulates development. The HiGHS team interacts with a range of users and contributors, a substantial proportion of whom are industrial. These interactions take many forms, including usage queries, feature requests, code contributions, and sponsorship. This talk outlines the key proceedings at the second annual HiGHS Workshop, an event bringing together many members of the HiGHS ecosystem. As with any open-source software project, planning for long-term survival is crucial. This talk presents some thoughts on the evolution of the HiGHS team.

4 - Latest Developments in the COPT Optimizer

Joachim Dahl, Cardinal Operations, Ballerup, Denmark

We discuss recent advances in the COPT optimizer from Cardinal Operations. The advances include improvements in the mixed-integer optimizer for various problem classes, as well as improvements of the conic optimizer.

5 - Recent Developments in the Gurobi Optimizer

Dan Steffy, Gurobi Optimization, Bloomfield Hills, MI, United States

This talk will discuss new features and performance enhancements in the Gurobi Optimizer for LP, MILP and Global MINLP. We will also present preliminary performance results for the upcoming release.

Theoretical and Computational Advances in Branch-and-Cut Algorithms

Invited Session

OPT: Integer and Discrete Optimization

Chair: Aleksandr Kazachkov, University of Florida, Gainesville, United States

1 - Generalization Guarantees for Learning Branch-and-Cut Policies

Hongyu Cheng, Johns Hopkins University, Baltimore, MD, United States, Amitabh Basu

Mixed-integer programming (MIP) provides a powerful framework for optimization problems, with Branch-and-Cut (B&C) being the predominant algorithm in state-of-the-art solvers. The efficiency of B&C critically depends on heuristic policies for making sequential decisions, including node selection, cut selection, and branching variable selection. While traditional solvers often employ heuristics with manually tuned parameters, recent approaches increasingly leverage machine learning, especially neural networks, to learn these policies directly from data. A key challenge is to understand the theoretical underpinnings of these learned policies, particularly their generalization performance from finite data. This paper establishes rigorous sample complexity bounds for learning B&C policies where the scoring functions guiding each decision step (node, cut, branch) have a certain piecewise polynomial structure. This structure generalizes the linear models that form the most commonly deployed policies in practice and investigated recently in a foundational series of theoretical works by Balcan et al. Such piecewise polynomial policies also cover the neural network architectures (e.g., using ReLU activations) that have been the focal point of contemporary practical studies. Consequently, our theoretical framework closely reflects the models utilized by practitioners investigating machine learning within B&C, offering a unifying perspective relevant to both established theory and modern empirical research in this area. Furthermore, our theory applies to quite general sequential decision making problems beyond B&C.

2 - Extended Abstract Branch-and-Cut Model

Boyang Han, University of Florida, Gainesville, FL, United States, Aleksandr Kazachkov

We extend the abstract branch-and-cut tree frameworks considered by Kazachkov, Le Bodic, and Sankaranarayanan [3], in which branching leads to known (constant) bound improvements while cut nodes provide diminishing strength across rounds and potentially increase node solving time. We generalize these models to optimize branching and cutting decisions to minimizing solving time when incorporating cut generation time and multiple cut families in the same model as both diminishing-strength cuts and general monotonic node-processing time functions. We prove that it is sufficient to only add root cuts in the symmetric branching case (when branching in each direction provides the same bound improvement). Next, we analyze optimal tree structure in the nonsymmetric branching setting, for which we show that local cuts (beyond the root node) can be necessary in optimal trees.

3 - Speeding up Mixed-Integer Solvers with Sparse Learning for Branching

Selin Bayramoglu, Georgia Institute of Technology, Atlanta, GA, United States, George Nemhauser, Nikolaos Sahinidis

Machine learning is being increasingly used to accelerate branch-and-bound algorithms for mixed integer optimization. Studies in the literature demonstrate success in approximating branching criteria based on strong branching, a local and expensive strategy which empirically leads to small search trees. The state-of-the-art learning methods for this problem are based on neural networks, with many parameters and a need for a large amount of data for training. In this work, we demonstrate the effectiveness of sparse models in approximating strong branching scores, showing that our models remain simple yet powerful even when trained on limited data. Moreover, our approach achieves significant solver speedups without requiring GPU hardware. We demonstrate that our methodology speeds up SCIP when applied to commonly studied mixed-integer linear problems, and a challenging mixed-integer nonlinear problem from the energy sector.

4 - Learning to Parallelize Branch & Bound

Kavitha G Menon, Argonne National Laboratory, Lemont, IL, United States, Santanu Dey, Alinson Santos Xavier

Branch-and-bound is theoretically well suited for parallel processing, but achieving significant speedups in practice is challenging due to imbalanced workloads and communication overhead. In this study, we propose a new learning-based parallelization approach, which statically partitions Mixed-Integer Programming (MIP) problems into well-balanced subproblems, avoiding both issues. We first solve a representative set of MIP instances with MIPLearn, an open-source package for learning-enhanced optimization, capture the B&B tree, then identify B&B tree edges whose removal creates balanced subtrees. This data is then used to train machine learning models capable of partitioning new MIP instances. Unlike existing methods, our approach allows edge removal throughout the entire tree, not just near the root, resulting in more balanced partitions. Computational results, conducted on eight families of discrete combinatorial problems, show that the method is able to significantly outperform Gurobi's parallel performance, often achieving near-linear speedups up to 16 processors. The study demonstrates the effectiveness of parallelizing B&B through strategic partitioning and highlights areas for further optimization.

5 - Recent Developments in the Gurobi MILP Solver

Ed Klotz, Gurobi Optimization, Incline Village, NV, United States

Performance improvements to the Gurobi MILP Solver will be discussed. Topics include extending large neighborhood search heuristics such as RINS (Relaxation Induced Neighborhood Search) to make use of infeasible integral vectors, and extensions to Optimization Based Bound Tightening (OBBT) to handle specific constructs common to some challenging MILP and MINLP problems.

1 - Network Formation Through Mechanism Design

Bo Cowgill, Columbia University, New York, NY, United States, Zikai Xu

This paper develops a mechanism design approach to network formation. A principal has a willingness-to-pay (WTP) for different network configurations, while agents have preferences over their network positions. Our approach allows the principal to optimize for global properties of the network, while respecting IC/IR constraints of network participants. We focus on direct mechanisms, but develop a broader family of mechanisms in which transfers are set by the allocation rule ("revenue equivalence"). We characterize optimal mechanisms under novel multidimensional regularity conditions, and provide an ironing procedure for irregular distributions. These findings contribute to multidimensional mechanism design, with potential applications to network formation in social, economic, and organizational contexts.

2 - Incentivizing In-Store Customers for Last-Mile Delivery: a Dynamic Compensation Framework

Rouven Schur, University Duisburg-Essen, Duisburg, Germany, Matthias Soppert, Kai Winheller

Last-mile delivery remains one of the most challenging and cost-intensive components of modern retail logistics. A promising approach to alleviate these challenges is to crowdsource deliveries to in-store customers who, after completing their own shopping, may be willing to transport goods along their homeward routes. These occasional drivers (ODs) can serve as a flexible and cost-efficient supplement to traditional delivery fleets. However, their successful integration into delivery operations hinges on overcoming two challenges: the uncertainty of ODs' destinations and their voluntary decision to accept delivery tasks.

We address these challenges through the application of dynamic pricing, using monetary incentives to influence OD behavior in real time. The retailer's decision problem is modeled as a finite-horizon Markov decision process, where compensation offers are dynamically adapted to the current system state – specifically, the set of remaining delivery locations and the time left to attract ODs before tasks must be fulfilled by dedicated drivers. In contrast to prior work, our model does not assume knowledge of ODs' destinations or guaranteed participation. Instead, it captures the stochasticity in both OD availability and willingness to accept tasks.

We derive analytical results for a one-dimensional setting and identify structural properties of the optimal policy. These insights enable the development of a decomposition-based heuristic for the more complex two-dimensional case. A simulation study demonstrates the benefits of a dynamic, state-dependent compensation scheme in effectively engaging in-store customers for last-mile delivery.

3 - Dynamic Control of Add-on Services in Queueing Systems

Yuan-Mao Kao, Baruch College, CUNY, New York City, NY, United States, Chen-An Lin

We study a dynamic control problem in a service system where a provider offers an add-on service to each customer after completing a primary service. Customers choose whether to use the primary and add-on services based on their evaluations of service quality, prices, and expected wait times. Their expectations for the quality of the add-on service depend on their experiences with the primary service. The provider can dynamically adjust prices and service rates to manage congestion and customer experience in order to optimize long-run performance.

4 - Pricing and Wage Decisions for on-Demand Food Delivery Platforms with Multiple Customer Classes and Courier Pools

Yooseok Seo, Seoul National University, Seoul, Korea, Republic of, Jungwook Lim, Byeongkwon Lee, Kunsoo Park

The recent proliferation of food delivery services with crowdsourced couriers (delivery workers) has introduced new problems in the operations of on-demand food delivery platforms. An increase in crowdsourced couriers has diversified delivery transportation modes such as motorcycle, bike, and walk, which results in mode-specific maximum delivery distances according to their speeds. In addition, it is necessary to manage various customer classes with specific delivery distances between restaurants and customers.

For a food delivery platform with multiple customer classes and courier pools, it is essential to optimize the delivery price charged to each customer, the wage paid to couriers, and matching between them to complete the food delivery within a reasonable amount of time. Hence, we study the operations decisions for the online food delivery platform that faces price- and time-sensitive customers with heterogeneous delivery distances and earning-sensitive couriers with heterogeneous transportation speeds. We formulate this problem as a multi-class multi-pool queueing and allocation problem.

We find that the objective function of this optimization problem is inherently complex with respect to the number of customer classes and courier pools, making it unsuitable for standard convex optimization techniques.

Hence, we propose a new Utilization-Based Multipoint (UBM) heuristic that exploits multiple initial points to derive near-optimal results efficiently. Our numerical experiments on both generated instances and real delivery data demonstrate that the proposed heuristic algorithm significantly outperforms the benchmark for all experiments.

5 - Coach Reservation for Groups Requests

Carlos Cardonha, University of Connecticut, Storrs, CT, United States, Arvind Raghunathan

Passenger transportation is a cornerstone of a railway company's business, with ticket sales playing a pivotal role in revenue generation. This work extends traditional revenue management models by addressing the coach reservation problem for group requests, where two or more passengers must be seated in the same coach. We propose an exact mathematical programming formulation incorporating a first-come, first-served fairness condition for the offline case, in which all requests are known in advance. We also propose algorithms for online models of the problem. Our analysis for one of these models overcomes known barriers in the packing literature, yielding strong competitive ratio guarantees when group sizes are relatively small compared to coach capacity. Using data from the Shinkansen Tokyo-Shin-Osaka line, our numerical experiments demonstrate the practical effectiveness of the proposed policies.

6 - Analysis of the Revenue Sharing Ratio of A Virtual Product Between A Developer and A Distribution Platform Under A Consignment Contract with Revenue Sharing

SEONG-HYUN NAM, University of North Dakota, GRAND FORKS, ND, United States

Virtual products such as software and applications, movie and music streaming, online games, e-books, and mobile applications have been rapidly increasing their market share recently. We consider the case where owners or developers of virtual products contract to sell their virtual products through a third-party sales or distribution platform. Different types of contracts can be established between the owner (developer) of a virtual product and the distribution platform. In this study, we considered in particular a consignment contract with revenue sharing. In such a contract, the developer transfers ownership of the virtual product and sets its selling price, with the platform charging the developer an agreed percentage of the selling price for each virtual product sold. Under a consignment contract with revenue sharing, we examined the range of revenue sharing percentages that developers can accept when they delegate everything to the sales platform, how the revenue sharing percentage differs when developers use a hybrid format in which they sell directly through their own sales channels (direct channel) and the sales platform (indirect channel) compared to when they delegate everything to the sales platform, and how much the accuracy of developer and platform demand forecasts affects the revenue sharing percentage.

7 - Political Posturing: Market Expectations, Profit Maximization, and Consumer Surplus

Saman Modiri, Lehigh University, Emmaus, PA, United States

Brand activism has become an increasingly prominent aspect of firm strategy, particularly as companies navigate heterogeneous consumer segments. However, firms have demonstrated inconsistent patterns—shifting between political engagement, neutrality, and even ideological reversal—raising questions about the strategic logic underlying such actions. This study develops a stylized analytical model in which firms select their political alignment to maximize profit, accounting for consumer heterogeneity, issue salience, and market expectations. The model further incorporates consumer surplus to evaluate the broader implications of political posturing on market outcomes. Findings reveal that when political alignment is expected by the market, firms gain from activist positioning; yet, consumer surplus declines as the issue becomes more salient in daily life. In contrast, for issues with lower salience, firms can satisfy market expectations with minimal surplus distortion and, at times, even an increase in consumer surplus, leading to potential gains for both the firm and consumers. Additionally, when neutrality is not penalized, firms face fewer pressures to signal alignment, and consumer surplus improves. These results highlight brand activism as a strategic tool driven by market expectations, consumer preferences, and the perceived relevance of political issues. This research provides a theoretical foundation for interpreting recent shifts in corporate political behavior and contributes to a broader understanding of the market dynamics underpinning brand activism.

Operational Perspectives to Clinical Trial Design

Invited Session

Health Applications Society

Chair: Amin Khademi, Clemson University, Clemson, SC, United States

1 - To Abandon OR Not? Understanding the Impact of Participant Retention on Clinical Trial Outcomes

Xueze Song, The University of Alabama, TUSCALOOSA, AL, United States, Mili Mehrotra, Ujjal Mukherjee, Tharanga Rajapakshe

The process of drug development is replete with significant risks and uncertainties, with as many as 12% of clinical trials terminated early. One leading factor of trial termination is poor recruitment or retention. In this work, we study the impact of strategies to improve participant retention on clinical trial sponsor's decision to terminate the clinical trial. Specifically, we address the following research questions: How does the adoption of incentives and effort affect the sponsor's decision to terminate the clinical trial? How does the impact of such strategies vary across different clinical trials? How can the sponsor adjust their retention strategies to minimize the likelihood of termination? To answer these questions, we formulate a sponsor's decision to terminate a clinical trial as an optimal stopping problem with partial information on the drug's efficacy. We then leverage the data from the clinical study registry from the U.S. and empirically estimate the effect of various clinical trial characteristics on the likelihood of termination. Our analysis sheds light on the key factors that drive clinical trial termination and can inform future drug development efforts.

2 - Optimal Enrollment in Late Stage New Drug Development with Learning of Drug's Efficacy for Group Sequential Clinical Trials

Zhili Tian, Univ. of Houston, Houston, TX, United States, Gordon Hazen, Hong Li

The cost for developing a new drug ranges is close to more than \$2 billion between 2010 and 2019. The efficacy of the candidate drug, patient enrollment, the market exclusivity period (MEP), and the planning horizon are uncertain. Slow enrollment leads to increased costs, canceled clinical trials, and lost potential revenue. Firms, hoping to detect efficacy versus futility of the candidate drug early to save development costs, plan interim analyses (IAs) of patient response data.

We developed a continuous-time dynamic programming (DP) model with learning of a drug's efficacy to assist firms in developing optimal enrollment policies in their clinical trials. We also established the optimality equation for this DP model. Through a clinical trial for testing a cancer drug developed by a leading pharmaceutical firm, we demonstrate that our DP model can help firms effectively manage their trials with a sizable profit gain. Firms can also use our model in simulation to select their trial design parameters (e.g., the sample sizes of IAs).

We established that the value of the drug development project increases as the average response from patients using the candidate drug increases. For drugs having low annual revenue or a strong market brand or treating rare diseases, we also established that the optimal enrollment policy is monotonic in the average patient response. The optimal enrollment rate increases as the variance of the MEP decreases.

Firms can use our optimal policy to guide patient recruitment in clinical trials considering competition from other drugs in the market place.

3 - Online Learning with Survival Data

Arielle Anderer, Cornell University, Johnson School, Ithaca, NY, United States, Hamsa Bastani, John Silberholz

In many healthcare settings it is imperative to be able to quickly converge to the best intervention, but the structure of the data makes using traditional methods challenging. This project adapts online learning techniques to scenarios with time-to-event data, such as time-to-screening and time-to-disease-progression, where there is a delay between choosing an arm and observing feedback that is endogenous to the quality of the arm. We posit a multi-armed bandit algorithm that uses a cox-proportional hazards estimator. We theoretically analyze and prove guarantees on the regret under this algorithm. Lastly, we examine its performance on a dataset of behavioral health interventions for cervical cancer screening, and compare it to that of other adaptive allocation schemes.

4 - Planning Micro-Randomized and Adaptive Trials with Nonstationary Multi-Armed Bandits

Yonatan Mintz, University of Wisconsin Madison, Madison, WI, United States, Fengxu Li, Qinyang He

Mobile health interventions enable personalized treatments in areas like diabetes, mental health, and weight loss. These interventions generally use reinforcement learning methods and multi armed bandits to personalize treatment recommendations to trial participants and improve resource allocation. However there are several key challenges that arise when using these methods. First, since the goal of the trial is to use the data for post hoc analysis it is critical to have sufficient statistical power when allocating treatments to participants. When treatments are personalized however, there is a risk that not all treatments will be dispensed sufficiently often to ensure high statistical power. Furthermore, if interventions given to participants are costly or impact participant engagement, it is critical that the randomization methods account for not just the maximum effect but also how much cost is incurred by the participants. In this talk we will discuss a specific class of non-stationary bandit models that apply in these scenarios, and examine how they can be adapted to meet the unique needs of clinical trial design. We will discuss both theoretical and computational results of these methods including regret and power guarantees. We will also present results from case studies in the areas of weight loss and physical activity and show how these methods can be applied in practice.

1 - Early Warning Index for Patient Deteriorations in Hospitals

Yu Ma, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas, kimberly villalobos

Capacity-constrained hospitals lack automated systems to harness the growing volume of heterogeneous clinical and operational data—ranging from vital signs and lab results to scheduling and patient flow metrics—to effectively forecast critical events. Early identification of patients at risk for deterioration is essential not only for patient care quality monitoring but also for physician care management. However, translating varied data streams into accurate and interpretable risk assessments poses significant challenges due to inconsistent data formats.

We develop a multimodal machine learning framework, the Early Warning Index, to predict the aggregate risk of ICU admission, emergency response team dispatch, and mortality. Using a dataset of patients at a large U.S. hospital, our approach automatically extracts features from both structured and unstructured electronic health record data. Key to EWI's design is a human-in-the-loop process: clinicians help determine alert thresholds and interpret model outputs, which are enhanced by explainable outputs to highlight clinical and operational factors driving each patient's risk. We deploy EWI in a hospital dashboard that stratifies patients into three risk tiers. It is currently used as a triage tool for proactively managing at-risk patients.

The proposed approach saves physicians valuable time by automatically sorting patients of varying risk levels, allowing them to concentrate on patient care. By further pinpointing specific risk drivers, the proposed model provides data-informed adjustments to care giver scheduling and allocation of critical resources. As a result, clinicians and administrators can avert downstream complications including costly procedures or high readmission rates and improve overall patient flow.

2 - When Less is More: Optimizing Prescription Alerts Under Fatigue

Hossein Piri, Haskayen School of Business-University of Calgary, Calgary, AB, Canada, Michael Lingzhi Li

As healthcare systems grow more complex, ensuring safe medication practices remains a critical challenge. Pharmacists play a key role in preventing medication errors, aided by Computerized Provider Order Entry (CPOE) systems that generate alerts for potential drug interactions, dosages, and contraindications. However, to capture all potential risks, these systems generate a significant number of alerts, leading to alert fatigue and diminishing pharmacists' responsiveness to critical warnings. This study develops a fluid model to optimize CPOE alert strategies while accounting for pharmacist fatigue. The key challenge lies in the interdependence of decisions: each alert shown increases fatigue, which in turn reduces the pharmacist's capacity to act on future alerts, creating a dynamic feedback loop. We derive the general optimal policy, which follows a decreasing threshold structure—alerts are initially shown selectively but become more frequent as fatigue accumulates. Our analysis further shows that the heavier the tails of the risk distribution, the more conservatively alerts should be shown. While the dynamic thresholding strategy is optimal, its implementation is challenging due to operational complexity and the potential for strategic behavior. We show that a constant threshold policy is asymptotically optimal for a broad class of risk distributions, offering a simpler alternative with strong performance. Numerical experiments across a wide range of scenarios demonstrate that the optimized alert strategy reduces patient risk by 8–9% while cutting the number of alerts by 40–50%, highlighting its robustness and practical impact.

3 - Mosaic: Model-Agnostic Optimal Subgroup Identification with Multi-Constraint for Improved Reliability

Wenxin Chen, Cornell University, New York, NY, United States, Weishen Pan, Kyra Gan, Fei Wang

Identifying subgroups that benefit from specific treatments using observational data is a critical challenge in personalized medicine. Most existing approaches solely focus on identifying a subgroup with an improved treatment effect. However, practical considerations, such as ensuring a minimum subgroup size for representativeness or achieving sufficient confounder balance for reliability, are also important for making findings clinically meaningful and actionable. While some studies address these constraints individually, none offer a unified approach to handle them simultaneously. To bridge this gap, we propose a model-agnostic framework for optimal subgroup identification under multiple constraints. We reformulate this combinatorial problem as an unconstrained min-max optimization problem with novel modifications and solve it by a gradient descent ascent algorithm. We further prove its convergence to a feasible and locally optimal solution. Our method is stable and highly flexible, supporting various models and techniques for estimating and optimizing treatment effectiveness with observational data. Extensive experiments on both synthetic and real-world datasets demonstrate its effectiveness in identifying subgroups that satisfy multiple constraints, achieving higher treatment effects and better confounder balancing results across different group sizes.

4 - A Responsible Framework for Assessing, Selecting, and Explaining Machine Learning Models in Cardiovascular Disease Outcomes Among People with Type 2 Diabetes: Methodology and Validation Study

Yang Yang, Georgia Institute of Technology, Atlanta, GA, United States

Building machine learning models that are interpretable, explainable, and fair is critical for their trustworthiness in clinical practice. Interpretability, which refers to how easily a human can comprehend the mechanism by which a model makes predictions, is often seen as primary consideration when adopting a machine learning model in health care. However, interpretability alone does not necessarily guarantee explainability, which offers stakeholders insights into a model's predicted outputs. Moreover, many existing frameworks for model evaluation focus primarily on maximizing predictive accuracy, overlooking the broader need for interpretability, fairness, and explainability. This study proposes a 3-stage machine learning framework for responsible model development through model assessment, selection, and explanation. We demonstrate the application of this framework for predicting cardiovascular disease (CVD) outcomes, specifically myocardial infarction (MI) and stroke, among people with type 2 diabetes (T2D). We developed several interpretable machine learning models (linear, tree-based, and ensemble) to predict the risks of MI and stroke among patients with diabetes. Our 3-stage framework first assesses these models via predictive accuracy and fairness metrics. Then, in the model selection stage, we quantify the trade-off between accuracy and fairness using area under the curve (AUC) and Relative Parity of Performance Scores (RPPS), wherein RPPS measures the greatest deviation of all subpopulations compared to the population-wide AUC. Finally, we quantify the explainability of the chosen models using methods such as SHAP (SHapley Additive exPlanations) and partial dependence plots to investigate the relationship between features and model outputs.

1 - Nft Market Design: Resale Royalty, Decentralization, and Interoperability

Jingchen Liu, Renmin University of China, Beijing, China, People's Republic of, Yao Cui

The Non-Fungible Token (NFT) market is fast-growing, but increasing competition among platforms poses significant challenges in choosing the optimal operational strategies and finding the right ways to collaborate. This paper provides a theoretical investigation into NFT market design by focusing on two key platform policies: (1) royalty payments the original NFT creators receive when a resale transaction occurs, and (2) NFT interoperability, i.e., whether resale is allowed on a different platform than where the NFT was originally minted. We show that when platforms maintain centralized control over royalty policies and do not permit interoperability, the NFT equilibrium can take one of three forms depending on the degree of market speculation: "free royalty", where creators earn exclusively from the primary price; "free airdrop", where creators earn exclusively from the resale royalty; and "intermediate royalty", where creators earn from both sources. However, the equilibrium shifts when interoperability is permitted (always to free royalty) or when royalty decisions are decentralized to individual creators (always to free airdrop). Comparing the NFT equilibria under different policies, we find that under centralized royalty policies, NFT interoperability can create a win-win outcome by improving both platform profits and social welfare. In contrast, under decentralized royalty policies, NFT interoperability consistently results in a lose-lose outcome. These findings suggest that platforms should only collaborate on NFT interoperability if they maintain decision-making authority over royalty policies. In this case, we further identify that the win-win outcome is most likely to occur when market speculation is at moderately low levels.

2 - Generative AI and Organizational Structure in the Knowledge Economy

Fasheng Xu, University of Connecticut, Stamford, CT, United States, Jing Hou, Wei Chen, Karen Xie

The adoption of Generative Artificial Intelligence (GenAI) is fundamentally reshaping organizations in the knowledge economy. GenAI can significantly enhance workers' problem-solving abilities and productivity, yet it also presents a major reliability challenge: hallucinations, or errors presented as plausible outputs. This study develops a theoretical model to examine GenAI's impact on organizational structure and the role of human-in-the-loop oversight. Our findings indicate that successful GenAI adoption hinges primarily on maintaining hallucination rates below a critical level. After adoption, as GenAI advances in capability or reliability, organizations optimize their workforce by reducing worker knowledge requirements while preserving operational effectiveness through GenAI augmentation—a phenomenon known as deskilling. Unexpectedly, enhanced capability or reliability of GenAI may actually narrow the span of control, increasing the demand for managers rather than flattening organizational hierarchies. To effectively mitigate hallucination risks, many firms implement human-in-the-loop validation, where managers review GenAI-enhanced outputs before implementation. While the validation increases managerial workload, it can, surprisingly, expand the span of control, reducing the number of managers needed. Furthermore, human-in-the-loop validation influences GenAI adoption differently based on validation costs and hallucination rates, deterring adoption in low-error, high-cost scenarios, while promoting it in high-error, low-cost cases. Finally, productivity improvements from GenAI yield distinctive organizational shifts: as productivity increases, firms tend to employ fewer but more knowledgeable workers, gradually expanding managerial spans of control. Our research directly addresses calls for theoretical frameworks to understand how GenAI technologies reshape organizational structures and the future of work, while providing practical guidance for organizations navigating this transformation.

3 - Supporting Teachers to Support Students in Individualized Learning

Owen Wu, Kelley School of Business, Indiana University, Bloomington, IN, United States

Individualized learning platforms are designed to optimize student progress by adapting content to each learner's needs. However, these systems often assume that students can work independently once a learning path is established. In practice, many students encounter difficulties that require timely support from teachers—support that current systems do not effectively facilitate. At present, teachers must manually review student records to infer when intervention is needed, a process that is both time-consuming and error-prone. In collaboration with an individualized learning platform, we aim to develop an intelligent system that detects when students need help during individualized learning. Our model identifies signs of struggle or frustration and alerts teachers in real time. The system not only indicates when intervention is needed, but also provides insights into what kind of support may be most effective. By supporting teachers in their ability to support students, we strengthen the human element of individualized learning and move toward a more responsive and inclusive educational model.

4 - Economics of NFTs: The Value of Creator Royalties

Niuniu Zhang, University of California, Los Angeles, Los Angeles, CA, United States, Brett Falk, Bin Gu, Gerry Tsoukalas

Non-Fungible Tokens (NFTs) are transforming how content creators, such as artists, price and sell their work. A key feature of NFTs is the inclusion of royalties, which grant creators a share of all future resale proceeds. Although widely used, critics argue that sophisticated speculators, which dominate the NFT market, simply price in royalties upfront, neutralizing their impact. We show this intuition to be true only under the assumption of perfect frictionless markets. Under more realistic market conditions, royalties enable creators to capitalize on the presence of speculators in at least three ways: They can enable risk sharing (under risk aversion), mitigate information asymmetry (when speculators are better informed) and unlock price discrimination benefits (in multi-unit settings). Moreover, in all three cases, royalties also meaningfully expand trade, implying increased transaction volume for platforms. These theoretical results offer testable predictions that could drive future NFT economics research.

5 - Optimal Collateral for Clearing Interbank Payments

Shuzhen Chen, Central South University, Changsha, China, People's Republic of, Opher Baron, Ningyuan Chen

We investigate the daily collateral collecting problem of a central bank for clearing payment obligations among numerous banks who incur an opportunity cost of posting collateral and a borrowing cost from the central bank. The central bank chooses optimal collateral collection and debt offsetting policies in order to minimize the total expected costs of all banks. We formulate the problem as a two-stage stochastic program and derive a closed-form solution for the optimal collateral amount under standard linear cost assumptions. We extend the framework using cooperative game theory to analyze the benefits and stability of bank coalitions. Going beyond standard core allocation concepts from the cooperative game literature, we design a practical mechanism involving internal borrowing rules and a novel collateral allocation algorithm. We validate our theoretical findings and demonstrate the potential for significant system-wide cost savings using real daily interbank payment data from Payments Canada.

1 - Multi-Channel Healthcare Operations: the Impact of Video Visits on the Usage of in-Person Care

Tan (Suparek) Lekwijit, W. P. Carey School of Business, Arizona State University, Tempe, AZ, United States, Hummy Song, Christian Terwiesch, Krisda Chaiyachati

Healthcare organizations have increasingly adopted video visits as an alternative care channel that offers greater convenience and holds promise for improving patients' access to care. Despite the growing use, the impact of a new digital channel on care demand within existing physical channels has not been thoroughly investigated, especially in the primary care context of a traditional healthcare organization. We study a large healthcare system that made video visits available to a subset of its patients for primary care needs, prior to the COVID-19 pandemic. Using a difference-in-differences approach and visit data spanning over 9.5 million patient-months, we find that the introduction of video visits increases the demand for in-person primary care provider (PCP) visits by 20% and the demand for emergency department (ED) visits by 30%. When considering only patient-initiated visits, we find that the introduction of video visits increases the overall number of care initiations but does not affect in-person care initiations, suggesting that patients initiate care through video visits for care needs that may have otherwise gone unattended. Furthermore, we find that the increase in in-person demand arises primarily from patients who have poorer access to in-person care, as measured by distance and provider busyness. Lastly, compared to in-person visits, we find that video visits are less likely to provide care that can successfully conclude a care episode, especially when the medical condition is acute. Our findings have important capacity and revenue implications for healthcare organizations that are considering offering video visits as an additional care channel.

2 - The Impact of Information-Granularity and Prioritization on Patients' Care Modality Choices

Lin Zang, Stanford University, Stanford, CA, United States, Yue Hu, Ricky Roet-Green, Shujing Sun

The past few years have witnessed a significant expansion in telemedicine adoption by healthcare providers. On one hand, telemedicine has the potential to increase patients' access to medical appointments. On the other hand, due to the limitations of remote diagnostic and treatment methods, telemedicine may be insufficient for patients' treatment needs and may necessitate subsequent in-person follow-up visits. To better understand this tradeoff, we model the healthcare system as a queueing network providing two types of service: telemedicine and in-person consultations. We assume that an in-person visit guarantees successful treatment, whereas a telemedicine visit may fail to meet the patient's treatment needs with a probability that is contingent on individual patient characteristics. We formulate patients' strategic choices between these care modalities as a queueing game, and characterize the game-theoretic equilibrium and the socially optimal patients' choices. We further examine how improving patients' understanding of their telemedicine suitability through predictive analytics at the online triage stage affects system performance. We find that increasing information granularity maximizes the stability region of the system but may not always be optimal in reducing the average waiting time. This limitation, however, can be overcome by simultaneously deploying a priority rule that induces the social optimum under specific conditions. Finally, leveraging real-world data from a large academic hospital in the United States, we perform a comprehensive case study that encompasses both the development of a prediction model for in-person follow-up needs and the implementation of effective information provision and prioritization strategies.

3 - Balancing Health Outcomes and Patient Fatigue in Chronic Care

Wanting Yang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Jimmy Qin, Jingwei Zhang

We study the problem of scheduling appointments for patients with chronic diseases, incorporating the behavioral phenomenon of appointment fatigue, where a patient's no-show probability increases with their history of unnecessary false-positive recalls. We model this problem as a partially observable Markov decision process (POMDP) with the objective of maximizing finite-horizon health outcomes while mitigating the patient disengagement caused by fatigue. We analyze the structure of the optimal policy and establish several key properties. For the single-patient case, we prove the optimal policy is governed by a simple threshold on the provider's belief about the patient's health. We generalize this result to the N -patient setting, showing that the optimal policy possesses an elegant structure that partitions the high-dimensional state space into $N+1$ distinct regions, each corresponding to a unique optimal action. We develop three approximation policies: a theory-informed heuristic derived from our structural results, a Lagrangian relaxation-based policy, and an approximate linear programming (ALP) approach. Our work provides both deep structural insights and computationally tractable policies to help healthcare providers improve chronic care management by intelligently navigating the trade-off between clinical effectiveness and patient engagement.

4 - Understanding Customer Preferences for Virtual Versus in-Person Services

Alex Mills, Baruch College, New York, NY, United States, Omer Berk Olmez

As multi-channel services become more common, understanding the value customers place on virtual and in-person services has become increasingly important. Using data from a provider with in-person and virtual channels, we examine how service delivery channels and attributes—such as duration and distance—shape customer choices.

1 - Towards An Operational Framework for Assessing Person-Job Fit

Bhavot Singh, Michigan State University, East Lansing, MI, United States, Sriram Narayanan, Rajiv Ranganathan, Hung Kuo

Inclusion of people with disabilities in the workforce is crucial for addressing labor shortages in the US. Despite comprising nearly 12% of the population, people with disabilities face significant barriers, however, current frameworks for fitting people with disabilities into jobs are inadequate. This study proposes a novel framework for inclusion.

2 - Spillover Benefits of Workplace Fairness on Manufacturing Operations: Evidence from Employment Non-Discrimination Acts in the United States

Max Ji, The Pennsylvania State University, University Park, PA, United States, Suvarat Dhanorkar, Kevin Linderman, Suresh Muthulingam

A growing body of work has examined how workplace policies promoting fair treatment positively influence workplace culture and the work environment. Beyond these foreseeable benefits, the impact of fair workplace initiatives on manufacturing processes remains underexplored. We seek to bridge this gap by leveraging a quasi-natural experiment that arises with the staggered adoption of Employment Non-Discrimination Acts (ENDAs), which prohibit discrimination based on characteristics such as gender, race or sexual orientation. Our results show that manufacturing facilities in states that have enacted ENDAs experience positive spillovers, as evidenced by significant reductions in their process waste. Our analysis reveals that this waste reduction effect operates through two separate pathways: operational pathway (i.e., based on the state where the manufacturing facility is located) and the management pathway (i.e., based on the state where the parent firm is headquartered). Our findings suggest that policies promoting workplace fairness can add value to manufacturing processes by fostering fair and merit-based practices.

3 - Labeling the Supply Chain: Signaling Supply Chain Transparency to Consumers Through Eco-Labels

Katelyn Thompson, University of South Carolina, Columbia, SC, United States, Blair Flicker, Priyank Arora

A central concern in operations and supply chain management is the processes by which products are made, an issue that has become increasingly salient among consumers. In response, many firms disclose their sustainability practices on product packaging through eco-labels, which are binary indicators of supply chain transparency. In the recent years, there is proliferation of not only the total number of labels in the market but also the number of labels on a product. Given the growing emphasis in practice on supply chain transparency, this paper explores how the use of multiple eco-labels affects consumers' perceptions of firm performance across different dimensions of sustainability, including environmental, social, and animal welfare. Specifically, we conduct incentivized studies to answer the following research question: For a firm that has already earned an eco-label pertaining to one dimension of sustainability, how does the addition of a second (or third) disclosure related to another dimension affect consumers' perception of the firm's performance on these multiple dimensions? Our work adds nuances to the understanding on supply chain transparency by examining interactions among multiple sustainability disclosures rather than evaluating each in isolation. By deepening the understanding of how multiple sustainability disclosures interact and how such interactions shape consumers' perceptions, this study offers practical insights for firms engaged in sustainable operations.

4 - Mobile Application with Real-TIME AI Exercise Feedback Improves Physiotherapy Adherence and Recovery

Pierre Gautreau, York University - Schulich School of Business, North York, ON, Canada, Phil Boyer, Moren Levesque, Helen Razmjou, Cristian Renteria, Ujash Sheth, Robin Richards, Jay Shaw, Cari Whyne, David Burns

This study investigates the impact of the Smart Physiotherapy Activity Recognition System (SPARS) and its companion mobile application, PT+ on patient exercise adherence and recovery outcomes in shoulder physiotherapy. SPARS uses inertial sensors in commercially available smartwatches to track the quantity and quality of exercise performed. PT+ provides real-time feedback on exercise technique and monitors patient progress. Our comparative cohort study followed participants for 12 weeks. The intervention group (N=24) received a smartwatch and tablet equipped with SPARS/PT+, while the control group (N=100) received a smartwatch that passively tracked physical therapy participation using SPARS without displaying results. 6,498 patient-days of exercise data and 2,093 hours of movement records indicates that the intervention group performed significantly more exercise and had better recovery outcomes. Analysis of technique adherence and patient interviews revealed that sharing the SPARS/PT+ feedback with a physiotherapist was a key motivator, leading to increased exercise participation and improved recovery.

5 - Pack Size and Pricing in a Developing Economy: the Strategic Role of Small Packs

Anant Mishra, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States, Arzi Adbi, Ajay Bhaskarabhatla, Jingwen Yang

Although small-packs, originally designed to serve the base of the pyramid (BOP), are ubiquitous, we know very little about how manufacturers price these offerings relative to their large packs. Conceptual works drawing from quantity discount models predict a per-unit price premium on small packs, reflecting the economies of scale in production and distribution. Yet liquidity constraints and limited consumer awareness associated with the BOP challenge this logic. Our study explores the interplay between pack size and pricing by analyzing how manufacturers price their small-packs relative to large-packs.

1 - Dynamic Adherence Markov Decision Process

Zhengchao Wang, Imperial College London, London, United Kingdom, Huikang Liu, Huan Xu

Algorithmic recommendations are seldom followed to the letter: real-world users may only partially adopt, delay, or abandon suggested actions as their trust fluctuates. Adherence-aware Markov decision processes (AAMPDs) address this gap by modelling the implemented policy as a stochastic blend of the algorithmic recommendation and a baseline strategy. We extend this framework to settings in which adherence evolves over time and introduce Dynamic Adherence-Aware MDPs (DAAMPDs), where a latent trust variable governs the probability of compliance. Our first contribution shows that a DAAMPD can be reformulated as a conventional MDP with augmented state, yielding transition and reward kernels that embed both trust dynamics and user inertia. Second, we develop efficient algorithms for computing optimal recommendation policies within the extended state space. Finally, we prove that, under a mild regularity condition on outcome-driven trust updates, the decision maker's adherence level converges almost surely to one, guaranteeing eventual full adoption of the learned policy. The proposed framework bridges the gap between prescriptive analytics and human behaviour, providing a principled basis for algorithms that must earn and retain user trust over time.

2 - Risk-Averse Total-Reward MDPs with Erm and Evar

Marek Petrik, University of New Hampshire, Durham, NH, United States, Xihong Su, Julien Grand-Clement

Optimizing risk-averse objectives in discounted MDPs is challenging because most models do not admit direct dynamic programming equations and require complex history-dependent policies. In this paper, we show that the risk-averse $\{\text{total reward criterion}\}$, under the Entropic Risk Measure (ERM) and Entropic Value at Risk (EVaR) risk measures, can be optimized by a stationary policy, making it simple to analyze, interpret, and deploy. We propose exponential value iteration, policy iteration, and linear programming to compute optimal policies. Compared with prior work, our results only require the relatively mild condition of transient MDPs and allow for $\{\text{both}\}$ positive and negative rewards. Our results indicate that the total reward criterion may be preferable to the discounted criterion in a broad range of risk-averse reinforcement learning domains.

3 - Strongly-Polynomial TIME and Validation Analysis of Policy Gradient Methods

Caleb Ju, Georgia Institute of Technology, Atlanta, GA, United States

We propose a novel termination criterion, termed the advantage gap function, for finite state and action Markov decision processes (MDP) and reinforcement learning (RL). By incorporating this advantage gap function into the design of step size rules and deriving a new linear rate of convergence that is independent of the stationary state distribution of the optimal policy, we demonstrate that policy gradient methods can solve MDPs in strongly-polynomial time. To the best of our knowledge, this is the first time that such strong convergence properties have been established for policy gradient methods. Moreover, in the stochastic setting, where only stochastic estimates of policy gradients are available, we show that the advantage gap function provides close approximations of the optimality gap for each individual state and exhibits a sublinear rate of convergence at every state. The advantage gap function can be easily estimated in the stochastic case, and when coupled with easily computable upper bounds on policy values, they provide a convenient way to validate the solutions generated by policy gradient methods. Therefore, our developments offer a principled and computable measure of optimality for RL, whereas current practice tends to rely on algorithm-to-algorithm or baselines comparisons with no certificate of optimality.

4 - Robust Weakly Coupled Markov Decision Processes

Fupeng Sun, Imperial College Business School, London, United Kingdom, Huikang Liu, Zhe Liu, Wolfram Wiesemann

We study Robust Weakly Coupled Markov Decision Processes (RWCMDPs), a modeling paradigm for sequential decision-making under uncertainty in the transition kernel, where the global problem decomposes into independent subproblems coupled through linking constraints. The objective is to maximize the expected reward under the worst-case realization of the uncertainty for the finite horizon. We develop a general solution framework based on robust Lagrangian relaxation with state-action ambiguity sets. We prove that the resulting robust Lagrangian dual problem is non-convex and admits three equivalent formulations. These formulations enable the derivation of upper and lower bounds via subgradient methods and constant decision rule approximations. In a data-driven setting—where the ambiguity set is centered at the maximum likelihood estimator and converges in infinity-norm to the true transition kernel—we prove that the resulting policies constructed from both the upper and lower bounds are asymptotically optimal for the weakly coupled MDP under the true model, as both the ambiguity set radius and the number of subproblems grow large. Numerical experiments demonstrate the superior performance of our proposed methods.

5 - Fast Convergent Risk-Aware Reinforcement Learning

Junjie Lei, The University of Hong Kong, Hong Kong, China, People's Republic of, Wenjie Huang, Dionysios Kalogerias

This work proposes a fast-converging reinforcement learning algorithm under risk-aware objectives, termed Zap Risk-aware Q-learning (Zap RaQL). By integrating elicitable and coherent risk measures—specifically, expectiles—into the Q-learning framework, we effectively capture the downside risk in Markov decision processes (MDPs). The algorithm employs a two-timescale stochastic approximation scheme combining Zap Q-learning with a Zap-style Newton-Raphson method for risk estimation, both of which benefit from second-order updates. We prove that the proposed algorithm achieves almost sure convergence. Theoretical analysis is supported by numerical experiments demonstrating that Zap RaQL significantly reduces the variance of Bellman errors compared to standard risk-aware Q-learning. Our work provides a principled and efficient framework for risk-sensitive decision-making in reinforcement learning.

Chair: Keji Wei, Tongji University, Shanghai, N/A, China, People's Republic of

1 - Assortment Optimization with Customer-Centric Fairness

Yihua He, The Hong Kong University of Science and Technology, Hong Kong, China, People's Republic of, Qian Liu, Jin Qi

The rapid growth of e-commerce platforms has enabled businesses to implement customized assortment strategies, tailoring product offerings to different customer groups. While these strategies can significantly enhance profitability, they often raise concerns about fairness, particularly when certain customer groups receive fewer options. Such practices can provoke customer backlash and damage a company's reputation. Motivated by these issues, we propose a fairness-aware framework for assortment optimization that balances revenue maximization with equitable treatment of customer groups. By introducing cardinality-based fairness constraints, our framework ensures that sellers provide a similar number of products to different groups, subject to varying levels of fairness tolerance. Our analysis demonstrates that fairness constraints compel sellers to offer more products to disadvantaged groups while reducing the advantages previously enjoyed by privileged groups. In the meantime, the fairness constraints also enhance the discriminated group's customer surplus even though the seller does not explicitly target this outcome. On the other hand, the sellers have no incentive to exceed the minimum fairness requirements. Moreover, we develop efficient polynomial algorithms to solve the problem exactly when customers are categorized into two categories and for the multi-type scenarios with semi-independent tolerance levels. We also propose an approximate algorithm for the most general multi-type scenarios with a guaranteed performance bound. Numerical results show that fairness constraints have a limited impact on seller revenue, making them less likely to resist such regulations. However, policymakers must carefully weigh the trade-offs as fairness constraints can reduce overall customer surplus in some cases.

2 - Optimizing Tiered Product Pricing with Choice-Based Demand and Capacity Constraints

Sai Krishna Reddi, University at Buffalo, Buffalo, NY, United States

We present an optimization framework for pricing and designing tiered products using a discrete-choice demand model. The approach maximizes expected profit by jointly optimizing product prices and feature configurations, while accounting for visit frequency, feature costs, and ancillary revenues. The model incorporates capacity constraints and feature hierarchy, supporting interpretable, profitable designs across subscription or access-based industries.

3 - Bad Store or Bad Inventory? a Structural Model of Multi-Location Retail Performance with Assortment Variation

Katherine Ashley, Northeastern University, Boston, MA, United States

Fashion retailers with multiple brick-and-mortar store locations face two challenges simultaneously: they must select an appealing range of products to make or buy from garment manufacturers, and they must allocate available units of inventory across store outlets to match supply with uncertain demand in multiple markets. Yet once these decisions have been made, a further challenge remains: fairly evaluating the outcomes that are observed in different stores that received inventory allocations of varying consumer appeal. While extensive research examines assortment optimization and inventory allocation decisions, the existing literature does not focus on disentangling store-specific operational efficiency from product-specific appeal in a large-scale empirical setting.

Using data from a U.S. fashion retailer, we propose a simultaneous equations model that allows for the estimation of store effects and product effects on item-level profitability. Our identification strategy exploits cross-sectional variation in product availability: items sold in multiple locations enable separation of inherent product appeal from store-specific factors, while stores carrying overlapping assortments allow identification of location-specific operational capabilities. The framework accounts for potential endogeneity in allocation decisions, where better-performing stores may receive more appealing inventory.

This research extends structural estimation techniques in operations management and provides an econometric framework designed specifically for the multi-location retail attribution problem. The results of this model can inform store- and chain-level assortment planning, inventory allocation, and store closing decisions with separate insights into product performance and store-level execution.

4 - Assortment Planning and Free Shipping Strategies Under the Multinomial Logit Choice Model

Sahika Sahan Konur, Texas State University, San Marcos, TX, United States, Hafila Morais Max Morais

In this study, we examine the integrated problem of assortment planning, free shipping strategies, and shipping fee settings under the Multinomial Logit (MNL) model. We first establish that the general version of the problem is NP-hard. To explore more practical approaches, we analyze the problem across nine scenarios formed by the combination of three free shipping strategies—all-or-none, threshold-based, and selective free shipping—and three shipping fee policies: box-rate, flat-rate, and discounted box-rate. For most of these scenarios, we are able to characterize the optimal solution. However, when selective free shipping is combined with either flat-rate or discounted box-rate fees, the problem remains NP-hard. For these two challenging cases, we propose pseudo-polynomial ϵ -approximation algorithms. Finally, we conduct a series of numerical experiments to investigate the conditions under which each scenario performs best, as well as to assess the impact of retailers' shipping costs and customers' sensitivity to shipping fees on overall revenue.

5 - Product Line Design Under a Context-Dependent Multinomial Logit Model

Keji Wei, Tongji University, Shanghai, China, People's Republic of, Xiaoyun Niu, Yufeng Cao

When an airline passenger selects among flights departing at similar times, the availability of nearby alternatives can subtly alter the perceived appeal of each option—a phenomenon that traditional discrete choice models often overlook. Using a proprietary dataset of airline sales, we empirically show that passenger utility is shaped not only by flight attributes but also by the density of competing options and their temporal proximity.

Building on these insights, we develop a **product line design framework** under a **context-dependent multinomial logit model**, where the attractiveness of each flight dynamically adjusts based on the offered set. We apply this framework to **airline fleet assignment and timetabling decisions**, explicitly modeling how product availability and scheduling influence customer choice and generate cannibalization effects between competing flights. To address the computational complexity introduced by context-sensitive interactions, we propose **mixed-integer reformulations** and **tractable solution techniques**.

Our work advances both **empirical understanding of context effects** in choice behavior and **methodological innovation in revenue management optimization**, enabling more sophisticated decision-making under flexible, context-dependent utility models.

Decision Analysis Society

Chair: Manel Baucells, Darden School of Business, Charlottesville, VA, 22903, United States

1 - On the Properties of the Metalog Distribution

Manel Baucells, Darden School of Business, Charlottesville, VA, United States

There has been a longstanding interest among statisticians and analysts for parametric probability distributions flexible enough to match arbitrarily shaped, non-normal data sets (e.g., the Pearson family, or the Johnson family). The metalog quantile function emerged in 2016 as a new alternative and has been widely adopted for use in practice for its simplicity and flexibility. Important properties of the metalog such as moments and modes or how to address infeasibility, remain poorly understood. We introduce the redefined metalog 2.0 which provides guarantees of non-degeneracy. We establish the possible number of modes, and uncover elementary expressions for the moments and the partial expectations. We also show a new way to control the support of the distribution, a precise diagnosis of feasibility and—in case of infeasibility—an efficient algorithm to estimate the best feasible fit. We conclude by showcasing some applications.

2 - A Walk Down Memory Lane: How Memories Influence Stock Investment and Information Processing

alessandra cillo, LIUC University, Castellanza (Va), Italy, Giovanni Burro, Sergio Alessandro Castagnetti, Giovanni Crespi

We study the impact of memories on investment decisions and how they affect the way individuals use stock-related information. In the first experiment, we find that eliciting memories before an investment task polarizes the level of the amount invested: positive memories increase the level invested compared to recalling non-positive ones. In the second experiment, we elicit memories of the investment from all participants before the investment, but only some of them receive positive and truthful financial information about the stock they are about to invest in. While information provision increases investment, it only does so for those who do not recall personal memories, as opposed to personal ones. We rationalize our findings in light of a memory-based model.

3 - Truthful Budget Aggregation: Beyond Moving-Phantom Mechanisms

Rupert Freeman, University of Virginia, Charlottesville, VA, United States, Mark de Berg, Ulrike Schmidt-Kraepelin, Markus Utke

We study a budget-aggregation setting in which a number of voters report their ideal distribution of a budget over a set of projects, and a mechanism aggregates these reports into an allocation. In the first part of this work, we study the space of truthful mechanisms, i.e., those mechanisms that do not incentivize voters to misreport their preferences. For the case of two projects, the set of mechanisms that are truthful and additionally meet a range of basic desiderata (anonymity, neutrality, and continuity) exactly coincides with the so-called moving-phantom mechanisms, but whether this space is richer for more projects was repeatedly stated as an open question. We answer this question in the affirmative by presenting a class of truthful mechanisms that are not moving-phantoms. In the second part, we explore the interplay between truthfulness and fairness. On the negative side, we show that there exist instances where all truthful mechanisms must disregard the preferences of half the electorate, violating key fairness principles. On the positive side, we propose a novel moving-phantom mechanism and show that it provides project fairness guarantees that are optimal among all truthful mechanisms. Project fairness uses the mean allocation as a baseline and quantifies the maximum deviation of funding received by any project from this baseline. As a corollary of our results, we show that our new mechanism minimizes the worst-case ℓ_1 distance to the mean for three projects and gives the first non-trivial bounds on this quantity for more than three projects.

4 - Optimal Index Policies for Sequential Search: a Unified Framework Under Bayesian Learning

Zixin (Stephen) Xu, Darden Business School, University of Virginia, Charlottesville, VA, United States, Manel Baucells, Sasa Zorc

Sequential search models are critical tools in operations management, with extensive applications ranging from job hunting and consumer purchasing to technology adoption. However, traditional models often unrealistically assume complete knowledge of underlying distributions. Addressing this limitation, we develop a unified Bayesian framework for optimal sequential search with unknown distribution parameters, applicable to diverse recall structures, risk preferences, and discounting behaviors. Our approach introduces a general family of distributions, classified into subfamilies based on parameter types—location, scale, or both—and derives an optimal index policy valid across these subfamilies. This policy simplifies complex dynamic programming problems by using standardized sufficient statistics, thus maintaining tractability even when incorporating different utility transformations (CARA, CRRA) and discounting methods (exponential, hyperbolic). We further disprove a longstanding conjecture by showing that, contrary to prior belief, search without recall under exponential families and conjugate priors need not follow a single-reservation-price rule. Importantly, our framework offers immediate applications in the computer science community, particularly in sequential sampling problems such as Bayesian optimal stopping for Large Language Model (LLM) inference. Beyond its theoretical contributions, our method enables robust and adaptive sampling strategies under uncertainty, bridging behavioral modeling and machine learning. This result significantly expands the theoretical and practical understanding of sequential search, providing a versatile, computationally efficient methodology that captures a wide range of behavioral, economic, and computational scenarios.

1 - Optimizing Electric Vehicle Charging Infrastructure on University Campuses: a Queueing-Theoretic Analysis of Capacity and Congestion**Yikai Zhang, Boston University, Boston, MA, United States, Jinglong Zhao, Justin Ren**

As the transition to electric vehicles (EVs) accelerates in both urban and academic environments, effective management of EV charging infrastructure is becoming increasingly critical. This study evaluates the operational performance of a small-scale EV charging station equipped with limited chargers, addressing issues of capacity constraints and user congestion through a queueing-theoretic framework and Monte Carlo simulations. Empirical data reveal high blocking probabilities that prevent users from accessing charging services, highlighting substantial user inconvenience. Across multiple policy scenarios varying in charger availability and pricing strategies, the analysis finds the policy which minimizes total annual cost and alleviates current congestion. This scalable framework provides actionable insights for decision-makers managing EV infrastructure in campuses or other small-scale settings, contributing to broader sustainable transportation efforts.

2 - Encoding and Decoding Illegal Wildlife Trade Networks with Machine Learning and Centrality Analysis**Hannah Murray, University of Southern California, Los Angeles, CA, United States, Meredith Gore, Bistra Dilkina**

The illegal wildlife trade is a key driver of biodiversity loss and a barrier to desired transformations in socio-environmental systems. It is known to exploit licit networks, such as the global airline flight network, yet the ability of science to support efforts to reduce the illegal wildlife trade remains underdeveloped. Research on the illegal wildlife trade relies on biased aggregate counts of observed incidents, leading to potential policy misguidance. Here we utilize centrality analysis and predictive modeling to encode and decode illegal wildlife trade flight networks to improve sensemaking with implications for sustainable futures. Methods advance existing analyses by revealing traffickers prioritize airports with high centrality in the global airline flight network, high incidence of flora crimes, and a limited level of non-state actor oversight. Machine learning models identify airports likely to be involved in the illegal wildlife trade not currently implicated in seizure data, including in the United States.

3 - Evidence of Spillovers from (Non)Cooperative Human-Bot to Human-Human Interactions**Margaret Traeger, University of Notre Dame, Notre Dame, IN, United States, Ashley Harrell**

It is well-documented that cooperation spills over among humans: people's cooperative choices are influenced by their (non)cooperative alters, even in downstream interactions with new partners. We ask: do (non)cooperative interactions with bots spill over to subsequent interactions with humans—and if so, how? Across two pre-registered experiments (combined N = 83,411 decisions by 4,171 participants told they are interacting with a bot or human), we demonstrate that human-bot interactions do spill over to human-human ones, and in two ways. First, interacting with a bot reduces cooperation not only during the initial interaction; it also reduces downstream cooperation toward a new human partner. Additionally, bots' (like human partners') behavior matters: interactions with bots playing tit-for-tat promote cooperation, and interactions with noncooperative bots reduce cooperation, toward downstream human partners. The implementation of bots in previously human-only spaces alters human cooperation, not just toward bots, but toward other humans as well.

4 - Tip Your Farmer? Implications of Tipping on Smallholder Welfare in Agricultural Supply Chains**Basak Kalkanci, Georgia Institute of Technology, Atlanta, GA, United States, Saeed Alizamir**

An emerging financial innovation enabled by technological advancements in agricultural supply chains is the ability to “tip the farmers”. This mechanism empowers socially-conscious consumers to identify and support the individual farmers of their products by sending the direct payments, or tips. We shed light on the implications of tipping through a game-theoretic model that captures the interactions between a mass of infinitesimal farmers, a population of socially-conscious consumers, and an agricultural firm who plays the intermediary role between farmers and consumers. We find that if tipping is implemented under the right conditions, it can create a triple-win for all supply chain members including every individual farmer. This happens when farmers' outside option takes moderate values and the consumers' social-consciousness is sufficiently high. When these conditions are violated, however, farmers and/or consumers could be worse off in the presence of tipping. Furthermore, even in situations where farmers benefit from tipping in expectation, it may entail disparity and exacerbates inequity in the farmer population, which is undesirable from a social responsibility standpoint. Adverse outcomes such as these occur in parameter regions wherein the firm exploits the consumers' tip to lower its wholesale price commitment to the farmers. Thus, caution must be exercised in implementing a tipping program as it may lead to reduction in farmers' expected and/or realized income as well as consumer welfare. Even when the firm commits to maintaining the same wholesale price a priori, tipping can be detrimental to the firm while helping consumers and farmers.

1 - Dynamic Matching with Post-Allocation Service and Its Application to Refugee Resettlement**Vahideh Manshadi, Yale, New Haven, CT, United States**

Motivated by our collaboration with a major refugee resettlement agency in the U.S., we study a dynamic matching problem where each arrival (a refugee case) must be matched immediately and irrevocably to one of the static resources (a location with a fixed annual quota). In addition to consuming the static resource, each case requires post-allocation service from a server, such as a translator. Given the time-consuming nature of service, a server may not be available at a given time, thus referred to as a dynamic resource. Upon matching, the case waits to avail service in a first-come-first-serve manner. Bursty matching to a location may result in undesirable congestion at its corresponding server. Consequently, the planner (the agency) faces a dynamic matching problem with an objective that combines matching reward (pair-specific employment outcomes) with costs for congestion at dynamic resources and over-allocation of static ones. Motivated by observed fluctuations in refugee composition across years, we design algorithms without relying on distributional knowledge from past years' data. We develop learning-based algorithms that are asymptotically optimal in certain regimes, interpretable, and computationally fast. Our design is based on learning the dual variables of the underlying optimization problem; however, the main challenge lies in the time-varying nature of dual variables associated with dynamic resources. To address this, our theoretical development draws on Lyapunov analysis, adversarial learning, and stochastic optimization. When tested on real data from the partner agency, our method outperforms existing ones, making it a viable candidate for replacing current practices upon experimentation.

2 - Regulating Wait-Driven Requests in Queues**Daniel Freund, MIT, Cambridge, MA, United States**

Rational queueing has fundamentally relied on the assumption that service requests lose utility while waiting in queues. This paper is motivated by applications where this assumption fails to hold and certain requests actually benefit from waiting. One such application is the US affirmative asylum system, for which it has been suggested that long wait times incentivize non-meritorious applications. We study the impact of scheduling policies in such a setting through a dynamical system where, in each round, a given scheduling policy and a realized request rate determine the wait time distribution in a fluid queueing system. Observing the expected benefit from waiting in one round, requests update their decisions for the next round. Assuming (i) a concave benefit function from waiting and (ii) that the distribution of abandonment times has an increasing hazard rate, we prove that Last-In-First-Out (LIFO) minimizes while First-In-First-Out (FIFO) maximizes the backlog among all work-conserving policies. Moreover, we show that the dynamical system exhibits metastability: for either FIFO or LIFO, the system converges, through two different types of herd behavior, to either a zero-wait or a congested equilibrium. In practice, LIFO is often critiqued for its failure to maintain fairness: earlier requests should get earlier service. Our results demonstrate a fairness-efficiency trade-off between LIFO and FIFO, but also illustrate limitations of hybrid policies, which probabilistically follow either LIFO or FIFO to navigate this trade-off. Upon extending a known fairness notion to queueing systems with abandonment, we demonstrate that LIFO may Pareto-dominate hybrid policies with respect to

3 - Alignment and Misalignment of Fairness Constraints in Candidate-Job Matching

Marcela Vasconcellos, Worcester Polytechnic Institute, Worcester, MA, United States, Swati Gupta, Andrew Trapp

As AI-driven systems increasingly mediate labor market access, concerns about fairness and bias in candidate to job matching have intensified. We examine how fairness constraints align with the true compatibility signals in predictive candidate-to-job matching systems. Specifically, we investigate whether fairness interventions intended to equalize opportunities across groups move predicted matching scores closer to true candidate to job compatibility, or instead introduce further misalignment. Starting from a machine learning model that estimates candidate-to-job fit, we account for bias in these predictions arising from taste-based or statistical discrimination. We examine the effect of adjusting fit scores using weights from dualized fairness constraints of a bipartite matching formulation solved via linear programming. We show that, in some cases, these constraints can correct for taste-based and statistical discrimination. We evaluate our approach on real-world data from a social startup focused on improving equitable employment access, measuring how closely the interventions align with real-world weights via group-specific accuracy, precision, and error rates. Our findings identify when fairness constraints are aligned or misaligned with actual compatibility signals, providing practical guidance for designing equitable AI systems in hiring.

4 - Data Envelopment Analysis Meets Private Refugee Resettlement

Fatemeh Farajzadeh, Worcester Polytechnic Institute, Worcester, MA, United States, Sarah Stanlick, Vincent Charles, Andrew Trapp

This study introduces a data-driven framework to evaluate success factors in private refugee resettlement, with a focus on Neighborhood Support Teams (NSTs). These community-based groups supported refugees admitted under the humanitarian parole program for private resettlement in the United States from late 2021 through 2022. We develop a customized Data Envelopment Analysis (DEA) to assess NST performance, informed by targeted data collection capturing key influencing factors and the complexity of their operations. To address the sensitivity of DEA to variable selection, we develop an iterative method combining logistic regression and statistical significance testing. The results provide actionable insights for policymakers and resettlement agencies to enhance decentralized refugee support through evidence-based decision-making.

1 - Incentive Design for Long-Term Retention of New Gig Workers

Natalie Epstein, Harvard Business School, Cambridge, MA, United States, Ignacio Rios

High worker turnover remains a persistent challenge for platform-based businesses. Not only does it increase acquisition and training costs, but it also negatively impacts service quality. In this paper, we explore how the design of short-term monetary incentives impacts worker retention and engagement in the long term.

We gather data from a B2B platform that offers last-mile delivery services to a beverage conglomerate in Brazil. High worker turnover and different threshold-based incentive structures across markets make this an ideal setting. We analyze the company's change in incentive design using a difference-in-differences (DiD) model and show that when the incentive compensates workers on the number of deliveries in the extra route (intensive margin) as opposed to just on taking an extra route (extensive margin) they are more likely to work until they reach the bonus and to continue working more intensively even after the bonus period. We show that this long-lasting effect is not entirely driven by earning more money through the bonus, and discuss potential mechanisms that can drive this behavior, such as early learning, inertia, and goal setting.

Monetary incentives are a valuable tool to increase payment in return for effort and engagement. The design of such incentives is not straightforward, and the structure of short-term incentives can increase worker engagement and have lasting effects in the long run. Providing incentives early on and structuring them to induce such behavior can turn into a valuable and low-cost lever for platforms that seek to increase worker retention.

2 - Algorithms in Retail Marketplaces

Nil Karacaoglu, The Ohio State University, Columbus, OH, United States, Santiago Gallino, Antonio Moreno

This paper examines how algorithmic recommendations influence customer behavior in online marketplaces using proprietary data from a leading digital marketplace.

3 - Digital Platforms and the Fissured Workforce - Consequences of Temporary Workforce Strategies in Service Operations

Jose Lopez, Texas A&M University, College Station, TX, United States

Service organizations frequently rely on temporary workers to manage fluctuating workloads, leveraging short-term flexibility and reduced fixed costs. However, this strategy may inadvertently lead to long-term operational inefficiencies. Our study examines the impact of temporary labor strategies on service performance, workforce productivity, and operational stability using a dynamic model in a logistics-oriented service context. We study four main sectors: processing and shipment, workforce dynamics (including rookies, experienced temporary, and permanent employees), capacity adjustments based on workload pressures, and performance feedback mechanisms. Simulations informed by empirical data from a cross-docking logistics provider highlight critical trade-offs. Heavy reliance on temporary labor results in continuous inefficiencies due to high turnover and perpetual training needs, negatively affecting productivity. Mixed labor approaches offer moderate flexibility but still incur elevated management overhead and decreased workforce cohesion. Findings underscore managerial tendencies to underestimate turnover's compounded productivity impacts.

4 - Spillover Effects of Labor Disruptions

Xabier Barriola, Tilburg University, Tilburg, Netherlands

Grocery stores provide an essential and highly competitive service in many communities. Hourly employees play a critical role in the provision of this service through a wide range of functions, including receiving, stocking, checkout, and customer care. We examine the effects on the customer experience, store performance, and supplier performance when these functions are disrupted through an organized strike.

1 - Resale-as-a-Service: The Impact of Second-Hand Platforms on Fashion Goods Retailer**Yuan Guo, George Washington University, Washington, DC, United States, Fernando Bernstein, Robert Swinney**

Fashion resale has evolved from peer-to-peer exchanges to platform-mediated services, prompting brands to reassess the role of secondhand markets. We study a setting where resale is offered as a service (RaaS) via a platform that intermediates used product flows. Our model captures the interaction between a fashion retailer and the resale platform under a passive resale design, where returned goods are accepted and resold by default.

We analyze how resale access reshapes the retailer's assortment and pricing strategies in the primary market, and identify conditions under which resale acts as a liability, neutral byproduct, or strategic complement. The model reveals how resale margins, return composition, and consumer taste shifts jointly determine the retailer's optimal design. We also explore how platform coordination through revenue-sharing affects market outcomes and incentives.

Our findings offer insights into the operational design of RaaS partnerships, and suggest directions for future work on platform-driven control in fashion recommerce.

2 - Dynamic Battery Swapping and Charging in Large-Scale Electric Vehicle Networks**Zuguang Gao, UC Irvine, Irvine, CA, United States, Deniz Akturk**

This talk addresses the daily operational challenges faced by electric vehicle (EV) companies managing large-scale battery swapping stations in urban environments, where meeting customer demand while optimizing charging strategies is a critical objective. We present a novel stochastic programming model that accommodates multiple charging levels and accounts for uncertain demand across discrete time periods. By reformulating the underlying Markov Decision Process (MDP), we propose a mean-field approximation that leverages aggregated system behavior to reduce computational complexity. The key insight of our approach is that, as the number of swapping stations grows, the mean-field policy remains asymptotically near-optimal, with a sublinear deviation from the true optimal cost. To enforce feasibility after rounding decisions, we develop a systematic procedure that ensures the resulting solution respects capacity constraints and battery inventory limitations. This research contributes to the growing body of literature on decision-making under uncertainty in battery management systems, offering valuable insights for both academic researchers and industry practitioners seeking scalable and efficient operational strategies in emerging urban mobility ecosystems. We also incorporate theoretical guarantees to show that the total cost incurred by the proposed policy grows sublinearly in the number of stations. This ensures scalable performance for large EV networks under diverse operational conditions.

3 - Reduce and Reveal: Emissions Abatement and Disclosure in Supply Chains**Vishal Agrawal, Georgetown University, Washington, DC, United States, Soudipta Chakraborty**

To reduce their exposure to climate change risks, investors increasingly factor firms' emissions into their investment decisions. Consequently, firms exert effort to abate emissions and disclose these emissions annually. When disclosing emissions is voluntary, firms are often strategic in their reporting: some engage in greenwashing—portraying themselves as more sustainable than they truly are—while others participate in greenhushing—appearing less sustainable than they actually are. Such strategic behavior has led to growing calls for regulations mandating accurate emissions disclosure. We study firms' emissions abatement and reporting strategies under both voluntary and mandatory disclosure. Our findings reveal that the disclosure strategy significantly influences firms' abatement efforts. Contrary to common intuition, we demonstrate that although mandatory disclosure ensures accurate emissions reporting, firms sometimes exert greater abatement effort under voluntary disclosure, even when they engage in greenwashing.

4 - Flock Management for Solar Grazing**Vincent Slaugh, Cornell University, Ithaca, NY, United States, Linwei Xin, Shane Henderson**

To control vegetation, solar asset owners employ farmers to graze sheep on solar sites. While earning revenue from vegetative maintenance, farmers have the opportunity to provide agricultural value through raising and selling sheep. Accounting for flock dynamics of births, deaths, and sales, we model the operational economics of solar grazing for farmers and focus on key flock management decisions.

We develop analytical models that determine how many sheep farmers should buy initially and how to manage flock ages over the long term. First, we show that a farmer's total profit—including revenue from mowing contracts and livestock sales—behaves as a piecewise linear and concave function of the number of sheep purchased. Second, we introduce an age-based model showing that a simple "maximum-lifetime" approach—i.e., keeping sheep for their entire productive lifetime before culling matches the performance of more complicated strategies. We also find that as a flock grows large, uncertainty (e.g., birthrate variations) has minimal impact if farmers retain young ewes consistently and cull only in their final productive year.

Our results help small-scale farmers, renewable energy developers, and policymakers see how solar grazing enhances the environmental benefits of solar farms and preserves agricultural value in land converted to solar farms. Through a partnership with a solar grazing platform that helps solar grazers and connects them with site owners, a spreadsheet implementation of our model has helped dozens of farmers make procurement decisions, predict cash flows, and even procure financing to purchase a flock.

5 - The Environmental and Social Implications of Pay-What-You-Want Food Waste Supermarkets**Xi Henry Lin, UC Irvine, Paul Merage School of Business, Irvine, CA, United States, Luyi Gui, Luyi Yang**

Around 1.3 billion tons of food are wasted globally each year, accounting for about one-third of all food produced for human consumption; nevertheless, a substantial portion of the global population faces moderate or severe food insecurity, indicating a significant disparity in food distribution.

Food donation, particularly at the retail level, has become an important approach to recovering surplus but edible food. In addition to traditional donation channels, food waste supermarkets—retail outlets selling donated food at low prices—have gained traction. These outlets adopt either posted pricing or the more flexible "pay-what-you-want" (PWYW) model, the latter of which is often advocated for its social and environmental benefits. However, it remains unclear whether PWYW can consistently deliver such benefits.

This study develops a game-theoretic model to analyze the interplay between a regular retailer's procurement decision, consumer purchase behavior, and the impact of different pricing schemes. We show that the difference in procurement quantities between the two pricing schemes is driven by consumer characteristics, such as the size of the food-insecure population and their sensitivity to advantageous inequality. Under PWYW, moderate sensitivity may lead to higher procurement and increased food waste, while low or high sensitivity may result in lower procurement and reduced food access.

Overall, our study indicates that the common belief that PWYW can reduce food waste and improve access for the food-insecure community simultaneously does not always hold: depending on consumer characteristics, there are cases where the environmental benefit comes at the expense of the social benefit, and vice versa.

Recent Advancements in the Practice of Revenue Management and Pricing

Invited Session

Revenue Management

Chair: Ezgi Eren, PROS, Inc., Houston, 77098, United States

1 - Real-Time Competitor-Aware Dynamic Pricing for Airline Revenue Management

Yuxuan Lu, Sabre, Boston, MA, United States

Customer purchase decisions hinge not only on an airline's own fares but also on the competitor prices shown at shopping time. Yet many carriers still rely on judgment-based manual overrides to react to those competitive moves. We introduce an end-to-end framework that embeds real-time competitive intelligence directly into dynamic pricing.

The approach has two pillars. First, we estimate a multinomial-logit passenger choice model that treats every itinerary—host and competitor alike—as an option in the customer's consideration set, explicitly including a “do-not-fly” outcome when the offered prices exceed the traveler's budget. Second, we embed this choice model in an optimizer that recalculates the host airline's fare in real time, maximizing expected revenue while fully accounting for competing itineraries and their prices.

2 - A Win-Only Logistic Model for B2B Pricing Decisions

Zijian Zeng, PROS, Houston, TX, United States, Jonas Rauch, Mohit Mahajan, Manu Chaudhary

In business-to-business pricing, organizations aim to maximize profits by developing optimized strategies based on historical transactions across a wide range of customers, products, and other characteristics. Each customer typically receives a unique price for a product through negotiation, making it essential to consider both customer-specific prices (CSP) and market prices (MP) in pricing decisions. This task has become increasingly difficult due to the presence of millions of transaction records and countless possible combinations of transaction features. Moreover, the data collection process in negotiation settings can be flawed. Business owners often record only winning transactions, omitting losses, which limits the data available.

Current pricing solutions often rely on probability-based models to compute win-rate elasticity. However, this approach fails entirely if loss data is not recorded and therefore unavailable for modeling. To address this issue, we propose a win-only logistic model with a policy-based optimal price. The policy-based optimal price is derived using CSP and MP estimates generated by a deep neural network and determines a target for price changes. This information serves as an optimal price constraint, passed to the win-only logistic model along with all learned feature embeddings. The win-only logistic model is a Bayesian logistic model that computes the probability of a win, conditional on only observed wins. Within this structure, the model parameters -- framed in terms of the optimal price -- become identifiable and estimable.

This win-only logistic model has been implemented in daily pricing decisions, demonstrating high credibility and delivering strong practical results.

3 - Robust Revenue Management Under Market Volatility

Ezgi Eren, PROS, Inc., Houston, TX, United States

In an era marked by unprecedented market volatility, adaptive pricing and revenue management strategies have become increasingly vital. This study revisits the data-driven methodology introduced by Eren et al. (2024), emphasizing its resilience under volatile demand conditions. Unlike traditional revenue management frameworks that rely on demand forecasting and mathematical optimization, this approach leverages heuristic techniques and machine learning models. Our simulation results demonstrate exceptional robustness to demand shocks, with revenue outcomes consistently within 1% of the theoretical optimum across a wide range of demand parameter variations. We offer in-depth insights into the methodology's implicit adaptivity, achieved without an explicit feedback loop. Finally, we discuss practical implications for implementing this strategy in demand-volatile industries such as air cargo and car rental.

4 - Enhancing Price Elasticity Estimation for Airline Dynamic Pricing via Kde-Based Sampling and Clustering

Laleh Kardar, PROS, Houston, TX, United States, Ravi Kumar

We address the challenge of estimating price elasticities of passenger demand in airline dynamic pricing when no-purchase data is unavailable. Building on a two-stage Poisson semi-parametric framework that combines machine learning with causal inference techniques, we propose two enhancements to improve robustness in sparse data settings. First, we apply a KDE-based sampling strategy to densify sparse regions of the feature space without imposing strong parametric assumptions. This improves model stability in underrepresented segments. Second, we introduce a top-down clustering approach that replaces rigid partitioning with data-driven groupings that respect operational constraints while capturing behavioral variation across segments. Empirical results on real airline transaction data show that these enhancements lead to more stable and differentiated elasticity estimates, supporting more effective and interpretable pricing decisions.

Estimation and Optimization for Data-Driven Decisions

Invited Session

Revenue Management

Chair: Ke Li, INSEAD, Fontainebleau, France

Co-Chair: Spyros Zoumpoulis, INSEAD, Fontainebleau, France

1 - Online Inventory and Pricing with (Biased) Offline Data

Mengzhenyu Zhang, University College London, London, United Kingdom, Hyun-Soo Ahn, Zijin Zhang

With the growing amount of offline data, using the available offline data to facilitate online decision making becomes relevant to practice. A prominent challenge of using offline data, however, is that the true online data-generating process may differ unpredictably from the offline distribution. In this paper, we study the problem of how to use available and potentially biased offline data to support online decision making for two canonical decision problems: the dynamic newsvendor, where the demand tail distribution plays a key role in the decision, and dynamic pricing, where the point estimations are critical. We develop two online learning frameworks that incorporate offline data. The soft-switch algorithm automatically balances offline information and online feedback without requiring bias knowledge, while the hard-switch algorithm leverages known distributional shifts. Both learning algorithms achieve the optimal regret up to a logarithmic factor. We also derive explicit bounds showing how regret improvements scale with the size and bias of the offline data.

2 - From Small to Large: a Graph Convolutional Network Approach for Solving Assortment Optimization Problems

Guokai Li, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Pin GAO, Stefanus Jasin, Zizhuo Wang

Assortment optimization involves selecting a subset of substitutable products (subject to certain constraints) to maximize the expected revenue. It is a classic problem in revenue management and finds applications across various industries. However, the problem is usually NP-hard due to its combinatorial and non-linear nature. In this work, we explore how graph convolutional networks (GCNs) can be leveraged to efficiently solve constrained assortment optimization under the mixed multinomial logit choice model. We first develop a graph representation of the assortment problem, then train a GCN to learn the patterns of optimal assortments, and lastly propose two inference policies based on the GCN's output. Due to the GCN's inherent ability to generalize across inputs of varying sizes, we can use a GCN trained on small-scale instances to facilitate large-scale instances. Extensive numerical experiments demonstrate that given a GCN trained on small-scale instances (e.g., with 20 products), the

proposed policies can achieve superior performance (90%+ optimality) on large-scale instances (with up to 2,000 products) within seconds, which outperform existing heuristic policies in both performance and efficiency. Furthermore, we extend our framework to a model-free setting where the underlying choice model is unknown but transaction data is available. We also conduct numerical experiments to demonstrate the effectiveness and efficiency of our proposed policies in this setting.

3 - Beyond SVD: the F-SVD Revolution for Discrete Choice Estimation

Man Luo, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Guillermo Gallego

We present Filtered Singular Value Decomposition (*F-SVD*), a novel matrix decomposition framework that addresses the longstanding challenge of enforcing structural constraints in low-rank approximations. While conventional dimensionality reduction techniques like Singular Value Decomposition (SVD) and Non-negative Matrix Factorization (NMF) offer foundational solutions, they falter in critical applications like discrete choice modeling, where matrices must satisfy strict non-negativity, normalization, and exact-zero constraints. *F-SVD* resolves this by: (1) embedding a *structured mask* into the factorization process, and (2) enabling precise adherence to constraints while retaining the flexibility of SVD and the interpretability of NMF.

Theoretically, we establish convexity properties in alternating optimization steps that guarantee convergence to parsimonious solutions with errors matching or surpassing standard SVD. Empirically, *F-SVD* demonstrates three critical advantages:

- (i) *Exact reconstruction* of constrained entries (e.g., strict zeros in probability matrices),
- (ii) Great performance on real-world datasets – achieving superior results in 29/30 IRI consumer preference cases at “rank”-1 compared to a suite of parsimonious models, with the remaining case matching performance at “rank”-2,
- (iii) Computational tractability enabling high-dimensional inference.

Current work extends validation to synthetic matrices and industrial choice datasets, with full theoretical extensions and empirical results to be presented at the INFORMS Annual Meeting. By unifying constraint preservation with adaptive low-rank approximation, *F-SVD* establishes a new paradigm for structured matrix factorization, particularly in applications requiring simultaneous precision and interpretability – from consumer analytics to biomedical signal processing and operations decision systems.

4 - Decision-Focused Adjustments for the Predict-Then-Optimize Framework with Applications in Pricing

Guan Wang, Rotman School of Management, Toronto, ON, Canada, Michael Albert, Max Biggs, Ningyuan Chen

A common approach in data-driven decision-making is the predict-then-optimize (PTO) framework, where a decision-maker first estimates an unknown parameter from historical data and then uses this estimate to solve an optimization problem. While widely used for its simplicity and modularity, PTO can lead to suboptimal decisions when the estimation step does not account for the structure of the downstream optimization problem. We study a class of problems where the PTO decision introduces asymmetry in the objective with respect to the unknown parameter, creating a systematic preference for under- or over-estimation when the estimate is noisy. To address this, we present a data-driven post-estimation adjustment that improves PTO's decision quality while remaining practical and easy to implement. We show that when the objective satisfies a curvature condition based on the ratio of the third to the second derivative, the adjustment takes a simple closed-form expression. This applies to a broad range of pricing problems, including those with commonly used linear, log-linear, and power-law demand models. Under this condition, we establish theoretical guarantees that our adjustment uniformly outperforms standard PTO asymptotically, and we precisely characterize the resulting improvement. Additionally, we extend our framework to multi-parameter optimization settings and discuss applications where estimation bias is present. Numerical experiments demonstrate that our method consistently enhances revenue performance, particularly in small-sample regimes where estimation uncertainty is most pronounced, making it especially well-suited for pricing new products or those with limited price variation.

1 - An Large Language Model Agentic System for Outcome Prediction

Jiayi Wang, Stanford University, Stanford, CA, United States, Mohsen Bayati

We present an agentic system composed of multiple large language model (LLM) agents that automatically support outcome prediction. Our results demonstrate that this fully automated pipeline achieves predictive performance comparable to machine learning and human experts.

2 - Probabilistic Design in the Operation of Service Systems

Jiangze (Jay) Han, Columbia University, New York, NY, United States, Christopher Ryan, Mahesh Nagarajan, Xin Tong

I will discuss two papers addressing infinite-dimensional optimization problems over the space of probability distributions in the context of service system design.

The first paper explores optimal decomposition of a user distribution into sub-distributions to maximize operational targets. The second studies online optimization, where the decision maker sequentially determines a sequence of probability distributions to minimize cumulative loss. Examples include matching supply with unknown and dynamic demand in an online fashion, when supply is a spatial distribution over the service region.

To solve these problems, we propose novel gradient descent algorithms in the space of probability distributions, leveraging advances in optimal transport theory and Wasserstein gradient flow.

Our key results include:

1. In the first paper, our gradient-based algorithm finds a feasible decomposition of user distribution which also satisfies our proposed optimality condition, at a certain rate.
2. In the second paper, we establish static and dynamic regret bounds that match the optimal bounds in Euclidean space.

3 - Learning User Behavior in a Social Network Under Limited Data

Yunduan Lin, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Haoting Zhang, Zeyu Zheng, Zuo-Jun Shen

Accurately calibrating diffusion models in network studies is essential for linking theoretical results to real-world applications, such as predicting user behavior in new network structures and optimizing network operations. Effective calibration depends on connecting model parameters with available data. However, this task is complicated by two primary challenges: the dynamic nature of network diffusion and the limitations of available data. The diffusion process is complex, often resisting simple analytical representation, while data scarcity — both temporal (inability to capture the entire diffusion trajectory) and spatial (difficulty in obtaining network-level data) — can hinder model accuracy, leading to results that may not generalize well.

This work introduces a novel approach for calibrating diffusion models based on a single observed network instance, without requiring full data from the entire diffusion process. We use simulation to generate network-structured data under different parameter settings and minimize the discrepancy between observed and simulated

outcomes. We also analyze the performance of calibration under both full data and limited data schemes, characterizing the discrepancy caused by data scarcity. This approach provides a practical solution for calibrating network models under data limitations and has broad applications in real-world network studies.

4 - Mitigating Waste for Perishable Products Through Markdown

Jing Yu, Tsinghua University, Beijing, China, People's Republic of, Ganesh Janakiraman, Anyan Qi, Yongbo Xiao

We study a grocery retailer selling a perishable product with a two-period lifetime. To mitigate waste, the retailer employs markdown pricing for old products nearing expiration. Our model incorporates customer substitution behavior, where customers prioritize their preferred product type but substitute if unavailable, with unmet demand lost. Through this framework, we analyze the retailer's optimal markdown and inventory replenishment policies to balance waste reduction and revenue maximization.

5 - Order Stacking in on-Demand Delivery Platforms

James Scott, Duke University, Durham, NC, United States, Bora Keskin, Robert Swinney

Food delivery platforms routinely bundle orders together and assign the entire "stack" of orders to a single driver to deliver. We examine the impact of a restaurant's service region's geography on where within that region the stacks should be large or small.

Information Acquisition in Digital Platforms

Invited Session

Auctions and Market Design

Chair: Ying Gao, UBC, Vancouver, BC, V6T0C2, Canada

1 - Consumer Profiling via Information Design

Itai Fainmesser, Johns Hopkins Carey Business School, Baltimore, MD, United States, Ruslan Momot, Andrea Galeotti

A platform uses purchase histories to profile consumers, form market segments, and disclose them to a seller. The seller tailors prices to these segments, generating new data that supports further profiling. We characterize the platform's ability to learn consumer valuations over time. We show that the platform cannot accurately learn consumers' valuations above the seller's optimal uniform price, but can below it. There is a complementarity between information design and other tools available to the platform to influence pricing—such as listing fees or proportional sales fees—for learning the valuations of high-value consumers.

2 - Naïve and Bayesian Learning with Misinformation Policies

James Siderius, Tuck School of Business at Dartmouth College, Hanover, NH, United States, Mohamed Mostagir

We study the effectiveness of two canonical interventions aimed at curbing the spread of misinformation—censorship and algorithmic regulation—through the lens of an economic model of information assimilation. Our framework accommodates heterogeneous agents, including both naïve DeGroot learners and more sophisticated Bayesian updaters who behave strategically. For naïve agents, optimal policies take a relatively intuitive form: removing content with low informational value and promoting exposure to more diverse viewpoints. However, we find that these same interventions are often ineffective—or even counterproductive—when applied to populations of Bayesian agents. In particular, censorship can exacerbate misinformation by distorting inference, and algorithmic regulation is only beneficial when the underlying level of misinformation is sufficiently low. Our results underscore the importance of accounting for agent sophistication when designing regulatory responses to misinformation and suggest limits to one-size-fits-all policy approaches in complex information environments.

3 - Screening Before and Auditing After: Information Design to Support Environmental Investment

Victoria Hang, Texas Tech University, Lubbock, TX, United States

This paper examines a dynamic principal-agent problem motivated by environmental regulation, where a regulator seeks to induce a firm's costly, non-contractible investment—such as adopting cleaner technology or mitigation measures—prior to the realization of uncertain environmental risk. After the investment stage, the firm also chooses an unobservable level of ongoing compliance effort. The regulator cannot commit to future enforcement policies but can influence behavior through the design of ex-ante signals (e.g., permitting thresholds, ESG ratings) and ex-post audits (e.g., inspections, compliance tests).

The regulator's objective is to maximize social welfare by inducing both appropriate investment and sufficient compliance effort. I compare two institutional mechanisms: signal design before investment and auditing after effort is chosen. Each mechanism generates different incentive structures and imposes different constraints on the regulator's ability to balance investment incentives, rent extraction, and effort distortion. When investment is relatively inexpensive, signal design is optimal as it efficiently screens agents and aligns investment decisions with social objectives. In contrast, when investment costs are high, auditing becomes preferable because it limits rent extraction while preserving incentives for compliance.

I characterize equilibrium behavior under each regime and identify the optimal information structure in both cases. Comparative statics show how the choice between screening and auditing depends on investment cost, the elasticity of compliance effort, and the distribution of environmental risk. These results inform the design of environmental planning tools and regulatory regimes that operate without commitment power.

4 - Optimal Recommendation with Costly Verification

Ying Gao, UBC, Vancouver, BC, Canada

Consumers who are targeted for recommendation by a designer (an advertiser or e-commerce platform) can often choose to accept, reject, or verify the recommendation, e.g., by reading reviews. We ask how optimal recommendation policies depend on the cost of verification. A recommender who wishes to persuade the buyer to purchase and can commit to their recommendation policy would prefer more costly verification. On the other hand, a recommender who cannot commit to their policy would prefer it to be easier for buyers to obtain information about the recommended product, as this circumvents their excessive temptation to falsely recommend lower-quality products.

1 - Credit Rating Design Under Adverse Selection

Qinzheng Li, National University of Singapore, Singapore, Singapore, Yifan Feng, Jussi Keppo

We study a strategic credit rating model where investors rely on credit rating agencies (CRAs) to assess firms' default probabilities. Firms seeking funding can solicit ratings by paying the CRA, who then optimizes a profit-maximizing rating policy based on firms' quality and solicitation decisions. We find that, in equilibrium, high-quality firms are more likely to solicit ratings and receive higher ratings compared to low-quality ones. Although solicited ratings are observed to be higher than

unsolicited ones, this discrepancy diminishes when accounting for firms' intrinsic qualities. Our model suggests that even if the CRA is purely self-interested, the reported discrepancy between unsolicited and solicited ratings in the existing literature could be primarily explained by adverse selection on the demand side of the credit rating market.

2 - Delegation with Costly Inspection

Suho Shini, University of Maryland, College Park, MD, United States, Mohammad Hajiaghayi, Piotr Krysta, Mohammad Mahdavi

We study the problem of delegated choice with inspection cost (DCIC), which is a variant of the delegated choice problem by Kleinberg and Kleinberg (EC'18) as well as an extension of the Pandora's box problem with nonobligatory inspection (PNOI) by Doval (JET'18). In our model, an agent may strategically misreport the proposed element's utility, unlike the standard delegated choice problem which assumes that the agent truthfully reports the utility for the proposed alternative. Thus, the principal needs to inspect the proposed element possibly along with other alternatives to maximize its own utility, given an exogenous cost of inspecting each element. Further, the delegation itself incurs a fixed cost, thus the principal can decide whether to delegate or not and inspect by herself. We show that DCIC indeed is a generalization of PNOI where the side information from a strategic agent is available at certain cost, implying its NP-hardness by Fu, Li, and Liu (STOC'23). In fact, we observe that DCIC becomes significantly more challenging than PNOI or the delegated choice problem in several aspects. First, neither of (i) running PNOI policy without delegation nor (ii) running a simple delegation mechanism can achieve a constant approximation to the optimal mechanism for DCIC, implying that we need to use both the delegation and inspection for efficient mechanisms. Furthermore, the standard approaches to PNOI (or Pandora's box problem) for upper bounding the optimal policy in a structured way to obtain algorithms, do not easily extend to DCIC.

3 - The Pseudo-Dimension of Contracts

Tomasz Ponitka, Tel Aviv University, Tel Aviv, Israel, Paul Duetting, Michal Feldman, Ermis Soumalias

Algorithmic contract design studies scenarios where a principal incentivizes an agent to exert effort on her behalf. In this work, we focus on settings where the agent's type is drawn from an unknown distribution, and formalize an offline learning framework for learning near-optimal contracts from sample agent types. A central tool in our analysis is the notion of pseudo-dimension from statistical learning theory. Beyond its role in establishing upper bounds on the sample complexity, pseudo-dimension measures the intrinsic complexity of a class of contracts, offering a new perspective on the tradeoffs between simplicity and optimality in contract design. Our main results provide essentially optimal tradeoffs between pseudo-dimension and representation error (defined as the loss in principal's utility) with respect to linear and bounded contracts. Using these tradeoffs, we derive sample- and time-efficient learning algorithms, and demonstrate their near-optimality by providing almost matching lower bounds on the sample complexity. Conversely, for unbounded contracts, we prove an impossibility result showing that no learning algorithm exists. Finally, we extend our techniques in three important ways. First, we provide refined pseudo-dimension and sample complexity guarantees for the combinatorial actions model, revealing a novel connection between the number of critical values and sample complexity. Second, we extend our results to menus of contracts and piecewise linear contracts, showing that their pseudo-dimension scales linearly with the menu size and polynomially with the number of linear pieces.

4 - Stable Matching with Contingent Priorities

Ignacio Rios, The University of Texas at Dallas, Richardson, TX, United States, Federico Bobbio, Margarida Carvalho, Alfredo Torrico

Using school choice as a motivating example, we introduce a stylized model of a many-to-one matching market where the clearinghouse seeks to implement contingent priorities—i.e., priorities that depend on the current assignment—to improve the likelihood that students with siblings are assigned together. We provide a series of guidelines and introduce two natural approaches to implement them: (i) absolute, whereby a prioritized student can displace any student without siblings assigned to the school, and (ii) partial, whereby prioritized students can only displace students that have a less favorable lottery than their priority provider. We study several properties of the corresponding mechanisms, including the existence of a stable assignment under \emph{contingent} priorities, the complexity of finding one if it exists, and its incentive properties. Furthermore, we introduce a soft version of these priorities to guarantee existence, and we provide mathematical programming formulations to find such stable matching or certify that one does not exist. Finally, using data from the Chilean school choice system, we show that our framework can significantly increase the number of students assigned to their top preference and the number of siblings assigned together relative to current practice.

5 - Admissibility of Completely Randomized Trials: A Large Deviation Approach

Chao Qin, Stanford University, Palo Alto, CA, United States, guido Imbens, Stefan Wager

When an experimenter has the option of running an adaptive trial, is it admissible to ignore this option and run a non-adaptive trial instead? We provide a negative answer to this question in the best-arm identification problem, where the experimenter aims to allocate measurement efforts judiciously to confidently deploy the most effective treatment arm. We find that, whenever there are at least three treatment arms, there exist simple adaptive designs that universally and strictly dominate non-adaptive completely randomized trials. This dominance is characterized by a notion called efficiency exponent, which quantifies a design's statistical efficiency when the experimental sample is large. Our analysis focuses on the class of batched arm elimination designs, which progressively eliminate underperforming arms at pre-specified batch intervals. We characterize simple sufficient conditions under which these designs universally and strictly dominate completely randomized trials. These results resolve the second open problem posed in Qin [2022]. The full version of this paper is available at <https://arxiv.org/pdf/2506.05329>.

Chair: Jeremy Watts, I-O Urology, Chattanooga, TN, United States

1 - Addressing Rural Urban Health Disparities Through Predictive Medicine and AI-Driven Decision Support

Dursun Delen, Oklahoma State University, Tulsa, OK, United States, William Paiva

The disparity in access to healthcare between urban and rural communities remains a critical public health challenge, particularly due to the scarcity of subspecialty care in rural areas—termed here as the “lack of 'ologists.” This shortage places undue burden on rural primary care physicians who must manage complex cases without specialist support, exacerbating health disparities and compromising outcomes. This study explores the role of artificial intelligence (AI) in addressing these systemic gaps through the development and deployment of clinical decision support systems (CDSS). Specifically, we present a case study from Oklahoma State University's Center for Health Systems Innovation: a predictive AI tool designed to support diabetic retinopathy screening in rural primary care settings. This tool enables frontline physicians to make earlier and more accurate referrals, helping to prevent vision loss in diabetic patients. By leveraging real-world data and predictive modeling, such AI systems offer scalable, low-cost interventions to improve diagnostic accuracy and patient management in underserved regions. We discuss the challenges of implementation, including data quality, physician adoption, and workflow integration, and propose a framework for scaling AI-enabled tools in rural health ecosystems. This work highlights the promise of AI in mitigating rural health inequities and empowering local providers.

2 - Happily, Ever After &Ndash; the Effect of Marriage and Children on Life Expectancy in the United States

Banafsheh Behzad, California State University, Long Beach, Long Beach, CA, United States, Susan Martonosi, Katja Crusius

Life expectancy refers to the average number of years a person is expected to live based on various demographic and health factors. It is often used as a statistical measure to assess the overall health and mortality rates of a population. Life expectancy can vary significantly from one place to another and is influenced by factors such as health related factors, socioeconomic conditions, lifestyle choices, genetics, and more. This study examines the effect of marriage and children on life expectancy in the United States at the state level using data spanning from 2000 to 2017 in a fixed effects model. The findings suggest that, after controlling for other factors, states where a significant portion of the population is both married and employed tend to experience higher average life expectancies. Additionally, states with a substantial percentage of individuals having at least one child and having an annual income exceeding \$50,000 tend to exhibit increased average life expectancies among their populations.

3 - Mapping Perinatal Care Pathways to Address Maternal Health Disparities by Race

Hayley Falk, University of Michigan, Ann Arbor, MI, United States, Julie Ivy

This study maps the care pathways of maternal patients during the perinatal period by race in order to improve the understanding of maternal disparities in morbidity and mortality for Black and White patients. We utilize electronic health record (EHR) data to model the care trajectory of patients during the perinatal period (i.e., prenatal, labor and delivery, and first year postpartum) as a function of race, age, socioeconomic status, insurance status, and comorbidities using continuous time stochastic modeling. Specifically, for each patient, we track each patient-provider interaction during pregnancy, birth, and postpartum. The proposed work seeks to use data analytics, text analytics and systems science methods to (i) explore the role of race in birth outcomes using the EHR, (ii) characterize the care trajectories for Black and White patients through the perinatal period, and (iii) identify opportunities for intervention ante-, intra-, and post-partum.

4 - Enhancing Diagnostic Accuracy in Noisy Breast Ultrasound Images Through Hybrid Cnn&Ndash;Transformer Denoising

Mariana Arriz Jorquiera, University of South Florida, Tampa, FL, United States, Ahtesham Bakht, Yashraj Jadhao, Ismail Uysal, Miguel Del Toro, Jose Zayas-Castro

Noise in medical imaging can compromise image clarity and significantly reduce the performance of diagnostic models. This is particularly evident in breast ultrasound, where variability in image acquisition and ultrasound-specific noise can make it difficult to detect important features. In this study, we examine the impact of three clinically relevant types of noise: Gaussian (sensor-related), Poisson (signal-dependent), and Speckle (coherent noise from ultrasound), each applied at low, moderate, and high intensity levels. Our findings show a consistent decline in classification accuracy as noise levels increase, highlighting the vulnerability of current machine learning models in realistic imaging conditions.

To address this challenge, we explore the application of a hybrid denoising model that combines a convolutional neural network (CNN) encoder, a transformer encoder, and a CNN decoder. Although CNN–transformer combinations have been applied in other domains, their use for denoising breast ultrasound images remains largely unexplored. By capturing both local spatial features and global contextual patterns, this architecture aims to reduce noise while preserving critical diagnostic information. We evaluate its performance by assessing improvements in classification accuracy on noisy and denoised images against established baselines, including Fourier-based methods and a conventional CNN denoiser. This study offers insight into how hybrid denoising strategies can improve diagnostic reliability in settings where noise is difficult to avoid.

5 - AI-Driven Assessment of BPH Symptoms from Multi-Day at-Home Urological Testing

Jeremy Watts, IO Urology, Knoxville, TN, United States, John Knoedler

We present **LUCI** (Lower Urinary Computational Insights), an AI-enabled system for objective evaluation of lower urinary tract symptoms (LUTS) associated with benign prostatic hyperplasia (BPH). LUCI analyzes time-series uroflow data collected by **CarePath** (iO Urology Corporation), a non-invasive, at-home testing platform that captures all voiding events over a multi-day period.

LUCI employs a modular AI architecture that integrates signal processing, anatomical estimation, and symptom modeling. From raw flow rate data, the system infers anatomical parameters and generates clinically aligned metrics, including the International Prostate Symptom Score (IPSS) and nocturnal polyuria frequency. This approach enables consistent, repeatable characterization of symptom severity—addressing the variability and subjectivity of traditional clinical assessments.

We evaluate LUCI on a dataset of BPH patients collected at Urology of Virginia. Results demonstrate LUCI's ability to replicate symptom trends captured by IPSS, quantify nocturnal voiding patterns, and provide continuous, real-world symptom monitoring. This work highlights the potential for AI-driven systems to enhance at-home diagnostics and support clinical decision-making in urology.

1 - Predicting Permanent Molar Caries in Children and Adolescents Using Machine Learning

Lin Li, Kennesaw State University, Marietta, GA, United States, Pritam Deb, Christina Scherrer

Dental caries in permanent molars significantly impacts the well-being of children and adolescents, yet predictive modeling in this area remains limited. This study developed and tested machine learning (ML) models to predict caries using NHANES data from U.S. youth aged 6–19. We used the 2011–2014 cycles for model training/validation and 2015–2016 for testing. The outcome was a binary indicator of caries in at least one permanent molar, with predictors including demographics, diet, BMI, and behavioral factors.

Among 5,710 participants, 37.3% had molar caries. Of five ML models evaluated, logistic regression had the highest AUC (78.5%), the deep neural network (DNN) had the best accuracy (70.0%) and F1 score (64.9%), and the support vector machine (SVM) led in recall (81.3%). SHAP analysis of the XGBoost model highlighted age, family income, and household education as key predictors.

Our results show that ML models can effectively identify children at higher risk of molar caries, offering a potential tool for targeted screening and intervention strategies in oral health.

2 - Advanced Deep Learning for Predicting RNA Secondary Structure

You Zhou, Arizona State University, Tempe, AZ, United States, Giulia Pedrielli, Teresa Wu

RNA molecule plays a critical role in Gene Regulation, Catalysis, and Protein Synthesis. Nowadays, RNA has been applied in various biomedical applications, such as Genome Editing, Vaccines, and Cancer Immunotherapy.

Having a good understanding on how to predict RNA structure can benefit understanding the function of RNA. When predicting RNA structure, there are two challenges. Firstly, enumerating all feasible structures for an RNA sequence has searching space which increases exponentially and is intractable to resolve. Secondly, determining the RNA structure by using experimental approaches, such as X-ray, has high time and expense cost.

In this study, we propose a deep learning (DL) based approach to predict RNA secondary structure for a given RNA sequence. The proposed DL model relies on Transformer. We test our proposed model on two benchmark datasets, where our proposed approach presents superior performance compared other state-of-the-art approaches. Our proposed approach introduces how to leverage the attention mechanism to tackle RNA secondary structure prediction problem efficiently and accurately.

3 - Machine Learning&Ndash;Guided Early Discharge in Acute Myocardial Infarction: Equity, Efficiency, and Physician-Algorithm Concordance in a Microsimulation of Cadillac Risk Score Implementation

Emily Garcia, Purdue University, West Lafayette, IN, United States, Zachary J. Hass

As machine learning (ML)-based clinical decision support systems (CDSSs) become increasingly embedded in healthcare workflows, evaluating their downstream clinical and economic effects particularly in time-sensitive conditions like acute myocardial infarction (AMI) is critical. This study builds on prior work assessing the algorithmic

fairness of the Controlled Abciximab and Device Investigation for Lower Late Angioplasty Complications (CADILLAC) Risk Score, an ML-enabled CDSS designed to predict one-year mortality and major adverse cardiac events (MACE) following AMI hospitalization. While earlier analysis revealed modest but notable disparities in predictive performance across racial and insurance groups, the clinical and economic consequences of these discrepancies remain poorly understood. To address this gap, we use a microsimulation model informed by 4,364 distinct AMI patients from the MIMIC-IV database to estimate the impact of CADILLAC-guided early discharge decisions under varying levels of physician-algorithm concordance. Key outcomes include the cost implications of prolonged versus reduced length of stay, rates of 30-day readmission associated with MACE, and one-year mortality. The model also evaluates clinical decision-making dynamics—specifically, physician agreement or override of CADILLAC recommendations—and stratifies results by demographic subgroup to examine differential impacts. This study provides a rigorous framework for quantifying the downstream consequences of CDSS use in AMI care. By simulating both economic and clinical outcomes, it offers insights into how algorithm-informed decisions interact with clinical judgment and patient characteristics, with the goal of supporting more equitable and effective deployment of CDSSs in practice.

4 - Predicting Drug Shortages : A Machine Learning Approach

Vincent Hargaden, University College Dublin, Dublin, Ireland, Sean McGarraghy, Nikos Papakostas, Abu Shakil Ahmed, Ali Ala, Jamie MacMahon

This research develops an initial machine learning model for prediction of shortages in drug supply chains. It starts with acquiring publicly available drug shortages data from two countries (Belgium and Italy). Pre-processing steps include dimensionality reduction, label encoding and text pre-processing. Additionally, feature engineering is applied to the temporal features to capture seasonal trends. The machine learning approach used to develop the prediction model is Extreme Gradient Boosting (XGBoost) due to its regression and classification potential. The model is refined through hyperparameter tuning, feature selection and time-series cross-validation. The output from the model is a prediction when a particular drug will be unavailable. The results from this initial model underscore the importance of the availability of more extensive historical shortage data through reporting, larger sample sizes and diverse features for better prediction of drug shortages.

5 - Predicting Metabolic Dysfunction-Associated Steatotic Liver Disease with Machine Learning: Trinetx Database

Mary Ogidigben, Pennsylvania State University, State College, PA, United States, Paul Griffin, Soundar Kumara

Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) affects approximately 25% of the U.S. adult population and is the most common chronic liver disease. The condition is asymptomatic in most individuals, but the progression of the disease leads to liver cirrhosis and is a leading indication for liver transplant. Although universal screening is not recommended, early detection is beneficial since lifestyle changes can control or reverse the condition. Several MASLD risk prediction models have been developed and often modeled with machine learning techniques. However, most previous methods have been developed for homogenous populations and there is no consensus on the best predictive factors to use. We focus on the importance of creating an algorithmically fair, rigorous, and reproducible prediction model for MASLD. With this in mind, we tested different machine learning algorithms and ultimately selected a logistic regression model with only 10 features due to its explainability, interpretability, and model performance. Our final logistic regression model had an AUROC of 0.836, accuracy of 77.6, and F1 score of 0.641.

6 - Fairness-Aware Machine Learning for Dental Caries Prediction

Pritam Deb, Kennesaw State University, Marietta, GA, United States, Lin Li, Christina Scherrer

While several studies have identified factors influencing dental caries, understanding caries in permanent molars among children and young adults still lacks clarity. This study aimed to develop a fairness-aware machine learning (ML) model to predict dental caries using publicly available National Health and Nutrition Examination Survey (NHANES) data from 2011 to 2016. We focused on the presence of caries (DMFT: decayed, missing, filled teeth) in permanent molars, considering demographics, dietary habits, body mass index (BMI), and lifestyle behaviors. Out of 5,710 participants aged 6 to 19, about 37.3% had caries. Fairness analysis highlighted important disparities in model accuracy: Non-Hispanic Black and Mexican American groups were identified correctly more often compared to Non-Hispanic Asian and Multi-Racial groups. Meanwhile, Non-Hispanic White participants had the lowest false-positive rates, and Mexican Americans were flagged for follow-up most frequently. To improve fairness, we applied standard bias mitigation techniques. This fairness-aware ML model can serve as an equitable screening tool to enhance oral health interventions for children and adolescents.

7 - Evaluating the Reliability of Online Drug Reviews: a Comparative Analysis of User-Reported and Official Adverse Drug Events

Yaoyao Huang, Simon Fraser University, Burnaby, BC, Canada, JM Goh, Aishwarya Shukla

Online drug reviews on online platforms is a major source of health information for patients and consumers seeking information about medications. While the online reviews on such platforms may be valuable, they carry the risk of disseminating misinformation, particularly regarding adverse drug reactions. Such misinformation can potentially result in harmful health outcomes. We compare adverse effects reported in user reviews from a popular online drug review platform to data from a database based on FDA-approved labels and clinical trials. We report our initial findings on overreported ADRs compared to underreported ones. Additionally, we report the findings from our clustering analysis where we identify two prominent perceptual patterns among user-reported adverse events.

1 - LLMs in Product Selection for Small E-Commerce

Yi Jie, The University of Hong Kong, Hong Kong, Hong Kong, Shan Huang

With the rapid advancement of AI and the need to reduce costs and improve efficiency in traditional experimental methods, large language models (LLMs) have shown significant potential in supporting causal inference tasks. We propose an LLM-based multi-agent causal inference system to replace traditional online randomized experiments through a collaborative framework consisting of reasoning induction, attribution analysis, and feedback correction. This system enables the automated discovery and validation of effective product strategies while addressing key challenges, such as activating the causal inference capabilities of LLMs, designing a collaborative division-of-labor model for multi-agent systems, and optimizing the structured input of experimental data. By evaluating the framework using historical WeChat experimental data, we demonstrate its ability to enhance decision-making processes with greater effectiveness and reliability.

2 - Generative AI-Driven Customer Experience Optimization

Nuo Xu, Wenzhou-Kean University, Wenzhou, China, People's Republic of, Xinci Chang, Jing Ma

This study develops an integrative framework to investigate how Generative Artificial Intelligence (GAI) shapes customer experience and purchase intention. Focusing on functional competence of GenAI, previous studies fail to address its emotional characteristics and its impact. Drawing on Stimulus-Organism-Response (SOR) theory and Value-Based Adoption Model (VAM), we conceptualize GAI's functional and emotional features as external stimuli that generate distinct utilitarian and hedonic value perceptions, which ultimately drive customer satisfaction and purchase intention. To test this framework, we adopt a mixed-methods approach comprising quantitative surveys, experimental designs, and semi-structured interviews, thereby offering cross-cultural insights into the multifaceted impact of enAI. By disentangling the functional and emotional dimensions of GenAI interactions—and accounting for both positive and negative influences—the study contributes to a deeper theoretical understanding of GenAI-driven consumer experience and offers practical guidance on developing customized GenAI-powered solutions that optimize user satisfaction and loyalty.

3 - An LLM-Driven Pipeline for Extracting EU Taxonomy Disclosures from Fossil Fuel Annual Reports

Jiahe Huang, University of Waterloo, Waterloo, ON, Canada, Stanko Dimitrov, Jangho Yang

The EU Taxonomy, adopted in 2020 as a pillar of the EU Sustainable Finance Action Plan, provides a common yardstick for assessing environmental sustainability and guiding green investment. Firms began reporting eligibility data for climate objectives in 2022, with alignment disclosures phased in through 2025. While designed to combat greenwashing and redirect capital toward net-zero targets, its behavioral impact remains largely untested. Given their critical role in global emissions and regulatory exposure, fossil-fuel companies offer a valuable lens through which to assess the Taxonomy's influence. To examine its impact on greenhouse gas trajectories and green investment behavior among major emitters, we develop an automated data extraction pipeline targeting unstructured annual and sustainability reports from over 20 fossil fuel companies operating in the EU across ten fiscal years (2015–2024). The pipeline begins with Mistral OCR, which converts each PDF into structured JSON format and archives the output in an SQL database to ensure traceability and consistency. We then fine-tune and benchmark three state-of-the-art generative language models—GPT-4o Mini, LLaMA-3.3-70B-Instruct, and DeepSeek-V3—for multi-task learning on a manually labeled dataset of sustainability disclosures. The best-performing model processes the JSON files and generates structured tables detailing CapEx, OpEx, turnover, R&D investment flows, and other green activities, annotated with EU Taxonomy alignment scores and progress indicators. This approach enhances extraction speed and accuracy, enabling systematic, longitudinal analysis of the Taxonomy's real-world impact. Beyond this study, the pipeline provides a scalable, adaptable framework for large-scale data extraction from unstructured corporate reporting in other regulatory and ESG domains.

4 - Llm-Based Multi-Robot Task Allocation and Path Planning for Heterogeneous Robots in Search and Rescue Operations

Kaushik Kannan, Michigan Technological University, Houghton, MI, United States, Jung Yun Bae

Urban Search and Rescue (USAR) missions in post-disaster environments demand rapid, adaptive task allocation and path planning for heterogeneous robot teams. While classical Multi-Robot Task Allocation (MRTA) methods exhibit limitations—including a lack of workload balance, rigid adherence to task requirements, and cross-scenario generalization—this work demonstrates that large language models (LLMs) with proper prompt engineering offer a transformative solution. We propose MTU-LLM, a structured prompt engineering for LLMs to generate optimized task allocation and path planning scripts. This approach reduces development time, ensures scalability and consistency across environments, and accelerates robot deployment. Evaluated on standard maps with varying team sizes and victim counts, MTU-LLM achieves significantly faster computation, improved workload balance, and comparable task fulfillment to classical methods. We further explore prompt engineering techniques to optimize LLM performance, revealing optimization strategies for different model characteristics.

5 - Bridging the Gap Between Business Users and Optimization: a Novel LLM-Powered Interactive Framework for Production Planning

Lennard Heuer, Korea Advanced Institute of Science & Technology (KAIST), Daejeon, Korea, Republic of

This presentation introduces an interactive framework powered by Large Language Models (LLMs), enabling business users—without coding or operations-research expertise—to build, refine, and validate sophisticated production-planning optimization models through natural language dialogue. Unlike most existing approaches for converting natural language into optimization models, which generate code in a single pass, our LLM-powered system supports incremental model construction, feasibility checks, simulation-based feedback, and collaborative edits. As a result, tasks typically handled by algorithm engineers are delegated to a hierarchical multi-agent architecture built on AutoGen. Dedicated agents manage (i) information retrieval, (ii) optimization-model generation and execution, (iii) simulation-model construction (for requests involving randomness), execution, and statistical result analysis, and (iv) visualization. Early evaluations show strong usability, suggesting the potential of this approach to effectively bridge the gap between non-technical business users and advanced optimization modeling.

6 - Chitchat with AI: Understand the Supply Chain Carbon Disclosure of Companies Worldwide Through Large Language Model

Vicky Zhu, Babson College, Wellesley, MA, United States, Haotian Hang, Yueyang Shen, Michelle Li, Jose Cruz

In the era of the rapidly growing economy, environmental sustainability is a crucial aspect of economic and social development. Maintaining climate responsibilities while generating financial success is challenging for companies to sustain their global portfolio. The Carbon Disclosure Project (CDP) dataset, being the world's largest, most comprehensive dataset for documenting companies' efforts on carbon disclosure, captures various responses from major companies across different industries and regions. Harmonizing these open-ended textual responses poses a heterogenic data challenge that demands novel language processing analytics to comprehensively derive actionable knowledge. Currently, there lack of an extensive framework to quantitatively evaluate the reliability of survey responses and quantify their alignment with companies' behavior. We study the CDP data using large language models (LLMs) that excel at effective summarization, instruction following, and semantic analysis. We propose a novel framework that leverages LLMs to assess carbon disclosures from the corporate supply chain. Our analyses demonstrate a correlated trend in the environmental awareness of different companies within certain industries. This framework is applicable to other longitudinal text-based business surveys.

1 - Adaptive Data Collection for Post-Disaster Rapid Damage Assessment

Mostafa Reisi, University of Florida, Gainesville, FL, United States, Mohammad Ilbeigi, Hojat Behrooz

Post-disaster rapid damage assessment is essential for successful emergency operations. However, existing data collection solutions for rapid damage assessment rely on static prior data and lack adaptability to new observations during assessment operations. This lack of adaptability limits the ability of emergency responses to systematically and effectively address unprecedented and dynamic situations in a data-driven manner. To address this research gap, our study proposes a novel adaptive data collection framework for post-disaster rapid damage assessment. The framework aims to maximize information gain in the shortest possible time by effectively targeting the most informative locations, while accounting for data collection costs—measured by total travel distance—and promoting sample diversity to prevent biased estimations. More specifically, the method consists of two main components: (1) an ordinal probabilistic gradient boosting model that forecasts the probabilities of damage severity levels for buildings affected by a disaster, and (2) an adaptive sampling mechanism that iteratively evaluates the forecasting model's performance and enhances it by identifying and incorporating the most informative samples. The adaptive sampling process is guided by a multi-objective optimization problem designed to reduce prediction uncertainty, minimize data collection costs, and maintain balanced sampling. The optimization problem is solved using the Non-Dominated Sorting Genetic Algorithm II. We empirically validated the proposed framework using historical damage assessment data from Hurricanes Michael and Dorian. The results demonstrated the method's ability to continuously improve the predictive power of the forecasting model by identifying the most informative target observations while minimizing data collection costs and preserving sample diversity.

2 - Natural Hypergradient Descent: Algorithm Design, Convergence Analysis and Parallel Implementation

Shancong Mou, University of Minnesota Twin Cities, Minneapolis, MN, United States, Deyi Kong, Zaiwei Chen, Shuzhong Zhang

Bi-level optimization has emerged as a powerful framework for modern machine learning applications such as meta-learning, data synthesis, and hyperparameter tuning. Hypergradient descent is commonly used to solve bi-level optimization problems, but computing the hypergradient—particularly the Hessian inverse of the inner problem, either explicitly or implicitly—poses significant computational challenges when the inner problem involves large-scale models. In this paper, we propose a simple and scalable method, Natural Hypergradient Descent (NHGD), which follows an optimize-and-approximate strategy. NHGD approximates the Hessian inverse using a running average of the inverse empirical Fisher information matrix (EFIM), computed directly from the gradients generated by each inner-loop SGD update. We provide a detailed non-asymptotic analysis demonstrating convergence to stationary points with iteration complexity matching that of existing optimize-then-approximate hypergradient methods, which first solve the inner problem to a desired accuracy and then approximate the Hessian inverse via Neumann series or conjugate gradient solvers. A key

advantage of NHGD is that its optimize-and-approximate design enables parallel computation of the hypergradient approximation alongside the inner-loop SGD steps. This leads to substantial improvements in computational efficiency, particularly for large-scale problems. Experiments on hyper data cleaning and learning data augmentation tasks demonstrate that NHGD achieves comparable or better performance with significantly reduced runtime overhead. Natural Hypergradient Descent: Algorithm Design, Convergence Analysis and Parallel Implementation

3 - Physics-Informed Attention-Enhanced Fourier Neural Operator for Solar Magnetic Field Extrapolations

Jinghao Cao, New Jersey Institute of Technology, Newark, NJ, United States, Qin Li, Mengnan Du, Haimin Wang, Bo Shen

We propose Physics-informed Attention-enhanced Fourier Neural Operator(PIANO) to solve the Nonlinear Force-Free Field (NLFFF) problem in solar physics. Unlike conventional approaches that rely on iterative numerical methods, our proposed PIANO directly learns the 3D magnetic field structure from 2D boundary conditions. Specifically, PIANO integrates Efficient Channel Attention (ECA) mechanisms with Dilated Convolutions (DC), which enhances the model's ability to capture multimodal input by prioritizing critical channels relevant to the magnetic field's variations. Furthermore, we apply physics-informed loss by enforcing the force-free and divergence-free conditions in the training process so that our prediction is consistent with underlying physics with high accuracy. Experimental results on the ISEE NLFFF dataset show that our PIANO not only outperforms state-of-the-art neural operators in terms of accuracy but also shows strong consistency with the physical characteristics of NLFFF data across magnetic fields reconstructed from various solar active regions.

4 - Modeling Spatially Correlated Failure-TIME Data Under Two Distance Functions with An Application to Titan Gpu Data

Jared Clark, Virginia Tech, Blacksburg, VA, United States, Jie Min, Yueyao Wang, Yili Hong, George Ostrouchov

One common approach to the statistical analysis of spatially correlated data relies on defining a correlation structure based solely on the physical distance between the locations of observed values. However, some data have a complex spatial structure that cannot be adequately described with the physical distance alone. In this work, the spatial failure-time data of focus contains information on GPUs that are linked through a series of wired connections, where it is expected that the failure-times of GPUs with few connections between them will be highly correlated. The proposed lifetime regression model includes random effects capturing the dependency due to physical location as well as random effects explaining the dependency due to the number of logical connections between GPUs. The analysis of this GPU dataset serves as an example of models with multiple spatial random effects and the ideas presented can be extended to other applications with complex spatial structures. A Bayesian modeling scheme is recommended for this class of analyses. The examples in this work use the software package, Stan, to produce Markov chain Monte Carlo draws for parameter estimation. This modeling effort is validated through simulation which demonstrates the accuracy of statistical inference. We also apply the developed framework to the large-scale Titan GPU failure-time data.

5 - Point-ITR: Task-Oriented Importance Sampling for Large-Scale 3D Point Clouds in Manufacturing

Yichen Ma, Georgia Tech, Atlanta, GA, United States, Michael Biehler, Chiehyeon Lim, Jianjun Shi

The increasing adoption of advanced three-dimensional (3D) scanning technologies has made large-scale point clouds containing millions of 3D measurement points standard in applications like manufacturing. However, processing immense amounts of 3D data imposes significant computational loads, often resulting in discarded critical information and suboptimal outcomes for downstream tasks. This paper introduces Point-ITR, a task-oriented sampling method tailored for regression tasks, which selectively retains the most informative points within large-scale point clouds. Specifically, we propose a gradient-based importance sampling framework for intra-sample selection (selecting points within a 3D point cloud) and a feature-based weighting scheme for inter-sample selection (selecting among different 3D point cloud sub-samples). Additionally, we introduce an iterative random sampling (ItrRS) module for preprocessing and an Offset Residual Block that utilizes a reference design model to learn structural features and accelerate both training and testing, which allows a simple fully connected network to process large-scale point clouds. Our approach improves prediction accuracy across downstream tasks while ensuring that the rich details captured are fully utilized for interpretation, offering a more effective and efficient solution. We validate our methodology through simulation studies and real-world case applications in additive manufacturing, demonstrating its robustness and practical applicability.

1 - An Entropy-Based Causality Framework for Cross-Level Faults Diagnosis and Isolation in Building HVAC Systems

Jiajing Huang, Kennesaw State University, Atlanta, GA, United States

Faults, such as malfunctioning sensors, equipment, and control systems, significantly affect a building's performance. Automatic fault detection and diagnosis (AFDD) tools have shown great potential in improving building performances, including both energy efficiency and indoor environment quality. Since modern buildings have integrated systems where multiple subsystems and equipment are coupled, many faults in a building are cross-level faults, i.e., faults occurring in one component that trigger operational abnormalities in other subsystems. Compared with non-cross-level faults, it is more challenging to isolate the root cause of a cross-level faults due to the system coupling effects. Bayesian networks (BNs) have been studied for the root cause isolation for building faults. While promising, existing BN-based diagnosis methods highly rely on expert domain knowledge, which is time-consuming and labor expensive, especially for cross-level faults. To address this challenge, we propose an entropy-based causality learning framework, termed Eigen-Entropy Causal Learning (EECL), to learn BN structures. The proposed method is data-driven without the use of expert domain knowledge; it utilizes causal inference to determine the causal mechanisms between faults status and symptoms to construct the BN model. To demonstrate the effectiveness of the proposed framework, three fault test cases are used for evaluation in this study. Experimental results show that the BN constructed by the proposed framework is able to conduct building cross-level faults diagnosis with a comparable isolation accuracy to those by domain knowledge while maintaining less complexed BN structure.

2 - Human-Machine Collaborative Experimental Design for High-Quality Material Manufacturing

Guoyan Li, Northeastern University, Medford, MA, United States, Xiaoning Jin

Due to the substantial expenses associated with the manual annotation process, Bayesian Optimization (BayesOpt) is extensively employed within engineering optimization to substantially reduce the need for labor-intensive manual labeling through experimentation. BayesOpt involves a closed-loop where a probabilistic surrogate model is trained iteratively to guide sequential experimental design. Traditional BayesOpt methods that leverage a small labeled dataset to quantify the unlabeled information usually start a pure exploration of the whole design space in the initial optimization phase, which causes an over-exploration problem. In this work, we aim to improve the efficiency of exploring the entire design space by implementing a graph-based Gaussian Process as a surrogate model, which integrates geometric information within the design space. In addition, we designed a pseudo-label generator, which estimates the labels of informative yet unlabeled data, thereby expanding the training dataset. This new framework enhances the learning efficiency of the surrogate model, enabling more precise and faster design space exploration for optimal design. We

validated the effectiveness of our proposed approach through simulation data and applied this method to optimize mechanical structures in the additive manufacturing process.

3 - Reinforcement Learning Based Framework for Rna Secondary Structure Prediction

Menghan Liu, Arizona State University, Tempe, AZ, United States

Ribonucleic acid (RNA) is a fundamental biological molecule that is essential to all living organisms, performing a versatile array of cellular tasks. The function of many RNA molecules is strongly related to the structure it adopts. As a result, many efforts were put to solve the RNA secondary structure prediction problem: given a sequence of nucleotides, return a probable list of base pairs, referred to as the secondary structure prediction. Early algorithms have largely relied on finding the structure with minimum free energy. However, the predictions rely on effective simplified free energy models that may not correctly identify the correct structure as the one with the lowest free energy. In light of this, new, data-driven approaches that not only consider free energy, but also use machine learning techniques to learn motifs have also been investigated, and have recently been shown to outperform free energy based algorithms on several experimental data sets. In this work, we introduce the new ExpertRNA algorithm that provides a modular framework which can easily incorporate an arbitrary number of rewards and secondary structure prediction algorithms. We argue that this capability of ExpertRNA has the potential to balance out different strengths and weaknesses of state-of-the-art folding tools. We test the ExpertRNA on several RNA sequence-structure data sets, and we compare the performance of ExpertRNA against a state-of-the-art folding algorithm. We find that ExpertRNA produces, on average, more accurate predictions of non-pseudoknotted secondary structures than the structure prediction algorithm used, thus validating the promise of the approach.

4 - Bayesian Active Learning by Confidence Gradient-Based Mean Objective Cost of Uncertainty

Feng (Ryan) Lin, University of Washington, Mountlake Terrace, WA, United States

Many active learning methods adopt one-step-look-ahead acquisition functions to select the data to query their labels that can help improve the model performance the most. For example, expected loss reduction (ELR) or mean objective cost of uncertainty (MOCU) based methods focus on greedy maximization of uncertainty reduction related to learning objectives. However, without considering the long-term impact of the queried data, the one-step-look-ahead strategy suffers from myopic behavior. To relieve this myopia while still taking advantage of the simplicity and efficiency of one-step-look-ahead, we introduce a confidence cumulation mechanism by a new concept called confidence gradients (CG) and propose CG-MOCU to buffer against the risk of developing myopia for MOCU-based active learning. Theoretically, CG-MOCU will not get stuck in the long run and can converge to the true optimal classifier without additional constraints on the acquisition function. Empirical results on both synthetic and real-world data show that CG-MOCU outperforms the state-of-the-art active learning methods.

5 - Unsupervised Quality Control in Crowdsourcing via Mixture Random Utility Models

Hanming Zheng, City University of Hong Kong, Hong Kong, Hong Kong

Crowdsourcing is a transformative approach that harnesses collective intelligence to develop innovative and effective solutions. Despite its growing popularity, it faces challenges in ensuring the reliability and accuracy of crowdsourced results, making quality control crucial for effectively aggregating worker responses. This study proposes a novel probabilistic framework for worker response aggregation that unifies random utility model (RUM)-based choice modeling with latent worker clustering. We introduce a Mixture of Plackett-Luce Model (MPM), where worker responses are modeled as a mixture of choices from different latent clusters, each characterized by unique RUM parameters. The model parameters, including cluster-specific RUM attributes, task parameters, and worker cluster membership probabilities, are jointly learned using an expectation-maximization (EM) algorithm. This integrated approach enables mutual refinement between parameter estimation and cluster identification, leading to more accurate modeling. Simulation studies demonstrate the model's ability to recover ground-truth parameters, particularly the worker-task utility structure, across various data generation scenarios. Real-world case studies confirm that the proposed method outperforms existing methods in both accuracy and robustness. This work establishes a theoretically more coherent and powerful foundation for unsupervised quality control in crowdsourcing.

6 - Optimizing Two-Arm Clinical Trials for Personalized Medicine Using Integer Programming and Heuristic Algorithms

Alan Vazquez, Tecnologico de Monterrey, Monterrey, Mexico

Subjects with complex and serious diseases, such as malaria and leukemia, can have adverse reactions to the best-known treatments. The personalized medicine approach becomes beneficial because the subjects' characteristics or covariates are considered before a treatment assignment. Attractive statistical methods for personalized medicine determine the best treatment using the interaction between the treatments and the subject's covariates. To estimate this interaction, we use a two-arm clinical trial in which one of two treatments is assigned to each subject in a pre-selected sample. In this presentation, we introduce a statistical criterion to evaluate two-arm clinical trials in terms of the interaction estimation for all potential subjects' covariates, which can be quantitative or categorical. We develop theoretical results and two optimization algorithms to construct trials based on this criterion. Specifically, we introduce an integer programming algorithm that guarantees convergence to the optimal trial and a computationally efficient coordinate-exchange algorithm with a novel updating formula. Numerical experiments demonstrate the computational performance of our algorithms to construct two-arm clinical trials for various problems. As an application, we show that our algorithms can redesign a two-arm Scleroderma clinical trial with a smaller variance of the interaction estimate than the implemented trial for a test set of subjects.

1 - Digital Transformation in Traditional Manufacturing: a Three-Phase Strategy for Efficiency and Sustainability

Kun Zhong Lin, National Cheng Kung University/Department of Business Administration, Tainan, Taiwan, Tai-Yu Lin, Sheng-pin Wu, Chien-Chih Wang

Traditional manufacturers often struggle with outdated systems and poor tech integration in the face of globalization and digitalization. This study analyzes a Taiwanese marine diesel engine parts maker's digital journey through three phases: Digitization, Optimization, and Transformation. The company first adopted basic digital tools to streamline operations, then applied real-time data to improve monitoring and engagement, and finally visualized data to enhance decision-making. Using a case study approach and resource-based view, the study finds improved order speed, paperless processes, higher profits, and lower carbon emissions. A data-driven culture also boosted agility, communication, and leadership. Successful transformation aligns with core operations to enhance efficiency, competitiveness, and sustainability.

2 - AI Avatars on Douyin: Impacts on Engagement and Productivity

Yuzhou Chen, Southeast University, Nanjing, China, People's Republic of, Yulin Zhang, Yiting Guo, Haowen Fan

As generative artificial intelligence continues to reshape the creator economy on digital platforms, AI-generated avatars are emerging as powerful tools for influencers on video-sharing platforms. These avatars mimic an influencer's persona to engage with followers autonomously, raising important questions about their impact on creator performance. This study examines the causal effects of AI avatar adoption by leveraging a quasi-natural experiment on a major Chinese short-video platform. Combining difference-in-differences estimation with propensity score matching (PSM-DID), we assess how AI avatars influence two key outcomes: user engagement—measured by likes, comments, shares, and follower growth—and content output, measured by the number of videos posted. Our results show that AI avatars significantly increase user engagement across all metrics, but have no measurable impact on content production. This indicates that avatars improve the quality of interaction rather than stimulating greater creative output. Furthermore, moderation analysis reveals that the positive effects are more pronounced for utilitarian content, suggesting that content type moderates the effectiveness of AI-mediated engagement. These findings contribute to the literature on human-AI collaboration and influencer strategy by challenging the assumption that automation necessarily boosts productivity. Instead, they highlight AI avatars as strategic tools for deepening audience engagement without increasing labor demands. Practical implications for platforms and content creators include aligning AI avatar use with content type, audience expectations, and creator workload management.

3 - Content-Embedded Advertising Response Prediction for Informed Multimodal Branded Posts Diffusion: a Novel Deep Learning Method

Renzhi Gao, School of Management, Zhejiang University, Hangzhou, China, People's Republic of, Gang Chen, Xiangwei Kong, Junjie Wei

Content-embedded advertising is an emerging advertising format where sellers seamlessly integrate advertising content into multimodal social media posts, such as blogs, images, and videos (i.e., multimodal branded posts). These multimodal branded posts help make ads appear more natural and less intrusive. Diffusing multimodal branded posts through strategic traffic investment is effective operational strategy for sellers to boost user engagement and responses to their advertised products. However, when launching a new product, sellers often face challenges in cost-effectively creating and diffusing multimodal branded posts, including: (1) determining which topics to focus on during the post creation phase, (2) deciding how much traffic to invest in the post heating phase, and (3) allocating additional traffic to posts that have already received initial investment in the post diffusion phase. In this study, as inspired by the spreading activation theory, we propose a multimodal branded posts diffusion (MBPD) method, which: (1) simulates sellers' behavior in creating diversified branded posts across various topics in the post creation phase, (2) simulates sellers' traffic investment behavior across posts on certain topics in the post heating phase, (3) simulates sellers' additional traffic allocation behavior based on user responses to initial traffic investment in the post diffusion phase, and (4) optimizes the post diffusion framework through advertising response prediction. For a new product promotion, MBPD provides quantitative insights that help sellers optimize post creation, traffic investment, and additional traffic allocation for profitability. Empirical evaluation and explanatory analyses based on two real-world content-embedded advertising cases demonstrate the effectiveness of MBPD.

4 - Beyond Transparency: Explanations for Asymmetry and Irreversibility in AI-Assisted Decision Making

Nolan Talaei, University of Massachusetts Lowell, Lowell, MA, United States, Asil Oztekin, Hongwei Zhu, Luvai Motiwalla, Anol Bhattacharjee, Salih Tutun

Integrating artificial intelligence (AI) into decision-making and business processes, such as credit underwriting, pricing strategy, and operational planning, demands explainability beyond transparency to support targeted, domain-relevant action. Prevailing explainable AI (XAI) techniques often rely on static feature importances or one-shot counterfactuals, which overlook deeper behavioral properties of decision models. This work introduces a novel framework that leverages bidirectional perturbation analysis to expose asymmetric feature sensitivity and irreversibility, two properties critical to understanding and intervening in complex predictive systems.

By analyzing the effects of both increases and decreases in input features, the method uncovers cases where a shift in one direction significantly alters predictions while a change in the other direction has minimal or no impact. It further reveals decision irreversibility, where reversing an unfavorable outcome requires disproportionately large or qualitatively different input changes. Applied to a real-world consumer credit dataset characterized by binary lending outcomes and behavioral risk indicators, the approach identifies hidden thresholds, decision cliffs, fragile boundary regions, and zones of predictive inertia, offering plausible “what-if” scenarios aligned with feasible interventions.

Evaluations demonstrate that the method surfaces structural properties of model behavior that remain hidden under conventional explainability techniques. It consistently produces context-sensitive counterfactuals while maintaining interpretive stability across similar applicant profiles. These insights empower decision-makers to distinguish between fragile and stable cases, assess trade-offs more effectively, and intervene more confidently. This work reframes explainability as an interactive, scenario-driven tool for strategic reasoning in AI-assisted decision systems.

5 - Customized Assessment of Decision-Making Expertise Using Machine Learning

Wanxue Dong, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Dongcheng Zhang, Yunduan Lin, Weiwan Wang

Experts' decision accuracy is a fundamental determinant of professional outcomes such as compensation, retention, and task allocation, and it enables consumers to make more informed choices. While recent studies have introduced scalable and effective methods to evaluate overall decision accuracy, current approaches fall short in supporting customized, task-level assessments of experts' decision expertise. Given that decision quality often varies across different types of tasks, task-level evaluation is particularly valuable in high-stakes settings. In this work, we propose a novel and general framework for customized assessment of experts' decision quality, where the goal is to estimate how well an expert is likely to perform on specific decision tasks. To the best of our knowledge, this is the first study to address task-level evaluation of decision quality in a generalized, data-driven manner. We demonstrate the effectiveness of our method through a downstream application: assigning experts to new tasks based on their areas of expertise. Our approach achieves state-of-the-art performance, highlighting the practical value of customized evaluation of experts' decision-making quality.

Special topics in Behavioral Operations Management

Invited Session

Behavioral Operations Management

Chair: Sebastian Villa, University of New Mexico, Albuquerque, NM, United States

Co-Chair: Vinit Tipnis, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States

1 - Not-for-Profit Provider Operational Transparency and Donations

Kevin Mayo, Washington State University, Pullman, WA, United States, Telesilla Kotsi, Chengcheng Zhai

In many not-for-profit settings, providing beneficiary information is unethical or impossible. We examine the effects of provider transparency in the not-for-profit sector on the likelihood and amount of donations. We run experiments examining the value of provider information and different dimensions of operational transparency, information about reactive versus proactive programs, and information about direct aid versus overhead funding. We aim to first establish these results in laboratory conditions to identify the underlying mechanisms, then test our findings through real-world experiments.

2 - When Workers Monitor: How Engagement with Energy Management Systems Affects Energy Efficiency

Donggyu Jeon, Indiana University - Kelley School of Business, Bloomington, IN, United States, Christopher Chen, Owen Wu, Amrou Awaysheh

This study examines the impact of user engagement with energy management systems (EMS) on energy efficiency in manufacturing settings. EMS, a vital part of operational infrastructure, provides comprehensive data on energy and electricity usage, consumption flows and patterns, and CO2 emissions, collected by energy meters installed at manufacturing sites. Drawing on site-month data from a global conglomerate spanning 2017–2022, we examine how four dimensions of user engagement—frequency (sessions), breadth (users), volume (actions), and duration—affects EE. We find a significant positive relationship between user engagement with EMS and overall energy efficiency. Additionally, the nature of these engagement matters. Sessions exhibiting greater intensity and an explicit focus on energy management yield noticeably stronger improvements in energy performance than lower-intensity or administrative interactions. We further validate the causal effect of user engagement using an instrumental variable (IV) approach, where the number of energy meters installed—exogenously determined by corporate headquarters—serves as an instrument for user engagement. The results confirm that energy meters enhance EE only when site managers and operators actively exploit EMS energy data. We employ an inverse probability weighting to address potential selection bias in our IV design. Further, we conduct a control function approach with IV to account for any residual endogeneity bias in our IV estimations. Finally, we find that engineering teams and line workers—those in direct control of machinery and day-to-day processes—are especially effective at converting EMS insights into tangible energy savings. Collectively, our findings highlight the importance of human interventions in unlocking the full potential of EMS technology.

3 - Queuing and Donations: Effects of Waiting Time in Checkout Charity

Sebastian Villa, University of New Mexico, Albuquerque, NM, United States

Firms frequently give consumers the option to donate to a nonprofit organization (NPO) at checkout counters. This approach improves firm's image and allows NPOs to gain additional sources of donations. Through experiments, we investigate how operational and donation-related attributes influence consumers' donation at checkouts. Our findings have implications for optimizing charitable giving without compromising firms' customer satisfaction.

4 - The Impact of Scheduling Fairness on Employee Turnover

Paige Tsai, Harvard Business School, Boston, MA, United States, Ryan Buell

Using a combination of field and lab data, we explore drivers of job sustainability in the restaurant industry. We leverage shift data from a large restaurant group to better understand the impact of shift unfairness on employee turnover and find that relative unfairness — as compared to one's peers — is associated with higher employee turnover. A series of lab experiments suggests this relationship may be causal and reveals that perceived schedule fairness mediates the relationship between schedule quality and schedule ratings as well as likelihood to stay in the job. Taken together, these findings highlight the role of both absolute and relative working conditions in shaping employee retention. While previous research has emphasized the importance of sufficient, stable, and predictable scheduling on firm performance, our results indicate that perceptions of fairness with respect to these dynamics — shaped by relative differences in scheduling quality — could play a critical role as well.

5 - When Transparency Backfires: Why Contingent Discounts May Outperform Preannounced Ones

Federico Zimmerman, Harvard University, Cambridge, MA, United States, Joaquín Navajas, Gustavo Vulcano

We study how preannounced discounts influence consumer behavior when inventory is limited. We develop a two-period game-theoretic model in which rational consumers with identical valuations choose whether to buy at full price or wait for a possible markdown. We consider two settings: (i) discounts contingent on remaining inventory, and (ii) preannounced discounts. In the contingent case, the seller maximizes revenue by keeping the full price, prompting all consumers to buy early. In contrast, preannounced discounts yield both pure and mixed-strategy equilibria. In the pure strategy equilibrium, all consumers defer purchases, lowering seller revenue. In the mixed-strategy equilibrium, deeper discounts reduce deferral by increasing competition for limited inventory, thereby benefiting the seller. To test these predictions, we conducted an online experiment where participants chose to buy or wait under contingent and preannounced discount regimes. Contrary to rational expectations, deeper discounts increased the likelihood of deferral. Furthermore, consumers were more likely to wait when discounts were preannounced with certainty, suggesting a behavioral aversion to ambiguity. These tendencies led to lower effective prices and reduced retailer revenue, particularly at higher discount levels. Our findings reveal a disconnect between theoretical predictions and actual behavior. While preannounced discounts may mitigate strategic delay under rational models, they can encourage deferral in practice. This highlights the need to incorporate behavioral elements — such as ambiguity aversion — into pricing strategies to design more effective markdown policies and optimize revenue under inventory constraints.

AI-Driven Entrepreneurship and Innovation

Invited Session

Artificial Intelligence

Chair: Tung Cu, Northeastern Illinois University, 5500 North St. Louis Avenue, Chicago, IL, United States

1 - Unlocking Competitive Advantage in the Age of Intelligent Systems

Dave Chatterjee, Duke University, Johns Creek, GA, United States

Artificial Intelligence is redefining the boundaries of what's possible in business. As the technology rapidly evolves, forward-thinking entrepreneurs are leveraging AI not just to enhance existing processes — but to reimagine entire industries. This keynote highlights the transformative role of AI in driving entrepreneurship and innovation, drawing from rich, real-world insights featured in the acclaimed Cybersecurity Readiness Podcast Series. Through the journeys of pioneering founders — from behavioral biometrics and insider threat detection to AI model security and deepfake fraud prevention — attendees will discover how AI is being used to build high-impact, scalable, and secure businesses. These innovation stories illuminate how personal adversity and professional expertise often intersect to spark ventures with global relevance. Yet, as AI enables unprecedented growth and agility, it also introduces new risks. This session explores the dual-use nature of AI — its power to enable as well as undermine — and presents pragmatic strategies for aligning AI innovation with ethical guardrails and cybersecurity resilience.

2 - Does Serendipity Mitigate Online Dating Burnout? a Randomized Field Experiment on Serendipity-Oriented Recommender Systems

Yue Guan, Communication University of China, Beijing, China, People's Republic of

Users of online dating platforms increasingly experience burnout. This is partly driven by recommender systems that reinforce sorting patterns based on explicit attributes such as social status, age, or geographic distance. Accordingly, we propose a serendipity-oriented recommender system by (1) relaxing constraints on explicit attributes while maintaining relevance through personalized preference learning, and (2) leveraging a deep learning attention network to extract intrinsic compatibility from profile Q&A texts. In a randomized field experiment on a leading online dating platform, users in the treatment group exhibited a 5.2% decrease in profile views and a 36% reduction in match requests, but achieved a 29.4% increase in match probability. Additionally, they showed a 38.5% increase in positive emotion scores, expanded their consideration sets across age and geography, and formed reciprocal matches more efficiently. Our findings offer causal evidence that incorporating serendipity into reciprocal recommendation can enhance match quality and mitigate user burnout.

3 - How Governance of Startup Ecosystems Can Unleash AI-Driven Innovations in Developing Countries

Lan Le, Metropolitan University Prague, Prague, Czech Republic, Tung Cu

Startup ecosystems consist of entrepreneurs, investors, academic institutions, government agencies, and support organizations that collaborate to foster innovation. Governance in these ecosystems involves regulatory policies, institutional support, financial incentives, infrastructure development, and cooperative frameworks that collectively enable startups to thrive. Effective governance can stimulate entrepreneurship, accelerate technology adoption, and contribute to sustainable economic development. This study investigates how governance of startup ecosystems can catalyze AI-driven innovations in developing countries. Specifically, it compares governance structures that support entrepreneurship leveraging generative AI (GenAI) in countries such as India and Vietnam, with reference to models from developed nations in Europe and the United States. The analysis focuses on both financial and non-financial support mechanisms, including the roles of public and private sector venture capital, technology training, social networks, and cultural factors. To address the research questions, data will be collected and analyzed across multiple dimensions of governance and ecosystem dynamics. The study follows a structured research process encompassing background and context, literature review, research questions, data collection and analysis, and conclusions with actionable recommendations. The goal is to develop strategic insights into optimizing governance frameworks for AI innovation in emerging markets.

Adaptive Experimental Design And Policy Evaluation Under Nonstationarity

Invited Session

Data Mining

Chair: Kyra Gan, Cornell Tech, Cornell University, New York, NY, United States

Co-Chair: Jiamin Xu, Cornell University, New York, NY, 14850, United States

1 - Sample Complexity Reduction via Policy Difference Estimation in Reinforcement Learning

Kevin Jamieson, University of Washington, Seattle, WA, United States

Abstract: An autonomous agent is placed into an unfamiliar environment with unknown rules and hidden rewards — how quickly can it learn to navigate and maximize its rewards? Efficient exploration is central to reinforcement learning (RL), with critical applications from robotics to personalized healthcare. In this talk, we focus on the pure exploration problem in contextual bandits and tabular RL, aiming to identify an approximately optimal policy from a set of candidates with high probability. Previous work in contextual bandits significantly improved sample efficiency by estimating only differences between policies rather than behaviors individually. However, existing methods in tabular RL fail to exploit this insight, instead estimating each policy's behavior directly. We investigate extending this efficient approach from bandits to RL and present a nuanced answer: difference estimation is sufficient for contextual bandits but fundamentally insufficient in tabular RL. Inspired by this limitation, we

propose anchoring policy estimates to a single reference policy, achieving substantial sample complexity improvements and delivering the tightest known bounds in tabular RL. Our findings provide new theoretical insights and practical strategies for efficient exploration in RL. Based on [joint work](#) with Adhyayan Narang, Andrew Wagenmaker, and Lillian Ratliff

2 - Efficient Learning for Finite-Horizon Restless Bandits

Kyra Gan, Cornell Tech, Cornell University, New York, NY, United States

In this work, we will present an efficient learning algorithm designed for finite horizon restless bandit problem. We adopt a budgeted thresholding contextual multi-armed bandit reformulation that we established in a prior work, and show that the reformulation can be efficiently learned through a novel construction of the ϵ -process in conjunction with a two-phase sampling algorithm.

3 - On the Limited Representational Power of Value Functions and Its Links to Statistical (in)Efficiency

David Cheikhi, Columbia University, New York, NY, United States, Daniel Russo

Identifying the trade-offs between model-based and model-free methods is a central question in reinforcement learning. Value-based methods offer substantial computational advantages and are sometimes just as statistically efficient as model-based methods. However, focusing on the core problem of policy evaluation, we show information about the transition dynamics may be impossible to represent in the space of value functions. We explore this through a series of case studies focused on structures that arises in many important problems. In several, there is no information loss and value-based methods are as statistically efficient as model based ones. In other closely-related examples, information loss is severe and value-based methods are severely outperformed. A deeper investigation points to the limitations of the representational power as the driver of the inefficiency, as opposed to failure in algorithm design.

Advances in Machine Learning and Deep Learning for Multivariate Time Series Forecasting

Invited Session

Data Mining

Chair: Shouyi Wang, The University of Texas at Arlington, Arlington, TX, United States

Co-Chair: Dervis Ozay, The University of Texas at Arlington, Arlington, TX, United States

1 - Feature-Sparse Probabilistic Time Series Forecasting for Demand Prediction: Benchmarking and Advancing State-of-the-Art Methods

Dervis Ozay, The University of Texas at Arlington, Arlington, TX, United States

Accurate demand forecasting underpins key operational decisions in dynamic pricing, inventory planning, and marketing optimization. Traditional time series models such as ARIMA, VAR, and tree-based machine learning algorithms (e.g., Random Forest, XGBoost) often struggle to address modern forecasting challenges, including high-dimensional input spaces with redundant features, non-linear dependencies, sudden structural shifts, and uncertainty quantification in volatile markets. This study presents a twofold contribution. First, we conduct a comprehensive benchmarking of state-of-the-art (SOTA) forecasting approaches, including classical statistical models, machine learning algorithms, and deep learning architectures, assessing their predictive accuracy and robustness across multiple demand forecasting scenarios. Second, we introduce a **Feature-Sparse Probabilistic Demand Learning Model (FS-PDLM)**, a novel Transformer-based framework that jointly performs time series forecasting and embedded feature selection. By enforcing sparsity constraints, FS-PDLM identifies the most informative factors driving demand while quantifying forecast uncertainty. Experimental results on synthetic and real-world datasets demonstrate that FS-PDLM not only enhances prediction accuracy and interpretability but also maintains competitive or superior performance compared to leading SOTA models.

2 - Topology-Aware Conformal Prediction for Stream Networks

Jifan Zhang, Northwestern University, Evanston, IL, United States

Stream networks, a unique class of spatiotemporal graphs, exhibit complex directional flow constraints and evolving dependencies, making uncertainty quantification a critical yet challenging task. Traditional conformal prediction methods struggle in this setting due to the need for joint predictions across multiple interdependent locations and the intricate spatio-temporal dependencies inherent in stream networks. Existing approaches either neglect dependencies, leading to overly conservative predictions, or rely solely on data-driven estimations, failing to capture the rich topological structure of the network. To address these challenges, we propose Spatio-Temporal Adaptive Conformal Inference (STACI), a novel framework that integrates network topology and temporal dynamics into the conformal prediction framework. STACI introduces a topology-aware nonconformity score that respects directional flow constraints and dynamically adjusts prediction sets to account for temporal distributional shifts. We provide theoretical guarantees on the validity of our approach and demonstrate its superior performance on both synthetic and real-world datasets. Our results show that STACI effectively balances prediction efficiency and coverage, outperforming existing conformal prediction methods for stream networks.

3 - Spatio-Temporal Generative Foundation Model for Power Outage Prediction and Simulation

Feng Qiu, Argonne National Lab, Lemont, IL, United States

As extreme weather events grow more frequent and grid topologies more complex, electric utilities require reliable tools to forecast where and when outages will occur and to simulate plausible outage scenarios for resilience assessment. Existing approaches for power outage analysis are typically tailored to a specific machine learning task or local service territory, which limits their scalability and transferability. Inspired by the success of large-scale generative pretraining in language and vision, we propose the first spatio-temporal generative foundation model for power outages that learns from massive archives of customer outage records across the U.S. alongside multi-modal covariates (e.g., weather, census data, and network topology). Our model employs a flow matching objective within a latent generative framework, ensuring generated trajectories remain statistically consistent with observed data. Inference then reduces to sampling from the model's conditional distributions, unifying prediction and simulation under a single probabilistic umbrella. The learned outage dynamics can be transferred to region-specific data with minimal fine-tuning effort. Preliminary experiments demonstrate that our model delivers strong predictive accuracy for outage forecasting and generates realistic scenarios for "what-if" resilience analyses. This equips utilities and planners with a flexible, data-efficient tool to anticipate emerging risks and stress-test grid resilience under diverse conditions.

4 - Change-Point Detection in Time Series Using Mixed Integer Programming

Artem Prokhorov, University of Sydney Business School, CEBA, CIREQ, Sydney, Australia

We use cutting-edge mixed integer optimization (MIO) methods to develop a framework for detection and estimation of structural breaks in time series regression models. The framework is constructed based on the least squares problem subject to a penalty on the number of breakpoints. We restate the L_0 -penalized regression problem as a quadratic programming problem with integer- and real-valued arguments and show that MIO is capable of finding provably optimal solutions using a well-known optimization solver. Compared to the popular L_1 -penalized regression (LASSO) and other classical methods, the MIO framework permits simultaneous estimation of the number and location of structural breaks as well as regression coefficients, while accommodating the option of specifying a given or minimal number of breaks. We derive the asymptotic properties of the estimator and demonstrate its effectiveness through extensive numerical experiments, confirming a more accurate estimation of multiple breaks as compared to popular non-MIO alternatives. Two empirical examples demonstrate usefulness of the framework in applications from business and economic statistics.

Resilient and Optimized Rail Freight Networks

Contributed Session

Contributed

Chair: Yiduo Huang, University of Illinois Urbana Champaign, 103 E Healey St, Champaign, IL, 61820, United States

1 - How Intercontinental Rail Freight Planning Responses to Geopolitical Risks**Jing Shan, Chair of Logistics Management, Zürich, Switzerland, Stephan Wagner**

Global supply chains are becoming more volatile as geopolitical conflicts interrupt transport flow patterns and require constant redesign of transport networks. In particular, the Russia–Ukraine conflict has pushed shippers and planners to seek safer alternatives. The Middle Corridor has rapidly emerged as a pivotal rail link between Asia and Europe, offering a strategically important bypass that avoids Russian territory. A significant amount of financial resources has been reallocated to the Middle Corridor. However, it remains questionable to what extent the investment could improve throughput, decrease average delay per container, reduce average cost, and increase average profit and margins. Transport planners and policymakers need an effective tool capable of analyzing potential geopolitical disruptions and adapting network designs accordingly. However, existing rail planning research mostly neglects geopolitical factors. This paper therefore introduces the Geopolitically Intercontinental Service-Network Design (G-ISSND) model. The G-ISSND model integrates the routing preferences of avoiding Russia territory, while also considering service quality of the supply chain, rail resource efficiency, rail network capacity constraints, and border crossing times. Our results demonstrate that the performance of an intercontinental rail network must be optimized by balancing capacity expansion with faster transit times, while also considering the time-sensitivity of the goods structure and routing preferences of the shippers. The G-ISSND model serves as both a strategic and operational planning tool, enabling policymakers and transport planners to better respond to geopolitical disruptions in intercontinental rail freight network.

2 - Strategic Resilience in Eurasian Trade Corridors: a Game-Theoretic Approach**Nahid Jafari, SUNY, Farmingdale, Farmingdale, NY, United States, Bruno Kamdem**

Ensuring resilient and sustainable supply chains for goods and energy between Europe and Asia presents a complex challenge, influenced by long distances, political risks, economic sanctions, environmental concerns, and volatile geoeconomics conditions. This study focuses on a transnational transport corridor that spans multiple jurisdictions, each with distinct economic and geopolitical agendas. The region is further complicated by fluctuating commodity prices driven by geopolitical tensions and evolving international agreements.

To address these challenges, we develop a model based on Stochastic Differential Game Theory and Optimal Control, capturing the strategic interactions among key stakeholders, including transportation companies and national governments. In our framework, transportation firms (Player 1) aim to maximize profit while minimizing operational costs, including taxes, by leasing infrastructure—such as roads, railways, or pipelines—from corridor authorities controlled by governments (Player 0), who seek to maximize revenue from taxes and commodity sales.

These interactions unfold within a stochastic game setting, where the market value of a unit of the transported commodity is modeled as a log-normal mean-reverting process, reflecting both price volatility and long-term stabilization tendencies. This approach enables the formulation of robust, adaptive strategies that integrate transportation costs and geopolitical risks. We identify a unique Nash Equilibrium that optimally balances taxation and transport rates, thereby minimizing disruptions and fostering economic stability across politically sensitive and economically volatile regions.

3 - Practice-Based Optimization for Strategic Locomotive Assignment Problem**Yunji Kim, Georgia Technology of Institute, Atlanta, GA, United States, Amira Hijazi, Kevin Dalmeijer, Pascal Van Hentenryck**

This study presents a strategic optimization framework for the Locomotive Assignment Problem (LAP), developed in collaboration with a major North American Class I Freight Railroad. The problem is formulated as a network-based integer program over a cyclic space-time network, producing a repeatable weekly assignment plan for locomotives. The model incorporates a comprehensive set of real-world operational constraints while endogenizing the placement of work events—i.e., locomotive pick-ups and set-outs—throughout space and time. Unlike prior studies that treat these locations as fixed, this approach jointly optimizes them, improving feasibility and effectiveness of subsequent planning. One of the key contributions of this work is solving the LAP exactly with all feasible light travel arcs, a task previously considered computationally intractable due to the sheer scale of the arc set. To overcome this, a set of network-topology-aware reduction rules are introduced that dramatically reduce the candidate arcs without compromising optimality. This enables exact solutions on large-scale instances for the first time and provides provable lower bounds for evaluating the true quality of heuristics methods. Extensive computational studies demonstrate how strategic decisions and network behaviors adapt under varying cost and capacity regimes. The results highlight key operational trade-offs and identify critical network components essential for robust system design. Beyond delivering scalable, high-quality solutions, the proposed framework serves as a practical decision-support tool grounded in the operational realities of modern freight railroads.

4 - Trailer Path Optimization on Large Scale Network Using Scheduled Services**Mohammed Faisal Ahmed, Georgia Institute of Technology, Atlanta, GA, United States, Ahmed El-Nashar, Pascal Van Hentenryck**

This paper introduces the trailer path optimization with schedule services problem (TPOSSP) and proposes a column generation-based heuristic (CG-Heuristic) to efficiently solve large instances in tactical planning settings. The TPOSSP aims at determining trailer routes over a time-dependent network using existing scheduled services, while considering tractor capacity constraints and time windows for trailer pickups and deliveries. The objective is to minimize both the number of schedules used and the total miles traveled. Both arc-based and path-based formulations of TPOSSP are examined. To improve computational efficiency, a novel pruning algorithm called Earliest Latest Start Time Pruning (ELSP) is introduced to identify the exact feasible search space for each trailer. A fast time dependent shortest path algorithm is developed to solve the pricing problem of column generation. To stabilize the column generation process, a weighted Dantzig-Wolfe decomposition is applied. The models and algorithms are evaluated using a real-world dataset from a major logistics service provider. ELSP achieves runtime reductions of 85%–99% for arc-based formulations and 53%–85% for the CG-Heuristic. The CG-Heuristic produces solutions within a 3% optimality gap for small instances and within a 5% gap for large instances. Additionally, the heuristic reduces the net cost of operations by up to 3% for large-scale scenarios.

5 - Integrated Optimization of Skip-Stop Freight Trains Timetabling and Delivery Routing on Multi-Line Urban Metro Systems**Younju Jung, Korea University, Seoul, Korea, Republic of, Haneul Kim, Soon-Kyo Lee, Taesu Cheong**

The lack of urban logistics hubs sparks interest in incorporating skip-stop freight trains into passenger train schedules. This approach aims to maintain punctuality for passenger trains while ensuring timely delivery of freight. However, existing research remains on single-line scenarios and neglects transfers, limiting its applicability to real-world rail networks. In this study, we propose a mixed-integer linear programming (MILP) model that determines the timetables for skip-stop freight trains and the routes for freight delivery on a multi-line rail network at the same time. In order to solve large-scale instances efficiently, three methods are applied: (i) reducing the network based on commodities, (ii) determining the maximum number of freight trains per interval, and (iii) using a column generation-based reformulation. The effectiveness of the proposed method is verified through computational experiments and a case study on the Seoul Metro network. Furthermore, the unit prices per order that reflect target margins and the number of freight trains required to meet demand forecast are analyzed, offering valuable insights for strategic decision-making.

6 - Multiscale Data-Driven Intermodal Freight Traffic Assignment on Large Networks**Yiduo Huang, University of Illinois Urbana Champaign, Champaign, IL, United States, Yanfeng Ouyang, Jesus Osorio**

Intermodal freight transportation seamlessly integrates modes such as road, rail, and water to reduce congestion, costs, and environmental impacts. However, modeling these systems at a national scale is challenging due to heterogeneous data sources, varying regional shipper and carrier decisions, unknown regional and inter-modal transfer delay functions, and significant computational demands. To address these issues, this paper proposes a multi-source, data-driven intermodal freight traffic assignment framework that combines high-resolution regional data and simulation outputs with lower-resolution, large-scale network information to predict overall flow distributions and delays. Our hierarchical hybrid modeling approach represents each regional sub-network as a hyperlink in a hypergraph. We use an integrated inverse optimization and regression model with kernel methods to learn hyperlink travel time functions from both large-scale and regional data, and then apply a gradient-projection algorithm to solve for equilibrium flows on the resulting hypergraph. We also establish generalization guarantees for the learned kernel-based hyperlink cost

function, showing how the quantity of both upper- and lower-level data influences the expected prediction error. This integrated methodology enables robust evaluations of intermodal configurations and operational strategies, ultimately promoting more efficient and sustainable freight systems.

1 - Bayesian Optimization for Efficient Decision-Making in Complex Systems

Ross Metusalem, JMP Statistical Discovery, Tampa, FL, United States

Bayesian Optimization (BO) is a sequential learning method for efficiently optimizing noisy, black-box, or expensive-to-evaluate functions. Starting with a small set of observations, BO fits a flexible probabilistic model to the data and uses that model to determine the next observation(s) to collect. Iterating on this process, BO balances exploration of uncertain areas of the factor space with exploitation of potential optima to arrive at a globally optimal solution. This session will establish the foundational concepts underlying BO and present a case study of BO in action.

2 - Optimization Education with Gurobi: A Social-Impact Case Study

Lindsay Montanari, Gurobi Optimization, Minneapolis, MN, United States, Everett Dutton

Gurobi, in partnership with ESUPS (Emergency Supply Pre-positioning Strategy), presents a new educational case study showcasing ESUPS' utilization of optimization to stage relief inventory for humanitarian organizations. ESUPS unites NGOs, UN agencies, governments, and academics to improve logistics preparedness. The STOCKHOLM platform (STOCK of Humanitarian Organizations Logistics Mapping) applies data analytics techniques including optimization to determine where to pre-position supplies, minimize response times, and maximize coverage in crises where every hour matters. This case study guides students and instructors through the full optimization pipeline: translating a complex humanitarian challenge into data, math, and models that support real-world decision making. Freely available, it gives learners hands-on experience with optimization in action, demonstrating how these methods can transform disaster response and deliver measurable social impact.

1 - Robust Paths: Geometry and Computation (ICS Student Paper Award Winner)

Hao Hao, Carnegie Mellon University, Pittsburgh, PA, United States, Peter Zhang

Applying robust optimization often requires selecting an appropriate uncertainty set both in shape and size, a choice that directly affects the trade-off between average-case and worst-case performances. In practice, this calibration is usually done via trial-and-error: solving the robust optimization problem many times with different uncertainty set shapes and sizes, and examining their performance trade-off. This process is computationally expensive and ad hoc. In this work, we take a principled approach to study this issue for robust optimization problems with linear objective functions, convex feasible regions, and convex uncertainty sets. We introduce and study what we define as the robust path: a set of robust solutions obtained by varying the uncertainty set's parameters. Our central geometric insight is that a robust path can be characterized as a Bregman projection of a curve (whose geometry is defined by the uncertainty set) onto the feasible region. This leads to a surprising discovery that the robust path can be approximated via the trajectories of standard optimization algorithms, such as the proximal point method, of the deterministic counterpart problem. We give a sharp approximation error bound and show that it depends on the geometry of the feasible region and the uncertainty set. We also illustrate two special cases where the approximation error is zero: the feasible region is polyhedrally monotone, or the feasible region and the uncertainty set follow a dual relationship. We demonstrate the practical impact of this approach in two settings: portfolio optimization and adversarial deep learning.

2 - Improving the Security of United States Elections with Robust Optimization (Harvey J. Greenberg Research Award Winner)

Bradley Sturt, University of Illinois Chicago, Chicago, IL, United States, Braden Crimmins

For more than a century, election officials across the United States have inspected voting machines before elections using a procedure called logic and accuracy testing (LAT). This procedure consists of election officials casting a test deck of ballots into each voting machine and confirming the machine produces the expected vote total for each candidate. We bring a scientific perspective to LAT by introducing the first formal approach to designing test decks with rigorous security guarantees. Specifically, our approach employs robust optimization to find test decks that are guaranteed to detect any voting machine misconfiguration that would cause votes to be swapped across candidates. Of all the test decks with this security guarantee, our robust optimization problem yields the test deck with the minimum number of ballots, thereby minimizing implementation costs for election officials. To facilitate deployment at scale, we develop a practically efficient exact algorithm for solving our robust optimization problems based on the cutting plane method. In partnership with the Michigan Bureau of Elections, we retrospectively applied our approach to all 6,928 ballot styles from Michigan's November 2022 general election; this retrospective study reveals that the test decks with rigorous security guarantees obtained by our approach require, on average, only 1.2% more ballots than current practice. Our approach has since been piloted in real-world elections by the Michigan Bureau of Elections as a low-cost way to improve election security and increase public trust in democratic institutions.

3 - Modeling and Solving Mixed-Integer Quadratic Optimization Problems (Ics Prize - Co-Winner)

Alper Atamturk, University of California - Berkeley, Berkeley, CA, United States, Andres Gomez, Shaoning Han

Quadratic optimization with discrete decisions lies at the core of modern optimization, connecting classical problems in operations research with pressing challenges in machine learning and signal processing. Yet the combination of nonconvex quadratic structure and combinatorial constraints makes these problems notoriously difficult. In this talk, I will present recent advances in mixed-integer nonlinear optimization that demonstrate how structural insights can be systematically leveraged to overcome these challenges.

The key idea is to identify and exploit simpler building blocks within complex models, such as low-dimensional sets, rank-one quadratic forms, or submodular nonlinear functions. For these structures, we can derive ideal convex relaxations that capture their combinatorial and algebraic properties exactly. Embedding these relaxations into mixed-integer optimization formulations yields models that are not only theoretically tight but also computationally effective.

This perspective leads to substantial improvements in solving small- and medium-scale problems directly with modern solvers, while also enabling tailored presolve routines and specialized algorithms that extend tractability to high-dimensional structured instances. Taken together, these results suggest a unifying approach: by decomposing nonlinear models into their convexifiable components, we can design formulations and algorithms that achieve both provable strength and practical efficiency.

4 - Acceleration by Stepsize Hedging (ICS Prize Co-Winner)

Jason Altschuler, University of Pennsylvania, Philadelphia, PA, United States, Pablo Parrilo

Can we accelerate the convergence of gradient descent without changing the algorithm — just by optimizing stepsizes? Surprisingly, we show that the answer is yes. Our proposed Silver Stepsize Schedule optimizes strongly convex functions in $k^{\log_2 p} = k^{0.7864}$ iterations, where $p=1+\sqrt{2}$ is the silver ratio and k is the condition number. This is intermediate between the textbook unaccelerated rate k and the accelerated rate $\sqrt{k}$ due to Nesterov in 1983. The non-strongly convex setting is conceptually identical and leads to an analogously accelerated rate $\epsilon^{-\log_2 p} = \epsilon^{-0.7864}$. We conjecture and provide partial evidence that these rates are optimal among all possible stepsize schedules.

The Silver Stepsize Schedule is an explicit non-monotonic fractal. Why should such stepsizes help? The core intuition is “hedging” between individually suboptimal strategies — short steps and long steps — since bad cases for the former are good cases for the latter, and vice versa. Properly combining these stepsizes yields faster convergence due to the misalignment of worst-case functions. This talk is based on a line of work with Pablo Parrilo that originates from my 2018 Master’s Thesis — which established for the first time that judiciously chosen stepsizes can enable accelerated convex optimization. Prior to this thesis, the only such result was for the special case of quadratics, due to Young in 1953.

From Expertise to Influence: Advocacy Training for the INFORMS Community and the 2025 AGC Award Winner

Invited Session

Advocacy

Chair: Jeffrey M. Cohen, INFORMS, 5521 Research Park Drive, Baltimore, MD, 21228, United States

1 - From Expertise to Influence: Advocacy Training for the INFORMS Community

Jeffrey M. Cohen, INFORMS, Baltimore, MD, United States

Your voice matters—and when informed by data and expertise, it can shape the future of federal science and technology policy. Led by INFORMS Chief Strategy Officer Jeff Cohen this session will equip INFORMS members with the tools, tactics, and confidence to engage effectively in public policy conversations that affect research funding, workforce development, AI, healthcare, and more. Using the new INFORMS Advocacy Toolkit as a foundation, this interactive training will walk participants through how to craft compelling messages, build relationships with policymakers, leverage media, and activate advocacy at the local, national, and institutional levels. Whether you’re advocating for your field, your work, or the broader operations research and analytics professions, this session will help turn your technical credibility into public impact.

2 - Advocacy Governance Committee Award

Zachary Collier, Radford University, Salem, VA, United States

Join us as we announce the winner of the 2025 Advocacy Governance Committee Award for Public Engagement The Advocacy Governance Committee (AGC) award for Public Engagement recognizes excellence of an INFORMS member who has actively engaged with the public to advance the profession in the topic areas covered by INFORMS, either by communicating relevant research results or by advocating for use of management science, operations research, and analytics to inform policy decision making. This award is meant to highlight, recognize, and honor the work that INFORMS members do to connect their work to public and private sector decision making processes that can have an impact for society, including multiple stakeholders, in any public policy area.

1 - The Predictive Power of The Inventory-to-Sales Ratio

Yifei Wang, New York University, Leonard N. Stern School of Business, New York, NY, United States, Zhengyuan Zhou, Evan Xiao

This study explores the predictive power of the inventory-to-sales ratio (ISR) in forecasting gross margin performance for companies within the S&P 500. By analyzing historical financial data, we examine how changes in ISR impact the profitability and efficiency of firms, particularly focusing on gross margin as a key indicator of financial health. Our findings reveal that a higher or lower ISR can signal potential shifts in cost structures, supply chain effectiveness, and pricing strategies, all of which directly influence gross margin outcomes. The study demonstrates that the inventory-to-sales ratio provides valuable foresight for investors and managers, as it reflects both operational efficiency and market demand dynamics. These results offer a novel approach to financial forecasting, highlighting the ISR as a critical predictor for gross margin trends within large-cap companies in the S&P 500.

2 - An Potential Game Framework for N-Player Dynamic Games

Xinyu Li, UC Berkeley, Berkeley, CA, United States, Xin Guo, Yufei Zhang

This paper proposes and studies a general form of dynamic N-player non-cooperative games called α -potential games, where the change of a player’s objective function upon her unilateral deviation from her strategy is equal to the change of an α -potential function up to an error α . Analogous to the static potential game (which corresponds to $\alpha = 0$), the α -potential game framework is shown to reduce the challenging task of finding α -Nash equilibria for a dynamic game to minimizing the α -potential function. Moreover, an analytical characterization of α -potential functions is established, with α represented in terms of the magnitude of the asymmetry of objective functions’ second-order derivatives. For stochastic differential games in which the state dynamic is a controlled diffusion, α is characterized in terms of the number of players, the choice of admissible strategies, and the intensity of interactions and the level of heterogeneity among players. Two classes of stochastic differential games, namely distributed games and games with mean field interactions, are analyzed to highlight the dependence of α on general game characteristics that are beyond the mean-field paradigm, which focuses on the limit of N with homogeneous players. To analyze the α -NE, the associated optimization problem is embedded into a conditional McKean–Vlasov control problem. A verification theorem is established to construct α -NE based on solutions to an infinite-dimensional Hamilton–Jacobi–Bellman equation, which is reduced to a system of ordinary differential equations for linear-quadratic games.

3 - Investment, Financing, Strategic Debt Service, and Liquidation

Takashi Shibata, Hosei University, Tokyo, Japan, Michi Nishihara, Yuan Tian

We develop a dynamic real options model to examine how the introduction of both collateral and debt renegotiation (i.e., strategic debt service) influences a firm’s investment and financing (capital structure) decisions. Our findings show that the inclusion of these features accelerates investment and reduces debt issuance, resulting in

lower credit spreads and higher leverage. When firms can issue one of two types of collateralized debt—bank (renegotiable) debt or market (non-renegotiable) debt—those with substantial collateral are more likely to prefer market debt over bank debt. These results are consistent with existing empirical evidence.

4 - Vector Dependence and Global Systemic Financial Risk

Robert James, NGS Super/The University of Sydney, Melbourne, Australia, Jessica Leung, Artem Prokhorov

This paper introduces a new measure of global systemic financial risk by modeling the dependence between vectors of equity returns for systematically important banks listed in the U.S., Europe, and Asia. Our approach uses vector copulas to construct distributions with multivariate margins. The new measure of systemic risk captures the degree to which the stock return losses of systematically important banks and insurers are co-monotonic between geographical regions, identifying periods where the global economy is highly susceptible to a financial shock. Crucially, the new measure is robust to changes in the within region dependence. We study the evolution of this new measure around key historical financial stress events and compare it to other dependence based measures of systemic risk from prior literature. Quantile regressions demonstrate that our new measure predicts statistically significant declines in the left tail of the distribution of global financial sector stock returns and real macroeconomic variables, such as global industrial production.

5 - Informed Option Trading: Evidence from Cybersecurity Event Disclosures

Xiaoyu Zhao, University of Massachusetts Amherst, Amherst, MA, United States

This paper investigates the information content of options trading before data breach disclosures. I find abnormal implied volatility (IV) skew prior to the disclosures, a measure that captures the relative expansiveness of put options, negatively and significantly predicts the stock returns around the disclosures. The finding is robust to a placebo test and propensity score matched sample. Moreover, the predictive power of IV skew is stronger when the option market is more liquid relative to the stock market. It is also stronger when the underlying stock under-performs before the disclosures. Overall, my research results confirms the information content of cybersecurity event disclosures and suggests that there is informed option trading prior to such events.

6 - A Dynamic Model for Open Banking

Ranu Castaneda Medina, University of Alberta, Edmonton, AB, Canada, Christoph Frei

First introduced in the United Kingdom, open banking has been adopted or explored in various countries worldwide. Recent efforts in the USA, including proposed rules by the Consumer Financial Protection Bureau, signal a growing commitment to fostering competition and data portability in financial services. Open banking allows customers to share their financial data with third-party providers, such as fintech companies, thereby increasing competition and expanding access to financial services. While this shift promises benefits such as improved product offerings and expanded financial inclusion, it also introduces significant technical, social, and economic risks. We develop a continuous-time model using a search-and-match framework to analyze borrower heterogeneity and competition between banks and fintechs. Our preliminary analysis shows that open banking reshapes financial services by leveling the playing field between banks and fintechs. However, while it enhances competition, it could also over-empower fintechs, potentially reversing the benefits to borrowers.

1 - Glass Half Full: Strategic Packaging Decisions and Environmental Outcomes

Neda Mirzaeian, University of Texas at Dallas, Richardson, TX, United States, Yanhan (Savannah) Tang

Amid rising environmental concerns and regulatory pressures, firms, particularly beverage manufacturers, face complex trade-offs when choosing among packaging options such as non-recycled plastic, recycled plastic, and glass. While glass is often perceived as the most sustainable option, its true environmental impact depends critically on return and reuse rates, which are influenced by firm-led deposit-refund systems and sustainability advertising. We develop an analytical model to study a firm's joint decisions on packaging type, pricing, and advertising efforts in a setting with heterogeneous consumer environmental awareness and greenwashing risk. We quantify the conditions under which glass can outperform plastic in terms of profit and emissions—or, paradoxically, lead to higher environmental harm. Under optimal pricing and advertising efforts, the firm can achieve a rare “win-win-win”: prevent potential greenwashing while simultaneously improving profits and customer utility. We extend the model to examine the effects of recycled content mandates and endogenous deposit values, showing how firms can balance deposit incentives and advertising strategies to engage both environmentally aware and unaware consumers. A calibrated numerical study using data from a regional U.S. dairy firm reveals that adopting the model's recommended policy—glass packaging with a premium price and targeted advertising—can increase profits by almost 60% while reducing emissions by over 30%. Our findings can help identify when glass containers outperform plastic alternatives and guide how sustainability advertising and refundable deposits can be leveraged to boost glass return rates, improve environmental outcomes, enhance customer utility, and increase profits.

2 - Subsidizing Social Welfare Programs: Contracted Slots or Vouchers?

Priyank Arora, University of South Carolina, Columbia, SC, United States, Senay Solak

Subsidy welfare programs rely on the private service providers' participation to offer services to beneficiaries and, in turn, generate societal outcomes. The voucher program is a widely used program wherein providers serve beneficiaries using their remaining capacity after serving private customers. However, overall service quality for beneficiaries may be low due to limited restrictions on participating providers' quality, and reimbursement payments for providers are uncertain as beneficiaries often do not use the offered vouchers. Alternatively, the contracted slot program restricts participation to high-quality providers who must reserve some capacity to serve beneficiaries (for guaranteed reimbursements). In each program, since providers' benefit of mitigating demand uncertainty by serving beneficiaries differs, providers' decisions and equilibrium outcomes could differ significantly. We develop an analytical model to characterize the optimal participation strategy of providers in each program and identify conditions when one program outperforms the other from the beneficiaries' and providers' perspectives. Our findings on the optimal participation strategies of providers imply that: Providers should carefully reevaluate their decisions if the government switches program types. More importantly, our comparative analysis of societal outcomes for beneficiaries and total providers' profit under these programs imply that: While practitioner debates on these programs typically focus on the number of providers, our findings underscore the importance of considering other localized factors when evaluating program outcomes. Further, based on Massachusetts' child care subsidy programs, our case study illustrates that the contracted slot (versus voucher) program can generate approximately 16% greater societal outcomes and 4% higher total providers' profit.

3 - The Impact of Recommender Systems on Content Consumption and Production: Evidence from Field Experiments and Structural Modeling

Zhiyu Zeng, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Zhiqi Zhang, Tat Chan, Dennis Zhang

Online content-sharing platforms such as Facebook and TikTok, where users act as both content creators and consumers, have become integral to daily life, relying on complex algorithms to recommend user-generated content (UGC). While prior research and industry efforts have primarily focused on designing recommender systems to encourage users to consume more content, the impact of the content recommended to users on their own content production remains understudied. To address this gap, we conducted a large-scale randomized field experiment on a major video-sharing platform. Users were randomly assigned to either a treatment or control condition, and we manipulated content recommendations by excluding a subset of highly popular creators from being recommended to treated users. This reduced recommendation quality of treated users compared to control counterparts. Our results indicate that this decline led to a 1.34% decrease in video-watching time but a 2.71% increase in videos uploaded by treated users. These findings reveal a trade-off in recommender system design: while higher recommendation quality boosts consumption, it may suppress production. To optimize recommendations, we developed a structural model in which users' choices between consuming and producing content are inversely affected by recommendation quality. Counterfactual analyses suggest that slightly lowering recommendation quality—rather than prioritizing the most popular creators—can maximize the overall value of both production and consumption for platforms. This highlights the need to balance content consumption and production when designing

recommender systems on these social media platforms. Keywords: User-Generated Content, Recommender System, Field Experiment, Structural Model, Platform Operations, Production

4 - Information Provision In Platform Competition

Wenchang Zhang, Indiana University Bloomington, Bloomington, IN, United States, Kostas Bimpikis, Yiangos Papanastasiou

This paper studies how platform competition shapes information provision strategies in freelance marketplaces. We introduce a novel steady-state model in which competing platforms choose how to disclose freelancer quality information to heterogeneous consumers. Although the problem of computing competitive equilibria that involve endogenous information provision is inherently infinite-dimensional and seemingly intractable, we demonstrate that it can be reduced to a finite-dimensional convex quadratic program. This structure allows us to solve for competitive equilibria efficiently, extracting the main effects of platform competition. When the number of competing platforms is small, we find that equilibrium information policies involve significant levels of obfuscation in order to create the most profitable “product lines” (as in the case of platform monopolies). However, as the number of competing platforms increases, we show that platforms adopt increasingly transparent information policies. This transparency improves the efficiency of matching between service providers and consumers and decreases transaction prices, increasing total welfare and consumer surplus, but significantly decreasing total platform revenues. Furthermore, in markets characterized by asymmetric platform costs, specialization emerges, with lower-cost (higher-cost) platforms concentrating on higher-quality (lower-quality) freelancers. At the same time, asymmetric decreases in platform costs do not necessarily translate to increases in total welfare or consumer surplus.

1 - Strategic Rating Effort and Platform Revenue in Gig Markets: A Stackelberg Mean Field Game Approach

Joohyun Kim, University of North Carolina at Charlotte, Charlotte, NC, United States, Monica Johar, Vijay Mookerjee

Digital labor platforms have redefined traditional employment by introducing decentralized, task-based work arrangements, where platform ratings play a central role in shaping worker incentives and outcomes. In this paper, we model a dynamic competition among gig workers who strategically choose their continuous effort levels to improve platform ratings that depend on both their own efforts and those of other workers. Meanwhile, the platform sets its commission rate based on the aggregate rating outcome, aiming to optimize revenue. To analyze this interdependent system, we formulate a Stackelberg Mean Field Game (MFG) that captures the strategic interactions between a large population of homogeneous agents and the platform. Within a linear-quadratic control setting, we derive closed-form expressions for agents' optimal effort levels and their steady-state rating trajectories. We also determine the platform's optimal commission rate under steady-state dynamics. Finally, we quantify the inefficiency arising from decentralized decision-making through the Price of Anarchy (PoA), highlighting the gap between individual incentives and socially optimal outcomes. Our findings offer insights into three key questions: (1) how agents adjust their effort in response to rating-based incentives when dynamically interconnected; (2) how platform-designed commission policies influence long-term agent engagement and revenue; and (3) how PoA can guide platform design to mitigate inefficiencies in gig ecosystems.

2 - Phantom Capacity: Informational Cost of Multihoming on Ride-Hailing Platforms

Jaelynn Oh, Wake Forest University, Winston-Salem, NC, United States

This paper examines the phenomenon of multihoming among drivers on ride-hailing platforms—where drivers simultaneously operate on multiple platforms. While multihoming can obscure real-time availability, leading to inefficiencies in matching supply with demand, it also enhances overall system efficiency by effectively pooling driver capacity across platforms. We investigate this fundamental trade-off between reduced matching accuracy and increased resource availability.

3 - A Game-Theoretic Analysis of Pricing in Blockchain-Based Storage Sharing Platforms

Kun Soo Park, Seoul National University, Seoul, Korea, Republic of, Youngjae Jang, Jaegung Sim, Daegon Cho

As data storage demands grow, blockchain-based peer-to-peer (P2P) storage platforms offer alternatives to traditional cloud services but face challenges in ensuring reliable availability. This study analyzes how three pricing schemes—two-part tariff, subscription, and hybrid—affect short-term profits and overall welfare in P2P markets. Using a game-theoretic model, we find that two-part tariffs maximize platform profits, while subscription pricing benefits renters most. Total welfare depends on provider availability: subscription excels when providers are plentiful, whereas hybrid or two-part tariffs perform better with scarcity. These findings guide early-stage platforms in balancing profit and user growth based on provider and renter dynamics.

4 - When Data Can't Flow Upstream: Implications of API Training Restrictions on GenAI Providers

Zhe Wang, City University of Hong Kong, Hong Kong, Hong Kong, Yi Gao, Xinxin Li

This study examines the strategic and welfare implications of restricting generative AI (GenAI) companies from using API-generated data for model training. Motivated by emerging debates and the conflicting reality, we develop a game-theoretic model featuring a foundation model provider, a developer, and consumers with heterogeneous preferences. The provider offers its base model through API licensing to the developer, who builds upon it to provide a differentiated service. We compare two regimes: a regime where the provider can use API-generated data for training, and a restricted regime where such usage is prohibited. Our analysis reveals that restricting API data for training may paradoxically enhance the foundation model's service quality. However, we also show that under certain conditions, despite alleviating privacy concerns, such a restriction may reduce consumer surplus by limiting product differentiation. Our findings offer actionable insights for AI providers, developers, and policymakers navigating data governance in GenAI ecosystems.

1 - A Physically and Socially Inspired Hybrid Model for Trajectory Prediction of Neighboring Vehicles in Autonomous Driving

Yuhao Li, School of Transportation, Southeast University, Nanjing, China, People's Republic of, Wang Jian, Zhening Liu

Predicting the motions of surrounding human-driven vehicles is vital for path planning and collision avoidance of autonomous driving systems in mixed flow scenarios. However, accurately predicting the trajectories of surrounding vehicles still remains as a challenging research issue due to the complex dynamics of vehicle interactions and heterogeneity of different drivers' driving styles in real-world driving scenarios, particularly when striving for socially and compliant personified predictions. To tackle this challenge, we propose an innovative multimodal hybrid model for collaboratively predicting the trajectories of neighboring vehicles. Inspired by the Potts model in physics, we perform graph-structured encoding on the directly obtainable features from each neighboring vehicle, including position, velocity, acceleration, as well as drivers' personalized characteristics such as driving style and intention. Moreover, the concept of Blau Space from sociology is incorporated to aggregate the encoding results of these heterogeneous features. The aggregated features are then processed through several Spatio-Temporal Graph Convolutional Network (STGCN) layers and spatio-temporal transformer layers to capture the dynamic interactions among neighboring vehicles and across the global traffic environment, respectively. Finally, the candidate predicted trajectory with the highest probability is selected based on the negative logarithmic likelihood calculation results. Experimental results on the NGSIM

and highD datasets demonstrate that the proposed model outperforms seven selected baseline models. Furthermore, ablation studies are conducted to validate the effectiveness of model design.

2 - A Real-TIME Control to Connected Automated Vehicles Operation in Roundabouts

Abdullah Farabi, NC State University, Raleigh, NC, United States, Ali Hajbabaie

This study presents an efficient control framework for connected and automated vehicles (CAVs) operating in roundabouts. A throughput-maximizing optimization model is developed that utilizes vehicle state information (position and speed) to determine optimal safe trajectories. The model, being non-linear, requires efficient techniques for practical implementation. First, the problem is simplified using Frenet coordinates, reducing the two-dimensional spatiotemporal domain to a single dimension. A safe trajectory construction heuristic is then applied to solve the simplified model. This heuristic ranks CAVs based on their proximity to potential conflict points within the roundabout and generates trajectories sequentially according to this priority. The constructed trajectories satisfy both kinematic feasibility and safety constraints. To address uncertainties in the system, a receding horizon control framework is integrated into the approach. The proposed framework is evaluated against conventional roundabout operations. A case study results show improvements across several performance metrics, including delay, number of stops, travel time, and throughput. Moreover, the framework, exhibiting computational efficiency, supports its potential use for real-time deployment. Overall, this research contributes a practical and scalable solution for enhancing roundabout operation through an intelligent CAV coordination framework.

3 - Accelerating the Net-Zero Pathway via Technology-Driven Transition: A CGE-Based Analysis of the Steel Sector

Yoonha Lee, Seoul National University, Seoul, Korea, Republic of, Yoonmo Koo

This study applies a dynamic Computable General Equilibrium (CGE) model to analyze Korea's steel sector transition under carbon neutrality targets. The model structurally differentiates three production technologies—BF-BOF, DRI-EAF, and H₂-DRI-EAF—by assigning each as an individual sector and nesting them within a CES production structure. Although technological change is not endogenously determined in standard CGE frameworks, the model design introduces a competition-like mechanism by embedding distinct input characteristics based on disaggregated data. This setup allows the simulation of technology diffusion without relying on exogenously imposed adoption rates, distinguishing it from conventional approaches.

The scenario analysis includes a baseline reflecting Korea's 2050 net-zero power mix, along with policy packages that combine carbon pricing and technology-specific efficiency improvements.

Results indicate that carbon pricing alone induces only limited technological shifts. However, when combined with efficiency gains in hydrogen production and steelmaking, the hydrogen-based route achieves a meaningful market share by 2050 without imposing significant economic costs. Emissions are substantially reduced while macroeconomic performance remains stable, underscoring the importance of coordinated policy mixes over standalone instruments.

4 - Navigating the Future of Transportation Technologies: Translating Expert Knowledge into Actionable Scenarios

Farah Naz, University of Texas at Arlington, Arlington, TX, United States, Stephen Mattingly, Kate Hyun

The rapid evolution of transportation technologies necessitates a proactive approach from agencies to navigate an uncertain future. Given the scarcity of historical data for predictive modeling, understanding subject matter experts' (SMEs) perspectives is crucial for aligning infrastructure and policy with societal and economic objectives. This study introduces a framework to translate SME insights, gathered via surveys, into practical scenarios that guide future transportation planning.

The research employs hierarchical clustering, an unsupervised machine learning technique, to develop unbiased scenarios. Initially, SME responses were grouped based on their answers across four key attributes: preferred technologies, anticipated goals, effective solution strategies, and impactful technologies. A subsequent granular analysis examined each attribute individually to identify any overlooked scenarios. The final scenarios are derived from both the complete dataset and its subsets, emphasizing significant patterns within crucial clusters.

To manage mixed data types, the Gower distance method was used, handling both categorical and numerical data effectively. The Ward's minimum variance method (Ward2) served as the linkage function, minimizing within-cluster variance and resulting in six distinct clusters. Validation techniques including Average Silhouette Width, Gap Statistics, and the Calinski-Harabasz Index confirmed the optimal number of clusters and consistency of the derived scenarios, each illustrated with practical examples.

These scenarios offer a structured framework for stakeholders in transportation planning and policymaking, aligning technology adoption with expert insights and strategic goals. This study offers a methodological contribution to scenario analysis and a thorough understanding of expert-driven forecasts in transportation technology planning, providing strategic insights for future development.

5 - Efficiency Gains OR Behavioral Losses? Experimental Evidence of the Energy Rebound Effect Among Polish Participants

Umar Ashraf Rana, Faculty of Economic Sciences, University of Warsaw, Warsaw, Poland, Bartlomiej Dessoulavy-Sliwinski

This study experimentally investigates the rebound effect arising from adopting energy-efficient technologies, introducing a novel production-oriented framework primarily focused on Poland, supplemented by comparative data from Spain, Uruguay, and the Dominican Republic. Departing from conventional consumption-focused approaches, we employ a laboratory-based Two-Factor Production Technology task (2FPT). Participants engage in solving visual puzzles under constrained time and brightness conditions, with brightness levels serving as a proxy for costly energy consumption decisions.

The experiment comprises ten rounds divided into baseline (fixed brightness price) and two treatment conditions: a reduced price scenario (PD) and a reduced price scenario incorporating explicit environmental externalities (PD-E). Specifically, we examine whether Polish participants under the PD condition significantly increase brightness consumption without corresponding gains in productivity (H1), and whether integrating environmental externalities into pricing (PD-E) effectively curbs this rebound behavior (H2). Additionally, we assess cross-country heterogeneity (H3), hypothesizing greater responsiveness to externalities in countries with higher renewable energy usage. Finally, the study explores cognitive factors, predicting a negative correlation between inefficient brightness consumption and participants' energy literacy and fluid intelligence scores (H4).

Focusing primarily on Poland, this research sheds light on behavioral mechanisms underlying energy efficiency adoption, the effectiveness of environmental externalities in mitigating rebound effects, and the role of individual cognitive characteristics in shaping sustainable production decisions.

6 - Algorithmic Nudging for Energy Savings and Environment: Evidence from An Iot Platform

1 - Cnn-Based Path Planning for Unmanned Aerial Vehicle Routing

Matthias Winkenbach, Massachusetts Institute of Technology, Cambridge, MA, United States, Rodrigo Hermosilla

Unmanned aerial vehicles (UAVs) for last-mile delivery face complex routing challenges in urban environments, including regulatory altitude restrictions, obstacle avoidance, and noise mitigation requirements. We present a novel application of convolutional neural networks (CNNs) with spatial attention mechanisms to optimize UAV routing decisions while maintaining compliance with urban airspace regulations. Our approach extends existing CNN-based path planning by incorporating altitude awareness into the path finding process, transforming the traditional 2D planning problem into a more nuanced 3D routing framework. The model accounts for various regulatory constraints derived from aviation guidelines, including altitude limitations, clearance requirements around structures, and designated no-fly zones. The proposed architecture employs a U-Net backbone with spatial attention mechanisms that dynamically highlight critical routing information while maintaining awareness of the three-dimensional environment. By training on high-quality solutions derived from traditional optimization methods, our CNN can generate compliant flight paths with inference times suitable for real-time applications. This research bridges the gap between theoretical path planning algorithms and practical urban airspace management, offering a scalable solution for future UAV delivery operations. The approach balances computational efficiency with regulatory compliance, providing a foundation for safe, efficient autonomous aerial delivery in complex urban environments.

2 - Joint Inventory Routing for EV Battery Swapping Networks with Hybrid Charging

Long He, George Washington University, Washington, DC, United States, Ningwei Zhang, Shanshan Wang, Yuli Zhang

We study a joint inventory-routing problem for electric vehicle (EV) battery swapping systems that feature hybrid charging, where batteries may be charged either on-site at local stations or centrally at a depot, under uncertain vehicle arrival rates and stochastic battery charging durations. The system comprises a central charging station and multiple battery swapping stations, each experiencing random demand and constrained by service-level requirements. Returned batteries with short charging times are charged locally, while those exceeding a threshold are routed to the central station, introducing a two-echelon logistics structure with state-dependent flows.

We develop a two-stage optimization model that simultaneously determines the battery delivery routes and inventory replenishment levels across the network. The model incorporates a probabilistic stockout constraint to ensure high service quality and accounts for the impact of hybrid charging on inventory pooling and routing efficiency. To address the problem's non-convexity and computational complexity, we derive closed-form approximations for service-level constraints and reformulate the problem using second-order cone programming. We further propose an efficient branch-and-cut algorithm enhanced with extended polymatroid cuts to improve tractability and scalability.

Our model generalizes existing battery logistics frameworks by integrating hybrid service modes, stochastic charging durations, and routing constraints into a unified optimization framework. Numerical results demonstrate the operational benefits of hybrid charging and validate the effectiveness of the proposed solution approach. This work provides a tractable, analytically grounded method for managing EV battery logistics in urban mobility systems under uncertainty.

3 - Measuring the Value of Information Systems for Virtual Power Plants: the Case of Electric Vehicle Aggregators

Diego Cebreros, CentraleSupélec Université Paris Saclay, Gif-sur-Yvette, France, Jan Lepoutre, Yannick Perez

The transition toward low-carbon energy systems increasingly relies on digital solutions enabling flexible use of distributed energy resources. One promising avenue is aggregating Electric Vehicle (EV) batteries into Virtual Power Plants (VPPs), allowing coordinated charging and discharging to support grid stability and renewable energy integration. This paper investigates the role of information systems (IS) in enabling such coordination, focusing on how enhanced communication affects system performance and value creation. We develop a simulation framework modeling interactions among EV aggregators, electricity system operators, and EV users. The framework captures operational constraints—such as grid reliability and market signals—and user mobility requirements. By evaluating scenarios beyond current communication standards, we quantify the value of different scenarios of information exchanges. Our findings show that improved IS can significantly increase aggregator profitability—doubling it in some cases—while better aligning energy dispatch with renewable generation. This study contributes theoretically by introducing a novel simulation-based framework to assess the value of information in settings where EV owners' mobility behavior is independent across actors, rendering statistical knowledge of the fleet insufficient for accurate prediction. It also has practical implications for IS architecture design in energy-mobility integration and provides insights for policymakers and firms developing IS standards for VPPs.

4 - Estimating the Effects of Congestion Pricing Using Predicted Counterfactuals

Julius Kuhmann, University of Cologne, Cologne, Germany, Gordon Burtch, Wolfgang Ketter

Evaluating the effects of policy interventions in urban mobility can present methodological challenges, particularly due to the lack of suitable control observations. Even when interventions are geographically localized, the highly interconnected nature of mobility systems often precludes surrounding areas from serving as valid counterfactuals. Consequently, many conventional methods from the causal inference toolkit cannot be readily applied in such settings.

We address this issue in the context of New York City's congestion pricing program, implemented in early 2025, which introduced a fee for vehicles entering Manhattan's central business district. To estimate the program's short-term impact on mobility behavior, we adopt a machine learning-based approach that predicts counterfactual outcomes using historical pre-intervention data. This method allows us to gain insights on the effect of the policy despite the absence of a traditional control group.

Focusing on ride-hailing activity, we document substantial changes in ridership volumes following the policy's implementation. Our findings demonstrate the potential of predictive, data-driven methods to support causal inference in complex urban environments where traditional approaches fall short.

2 - Should You use LLMs to Simulate Opinions? Quality Checks for Early-Stage Deliberation

Terrence Neumann, University of Texas at Austin, Austin, TX, United States

The emergent capabilities of large language models (LLMs) have sparked interest in assessing their ability to simulate human opinions in a variety of contexts, potentially serving as surrogates for human subjects in opinion surveys. However, previous evaluations of this capability have depended heavily on costly, domain-specific human survey data, and mixed empirical results about LLM effectiveness create uncertainty for managers about whether investing in this technology is justified in early-stage research. To address these challenges, we introduce a series of quality checks to support early-stage deliberation about the viability of using LLMs for simulating human opinions. These checks, designed to evaluate Likert-scale opinion data, emphasize **logical consistency**, **prompt stability**, and **alignment with stakeholder expectations of model outputs**, thereby reducing dependence on human-generated data in the initial stages of evaluation. We demonstrate the usefulness of the proposed quality control

tests in the context of AI-assisted content moderation, an application that both advocates and critics of LLMs' capabilities to simulate human opinion see as a desirable potential use case. None of the tested models passed all quality control checks, revealing several failure modes. We conclude by discussing implications of these failure modes and recommend how organizations can utilize our proposed tests in their risk management practices when considering the use of LLMs for opinion simulation. We make our crowdsourced dataset of claims with human and LLM annotations (**TopicMisinfo**) publicly available for future research.

3 - AI Generated Content and Home Bias: Answer Inclination on Q&A Websites

Vincent Zhao, University of Florida, Gainesville, FL, United States, Jingchuan Pu

Knowledge Sharing or Q&A websites are popular venues for users to seek professional help in answering their questions. Answering questions is a non-trivial task that is significantly costly in terms of time and cognitive effort. With the introduction of AI Generated Content (AIGC) from large language models (LLMs) such as ChatGPT, the cost for providing answers has dramatically decreased. Users can use LLMs to help research, write, and format responses reducing cognitive burden. In this paper, we identify the effect that the presence of LLMs has on user home bias in a Q&A website. We show that after the existence of ChatGPT, users' home bias in answering questions has significantly changed.

1 - How Does a Successful Initial Coin Offering (Ico) Event Affect Blockchain-Related Firm's Stock Market Return?

Lingyu Li, Virginia Commonwealth University, Richmond, VA, United States

This paper studies the impact of successful ICO events on the equity returns of blockchain-related firms. We use 494 successful ICOs from 2018 to 2023 and estimate cumulative abnormal returns (CARs) over a [-30, +30] days event window using the market model, Fama-French 3-factor, and 5-factor models. Results show significant positive CARs, with 0.227% on the event day and 0.495% over the 30-day window (Fama-French 3-factor), indicating that the blockchain stock market positively values ICOs. Random effects regression reveals stronger positive reactions when ICOs exhibit greater rating variance and raise more capital, while bonus offerings in the ICOs are associated with weaker reactions. These findings suggest that perceived evaluation credibility and financial commitment enhance market valuation, whereas offering bonus in ICOs may signal lower project quality and reduce market valuation.

2 - The Differential Effect of Developer Expertise on The Knowledge Creation in Open Source Software (OSS) Development

Orunc Temizkan, Özyeğin University, Istanbul, Turkey, Ram Kumar

OSS projects depend on contributions from software developers with expertise in different knowledge areas to facilitate knowledge creation. Prior research has illustrated that network structure is related to knowledge creation in the context of OSS development. However, the effect of developer expertise is under researched. A developer may have deep knowledge in a specialized knowledge area as well as broad knowledge in several generalized knowledge areas. Knowledge transfer between developers to facilitate project success depends on the depth and breadth of knowledge that individual developers have as well as their position in the network. We examine the effect of developer expertise through their contribution to different activities on project success in the context of OSS development. We also empirically illustrate the differential impact of developer expertise (in terms of breadth and depth of knowledge) on project success. Data collected from GitHub projects, which is a leading OSS hosting website, is used to illustrate these effects. Research and managerial implications will also be discussed.

3 - A Data-Centric Framework for Reproducible Machine Learning in Interdisciplinary Collaborations

Zhiwei Li, Viterbi School of Engineering, University of Southern California, Los Angeles, CA, United States, Carl Kesselman, Tran Huy Nguyen, Benjamin Y. Xu, Kyle Bolo

As machine learning (ML) becomes increasingly central to high-impact domains such as healthcare, concerns about reproducibility and social consequences have grown. ML development often involves interdisciplinary teams of domain experts, ML engineers, and data managers who iterate over data, models, and decisions. This exploratory process introduces challenges in maintaining consistency, traceability, and accountability, especially when early-stage errors propagate across the lifecycle and undermine confidence in outcomes.

This work introduces a data-centric framework that supports reproducibility by treating data artifacts as evolving rather than static. The framework is centered on six core artifact types—Dataset, Feature, Workflow, Execution, Asset, and Controlled Vocabulary—which are independently versioned and tightly linked to unify activities across the ML lifecycle. By modeling the relationships among these artifacts, the framework captures the evolution of data, code, and decisions across roles, enabling teams to trace modeling rationale and revisit past iterations. This structure aligns human and technical workflows through traceability, transparency, and decision accountability.

The framework is implemented in Deriva-ML, a data-centric information system that automates full-lifecycle experiment tracking. We evaluated our approach in a clinical application that uses AI models and retinal images to diagnose glaucoma, supporting tasks such as feature extraction, manual label refinement, and robustness evaluation. This evaluation demonstrates how the framework can enhance reproducibility and interdisciplinary collaboration in ML workflows across domains where reliable, transparent decision-making is critical.

4 - Cohesion OR Equivalence? the Social Network Mechanisms Driving Innovation Diffusion Among Talents in Quantum Communication

Zhuyan Hui, Renmin University of China, Beijing, China, People's Republic of, Zhiyang Liu, Xuansheng Wang, Zengxiang Shi, Lifan Chen

Quantum communication, due to its theoretically absolute security, has become a pivotal area in international competition for safeguarding national information security. Attracting and continuously stimulating innovative talents is crucial for advancing this field, yet the underlying mechanisms remain underexplored. Grounded in social influence theory, this study examines how social influence within research networks affects talents' entry into the quantum communication field and their innovative productivity, and further investigates the moderating role of triple helix (government-industry-university) collaboration. Analyzing panel data of 1,160 researchers across ten countries from 2016 to 2021, we reveal three primary findings: (1) Innovations produced by collaborators and structurally equivalent peers positively influence focal researchers' own productivity; (2) Strong government-industry-university collaboration negatively moderates the influence of collaborators' innovation outputs on focal researchers' productivity, but has limited effect on structurally equivalent peers; (3) Both collaborator and structurally equivalent peer innovations significantly encourage new talent entry into quantum communication, with stronger triple helix collaboration enhancing this effect. This research contributes to understanding the dynamics of talent acquisition and innovation diffusion in quantum communication, providing practical guidance for institutional collaboration. Specifically, we uncover a dynamic "early-stage stimulation and later-stage inhibition" pattern in the role of government-industry-university cooperation on talent development, suggesting the need for dynamically adjusting collaboration strategies in line with national development stages in the quantum communication field to optimize innovation outcomes.

5 - Tipping vs. Subscription System on Video Streaming Platforms: a Game-Theoretic Analysis

Tomoyuki Ichikawa, Keio University, Yokohama, Japan, Nobuo Matsubayashi

In recent years, many video streaming platforms have introduced tipping systems, such as YouTube's Super Chat and TikTok's Gift. These systems allow consumers to donate to content creators, and the platforms earn revenue by receiving a portion of the tips as a commission. This study conducts a game-theoretic analysis to investigate the profitability of the tipping system for platforms and content creators compared to the subscription system. Specifically, we analyze an equilibrium of game where two symmetric platforms can adopt either a tipping or subscription system. Our results reveal that platforms are likely to benefit from adopting tipping systems under a

duopoly and subscription systems under a monopoly. Additionally, we show that, under a duopoly and when content is less differentiated and the number of content creators is large, the tipping system achieves a win-win outcome for platforms and content creators.

6 - Don't Kill the Game: Strategic Cheat Pricing Under Network Effects

Jing Hou, California State University, San Marcos, San Marcos, CA, United States, Thanh Nguyen

The rapid growth of online gaming has been accompanied by a significant rise in cheating, driven by a market for third-party tools that give users unfair advantages through cheating add-on software. Unlike traditional malicious hackers who seek to disrupt target systems, cheat developers operate parasitically: their profits depend on the continued participation of honest players and the long-term viability of the game ecosystem. Excessive cheating degrades gameplay quality, prompting regular players to leave and ultimately reducing the profitability of cheating software.

This study develops a game-theoretic model to examine the optimal pricing strategy for cheat developers in the presence of both cheating and non-cheating players. The model incorporates three network effects: (1) a positive direct effect, where gameplay becomes more enjoyable as the number of regular players increases; (2) a negative indirect effect, where the prevalence of cheating reduces enjoyment for regular players; and (3) a positive indirect effect, where the value of cheating increases with the number of regular players. We model a Stackelberg game in which the cheat developer acts as a leader, setting prices while anticipating the strategic responses of heterogeneous players. Our findings offer new insights into the dynamics of cheating in online games and illustrate how cheat developers are strategically exploiting the gaming ecosystems to maximize their profit.

1 - Path Planning for Tethered Unmanned Systems in Partially Known Environments

Sachet Khatiwada, Clemson University, Clemson, SC, United States, Pamela Murray-Tuite, Matthias J. Schmid

The use of unmanned aerial vehicles (UAVs) and unmanned ground vehicles (UGVs) in a tethered system benefits both vehicles. The advantages for the UAV are the possibility to off-load computations to the UGV and siphon power from the UGV to increase flight time. The UGV benefits from the information obtained by the UAV from a higher vantage point, which is beneficial in partially known environments. We propose a path planning framework for such systems operating in partially known environments. We use the a priori information about the environment to generate a collision-free global path for the tethered UAV-UGV system. Then we rapidly replan to avoid newly detected obstacles as the tethered system moves along the original global plan. We use a hybrid approach that benefits from the rapid exploration of the RRT* algorithm to generate the global plan, then we leverage the random tree it generates alongside a mixed integer quadratic programming model to rapidly replan for a collision-free final path.

2 - Mixed Traffic Assignment Under Connected and Autonomous Environment: Model and Algorithm

Zhenning Liu, Southeast University, Nanjing, China, People's Republic of, Wang Jian, Yuhao Li

With the increasing penetration of connected and autonomous vehicles (CAVs), traffic systems will involve a mix of human-driven vehicles (HDVs) and CAVs. Due to the significant differences between human-driven vehicles and CAVs in driving characteristics and route choice behaviors, traffic dynamics and network flow will undergo profound changes. This study develops a mixed traffic assignment model that incorporates both HDVs and CAVs, along with a corresponding fast-solving algorithm. The model is built upon an analysis of mixed traffic flow characteristics, focusing on how CAV platooning and aggregation affect road capacity and travel impedance. HDV users and CAV users follow different route choice principles, described by the stochastic user equilibrium model and the user equilibrium model, respectively. To address the low precision and slow convergence issues in traditional mixed traffic assignment methods, a revised gradient projection algorithm is proposed, which incorporates second-order derivative information to enhance convergence speed, improve solution accuracy, and reduce computational time. Numerical examples in the Sioux-Falls

network and Ningbo city networks demonstrate that the proposed revised gradient projection method achieves an order-of-magnitude improvement in accuracy over the route swapping algorithm. Compared to existing algorithms, the computation time for the same level of accuracy is reduced by 91.1% and 92.4%, respectively.

3 - Modeling the Fundamental Diagram in Pure Cav Multi-String Traffic Environment with Lane-Changing Considerations

Ruining Yang, Georgia Institute of Technology, Atlanta, GA, United States, Yongyang Liu, Srinivas Peeta

Recent advances in connected autonomous vehicles (CAVs) provide a promising opportunity for leveraging automated vehicle platoons to improve roadway capacity, driving safety, and energy efficiency. However, existing studies fail to consider the impacts of lane-changing maneuvers on the dynamics of platooning, as such maneuvers tend to disrupt platoons and increase the inter-platoon spacing for speed harmonization across lanes. As a result, the heterogeneous platoon sizes and non-uniform inter-platoon spacing make it challenging to estimate the Fundamental Diagram (FD), which limits the utility of FD in determining the optimal platoon size at the macroscopic level. To bridge this gap, this paper theoretically analyzes the dynamics of platooning with the corresponding FD under the impacts of lane-changing maneuvers in multi-string environments. First, we develop a probabilistic model to characterize the distribution of platoon sizes as a function of lane-changing frequency, thereby quantifying the disruptive impact of lane changes on platoon formation. Second, to account for the additional spacing introduced by lane-changing maneuvers, we propose the concept of effective spacing based on minimum-energy principles, from which we derive the relationship between traffic flow and cruising speed. Third, we investigate the impact of lane-changing frequency and the maximum allowable platoon size on the shape and evolution of the FD. Theoretical derivations and simulation results are used to support platoon management in multi-string environments by providing quantitative insights into how lane-changing behaviors influence traffic flow and overall roadway capacity.

4 - Evaluating the Impacts of Mental Stress on Car-Following Performance Under Cav Cyberattacks in Mixed-Flow Traffic

Yangjiao Chen, Georgia Institute of Technology, Atlanta, GA, United States, Shubham Agrawal, Irina Benedyk, Srinivas Peeta

As connected and automated vehicles (CAVs) become increasingly prevalent, their susceptibility to cyberattacks introduces new safety challenges. While analytical methods for detecting such threats are advancing, there is little literature on the psychological effects of these disruptions on human drivers. Given the rarity and unpredictability of real-world CAV cyberattack scenarios, this study employs interactive, simulator-based experiments to investigate human responses when following compromised CAVs. A high-fidelity, human-in-the-loop driving simulator—integrating real-world SAE Level 4 vehicle trajectories—is employed to assess the effects of ongoing cyberattacks on car-following behavior. The simulator is equipped with in-vehicle driver monitoring systems that capture multimodal physiological data, including eye-tracking, electrocardiography (ECG), and electroencephalography (EEG), to assess mental stress. Eye-tracking features (e.g., fixation patterns, blink rates), heart rate variability (HRV) derived from ECG, and changes in brain activity from EEG, are analyzed. These physiological indicators are validated against behavioral measures (e.g., reaction time) and subjective assessments (e.g., post-drive questionnaires). Car-following performance is quantified using metrics including mean headway distance, headway variance, and root-mean-square (RMS) velocity error. The results indicate significant changes in driving performance when drivers perceive CAVs to be compromised by cyberattacks. These findings provide actionable insights for the development of adaptive vehicle interfaces and mitigation strategies that enhance driver safety and performance under cyber-physical disruptions.

5 - Human-like Lane-Change Control Strategy for Connected and Autonomous Vehicles to Improve Interactions with Human-Driven Vehicles

Yongyang Liu, Georgia Institute of Technology, Atlanta, GA, United States, Srinivas Peeta

Connected and autonomous vehicles (CAVs) promise enhancements to traffic safety, efficiency, and smoothness. However, their coexistence with human-driven vehicles (HDVs) in mixed-traffic environments presents significant challenges such as weakened CAV control performance and induced mental discomfort for HDV drivers, particularly during lane changes. To address these challenges, this study proposes a human-like lane-change control strategy (HLCS) for CAVs to integrate human intelligence and cognition with advanced CAV capabilities (in situational awareness and reaction times) to produce human-like lane-change behavior, improving CAV-HDV interactions and promoting smooth integration of CAVs into existing traffic flow. Operating within a theory of mind framework, the HLCS introduces human-like reasoning into CAV operations. It first develops a human-like lane-change model (HL-LCM) that combines the enhanced control of robot driving and the human expertise of natural human driving. The model produces human-like lane-change maneuvers to improve CAV performance and mitigate HDV drivers' mental discomfort. Further, the HLCS proposes a HDV behavior predictor that learns human driving patterns to model human decision-making. By anticipating HDV responses to CAV lane changes, the HL-LCM performs informed and adaptive maneuvers that mitigate disruptions and maintain traffic smoothness. Numerical experiments illustrate that HLCS can leverage rich human driving experience and advanced CAV capabilities to improve CAV-HDV interactions in lane changes, resulting in fewer traffic oscillations and enhanced safety, CAV smoothness, and mental comfort for HDV drivers. The study provides insights for developing human-like CAV systems to manage complex interactions with HDVs, to promote human-friendly mixed-traffic environments.

6 - Revisiting Followerstopper: Phase-Space Based Traffic Decongestion Controller

Rahul Bhadani, The University of Alabama in Huntsville, Huntsville, AL, United States

We provide a detailed description of the control law in the Followerstopper, a velocity controller based on the phase-space, that demonstrated its ability to mitigate emergent traffic jams due to stop-and-go traffic during rush hour in the mixed-autonomy setting. We deployed the Followerstopper on an autonomous vehicle to follow human drivers. The controller attenuates the emanant traffic waves by regulating its velocity according to the relative distance and velocity of the leader car. While controlling the velocity, the controller also prevents the collision of the ego vehicle with the lead vehicle within the range specified by the controller's design parameter. The controller design is based on the relative distance-relative velocity phase-portrait that allows the transition of the regulated velocity from (i) no modification of the desired maximum velocity, (ii) decelerating to match the leader's velocity; (iii) braking to avoid an imminent collision. Further, we explore the phase-space properties of the Followerstopper and provide a detailed description of a nonlinear control law that regulates the reference input to the Followerstopper within the physics-informed boundaries to prevent any unsafe behavior or imminent collision.

1 - Fresh Produce Spatial Price Equilibrium on General Networks: Capturing Commodity Quality Deterioration Through Endogenous Transportation TIME Delay Functions with Capacities

Samirasadat Samadi, University of Massachusetts Amherst, Amherst, MA, United States, Anna Nagurney, Deniz Besik

Fresh produce is vital to global food security but is highly vulnerable to transportation delays and capacity disruptions, as in critical links such as the Panama Canal. This paper develops a multicommodity fresh produce trade equilibrium model under quality deterioration on a general network, allowing for multiple transportation links on a path between supply and demand markets. We extend the Bureau of Public Roads (BPR) congestion function to endogenize time delay as a function of all commodity shipments on a link. By embedding link upper bounds in time delay functions, we capture how upper bounds impact transportation times and fresh produce quality. The spatial price equilibrium conditions are formulated as a variational inequality problem. We also propose commodity quality trade network performance measures — supply-based, demand-based, and network-based — that can be applied for an individual commodity or across all commodities. We apply the model to bananas, a globally popular and nutritious fruit, and its trade from Ecuador and Costa Rica to the European Union, the United States, and Russia, focusing on drought-driven congestion at the Panama Canal. Numerical scenarios show that reductions in transportation link upper bounds significantly lower banana shipments, degrade their quality, and shift prices at both supply and demand markets. The results align closely with real-world data on banana prices, transportation costs, and export volumes, reinforcing the model's

practical relevance. Our model provides decision-makers with essential insights on the impacts of congestion and increasing transportation times on fresh produce trade and its quality, along with the performance of the trade network.

2 - Generative AI-Driven Stochastic Maritime Route Optimization Under Environmental Uncertainty for Fuel Efficiency

Hyunha Lee, Pusan National University, Busan, Korea, Republic of, Dohee Kim, Yongjae Lee, Hyerim Bae

As maritime trade volume continues to grow, carbon emissions from the shipping industry are increasing accordingly. To address this challenge, the International Maritime Organization (IMO) has implemented stricter environmental regulations, including the Carbon Intensity Indicator (CII) and the Ship Energy Efficiency Management Plan (SEEMP). These developments necessitate transitioning from voyage planning focused on punctuality to strategies considering fuel efficiency and operational uncertainty. Prior research has predominantly employed deterministic approaches, which are limited in capturing uncertainties like route deviations caused by regional heterogeneity or environmental changes. While recent studies have introduced a stochastic generative artificial intelligence model, their disregard for fuel efficiency limits their usefulness in sustainable operations planning. To fill this gap, this study presents a data-driven framework that builds a dynamic maritime network using regional ocean characteristics such as congestion, environmental conditions, and interregional connectivity. A probabilistic route generation process is then employed to simulate feasible routes within the network. Each candidate route is assessed based on predicted fuel consumption, and the optimal route is chosen to minimize expected fuel consumption while adhering to punctuality constraints.

The proposed method is validated by using real-time sensor data from the Automatic Identification System (AIS) and Metocean datasets. The results demonstrate its effectiveness in generating operationally feasible routes optimized for fuel efficiency under uncertainty. Integrating stochastic modeling and predictive analytics into maritime network-based route optimization facilitates sustainable logistics practices aligned with environmental regulations. It also contributes to decision support systems that advance decarbonization in the shipping industry.

3 - Underground Freight Transportation for Middle Mile Delivery

Sarah Powell, University of St. Thomas, St. Paul, MN, United States, Ann Campbell

The use of underground tunnels for freight transportation is gaining attention in both industry and academia as a way to efficiently move packages between or within urban areas. We propose a new problem, the middle mile tunnel dispatching problem (MMTDP), to capture the use of tunnels between cities, inspired by the Cargo Sous Terrain project in Switzerland. We model this problem as an integer program with the objective of maximizing the demand volume that arrives at its destination by its primary deadline. In the MMTDP, vehicles carry pallets of goods between distribution centers in different cities. We evaluate the complexity of different variants of the MMTDP and provide a set of computational results to demonstrate the tunnel system's performance and the impact of different design parameters. We find that the size of tunnel vehicles significantly impacts the amount of demand that can be delivered by its deadline and a larger proportion of tunnel capacity can be utilized when there are more orders with short distances between origin and destination pairs. We offer managerial insights on dispatching strategies for linear middle-mile tunnel networks. For example, we show that it can be helpful to consolidate orders with the same origin, especially for small tunnel vehicle sizes, and the same origin and destination with larger tunnel vehicle sizes.

4 - Weather Impact on Fast Charging Infrastructure Planning for Large-Scale Electric Vehicle Fleets (Archive Only)

Gustavo Campos, National Renewable Energy Laboratory, Golden, CO, United States, Roberto Vercellino, Yanbo Ge, Monte Lunacek, Devon Sigler, Juliette Ugurumera, Margaret Mann

Fast charging technology is an essential component for promoting the rapid adoption of electric vehicles. Although shown to have a significant impact, weather conditions - particularly low temperatures - are often neglected in the literature due to the lack of experimental data. This work aims to fill this gap by investigating the impact of weather conditions or low-temperatures on fast charging infrastructure planning, particularly in the context of high-utilization fleets, such as airport rental car facilities, which may handle up to thousands of vehicles per day with quick turnaround times. A recently developed discrete event simulator is used to represent the operations of a large-scale electrified rental car facility, while a recently published experimental dataset is used to incorporate weather effects on fast charging curves. Different ways to perform the latter are discussed. Results demonstrate the impact of weather on infrastructure planning metrics, such as number of chargers, customer wait times, and station peak loads.

5 - Modeling Early-Stage Advanced Air Mobility for Commuting with Integrated Air-Ground Services

Bo Zou, University of Illinois Chicago, Chicago, IL, United States, Heeseung Shon, Danesh Hosseinpahani

This study proposes a mathematical framework for optimizing an Advanced Air Mobility (AAM)-embedded multimodal transportation system at an early-stage, focusing on coordinated operations between electric vertical take-off and landing aircraft (eVTOLs) and shuttle services for commuting between a suburb and the central business district in a metropolitan area. The framework addresses joint scheduling of air and ground vehicles to ensure first- and last-mile connectivity and meet commuter demand, as well as eVTOL charging and relocation to balance AAM supply and demand. An integer linear program (ILP) is formulated on a time-expanded network encompassing both air and ground operations. Given the numerous variables and constraints involved and the combinatorial nature of the ILP, commercial solvers can yield optimal solutions only for small instances. Recognizing the fact that the ILP involves only a few coupling constraints, a dual decomposition solution approach based on the Alternating Direction Method of Multipliers (ADMM) algorithm is devised. The approach decomposes the ILP into eVTOL operation, shuttle operation, and passenger routing subproblems. A subproblem is decomposed further into even smaller subproblems, each dealing with the routing of just an individual eVTOL, shuttle, and passenger group. We implement the ILP and the solution approach in the Chicago metropolitan area. The numerical results provide several insights into the practical implementation of integrated AAM systems and strategies to enhance the system operational efficiency and passenger satisfaction. The proposed solution approach is also found to significantly reduce the computation time while achieving near optimal solutions.

6 - The Geography of Transportation Cybersecurity: Visitor Flows, Industry Clusters, and Spatial Dynamics

Kailai Wang, University of Houston, Houston, TX, United States, Yuhao Wang

The rapid evolution of the transportation cybersecurity ecosystem—encompassing cybersecurity, automotive, and transportation and logistics sectors—has led to the formation of distinct spatial clusters and visitor flow patterns across the US. This study examines the spatiotemporal dynamics of visitor flows, analyzing how socioeconomic factors shape industry clustering and workforce distribution within these evolving sectors. To model and predict visitor flow patterns, we develop a BiTransGCN framework, integrating an attention-based Transformer architecture with a Graph Convolutional Network (GCN) backbone. Using SafeGraph's 2022 weekly visitor flow data along with additional socioeconomic indicators, we conduct a multi-scale spatial clustering analysis to identify distinct industry concentration trends, workforce mobility patterns, and geographic interdependencies across three key transportation cybersecurity-related industries. Our findings reveal that geolocation and education levels are the most significant factors influencing industry cluster formation. Furthermore, our predictive model anticipates a 14.16% average increase in visitor flow across the US in the next term, highlighting emerging industry growth, regional workforce shifts, and cross-sector innovation. By integrating AI-driven forecasting methods with spatial analytics, this study enhances our ability to track, understand, and anticipate shifts in industry clustering and mobility trends, supporting strategic planning for a secure and resilient transportation network. This research provides a data-driven foundation for economic planning, workforce development, and targeted investments in the transportation cybersecurity ecosystem.

7 - Neural Operators Struggle to Learn Complex Pdes in Pedestrian Mobility: Hughes Model Case Study

Prajwal Chauhan, New York University Abu Dhabi, Abu Dhabi, United Arab Emirates, Salah Eddine Choutri, Mohamed Ghattassi, Nader Masmoudi, Saif Eddin Jabari

This work investigates the limitations of neural operators in learning solutions for the Hughes model, a first-order hyperbolic conservation law for crowd dynamics. The model couples a Fokker-Planck equation representing pedestrian density with a Hamilton-Jacobi-type (eikonal) equation. The Hughes model belongs to the class of nonlinear hyperbolic systems that often exhibit complex solution structures, including shocks and discontinuities. In this study, we evaluate the performance of three state-of-the-art neural operators (Fourier Neural Operator, Wavelet Neural Operator, and Multi-wavelet Neural Operator) in various challenging scenarios. Specifically, we consider discontinuous and Gaussian initial conditions with diverse boundary conditions, while also examining the impact of different numerical schemes.

Our results show that these neural operators perform well in easy scenarios with fewer discontinuities in the initial condition, but struggle in complex scenarios with

multiple initial discontinuities and dynamic boundary conditions, even when trained specifically on such complex samples. The predicted solutions often appear smoother, resulting in a reduction in total variation and a loss of important physical features. This smoothing behavior is similar to what happens in models that introduce artificial diffusion, causing them to miss essential features, such as shock waves, in hyperbolic systems. These results suggest that current neural operator architectures may introduce unintended regularization effects that limit their ability to capture transport dynamics governed by discontinuities. They also raise concerns about generalizing these methods to traffic applications where shock preservation is essential.

1 - Large-Scale Evacuation with Electric Vehicles: Emerging Challenges in South Texas Disaster Management

Joon-Yeoul Oh, Texas A&M University-Kingsville, Kingsville, TX, United States, Olusola Ogungbeje, Delia Valles-Rosales, Nuri Yilmazer

The expanding adoption of electric vehicles (EVs) in the U.S. is transforming transportation by reducing reliance on fossil fuels and curbing emissions. However, concerns remain regarding vehicle range limitations, the vulnerability of the power grid during disasters, and gaps in charging infrastructure, all of which may compromise transportation reliability during large-scale evacuations for hurricanes, wildfires, or other emergencies. There is little evidence regarding the security, sustainability, and accessibility of EV charging stations during such events. The proposed study will estimate the number of EVs in the South Texas area by 2035 and investigate the impacts of emergency evacuations involving EVs and their charging stations during natural disasters. This research aims to assess the sustainability and accessibility of EVs during such events and to propose strategies for increasing accessibility in the South Texas region. The study will assist stakeholders in designing electric vehicle systems, including disaster-resilient infrastructure for EVs and charging stations, to mitigate risks and ensure safer, more inclusive evacuation strategies.

2 - Modeling and Solving the Electric Truck and Trailer Routing Problem Using Simulated Annealing with Extensions to Other EV Routing Variants

Ahmad Bassaleh, Wichita State University, Wichita, KS, United States, Mehmet Yildirim

The integration of electric vehicles (EVs) into logistics systems has accelerated in recent years, motivating the development of advanced routing models that account for energy limitations, charging times, and customer time windows. This study extends the classical Electric Vehicle Routing Problem with Time Windows (EVRPTW) to a variant based on the Truck and Trailer Routing Problem (TTRP). In this setting, trucks may carry detachable trailers that must be left behind and picked up later when visiting specific customers. We propose a novel mixed-integer linear programming (MILP) formulation that captures the operational constraints of electric trucks, including energy consumption, charging station usage, time window compliance, and trailer-handling logic. We develop a customized Simulated Annealing (SA) algorithm tailored to the problem structure. For benchmarking, we modified existing EVRPTW instances to incorporate trailer detachment constraints. The SA algorithm was applied to these extended instances, and its performance was evaluated through comparative analysis. To assess the generalizability of our approach, the same SA algorithm was also applied to standard EVRPTW instances. Results demonstrate that our method is competitive with existing solutions while offering greater modelling flexibility. This adaptability makes both the model and algorithm well suited to a broad range of electric vehicle routing scenarios, supporting the advancement of sustainable transportation systems.

3 - Two-Stage Stochastic EV Fleet Planning for E-Commerce Delivery via Predictive Learning

Manzi Li, University of Michigan, Ann Arbor, MI, United States

The escalating demand in e-commerce, coupled with the global push for sustainability, has made the operational planning of electric vehicle (EV) fleets a problem of critical importance. The inherent uncertainties in daily customer demand and potential charging station congestion make this a complex challenge. To capture this complexity, we formulate the EV fleet deployment and routing problem as a two-stage stochastic optimization model. The first-stage decisions determine the strategic fleet size and vehicle-to-depot assignments, while the second-stage recourse actions define the operational routing and charging schedules once demand is realized. However, the computational burden of solving such models prohibits their use in real-time decision-making environments. To overcome this, a novel machine learning framework is introduced in this paper. We first generate a comprehensive training dataset by solving numerous problem instances offline. A predictive model is then trained to learn the direct mapping from problem parameters to the optimal here-and-now decisions. In the online phase, these predictions are used to formulate a simplified, single-level optimization problem for the wait-and-see actions, which can be solved almost instantaneously. This approach transforms a computationally intractable problem into a practical, data-driven tool for dynamic and sustainable e-commerce logistics.

4 - Optimizing Fleet Composition and Charging Strategies for Urban Bus Systems

Sadjad Bazarnovi, University of Illinois Chicago, Chicago, IL, United States, Taner Cokyasar, Omer Verbas, Abolfazl Mohammadian

Electrification of transit fleets offers a potential pathway to reducing cost of mobility. However, the limited battery range and long charging durations of battery electric buses (BEBs) introduce significant operational complexities, necessitating innovative scheduling and charging strategies. This study proposes an integrated Mixed-Integer Linear Programming (MILP) model to optimize vehicle scheduling and charging strategies for mixed fleets of BEBs and Diesel Buses (DBs). Unlike existing models, which often assume a fixed BEB fleet size or restrict charging to a single charger type, our approach simultaneously determines the optimal fleet composition, scheduling, and flexible and partial charging strategy incorporating both slow and fast chargers at garages and terminal stations. The model minimizes combined fleet purchase and operational costs. A deterministic queueing strategy is introduced, departing from traditional first-come, first-served methods by dynamically allocating waiting and charging times based on operational priorities and resource availability, improving the overall scheduling efficiency. To overcome computational complexities arising from numerous variables, a genetic algorithm-based metaheuristic (GA) is developed, facilitating scalable solutions for large-scale transit networks. Numerical experiments using real-world transit data from the Chicago Transit Authority and the Pace suburban bus systems demonstrate the model's effectiveness, highlighting that BEBs, despite higher initial acquisition costs, effectively serve a greater proportion of trips due to lower energy costs. Results highlight the feasibility and economic viability of mixed-fleet electrification, illustrating the potential for substantial operational efficiencies through optimized scheduling and flexible charging strategies.

5 - Integrated Bus Fleet Electrification Planning Through Accelerated Logic-Based Benders Decomposition and Restriction Heuristics

Robin Legault, Massachusetts Institute of Technology, Cambridge, MA, United States, Filipe Cabral, Xu Sun

To meet sustainability goals and regulatory requirements, transit agencies worldwide are planning partial and complete transitions to electric bus fleets. This work presents a comprehensive and computationally efficient multi-period optimization framework integrating the key planning decisions necessary to support such electrification initiatives. Our model, formulated as a two-stage integer program with integer subproblems, jointly optimizes yearly fleet and charging infrastructure investments as well as hourly vehicle scheduling and charging operations. To solve instances of practical relevance to proven optimality, we develop a logic-based Benders decomposition method enhanced by several techniques, including preprocessing, partial decomposition, and a range of classical and monotone Benders cuts derived from relaxations of the operational subproblems. These accelerations yield speedups of up to three orders of magnitude, and lead to practical and theoretical insights into Benders cut selection. We also propose a heuristic tailored for long-term, citywide electrification planning. This approach, which imposes and progressively relaxes additional scheduling constraints, consistently delivers high-quality solutions with optimality gaps below 1% for instances an order of magnitude larger than those considered in prior studies. We illustrate our model using data from the Chicago public bus system, providing managerial insights into optimal investment and operational policies.

6 - Commercial Megawatt Charging Reservation Mechanism

Ridvan Aksu, The University of Alabama, Tuscaloosa, AL, United States, Goutham Takasi, Mesut Yavuz

Long-haul electric freight trucks require multiple charging stops in public stations, risking hours of waiting time in an industry governed by strict schedules. Megawatt charging stations (MCS), while capable of rapid energy delivery, place significant strain to the power grid, thus has to operate at a limited capacity. To address this challenge, we propose a pricing mechanism design for MCS that allows electric trucks with tighter schedules to reserve charging slots in advance. We demonstrate that an optimal pricing mechanism exists and allows EV trucks to alleviate long waiting times, while keeping charging stations balanced and profitable.

7 - Post-Disaster Damage Assessment from High-Resolution Satellite Imagery Using D-Linknet Hierarchical Transformer with Radon-Transformed Fixed Positional Encoding

Hyeong Suk Na, University of Missouri, Columbia, MO, United States, Shivam Shrivastava

Accurate and timely damage assessment is critical for effective emergency response and post-disaster recovery. A key task in this process is the generation of high-resolution damage segmentation maps that evaluate various levels of structural damage. Typically, this task includes three steps: feature extraction, change detection, and damage segmentation. Existing studies utilize these three steps independently on pre- and post-disaster satellite imagery to assess the damage level of buildings regionally. However, decoupling these steps can limit the evaluation speed and accuracy of damage assessment. To consider this gap, we propose a deep learning architecture, D-Linknet Hierarchical Transformer with Radon-Transformed Positional Encoding (DLHT-RTPE), that integrates all three steps in a single framework. We first preprocess satellite imagery using a Gaussian filter to improve image sharpness to facilitate effective feature extraction. The enhanced images are then processed through a dilation module to preserve high-level semantic information in downsampled, low-resolution feature maps. The change detection is performed at each level of feature maps using the hierarchical transformer-based difference blocks optimized with RTPE, enabling precise segmentation of damage at the highest resolution of feature maps. The RTPE method captures the sinusoidal patterns inherent in imagery and integrates them into the transformer decoder to recover the original token positions. This approach significantly reduces the number of learnable parameters and achieves a 10% reduction in prediction time. The proposed DLHT-RTPE model, trained on the xBD dataset, achieved a comparable accuracy of 81.5%, demonstrating efficient performance and computational efficiency compared to state-of-the-art models such as DAHiTrA and BiTransUNet.

1 - Baggage Handling via Bandit-Augmented Reinforcement Learning

Keyu TIAN, City University of Hong Kong, Hong Kong SAR, Hong Kong, Li Zeng

Efficient baggage delivery within baggage handling system (BHS) at airport is critical for optimal airport operations. Traditional shortest-path based routing planning methods, which depend on fixed strategies, often struggle to adapt to the complex, dynamical conditions of BHS and require frequent re-planning to avoid potential baggage collisions. Reinforcement learning (RL), particularly deep double Q-networks (DDQN), has shown promise in addressing these routing challenges. However, current studies mainly focus on controlling diverters for optimal baggage routing, neglecting other influential factors such as the arrangement of entry (check-in counters) and exit (unloading areas) points for different airlines, which can significantly impact routing efficiency. Moreover, many RL-based approaches rely on simplified models that fail to capture the complexity of real-world system dynamics, leading to suboptimal performance. To address these issues, we propose a system-level framework for baggage handling that simultaneously optimizes diverter control and airline entry-exit arrangement to enhance performance. This framework employs a DDQN-based routing strategy with adaptive learning for diverter control and uses the upper confidence bound (UCB), a bandit method, for airline entry-exit selection. Furthermore, a kernel-based data generation method is incorporated to create more realistic and diverse baggage data in order to improve the robustness and generalization of the learned policy. Experiments show that the proposed method outperforms existing approaches in accelerating baggage delivery and preventing collisions.

2 - Bridging the Revenue Gap: a Hierarchical Bayesian Framework for Personalized Airline Upgrade Pricing

Peng Li, Embry-Riddle Aeronautical University, Daytona Beach, FL, United States, aqi dong, Farshid Azadian, Lin Zhao

Airlines face a critical challenge in traditional tier-based upgrade pricing: capturing customers' true willingness-to-pay while accounting for individual preferences. Current approaches achieve only 68% of potential revenue due to rigid pricing structures that fail to adapt to individual customer contexts. This research introduces a hierarchical Bayesian framework that addresses this problem by modeling passenger willingness-to-pay at both individual and population levels. The methodology creates an adaptive personalization mechanism that balances sparse individual-level data with robust population-level information, enabling precise price customization even for customers with limited historical data. Our approach incorporates explicit uncertainty quantification in pricing decisions, allowing risk-aware pricing strategies that maximize expected revenue. Furthermore, we model contextual effects such as trip purpose, booking timing, and competitive offerings that significantly influence purchase decisions. Implementation results demonstrate 91% revenue capture compared to theoretical optimum—a 34% improvement over traditional approaches. The framework provides airlines with an implementable solution for dynamic personalized pricing that balances revenue maximization with computational feasibility, while respecting customer expectations regarding fair pricing practices.

3 - The Price of Routing with Preferences for Uncrewed Aerial Vehicles

Geoffrey Ding, Massachusetts Institute of Technology, Cambridge, MA, United States, Hamsa Balakrishnan

Increasing operations of uncrewed aerial vehicles (UAVs), or drones, bring growing concerns about safety, privacy, and noise. These risks may be reduced by routing along paths with less human activity such as waterways and railways, which we call "preferred segments." By varying the number of preferred segments and the degree of their preference in a modified visibility graph, we show how preferences can affect routing and operational efficiency. We quantify these impacts as the "price of preference." Illustrative examples of these concepts are provided in a synthetic environment and a drone-as-first-responder (DFR) case study in Detroit, Michigan. This work provides one possible approach for balancing the efficiency of drone operations with other public interests.

We adapt the weighted region problem to address path planning with preferred segments. By varying the degree to which preferred segments are discounted, we find a corresponding change in the efficiency of the resulting paths. We assess how different discount factors influence how much operations follow preferred segments in obstacle-free settings. We then extend visibility graphs, which allow us to model obstacles or no-fly zones, to account for preferred segments. Obstacles may alter the efficient path, so we also consider how they may change the lowest-cost path and the price of using preferred segments. Illustrative examples of these concepts are provided, including a case study of medical deliveries in Detroit, Michigan. This work presents one possible framework for trading off efficient operations of novel aircraft with public objectives such as safety and privacy.

4 - Sustainable Aviation Fuel (SAF) Supply Chain Design (in Thailand)

Rakesh Nagi, Singapore University of Technology and Design (SUTD), Singapore, Singapore, Jaghpaal Singh Baram

Abstract

Growing global air travel demands an important shift towards Sustainable Aviation Fuel (SAF) to lessen its environmental impact. This research develops a robust supply chain modeling and optimization framework for the entire SAF lifecycle, from feedstock sourcing to final airport delivery. Our core objective is to identify strategic opportunities to streamline processes, substantially reduce overall costs, minimize environmental footprints, and determine optimal biorefinery locations throughout the chain. The study's specific focus is Thailand, a nation with abundant, year-round availability of agricultural residues. Utilizing these waste-to-value feedstocks provides an excellent opportunity of transforming waste and reducing aviation environmental footprint at the same time!

The framework considers two primary conversion pathways that appear to be promising options: Biomass-to-Liquid Fischer-Tropsch (BtL-FT) synthesis and Cellulosic Alcohol-to-Jet (ATJ). These pathways involve unique logistical challenges like bulky residue handling, processing complexities, and significant capital (CAPEX) and operational (OPEX) expenditures. Thailand's consistent feedstock supply is pivotal, as its year-round availability critically enhances the viability of continuous refinery operations, especially for the capital-intensive BtL-FT process. A central component of this research involves applying supply chain modeling and optimization to strategically determine optimal biorefinery locations across Thailand. This meticulous planning is designed to minimize transportation routes, associated costs, and logistical constraints across the entire supply chain. A comprehensive mathematical model will be introduced to formalize and solve this complex, multi-objective optimization problem. Ultimately, this study aims to significantly enhance SAF's accessibility and affordability through data-driven strategic planning, fostering a greener aviation industry for sustainable future generations.

5 - Balancing Exploration and Exploitation: How Resource Reconfiguration and Sustainability Orientation Influence Market Performance in Global Aviation

Abhilash Vimal, The University of Texas at Arlington, Arlington, TX, United States, Seock-Jin Hong, Edmund Prater

The present manuscript empirically investigates the role that a firm's resource reconfiguration ability and sustainability orientation play in influencing the relationship between their ambidexterity efforts and market performance. Ambidexterity is further diverged into exploration and exploitation orientation. Data for the study comes from a survey administered to airline employees and airline customers of 13 US and Canadian passenger airlines. The commercial airline industry was an appropriate base for the study because of its high overhead/capital costs, sensitivity to jet fuel prices, susceptibility to disruption which are further aggravated by macro-predictability, micro-uncertainty & capacity constraints. Structural equations modeling is used for this study. We assess the positive association between an airline's exploration & exploitation orientation on market performance to be weaker for lower levels of resource reconfiguration ability. Likewise, the positive association between an airline's exploration/exploitation orientation and market performance is stronger at higher levels of sustainability orientation. Most significantly, the moderating effects of resource reconfiguration and sustainability orientation is stronger for a strategy of ambidexterity which combines exploitation and exploration orientation. Despite the abundance of research on the relationship between efficiency and performance, there is a dearth of research that deciphers the factors that affect ambidexterity outcomes for passenger airlines as extant literature has predominantly examined the effect of technical efficiencies, cost efficiencies and environmental efficiencies. This study sheds more light on the role of resource realignment and sustainability orientation on ambidexterity outcomes. Additionally we embed ambidexterity within a richer contextual framework by incorporating strategic alignment with environmental values and adaptive capabilities.

AI for Energy Systems

Invited Session

Practice Track

Chair: Russell Bent, Los Alamos National Laboratory, Los Alamos, United States

1 - Harnessing Artificial Intelligence for Enhanced Efficiency in Energy Systems: Challenges and Opportunities

Femi Omिताomu, Oak Ridge National Laboratory, Oak Ridge, TN, United States, Teja Kuruganti

The integration of artificial intelligence (AI) into energy systems represents a transformative evolution in the planning, deployment, and operational phases of energy management. This talk will explore the practical applications of AI technologies within the energy sector, with a specific focus on generation planning, site selection, demand forecasting, and operational optimization. By leveraging advanced algorithms and machine learning techniques, AI enhances decision-making processes, providing accurate predictions and insights that improve resource allocation and efficiency in generation planning. Furthermore, AI plays a crucial role in site evaluation by analyzing geographic and economic factors to identify the most advantageous locations for energy generation assets. The focus is on the importance of AI in ensuring optimal energy supply, as well as its impact on enhancing the operational performance of existing assets through predictive maintenance and resilience evaluations. Despite the promising advantages that AI offers, its implementation in the energy sector faces several challenges. Issues such as data integration, privacy concerns, algorithm trustworthiness, and workforce development must be addressed to fully harness the potential of AI technologies. By examining these aspects, this talk aims to provide a comprehensive understanding of how AI can revolutionize energy systems while also highlighting the necessary steps needed to overcome barriers to successful deployment.

2 - Bottleneck Challenges in Deploying AI to Power Systems Today

Colin Ponce, Lawrence Livermore National Laboratory, Livermore, CA, United States

The technology industry that produced AI's recent groundbreaking innovations often operates by "moving fast and breaking things." While this approach to technology development can lead to rapid progress, its acceptance of risk does not translate well to critical infrastructure sectors such as the power industry, where outages can be highly disruptive and even life-threatening. Due to the high cost of outages, the power industry is often resistant to deploying a new technology unless (A) it integrates seamlessly with the existing power grid and all its legacy systems, and (B) those deploying it have confidence that it will work as intended. To enable the power industry to leverage the massive potential of AI, therefore, we cannot focus only on the task of developing useful AI technology. The key challenge in this space is rather in creating a deployment pathway that meets the dual requirements of integration with existing systems and ability to ensure confidence in operation. In this talk, I will present current progress and pathways towards meeting these industry needs. First, I will discuss how in-use AI applications are both integrable and trustworthy, and I will show how some in-progress projects are building these requirements into every aspect of their development. Second, I will discuss some emerging approaches, such as AI testbeds and explainable AI, that can assist developers in meeting the requirements of integrating AI into power systems.

3 - The Role of AI in Control and Optimization of Energy Systems

Andrey Bernstein, NREL, Golden, CO, United States

Modern power and energy systems are rapidly evolving into complex, networked systems with significant challenges in design, planning, and operation across different levels. At the transmission level, a major challenge lies in the real-time monitoring and control of numerous dynamic "what if" scenarios. At the distribution level, distributed energy resources (DERs) are integrated at the system edge, often not visible to the system's operators. The future power system is anticipated to be a networked system of energy communities managed automatically, and in emergencies, semi-automatically, aggregating DERs at the customer level and functioning as virtual power plants (VPPs). This transformation renders traditional, model-based power system planning and operation paradigms inadequate, as they largely ignore variability and uncertainty at the distribution level. Precise physical models of complex energy systems are often unavailable, making model-based optimization and control approaches infeasible. Furthermore, as more controllable devices are added at the system's edge, human behavior increasingly influences the system, further complicating traditional planning and operation processes. These challenges highlight the need for the careful integration of AI/ML-based approaches in power and energy system planning and operation, with a strong emphasis on physics-informed AI/ML to better leverage physical system information. This talk provides an overview of major research challenges in power and energy systems that cannot be addressed using classical methods; the landscape of AI/ML methods suitable for energy system applications; examples of successful AI/ML applications; and an overview of open problems and the potential of AI/ML-based methods to solve them.

Top-Notch Applications of Queueing Theory

Invited Session

Applied Probability Society

Chair: Daniela Hurtado Lange, Northwestern University, Evanston, IL, United States

1 - Efficiency-Cost Trade-off in Queues with Dynamic Arrivals

Sushil Mahavir Varma, INRIA Paris, Paris, France

With the information technology revolution, online marketplaces like ride-hailing platforms and payment channel networks have become integral to our society. In such systems, system operators need to design optimal policies to improve customer experience by minimizing delays (efficiency) while optimizing platform rewards (cost), such as profit in ride-hailing and the number of successful transactions on payment channel networks. However, these dual objectives often conflict, naturally leading to a trade-off. In this talk, we characterize this fundamental trade-off observed in service systems.

We consider an M/M/1 queue with state-dependent arrivals, where the system operator can adjust the arrival rate $\lambda(q)$ as a function of the queue length. The service rate is fixed at 1. The efficiency is measured by $E[q]$, and the system operator's reward is defined by a general function F , given by $E[F(\lambda(q))]$, which represents the expected reward in the steady state. Let F^* denote the maximum attainable reward and define the cost as $F^* - E[F(\lambda(q))]$. The objective is to analyze the cost-efficiency trade-off: for a given $\epsilon > 0$, if cost $\leq \epsilon$, then, we show that $E[q] \geq d(\epsilon)$ under any state-dependent arrival setting, where d depends only on the reward function F . Contrary to the classical $1/\epsilon$ scaling for the static arrival setting, we show that $d(\epsilon) = \Omega(1/\epsilon^{0.5})$ when F is strictly concave and $d(\epsilon) = \Omega(\log(1/\epsilon))$ when F is sufficiently non-concave. We show that these bounds are attainable by constructing a state-dependent arrival sequence $\lambda(q)$ achieving the minimum possible $E[q]$, characterizing the fundamental trade-off between cost and efficiency.

2 - Evaluating Relational Continuity in Primary Care: a Mean-Field Queueing Model

Yueyang Zhong, London Business School, London, United Kingdom

Relational continuity (RC) in primary care improves health outcomes but creates operational inefficiencies. We analyze this trade-off using a queueing model where patients are routed to either their regular physician (preserving RC) or the earliest available physician (reducing wait times). Through mean-field analysis, we derive closed-form solutions for the system-wide optimal RC level, proving that full continuity is suboptimal; instead, an intermediate balance minimizes total costs (waiting + increased visit frequency). Game-theoretic analysis of decentralized patient decisions reveals inefficient Nash equilibria (all-or-nothing continuity), highlighting the need for centralized control. Extending the model to heterogeneous patient classes and calibrating it with NHS data, we demonstrate that: (1) moderate RC—where patients occasionally forgo their regular physician—optimizes both clinical and operational outcomes; (2) the equilibrium-optimum gap is largest when visit/waiting costs are balanced or high-RC-need patients dominate; and (3) class-dependent policies tailored to patient needs outperform across-the-board continuity management. These results provide actionable insights for primary care policy design, showcasing how queueing theory and mean-field approximation can resolve healthcare operations dilemmas.

3 - Delay Announcement and Utility in Healthcare Queueing Models

Cameron Curtis, Northwestern University, Evanston, IL, United States

We analyze patient utility in a healthcare queueing model with delay announcements. We consider whether and when a patient should be given an estimate of their waiting time and, if they are given one, whether to provide an unbiased estimate or to inflate their expected wait. Patients are more sensitive to loss than gain (as is predicted in prospect theory) and are permitted to abandon. We present initial simulation results to estimate the optimal policy as well as preliminary analytical results.

4 - Dynamic Control of Stochastic Matching Systems in Heavy Traffic

Yaosheng Xu, University of Chicago, Booth School of Business, Chicago, IL, United States, Baris Ata

Bipartite matching systems arise in many service environments in which agents or tasks from two distinct sets must be paired dynamically under compatibility constraints. We study such systems in a stochastic and high-dimensional setting, where the diversity of match types introduces notable complexity. Our goal is to develop a dynamic control policy that maximizes the long-run discounted total reward by balancing matching gains, holding costs, and abandonment penalties. To address both analytical and computational challenges, we approximate the system using a Brownian control problem (BCP) formulated under a balanced network, which offers a convenient baseline and can be readily extended to unbalanced settings. We characterize the structure of the BCP solution and develop a deep learning-based approach to estimate the value function gradient. Building on this, we propose a practical matching policy that performs effectively in high-dimensional systems and demonstrates consistent improvements over existing policies in extensive numerical experiments.

5 - Design and Control of Large Service Systems with Delay-Dependent Service Times

Achal Bassamboo, Northwestern University, Evanston, IL, United States, Deniz Simsek, Ohad Perry

Service systems often exhibit complex dynamics when customer service times depend on the delay experienced in queue, a phenomenon observed across various settings such as healthcare and hospitality. This delay-dependent service time introduces non-Markovian dynamics that render exact analysis of large service systems intractable. Deterministic fluid models approximating the system dynamics uncover some operational challenges arising from delay-dependence. These systems can exhibit multi-stability, where the queue fluctuates between multiple equilibria. In large systems, these transitions become infrequent, potentially leading to prolonged periods of severe congestion referred as congestion collapse. Conversely, in smaller systems, the system frequently shifts between equilibria, causing high variability. To mitigate these issues, we propose two tailored strategies: For large systems, we introduce the “slingshot policy”, a dynamic control that alternates between first-come-first-served (FCFS) and last-come-first-served (LCFS) scheduling to stabilize the system at the more desirable equilibrium. For smaller systems, we propose a “depooling mechanism”, where the service pool is strategically divided into smaller, uni-stable subsystems, effectively eliminating multi-stability at the design stage. Our framework provides actionable solutions for system design and control. The proposed approaches are supported by both theoretical analysis and simulation studies, offering practical insights to improve the stability, reliability, and efficiency of service systems affected by delay-dependent dynamics.

1 - Dynamic Buffer Allocation in a Two-Stage Tandem Queue

David Kaufman, University of Michigan - Dearborn, Dearborn, MI, United States, Jairo Alejandro Martinez Correa, Gabriel Zayas-Cabán

Emergency department (ED) boarding—when admitted patients remain in the ED due to insufficient inpatient capacity—continues to drive ED overcrowding and degrade care delivery, underscoring the need for coordinated, system-level interventions. In this talk, we address the problem of dynamically adjusting buffer capacity after phase-one service in a two-stage tandem queueing model. The goal is to temporarily alleviate congestion in the first stage while minimizing total holding costs from jobs waiting or receiving service across both stages. We model this scenario using a finite-horizon continuous-time Markov decision process, whose optimality equations yield differential equations—distinct from the algebraic/recursive equations of infinite-horizon problems. After establishing the existence of a solution to these equations, we implement a time-discretization approach to approximate the optimal value function and corresponding policy. Numerical examples illustrate the structure of the discretized policy.

2 - Dynamic Server Assignment in Queueing Systems with Synergistic Servers and Abandonments

Bihan Chatterjee, Georgia Institute of Technology, Atlanta, GA, United States, Hayriye Ayhan, Sigrun Andradottir

We study tandem queueing systems in which servers work more efficiently in teams than on their own and customers are impatient in that they may leave the system while waiting for service. Our goal is to determine the server assignment policy that maximizes the long-run average throughput. We show that when each server is equally

skilled at all tasks, the optimal policy has all the servers working together at all times. We also provide a complete characterization of the optimal policy for Markovian systems with two stations and two servers when each server's efficiency may be task dependent. We show that the throughput is maximized under the policy which assigns one server to each station (based on their relative skill at that station) unless station 2 has no work (in which case both servers work at station 1) or the number of customers in the buffer reaches a threshold whose value we characterize (in which case both servers work at station 2). We study how the optimal policy varies with the level of server synergy (including no synergy) and also compare the optimal policy for systems with different customer abandonment rates (including no abandonments). Finally, we investigate the case where the synergy among collaborating servers can be task-dependent and provide numerical results.

3 - Control of Queues with Outsourcing

Mark Lewis, Cornell University, Ithaca, NY, United States

We consider the control of a single server with the opportunity to outsource some of the workload. Customers arrive according to a Poisson process and service times have a general distribution. There is a cost for each outsourced customer and holding costs for those in the system. We characterize the structure of the policy that minimizes the discounted and long-run average cost.

4 - Optimal Service Rate Control in Queues with Abandonments

Runhua Wu, Georgia Institute of Technology, ATLANTA, GA, United States

We consider a Markovian, infinite capacity single server queueing system where customers waiting in queue may get impatient and leave without being served. There is a cost associated with abandonments and a holding cost associated with customers in the system. We consider two variants of the model: customers pay a reward either at the time of arrival or at the time of service completion. The system manager can set the service rate of the server to a value in a compact set or idle the server and there is a service cost associated with each service rate. Under these assumptions, our objective is to characterize the service rate control policy that maximizes the infinite-horizon discounted reward and the long-run average reward for both variants of the model. We formulate the problem as a continuous time Markov decision process problem and show that for both variants and optimality criteria, the optimal service rate is non-decreasing in the number of customers in the system. We conclude with a study of finite capacity systems and show that the optimal service rate is not necessarily monotone in the number of customers in the system.

5 - Dynamic Pricing in Queueing Systems with Customer Abandonments and Reimbursement

Jieqi Di, Georgia Institute of Technology, Atlanta, GA, United States

We study optimal pricing strategies for service providers when customers may leave before receiving service due to long wait times. We allow service providers to set prices dynamically based on the current number of customers in the system. A customer joins the system if the quoted price is below their willingness to pay, which follows a known probability distribution. The service provider earns the quoted price as revenue when a customer joins the system but must fully reimburse any customer who abandons the system while waiting. The system incurs a per time per customer holding cost. We aim to determine the pricing policy that maximizes the long-run average profit. We first construct a continuous-time Markov chain with infinite capacity and prove that the system should reject new customers once the number of customers in the system exceeds a certain threshold. Using this result, we formulate the problem as a finite state Markov decision process. Our analysis reveals that the optimal price increases with the number of customers in the system, allowing us to use monotone policy iteration to solve for the optimal policy. We then prove that the optimal long-run average gain is monotone increasing in the service rate and the number of servers. Furthermore, the numerical experiments show our policy is robust to small parameter estimation errors. We provide guidelines for policy modification when parameters significantly deviate from their true values.

TSL: Urban Transportation Planning and Modeling

Chair: Michel Gendreau, Polytechnique Montreal, Montreal, QC, Canada

1 - Visits to the TSP-Drone Polytope : Bi-Cycle Elimination Inequalities and Two Alternative Compact Formulations

Taekang Hwang, KAIST, Daejeon, Korea, Republic of, Changhyun Kwon

In this study, we introduce two novel compact formulations, which are the Hamiltonian formulation and the Arc-ring formulation of the TSP-D problem. And we suggest facet-defining inequalities for the TSP-D polytope, named Bi-cycle elimination inequalities. The TSP-D is one of the main research streams investigating how we can use drone support efficiently in last-mile deliveries. In the TSP-D problem, in order to serve all customers, a truck and a drone cooperatively travel all the customer nodes without any repetition. Exploiting the cooperation of the truck and the drone, we can take advantage of using both types of vehicles at the same time which may lead to a shorter time to serve all customers. Despite the advantage, there has been almost no research on TSP-D polytopes, making it hard to invent powerful algorithms that can be used for practical purposes. For those reasons, we investigate TSP-D polytopes by introducing the two new compact formulations that we mentioned and studying their computational and theoretical properties. According to our investigation, compared to the existing TSP-D compact formulation, those are expected to be better formulations with regard to computational performances and their polyhedral properties. Furthermore, we demonstrate that we can obtain better lower bounds over small to medium-size instances when we add Bi-cycle elimination inequalities over the Hamiltonian formulation and, up to optimality, the inequalities tend to shorten the computational times over small-size instances. Due to the advantages, our understanding of the TSP-D polytope is expected to be helpful in building more powerful algorithms.

2 - A Logic-Based Benders Decomposition for the Integrated Ride-Sharing and Parking Allocation Problem

Hector Carlo, University of Puerto Rico - Mayaguez, Mayaguez, PR, Puerto Rico, Tomas Pérez-Romero

The Parking Allocation and Ride-Sharing System (PARS) is a non-pricing travel demand management strategy where drivers receive guaranteed parking in a venue if they are willing to participate in a centrally-coordinated carpool system. In PARS, riders request a ride from their depot to (and from) a particular venue and state their latest arrival and earliest departure times. Drivers request a parking reservation, including the car capacity, latest arrival time, and earliest departure time. The PARS problem is the optimization problem that seeks to design the feasible carpools to (and from) a venue such that a metric related to the carpools travel distance is minimizes and reserves parking. In PARS, individuals that are not selected as drivers are incorporated as riders and assigned to carpools.

A previously published efficient Mixed Integer Programming (MIP) formulation for the PARS problem is able to solve instances of medium size instances. This study proposes an innovative Logic-based Benders Decomposition algorithm (LBBD) to solve large instances of the problem. The LBBD strategy decomposes the PARS problem into a master problem (MP) and a feasibility subproblem (FS). The FS generates cuts (i.e., mathematical constraints) to guide the MP to a feasible solution, at which point it has reached the optimal solution. By the nature of the LBBD strategy, a lower bound is obtained after each iteration which is useful to test heuristics for very large instances of the problem. The proposed LBBD is able to solve PARS problem instances twice the size than the MIP using Gurobi.

3 - Probabilistic Models for Maximizing Service Area in Route Deviation Bus Transit Systems

Nikola Markovic, University of Utah, Salt Lake City, UT, United States, Madhu Mausam Thapa, Ye Chen, Shijie Chen, Yanshuo Sun, Ilya Ryzhov

This paper considers a route deviation system where buses can deviate from their fixed routes to meet on-demand requests within a specified buffer zone, thereby enhancing the efficiency and flexibility of conventional bus routes. The objective is to maximize the buffer zone width while accounting for desired headway, demand distribution, and the use of fixed stops along the route. Underused fixed stops provide opportunities for greater route deviations, while heavily used stops necessitate smaller deviations to maintain bus headway. We introduce both analytical probabilistic models and Bayesian simulation-based models to design and optimize this semi-flexible transit system. These models ensure that bus tour duration remains within the conventional transit schedule with high probability, accommodating on-demand requests submitted with appropriate notice. In the case study applied to the Utah Transit Authority's flex routes, significant improvements were observed. The results

demonstrate the system's ability to adapt to varying demand levels and operational conditions, providing a more responsive and passenger-centric public transportation service.

4 - Tactical Prepositioning of a Mixed Bus Fleet to Improve Real-Time Rescheduling in Adverse Conditions

Krystal Coleman, SUNY, University at Buffalo, Buffalo, NY, United States, Rajan Batta

Bus transportation systems are gradually replacing diesel and natural gas-fueled buses with battery electric buses (BEBs). During this process, fleets consist of a mix of vehicle types. The differences in strengths and weaknesses of BEBs and internal combustion engine buses (ICBs) create opportunities for operational resilience. We capitalize on these differences when deciding what composition of heterogeneous buses to assign to bus garages. Tactical prepositioning of the mixed fleet across bus garages may not significantly alter normal transit operations. However, in times of crisis, these decisions have a non-trivial impact on the system's resilience. This cascading effect justifies hierarchical decision making. We integrate vehicle allocation and bus scheduling as the upper-level task in a bi-level optimization problem. To minimize arrival delays or trip cancellations, the lower-level task involves rescheduling buses under adverse conditions or after disruption events. Joint optimization over a long-term planning horizon returns greater cost savings than addressing the bus scheduling and rescheduling problems separately. We use real data from NJ Transit and simulate the system's performance to extract insights into the passengers' experience. In simulations, we vary the assumptions that parametrize the optimization model and use statistical testing to validate whether those assumptions significantly impact the model's performance.

5 - A Variable Neighborhood Search Approach for the Electric Dial-A-Ride Problem

Michel Gendreau, Polytechnique Montreal, Montreal, QC, Canada

The goal of this research is to develop an effective solution approach for large Dial-A-Ride Problems with electrical vehicles (DARP-EV). This involves satisfying a set of transportation requests for passengers traveling between given pick-up nodes and drop-off nodes by transporting them using a fleet of electric vehicles (EVs). The vehicles are heterogeneous in terms of seating capacity but homogeneous in terms of battery capacity. Due to their limited battery capacities, EVs may need to recharge at charging stations during their routes. Charging operations can occur at any charging station when vehicles are empty, and partial recharging is allowed. Our solution method is based on the variable neighborhood search (VNS) metaheuristic. Starting from an initial solution s created using a linear programming-based heuristic, followed by a procedure for inserting charging stations, a neighborhood class is used in each iteration to generate a random solution to which a local search algorithm is applied. If the resulting solution is better, it replaces s , and we go back to the first neighborhood; if it is worse, s is not replaced, and we move to the next neighborhood. This whole process is repeated until a stopping criterion is satisfied. Seven different neighborhood classes (shakers) are used in the algorithm. We consider different cases with respect to the objection function being optimized and the charging functions used (linear vs concave piecewise linear). Computational experiments are performed on several sets of benchmark instances from the literature. We solve instances with up to 900 vehicles and 10,000 requests.

1 - Statistical Inference for Markov Chains with Known Structure

Lin Fan, Northwestern University, Kellogg School of Management, Evanston, IL, United States, Peter Glynn

For Markov chains arising in many applications, the structure of the stochastic recursion defining the chain is known except for the distribution of the iid "driving noise" variables (the source of randomness in the chain). Given a dataset of such driving noise samples, and for a nonparametric model of the driving noise distribution, we study statistically efficient estimation of equilibrium and non-equilibrium expectation performance measures for the (general state space) Markov chain. Such expectations can be viewed as statistical functionals of the driving noise distribution, and we establish a framework based on semiparametric efficiency to characterize asymptotically minimum variance estimation for such functionals. In particular, we provide Foster-Lyapunov drift conditions to ensure suitable directional differentiability of the functionals and the existence of influence functions. Surprisingly, the nonparametric plug-in estimator, in which the empirical driving noise distribution is "plugged in" to the functional, can be inconsistent when the state space is infinite. To resolve the inconsistency issue, we introduce uniform versions of the classical Foster-Lyapunov drift conditions, which ensures that the conditions hold with the population kernels replaced by their empirical counterparts. Under such conditions, we establish asymptotic normality and efficiency of plug-in estimators of the performance measures of interest.

2 - Finite-Time Information-Theoretic Bounds in Queueing Control

Yunbei Xu, National University of Singapore, Singapore, Singapore, Yujie Liu, Vincent Tan

We establish the first finite-time information-theoretic lower bounds—and derive new policies that achieve them—for the total queue length in scheduling problems over stochastic processing networks with both adversarial and stochastic arrivals. Prior analyses of MaxWeight guarantee only stability and asymptotic optimality in heavy traffic; we prove that, at finite horizons, MaxWeight can incur strictly larger backlog by problem-dependent factors which we identify. Our main innovations are 1) a minimax framework that pinpoints the precise problem parameters governing any policy's finite-time performance; 2) an information-theoretic lower bound on total queue length; 3) fundamental limitation of MaxWeight that it is suboptimal in finite time; and 4) a new scheduling rule that minimizes the full Lyapunov drift—including its second-order term—thereby matching the lower bound under certain conditions, up to universal constants. These findings reveal a fundamental limitation on "drift-only" methods and points the way toward principled, non-asymptotic optimality in queueing control.

3 - Personalized Policy Learning Through Discrete Experimentation: Theory and Empirical Evidence

Ruohan Zhan, The Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, Zhiqi Zhang, Zhiyu Zeng, Dennis Zhang

Randomized Controlled Trials (RCTs), or A/B testing, have become the gold standard for optimizing various operational policies on online platforms. However, RCTs on these platforms typically cover a limited number of discrete treatment levels, while the platforms increasingly face complex operational challenges involving optimizing continuous variables, such as pricing and incentive programs. The current industry practice involves discretizing these continuous decision variables into several treatment levels and selecting the optimal discrete treatment level. This approach, however, often leads to suboptimal decisions as it cannot accurately extrapolate performance for untested treatment levels and fails to account for complex interactions between treatment effects and user characteristics. This study addresses these limitations by developing a theoretically solid and empirically verified framework to learn personalized continuous policies based on high-dimensional user characteristics, using observations from an RCT with only a discrete set of treatment levels. Specifically, we introduce a deep learning for policy targeting (DLPT) framework that includes both personalized policy value estimation and personalized policy learning. We prove that our policy value estimators are asymptotically unbiased and consistent, and the learned policy achieves a square root of n regret bound. We empirically validate our methods in collaboration with a leading social media platform to optimize incentive levels for content creation. Results demonstrate that our DLPT framework significantly outperforms existing benchmarks, achieving substantial improvements in both evaluating the value of policies for each user group and identifying the optimal personalized policy.

4 - When Learning Hurts: the Cost of Algorithmic Instability on Platforms

Jiaqi Lu, the Chinese University of Hong Kong (Shenzhen), Shenzhen, China, People's Republic of, Yilun Chen

When a platform uses conventional learning algorithms to allocate online demand to arms who are themselves agents, there can be an unintended consequence of highly fluctuating allocations in certain scenarios. This algorithmic instability raises concerns regarding the arms' welfare considerations such as fairness and risk-aversion. Motivated by this, we study two operational objectives for designing algorithms in stochastic multi-armed bandit environments, the expected regret and the standard deviation of the number of arm pulls. We characterize an interesting Pareto frontier: the product of the worst-case regret and the worst-case standard deviation of the number of arm pulls must be $\Omega(T^{\frac{3}{2}})$, asymptotically as the horizon length $T \rightarrow \infty$. This reveals a key impossibility result: any algorithm that is minimax optimal in expected regret must suffer from a standard deviation (in the number of pulls) of $\Theta(T)$ in the worst case; and any algorithm

having a standard deviation of $\sqrt{\Theta(T)}$ must incur a linear expected regret in the worst case. We then propose a simple class of UCB-f policies that is a natural generalization of the classic UCB1 policy, and show that it can achieve any point on the Pareto frontier by choosing the appropriate exploration function. We discuss the results' implications on the arms' welfare such as fairness and risk-aversion.

5 - Decision Making in Changing Environments: Robustness, Query-Based Learning, and Differential Privacy

Fan Chen, MIT, Cambridge, MA, United States

We study the problem of interactive decision making in which the underlying environment changes over time subject to given constraints. We propose a framework, which we call $\text{Hybrid Decision Making with Structured Observations}$ (hybrid DMSO), that provides an interpolation between the stochastic and adversarial settings of decision making. Within this framework, we can analyze local differentially private (LDP) decision making, query-based learning (in particular, SQ learning), and robust and smooth decision making under the same umbrella, deriving upper and lower bounds based on variants of the Decision-Estimation Coefficient (DEC). We further establish strong connections between the DEC's behavior, the SQ dimension, local minimax complexity, learnability, and joint differential privacy.

1 - Stochastic Sketchrefine: Decision-Making Under Uncertainty over Millions of Decision Variables

Riddho Haque, University of Massachusetts Amherst, Amherst, MA, United States, Anh L. Mai, Matteo Brucato, Azza Abouzied, Peter J. Haas, Alexandra Meliou

Decision-making under uncertainty often corresponds to choosing multisets ("packages") of probabilistic data tuples that collectively optimize expected outcomes while limiting risks. For large stochastic database relations, this involves solving integer programs having millions of decision variables. Monte Carlo methods can simulate numerous scenarios, i.e., sample realizations of the stochastic attributes of all the tuples, allowing for sample-average approximation (SAA). However, the number of scenarios needed for accurate approximation - and hence the size of the approximating deterministic optimization problem when using traditional SAA - increases with variance in the data, and the search space of the optimization problem increases exponentially with the number of tuples. Existing solvers take hours to process these problems on large relations containing stochastic attributes with high variance, often crashing before finding feasible results. We make two fundamental contributions towards scalably finding risk-constrained near-optimal packages. First, to handle high variance, we propose risk-constraint linearization (RCL), which converts a risk-constrained decision-making problem into an Integer Linear Program (ILP) whose size is independent of the number of scenarios used. Solving the ILP gives us a feasible and near-optimal package having an optimality guarantee. Second, to handle large relations, we propose Stochastic SketchRefine, a divide-and-conquer framework that breaks down a large stochastic optimization problem into subproblems involving smaller subsets of tuples, resulting in a final package with an overall optimality guarantee. Our experiments show that, together, RCL and Stochastic SketchRefine produce near-optimal results in orders of magnitude lower runtime than the state of the art.

2 - Global Sensitivity Analysis for Stochastic Models with Temporal Dynamics

Xi Chen, Virginia Tech, Blacksburg, VA, United States, Jingtao Zhang

Global sensitivity analysis is a critical tool for quantifying the influence of input parameters in complex models. Classical Sobol' indices, though widely used, have been primarily developed for deterministic computational models with a single output, limiting their applicability to stochastic systems with time-dependent, multidimensional outputs. In this work, we extend Sobol' indices to such settings by introducing a generalized Sobol' index that accounts for temporal dynamics. We propose three estimators for this index: a nested pick-freeze (NPF) estimator, a pick-freeze (PF) estimator, and a partition-based (PAR) estimator. Theoretical analysis shows that the NPF estimator achieves a mean squared error convergence rate of $O(B^{-2/3})$, while the PF and PAR estimators achieve a faster rate of $O(B^{-1})$, where B denotes the total number of model evaluations. Notably, the PAR estimator does not require a specific experimental design, enhancing its practical utility. We validate our approach through numerical experiments. The results reveal key temporal dynamics in model responses and highlight the advantages of the generalized Sobol' indices over classical indices in dynamic, stochastic settings.

3 - Automatic Generation of Models and Processes from Data

Zach Eyde, Arizona State University, Chandler, AZ, United States

Increasing demand for semiconductors from AI, HPC and automotive applications is driving the need for increased efficiency from manufacturers to keep pace. One major area of interest in both industry and academia is leverage digital twins (DT) to improve the efficiency of the semiconductor manufacturing process. An obstacle to the adoption of DTs in manufacturing is the development and maintenance of simulation and process models that power virtual representation. To tackle this, our research is focused on the automatic generation of modules and processes from production data, especially event logs from the equipment. We will demonstrate the full development flow from pre-processing the data to creating of graphs to represent the manufacturing process and finally incorporating the graphs into a simulation model. For our work, we preliminary look at queue networks to show the development steps and expand out to the manufacturing process of Assembly and Testing (A/T) of semiconductor devices.

4 - Moment-Based Approximations for Robust Optimization of Queueing Systems

Russell Barton, Penn State, University Park, PA, United States, Hyungkhee Eun, Sara Shashaani

Distributionally Robust Optimization (DRO) based on Wasserstein distance is preferred for general DRO settings where the computation of performance given the distribution form is straightforward. For complex queueing systems, the objective function evaluation requires computationally expensive simulation. We seek an effective proxy to identify input distributions with extreme system waiting times. Input distributions with large Wasserstein distance (from the nominal distributions) do not necessarily provide extreme objective values. We explore approximations for queue waiting time in a number of settings and show how they can provide low-cost guidance on extreme objective values, allowing for more computationally efficient DRO.

5 - Quantifying Uncertainty from Machine Learning Surrogate Models Embedded in Simulation Models

Mohammadmahdi Ghasemloo, Texas A&M University, College Station, TX, United States, David Eckman, Yaxian Li

Modern simulation models increasingly incorporate complex logic to emulate tactical decision-making supported by advanced decision support systems (DSSs). For practical reasons—such as computational burden, data privacy, or latency—modelers may replace embedded DSSs with machine learning (ML) surrogate models. We investigate the implications of using such surrogates on the estimation of system performance metrics. We distinguish this so-called surrogate uncertainty from conventional input uncertainty and propose new methods to quantify its impact. Specifically, we develop approaches based on bootstrapping and Bayesian model averaging to construct quantile-based confidence intervals for performance measures under surrogate approximation. We also introduce the use of regression-tree importance scores to apportion the total uncertainty between input variability and surrogate model error. Our methodology is demonstrated through a contact center simulation case study.

The Low-rank Hypothesis in Modern Machine Learning

Invited Session

Applied Probability Society

Chair: Devavrat Shah, Massachusetts Institute of Technology, Cambridge, MA, United States

Co-Chair: Yassir Jedra, MIT, Cambridge, MA, United States

1 - Improving Low-Rank Adaptation of LLMs via Infinite-Width Analysis

Soufiane Hayou, UC Berkeley, Berkeley, CA, United States

Low-Rank Adaptation (LoRA) is a widely popular finetuning method for Large Language Models (LLMs). In this talk, I will show how we can leverage an asymptotic analysis of feature learning with LoRA in order to understand and improve initialization, learning rates, and target modules for LoRA finetuning. I will discuss the infinite-width dynamics of LoRA training via an operator called "Gamma" that tracks the impact of various hyperparameters on the infinite-width dynamics of LoRA.

2 - Near-Optimal Rank Adaptive Inference of High Dimensional Matrices

Frédéric Zheng, KTH, Stockholm, Sweden, Yassir Jedra, Alexandre Proutiere

We address the problem of estimating a high-dimensional matrix from linear measurements, with a focus on designing optimal rank-adaptive algorithms. These algorithms infer the matrix by estimating its singular values and the corresponding singular vectors up to an effective rank, adaptively determined based on the data. We establish, for the first time, instance-specific lower bounds for the sample complexity of such algorithms, uncovering fundamental trade-offs in selecting the effective rank: balancing the precision of estimating a subset of singular values against the approximation cost incurred for the remaining ones. Our analysis identifies how the optimal effective rank depends on the matrix being estimated, the sample size, and the noise level. We propose an algorithm that combines a Least-Squares estimator with a universal singular value thresholding procedure. We provide finite-sample error bounds for this algorithm. These bounds are better than the performance guarantees of existing rank-adaptive algorithms and they nearly match the derived fundamental limits. Our results rely on an enhanced analysis of matrix denoising methods based on singular value thresholding.

We apply our findings to Hankel matrix estimation in system identification by introducing Thresholded Ho-Kalman. Our algorithm further recovers both the system order and its Markov parameters, and we provide upper bounds for the sample complexity required to identify the system order and finite-time error bounds for estimating the Markov parameters. Interestingly, these bounds match those achieved by state-of-the-art algorithms that assume prior knowledge of the system order.

Innovations in Last-Mile Delivery

Invited Session

TSL: Freight Transportation

Chair: Sara Reed, University of Kansas, Lawrence, KS, United States

1 - Last-Mile Delivery Routing with Parking Availability

Farima Salamian, University of Iowa, Iowa city, IA, United States, Ann Campbell, Sara Reed

Last-mile delivery is one of the most expensive parts of the supply chain. Thus, companies try to optimize the productivity of the delivery person via careful route planning. While route planning occurs prior to the driver starting the route, parking availability changes over time and can create implementation challenges for these route plans. However, with smart city technology, such as smart parking meters, companies may be able to incorporate parking availability information into their route planning to provide robust solutions. Unlike other models in the literature, we utilize this parking availability information to assist in route-planning. We formalize the routing problem as a Mixed Integer Program. As a baseline, we fix the route as a solution to the Traveling Salesperson Problem (TSP) based on driving times but must determine which parking spots to utilize and which customers to serve from each parking spot. For comparison, we then change the MIP to allow for optimizing the order of customers. We evaluate the performance over different levels of parking availability and numbers of customers. This allows us to (i) identify scenarios where the TSP order is not sufficient and (ii) provide routing techniques that incorporate parking availability information for last-mile delivery. These research questions are helpful for delivery providers to help improve their profitability, as well as for cities to understand the tradeoffs of investing in more sophisticated parking meter services in terms of reduction in congestion and other safety issues.

2 - Same-Day Delivery Integrated with Product Pickups

Mathias Klapp, PUC Chile, Santiago, Chile, Matias Gaete, Homero Larrain, Felipe Lagos

Same-day delivery (SDD) involves routing vehicles to deliver products from a warehouse to customers on the day orders are placed. Due to tighter deadlines and dynamic demand, SDD offers fewer consolidation opportunities than traditional delivery highlighting the need for alternative strategies to improve fleet utilization. We study an SDD operation integrated with product pickup requests, which represent customer returns or warehouse replenishments from local vendors. When first-mile (pickups) and last-mile (deliveries) are planned independently, requests in the same area are often handled by different vehicles. Integrating both operations can increase request density and improve operational efficiency. We aim to maximize the expected benefit of integrating the operation of both request types, each weighed differently. To this end, we design dynamic policies that adapt to the current fleet state and set of open requests while anticipating future arrivals, using a Multiple Scenario Approach combined with an ALNS heuristic for route planning. We estimate the value of integrated operations compared to a split-fleet alternative in computational experiments across varying requests, arrival rates, fleet sizes, and benefit weights. Results show that integration can increase total benefit by 8%. This improvement is more significant when request arrival rates are lower, the fleet is larger, or the benefit of serving deliveries relative to pickups is smaller.

3 - Recipient Preferences-Based Assignment of Parcels to Service Points

Margaretha Gansterer, University of Klagenfurt, Klagenfurt, Austria

The recent surge in e-commerce requires delivery companies to adapt and economize their logistic processes. Many parcels nowadays are delivered via automated service points (SPs), which prove to be an efficient, flexible, and sustainable alternative to home deliveries. Our study proposes a novel operation policy for parcel delivery firms. It is based on providing information about the availability of SPs in the recipient's vicinity and asking them to select their desired pickup location. Different recipients may have different sensitivities to delays and locations, leading them to make different selections. In contrast, the common practice in the industry is either to select the delivery SP solely based on the address of the recipient or based on the selection they made before real time information is known. We evaluate our preference-based policies against benchmarks that mimic common practice. We model a disutility function that represents the recipients' inconvenience due to the need to travel to the pickup locations and delays in the delivery process. We construct a simulation environment attempting to mirror the processes of parcel delivery for a realistic parcel delivery network. Our findings demonstrate the effectiveness of our preference-based policy, mainly when the recipient location preference variability is high or in moderately congested scenarios. We can significantly increase the recipient's satisfaction level and improve the load balance between the SPs in the network. Importantly, our policy is not only effective but also easy to implement, offering a promising avenue for enhancing service quality without the need for additional physical resources.

4 - Should Commercial Vehicles Double Park? Optimal Parking Decisions for Last-Mile Delivery in Urban Environments

Sara Reed, University of Kansas School of Business, Lawrence, KS, United States, Ann Campbell, Barrett Thomas

Parking is a challenge for last-mile commercial delivery drivers in urban environments. This work provides an analytical basis for understanding optimal parking decisions for commercial delivery drivers. We introduce the Stochastic Parking Problem (SPP) that determines whether a delivery driver should park at an available parking spot as well as whether the driver should double park at an unavailable parking spot at the risk of receiving a fine. We characterize the structure of the optimal policy for the SPP based on the probability that each parking spot is available and the expected cost of double parking. In particular, we show that the optimal policy for the SPP takes on one of four forms. We provide analytical results that determine which of the four forms achieves the optimal policy for a given problem instance of the SPP. Further, by exploiting the identified structure in these forms, we provide a polynomial time algorithm to determine the parameters of the optimal policy. Insights from this work

benefit both companies aiming to improve productivity of last-mile operations as well as cities aiming to control congestion, particularly congestion caused by double parking and cruising of commercial vehicles. We provide sufficient enforcement levels and fine amounts to eliminate double parking as well as improve utilization of limited parking infrastructure in urban environments.

Chair: Raul Astudillo, California Institute of Technology, Pasadena, CA, United States

Co-Chair: Peter Frazier, Cornell University, Ithaca, NY, 14850, United States

1 - Bayesian Optimization with Inexact Acquisition: is Random Grid Search Sufficient?

Chong Liu, State University of New York at Albany, Albany, NY, United States, Hwanwoo Kim, Yuxin Chen

Bayesian Optimization (BO) is a widely used iterative algorithm for optimizing black-box functions. Each iteration requires maximizing an acquisition function, such as the Upper Confidence Bound (UCB) or a sample path from the Gaussian process (GP) posterior, as in Thompson Sampling (TS). However, finding an exact solution to these maximization problems is often intractable and computationally expensive. Reflecting such realistic situations, in this work, we delve into the effect of inexact maximizers of the acquisition functions. Defining a measure of inaccuracy in acquisition solutions, we establish cumulative regret bounds for both GP-UCB and GP-TS without requiring exact solutions of acquisition function maximization. Our results show that under appropriate conditions on accumulated inaccuracy, inexact BO algorithms can still achieve sublinear cumulative regret. Motivated from such findings, we provide both theoretical justification and numerical validation for random grid search as an effective and computationally efficient acquisition function solver.

2 - A New Design Tool for Bayesian Optimization: the Gittins Index

Ziv Scully, Cornell University, Ithaca, NY, United States, Qian Xie, Theo Brown, Linda Cai, Raul Astudillo, Peter Frazier, Alexander Terenin

Many problems in practice do not fit cleanly into the classical Bayesian optimization setup, but are better modeled as Bayesian optimization "with a twist", or perhaps several twists. These twists include heterogeneous evaluation costs, multiple levels of fidelity, and partial feedback during evaluation. Handling any one of these twists alone, let alone a combination of them, is a significant challenge, and existing design principles (e.g. confidence bounds, expected improvement, Thompson sampling, knowledge gradient) do not always provide sufficient guidance about how to incorporate new twists.

We present a new design principle, based on the *Gittins index* from the theory of Markovian multi-armed bandits, that yields new policies for Bayesian optimization with any combination of these twists. The Gittins index is an acquisition function that yields the Bayes-optimal solution for a simplified version of Bayesian optimization where the objective function's domain is discrete, and its values at all points are mutually independent. Importantly, the Gittins index solves this simplified Bayesian optimization "with twists", thus guiding us towards Gittins-index-based policies for general Bayesian optimization "with twists". We demonstrate empirically that the Gittins index matches or outperforms state-of-the-art methods on realistic benchmarks. Among the obstacles we overcome is developing the first efficient algorithm that computes the Gittins index of a class of continuous-state Markov chains, namely linear Gaussian state space models.

3 - Newton-Step-Targeted Local Bayesian Optimization for High-Dimensional Black-Box Problems

Joel Paulson, The Ohio State University, Columbus, OH, United States, Wei-Ting Tang

Local optimization offers a compelling strategy for tackling expensive, high-dimensional black-box problems by bypassing the need to globally explore the entire domain. While traditional local methods often estimate descent directions using finite differences or random perturbations, these strategies can be sample-inefficient and produce noisy estimates – which is a particular challenge when derivatives cannot be directly observed. Local variants of Bayesian optimization (BO) provide an appealing alternative by building a probabilistic surrogate model of the objective and actively selecting informative samples to guide local search. Recent approaches, such as gradient-informed Bayesian optimization (GIBO), leverage this idea by reducing uncertainty in the estimated gradient and stepping in the direction of steepest descent. However, such first-order methods overlook curvature information, which plays a central role in accelerating convergence. In this work, we introduce NeST-BO, a new local BO framework that explicitly targets the Newton step, using both the gradient and Hessian estimates derived analytically from the Gaussian process surrogate model. Specifically, we develop a tractable acquisition function designed to reduce an upper bound on the one-step lookahead error in the Newton step and provide theoretical insight into its convergence properties. We demonstrate that NeST-BO achieves substantial gains over several existing local and global BO approaches across a range of challenging synthetic and real-world problems (ranging from 10 to 50 dimensions). In all cases, NeST-BO achieves faster convergence and lower regret than existing methods, establishing it as a powerful tool for efficient black-box optimization in high-dimensional settings.

4 - Scalable Bayesian Optimization of Composite Functions for High-Dimensional Inverse Problems in Electron Microscopy

Poompol Buathong, Cornell University, Ithaca, NY, United States, Dasol Yoon, Chia-Hao Lee, David Muller, Peter Frazier

We consider inverse problems from medical imaging and electron microscopy where we seek to recover a vector of latent parameters x by minimizing the recovery error $\|h(x) - y\|^2$. Here, y is the observed image, expressed as a vector, and $h(x)$ is a time-consuming vector-valued black-box derivative-free simulator. When y is low-dimensional, Bayesian Optimization of Composite Functions (BOCF), a previously-proposed method, effectively solves problems of this form. It models $h(x)$ with a multi-output Gaussian process (GP) and uses the fact that the objective function is a composition of $h(x)$ with a known simple function to reduce the number of costly evaluations of $h(x)$ needed for low recovery error. When y is high-dimensional, the computational time and memory requirements of high-dimensional multi-output GPs make this approach impractical. We propose a scalable alternative that groups components of $h(x)$ into lower-dimensional outputs, reducing the number of surrogates while continuing to support accurate query-efficient optimization. Demonstrated on an electron microscopy problem, where we determine the specimen thickness and object misorientation with Bayesian optimization. Our method successfully finds low-recovery-error solutions with fewer evaluations of $h(x)$ than standard Bayesian optimization and achieves significantly faster runtime than the estimated runtime of full BOCF.

5 - Marobo-Se: Multi Agent Rollout for Bayesian Optimization - Sample Efficient

Tanmay Khandait, Arizona State University, Tempe, AZ, United States, Giulia Pedrielli

Bayesian Optimization (BO) is a sample-efficient strategy for optimizing expensive black-box functions and has been widely adopted in various domains. However, BO's performance can degrade in high-dimensional or multi-modal settings, where optimizing the acquisition function becomes computationally challenging and prone to poor

local solutions. In this work, we introduce MAroBO-SE, a general-purpose, algorithm-agnostic wrapper that improves sampling efficiency by augmenting any existing BO method with coordinated multi-agent rollouts. MAroBO-SE deploys multiple agents that explore the acquisition landscape via stochastic trajectories, enhancing diversity and exploration without requiring changes to the surrogate model, acquisition function, or optimization routine. As a result, MAroBO-SE preserves the base BO algorithm's structure while improving robustness and performance in challenging optimization settings. We demonstrate that MAroBO-SE consistently improves optimization outcomes when integrated with state-of-the-art methods such as TuRBO, achieving superior results on both synthetic benchmarks and real-world tasks.

1 - Scientific Machine Learning for Optimization and Control

Jan Drgona, Johns Hopkins University, Baltimore, MD, United States

This talk presents a scientific machine learning perspective (SciML) on modeling, optimization, and control. Specifically, we will discuss the opportunity to develop a unified SciML framework for modeling dynamical systems, learning to optimize, and learning to control methods. We demonstrate the application of these emerging SciML methods in a range of engineering case studies, including modeling of networked dynamical systems, building control, and dynamic economic dispatch problem in power systems. Furthermore, we will introduce the NeuroMANCE open-source library, facilitating the implementation and prototyping of diverse SciML methods for a broad range of application problems.

2 - Learning Hybrid Representations of Differential-Algebraic Systems Through Nonlinear Programming Approaches

Laurens Lueg, Carnegie Mellon University, Pittsburgh, PA, United States, Victor Alves, Carl Laird, Lorenz Biegler

We consider so-called neural differential-algebraic systems of equations (neural DAEs), where some unknown relationships within a DAE are learned from available data. Training neural DAEs, similarly to neural ordinary differential equations (neural ODEs), is computationally expensive, as it usually requires the solution of a DAE for every parameter update. Furthermore, the rigorous consideration of algebraic constraints is difficult within common deep learning training algorithms such as stochastic gradient descent (SGD), which are fundamentally designed for unconstrained optimization. Therefore, in this work, we apply the so-called simultaneous approach to neural DAE problems. This results in a fully discretized nonlinear optimization problem that is solved to local optimality and simultaneously obtains the neural network parameters and the solution to the corresponding DAE. This eliminates the need for costly sequential calls to ODE/DAE solvers. Our presented framework is of general nature, with explicit consideration of hybrid models, where some components of the DAE are known, e.g. physics-informed constraints. Furthermore, we present a systematic strategy for improving the performance and convergence of the nonlinear programming solver, through specialized initialization strategies and appropriate Hessian approximations. Lastly, we provide several promising future directions to improve the scalability and robustness of our approach.

3 - Learning to Optimize for Mixed-Integer Non-Linear Programming with Feasibility Guarantees

Bo Tang, University of Toronto, Toronto, ON, Canada, Elias Khalil, Jan Drgona

Mixed-integer nonlinear programs (MINLPs) arise in domains as diverse as energy systems and transportation, but are notoriously difficult to solve, particularly at scale. While learning-to-optimize (L2O) methods have been successful at continuous optimization, extending them to MINLPs is challenging due to integer constraints. To overcome this, we propose a novel L2O approach with two integer correction layers to ensure the integrality of the solution and a projection step to ensure the feasibility of the solution. We prove that the projection step converges, providing a theoretical guarantee for our method. Our experiments show that our methods efficiently solve MINLPs with up to tens of thousands of variables, providing high-quality solutions within milliseconds, even for problems where traditional solvers and heuristics fail. This is the first general L2O method for parametric MINLPs, finding solutions to some of the largest instances reported to date.

4 - Systematically Comparing Embedded Surrogates for Optimization

Ali Asger, Carnegie Mellon University, Pittsburgh, PA, United States, Bashar Ammari, Logan Matthews, R. Cory Allen, Dimitri Papageorgiou, Carl Laird

The optimization community has witnessed a marked increase in the utilization of surrogate models in the design, development, and/or operation of complex systems and enterprise-wide supply chains. Libraries like OMLT (Optimization and Machine Learning Toolkit) and Gurobi's Machine Learning package allow users to automatically embed trained machine learning models into optimization models. With numerous surrogate options now available, an open question is: Given trained surrogates of tantamount predictive accuracy on a test set, which surrogate model leads to the best optimization performance in terms of overall solution quality and solution time? After adapting well-known benchmark MILP instances, we compare a representative surrogate from each of the following classes: (1) ReLU-based neural networks; (2) standard decision trees; (3) difference-of-convex piecewise linear models; (4) linear model decision trees; (5) gradient boosted trees.

5 - Learning to Tune Low-Fidelity Surrogates for Graph-Structured Optimization with One Training Example

Gonzalo Constante Flores, Purdue University, West Lafayette, IN, United States, André Quisaguano, Can Li

In this talk, we present a machine learning framework for training low-fidelity surrogate models tailored to optimization problems with underlying graph structures, using only a single high-fidelity training example. The goal is to enable efficient generalization to unseen graph instances by leveraging shared structural patterns across problems. The proposed framework consists of two key components: (i) a graph neural network that maps instance-specific features (e.g., topology, node or edge attributes) to the optimal tunable parameters of the low-fidelity model; (ii) a differentiable optimization layer that embeds the surrogate directly into the learning pipeline, allowing for end-to-end gradient-based training; and (iii) an implicit loss function that quantifies the mismatch between the low- and high-fidelity models, even when the high-fidelity model is non-differentiable. This architecture enables one-shot training of generalizable surrogates, without requiring labeled instances. We validate the framework on the AC optimal power flow problem using the DC-OPF as a tunable surrogate, demonstrating strong performance in terms of accuracy, feasibility, and inductive generalization on test systems with up to 13,659 buses.

1 - A Unified View of Optimization in the US Transplant System

Maura Hegarty, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas

The allocation and utilization of deceased-donor organs in the U.S. transplant system is governed by a fragmented, organ-specific decision process. Separate committees—Heart, Lung, Kidney, Pancreas, and Liver & Intestine—along with topic-focused groups (e.g., Living Donor, Histocompatibility) and an ad hoc Multi-Organ Committee, each prescribe distinct policies and allocation rules. While this vertical structure addresses organ-specific clinical nuances, it overlooks the reality that a single donor

frequently provides multiple transplantable organs that can be donated in pairs and triplets. As a result, current policy deliberations may inadvertently sacrifice overall patient benefit in favor of siloed decision-making. We propose a unified optimization framework that jointly considers all allocation and utilization decisions for a donor's full organ yield. Our approach models the transplant system as a large-scale, seeking to maximize aggregate patient-years of life and quality of life.

2 - Generative AI for Personalized Instruction

Romain Puech, MIT, Cambridge, MA, United States

One-to-one tutoring is one of the most efficient methods of teaching. With the growing popularity of Large Language Models (LLMs), there have been efforts to create LLM-based conversational tutors, which can expand the benefits of one-to-one tutoring to everyone. However, current LLMs are trained primarily to be helpful assistants and lack crucial pedagogical skills. For example, they often quickly reveal the solution to the student and fail to plan for a richer multi-turn pedagogical interaction. To use LLMs in pedagogical settings, they need to be steered to use effective teaching strategies: a problem we introduce as Pedagogical Steering. We develop StratL, an algorithm to optimize LLM prompts and steer it to follow a predefined multi-turn tutoring plan represented as a transition graph. We use this algorithm to implement an AI problem-solving tutor for MIT Open Learning.

3 - Interpretable AI-Driven Guidelines for Type 2 Diabetes Prevention and Treatment

Dewang Agarwal, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas

Objective: To develop precise, structured, data-backed guidelines for type 2 diabetes prevention and treatment progression, suitable for clinical adoption.

Research Design and Methodology: For prevention, we analyzed data from two randomized controlled trials: The Diabetes Prevention Program/Outcomes Study (DPP/DPP-OS) and ACT-NOW, both of which followed high risk individuals under different treatments. We created counterfactual models for treatment specific survival curves, after which tree-based AI models identified the optimal intervention.

For treatment prescription, we used observational data from Boston Medical Center (BMC) from 1998-2014. Patient visits were stratified by pre-visit treatment and then recommend the optimal treatment. Using optimization and machine learning, we reduced confounding bias to emulate randomized trial conditions. Multiple tree based models were trained and manually integrated into end-to-end prescription pipelines, one for each patient group. Performance was evaluated on held-out BMC data and externally validated on a Hartford dataset (visits between 2020-2024).

Results: The prevention pipeline was predicted to reduce T2DM incidence by 10% in high-risk patients. The prescription pipeline achieved median reductions in HbA1c (blood sugar) of 0.26% and 0.13% above physician performance at BMC and Hartford respectively.

Conclusion: Interpretable AI-driven guidelines for T2DM prevention and treatment outperform standard care and are ready for real world clinical deployment to improve patient outcomes.

4 - A Machine Learning Approach to Fluid Markov Decision Processes

Lisa Everest, Operations Research Center, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas, Cheol Woo Kim, Jose Nino Mora

We propose a machine learning approach to the optimal control of fluid Markov decision processes (MDPs) with state equations that are affine in the state variables. We derive fundamental properties of the MDP problems, which we then use to design a numerical algorithm. This algorithm begins with solving MDP instances with varying initial states to generate a dataset. We train an Optimal Classification Tree with hyperplane splits (OCT-H) to learn a control policy from this dataset.

5 - Adaptive Forests for Classification

Yubing Cui, MIT, Cambridge, MA, United States, Dimitris Bertsimas

We propose **Adaptive Forests (AF)**, a novel method that assigns input-dependent weights to CART trees using Optimal Predictive-Policy Trees and Mixed Integer Optimization. AF consistently outperforms Random Forests, XGBoost, and other weighted ensembles across 20+ datasets in both binary and multi-class classification tasks.

Algorithmic Approaches to Access and Affordability in Power Systems Optimization

Invited Session

ENRE: Energy

Chair: Rabab Haider, University of Michigan, Ann Arbor, MI, United States

1 - Integration of Critical Public Safety Needs Within Grid Planning and Optimization Methods

Jesse Dugan, National Renewable Energy Laboratory, Golden, CO, United States, Jordan Burns, Sara Peterson, Maya Fein-Cole

Extreme weather events and the threat of cyberattacks, coupled with the growing interdependence of infrastructure systems, have made resilience a critical objective for energy systems. Power outages and infrastructure disruptions pose significant societal risks, threatening public safety, the economy, and national security. Investments in distribution system resilience through grid modernization and hardening can help mitigate the impacts of long-duration power outages. However, traditional models and metrics used to assess infrastructure resilience often focus solely on the performance of physical infrastructure rather than the performance of the societal systems supported by infrastructure. This work presents a methodology to quantify the impacts of power outages on public safety by analyzing their effects on the availability of and access to critical services. This approach integrates grid models with residential and critical service locations, enabling us to explore outage consequences in a detailed spatial and temporal context. We employ routing algorithms, service value assignment, and travel cost analysis to examine the ways in which power outages impact households by decreasing their access to critical services. By integrating this methodology into power systems planning and operational decisions, we assess the performance of grid hardening and modernization investments from the public safety perspective. An application of this methodology in South Seattle, WA demonstrates how it can be used to site distribution automation equipment that optimizes public safety by providing households with continuous access to essential services during outages.

2 - Metrics to Support High-Resolution Community Impact Considerations in Electric Power System Decisions

Abigail Beck, University of Houston, Houston, TX, United States

The provision or absence of electricity has collective implications across an entire community, yet impacts from service disruptions have been shown to not occur uniformly but lead to disparate impacts on certain vulnerable populations (e.g., elderly, individuals with electric dependent medical devices). These populations can also be serviced by infrastructure more prone to outages only to exacerbate the likelihood of outage impacts. To improve community resilience these impact differences must be considered in power system optimization decisions (e.g., retrofit, restoration, operation, etc.). Aggregate community-wide metrics have previously been defined to assess broad system-level inequalities. However, high-resolution metrics are required to better detect the potential differential outage impacts and to target actions to reduce impact burdens on different groups or areas of concern. This talk presents high-resolution Theil's T-based metrics which are flexible to consider any community impact measure of concern and be implemented within multiple power system optimization decisions. The Theil's T-based metrics measure both the overall inequality and the amount a certain individual or group contributes to the overall inequality in impact. These metrics can be implemented within any power system decision to identify

inequalities, produce prioritizations, and formulate an objective function. The metric and its assessment and prioritization capability are demonstrated in simplified decision cases for distribution pole retrofitting and restoration. These applications demonstrate the metric's ability for high resolution impact-based prioritization and lays the groundwork for future optimization-based implementations.

3 - Embedding Affordability Goals into Grid Planning via Differentiable Optimization

Samuel Talkington, Georgia Institute of Technology, Atlanta, GA, United States, Amanda West, Ryan Piansky, Rabab Haider, Daniel Molzahn

With rapid load growth, extreme weather, and high penetration of intermittent generation, maintaining affordable access to electricity is of critical concern for system operators and utilities. This talk introduces a computational framework, Locational Marginal Burden (LMB), that is grounded in differentiable optimization. The LMB framework emerges as an intrinsic property of optimal power flow (OPF) problems. By differentiating through the dual solutions of OPF problems, i.e. the wholesale electricity prices, we reveal the impact of power system operating principles and grid infrastructure on affordability. The LMB framework endogenizes the energy burden experienced by customers (a metric for energy affordability) directly into grid optimization models. In doing so, the LMB operationalizes energy burden, providing a way to incorporate affordability considerations into planning and operating models. We propose the LMB framework as a way to support policymaking and investment decisions, such as line upgrades and capacity expansion while meeting critical energy affordability goals. This approach provides a mathematically grounded pathway for embedding equity considerations in power systems optimization.

4 - Energy Management for Prepaid Electricity Customers

Maitreyee Marathe, University of Massachusetts Amherst, Amherst, MA, United States

For a large and recently increasing number of households, affordability is a major hurdle in accessing sufficient electricity and avoiding service disconnections. Such households need to actively ration the amount of energy they use by deciding which appliances to use and for how long. In this work, we consider prepaid customers – a particularly vulnerable group of customers who are required to pay for their electricity a-priori and get immediately disconnected if their prepaid wallet runs out of balance. Low-income customers and prepaid customers have been largely neglected in home energy management literature. We present a tool that helps such households extend the availability of their critical appliances by limiting the use of discretionary ones, and prevents disconnections. The tool is based on a linear optimization problem that only uses average power demand forecasts and can be solved to optimality using a simple greedy approach. Our model accounts for daily variations in the relative priority of appliances and time-of-use pricing. Furthermore, we demonstrate the computational simplicity of our model by implementing it on an inexpensive 8-bit microprocessor. In a numerical case study based on real household data, we compare the performance of our model with two mixed-integer linear programming models that require more detailed demand forecasts and optimization solvers for implementation. Our results show that our proposed linear model is much simpler to implement, while providing similar performance under realistic circumstances, lending itself well to adoption across different regions and utility programs.

5 - Reducing the Academia Discourse Divide: How to Rethink Collaboration on Environmental Justice and Equity

Aneesha Manocha, University of California Berkeley, Berkeley, CA, United States

Various disciplines (engineering, social sciences, and humanities) have historically approached questions of environmental justice (EJ) and equity differently, from how they formulate the scope and impacts of the problem to how they propose enacting change and recommendations. While these broad disciplines have contributed immensely to problems related to EJ, there are opportunities for deeper interdisciplinary collaboration, especially in planning for clean, just energy transitions. In this piece, we present an EJ framework, where we trace epistemologies of how various disciplines conceptualize knowledge to their methods and how they present and publish work. We extensively survey the EJ literature across academic disciplines to determine how different fields discuss similar issues and can learn from each other. We highlight opportunities to facilitate collaboration through a few case studies. We conclude with recommendations on how researchers can work with scholars across fields who think about data, methods, and research outputs differently.

Distributed Energy Resource Integration: Statuses and Challenges

Invited Session

ENRE: Electricity

Chair: Feng Pan, Pacific Northwest National Laboratory, Richland, WA, United States

Co-Chair: Hugo Santarem de Araujo, Cornell University, Ithaca, NY, United States

1 - Price Consistency and Uplift in Wholesale Electricity Markets

Hugo Santarem de Araujo, Cornell University, Ithaca, NY, United States, Jacob Mays, Han Shu

Price formation is central to power market operations, but is complicated by two persistent challenges: non-convexities in unit commitment and the uncertainty introduced by variable renewable energy. While each issue has been studied independently, their combined effects remain poorly understood, especially in the sequential decision-making context. One consequence of sequential decisions is the occurrence of mismatches between provisional prices (based on initial schedules) and binding prices (those that ultimately clear the market). These mismatches often give rise to uplift payments, which keep generators financially whole when dispatch decisions deviate from profit-maximizing decisions. Due to their non-transparent and discriminatory nature, market operators and regulators have implemented price formation reforms seeking to limit uplift payments. Many of these reforms are inspired by Convex Hull Pricing (CHP), which has been shown to minimize uplift in deterministic settings. Our study examines how non-convexity and uncertainty jointly shape price formation. We model the unit commitment problem sequentially over time, reflecting how Independent System Operators (ISOs) operate in practice, and compare the performance of price formation alternatives. Simulations use a stylized model of the New York ISO grid, incorporating thermal, solar, wind, and hydro resources totaling approximately 40,000 MW under three different operational policies. For each run, we compute both provisional and binding prices and the corresponding uplift payments. Results show that while CHP reduces expected payments, it has little impact on actual binding payments. Instead, the choice of operational policy has a larger impact on price consistency and uplift.

2 - How to Procure Green Power for Real Emissions Reductions?

Yago del Barrio, Johns Hopkins University, Baltimore, MD, United States

This work investigates how corporate green power procurement strategies interact with national and regional carbon and renewable energy policies. It examines how procurement design choices, such as temporal and spatial matching requirements, affect system-wide emissions and cost outcomes. Multiple optimization frameworks are employed to reflect different assumptions and perspectives. In particular, a bilevel optimization model is developed to analyze the potential influence of large corporate buyers on market operations and emissions trajectories. This analysis is especially relevant given the rapid expansion of energy-intensive data centers, which are often concentrated in specific regions and can significantly impact local grid dynamics. The framework is applicable to other large procuring corporations seeking to ensure that their clean energy commitments lead to real emissions reductions.

1 - Multi-Island Power System Optimization: a Feasibility Study of the Eastern Caribbean Power Pool

Avery Barnett, Princeton University, Princeton, NJ, United States, Robert Brecha, Olivia Roslansky, Jesse Jenkins

Nearly all countries and territories in the Eastern Caribbean face high electricity costs and energy insecurity due to aging grids, small-scale demand, and above all, due to reliance on imported fossil fuels. To overcome this, we explore the feasibility of an Eastern Caribbean Power Pool (ECPP), a proposed interconnected grid that spans from Trinidad and Tobago to Antigua and Barbuda. This is the first study of its kind to apply a multi-island capacity expansion framework with geopolitical feasibility assessments for a Power Pool in the Eastern Caribbean. We use GenX, a capacity expansion model, to determine least cost generation and transmission investments and apply Modelling to Generate Alternatives (MGA) to identify a set of near-optimal interconnection pathways via subsea cables. This methodology seeks to balance technical feasibility, cost, and the resource potential within each country. Scenarios are evaluated for their ability to support the national renewable energy targets while maintaining or lowering electricity costs. We assess implementation feasibility by comparing model outcomes with qualitative geopolitical factors based on prior research. The results will offer insight to regional energy planning and provide a foundational analysis for the Caribbean Development Bank's CREGI-RES initiative.

2 - Data Injection Attacks on Distributed Systems: An Information-Theoretic Approach

Xiuzhen Ye, Department of Chemical and Biomolecular Engineering, North Carolina State University, Raleigh, NC, United States, Wentao Tang

The unprecedented data acquisition capabilities in modern cyber-physical systems (CPSs) have increased their vulnerability to malicious attacks. Typical CPSs—such as smart grids and chemical plants—are susceptible to threats such as data injection attacks (DIAs). As a fundamental requirement for ensuring safety and reliability, investigating DIAs in these domains is of critical importance. We are particularly interested in *distributed attack* and *sparse attack* strategies, which become feasible for attackers due to the integration of computing and communication components in CPSs.

This work considers DIA design from the attackers' standpoint, who are able to exploit the statistical properties of the system's state variables. To quantify the statistical information with fundamental metrics and thus effectively leverage them in optimal attack constructions, we adopt an *information-theoretic* approach. Specifically, the attackers aim for targeting the sensor measurements at the stationary operating points in the system, with the objective to disrupt the distribution of the state variables while remain stealthy. To this end, mutual information and Kullback-Leibler divergence are used to measure the attack disruption and stealthiness, respectively.

We hence use an optimization formulation under the restrictions of distributed attacks (where each attacker has access to an assigned set of sensors) and sparse attacks (where the number of sensors attacked should be limited). As a realistic solution, by modeling the interactions between attacks in different locations of distributed systems, *game-theoretic strategies* are proposed. Case studies on smart grids and chemical reactor systems are presented to illustrate the proposed method with comparison to *full attacks*.

3 - Port Resilience in Disruptive Scenarios: a Milp-Based Decision Support Model

Ruben Yie-Pinedo, Universidad el Norte, Barranquilla, Colombia, Johanna Padilla, Adriana Moros

Port resilience is essential for maintaining operational continuity and efficiency amid global supply chain disruptions. This study introduces a Mixed-Integer Linear Programming (MILP) model for the Discrete Berth Allocation and Quay Crane Assignment Problem (BACAP), enhanced by a quantitative resilience index. The model aims to optimize berth and crane scheduling in container terminals under systemic disruption scenarios.

Currently under development, the model explores six operational scenarios involving disruptions such as vessel delays, crane unavailability, and partial berth closures. A composite resilience index guides decision-making, built using Principal Component Analysis (PCA) and the Entropy Weight Method (EWM) on key performance indicators (KPIs). Bootstrap resampling ensures the statistical robustness of the indicator weights.

By integrating this resilience index into BACAP, the model enhances operational flexibility, reduces service time variability, and supports greenhouse gas mitigation. A case study in a Caribbean port will validate the model's applicability, aiming to improve port management and sustainability in uncertain environments.

This work offers a quantitative framework for resilient planning in port terminals, aligning operational efficiency with environmental sustainability and strengthening the competitiveness of maritime supply chains.

4 - Linear Ac Power Flow for Optimal Transmission Switching

Sergio A. Dorado-Rojas, Georgia Institute of Technology, Atlanta, GA, United States, Constance Crozier, Daniel Molzahn

Optimal transmission switching (OTS) is a valuable tool for enhancing grid operations, allowing system operators to achieve objectives like congestion reduction, cost minimization, and wildfire risk minimization. Conventionally, OTS problems are formulated with highly simplified (DC) or computationally intractable (AC) power flow models. The full AC optimal transmission switching (ACOTS) problem presents a significant computational challenge with its binary switching variables and nonconvex AC power flow constraints. While the DC optimal transmission switching (DCOTS) problem offers a tractable linear approximation, it sacrifices accuracy. This work introduces a linear AC power flow model into an OTS formulation, resulting in the linear ACOTS (LACOTS) problem. Despite its potential, this linear AC formulation is rarely used as a baseline in OTS. We demonstrate LACOTS's capability to serve as an effective linear surrogate for the nonlinear AC power equations through a combination of theoretical analysis and numerical experiments. Our ongoing efforts are concentrated on systematically comparing DCOTS and LACOTS solutions across a range of test cases, aiming to fully characterize the benefits and illuminate the power of this often-overlooked linear AC approach.

5 - Securing Firm Gas Capacity: Impacts on System Costs and Gas Plant Competitiveness of on-Site Fuel Storage in Current and Future U.S. Power Grids

Godwin Obi, ZERO Lab, Princeton University, Princeton, NJ, United States, Jesse Jenkins

Fuel supply disruptions during extreme weather events—such as Winter Storm Uri, which caused hundreds of billions in economic damage—highlight the vulnerability of gas-fired power plants and the importance of firming fuel supply. On the other hand, as renewables scale and gas plants face lower utilization rates, traditional financial mechanisms for pipeline-based fuel delivery may become harder to justify. This study examines the system-wide impacts of requiring 1 to 14 days (2 weeks) of on-site fuel storage, focusing on cost implications and deployed gas capacity in the short term (under current IRA policies and a no-IRA-policy scenario) and long term (under high-renewables and business-as-usual scenarios) across the U.S. grid.

Using GenX, a state-of-the-art capacity expansion model, we quantify changes in system fixed and fuel costs and shifts in gas capacity with increasing storage duration. We also conduct a breakeven cost analysis to estimate, under both policy scenarios, the capital costs at which LDES and SMRs could displace gas capacity with plausible fuel storage. We evaluate three storage options—diesel, LNG, and liquid hydrogen—with a focus on: What storage medium is most plausible? How do system and plant-level costs change? At what storage duration or capital cost do clean firm alternatives replace gas?

Results show 1–14 days of storage raise system costs by up to 3%, plant fixed costs by over 6%, and reduce gas capacity by nearly 2%, with diesel as the most cost-effective option. At 2 weeks, diesel storage needs reach one-quarter of U.S. annual commercial consumption.

Open-Source Tools for Modeling and Simulation in Power Systems Research

Invited Session

ENRE: Energy-Climate

Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL, United States

1 - Unitcommitment.Jl: A Julia/Jump Optimization Package for Security-Constrained Unit Commitment

Alinson Santos Xavier, Argonne National Laboratory, Lemont, IL, United States

Security-Constrained Unit Commitment (SCUC) is one of the most fundamental and challenging problems in power systems optimization, being solved daily by Independent System Operators (ISOs) to clear the electricity markets. In this talk, we present UnitCommitment.jl, an open-source optimization package designed to help researchers overcome common obstacles in developing and evaluating new solution methods for this problem. The package offers several features, including: (i) a flexible and well-documented data format for the problem, created with input from ISOs, that makes it easier for researchers to share data sets across institutions; (ii) a collection of large-scale benchmark problems, gathered from the literature and extended with data-driven methods to make them more complex and realistic; and (iii) implementations of state-of-the-art mathematical formulations and solution methods for the problem; and (iv) automated benchmark scripts to evaluate the performance of newly proposed methods accurately.

2 - Open-Source Tools for Modeling and Simulation in Power Systems Research

Wei Gao, Argonne National Lab, Lemont, IL, United States, Feng Qiu, Shijia Zhao

Reliability analysis is critical for ensuring secure and continuous power system operation under both normal and stressed conditions. With increasing grid complexity driven by renewable integration and extreme events, there is a growing demand for computational tools that are robust, scalable, and fast. Traditional numerical methods, such as Newton-Raphson iterations, often suffer from convergence issues and inefficiencies, particularly in large-scale contingency analysis.

This work presents PowerSAS.jl, a high-performance, Julia-based framework for power system reliability analysis built on the semi-analytical solution (SAS) methodology. SAS approximates system dynamics using power series expansions, yielding closed-form expressions over time intervals. This enables faster simulations, larger time steps, and improved numerical stability compared to iterative methods.

PowerSAS.jl supports steady-state, transient, and extended-term simulations, including N-1 contingency screening, voltage and frequency stability assessment, and cascading failure analysis. It inherits key capabilities from SAS: high numerical robustness, support for differential-algebraic systems, and the ability to simulate power systems with over 200,000 buses. Enhanced with Julia's parallel computing strengths, PowerSAS.jl achieves significant speedup and scalability improvements.

Released as open-source, PowerSAS.jl provides a flexible and transparent tool for planners and researchers, accelerating comprehensive reliability assessments essential for real-time and market operations.

3 - Andes Journey: Ten Years of Open-Source Innovation in Power Systems

Hantao Cui, North Carolina State University, Raleigh, NC, United States

ANDES, a Python software for power system simulation, started as a weekend project for learning Python and power system fundamentals. Ten years later, it is a full-fledged open-source simulator with tens of thousands of lines of code that is widely used for modeling, simulation and analysis. This talk reflects on the journey for getting there on both the technical decisions and the human side. Primarily, it took two major rewrites and deliberate efforts of community building to keep the project relevant and easy to use for both students and professionals. The talk will also discuss the sustainability of opensource software, focusing on tools in the engineering domains that typically attract a small pool of contributors. In addition, I will share the vision of an opensource ecosystem where a spectrum of opensource tools can develop synergy for applications such as production optimization, stability simulation, data-drive decision making, and climate impact studies.

4 - Diff2sp: Diffusion Models for Correlated Scenario Generation in Stochastic Programming

Haixiang Sun, Purdue, West Lafayette, IN, United States, Andrew Liu

The quality of scenario generation has a direct impact on the performance of decisions made under stochastic programming frameworks. Traditional Monte Carlo and supervised learning approaches are often computationally intensive, require large sample sizes or labeled data, and struggle to capture complex temporal and cross-variable dependencies. In this work, we introduce Diff2SP, a diffusion-based framework that learns joint uncertainty distributions from historical observations by embedding the downstream optimization objective into its training loss, so that the generator learns to prioritize uncertainty patterns that most impact decision outcomes.

We derive a finite sample regret bound that relates the Wasserstein distance between the learned and true distributions to loss in objective value and show that the bound achieved by Diff2SP is strictly tighter than the best available guarantee for Generative Adversarial Networks (GANs). Extensive evaluation supports the theory. In our numerical studies, Diff2SP outperforms vanilla diffusion and GAN variants in both distributional accuracy and decision quality, consistently achieving lower regret and better preservation of statistical structure. Real data experiments on two years of renewable energy scheduling confirm that Diff2SP preserves temporal dependence and cross variable correlations among wind, solar and load data, reducing expected operating cost by up to fifteen percent relative to competing methods. These results position Diff2SP as a practical and principled tool for scenario generation in stochastic optimization.

5 - Layout Optimization for a Large-Scale Grid-Connected Solar Power Plant

Chong Wang, Huazhong University of Science and Technology, Wuhan, China, People's Republic of

A solar power plant provides green electricity to the public via a power grid. As governments worldwide aim to reduce carbon emissions and achieve carbon neutrality, large-scale grid-connected solar power plants are booming. Developing such a plant requires significant investment, much of which covers construction costs. These costs, together with energy yield, critically depend on the plant's layout. Layout planning involves complex optimization problems such as district partitioning, PV component location, and cable routing. These problems are highly challenging due to large-scale instances, complex design principles, and physical constraints, and have received limited attention in the literature. Motivated by collaborative projects with an electrical engineering company in China, this paper focuses on the integrated location and routing (ILR) problem, involving locating service ways, inverters, combiner boxes, and routing cables to connect them. We develop exact algorithms to solve the ILR problem via a decomposition framework, yielding a variant of Benders decomposition (BD) proven to produce an optimal solution. An exact branch-and-cut scheme is designed to solve each subproblem by incorporating cutting planes and separation algorithms. Our approach is evaluated on 50 real-world data instances through extensive numerical experiments. Compared with the manual greedy heuristics used in practice, our method reduces total cost by about 20%. The decomposition method achieves an average gap of 0.02% between obtained lower and upper bounds, much smaller than the 16.08% gap achieved with traditional BD.

1 - Real-Time Pandemic Control: A Digital Twin Framework for Adaptive Interventions

Osman Ozaltin, North Carolina State University, Raleigh, NC, United States, Sebastian Rodriguez Cartes, Maria Mayorga, Kevin Flores, Julie Swann

This study investigates the dynamic application of interventions to control infectious disease outbreaks, with a specific focus on mask mandates. We introduce a digital twin approach, wherein a complex agent-based model serves as the real system, and its digital twin is a stochastic compartmental model of infectious disease spread. A Bayesian methodology is utilized to update the parameters of the compartmental model as new disease spread information becomes available from the agent-based model. Subsequently, the digital twin is employed for mask mandate policy planning, and the resulting policies are implemented in the agent-based model within a continuous feedback loop. We present computational results evaluating the performance of different planning algorithms, including a grid-based threshold search approach and reinforcement learning.

2 - Optimal Lockdown Timing During An Epidemic

Noura El Hassan, American University of Beirut - Mediterraneo, Pafos, Lebanon, Bael Maddah, Fouad Ben Abdelaziz

Our research uses a Markov Decision Process to determine the optimal time to impose a lockdown, as a careful trade-off between health-related and economic aspects should be considered. We assume that the pandemic evolves based on a well-known Susceptible-Infected-Susceptible epidemic model. We show that the value function is

concave in the number of infections, which implies an optimal policy based on threshold values on the number of infections. Accordingly, we propose an efficient search and storage method that allows handling real-world problems with a large population size reaching one million within a manageable CPU time. Numerical experiments show that our policy outperforms benchmark policies. Moreover, in a case study of the Island of Corsica, we find that our policy produces favorable health recommendations.

3 - An Optimization-Based Framework to Dynamically Schedule Hospital Beds in A Pandemic

Marwan Shams Eddin, George Mason University, Euless, TX, United States

Emerging pandemics and peak infection periods can overwhelm healthcare systems, especially under limited resource availability such as hospital beds, ventilators, and ICU capacity. This strain may lead to elevated mortality rates and increased healthcare costs. In this paper, we present a novel optimization-based framework that dynamically schedules hospital beds to minimize total healthcare costs—primarily composed of patient rejection costs and associated logistical expenses—while operating under strict resource constraints. Our model accounts for multiple sources of bed supply, including standard hospital beds, insitu hospital beds, and buffer beds, and incorporates flexible resource sharing to better accommodate patient demand. Recognizing the computational complexity of the resulting optimization model, we propose a reformulation that significantly reduces run-time. We also analyze key structural properties and derive optimal solutions under specific conditions. To account for demand uncertainty, we extend the framework by integrating an SEIRD model to simulate patient demand in future pandemics and to inform proactive bed scheduling. To evaluate the practical utility of our approach, we conduct a case study based on the COVID-19 pandemic in the Northern Virginia (NOVA) region. Our results demonstrate that the proposed framework can reduce total healthcare costs by more than 55%, highlighting its potential in guiding resource allocation and preparedness strategies during health crises.

4 - Decoding State-Relevance Weights in Dual Alp: a Patient Scheduling Case Study

Su Li, University of Toronto, Toronto, ON, Canada

Markov Decision Processes serve as a foundational framework for decision-making under uncertainty. However, in high-dimensional problem settings, obtaining exact solutions is impractical due to the exponential size of the state space (the curse of dimensionality). Approximate Linear Programming (ALP) is a commonly used technique for approximating the value function with a conical combination of basis functions. A critical aspect of the ALP approach is the selection of state-relevance weights, which can markedly influence the performance of the resulting policy. In this work, we present a novel perspective on state-relevance weights through Dual Approximate Linear Programming. We first demonstrate how the choice of state-relevance weights can affect policy performance. We then propose an approach for simultaneously computing state-relevance weights and approximate value function coefficients within the ALP framework. We prove several structural properties and numerically assess the quality of our approach using applications from queueing and patient scheduling.

5 - Assessing Thresholds of Resistance Prevalence at Which Empiric Treatment of Gonorrhea Should Change Among Men Who Have Sex with Men in the US: A Cost-Effectiveness Analysis

Xuecheng Yin, Oklahoma State University, Tulsa, OK, United States

Gonorrhea is typically treated without knowing whether the infection is resistant to the antibiotic used, since common tests do not check for drug resistance. As resistance to an antibiotic increases, treatment guidelines usually switch to a different drug once a certain resistance level (like 5%) is reached. Using a lower threshold (e.g., 1%) may improve treatment success but could lead to more frequent changes in recommended antibiotics. The effects of different thresholds on gonorrhea incidence, treatment failures, costs, and quality of life are not well understood.

We built a mathematical model to study the effects of different antibiotic switch thresholds (1% to 10%) on health and economic outcomes in men who have sex with men (MSM) in the U.S. The model considered infection spread, resistance, treatment, symptoms, long-term health issues, costs, and quality-adjusted life-years (QALYs). We summarized outcomes using net health benefit (NHB), which combines cost and QALY loss. When only three antibiotics are available over 50 years (two for initial treatment, one for retreatment), changing the switch threshold had little impact on overall gonorrhea cases, costs, or QALY losses. However, if a new antibiotic becomes available, a lower switch threshold (1–2%) may improve NHB especially if drug susceptibility testing (DST) is used to guide retreatment after a failed first therapy.

Switching first-line antibiotics at lower resistance levels may not always change outcomes, but it could be beneficial if new antibiotics and DST are available. Our model focused on MSM and did not include vaccines or DST for initial treatment.

1 - Fast and Accurate Estimation of Low-Rank Matrices from Noisy Measurements via Preconditioned Non-Convex Gradient Descent

Hong-Ming Chiu, University of Illinois Urbana-Champaign, Urbana, IL, United States, Gavin Zhang, Richard Zhang

Non-convex gradient descent is a common approach for estimating a low-rank matrix from noisy measurements, because it has per-iteration costs as low as linear time, and is in theory capable of converging to a minimax optimal estimate. However, the practitioner is often constrained to just tens to hundreds of iterations, and the slow and/or inconsistent convergence of non-convex gradient descent can prevent a high-quality estimate from being obtained. Recently, the technique of preconditioning was shown to be highly effective at accelerating the local convergence of non-convex gradient descent when the measurements are noiseless. In this talk, we describe how preconditioning should be done for noisy measurements to accelerate local convergence to minimax optimality. For the symmetric matrix sensing problem, our proposed preconditioned method is guaranteed to locally converge to minimax error at a linear rate that is immune to ill-conditioning and/or over-parameterization.

2 - On Strong Formulations for 0-1 Fractional Programming via Disjunctive Arguments

Soo bin Choi, University of Southern California, Los Angeles, CA, United States, Andres Gomez

In this study, we propose stronger convex relaxations for 0-1 fractional programs by leveraging disjunctive programming techniques. Specifically, we derive tight upper bounds for linear fractional functions over binary domains by combining disjunctive arguments with polymatroid inequalities. Additionally, we introduce a new family of second-order cone inequalities that provide stronger lower bounds than those established in the literature. Numerical experiments indicate that the proposed formulations yield tighter relaxation gaps than existing approaches.

3 - Learning Dynamics of Deep Matrix Factorization Beyond the Edge of Stability

Soo Min Kwon, University of Michigan, Ann Arbor, MI, United States

Deep neural networks trained using gradient descent with a fixed learning rate often operate in the regime of "edge of stability" (EOS), where the largest eigenvalue of the Hessian equilibrates about the stability threshold. In this work, we present a fine-grained analysis of the learning dynamics of (deep) linear networks (DLNs) within the deep matrix factorization loss beyond EOS. For DLNs, loss oscillations beyond EOS follow a period-doubling route to chaos. We theoretically analyze the regime of the 2-period orbit and show that the loss oscillations occur within a small subspace, with the dimension of the subspace precisely characterized by the learning rate. The crux of our analysis lies in showing that the symmetry-induced conservation law for gradient flow, defined as the balancing gap among the singular values across layers, breaks at EOS and decays monotonically to zero. Overall, our results contribute to explaining two key phenomena in deep networks: (i) shallow models and simple tasks do not

always exhibit EOS; and (ii) oscillations occur within top features. We present experiments to support our theory, along with examples demonstrating how these phenomena occur in nonlinear networks and how they differ from those which have benign landscape such as in DLNs.

4 - Fastest Algorithm, in Theory and Practice, for Densest Subgraph and Other Ratio Problems: the Incremental Parametric Cut

Dorit Hochbaum, UC Berkeley, Berkeley, CA, United States

The maximum density subgraph problem is one of ratio problems that are often employed in community detection, clustering, or identifying patterns in large scale data sets, or networks. Research on the problem, in the last couple of decades, has been focused on developing heuristic methods for solving the maximum density problem claiming that flow computations are computationally prohibitive for large scale problems. These heuristics are designed for speed while sacrificing optimality. We present here a new algorithm called, the incremental parametric cut algorithm (IPC), that solves optimally the maximum density problem, as well as other "monotone integer" ratio problems related to the conductance, Cheeger constant, graph expander and normalized cut problems. The theoretical complexity of IPC is that of a single minimum cut, matching the complexity of the previously known parametric cut method. Yet in practice, IPC is dramatically faster. This is due to targeting one specific "breakpoint" solution, whereas the parametric cut procedure generates all "breakpoints". Not only does IPC overcome the computational limitations of previous cut-based approaches, but it also outperforms the state-of-the-art heuristic approaches, both in terms of solution quality, and in terms of speed, by several orders of magnitude.

Chair: Qi (George) Chen, London Business School, London, United Kingdom

1 - The Sooner, The Better? Optimal Vaccination Policy with Limited Vaccine Supply

Qi (George) Chen, London Business School, London, United Kingdom, Miao Bai, Cuihong Li

We study the optimal single-dose vaccination policy during an infectious disease outbreak, considering both limited vaccine supply and imperfect efficacy, which provides partial immunity to each vaccinated individual. The inclusion of imperfect efficacy introduces an additional compartment to the celebrated Susceptible-Infectious-Recovered (SIR) model, giving rise to an infinite horizon nonlinear optimal control problem. We derive a closed-form expression for the optimal vaccination policy under infinite administrative capacity and establish theoretical structures of the optimal policy under finite capacity. Our results suggest that delaying the start of the vaccination process may be optimal, especially when the vaccine is less effective, the vaccine supply is more limited, and the disease is more infectious. We identify key terms as an integral part of the analysis that characterize the individual-level benefit of vaccination and, importantly, provide insights into the intuition behind vaccination delay. Building on these theoretical findings, our numerical study verifies these insights based on sensitivity results. We demonstrate the significant benefit of delay in reducing the total number of infections compared to policies without delay. Furthermore, we extend our analysis to alternative model dynamics and objective functions, confirming that our key findings remain robust and our methodology applicable across different settings. Our study contributes to the methodological framework to analyze optimal vaccination policies for infectious disease control, and uncovers an important policy structure -- vaccination delay -- that has been overlooked in the literature but has important implications for practice.

2 - Impact of Adding Cold Chain Equipment on Vaccination Timeliness

Rohan Bapat, Indian School of Business, Hyderabad, India, Sarang Deo, Sripad Devalkar

Delays in childhood vaccination remain a persistent health challenge in many low-resource settings, prolonging susceptibility to vaccine preventable diseases, and thereby undermining the effectiveness of vaccination programs. These delays stem from a combination of demand-side factors and supply-side constraints, where the former could be caregiver unavailability, child illness, or travel, while the latter includes the limited capacity of cold chain infrastructure, especially at the last mile. Inadequate last-mile cold chain capacity often necessitates a periodic or intermittent vaccination model, where vaccines are only administered on pre-determined session days, further delaying the time to vaccination. Recent multilateral initiatives to improve vaccination outcomes have focused on strengthening cold chain infrastructure through increased investments in cold chain equipment. Depending on how these investments are deployed, they can either *expand* inventory capacity at existing cold chain points or *extend* cold chain infrastructure closer to communities, potentially supporting a continuous vaccination delivery model. This research investigates how changes to cold chain infrastructure affect delays in vaccination by developing an analytical model that captures demand-side and supply-side contributors to vaccination delay. By modeling impact of these two distinct investment strategies - *expansion* and *extension* of cold chain capacity, we assess how such infrastructure improvements influence the likelihood of children receiving vaccines at age-appropriate times. Our findings offer operational insights to guide the design and allocation of vaccination program investments to improve timely vaccination.

3 - Mobile Vaccination Team Weekly Scheduling and Vehicle Routing

Jinghong Miao, University of Southern California, Los Angeles, CA, United States, Jing Jin, Sze-chuan Suen, Maged Dessouky, Fernando Ordonez

Every week, planners at the Los Angeles Department of Public Health (LADPH) Mobile Vaccination Team must route and schedule nurses to geographically dispersed vaccination sites for the following week. Each vaccination event has staff requirements, in addition weekly nurse working-hour limits and event time windows must be observed. This problem combines both aspects of scheduling and routing problems, resulting in a formulation of intersecting vehicle routing problems (VRPs) that must be solved simultaneously. We formulate a mixed-integer linear program that simultaneously determines nurse assignments and travel routes over a one-week horizon. The objective minimizes total travel distance while considering a fairness metric that caps workload disparities. However, standard solvers cannot identify feasible solutions within operational computational times for realistic problems at scale, so we propose a heuristic framework that 1) discretizes time into intervals to prune infeasible solutions, 2) partitions the full horizon into subproblems, and 3) iteratively refines solutions and bounds. Computational experiments on both simulated and real instances demonstrate that our heuristic provides a better solution than standard solvers in significantly less computation time. This work provides a scalable method for nurse scheduling and routing under fairness considerations.

4 - Optimized Hiv/Aids Resource Allocation in Ohio: a Linear Programming Approach

Godfred Ahenkroa Kesse, University of Central Florida, Orlando, FL, United States

This study employs a linear and integer programming approach to optimize HIV resource allocation in Ohio, aiming to minimize new infections and enhance the impact of limited resources. With the advances in HIV prevention and treatment, Ohio faces challenges in addressing disparities in access to healthcare, particularly among high-risk populations. The proposed model integrates data on infection rates, transmission patterns, demographic factors, and cost-effectiveness to provide a decision-support framework for policymakers. Using epidemiological data and equity constraints, the model prioritizes high-risk regions and populations while ensuring fair resource distribution. Results indicate that increased funding allocations significantly enhance the potential to avert new infections. This research underscores the importance of data-driven strategies in achieving the objectives outlined in the HIV National Strategic Plan, emphasizing targeted interventions and equitable healthcare access to curb the epidemic effectively.

5 - Antigenicity Prediction and Vaccine Recommendation of Human Influenza Virus A (H3n2) Using Convolutional Neural Networks

Eva Lee, The Data and Analytics Innovation Institute, Atlanta, GA, United States

The rapid and large-scale pathogenesis of influenza virus requires constant monitoring and frequent vaccine development to protect the world population not only from seasonal influenza but also from novel influenza A viruses that could trigger a pandemic. Analytical and machine learning models have been applied to facilitate the process of antigenicity determination. In this study, we designed deep convolutional neural networks to predict Influenza antigenicity. We first systematically compared the all 20 amino acid properties and amino acid substitution matrices for their predictability. We then optimized the structure of the convolutional neural networks using particle swarm optimization. The optimal neural networks outperform other predictive models with a validation accuracy of 0.958. Further, the results show that our model

outperforms other existing models, and could potential improve the vaccine recommendation process. Overall, we introduce a comprehensive pipeline for optimizing a convolutional neural network in the modeling of Influenza A's antigenicity and vaccine recommendation.

Adaptive Stochastic Nonlinear Optimization

Invited Session

OPT: Nonlinear Optimization

Chair: Qi Wang, Lehigh University, Bethlehem, PA, United States

1 - Adaptive Fixed-Step Stochastic Gradient

Raghu Pasupathy, Purdue University, West Lafayette, IN, United States, Akshita Gupta, Raghu Bollapragada, Nung Kwan Yip

A folklore adaptive fixed-step stochastic gradient method works as follows. Execute stochastic gradient with a fixed step until the iterates approach stationarity; now re-execute stochastic gradient starting from the final iterate of the previous execution and with the revised fixed step until the iterates again approach stationarity, and so on. This restart scheme is attractive on two accounts: (i) it is simple to implement, and (ii) due to the Markov structure, each execution of fixed-step stochastic gradient generates iterates that (provably) attain stationarity exponentially fast. The first version of this scheme seems to have been conceived by G. Pflug in 1983, and several prominent authors including U. Shanbhag, J. Nocedal, and L. Xiao have worked or commented on enhancements, with some reporting strikingly positive numerical results. Considering this empirical success, we present a unified view of adaptive fixed-step gradient methods using *statistical testing functionals*, reflecting our viewpoint that most if not all adaptive fixed-step methods are explicitly or implicitly attempting to detect stationarity of iterates as a signal for reducing step size. The unification we propose facilitates characterizing generic consistency and optimal complexity conditions for adaptive fixed-step gradient methods, while also providing a template for more general settings. Time permitting, we will present a specific variation that is robust to tuning and that has performed favorably against well-tuned fixed-step SGD algorithms on standard problems.

2 - On the Resolution of Stochastic Mpecs over Networks: Distributed Implicit Zeroth-Order Gradient Tracking Methods

Mohammadjavad Ebrahimi, Rutgers University, Piscataway, NJ, United States, Uday Shanbhag, Farzad Yousefian

The mathematical program with equilibrium constraints (MPEC) is a powerful yet challenging class of constrained optimization problems, where the constraints are characterized by a parametrized variational inequality (VI) problem. MPECs subsume broad subclasses of bilevel optimization and Stackelberg games, which have numerous applications in power markets, transportation networks, and structural design problems. While efficient algorithms for addressing MPECs and their stochastic variants (SMPECs) have been recently presented, distributed SMPECs over networks remain unexplored. This work aims to develop fully iterative methods with complexity guarantees for resolving distributed SMPECs in two problem settings: (1) distributed single-stage SMPECs and (2) distributed two-stage SMPECs. In both cases, the global objective function is distributed among a network of agents that communicate cooperatively, and the implicit objective is possibly nondifferentiable and nonconvex. We propose single-stage and two-stage zeroth-order distributed gradient tracking optimization methods where the gradient of a smoothed implicit objective function is approximated using two (possibly inexact) evaluations of the lower-level VI solutions. For the exact settings, we achieve the best-known complexity bound for centralized nonsmooth nonconvex stochastic optimization, that is $\mathcal{O}(\epsilon^{-\frac{3}{2}})$ where n denotes the upper-level decision dimension. This complexity bound is also achieved for the inexact setting of the distributed two-stage SMPEC. In addressing the inexact setting of the single-stage problem, we derive the overall complexity of $\mathcal{O}(\epsilon^{-\frac{7}{2}})$, improving the dependence on n compared to the existing results for the centralized SMPECs. Preliminary numerical experiments demonstrate the efficiency of our methods across various network topologies compared to centralized zeroth-order schemes.

3 - High Probability Complexity Bounds of Trust-Region Stochastic Sequential Quadratic Programming with Heavy-Tailed Noise

Yuchen Fang, University of California, Berkeley, Berkeley, CA, United States, Javad Lavaei, Sen Na

In this paper, we consider nonlinear optimization problems with a stochastic objective and deterministic equality constraints. We propose a Trust-Region Stochastic Sequential Quadratic Programming (TR-SSQP) method and establish its high-probability iteration complexity bounds for identifying first- and second-order ϵ -stationary points. In our algorithm, we assume that exact objective values, gradients, and Hessians are not directly accessible but can be estimated via zeroth-, first-, and second-order probabilistic oracles. Compared to existing complexity studies of SSQP methods that rely on a zeroth-order oracle with sub-exponential tail noise (i.e., light-tailed) and focus mostly on first-order stationarity, our analysis accommodates irreducible and heavy-tailed noise in the zeroth-order oracle and significantly extends the analysis to second-order stationarity. We show that under heavy-tailed noise conditions, our SSQP method achieves the same high-probability first-order iteration complexity bounds as in the light-tailed noise setting, while further exhibiting promising second-order iteration complexity bounds. Specifically, the method identifies a first-order ϵ -stationary point in $O(\epsilon^{-2})$ iterations and a second-order ϵ -stationary point in $O(\epsilon^{-3})$ iterations with high probability, provided that ϵ is lower bounded by a constant determined by the irreducible noise level in estimation. We validate our theoretical findings and evaluate the practical performance of our method on CUTEst benchmark test set.

4 - A Stochastic Linesearch Method (Slam) for Minimizing Expectation Residuals

Qi Wang, University of Michigan, Ann Arbor, Ann Arbor, MI, United States, Uday Shanbhag, Yue Xie

Most existing rate and complexity guarantees for stochastic gradient methods in L -smooth settings impose restrictive requirements on steplength sequences, mandating that such sequences be non-adaptive, non-increasing, and abide by an upper bound given by a/L for some positive scalar a . This severely limits the applicability and adversely affects the performance of such schemes for three key reasons: (i) requires knowing L ; (ii) precludes larger steps when L is large; and (iii) employs non-increasing steplength sequences. Motivated by these shortcomings, we present an Armijo-enabled stochastic linesearch framework with standard stochastic zeroth- and first-order oracles. The resulting steplength sequences are not non-increasing, while enjoying a mild bound related to L . We refer to the proposed scheme as quasi parameter-free since by appropriate selection of algorithm parameters, the dependence on L is seen to be almost insignificant. We then prove that the expected stationarity residual diminishes at a rate of $\mathcal{O}(1/\sqrt{K})$, where K denotes the iteration index. Furthermore, the resulting iteration and sample complexities for computing an ϵ -stationary point are $\mathcal{O}(\epsilon^{-2})$ and $\mathcal{O}(\epsilon^{-(4+\delta)})$, where $\delta > 0$ is a fixed small number. Analogous guarantees are provided in the PL setting as well as in convex regimes. Preliminary numerical experiments are promising as the performance of the scheme competes well with de-facto choices such as Adam.

5 - An Adaptive Augmented Lagrangian Method for Deterministic and Stochastic Non-Convex Optimization

Tianzhu Liu, The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Michael O'Neill

We present an inexact Augmented Lagrangian algorithm for solving non-linear, non-convex optimization problems. Unlike most recently proposed Augmented Lagrangian methods with worst-case complexity guarantees, we utilize adaptive penalty parameter updates and full dual step sizes. We show that the method matches the best-known worst-case complexity results for Augmented Lagrangian methods (up to logarithmic factors) when both the function and constraints are deterministic, when the function is stochastic and the constraints are deterministic, and when both are stochastic. Experiments on CUTEst test problems confirm the practical advantages of the proposed approach over Augmented Lagrangian methods with non-adaptive penalty parameters and/or short dual step sizes in the deterministic setting. Numerical results on stochastic constrained optimization problems in machine learning also confirm these findings.

6 - Riemannian Proximal Sampler for High-Accuracy Sampling on Manifolds

Yunrui Guan, Rice University, Houston, TX, United States, Krishnakumar Balasubramanian, Shiqian Ma

We introduce the Riemannian Proximal Sampler, a method for sampling from densities defined on Riemannian manifolds. The performance of this sampler critically depends on two key oracles: the Manifold Brownian Increments (MBI) oracle and the Riemannian Heat-kernel (RHK) oracle. We establish high-accuracy sampling guarantees for the Riemannian Proximal Sampler, showing that generating samples with ϵ -accuracy requires $O(\log(1/\epsilon))$ iterations in Kullback-Leibler divergence assuming access to exact oracles and $O(\log(1/\epsilon))$ iterations in the total variation metric assuming access to sufficiently accurate inexact oracles. Furthermore, we present

practical implementations of these oracles by leveraging heat-kernel truncation and Varadhan's asymptotics. In the latter case, we interpret the Riemannian Proximal Sampler as a discretization of the entropy-regularized Riemannian Proximal Point Method on the associated Wasserstein space. We provide preliminary numerical results that illustrate the effectiveness of the proposed methodology.

Scenario-Based Decomposition for Stochastic Programming: Methods and Software

Invited Session

OPT: Optimization Under Uncertainty

Chair: Jean-Paul Watson, Lawrence Livermore National Laboratory, Livermore, CA, 94550, United States

1 - Large-Scale Experimentation and Analysis of Hpc-Based Scenario Decomposition via Progressive Hedging with Mpi-Sppy

Jean-Paul Watson, Lawrence Livermore National Laboratory, Livermore, CA, United States, David Woodruff, Bernard Knueven

Parallel implementations of scenario-based decomposition strategies are now scalable to thousands and millions of scenarios, thanks to advances in modeling systems (e.g., Pyomo) and supporting meta-solvers (e.g., mpi-sppy). We describe challenges and their solution considering a large-scale power grid capacity expansion model, where scenarios represent individual days of weather. We discuss in detail various algorithmic tuning and approaches to rapidly finding high-quality solutions to these stochastic programs, utilizing the mpi-sppy meta-solver library.

2 - What's New in the MIP-SPPY Solver Library

David Woodruff, UC Davis, Davis, CA, United States, Bernard Knueven, Jean-Paul Watson

MIP-SPPY is software for stochastic programming that can run on a laptop, but uses MPI (message passing interface) to perform well on distributed memory computers. In this talk I will talk about high level changes to the user interface and low level changes to the way we manage interaction between algorithms running asynchronously in parallel.

3 - Primal and Dual Progressive Hedging Heuristics for Stochastic Mixed-Integer Programs

Bernard Knueven, National Renewable Energy Laboratory, Golden, CO, United States, Jean-Paul Watson, David Woodruff

The *mpi-sppy* meta-solver library facilitates scalable solutions to large-scale stochastic programming problems through the asynchronous execution of primary algorithms, such as Progressive Hedging, and assisting algorithms that compute objective value bounds or accelerate convergence of the primary algorithm. In this talk, we present recent enhancements to *mpi-sppy*, including newly developed assisting algorithms aimed at improving both primal and dual convergence of Progressive Hedging. We evaluate the effectiveness of these heuristic strategies on a challenging, large-scale power grid capacity expansion model.

4 - Progress Report: Toward Asynchronous Parallel Computation of Lagrangian Bounds for Multi-Stage Stochastic Mixed-Integer Programs

Jonathan Eckstein, Rutgers University, Piscataway, NJ, United States, Jean-Paul Watson, David Woodruff

We describe an effort to compute Lagrangian bounds for multi-stage stochastic MIPs in which scenario/bundle subproblems are solved in parallel through essentially continuous computational flows without synchronization gaps. The technical approach is to use the Frank-Wolfe-like simplicial decomposition (SD) approach of Boland et al., but in the context of a projective splitting procedure rather than standard synchronous progressive hedging. This combination is not entirely straightforward and involves some adjustments to the SD procedure (we may also discuss some enhancements to SD for this application). The implementation combines two levels of parallelism: a C++ native multithreading lower level and an upper level employing nonblocking MPI reductions.

Recent Progress in Optimization Software III

Invited Session

OPT: Computational Optimization and Software

Chair: Hans Mittelmann, Arizona State University, Tempe, AZ, United States

1 - The Latest Developments in The Knitro Optimization Solver

Richard Waltz, Artelys, Los Angeles, CA, United States

Knitro was originally developed in the 1990s as an interior-point algorithm for general nonlinear, non-convex optimization. Over the years, Knitro evolved into a more general optimization toolbox that includes an Active-Set LP-based solver, a Sequential Quadratic Programming (SQP) solver, specialized LP, QP, and SOCP solvers, a branch-and-bound solver for mixed integer programming, and multi-start heuristics for global optimization. To add to this toolbox of algorithms, we have recently started developing first-order methods that do not require any matrix factorizations. The hope is that these might be able to provide useful solutions to extremely large-scale models where the factorizations in interior-point methods become too expensive. In this talk we will present some of this work, primarily based on Augmented Lagrangian (AL) type methods, as well as present other updates from the latest Knitro 15.0 release.

2 - The Sas Optimization Solvers: Recent Improvements and Future Developments

Rob Pratt, SAS, Cary, NC, United States, Philipp Christophel, Menal Guzelsoy, Laszlo Ladanyi, Bochuan Lyu, Amar Narisetty

In this talk we present the recent improvements to the SAS linear and mixed integer linear optimization solvers and discuss future developments.

3 - Recent Progress in the Global Optimization of NLPs and MINLPs with Baron

Nikolaos Sahinidis, Georgia Tech, Atlanta, GA, United States, Yi Zhang

We review historical progress and recent developments toward the global optimization of nonlinear and mixed-integer nonlinear programming problems with BARON. We discuss relaxation construction, preprocessing, branching, and tree management techniques. We present results for a large test set and emphasize recent progress, especially for quadratic and integer programs.

4 - Recent Advances in the OSQP Solver

Ian McInerney, Imperial College London, London, United Kingdom, Amit Solomon, Vineet Bansal, Bartolomeo Stellato

OSQP is a fast, light, and widely popular open-source solver for quadratic optimization based on the alternating direction method of multipliers. OSQP includes a code-generation facility to generate a light embeddable version of the solver, and the ability to compute derivatives of its solution with respect to the problem parameters. It uses a modular linear algebra framework to seamlessly run on three different platforms: default single-threaded for embedded applications, the Intel Math Kernel Library for multicore CPUs, and CUDA for GPUs. In this talk, we present the latest changes, improvements, and additions to OSQP. These include algorithmic improvements such as duality-gap termination criteria and step-size selection, improved GPU performance, and better integration with the language ecosystems of the three major high-level wrappers: Python, Julia and MATLAB.

5 - Smoothie: A Highly Parallel Ensemble Solver

Yuji Shinano, Zuse Institute Berlin, Berlin, Germany

The Ubiquity Generator (UG) Framework is a software framework to parallelize state-of-the-art solvers. Based on UG, SCIP and its customized solvers for Steiner tree problems (SCIP-Jack), QUBOs (Qubowl), and Pseudo-Boolean optimization, are parallelized. The UG framework has been generalized in the upcoming version 1.0.0 so that the parallelization controlling mechanism can be highly customized. The feature allows us to develop ensemble solvers, in which several different solvers run in parallel and communicate information. An experimental implementation of Smoothie (Solver Mixing Object Oriented Hybrid Integrated Executable), in which SCIP and HiGHS can run in parallel, has been developed. In this talk, we present the latest status of Smoothie where commercial solvers Xpress and Gurobi are used jointly to solve hard MIP instances.

6 - Latest Results for the Xopt Solver

Xiaodong Luo, Chinese University of Hong Kong, ShenZhen Campus, ShenZhen, Guangdong province, China, China, People's Republic of

In this talk, we are introducing XOPS LP/MILP solver. We have added Objective splitting, max cut primal heuristic and distributed solving framework since last year. We will report on our automatic model building environment as well.

Leveraging Structure in Integer Programs: Decomposition, Symmetry, and Parameterization

Invited Session

OPT: Integer and Discrete Optimization

Chair: Santanu Dey, ISyE Georgia Tech, Atlanta, GA, United States

Co-Chair: Aleksandr Kazachkov, University of Florida, Gainesville, United States

1 - Symmetries and Lift-and-Project Operators

Yuri Faenza, Columbia University, New York, NY, United States, Victor Verdugo, José Verschae, Matias Villagra

Symmetries are functions that preserve an object's structure while mapping it onto itself. They are prevalent in mathematics, and integer programming is no exception -- at least 47% of mixed-integer linear programs in MIPLIB 2010 present some symmetry. It is now folklore that symmetric integer programs are difficult to solve: branch-and-cut algorithms typically show limited improvement in the dual bound when applied to such problems.

With the goal of further understanding why symmetries can slow down solvers, we theoretically investigate how various lift-and-project operators (Sherali-Adams, Lovasz-Schrijver, etc.) perform on polytopes as a function of properties of the group of symmetries acting on them (i.e., no specific structure of the polytopes is assumed). Our results show a hierarchy collapse: lift-and-project operators which are known in general to perform differently behave, will under certain conditions, be as (in)effective for improving LP bounds of symmetric linear programs.

2 - Random 2-Stage Stochastic Packing-Ips Can be Solved in Poly-TIME Using Decomposition Algorithm

jingye xu, Georgia Institute of Technology, Atlanta, GA, United States

Decomposition algorithms are widely used to solve linear integer programs (LIPs) with block structures. Classical methods like the Lagrangian decomposition or the Benders' method typically settle original problems by solving a sequence of smaller-dimensional LIPs over each block with possibly additional cutting planes. Although those decomposition algorithms are able to solve large-scale LIPs with block structures efficiently, the theoretical understanding of those methods is relatively weak. The existing convergence guarantees are all exponential in the number of variables in each block, which contradict their good practical performance. In this paper, our goal is to understand the behavior of a variant of Lagrangian decomposition recently introduced by Cifuentes, Dey, Xu (IPCO, 2025). When applied to random two-stage LIPs where the entries of the coefficient matrix and the objective function are randomly sampled, we show that such decomposition method solves the problem in poly-iteration when the number of constraints of each block is fixed.

3 - Parametric Polyhedra in Mixed-Integer Programming

Diego Moran, Rensselaer Polytechnic Institute, Troy, NY, United States, Gustavo Angulo, Silvia Di Gregorio

We present some old and new results on arbitrary families of parametric polyhedra. First, if the constraint matrix is fixed, in the literature there are structural results for the integer hull and the finiteness of cutting plane closures for varying r.h.s. For instance, recently, Becu et al. proved in "Approximating the Gomory Mixed-Integer Cut Closure Using Historical Data" that the GMI closure of this family is finitely generated, in the sense that there exists a finite list of aggregation weights defining the GMI cuts that give the GMI closure for any polyhedra in the family. We extend this result for other cutting plane closures. Second, if the family of parametric polyhedra is arbitrary but all polyhedra in the family have the same integer hull, they define the same MIP, and we can leverage this information to understand and solve MIPs better. These families have been used to understand theoretical properties of the rank of cutting planes and to obtain better formulations. We present an application of these same-integer-hull families to formulations for the Asymmetric Traveling Salesman Problem.

4 - Tensor Completion via Integer Programming

Chen Chen, The Ohio State University, Columbus, OH, United States, Alexander While, Anil Aswani, William Caballero, Nathan Gaw

Tensor completion is a general-purpose model for imputing missing or unobserved entries, typically under the assumption of underlying low-rank structure. We present new results on our approach, which leverages a linear number of calls to an integer programming oracle to ensure convergence to a low-rank solution. Although modestly slower than common approaches, our approach attains the information-theoretic bound on minimum error with respect to sample size. Latest results include GPU acceleration, as well as an application to power systems.

5 - Scaling the Simple Disjunctive Cut Principle

Aleksandr Kazachkov, University of Florida, Gainesville, FL, United States, Chen Chen, Connor Johnston, Diego Moran

We introduce a new perspective on computing facet-defining inequalities for the convex hull of a union of polyhedra, where each term in this disjunction is defined by a single linear inequality imposed on a (shared) simple cone. The classic approach to generating these inequalities is a linear program from a reverse polar formulation. We avoid such optimization and instead provide a tree-based enumeration algorithm through a geometric interpretation of scaling the disjunctive cut principle, which computes inequalities with a simple formula. Our results tighten the exponential upper bound from the literature on the number of extra constraints needed to obtain the convex hull, and we show complementary families of instances in which quadratically-many inequalities are needed.

1 - Innovation Efficiency Across Product, Service, and Combined Innovation

Jaeho Shin, Hansung University, Seoul, Korea, Republic of, Changhee Kim, Hongsuk Yang

Firms increasingly provide a combined offering of products and services, a trend often referred to as servitization or product-service systems (PSS). This approach enables firms to pursue innovation in both products and services. Based on innovation activity, this study classifies firms into three categories: (1) firms engaging in both product and service innovation, (2) firms engaging only in product innovation, and (3) firms engaging only in service innovation. We compare the innovation performance of these

three groups in terms of innovation efficiency, which accounts for both innovation outcomes and inputs such as resources and efforts. To measure innovation efficiency, we employ data envelopment analysis (DEA), a widely used non-parametric method for assessing efficiency. The empirical analysis uses firm-level data from the Korean Innovation Survey (KIS), which provides comprehensive information on innovation activities in Korea. The results may help managers identify appropriate innovation strategies by considering their available resources and innovation objectives.

2 - From Data Granularity to Model Connectivity: Emotion-Driven Customer Satisfaction Prediction in Call Center Conversations

Thomas De Cleen, Vlerick Business School, Gent, Belgium, Philippe Baecke, Frank Goedertier

Customer satisfaction is a crucial metric for evaluating call center performance, yet traditional survey methods suffer from low response rates and limited scalability leading to blind spots in service quality management. This study compares multiple frameworks that leverage utterance-level and call-level multimodal emotion recognition to predict customer satisfaction. Our pipeline processes 25008 conversations from a large utilities company, extracting textual and acoustic emotion features and feeding them into a transformer-based model with self-distillation for utterance-level emotion recognition. Customer satisfaction labels are self-reported on a 0–10 scale (mean 8.34, SD 2.59, N = 25 008).

Compared to baseline performance of weighted average emotions over the entire conversation, we test three strategies. First, predicting satisfaction from aggregated call-level emotion dynamics; second, using a many-to-one LSTM over the sequence of utterance-level emotions; and third, employing a hierarchical model that feeds utterance-level emotion embeddings directly into the LSTM. To our knowledge, this is the first study to structurally compare multiple methods of predicting satisfaction with utterance-level and call-level emotions. Early results indicate promising predictive performance.

Our framework is designed for seamless integration into existing contact-center systems: organizations that collect call transcripts, recordings, and post-call scores can train their own satisfaction predictors without any manual emotion annotation. By enabling reliable estimation for non-responders, this methodology promises to enhance service-quality monitoring and operational decision-making in real-world call centers.

3 - Context-Aware AI Recommendations: Integrating Situational and Attitudinal Dimensions

Sung Yeon Kim, Korea University, Sejong, Korea, Republic of, JAESEOK YUN, Seonghyeon Han, Jinmin Kim

Most AI recommendation systems primarily rely on users' past behaviors, often overlooking immediate situational contexts (e.g., current mood or goals) and broader attitudinal dispositions toward products or services. Such limitations can result in misaligned recommendations and decreased user satisfaction. This study proposes and empirically tests an AI recommendation model that integrates users' situational and attitudinal states, both classified along positive–negative spectrums. Through a survey study with 800 participants, we conduct a 2x2 group comparison (situation: positive/negative × attitude: positive/negative) to examine how these dimensions moderate the established relationship between information quality, system quality, recommendation quality, and user satisfaction. Prior research has shown that information and system quality influence recommendation quality, which in turn drives user satisfaction. Building on this foundation, we hypothesize that alignment with users' psychological states enhances satisfaction, with the highest satisfaction occurring under a positive situation and positive attitude, and the lowest under a negative situation and negative attitude. This study contributes a comprehensive theoretical framework that extends beyond physical contexts (e.g., location, time) to incorporate emotional and cognitive dimensions, addressing a significant gap in current research. Findings will inform the design of emotionally responsive AI recommendation systems that better align with users' dynamic psychological states and deliver more meaningful, context-sensitive user experiences. The findings of this study can also contribute to the future development of standards and conformity assessment criteria for user-centric context-aware AI recommendation systems.

4 - Adaptive Emotional Support Through Conversational System Design: The Role of Responsiveness and User Autonomy

Austin Zhiqi Wang, City University of HongKong, HongKong, Hong Kong

Digital conversational system shows potential for providing emotional support, but how its interactive design might be optimized to alleviate loneliness remains unknown. Prior research largely emphasizes static empathy mechanisms or anthropomorphic cues, while ignoring adaptive and user-driven interface elements. To address this gap, we develop and propose two novel features to renew the current conversational systems: Emotional Affordance Responsiveness (EAR) and User-Controlled Prompt Frequency (UCPF) from the system design perspective. EAR enables systems to adaptively tailor the tone and depth of prompts by detecting emotional cues in user input, for example, offering a reflective prompt after identifying sadness in sentiment. UCPF allows users to adjust prompt content during the dialogue. Integrating affective congruence theory and self-determination theory, we hypothesize that EAR enhances emotional congruence, while UCPF fosters interactional autonomy, both contributing to reduced loneliness. However, excessive user-set frequency may unintentionally result in short-term fatigue, especially among socially sensitive people. To address this issue, we propose social sensitivity as an individual difference moderator that modifies the effects of UCPF on the mediators. A randomized between-subjects experiment using an interactive conversational platform will be conducted to test the research model. Theoretically, this study enriches the design perspective on digital emotional support by identifying key socio-affective design variables. Practically, it offers insights for building digital conversational companions that are not only emotionally responsive but also customizable, thus better aligning with diverse users' preferences in loneliness interventions.

5 - Redeeming Third-Party Experiences: How Loss Aversion Influences Loyalty Point Redemption Decisions

Yiran Liu, James Madison University, Harrisonburg, VA, United States, Zheng Wu

As loyalty programs increasingly offer experiential rewards, such as concerts, sporting events, and culinary experiences, understanding consumer behavior in point-redemption settings has become more critical. While loss aversion is well studied in the context of tangible goods, its role in the experience economy remains under-explored. This study investigates how consumers' decisions are shaped when redeeming loyalty points, earned through service providers like airlines and hotels, for third-party experiential rewards, particularly when consumers exhibit loss-averse preferences. We examine two redemption mechanisms: fixed-price and auction-style. Drawing on prospect theory, we propose that each mechanism evokes two types of loss perception: financial loss (depletion of loyalty points) and anticipated regret (fear of missing a valued experience). Through controlled experiments, we explore consumer responses across two redemption mechanisms, three point commitment levels (low, medium, high) and two fear of missing out (FOMO) conditions, manipulated via perceived scarcity (low vs. high). In each scenario, participants decide whether to redeem their points immediately for a third-party experience or conserve points for future use with the original service provider. Interestingly, our findings reveal that loss-averse consumers are more likely to redeem points immediately when faced with higher point commitment levels. Moreover, auction-style redemptions further increase redemption likelihood, particularly under high FOMO conditions, as the anticipated regret of missing out outweighs concerns about financial loss. This research contributes to the behavioral operations and marketing literature on point-redemption behavior in experiential contexts and practically aid firms in loyalty program design, enhance consumer engagement, and inform policymakers in service-driven marketplaces.

6 - Matching Strategy and Product Line Design on Home Service Platforms

Hui Xiong, Donghua University, Shanghai, China, People's Republic of, Ying-Ju Chen, Lu Hsiao

In recent years, we have witnessed the growth of home service platforms. These platforms use commission-based contracts to recruit suppliers, provide multiple products to serve consumers, and match suppliers with the products. The platforms must optimize their matching strategies, commission-based contracts, and product quality decisions to improve the profit. Therefore, we build a model to investigate the matching strategies, the contract design, and the quality decisions in which suppliers with different service efficiency provide products for heterogeneous consumers. The consumers with relatively high (low) willingness to pay for quality belong to the high (low) segment. When low-segment consumers become very important (i.e., they take a large proportion, and their willingness to pay for quality is high), the platform may induce high-efficiency suppliers to offer low-quality products. Moreover, the platform is more likely to adopt this strategy when the matching probability for low-quality products is higher. However, when the heterogeneity between two segments is sufficiently small, the platform intends to induce high-efficiency suppliers to offer high-quality products and distort the quality level upward for the high segment. In this case, the quality difference between the two products increases in low-segment consumers' willingness to pay for quality.

7 - Store-Wide Shelf Space Planning in An Epidemic

Bacel Maddah, American University of Beirut, Beirut, Lebanon, Tulay Flamand, Ahmed Ghoniem

Epidemics like COVID-19 highlighted the importance of safety in public spaces. We address shelf-space allocation in a grocery store via a nonlinear integer program that allocates product categories to shelves in a way that minimizes congestion and reduce infections, while maintaining profitability from impulse buying. Queuing theory is used in estimating the congestion and health-related metrics.

8 - Home Service TIME-Dependent Routing and Appointment Scheduling: a Deep Reinforcement Learning Approach

Tana Wang, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Kaibin Wang, Guohua Wan

We investigate the Time-Dependent Routing and Appointment Scheduling (TDRAS) problem in home service systems by introducing an end-to-end decision-making framework that integrates a temporally-aware graph neural network with a deep reinforcement learning (DRL) policy to improve scheduling efficiency and adaptability. The proposed framework incorporates a learnable traffic prediction module that estimates travel durations from historical records and time-of-day patterns, supplying the model with context-sensitive temporal representations. These representations are embedded into an enhanced GINConv architecture to enable more informed and flexible node-level reasoning. A unified actor-critic network then jointly outputs discrete customer selection actions and continuous appointment time suggestions, facilitating the coordinated optimization of routing and time-slot allocation. Empirical results using real-world traffic data from Shanghai's Xuhui District show that our approach consistently outperforms traditional benchmarks—including mixed-integer programming and other heuristic algorithms—as well as solutions by large language foundation models, with respect to the weighted travelling cost, expected idle cost, and customer waiting time. This framework provides a compact, adaptive, and practically deployable solution for intelligent scheduling in time-dependently dynamic home service environments.

Diverse Interventions for a Healthier World

Invited Session

Health Applications Society

Chair: Amir Karimi, UTSA, San Antonio, TX, United States

Co-Chair: Yiqi Tian, University of Pittsburgh, Pittsburgh, PA, United States

1 - Empowering Frontline Health Workers in Lmics to Manage Stock-Outs: Evidence from a Training Program in Indonesia

Amir Karimi, University of Texas at San Antonio, San Antonio, TX, United States

Through a collaboration with JSI Research & Training Institute, Inc., we gain access to fine-grained, proprietary data from approximately 17,000 health facilities across Indonesia. Leveraging this data, we evaluate the impact of a large-scale inventory management training program targeted at frontline health workers. Our research highlights the practicality and scalability of human-capital-focused interventions, such as training, in improving health outcomes in LMICs.

2 - Optimizing Surveillance Protocols for Hospital-Acquired Infections: Case of Mrsa

Esma Akgun, University of Chicago Booth School of Business, Chicago, IL, United States, F. Safa Erenay, Sibel Alumur Alev, William A. Ciccotelli

Roommates of nosocomial methicillin-resistant *Staphylococcus aureus* (MRSA) cases have a high risk of MRSA acquisition. Infection prevention and control guidelines recommend that these individuals be isolated and undergo surveillance testing; however, optimal surveillance testing and isolation strategies are unknown. We develop a stochastic dynamic programming model to optimize testing and isolation decisions for the contacts of index MRSA cases in hospitals to minimize the loss of quality-adjusted life years and the number of MRSA colonizations. Our model provides a novel framework that formulates the problem as a Markov decision process, capturing the partial observability of patients' health states by keeping sufficient information within the model state and dynamically incorporating new test results, thereby overcoming the curse of dimensionality associated with partially observable Markov decision processes. We optimally solve the model using clinical data from a Canadian community hospital and perform sensitivity analyses on key parameters, including disutility values and disease parameters. We computationally analyze the structure of the optimal testing decisions, which recommend varying the frequency and timing of tests based on initial test results and room configurations. Optimal testing decisions offer valuable insight for policymakers in improving health outcomes while reducing associated costs compared to current guidelines and practices. In addition, we compare the performance of various practical MRSA testing protocols using the proposed modeling framework and determine those with close-to-optimal performance while balancing clinical efficacy and cost-effectiveness. The proposed modeling framework can be applied to other healthcare-associated infections and infectious diseases.

3 - Optimal Assignment Guidelines for Maternity Waiting Homes in Resource-Constrained Environments

Yuhang Du, London Business School, London, United Kingdom, George Chen, Jeremie Gallien, Jody Lori

Maternity waiting homes (MWHs) are increasingly used to increase skilled birth attendance in regions with low obstetric services density. We seek to optimize their assignment policy, that is whether and when a pregnant woman should go to her local MWH given available accommodation capacity and individual characteristics including living location. Our model leverages clinical data on labor onset and latent phase duration to minimize the predicted number of unassisted deliveries resulting from such policy in the local population. We present explicit mathematical solutions for different variants of this problem and IP formulations of discretized approximations capturing practical implementation constraints. Our numerical experiments leverage detailed primary and secondary data on the population and health facilities of Bong County, Liberia. They suggest that our proposed pooling and assignment policy interventions for the existing MWH capacity in that region may plausibly halve the incidence rate of unassisted deliveries and reduce the probability of unassisted deliveries for the most vulnerable women from 70% to 15%. Implementing data-driven individual assessments of unassisted delivery risk and MWH assignment policies may thus constitute impactful and low-cost interventions in regions with limited MWH accommodation capacity.

4 - Profit Meets Wellness: How Consumer Valuation Uncertainty and Operational Cost Structure Shape Multi-Attribute Product Line Design

Iva Rashkova, Washington University, St Louis, MO, United States, Lingxiu Dong

The rise of wellness-conscious consumers has led to record demand for products with wellness attributes, such as low-sugar foods and ultraviolet-protective clothing. This market trend presents a profit-growth opportunity for established companies, which have dominated the market based on traditional attributes, such as the taste of food and the appearance of clothing. Yet, taking advantage of this opportunity is challenging due to the increased operational costs associated with delivering products with wellness attributes and the lack of information on consumers' valuation of wellness. We present a model of a monopolist developing and producing conventional and wellness products to serve a two-segment market consisting of wellness-conscious and wellness-neutral consumers. We propose a two-dimensional differentiation-contingency framework to depict the rich set of possible optimal strategies the firm could use to segment the market and explore how the market environment and the firm's operational environment affect the firm's choice of the optimal product strategy. The firm's operational cost structure further leads to different prioritization within the wellness product's quality dimensions: low development cost (resp. low coupling cost between the two quality dimensions) induces prioritization of the wellness (resp. traditional) quality of a wellness product. Examining consumer wellness consumption under the firm's optimal product strategy offers insights for policy interventions such as consumer educational initiatives and financial incentives to foster innovation.

5 - From One-Size-Fits-All to Equitable Stratification: An Explainable Framework for Personalized Post-Cancer Surveillance

Reza Skandari, Imperial Business School, London, United Kingdom, Niloofar Zamani, Narges Mohammadi

Personalized medicine promises to improve health outcomes and reduce disparities by tailoring treatment guidelines to individual characteristics. However, its implementation is often hindered by complexity and scalability. We propose an *explainable clustering framework* to optimize the intensity and structure of population stratification, aiming to minimize health inequalities while maintaining the practicality of clinical guidelines. The population is partitioned into a manageable number of clusters, each assigned a single treatment policy—striking a balance between simplicity and equity. To ensure interpretability, the clustering is constrained to follow a decision tree structure.

We apply this method to the post-treatment surveillance problem for head and neck cancer patients, where the objective is to develop a cost-effective strategy that limits cancer recurrence detection delays to within six months. We define health-care outcome inequality as the deviation in expected detection delay from this target across subpopulations. Our results reveal diminishing returns in inequality reduction as the number of clusters increases, with the largest gains achieved by stratifying into just a few groups. Notably, the features selected in the optimal decision tree often diverge from clinical intuition, suggesting a misalignment between clinical prognosis and operational decision-making. Furthermore, we observe that as the decision tree deepens—allowing more clusters—earlier feature splits may be revised or replaced, highlighting the dynamic nature of optimal stratification as model complexity increases.

6 - Individual-Level Decision-Making for Self-Protection and Its Collective Impact on Disease Mitigation

Geonsik Yu, Purdue University, West Lafayette, IN, United States, Michael Garee, Mario Ventresca, Yuehwern Yih

Protecting public health from infectious diseases requires collective action, as individual behaviors—such as vaccination and mask-wearing—directly influence disease dynamics. During the COVID-19 pandemic, unexpected public responses often undermined the effectiveness of interventions, highlighting the need to understand behavioral patterns and motivations to design more effective strategies.

This study presents an agent-based simulation model that captures how individuals adjust self-protective behaviors based on their own individual characteristics such as evolving opinions about disease risk and how these decisions interact with external factors, such as public health interventions, to shape collective outcomes. To enhance realism, multiple datasets were integrated to generate artificial populations and calibrate individual behavior against observed patterns.

Simulation experiments were conducted under varying conditions, including optional non-pharmaceutical interventions (NPIs), heterogeneous responses to pro- and anti-intervention messaging, and alternative vaccine eligibility policies. Results reveal how decision-making patterns differ across demographic groups and how individual behaviors interact with interventions to influence disease spread.

The model explains real-world phenomena, such as the decline in mask-wearing following the first vaccination phase and disproportionately high infection rates among economically disadvantaged populations. It also identifies subpopulations likely to experience greater pressure under NPI mandates and shows how vaccination strategies—when accounting for behavioral dynamics—can significantly improve disease control and reduce disparities.

By offering insights into behavioral responses that are difficult to observe directly during real-world epidemics, this work underscores the importance of integrating behavioral dynamics into epidemic modeling and response planning to enhance the effectiveness and equity of public health interventions.

1 - Knowledge-Informed Deep Learning for Periapical Lesion Diagnosis in Cone Beam Computed Tomography Scans

Yeonju Lee, Georgia Institute of Technology, Atlanta, GA, United States, Rui Qi Chen, Hao Yan, Muralidhar Mupparapu, Fleming Lure, Frank C. Setzer, Jing Li

Periapical lesions are one of the most prevalent oral pathologies, originating from the tissues surrounding the apex of a tooth. Timely diagnosis of these lesions is critical for improving clinical outcome. Delayed intervention can allow a minor condition to progress, often necessitating surgical intervention, and potentially resulting in tooth extraction. Dental cone beam computed tomography (CBCT) offers three-dimensional images of oral cavity, including oral structures (i.e., teeth, bones, restorative materials, and periapical lesions) in a single scan. CBCT is widely regarded as a powerful tool for diagnosing periapical lesions. However, due to their small sizes and similar intensity to surrounding structures, even experienced clinicians may face challenges in accurate detection and diagnosis. Leveraging Artificial Intelligence (AI) to fully automate the diagnosis process could tremendously improve the quality and efficiency of dental healthcare. The main hurdle in this advancement is reducing AI's reliance on a large quantity of manually labeled images to train robust, accurate, and generalizable algorithms. To tackle this challenge, we propose a knowledge-informed deep learning method designed to diagnose periapical lesion using CBCT. The uniqueness of our method is its capability of integrating qualitative oral-anatomical knowledge into the deep learning design. Building upon this, we further explore differentiating periapical lesions into subtypes (i.e., granuloma and cyst) to facilitate more appropriate treatment planning. We validate our method on a real-world dataset, demonstrating its potential for clinical application.

2 - Omgpt: a Sequence Modeling Framework for Data-Driven Operational Decision Making

Hanzhao Wang, Imperial College London, London, United Kingdom, Guanting Chen, Xiaocheng Li, Kalyan Talluri

We build a Generative Pre-trained Transformer (GPT) model from scratch to solve sequential decision making tasks arising in contexts of operations research and management science which we call OMGPT. We first propose a general sequence modeling framework to cover several operational decision making tasks as special cases, such as dynamic pricing, inventory management, resource allocation, and queueing control. Under the framework, all these tasks can be viewed as a sequential prediction problem where the goal is to predict the optimal future action given all the historical information. Then we train a transformer-based neural network model (OMGPT) as a natural and powerful architecture for sequential modeling. This marks a paradigm shift compared to the existing methods for these OR/OM tasks in that (i) the OMGPT model can take advantage of the huge amount of pre-trained data; (ii) when tackling these problems, OMGPT does not assume any analytical model structure and enables a direct and rich mapping from the history to the future actions. Either of these two aspects, to the best of our knowledge, is not achieved by any existing method. We establish a Bayesian perspective to theoretically understand the working mechanism of the OMGPT on these tasks, which relates its performance with the pre-training task diversity and the divergence between the testing task and pre-training tasks. Numerically, we observe a surprising performance of the proposed model across all the above tasks.

3 - Learning Clinically Interpretable Lab-Ordering Policies from Irregular ICU Data via Continuous-TIME Clinical Decision Transformer

Nasim Sadat Mousavi, University of Arkansas, Fayetteville, AR, United States, Shengfan Zhang

Routine laboratory testing is an essential component of monitoring critically ill patients; however, previous studies demonstrate that approximately 20–40% of tests ordered in intensive care units are redundant, providing minimal diagnostic information, rarely altering management decisions, and causing unnecessary costs. In this paper, we present a Continuous-Time Clinical Decision Transformer (CT-CDT), an offline reinforcement learning framework designed to model irregular, event-driven clinical data. The model can recommend which lab tests to order and when, conditioned on a return-to-go objective capturing information gain from abnormal values and transitions. We conducted goal-conditioned sequencing, which generated a subsequence of treatment history with prepended future goal state, and our state representation integrates heterogeneous EHR modalities—lab tests, vital signs, prescriptions, procedures, and fluid inputs—on an irregular event grid. For contextual embedding over admissions, we adopted a GPT-based transformer architecture with an attention mask and column embedding. This combination of temporal context modeling and missingness-aware encoding enables robust, clinically interpretable policy learning from sparse, heterogeneous measurements, offering clear advantages over methods that ignore timing or treat missing data as noise. We evaluate CT-CDT on preprocessed MIMIC-IV CKD cohorts against state-of-the-art offline RL baselines—Behavior Cloning, Dueling-DQN. Our findings demonstrate that transformer-based, goal-conditioned sequence models can learn clinically sensible lab-ordering policies from offline data while explicitly modeling irregularity and missingness, offering a promising foundation for clinician-in-the-loop decision support in ICU settings.

4 - Personalized Prediction and Control of Blood Glucose Levels Using Dynamic System Modeling

Anjolaoluwa Popoola, Georgia Institute of Technology, Atlanta, GA, United States, Pooyan Kazemian, Kamran Paynabar

Patients with diabetes in the ICU typically rely on two methods to monitor their blood glucose levels: blood tests analyzed in the laboratory and fingerstick tests. While fingerstick tests offer a cost-effective and convenient approach, they sacrifice accuracy, providing only approximate measurements. We propose a dynamic system model combining deep learning models and Kalman filtering to accurately predict blood glucose trajectory and assist with personalized glucose control over time. The resulting model, called a deep Kalman filter (Deep-KF) model, can be applied in the ICU and other healthcare settings. We validate our model using randomized real-world glucose and insulin clinical data. Finally, we demonstrate how our model can deliver precise blood glucose forecasts and insulin delivery recommendations and be used as a decision-support tool for healthcare providers, hence making glucose monitoring more efficient and patient-centric.

5 - Verifiable Artificial Intelligence for Medical Decision Making: Application to Skin Cancer Diagnosis

Pooyan Kazemian, Case Western Reserve University, Cleveland, OH, United States, Hank Korth, Manoj Malhotra

Proprietary Artificial intelligence (AI) medical tools promise to improve healthcare operations and medical decision making. Most of these tools are offered through cloud-based environments, requiring healthcare providers to submit patient data and trust the authenticity of the returned results. Currently, there is no practical way for healthcare providers to verify that the outputs were generated by the authentic AI model. This lack of verifiability introduces significant risks.

We present a trustless AI verification framework that cryptographically verifies the authenticity of AI model predictions without revealing patient data or proprietary model parameters. Leveraging zero-knowledge proofs, our framework attaches a succinct validity proof to each model inference, which will be verified on a permissionless blockchain (e.g., Ethereum) using a smart contract. Because sensitive patient data and model parameters remain hashed commitments, data privacy and intellectual property are simultaneously preserved.

We empirically demonstrate the approach with a convolutional neural network trained on labeled dermoscopic images to triage malignant versus benign skin lesions. The proposed AI verification framework eliminates trust assumptions between vendors (model providers) and clinicians (users), mitigates model tampering, and provides cryptographic auditability that demonstrates regulatory compliance. Beyond dermatology, our framework generalizes to any AI tool offered remotely where verifiable and privacy-preserving decision support is required.

Designing Health and Wellness Interventions Based on Social Comparisons

Invited Session

MSOM: Healthcare

Chair: Steven Shechter, University of British Columbia, Vancouver, BC, Canada

Co-Chair: Shanshan Luo, UBC Sauder School of Business, Vancouver, BC, Canada

1 - Transparent or Not? Optimal Performance Feedback to Service Users

Guillaume Roels, INSEAD, Fontainebleau, France, Lin Chen

In many gamified services, in particular in e-health (e.g., Fitbit, Strava, sleep apps), users receive individual performance feedback upon service completion, which shapes their perception of goal achievement (through prospect theory) and relative status (when users are ahead-seeking or behind-averse). This feedback can vary in degrees of transparency, from disclosing individual scores to revealing only ranges of scores (e.g., top 5%). How transparent should service providers be in their individual performance feedback to maximize the utility users derive from their service? We employ a Bayesian persuasion framework to determine the optimal information disclosure policy.

2 - Empowering Chronic Disease Self-Management: Leveraging Social Comparison and Wellness Rewards Through Insurance Programs

Wenlin Chen, University of Electronic Science and Technology of China, Chengdu, China, People's Republic of, Jason Nguyen, Wenjie Huang, Chung-Li Tseng

The effective management of insurance for chronic diseases depends critically on patients' adherence to self-managed therapeutic regimens. Such adherence not only improves health outcomes but also reduces costs for insurers. Facing escalating treatment costs, insurers have increasingly adopted interventions aimed at encouraging subscribers to commit to managing their chronic health conditions, despite existing adherence barriers. In this study, we analytically examine how an insurer can strategically combine two prevalent interventions—a wellness reward and facilitating subscribers' social comparison—in chronic disease insurance management. We compare the insurer's optimal intervention strategies by evaluating resultant profits, insurance plan accessibility, and subscribers' health outcomes. Our findings highlight both synergistic and potentially conflicting interactions between wellness rewards and distinct forms of social comparison (upward and downward). These insights offer valuable managerial implications for insurers, healthcare providers, and policymakers, enabling informed decisions toward mutually beneficial outcomes.

3 - Optimizing Peer Matching for Performance Improvement

Steven Shechter, University of British Columbia, Vancouver, BC, Canada, Shanshan Luo

Motivation plays a key role in driving performance, yet maintaining it over time remains a challenge in domains such as fitness tracking and digital learning platforms. Research suggests that individuals are more motivated when paired with slightly stronger peers, but motivation declines when the performance gap becomes too large. Building on this principle, we develop a motivation effect model to optimize peer matching based on baseline performance levels. Our goal is to maximize motivated effort and sustained performance through structured matching. Using real-world fitness data, we evaluate the optimal matching strategy against other commonly used pairing methods. Our findings provide insights into how structured peer matching can be implemented in fitness programs to improve engagement and performance consistency.

4 - Smartphone Against Smartphone: An IT-Enabled Social Network Activation for Reducing Smartphone Overuse

Shaokang Yang, Virginia Polytechnic Institute and State University, Blacksburg, VA, United States, Idris Adjerd

This paper explores smartphone addiction through the lens of social network analysis. Using data from multiple longitudinal studies that track individual relationships and smartphone interactions, we provide empirical evidence that activating specific parts of one's social network affects smartphone usage patterns. Our results highlight the potential of strategic network interventions in managing digital addiction.

1 - Selling to Cash-Constrained Nanostore: Supplier's Revisit Schedule and Trade Credit

Xin Geng, University of Miami, Coral Gables, FL, United States, Zheyu Jiang, Harihara Natarajan, Nan Yang

Nanostores (mom-and-pop stores, micro-retailers, etc.) are usually family-owned small retailers whose inventory replenishment is initiated by supplier and are usually cash-constrained. In addition, the nanostore must consider the family side cash need, which gives rise to a liquidity risk of cash shortfall in between the supplier's two visits. To save logistics cost and help the nanostore make more sales, the supplier can implement adaptive revisit schedule based on the store's cash level at each visit. Moreover, the supplier can also offer trade credit to the nanostore. We take a game-theoretic modeling approach to study the implications of the adaptive revisit interval and trade credit on the supplier's and the nanostore's operational decisions and financial performance.

2 - Selling Smarter: How Digital Tools and Risk-Sharing Shape Agricultural Innovation Adoption

Heng Chen, Kansas State University, Manhattan, KS, United States, Lingxiu Dong, Jie Ning, Ying Zhang

Adopting agricultural innovations such as new seed varieties or agrochemicals is essential for increasing productivity amid rising climate volatility. Farmers, however, often hesitate to adopt due to unfamiliarity with new agronomic practices and exposure to weather-related risks. In response, agribusinesses have begun bundling these innovations with digital decision-support platforms and weather risk-sharing programs to encourage adoption. Yet, the effectiveness and the strategic relationship between these two mechanisms - whether they act as complements or substitutes - remain unclear. We develop an analytical framework to evaluate their impacts on adoption, farmer welfare, agribusiness profits, and total crop yield in a setting where an agribusiness sells to a market of loss-averse farmers. We identify conditions where bundling these tools or offering each in isolation is most effective. Our findings offer insights for agricultural innovation deployment strategies across different farmer populations and cost environments.

3 - Impacts of Smart Vending Machines in Different Urban Settings: Tensor Completion with Spatiotemporal Data

Mingrui Zhang, University of Denver - Daniels College of Business, Denver, CO, United States, Wanning Chen

We investigate the treatment effect of deploying smart vending machines (treatment) compared to traditional vending machines (control) across various urban settings. Based on our results, we discuss potential changes in consumer purchasing behavior due to the introduction of technologically enhanced smart vending machines across diverse settings. The dataset we use spans 25 cities, 20 distinct urban settings, and 81 weeks. We employ tensor completion algorithms to predict over 70% missing sales outcomes in both control and treatment groups. Benchmarked against traditional regression models and matrix-based approaches, the tensor completion methods demonstrate superior predictive accuracy. The predictions for unobserved and non-existent region-setting-time combinations shed light on how to strategically plan and optimize smart vending machine deployments. More broadly, our analysis underscores the value of leveraging spectral algorithms such as tensor completion to conduct causal analysis on high-dimensional spatiotemporal data, empowering more informed decision-making.

Manufacturing and Service Operations Management (MSOM)

Chair: Xavier Warnes, Indiana University, Bloomington, IN, United States

1 - Beyond Representation: Gender Diversity and Water Point Functionality in Rural Africa

Chengcheng Zhai, Univeristy of Notre Dame, South Bend, IN, United States, Kaitlin Wowak

In many rural areas of sub-Saharan Africa, community-led Water User Committees (WUCs) are responsible for maintaining village water points. However, service disruptions remain widespread. While leadership and group composition are known to influence organizational performance, little is understood about how gender dynamics within these informal governance structures affect access to clean water. We collect field data from 416 rural water points in Malawi, including detailed information on WUC composition and governance. This is matched with longitudinal functionality records from 2016 to 2024. Our outcomes measure the percentage of days each water point is fully working, in minor breakdown, or in major breakdown status. To estimate the impact of chair gender and WUC gender diversity on functionality, we use fractional logit models, propensity score matching, exact matching, and two-stage residual inclusion methods. We find that water points with female chairs perform significantly better, experiencing more fully working days and fewer minor breakdown days, than those with male chairs. In contrast, greater gender diversity within the WUC is associated with lower functionality, particularly when the chair is male. These findings are robust across model specifications and subsamples, addressing potential endogeneity concerns.

Our results suggest that simply increasing female representation on WUCs is not sufficient: placing women in leadership roles, particularly as chair, is key to improving water point functionality. NGOs and local governments should prioritize gender-inclusive leadership development and support women in decision-making positions.

2 - Multiplicity in Product Expiration Dates and Food Waste in Grocery Retail Stores

Ashish Kabra, University of Maryland-College Park, College Park, MD, United States, Nitish Jain, Varun Karamshetty

Expiration waste (EW) occurs when perishable grocery items are unsold past their expiration dates. A key contributor to EW is multiple-dates-led expiration waste (MDEW), which arises when products with varying expiration dates are simultaneously available. Consumers tend to select items with later dates, increasing the likelihood of earlier-dated items expiring. While retailers attempt to manage this through markdowns or inventory rotation, many lack visibility into MDEW's scale.

In collaboration with a grocery retailer, we assemble a multi-category-multi-store dataset (~15.3 million transactions) involving items with 3–14 days of shelf life. On average, EW accounted for 23% of sales. To quantify MDEW's share, we propose a novel and easy to implement methodology for computing its lower and upper bounds. In our retailer's context, the MDEW's lower and upper bounds equal 25% and 52% on average of the generated EW, respectively.

This study offers the first large-scale evidence of MDEW's impact and provides a practical tool for retailers to quantify and manage it, enabling more effective strategies to reduce waste and improve operations.

3 - Smarter Products, Shorter Lifespans: The Environmental Cost of Embedded Software

Sytske Wijnsma, UC Berkeley Haas, Berkeley, CA, United States, Beril Toktay, Dominique Lauga

Embedded software, due to its rapid development, has been shortening hardware lifespans, increasing e-waste. This paper examines how supply chains address obsolescence through legacy software support or hardware overbuilding. We analyze the impact of integrated vs. decentralized models and assess how cybersecurity regulations shift responsibility, influencing firm incentives, environmental outcomes, and consumer risk exposure.

4 - The Moto-Taxi Industry in Rwanda: Transition to Electric Motors

Maqbool Dada, Johns Hopkins University, Baltimore, MD, United States, Ali Fattahi, Yangfang Helen Zhou

In Rwanda, motorbikes (motos) are the pre-dominant vehicle for taxi fleets. Starting in 2019, the government announced a 5-year plan to phase out the use of internal combustion engines. Now, taxi services are operated by drivers using motorbikes. The key feature of taxi-motos is that they use portable rechargeable batteries that must be swapped periodically at charging stations as stored energy is depleted. Some e-bikes come with a single battery while others are equipped with offers two smaller swappable batteries. Since the driver has to visit a swapping center, as charge is depleted the operating range for accepting fares decreases. We build and analyze an integrated stochastic optimization model that derives policies that determines when to swap batteries; the timing is mediated by a look-ahead fare acceptance policy which depends on the distance from the current location and the passenger destination. A case study seeded from industry data is used to illustrate model application.

Decision Analysis Society

Chair: Jun Zhuang, University at Buffalo, Buffalo, NY, 14228, United States

1 - Understanding Active Shooter Dynamics Through Adversarial Inverse Reinforcement Learning: from Human-Subject Data to Context-Aware Multi-Agent Policies**Mohamad Dehghan Bonari, Department of Industrial and Systems Engineering, Mississippi State University, Starkville, MS, United States, Daniel Carruth , Haifeng Wang, Jun Zhuang, Randy Buchanan , Mohammad Marufuzzaman**

The growing frequency of active shooter incidents has become a major global concern, many of which occur in indoor public spaces such as schools, workplaces, and hospitals. Indoor active shooter incidents present complex multi-agent dynamics involving attackers, civilians, and law enforcement responders in confined environments. This interplay of human-human and human-building interactions, along with the uncertainty of individual behavior under extreme situations, demands a comprehensive understanding of how spatial configurations and real-time human decisions influence incident outcomes. Accordingly, we propose a scenario-based Adversarial Inverse Reinforcement Learning (AIRL) framework to guide the behaviors of agents (e.g., civilians, shooters, and law enforcement) under various, near-real-world active shooter scenarios in multi-story building settings. Our framework also captures the leader-follower behavior among civilians, where certain individuals tend to follow better-informed occupants. Moreover, we conducted a human-subject active shooter simulation study, collecting trajectory data from 40 participants through video recordings, along with their decision-making reasoning via pre- and post-trial surveys. Our proposed AIRL model benefits from trajectory data to learn the objective of each agent under different circumstances. Finally, multiple realistic scenarios are designed to evaluate the performance of the model by changing key factors in building layout configurations (e.g., entrances, hideouts, floorplans, stairs), shooter characteristics (i.e., number of assailants, weapon types, entry points), civilian distributions (i.e., the density and initial position of individuals in the buildings), and law enforcement strategies (response tactics and entry points).

2 - Evolutionary Game Analysis on Phishing Scams Using Attacker and Defender Model**Naraphorn PAOPRASERT, Faculty of Engineering, Kasetsart University, Bangkok, Thailand, Thinzar Aung, Pornthep Anussornnitarn**

This study aims to model and analyze the strategic interactions between phishing call center scammers and authorities using game theory. By identifying equilibrium stability conditions, it provides insights into optimizing cybersecurity defense strategies. The model was developed to represent the attacker (phishing call center scammers) - defender (authorities) interactions, incorporating key parameters such as costs, rewards, penalties, and success rates. The stability, primarily focusing on four pure strategy equilibrium points, was analyzed using the trace-determinant method, deriving inequalities from the eigenvalues of the Jacobian matrix. Stability conditions were examined under both general and specific assumptions to reflect realistic cybersecurity scenarios. The study identified scenarios where individual-target defense is more effective against low-cost attacks, while investing in overarching defense is preferable for countering high-cost attacks. The stability analysis revealed key factors influencing long-term strategic balance between attackers and defenders, including costs, arrest and defense rates, and successful attack rates. The findings offer important practical implications for cybersecurity policy, law enforcement, and corporate security measures. As phishing attacks become increasingly AI-driven and sophisticated, traditional, individual-target defense methods are proving less effective. This shift results in higher success rates for the attackers, highlighting the need for a transition toward overarching defense strategies, including AI-driven detection, legal enforcement such as blockage of necessary infrastructure, and public awareness campaigns to enhance cybersecurity resilience.

3 - Preferences for Security Complexity in a Constant Expected Value Environment: Evidence from a Multi-Layer Target Selection Task**Kevin Kapadia, University of Southern California, Los Angeles, CA, United States, Ian Unson, Jun Zhuang, Richard John**

Understanding how individuals evaluate structural complexity in decision-making is critical for modeling attacker behavior. In this study, 366 participants completed 12 decision scenarios in which they chose among three targets protected by one, two, or three sequential security layers. All targets were equated in expected value (EV), isolating complexity as the defining decision feature. Participants were randomly assigned to one of four between-subjects conditions crossing security layer dependency (dependent vs. independent) and incentive framing (incentivized vs. non-incentivized). Target selections were modeled using mixed-effects binary and ordinal logistic regressions. Participants were significantly more likely to choose multi-layered targets over 1-layer targets ($OR = 4.63, p < .001$). In the full ordinal model including external measures, greater boldness ($OR = 1.59, p = .009$), lower meanness ($OR = 0.61, p = .014$), and lower financial risk-taking ($OR = 0.67, p = .014$) predicted preference for more complex options. Importantly, both linear and quadratic effects of scenario EV were significant, suggesting that preferences for complex targets followed a non-linear trend across different EV configurations. Additionally, a significant interaction between information scheme and scenario EV revealed that participants in the independent condition were less likely to choose multi-layered targets in higher EV contexts. Incentive framing did not predict target selection. These findings suggest that, even when EV is controlled, perceived structural complexity carries subjective value influenced by both task framing and individual traits. Implications are discussed for security modeling, complexity preference, and personality-based prediction of adversarial behavior.

4 - Homeland Security Games in the Arctic**Jun Zhuang, University at Buffalo, Buffalo, NY, United States**

We will discuss the recent developments of homeland security games in the arctic, including foreign partners, federal, state, tribal, and local communities.

5 - Strategic Adaptation and Deception Detection Under Uncertainty in Multi-Round Attacker-Defender Games with LLMs**Sabiha Unal Eyi, University at Buffalo, Buffalo, NY, United States**

This study investigates how large language models (LLMs) perform strategic decision-making under uncertainty in attacker-defender games involving asymmetric information and potentially deceptive communication. The analysis begins with a replication of the 2x4 experimental designs introduced, where an attacker selects between two targets based on the defender's value signals and public security announcements. Across eight single-shot scenarios, LLMs were prompted to make a decision and justify their reasoning. Results show that the model predominantly targets the higher-value location and demonstrates a mix of trust and skepticism toward the defender's messages while consistently maintaining an aggressive posture by never aborting the mission.

Building on this foundation, we extend the framework to a multi-stage game setting, where the LLM plays multiple rounds against a dynamic defender. In this version, the model receives feedback on the outcome of each round and must update its beliefs accordingly. The multi-round analysis reveals that the LLM adapts its strategy over time, recognizes deceptive patterns in repeated announcements, and adjusts its target preferences based on prior outcomes and defender behavior. Thematic coding of justifications indicates emerging evidence of belief revision, pattern recognition, and rudimentary deception detection.

This work contributes to the understanding of LLMs as decision-making agents in adversarial environments and highlights their potential for strategic adaptation, especially when exposed to iterative feedback. It bridges behavioral game theory and AI by demonstrating how language models can develop context-sensitive responses in environments characterized by uncertainty and strategic signaling.

Interior Point Methods

Contributed Session

Contributed

Chair: Leandro Farias Maia, Oregon State University

1 - Breaking the Barrier of Self-Concordant Barriers: Faster Interior Point Methods for M-Matrices

Adrian Vladu, CNRS, Paris, France

We study two fundamental optimization problems: (1) scaling a symmetric positive definite matrix by a positive diagonal matrix so that the resulting matrix has row and column sums equal to 1; and (2) minimizing a quadratic function subject to hard non-negativity constraints. Both problems lend themselves to efficient algorithms based on interior point methods (IPMs). For general instances, standard self-concordance theory places a limit on the iteration complexity of these methods at $O(\sim(n^{1/2}))$, where n denotes the matrix dimension. We show via an amortized analysis that, when the input matrix is an M-matrix, an IPM with adaptive step sizes solves both problems in only $O(\sim(n^{1/3}))$ iterations. As a corollary, using fast Laplacian solvers, we obtain an ℓ_2 flow diffusion algorithm with depth $O(\sim(n^{1/3}))$ and work $O(\sim(n^{1/3} \cdot \text{nnz}))$. This result marks a significant instance in which a standard log-barrier IPM permits provably fewer than $\Theta(n^{1/2})$ iterations.

(Appears in STOC 2025, <https://arxiv.org/abs/2504.20619>)

2 - An Interior Point Method Using Mollified Indicators

Daniel Turizo, Georgia Institute of Technology, Atlanta, GA, United States, Daniel Molzahn

We propose a novel interior point method using a new type of barrier. The barrier is derived by approximating the indicator function of the positive orthant via a sequence of functions called mollified indicators. These functions are infinitely differentiable, possess the properties of a barrier (they tend to infinity at zero), and have compact and shrinking support (unlike the logarithmic barriers). We develop a Newton iteration using the mollified indicator as barrier, and show that inequality constraints lying outside the barrier's support can be removed to reduce the size of the Jacobian linear system. The proposed method behaves like an active set method, where "inactive" constraints are those outside the barrier's support. On the other hand, this method is of the interior point type, so it does not possess any of the combinatorial difficulties inherent to active set methods. We performed numerical experiments comparing our method to the standard interior point algorithm with logarithmic barrier. The results show that the amortized cost of factoring the Jacobian is significantly reduced in our method.

3 - A Primal Interpretation of the Bound Flipping Ratio Test

Clifford Blakestad, SimpleRose, St Louis, MO, United States

The bound flipping ratio test (BFRT) is a powerful tool in optimizing the dual simplex method when solving linear programs. With recent advances in the theory of General Symmetric linear programs (GSLP), we can recontextualize the BFRT as a primal program phenomena. In this talk, we will discuss the relationship of the BFRT to the Restricted Ratio Test, a tool provided by using the restricted variables afforded by a GSLP. In doing so, we bridge a theoretical and computational gap between the dual and primal simplex algorithms.

4 - An Adaptive Proximal Admm for Nonconvex Composite Programs

Leandro Farias Maia, Oregon State University, Corvallis, OR, United States, David Gutman, Renato D.C. Monteiro, Gilson Silva

We developed an adaptive Proximal Alternating Direction Method of Multipliers (P-ADMM) for solving linearly-constrained, weakly convex, composite optimization problems. This method is adaptive to all problem parameters, including smoothness and weak convexity constants. Without any rank assumptions on the constraint matrices, it is shown that the adaptive P-ADMM obtains an approximate first-order stationary point of the constrained problem in a number of iterations that matches the state-of-the-art complexity for the class of P-ADMMs.

Behavioral Decision Analysis I

Invited Session

Decision Analysis Society

Chair: Yucheng Su, IE Business School, MADRID, Spain

1 - Newsvendor Decisions in Regime Shift Environments

Yucheng Su, IE Business School - IE University, MADRID, Spain, Canan Ulu, Sreyaa Guha, Matthias Seifert

We examine how decision makers (DMs) adjust ordering decisions in response to demand signals that are indicative of demand regime shifts. We define demand regime shifts as fundamental changes in the underlying probabilistic demand distribution. Such shifts reflect the nonstationary nature of real-world product demand. We develop an analytical model, which extends the classical newsvendor framework, to predict ordering behavior in the face of impending regime shifts and empirically test the predictions using laboratory experiments. Our findings indicate that DMs tend to underreact to precise demand signals in unstable environments. This behavioral pattern enhances performance for low-margin products but diminishes it for high-margin products. We conclude by discussing implications of our findings for inventory management in settings where demand regime shifts are pronounced.

2 - Persuasions on Preventive Decisions

Lijia Tan, Eindhoven University of Technology, Eindhoven, Netherlands, Bochen Zhu, Rob Basten, Lijia Wei

Experts often advise decision-makers on preventive actions to mitigate potential losses. However, differences in how experts and decision-makers perceive costs and benefits can lead to a principal-agent problem. This study theoretically and experimentally examines how expert advice can persuade decision-makers to take preventive action. We propose two advisory policies: Bayesian and threshold. Our analytical results show that (1) the threshold policy outperforms the Bayesian policy in maximizing the expert's expected payoff when the conflict of interest between the expert and decision-maker is large; and (2) the two policies are equivalent when the conflict is sufficiently small. In laboratory experiments, decision-makers exhibited a relatively low adherence rate to expert advice, which reduced the expert's expected payoff. Notably, this low adherence persisted even when experts implemented the policies rationally. To capture this behavior, we employ the Agent Quantal Response Equilibrium (AQRE) model, which accounts for bounded rationality among decision-makers. Based on the irrationality estimated by the AQRE model, we propose an adapted threshold policy that improves adherence rates, thereby increasing the expert's expected payoff.

3 - Points Plus Money: Uncovering the Impact of Mixed Currency Redemptions

Freddy Lim, National University of Singapore, Singapore, Singapore, So Yeon Chun

In recent years, loyalty programs have rapidly expanded in scale. Loyalty points effectively serve as a new currency, and consumers often use loyalty point currency in the redemption of goods and services. Despite this redemption growth, consumers can still find it difficult to attain the points required to redeem rewards. In response, some firms allow consumers to perform mixed currency (points plus money) redemptions, instead of full point redemptions.

This study examines the impact of mixed currency redemptions on consumer behaviors and firm revenue, using data from a major loyalty program. We adopt an instrumental variables control function approach to model consumers' endogenous selection to perform mixed currency redemptions. We find that mixed currency redemptions significantly increase consumers' direct point purchases with the firm compared to full point redemptions, which increases firm revenue. Interestingly, earnings from traditional accrual channels such as credit cards remain similar between consumers using mixed currency and full point redemptions. This suggests that mixed currency redemptions deliver comparable impact as full point redemptions within traditional point earning channels, but uniquely drive higher levels of direct point purchases.

Although mixed currency redemptions may encourage consumers to drain their low point balances and become inactive, we find no evidence to support this. On the contrary, consumers who drain their balances through mixed currency redemptions remain engaged in the program. We also find that a consumer segment which is often overlooked in marketing efforts contributed significantly to the revenue increase. Finally, we consider plausible mechanisms that drive these results.

4 - Attention in Motion: Using Scroll Tracking to Measure the Dynamics of Preferential Choice

Ilkka Leppänen, Aalto University, Espoo, Finland

Understanding how preferences are formed in commonplace, ecologically relevant situations is highly valuable for researchers and practitioners. I develop scroll tracking, a process tracing method that uses responsive mobile web design and that can be used to study the cognitive process behind decision making. The method is based on recording a response curve in the pixel-millisecond coordinate space from the decision maker's scrolling behaviour. To demonstrate the value of response curve analysis for decision research, I propose different metrics that are derived from the response curve and that are rooted in other motor response and gaze dwell metrics in the literature. To validate the scroll tracking method I collect empirical data using an experimental study framed as a consumer choice problem and explore predictions made by attentional evidence accumulation models equipped with the scroll-based process tracing data. I also show that the way that the decision maker interacts in the app can be used to predict subjective valuations as well as latent individual difference measures and risk attitudes, as a complementary risky choice study shows. I then compare different drift diffusion models, stocked with the scroll tracking response metrics, in their predictive ability. All the models benefit from the richness of data that scroll tracking provides. These findings are evidence of the potential of naturalistic process tracing methods that are based on responsive designs of digital applications that can be used to covertly study latent decision processes, and should find use in various managerial and practical settings.

Co-Chair: Ling Li, Indiana University, Bloomington, IN, United States

1 - Nearby Childcare Retains Talents: An Empirical Study of Childcare Availability and Turnover of US Knowledge Workers

Zhihan Wang, London Business School, London, United Kingdom, Damian Beil, Jun Li

Childcare shortage is a widely-cited critical factor hindering labor market participation in the US, yet the empirical evidence on the real impact of nearby childcare availability on the turnover of knowledge workers is still rare. Leveraging nationwide, large-scale job profile data of workers in US knowledge industries from 1997 to 2019 and variations of state-level childcare licensing regulations, this paper is among the first to investigate the causal impact of nearby childcare availability on individual-level job departure outcomes. Our results suggest that higher childcare availability leads to lower likelihood of turnover for US knowledge workers. The effect is consistent across the major occupations, and is larger for female, early-career, and highly-educated workers. Our study highlights the critical role of proximity to childcare services in talent retention and equitable workplace, offering direct policy implications for employers and policymakers.

2 - Detecting Student Struggle for Timely Intervention in Self-Paced Online Learning

Ling Li, Kelley School of Business, Indiana University, Bloomington, IN, United States, Owen Wu, Christopher Chen, Wenchang Zhang

The rise of self-paced online learning offers flexibility and personalization for K–12 students but disrupts the real-time feedback loop that exists in traditional classrooms. In physical settings, teachers observe students' facial expressions, questions, and behavior to identify confusion or frustration and intervene accordingly. However, in online environments, such visible cues vanish. Teachers are often left reviewing activity logs after the fact—an approach that is delayed, inefficient, and hard to scale. Drawing on collaborations with an online learning platform, this work addresses two critical challenges to timely instructional support in digital settings. First, students rarely signal when they are struggling. Second, instructors lack the capacity to monitor and interpret behavioral data across large student populations. While current adaptive systems personalize content delivery, they offer limited guidance on when and how teachers should intervene. Our research bridges this gap by developing data-driven methods to detect student struggle in real time, enabling just-in-time instructional support.

3 - Breaking Enrollment Barriers for Refugee Children: Evidence from An Enrollment Support Program in Turkey

Hanwen Zhu, Cornell University, Ithaca, NY, United States, Nur Kaynar, Yao Cui

Millions of refugee children around the world face persistent barriers to enrolling and remaining in school. These challenges are driven by economic hardship, language difficulties, frequent displacement, and limited institutional capacity to effectively include and support refugee students within national education systems. In this work, we collaborate with a leading non-profit organization in Turkey to evaluate the impact of enrollment-focused support services—such as information sessions on the education system, individualized counselling, and direct assistance with school registration—on school (re)enrolment and term-end retention among refugee children. Using a combination of logit models and generalized causal forests, we estimate heterogeneous treatment effects across child and household characteristics. We find that receiving support significantly improves both enrolment and retention outcomes, with the largest gains observed among younger children (ages 5–7), those with higher Turkish proficiency, and families residing in formal housing. Effects diminish sharply after age 15. These results underscore the importance of prioritizing subgroups most responsive to intervention, and suggest that targeted, low-cost services can effectively close early-grade enrolment gaps. In contrast, older adolescents and highly vulnerable families may require more comprehensive approaches—such as financial incentives tied to school attendance or structured vocational preparation programs—to sustain engagement. Situated in Turkey, which hosts the world's largest refugee population, our study demonstrates how administrative data and machine-learning-based causal inference can be leveraged to optimize the allocation of scarce educational resources in humanitarian settings.

Operations and Analytics in Innovative Marketplaces

Invited Session

MSOM: Service Operations

Chair: Wenchang Zhang, Indiana University Bloomington, Bloomington, IN, United States

1 - Omnichannel Operations in on-Demand Delivery Platform with Buy-Online-and-Pick-up-in-Store

Yu Guo, University of Science and Technology of China, Hefei, China, People's Republic of, Fei Gao, Wenchang Zhang, Liu Ming

This paper studies an emerging omnichannel on-demand economy in which consumers choose how their orders are fulfilled—either via independent couriers or in-store pickup. We consider the endogenous behaviors of both consumers and couriers, and analyze the platform's optimal pricing strategies across channels and courier wage. Motivated by concerns over reduced courier income due to buy-online-and-pick-up-in-store (BOPS), we further examine the efficacy of wage regulations on platform profit, courier welfare, and consumer surplus.

We develop a stylized model to examine how BOPS affects pricing on both the consumer and courier sides. Using data from a major meal-delivery platform in China, we estimate key model primitives and simulate the effects of BOPS and wage regulation.

Our results highlight three insights. First, the conventional belief that price and demand are positively correlated for gig services may not hold in omnichannel settings—especially when consumers are less sensitive to delivery congestion. Second, although BOPS transfers delivery cost to consumers, its price may still exceed that of

delivery. Third, BOPS reduces courier welfare, but this can be mitigated by modest wage regulation: setting a minimum wage 20% above the average increases courier welfare by 15.96%, with only a 0.35% reduction in platform profit.

We conclude that traditional gig-economy pricing strategies may be suboptimal in omnichannel platforms. While BOPS boosts platform efficiency, it risks harming workers—yet a small wage floor can restore balance with minimal cost to the platform.

2 - Platform Entry and Vendor Competition

Xiaotang Yang, University of Toronto, Toronto, ON, Canada, Arseniy Gorbushin, Ming Hu, Yun Zhou

We investigate the impact of introducing a delivery platform on vendor competition. Each vendor strategically decides whether to join the platform, employ an in-house delivery, or not offer any delivery option to maximize its profit. Our findings indicate that the platform entry either intensifies vendor competition, leading to lower vendor profits and higher demand volume, or conversely, alleviates vendor competition, leading to higher vendor profits and lower demand volume. The intensifying or alleviating role of the platform on vendor competition hinges on the competitive environment of the market in which the vendors operate. We characterize conditions under which the platform's equilibrium strategy involves lowballing the delivery service to encourage vendor participation. However, perhaps surprisingly, the seemingly appealing lowballing of the delivery service (offered by the platform to attract vendor participation) hurts vendors by encouraging them to engage in more intensified competition, ultimately diminishing their profits. Conversely, if the platform overcharges from the delivery service, the platform entry alleviates vendor competition and benefits vendors. Therefore, the platform-enabled sharing of couriers can improve delivery efficiency and lower delivery costs but may intensify vendor competition through lowballing the delivery service, placing them in a prisoner's dilemma that ultimately lowers their profits. These insights also apply to an e-commerce platform that provides storage and fulfillment services with economies of scale enabled by aggregating the business of sellers operating on the platform.

3 - Incentive-Compatible Bidding and Contract Design In Digital Display Advertising

Sami Najafi Asadolahi, Santa Clara University, Santa Clara, CA, United States, Naren Agrawal, Stephen Smith

Digital advertising today operates under split incentives: advertisers fund campaigns, but agencies—or platforms—often control bidding strategies. This paper investigates that tension and proposes a coordinated solution. We develop a rigorous decision-theoretic framework to model the long-run interaction between advertisers and intermediaries, capturing how campaign pacing, budget control, and bidding incentives shape system performance over time.

We model the advertiser's and the intermediary's optimization problems as steady-state Markov decision processes and structure their interaction as a Stackelberg game. This formulation captures the dynamics of bidding, pricing, and campaign delivery under realistic operating constraints. Our central insight is that performance-based compensation, combined with active budget limits, naturally aligns agency bidding with advertiser objectives. Under such contracts, we prove that bidding becomes incentive-compatible and cost-efficient—achieving campaign outcomes at minimum total spend.

We compare three dominant industry structures—agency-managed, advertiser-managed, and platform-managed—and show that platforms like Google Ads, when subject to CPA or ROAS constraints, can replicate first-best efficiency. We further propose contract mechanisms that restore coordination and enable surplus sharing between parties.

Numerical experiments demonstrate that these coordinated pricing mechanisms can more than double advertiser surplus relative to decentralized models. The results provide both theoretical insight and practical guidance for designing revenue-optimal, incentive-aligned contracts in digital advertising markets.

Emerging Topics in Platform Operations and Retail

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Dmitry Mitrofanov, Boston College, Brighton, MA, United States

1 - Nudging Customers to Select High Stock Delivery Windows via Information Sharing

Dmitry Mitrofanov, Boston College, Brighton, MA, United States, Do Yoon Kim, Benjamin Knight

For decades, stockouts have posed a major challenge for retailers, and the rise of online platforms has not mitigated this issue, now nearing a trillion-dollar scale globally. Despite AI and other innovations, companies continue to struggle with order fulfillment. This paper examines a novel policy that nudges customers toward high-stock delivery windows to improve fulfillment rates. We evaluate the effectiveness of this policy using a large-scale field experiment with over a million users on Instacart, where customers in the treatment group were presented with the prompt 'Higher stock at this time' beneath delivery windows associated with peak supermarket inventory levels. Our cost-effective information-sharing policy increases the likelihood of customers selecting high-stock delivery windows by 8.31%, with stronger effects for users with a history of stockouts, higher variability in past delivery time slots, and larger order sizes. It also reduces item replacements by 1.77% and refunds by 2.08%, improving order fulfillment. Importantly, customer spending increases, driven by a 3.91% boost in order value and a 0.72% increase in conversion rates, while order frequency remains stable. However, we also find some negative externalities: treated users spend 19.88% more time at checkout, potentially making online shopping more time-consuming. Additionally, priority delivery selection drops by 3.68%, and delivery speed decreases by 5.8%, suggesting a trade-off between successful order fulfillment and service responsiveness. Finally, the policy encourages exploration, leading customers to visit new stores and try new items, potentially generating long-term benefits for both customers and the platform, further highlighting the power of information sharing.

2 - Fair Workweek, Fair Outcomes? the Heterogeneous Treatment Effects of Predictive Scheduling Laws

Yao Cui, Cornell University, Ithaca, NY, United States, Wee Kiat Lee, Karan Girotra

Workers in the service industry tend to have varying work schedules from week to week. Such unpredictable work schedules can negatively affect the welfare of service workers. Motivated by recent legislative efforts to implement a predictive scheduling law, where employers must give advance notice for any schedule changes, we build a game-theoretic model to analyze the effect of the law. We find that while the firm's hiring level may increase with the regulation, the contracted shift hours and social welfare can potentially decrease. We also find empirical evidence for the predictions from our model using data from the state-wide implementation of a predictive scheduling law in Oregon. These insights contribute to the broader discussions on how scheduling regulations impact labor markets and firms' hiring decisions.

3 - Scheduling with Uncertain Holding Costs and Its Application to Content Moderation

Thodoris Lykouris, Massachusetts Institute of Technology, Cambridge, MA, United States, Caner Gocmen, Deeksha Sinha, Wentao Weng

In content moderation for social media platforms, the cost of delaying the review of a content is proportional to its view trajectory, which fluctuates and is a priori unknown. Motivated by such uncertain holding costs, we consider a queueing model where job states evolve based on a Markov chain with state-dependent instantaneous holding costs. We demonstrate that in the presence of such uncertain holding costs, the two canonical algorithmic principles, instantaneous-cost ($\text{\$}\nu\text{\$}$ -rule) and expected-remaining-cost ($\text{\$}\mu/\theta\text{\$}$ -rule), are suboptimal. By viewing each job as a Markovian ski-rental problem, we develop a new index-based algorithm, "Opportunity-adjusted Remaining Cost (OaRC)", that adjusts to the opportunity of serving jobs in the future when uncertainty partly resolves. We show that the regret of OaRC scales as $\tilde{O}(L^{1.5}\sqrt{N})$, where L is the maximum length of a job's holding cost trajectory and N is the system size. This regret bound shows that OaRC achieves asymptotic optimality when the system size N scales to infinity. Moreover, its regret is independent of the state-space size, which is a desirable property when job states contain contextual information. We corroborate our results with an extensive simulation study based on two holding cost patterns (online ads and user-generated content) that arise in content moderation for social media platforms. Our simulations based on synthetic and real datasets demonstrate that OaRC consistently outperforms existing practice, which is based on the two canonical algorithmic principles.

4 - Online Matching and Market Imbalance

Benjamin Barrientos, MIT, Cambridge, MA, United States, Daniel Freund, Daniela Saban

Our work introduces the effect of supply/demand imbalances into the literature on online matching with stochastic rewards in bipartite graphs. We provide a parameterized definition that characterizes instances as over- or undersupplied (or balanced), and show that higher competitive ratios against an offline clairvoyant algorithm are achievable, for both adversarial and stochastic arrivals, when instances are more imbalanced. The competitive ratio guarantees we obtain are the best-possible for the class of delayed algorithms we focus on (such algorithms may adapt to the history of arrivals and the algorithm's own decisions, but not to the stochastic realization of each potential match).

We then explore the real-world implications of our improved competitive ratios. First, we demonstrate analytically that the improved competitive ratios under imbalanced instances is not a one-way street by showing that a platform that conducts effective supply- and demand management should incorporate the effect of imbalance on its matching performance on its supply planning in order to create imbalanced instances. Second, we empirically study the relationship between achieved competitive ratios and imbalance using the data of a volunteer matching platform.

5 - Assortment Optimization, Price Competition and Fairness

Ozge Sahin, Johns Hopkins Carey Business School, Baltimore, MD, United States, Wentao Lu, Ruxian Wang

Online retailers and department stores often serve as marketplaces for multiple sellers, with consumers depending on the platform's assortment and display decisions to explore products and make purchase choices. We examine how the platform's assortment optimization influences price competition among sellers. Our analysis shows that optimizing the assortment leads to higher equilibrium prices. We then extend the model by introducing fair market exposure constraints into the platform's decision problem and study the resulting price equilibrium.

Responsible Operations: Child Labor, Mining Operations, Foster Care, Financial Impact

Invited Session

MSOM: Sustainable Operations

Chair: Ashish Kabra, Nanyang Technological University, Singapore, Singapore, Singapore

1 - Search and Matching for Adoption from Foster Care

Ludwig Dierks, University of Illinois at Chicago, Chicago, IL, United States, Vincent Slaugh, Utku Unver, Sven Seuken, Nils Olberg

To find families for the more than 100,000 children in need of adoptive placements, most United States child welfare agencies have employed a family-driven search strategy in which prospective families respond to announcements made by the agency. However, some agencies have switched to a caseworker-driven search strategy in which the caseworker directly contacts families recommended for a child. In this talk, we present our work comparing these strategies, including new empirical evidence comparing a Florida agency that switched to caseworker-driven search with statewide benchmarks.

2 - Impact of Supply Chain Structures on Child Labor Violations

Jiacong Bao, R.H. Smith School of Business, UMD, College Park, MD, United States, Fred Bao, Ashish Kabra

This study examines child labor violations in US supply chains. Our analysis reveals that extended supply chain tiers and supplier network complexity significantly increase child labor violation risks, particularly in sectors with high subcontracting. Results emphasize the need for enhanced sourcing and enforcement strategies.

3 - Do Penalties Promote Responsible Operations? Evidence from the U.S. Mining Industry

Anna Saez de Tejada Cuenca, IESE Business School, Barcelona, Spain, Vibhuti Dhingra

Financial penalties—fines levied for violations found during site inspections—are widely used to encourage responsible operations (such as compliance with environmental and labor standards or with supplier codes of conduct). However, the effectiveness of penalties in achieving this objective remains unclear. In this paper, we empirically investigate whether higher penalties lead to more responsible operations using a large, granular dataset from the U.S. mining industry. Our identification strategy exploits a policy shock that sharply increased the penalty amounts for health and safety infractions in the mines. We find that higher penalties had, at best, a modest effect on responsible operations. While there was some decrease in violations, we find no evidence of a decrease in accidents or injuries at mines that faced higher fines. We show that this null effect is driven, at least in part, due to an unanticipated and unintended consequence of higher penalties: mining companies strategically contested the higher fines in court, that led to discounted payment amounts, delay in payment times, and higher regulatory costs. By examining the mechanisms through which higher penalties (fail to) promote responsible operations, our work offers insights that can be generalized to contexts beyond mining (e.g., global supply chains).

4 - Quantifying and Ranking the Impact of Social Unsustainability in Public Firms and Their Supply Chains

Christian Blanco, Ohio State University, Columbus, OH, United States, Soh Hyun Chu, James Hill

We quantify the effects of six social sustainability issues on firm market value by classifying articles from 187 news outlets published between 1990 and 2019. While the market effects are short-lived, the severity of these issues varies depending on whether they occur within the firm or its supply chain.

5 - Financial OR Productivity Interventions? A Nuanced View into Improving Farmer Welfare and Reducing Child Labor in Commodity Supply Chains

Andreas Kilian Gernert, KLU, Hamburg, Germany, Andre Calmon, Dan Iancu, Luk Van Wassenhove

Millions of smallholder farming households that produce agricultural commodities grapple with poverty and resort to their children's labor to boost farm production. In response, governments, commodity-buying firms, micro-finance institutions, and non-profit organizations have implemented various interventions to improve household welfare and mitigate child labor, but the effectiveness of these interventions remains unclear. Drawing inspiration from cocoa supply chains, we propose a model that captures a farming household's need to secure basic subsistence, alongside its decisions on borrowing, saving, consumption, and reliance on child labor for production. With this model, we evaluate the effects of common interventions—including improved access to credit and savings, price premiums, and yield improvement programs—examining their impacts on household welfare, consumption, and child labor. Our theoretical results reveal a complex landscape: improved access to credit can either decrease or inadvertently increase child labor, depending on whether households borrow for subsistence or discretionary expenses. Enhancing access to savings invariably curtails child labor, but might also depress household consumption. Price premiums can diminish child labor use only when they are large; otherwise, they may inadvertently incentivize increased child labor. Yield improvement programs can either decrease or increase child labor, depending on the household's risk aversion and prudence. We test and confirm several of these results using empirical survey data obtained from our industry partner. Our results highlight the dual-edged nature of interventions and underscore the need for tailoring strategies to the specific operational dynamics of farming households, ensuring interventions do not inadvertently exacerbate the issues they aim to resolve.

Chair: Tong Xie, Booth School of Business, Chicago, IL, United States

Co-Chair: Rene Caldentey, The University of Chicago, Chicago, IL, United States

1 - Incorporating Choice Overload into Assortment Planning

Tong Xie, The University of Chicago Booth School of Business, Chicago, IL, United States, Rene Caldentey, Srikanth Jagabathula

Consumers often experience choice overload when faced with too many product options, which can hinder decision-making and reduce sales. Traditional assortment models assume rational behavior and overlook this effect. We study how choice overload shapes purchase behavior, emphasizing its role in limiting consumers' ability to explore and switch brands over time. Using panel data from the IRI Academic Dataset, we find an inverted U-shaped relationship between assortment size and brand switching, suggesting an optimal assortment size that maximizes exploration.

To capture these dynamics, we introduce the Nested Logit Choice Overload (NL-CO) model, which adds a disutility term for large assortments, balancing the benefits of variety with the costs of overload. We formulate the retailer's optimization problem under this framework and prove it is NP-hard. We then propose a 1/2-approximation algorithm and a Fully Polynomial-Time Approximation Scheme (FPTAS) to efficiently compute near-optimal assortments.

We apply the NL-CO model to private-label planning and fair assortment planning. For private labels, assuming national brands yield uniform revenue (lower than private labels) and start with larger market shares, the optimal assortment can be identified by ranking products with an index representing market share and brand-switching shifts. For fair assortment, we show that as consumers become more overloaded, the platform's ability to influence product exposure weakens. Together, these applications demonstrate how the NL-CO model captures consumer behavior under overload and provides strategies for promoting private-label growth and fairness in assortment planning.

2 - Spatial Staffing

Ming Hu, University of Toronto, Toronto, ON, Canada, Yang Bo

We study the staffing problem for an on-demand vehicle-sharing platform operating over a d -dimensional service region. The platform makes a one-time capacity decision of how many vehicles to employ at the start of an infinite horizon, and dynamically controls vehicle-customer matching and routing over time. The objective is to minimize the long-run average cost, which includes vehicle operations costs and customer waiting costs. We show that the optimal staffing level consists of a nominal load (i.e., the minimum number of vehicles to ensure system stability) plus a safety buffer. This safety level depends on key system parameters, including the dimensionality d , the distributions of customer origins and destinations, and the ride-pooling capacity q (i.e., the maximum number of passengers per vehicle). Specifically, (i) when $q=1$, the safety level scales with the arrival rate raised to the power of $d/(d+1)$, a result that holds broadly across distributional assumptions and mirrors earlier findings under stylized spatial models. (ii) When $q>1$, the scaling becomes $2d/(2d+1)$, which, to our knowledge, was not discovered in the past. Importantly, we derive these results by analyzing exact vehicle routing without relying on stylized assumptions and by developing provably near-optimal policies for general spatial matching settings beyond those in prior work.

3 - An Operational Perspective to Online Content Moderation

Tingrui Shi, University of Chicago, Chicago, IL, United States, Rene Caldentey, Amy Ward

Social media platforms and their content moderation systems heavily rely on artificial intelligence (AI) and machine learning (ML) due to the vast scale of online content they are expected to manage. These technologies enable platforms to efficiently monitor and filter user-generated content, addressing challenges such as hate speech, misinformation, and other harmful material. Although AI significantly aids in moderating vast amounts of content, human reviewers remain essential for handling ambiguous cases that AI struggles to classify reliably. Additionally, humans play a crucial role in generating new labeling data to continually train these automated systems, ensuring they remain effective and up-to-date. Keeping humans in the loop is particularly important for addressing challenges arising from an ever-evolving environment, including concept drift caused by changes in social norms, language, and social media platform policies. With a finite human-reviewer capacity, there is a trade-off between (1) dedicating more resources to labeling training content, which increases the accuracy of the machine learning classifier, and (2) devoting more resources to classification tasks, where multiple reviewers aggregate results. We examine the operational problem of optimally allocating reviewers' time between content labeling (for training machine learning models) and policy enforcement to minimize long-term misclassification and delay costs.

4 - A New Estimator for Encouragement Design in Randomized Controlled Trials when the Exclusion Restriction is Violated

Cheng Lu, Washington University in St. Louis, St. Louis, MO, United States, Guangying Chen, Tat Chan, Zhengling Qi, Dennis Zhang

Encouragement design is widely used in randomized controlled trials when noncompliance in the treatment group, control group, or both is non-negligible. The standard identification strategy is to use the randomized group assignment as an instrumental variable to estimate the local average treatment effect (LATE). In many experiments, however, this instrument may violate the exclusion restriction condition, because the encouragement can directly impact the interested outcome variable. We develop a new root-n consistent estimator using the randomized group assignment to construct an instrument that relies on the heteroskedasticity of treatment intensities between groups. Our identification strategy can recover not only LATE but also the direct impact of the encouragement on outcomes. We further propose a min-max estimator for consistent nonparametric estimation of heterogeneous treatment effects. Finally, we conducted a large-scale field experiment with a social media platform to study how expanding users' social networks influences their platform usage. While ordinary least squares and standard two-stage least squares estimators report a positive effect, our estimator suggests that the effect comes solely from the encouragement. We find evidence supporting the null effect of network expansion, indicating that firms may waste resources on false positives when the exclusion restriction is violated in their field experiments.

5 - Strategic Implications of Free Cancellation Policies in Competitive Airline Markets

Surui Wang, School of Data Science, Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Zizhuo Wang

We developed a stylized model to analyze the impact of free cancellation policies on airline competition. We study a duopoly market with two airlines offering fixed fares across two booking periods: an early period with lower fares and cancellation uncertainty, and a late period with higher fares and certain travel needs. Passengers choose between booking early, considering potential cancellations, or waiting until their travel plans are confirmed. Airlines strategically determine their booking limits and whether to provide refundable tickets. Using a utility-based economic framework, we explicitly model passenger decisions based on expected utility maximization. We derive closed-form equilibrium booking limits and refund policies. Our analysis shows that in moderately competitive markets without extensive customer spillover, airlines adopt free cancellation policies as a dominant strategy, leading to higher early bookings and improved revenues. However, under intense competition with substantial passenger spillover, refundable policies may trigger aggressive early bookings that reduce overall profitability. This study provides theoretical insights into how free cancellation policies strategically impact airline revenue management and competitive interactions.

1 - Two-Sided Pricing and Learning with Buyer Choice: a Generalized Sgd Method

Meichun Lin, Singapore Management University, Singapore, Singapore, Woonghee Huh

Motivated by online used-car platforms, we study pricing decisions for purchasing and selling multiple products in a two-sided market. While supply for each product is independently acquired from individual sellers, demand is substitutable and follows a choice model. With uncertainty from both supply and demand, a platform sequentially adjusts purchase and selling prices to maximize profit while satisfying inventory constraints. Moreover, the platform does not know in advance the supply and demand as functions of prices. The pricing decisions should account for learning of the supply and demand functions in addition to the two sides of uncertainty and potential stockouts. When the supply and demand functions are known, we find a class of fixed-price policies that achieve provably good performance. Our finding suggests that we can target a fixed-price policy rather than the state-dependent optimal policy when the supply and demand functions are unknown. We propose a novel generalization of the classical SGD method for learning the target prices on each side. Our algorithm with the generalized SGD is asymptotically optimal when the planning horizon is large.

2 - Dynamic Pricing with Infrequent Inventory Replenishments

Menglong Li, City University of Hong Kong, Kowloon Tong, Hong Kong, Boxiao Chen, David Simchi-Levi

We consider a joint pricing and inventory control problem where pricing can be adjusted more frequently than inventory ordering decisions. More specifically, the pricing decision is adjusted every period, while new inventories are ordered every epoch that consists of multiple periods. In this setting, the retailer determines the inventory level at the beginning of each epoch and solves a dynamic pricing problem within each epoch with no further replenishment opportunities. The optimal pricing and inventory control policy is solved by an intricate dynamic programming (DP), in which the inventory level is the state variable and the pricing policy is characterized by a function of the inventory level. We consider the situation where the demand-price function and the distribution of random demand noise are both unknown to the retailer, and the retailer needs to develop an online learning algorithm to learn those information and at the same time maximize total profit. We propose a learning algorithm by applying linear bandit techniques under the upper confidence bound (UCB) framework and prove that the algorithm converges through the DP recursions to approach the optimal pricing and inventory control policy under complete demand information. The theoretical lower bound for convergence rate of a learning algorithm is proved based on the multivariate Van Trees inequality coupled with some structural DP analyses, and we show that the upper bound of our algorithm's convergence rate matches the theoretical lower bound.

3 - Operational Data Analytics (Oda) Embedded Neural Network Learning for the Newsvendor Problem with General Demand

Jian Wu, City University of Hong Kong, Hong Kong, Hong Kong, Qi Feng, J Shanthikumar

We analyze the data-integrated contextual newsvendor problem with a general demand model and high dimensional covariates. Utilizing the structural properties in the decision problem, we develop an efficient Operational Data Analytics (ODA) embedded neural network solution.

4 - Closing the Gaps: Optimality of Sample Average Approximation for Data-Driven Newsvendor Problems

Shilin Yuan, Tsinghua University, Beijing, China, People's Republic of, Jiameng Lyu, Bingkun Zhou, Yuan Zhou

We study the regret performance of Sample Average Approximation (SAA) for data-driven newsvendor problems with general convex inventory costs. In literature, the optimality of SAA has not been fully established under both α -global strong convexity and (α, β) -local strong convexity (α -strongly convex within the β -neighborhood of the optimal quantity) conditions. This paper closes the gaps between regret upper and lower bounds for both conditions. Under the (α, β) -local strong convexity condition, we prove the optimal regret bound of $\Theta(\log T/\alpha + 1/(\alpha\beta))$ for SAA. This upper bound result demonstrates that the regret performance of SAA is only influenced by α and not by β in the long run, enhancing our understanding about how local properties affect the long-term regret performance of decision-making strategies. Under the α -global strong convexity condition, we demonstrate that the worst-case regret of any data-driven method is lower bounded by $\Omega(\log T/\alpha)$, which is the first lower bound result that matches the existing upper bound with respect to both parameter α and time horizon T . Along the way, we propose to analyze the SAA regret via a new gradient approximation technique, as well as a new class of smooth inverted-hat-shaped hard problem instances that might be of independent interest for the lower bounds of broader data-driven problems.

1 - The Cost of Balanced Training-Data Production in An Online Data Market

Augustin Chaintreau, Columbia University, New York, NY, United States, Juba Ziani, Roland Maio

Many ethical issues in machine learning are connected to the training data. Online data markets are an important source of training data, facilitating both production and distribution. Recently, a trend has emerged of for-profit "ethical" participants in online data markets. This trend raises a fascinating question: Can online data markets sustainably and efficiently address ethical issues in the broader machine-learning economy?

In this work, we study this question in a stylized model of an online data market. We investigate the effects of intervening in the data market to achieve balanced training-data production. The model reveals the crucial role of market conditions. In small and emerging markets, an intervention can drive the data producers out of the market, so that the cost of fairness is maximal. Yet, in large and established markets, the cost of fairness can vanish (as a fraction of overall welfare) as the market grows. Our results suggest that "ethical" online data markets can be economically feasible under favorable market conditions, and motivate more models to consider the role of data production and distribution in mediating the impacts of ethical interventions.

2 - Econevals: Benchmarks and Litmus Tests for LLM Agents in Unknown Environments

Sara Fish, Harvard University, Cambridge, MA, United States, Julia Shephard, Minkai Li, Ran Shorrer, Yannai Gonczarowski

We develop benchmarks for LLM agents that act in, learn from, and strategize in unknown environments, the specifications of which the LLM agent must learn over time from deliberate exploration. Our benchmarks consist of decision-making tasks derived from key problems in economics. To forestall saturation, the benchmark tasks are synthetically generated with scalable difficulty levels. Additionally, we propose litmus tests, a new kind of quantitative measure for LLMs and LLM agents. Unlike benchmarks, litmus tests quantify differences in character, values, and tendencies of LLMs and LLM agents, by considering their behavior when faced with tradeoffs (e.g., efficiency versus equality) where there is no objectively right or wrong behavior. Overall, our benchmarks and litmus tests assess the abilities and tendencies of LLM agents in tackling complex economic problems in diverse settings spanning procurement, scheduling, task allocation, and pricing -- applications that should grow in importance as such agents are further integrated into the economy.

3 - Designing Enterprise AI Systems: Hallucination, Creativity, and Moral Hazard

Terry Taylor, UC Berkeley, Berkeley, CA, United States, Tinglong Dai

We explore the interplay between the design of Generative AI (GenAI) systems and the compensation of human agents. A key hyperparameter, temperature, governs the trade-off between creativity and reliability, such that higher temperatures enable more creative outputs but increase the risk of hallucinations. We examine how temperature interacts with agent effort in a principal-agent framework. The firm sets the GenAI system's temperature, while the agent chooses an unobservable effort level, both of which jointly determine the probability of success. We compare this decentralized system, where the agent chooses her effort, with the benchmark centralized system, where the firm dictates both temperature and effort.

We show that when the firm's design of its GenAI system is taken into account, classical moral hazard results are reversed: decentralization can distort agent effort *upward*; and as the value of a successful outcome increases, the optimal effort level can *decrease*. One might expect the optimal temperature to be monotone in the value of a successful outcome; indeed, this is the case for the centralized system. We show how this result is reversed for the decentralized system. Together, these findings offer a comprehensive framework for understanding the interplay among GenAI system parameters, incentive design, and performance.

4 - Rethinking the Role of Genai in Content Creation Ecosystem

Fan Yao, The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

The advent of generative AI (GenAI) is transforming the landscape of content creation industry, enabling the rapid production of diverse, high-quality media. While GenAI reshapes online content ecosystems, it also raises concerns about market saturation and the potential marginalization of human creativity. In this talk, we introduce a competition model to analyze the dynamics between authentic human creators and GenAI. Our theoretical and simulation results suggest that, despite the challenges, a stable equilibrium between human- and AI-generated content is achievable under certain conditions. This study aims to advance the conversation around competitive dynamics in online content ecosystems and offer insights into the evolving interplay between human creativity and generative technology.

5 - Tokenized Bandit for LLM Decoding and Alignment

Suho Shin, University of Maryland, College Park, MD, United States

We introduce the tokenized linear bandit (TLB) and multi-armed bandit (TMAB), variants of linear and stochastic multi-armed bandit problems inspired by LLM decoding and alignment. In these problems, at each round $t \in [T]$, a user submits a query (context), and the decision maker (DM) sequentially selects a token irrevocably from a token set. Once the sequence is complete, the DM observes a random utility from the user, whose expectation is presented by a sequence function mapping the chosen token sequence and the query to a real value. In both problems, we first show that learning is impossible without any structure on the sequence function. We introduce a natural assumption, diminishing distance with more commons (DDMC), and propose algorithms with regret $\tilde{O}(\sqrt{T})$ and $\tilde{O}(\sqrt{T^{2/3}})$ for TLB and TMAB, respectively. As a side product, we obtain an (almost) optimality of the greedy decoding for LLM decoding algorithm under DDMC, which justifies the unreasonable effectiveness of greedy decoding in several tasks. This also has an immediate application to decoding-time LLM alignment, when the misaligned utility can be represented as the frozen LLM's utility and a linearly realizable latent function. We finally validate our algorithm's performance empirically as well as verify our assumptions using synthetic and real-world datasets.

Combinatorial Markets

Invited Session

Auctions and Market Design

Chair: Benjamin Lubin, Boston University, Boston, 02215, United States

Co-Chair: Robert Day, University of Connecticut, Storrs, CT, United States

1 - Iterative Vickrey Auctions via Linear Programming

Sébastien Lahaie, Google Research, New York, NY, United States, Benjamin Lubin

Building on the linear programming approach to competitive equilibrium pricing, we develop a general method for constructing iterative auctions that achieve Vickrey-Clarke-Groves (VCG) outcomes. We show how to transform a linear program characterizing competitive equilibrium prices into one that characterizes universal competitive equilibrium (UCE) prices, which elicit precisely the information needed to compute VCG payments. By applying a primal-dual algorithm to these transformed programs, we derive iterative Vickrey auctions that maintain a single price path, eliminating the overhead and incentive problems associated with multiple price paths used solely for payment calculations. We demonstrate the versatility of our method by developing a novel iterative Vickrey auction for the multi-unit setting and an iterative variant of the Product-Mix auction. The resulting auctions combine the transparency of iterative price discovery with the efficiency and incentive properties of the VCG mechanism.

2 - Risk-Aware Market Clearing for Electricity Markets

HRITHIK NAMBIAR, Brown University, Providence, RI, United States, Amy Greenwald, Wirattawut Boonbandansook, Ryan Edmonds, Sidharth Anand, Gianluca Brero, Benjamin Lubin

Building on earlier work employing stochastic optimisation in two-period electricity markets, we propose a market-clearing mechanism that prices and allocates in the first stage to better manage extreme events in the second stage.

3 - Pricing Valid Cuts for Price-Match Equilibria

Robert Day, University of Connecticut, Storrs, CT, United States, Benjamin Lubin

We use valid inequalities (cuts) of the binary integer program for winner determination in a combinatorial auction (CA) as “artificial items” that can be interpreted intuitively and priced to generate Artificial Walrasian Equilibria. While the lack of an integer programming gap is sufficient to guarantee a Walrasian equilibrium, we show that it does not guarantee a “price-match equilibrium” (PME), a refinement that we introduce, in which prices are justified by an iso-revenue outcome for any hypothetical removal of a single bidder. We prove the existence of PME for any CA and characterize their economic properties and computation. We implement minimally artificial PME rules and compare them with other prominent CA payment rules in the literature.

4 - Expressive Side Information in Combinatorial Markets

Siddharth Prasad, Carnegie Mellon University, Pittsburgh, PA, United States, Maria-Florina Balcan, Tuomas Sandholm

I will present a new framework for efficient mechanism design with *expressive side information*. Expressive side information is a new paradigm where any knowledge the mechanism designer has about the agents—modeled through constraints on the agents' type spaces—can be used to design efficient mechanisms with better pricing structures. We characterize the revenue-optimal efficient mechanism under a very general model of type spaces and design better core-selecting auctions and better budget-balanced exchanges.

Joint work with Nina Balcan and Tuomas Sandholm.

5 - Service Assignment at the United States Naval Academy

Naomi Utgoff, US Naval Academy, Annapolis, MD, United States

This paper studies service assignment at the United States Naval Academy (USNA). Service assignment is the process which assigns each member of USNA's senior class to one of several communities, each representing a career path within the Navy. This matching problem is unique to the literature in that it features hard minimums, individual rationality constraints, and the requirement that every midshipman be assigned to a community. A stable assignment is generally impossible under these requirements: we characterize a natural relaxation that we call minimal unfairness. We then introduce the individual rationality adjusted deferred acceptance algorithm (IRDA) and show that it always selects a minimally unfair assignment which respects the Navy's requirements. This mechanism relies on the construction of a series of caps which combine the minimums, maximums, and individual rationality constraints. These caps thus determine when a community must reject a midshipman, as well as which midshipman should be rejected. Unlike standard deferred acceptance in which the rejecting community simply rejects its least favorite proposal(s) above its ceiling, IRDA identifies a rejectable set of midshipmen, and forces the rejection of a midshipman in that set. We also discuss two alternative mechanisms, generalized serial dictatorship (GSD) and eligibility type capped deferred acceptance (ECDA), and contrast their properties with IRDA.

1 - Competition Complexity in Multi-Item Auctions: Beyond Vcg and Regularity

Yiding Feng, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Hedyeh Beyhaghi, Yingkai Li, Matthew Weinberg

We quantify the value of the monopoly's bargaining power in terms of competition complexity—that is, the number of additional bidders the monopoly must attract in simple auctions to match the expected revenue of the optimal mechanisms—within the setting of multi-item auctions. We show that for simple auctions that sell items separately, the competition complexity is $\Theta(n/\alpha)$ in an environment with n original bidders under the slightly stronger assumption of α -strong regularity, in contrast to the standard regularity assumption in the literature, which requires $\Omega(n \cdot \ln(m/n))$ additional bidders. This significantly reduces the value of learning the distribution to design the optimal mechanisms, especially in large markets with many items for sale. For simple auctions that sell items as a grand bundle, we establish a constant competition complexity bound in a single-agent environment when the number of items is small or when the value distribution has a monotone hazard rate. Some of our competition complexity results also hold when we compete against the first best benchmark (i.e., optimal social welfare).

2 - On the Theoretical Foundations of Data Exchange Economies

Aniket Murhekar, Northwestern University, Evanston, IL, United States, Hannaneh Akrami, Bhaskar Chaudhury, Jugal Garg

Organizations increasingly seek to share and access datasets to improve their ML models and derive insights. Despite the immense demand for quality data, data exchange and collaboration have not reached their full potential. One of the key reasons is the lack of reciprocity, where some participants perceive their contribution to others to be of higher value than what they receive in return.

3 - Inspection Game with Location-Specific Detection Capabilities

Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA, United States, Bastián Bahamondes

We consider a two-person inspection game, in which a defender positions a limited number of detectors across a critical system to detect multiple attacks caused by an attacker. We assume that detection is imperfect, and each detector location is associated with a probability of detecting attacks within its set of monitored system components. The objective of the defender (resp. attacker) is to minimize (resp. maximize) the expected number of attacked components that remain undetected. To compute Nash Equilibria (NE) for this large-scale zero-sum game, we formulate a linear program with a small number of constraints, which we solve via column generation. We provide an exact mixed-integer program for the pricing problem, which entails computing a defender's pure best response, and leverage its supermodular structure to derive two efficient approaches to obtain approximate NE with theoretical guarantees: A column generation and a multiplicative weights update (MWU) algorithm with approximate best responses. To address the computational challenges posed by combinatorial attacker strategies, each iteration of our MWU algorithm requires computing a projection under the unnormalized relative entropy. We provide a closed-form solution and a linear-time algorithm for the projection problem. Our computational results in real-world gas distribution networks illustrate the performance and scalability of our solution approaches.

4 - Markets with Heterogeneous Agents: Dynamics and Survival of Bayesian vs. No-Regret Learner

Yoav Kolumbus, Cornell University, Ithaca, NY, United States, David Easley, Eva Tardos

We analyze the performance of heterogeneous learning agents in asset markets with stochastic payoffs. Agents aim to maximize the expected growth rate of their wealth but have different theories on how to learn to do this best. Our main focus is on comparing Bayesian learners and no-regret learners who compete in markets and identifying the conditions under which each approach is more effective. Bayesian learners with a finite prior that assigns positive probability to the correct model have posterior beliefs that converge exponentially fast, and such agents survive even in the presence of agents who invest according to the correct model. Bayesian learners with a continuum prior converge at a slower rate of $O((\log T)/T)$. Online learning theory provides no-regret algorithms for maximizing the log of wealth, achieving worst-case regret bounds of $O((\log T)$ without assuming a stationary stochastic process, but comparing against the best fixed investment rule. This regret, as we observe, is of the same order as that of a Bayesian learner with a continuum prior. Surprisingly, we find that even such low regret may not guarantee survival: an agent with regret $O((\log T)$, converging to the correct model at rate $O((\log T)/T)$ still vanishes when competing against an agent who invests according to the correct model, or even against a perfect Bayesian with a finite prior. On the other hand, we show that Bayesian learning is fragile, while no-regret learning requires less knowledge of the environment and is therefore more robust.

5 - Reallocating Wasted Votes in Proportional Parliamentary Elections with Thresholds

Rupert Freeman, University of Virginia, Charlottesville, VA, United States, Théo Delemazure, Jérôme Lang, Jean-François Laslier, Dominik Peters

In many proportional parliamentary elections, electoral thresholds (typically 3-5%) are used to promote stability and governability by preventing the election of parties with very small representation. However, these thresholds often result in a significant number of "wasted votes" cast for parties that fail to meet the threshold, which reduces representativeness. One proposal is to allow voters to specify replacement votes, by either indicating a second choice party or by ranking a subset of the parties, but there are several ways of deciding on the scores of the parties (and thus the composition of the parliament) given those votes. We introduce a formal model of party voting with thresholds, and compare a variety of party selection rules axiomatically, and experimentally using a dataset we collected during the 2024 European election in France. We identify three particularly attractive rules, called Direct Winners Only (DO), Single Transferable Vote (STV) and Greedy Plurality (GP). The full version of this paper is available at <https://arxiv.org/abs/2503.17>.

Chair: Parisa Lotfibagha, University of Massachusetts Amherst, Amherst, MA, United States

1 - An Adaptive Large Neighborhood Search Algorithm with Customized Search Operators for Solving Home Healthcare Scheduling and Routing Problem with Skill Matching and Periodic Visits

Qu Wei, Department of Emergency Medicine and West China Biomedical Big Data Center, West China Hospital, Sichuan University, Chengdu, 610041, China, Chengdu, China, People's Republic of, Kang Li

Home healthcare services are increasingly recognized as a crucial solution to challenges such as population aging, medical resource shortages, and growing service demands. However, efficiently scheduling healthcare services to minimize operational costs, optimize provider utilization, and ensure high-quality provider-patient matching remains a significant challenge. This study develops a comprehensive optimization model that incorporates practical constraints, including skill matching, work time limits, and periodic scheduling, to enhance service efficiency and resource allocation. Given the large-scale nature and computational complexity of the problem, traditional exact algorithms struggle to find optimal solutions within a reasonable timeframe. To address this, we propose an adaptive large neighborhood search algorithm with customized search operators designed specifically for home healthcare scheduling. The algorithm intelligently explores the solution space, improving convergence speed and solution quality. Extensive computational experiments using both synthetic and real-world data demonstrate that our approach consistently outperforms commercial solvers like Gurobi and conventional metaheuristics in both solution quality and computational efficiency, particularly in large-scale instances. A case study using real-world data from West China Hospital further validates the algorithm's practical applicability, showing significant reductions in operational and provider-related costs while enhancing service delivery. These findings offer valuable insights for healthcare managers, providing advanced decision-support tools to improve service quality, reduce expenses, and better meet the increasing demand for home healthcare services. This study contributes to healthcare operations research by presenting a scalable and efficient scheduling framework that integrates advanced optimization techniques with real-world constraints.

2 - Optimizing Chemotherapy Patient Selection and Timing for Home-Based Cancer Care

Lauren Moore, Mayo Clinic, Rochester, MN, United States, Yu-Li Huang

Timely access to chemotherapy is critical for cancer treatment outcomes. Home-based chemotherapy administered by mobile clinicians offers a safe and patient-centered alternative to in-clinic infusions, and it can reduce clinic appointment burden and patient treatment start lead time. However, not all patients are eligible or willing to receive care at home, and resources must be effectively managed. This study develops a tactical-level framework to support decision-making around the initiation timing of home-based chemotherapy under the Cancer Care Beyond Walls (CCBW) program at Mayo Clinic in Florida. A mixed-integer linear programming model (MILP) was developed to maximize utilization of home-based care resources while adhering to clinical and resource constraints. The model is adjusted for multiple policy options that reflect different levels of operational flexibility: Fixed-Term, Flexible-Term, and Recurrent. Using simulated data and weekly decision-making intervals, we evaluate the impact of each policy on patient lead time and in-clinic resource availability. Results show that the scheduling model is feasible for managing home-based patient volumes. More flexible policies may increase resource utilization and reduce average lead times, though we consider additional coordination and dynamic staffing considerations. This work anticipates the future implementation of the CCBW program, providing practical guidance for scheduling decisions and informing infrastructure planning for a sustainable practice offering.

3 - Strategic Disinformation Generation and Detection

Pengxiang Zhou, University of Southern California, Los Angeles, CA, United States, Wenxiao Yang, Yunfei (Jesse) Yao

Disinformation detection is becoming increasingly important and relevant because it is easier than ever to create and disseminate disinformation. How does detection ability affect the incentive to generate disinformation? Given the practical constraints of classification technology, how should a detector be designed? To answer these questions, this paper studies the problem where a sender strategically communicates his type (high or low) to a receiver, and a lie detector generates a noisy signal on the truthfulness of the sender's message. The receiver then infers the sender's type both through the message from the sender and through the signal from the detector. We find a non-monotonic relationship between the probability that the low-type sender is lying and the accuracy of detection. More accurate detection (a higher true-positive rate and a lower false-positive rate) increases the probability of lying when the true-positive rate is low, because of a persuasive effect. By contrast, more accurate detection decreases the probability of lying when the true-positive rate is high, due to an alarm effect. We also characterize the optimal detector design. The designer always chooses the lowest feasible false-positive rate for any true-positive rate. The possibility of false-positive alarms implies that the designer chooses an intermediate true-positive rate rather than the highest true-positive rate. Counter-intuitively, the optimal detector may raise an alarm about a smaller percentage of disinformation when its underlying classifier is better at distinguishing the sender's type.

4 - Optimizing Service Mix in Substance use Treatment: the Role of Supplemental Services in Improving Treatment Retention

Matt Baucum, Oklahoma State University, Stillwater, OK, United States, David Dreyfus

Substance use disorder (SUD) represents a significant public health challenge. Yet no research to date has investigated the impact of SUD treatment service mix on patient outcomes using nationally-representative data. In this study, we investigate whether SUD treatment retention is improved when providers offer supplemental services (i.e., 'wraparound services') to patients, and whether this effect is moderated by the barriers patients face when accessing treatment. To address this, we extract all SUD treatment facility information from the SAMHSA National Directory of Drug and Alcohol Abuse Treatment Facilities from 2017 - 2022, including location and service offering data for each facility. We link this data to metro area-level treatment records from the SAMHSA Treatment Episode Dataset, along with a state-level analysis of restrictive SUD treatment regulations. We find that SUD treatment completion rates increase when centers offer supplemental services to patients, and that this effect is strongest in areas where patients have poor access to treatment. We then investigate whether it is cost effective (from either a provider or policymaker perspective) to increase patient retention rates through supplemental service offerings. We find that the increased revenue to providers (due to longer patient stays) is generally not sufficient to cover the cost of increased supplemental service offerings. Yet we find that it is cost effective for states to increase reimbursement rates for such services, due to the positive societal spillover effects of increased SUD patient retention. This suggests a possible role for policymakers to steer SUD providers to more holistic service offerings.

5 - Anxiety vs. Trust: Emotional Factors Affecting the Medical Service Supply Chain

Li Hou, Ningbo University of Technology, Ningbo, China, People's Republic of, Mengbi Zeng

With rising living standards and an aging population, China faces a significant shortage of medical resources and an unbalanced allocation. The mismatch between high-quality resources and patient needs leads to low operational efficiency in the medical service supply chain. This study applies the Elaboration Likelihood Model (ELM) to explore the emotional drivers behind patients' irrational preferences for tertiary hospitals, which contribute to systemic inefficiencies. Moving beyond traditional analyses focused on cost and accessibility, we reveal how health anxiety and institutional distrust interact with rational cognition, exacerbating resource misallocation. Using structural equation modeling based on patient surveys, three key findings emerge: First, anxiety influences decision-making as a peripheral ELM pathway, overshadowing logical assessments of primary care suitability. Second, health literacy moderates this emotional bias; cognitively empowered patients exhibit stronger rational decision-making abilities. Third, trust-building mechanisms within primary care institutions prove unexpectedly ineffective due to deep-rooted societal stigma. This paper pioneers the use of ELM in analyzing healthcare supply chains by establishing a dual-path framework that enhances our understanding of behavioral barriers to hierarchical diagnosis reform in China. It advocates for emotion-centric interventions—specifically utilizing health education to reduce anxiety-driven choices—and redesigning community healthcare experiences to restore both visual and psychological trust. These conclusions provide policymakers with behavioral tools that complement structural reforms aimed at addressing both the “visible” resource imbalances and the “invisible” affective barriers hindering optimization within China’s medical system.

6 - A Semi-Markov Decision Process Model to Optimize Return to Clinic Decisions in Primary Care

Parisa Lotfibagha, University of Massachusetts Amherst, Amherst, MA, United States, Muge Capan, Kristen Miller, William Gallagher, Elizabeth Selden

Optimal return-to-clinic strategies for patients with type 2 diabetes (T2D) managed in primary care influence glycemic control, prevention of organ damage, healthcare utilization, and related costs. Current clinical guidelines, however, predominantly rely on Hemoglobin A1c (HgA1c) levels and recommend uniform follow-up intervals, inadequately capturing variability in patient characteristics and clinical complexities. To overcome this limitation, we developed a finite state infinite horizon Markov model to represent a subpopulation-specific return-to-clinic decision framework. The model analyzes patient health trajectories derived from comprehensive, de-identified longitudinal Electronic Health Record data (2017–2023) from two primary care settings affiliated with a large scale healthcare system in the mid-Atlantic region with 1703 unique patients diagnosed with T2D. Specifically, the framework integrates T2D related comorbidities, such as chronic cardiovascular disease, chronic kidney disease, and a smoothing function applied to HgA1c measurements to estimate unobserved glycemic values indicative of potential organ damage, alongside healthcare utilization metrics, notably emergency department visits. The results provide optimal subpopulation-specific return-to-clinic policies which deviate from the standard six to twelve months follow-up intervals recommended by the American Diabetes Association. For patients with chronic conditions and out-of-control HgA1c values the optimal policy requires more frequent intervals between subsequent primary care visits, such as one to three months. This study highlights the importance of personalized chronic disease management to achieve glycemic control. Future work will focus on the tradeoff between time interval for follow-up and the value of new clinical information and develop transition probabilities informed by additional patient characteristics to personalize return-to-clinic policies.

1 - Domain-General Reconstruction Through Invariant and Specific Representations

Hyewon Ryu, KAIST, Daejeon, Korea, Republic of, Hyungkwon Lee, Jong-Seok Lee

Reconstruction is a fundamental task employed across various fields, especially in unsupervised learning contexts. However, reconstruction models often struggle to generalize to unseen domains due to an inherent trade-off between preserving reconstruction fidelity and learning robust, domain-invariant representations. This limitation becomes particularly critical when data distributions shift across domains, leading to significant performance degradation. To address this challenge, we propose a novel method designed to explicitly separate domain-invariant from domain-specific information using a single encoder. By leveraging selective network connectivity, our method projects input data into two complementary latent spaces—domain-invariant and domain-specific—ensuring that domain-specific variables capture only residual information conditioned on invariant features, without reciprocal influence. We validate our approach on both synthetic and real-world multivariate time series benchmarks with induced domain shifts. Our experiments demonstrate that the proposed architecture consistently achieves lower reconstruction error and maintains stable performance on unseen domains. These results confirm that jointly modeling invariant and specific variables enables high-fidelity reconstruction while ensuring robust generalization in dynamic environments.

2 - Modernizing TIME Series Forecasting: Reuniting Statistical Structure with Deep Learning Through Transformer Innovation

Shihao Yang, ISyE Georgia Tech, Atlanta, GA, United States, Jiecheng Lu

The accelerating adoption of deep learning in time series forecasting has brought renewed attention to Transformer-based architectures. Despite their empirical success, many existing models lack interpretability and alignment with traditional statistical principles, often underperforming in multivariate or long-horizon settings. This talk presents a unifying framework that bridges classical time series models with modern deep architectures, advancing both accuracy and interpretability.

We begin by revisiting linear attention in Transformers through a Vector Autoregressive (VAR) lens, revealing structural misalignments in current deep models and introducing SAMoVAR, a VAR-aligned Transformer that restores interpretability and forecasting fidelity. Building on this foundation, we propose WAVE, a novel attention mechanism integrating ARMA dynamics via implicit moving average weights, boosting the ability to capture both local and global temporal dependencies efficiently.

Addressing scalability and context-awareness, we introduce the In-Context Time Series Predictor, which reformulates time series forecasting tasks for efficient in-context learning, eliminating the need for parameter updates while maintaining competitive performance in full, few-, and zero-shot scenarios. For complex multivariate forecasting challenges, we explore two orthogonal innovations: (1) ARM, which adapts to series-specific temporal patterns using techniques like Adaptive Univariate Effect Learning, Random Dropping, and Multi-kernel Local Smoothing; and (2) CATS, which constructs Auxiliary Time Series to enrich inter-series dependencies while minimizing model complexity.

Together, these works underscore a unified theme: bridging statistical rigor with architectural innovations in Transformers to overcome limitations in generalization, overfitting, and computational complexity.

3 - General Supervised Learning Framework for Open World Classification

Mohammad Amin Basiri, University of Oklahoma, Norman, OK, United States, Sai Krishna Theja Bhavaraju, Charles Nicholson

In many real-world classification tasks, new data may include classes not represented in the training set, posing challenges for traditional supervised learning models. This open-world classification (OWC) scenario is especially relevant in dynamic environments such as social media analytics, cybersecurity, and autonomous systems. Most existing solutions are domain-specific or tightly coupled to particular algorithms, limiting their applicability. We propose a flexible framework, adaptable to diverse data types and models, that integrates two core capabilities: (1) identifying novel data instances by measuring how different their prediction patterns are from known classes, and (2) grouping these instances into new classes based on similarity in those prediction patterns. By operating in the classifier's output probability space and decoupling detection from categorization, the framework remains flexible across domains and model types. It supports continuous model updates without human intervention, enabling real-time adaptation in dynamic settings. Experiments across diverse datasets, including text, sensor, image, and numeric data, demonstrate consistent improvements in classification performance. A case study on disaster-related Twitter data demonstrates how the framework can support real-time situational awareness by detecting emerging crisis topics, with potential applications in humanitarian coordination, resource deployment, and disaster recovery logistics.

4 - Multivariate TIME-Series Self-Supervised Learning for Domain Adaptation : Application to Tool Wear Prediction

Seonyoung Kim, Ewha Womans University, Seoul, Korea, Republic of, Soomin Lee, Dongil Kim

Tool condition monitoring is critical for manufacturing efficiency, with accurate tool state detection directly impacting process reliability. While self-supervised learning (SSL) offers promising approaches for representation learning with limited labeled data, its application to process time-series data remains underdeveloped. Our research introduces a novel SSL framework specifically designed for tool condition monitoring using sensor data collected during machining operations. The framework incorporates pretext tasks tailored to capture the temporal and contextual characteristics of multivariate time-series data, while integrating domain adaptation techniques to enhance model generalization across different operating conditions. This approach addresses the critical challenge of domain shifts that occur when process parameters change or new fault patterns emerge. Through comprehensive experiments on classification and regression tasks, we demonstrate that our method achieves superior performance compared to conventional approaches, particularly in scenarios with limited labeled data and when transferring knowledge between different machining environments, advancing the development of adaptive and intelligent tool condition monitoring systems.

5 - Detecting Temporal State Changes in Astronomical TIME Series Data Using Physics-Informed Neural Differential Equations

Seungsu Kam, Ulsan National Institute of Science and Technology (UNIST), Ulju-gun, Korea, Republic of, Yongkyung Oh, Minsu Shin, Sungil Kim

We present a novel unsupervised deep learning approach for detecting changing-state quasars (CSQSOs), which exhibit abrupt temporal transitions in their optical properties and are of growing interest in quasar research. Detecting CSQSOs is challenging due to irregular sampling, data sparsity, complex variability, and the scarcity of labeled data. To overcome these issues, we develop a physics-informed neural differential equation model that incorporates the known physical properties of quasars into its loss function, while effectively handling irregularly sampled time series. Our proposed model captures both stochastic and physical aspects of quasar behavior and performs anomaly detection based on reconstruction error. This framework enables robust CSQSO detection without labeled supervision, and its effectiveness is validated through extensive simulations using datasets derived from physically motivated quasar models.

6 - Fusing Federated Learning and Knowledge Distillation for Fair Travel Choice Prediction

Yufei Xu, Georgia Institute of Technology, atlanta, GA, United States, Zhiwei Chen, Srinivas Peeta

Accurate travel choice prediction is essential for demand modeling and transportation planning. Although Deep Learning (DL) models offer substantial potential for travel choice prediction, they often exhibit algorithmic unfairness, yielding systematically poorer predictions for disadvantaged population groups such as racial minorities and low-income populations compared to their counterparts. Existing studies that attempt to handle this issue in the transportation domain are few and often confront a steep tradeoff between accuracy and fairness due to the in-processing approaches they utilize, which sacrifice accuracy to improve fairness. This study introduces a novel DL approach that fuses federated learning and cross-client knowledge distillation to overcome this challenge. Since imbalanced data can prompt DL models to treat minority observations as noise or pay less attention, the dataset is partitioned into demographic subgroups (e.g., racial minority vs. majority, low-income vs. high-income) and trained on local client models utilizing federated learning. A well-trained, fairness-aware “teacher” model then learns robust, group-balanced representations, and its distilled knowledge is transferred to the client models, enabling them to achieve fairer predictions without compromising overall accuracy. Numerical experiments on a large-scale travel survey dataset illustrate the effectiveness of the proposed approach to preserve overall prediction accuracy and mitigate demographic-specific unfairness.

1 - Multi-Level Sensor Fusion Through Factor Graphs

Arpan Kusari, University of Michigan, Ann Arbor, MI, United States, Jiahang Li, Hojun Son

Sensor fusion presents a robust method to assimilate sensing data from diverse modalities to provide robust and accurate estimates for dynamic objects in a scene. This paper presents a comprehensive approach to sensor fusion leveraging the power of factor graphs—a highly flexible and efficient framework that represents complex estimation problems involving multiple sensors. By modeling the relationships between each sensor measurements and the states as a first level bipartite factor graph to create sensor tracks and between pairs of sensor tracks to create a fused track, our method efficiently encodes and solves estimation tasks. The proposed framework incorporates measurements from diverse sensor modalities, such as cameras, and LiDAR, and optimally fuses this information by solving for the maximum a posteriori (MAP) estimates. Through extensive experimentation across various scenarios, we demonstrate the superiority of factor graph-based sensor fusion in achieving high-accuracy state estimates with improved resilience to sensor noise and faults. This work highlights the adaptability and scalability of factor graphs as a unifying approach to sensor fusion, paving the way for future advancements in autonomous systems and intelligent perception technologies.

2 - A Weighted Dirichlet Process Mixture Model for Spatial Clustering of Child Trafficking Vulnerabilities

Wenyu Gao, UNC Charlotte, Charlotte, NC, United States

Child trafficking remains a critical social challenge characterized by complex spatial and contextual variations. This study employs a weighted Dirichlet process mixture (WDPM) model to investigate trafficking vulnerability patterns across 138 Sierra Leonean enumeration areas (EAs). Incorporating areal information from the EAs as random effects, a generalized linear mixed model (GLMM) is developed to examine the relationship between trafficking prevalence and potential risk factors. By applying the nonparametric Bayesian clustering approach to the random effects, this research innovatively identifies latent risk factors and spatial dependencies. The WDPM model is able to integrate socioeconomic and cultural factors into its weight function, enhancing clustering precision and model estimation accuracy. Unlike traditional clustering techniques, the WDPM approach dynamically determines cluster configurations without requiring predefined cluster numbers. Clustering results are rigorously validated through community-level hypothesis testing, ensuring robustness and reliability. This novel framework provides a sophisticated analytical method for understanding trafficking risks in resource-constrained settings. By uncovering latent vulnerability patterns, the study offers actionable insights for designing targeted, context-specific intervention strategies. The findings highlight a data-driven approach with significant potential to inform policy-making and optimize resource allocation to combat child trafficking effectively.

3 - Registration-Free Monitoring of Unstructured Point Cloud Data via Intrinsic Geometrical Properties

Mariafrancesca Patalano, University of Padua, Padua, Italy, Giovanna Capizzi, Kamran Paynabar

Recent advances in 3D printing technologies have enabled the production of lightweight and topologically optimized components, now widely adopted in several fields, including prosthetic design, aerospace, and automotive industries. Such innovative shapes are inspected in the form of high-dimensional unstructured point clouds of varying size. In this context, preliminary alignment of the nominal and real point clouds (i.e., registration) can be avoided by monitoring the intrinsic properties of the underlying manifold. Nevertheless, existing approaches rely on surface reconstruction and decimation algorithms that can introduce artifacts and non-manifold components, potentially affecting monitoring outcomes.

Our aim is to provide a flexible solution for inspecting arbitrarily complex shapes while avoiding surface reconstruction. To this end, we operate directly on point clouds and propose a registration-free online monitoring procedure. Our proposal consists of two alternative schemes that leverage the intrinsic properties of the shape, captured via geodesic distances and the Laplace operator. In both schemes, thresholding techniques are used to select intrinsic features most indicative of potential out-of-control conditions. Numerical studies suggest the effectiveness of the proposed procedure and its potential to identify different types of defects.

4 - Autonomy vs. Safety: Joint Modeling of Disengagement and Collision Events from Autonomous Driving Study

Simin Zheng, Virginia Tech, Blacksburg, VA, United States, Jared Clark, Jie Min, Yili Hong

As the popularity of artificial intelligence (AI) continues to grow, AI systems have become increasingly embedded into various aspects of daily life, leading to significant transformations in industries and changing how people live. One of the typical applications of AI systems is autonomous vehicles (AVs). In AVs, the relationship between the level of autonomy and safety is an important research question to answer, which can lead to two types of recurrent events data being recorded: disengagement and collision events. This paper proposes a joint modeling approach with multivariate random effects to analyze these two types of recurrent events data. The proposed model captures the inter-correlation between the levels of autonomy and safety in AVs. We apply an expectation-maximization (EM) algorithm to obtain the maximum likelihood estimates for the functional form of the fixed effects, variance-covariance components, and the tuning parameter for the penalty term. This proposed joint modeling approach can be useful for modeling recurrent events data with multiple event types from various applications. We analyze disengagement and collision events data from the California Department of Motor Vehicles AV testing program to demonstrate its application.

Key Words: AI reliability; AI robustness; Correlated frailty; EM algorithm; Recurrent events data; Survival models.

5 - Reliability Modeling for Perception Systems in Autonomous Vehicles: a Recursive Event-Triggering Point Process Approach

Fenglian Pan, University of Arizona, Tucson, AZ, United States, Jian Liu

Ensuring the reliability of sensor-fusion-based perception systems is crucial for the safe deployment of autonomous vehicles. Such systems function through a sequence of interconnected stages, where errors in upstream stages may propagate to downstream stages and trigger additional errors. The cross-stage error propagation conceptually exists and makes errors in different stages, not independent, posing model challenges, estimation challenges, and data challenges for reliability modeling. The existing methods cannot be applied to address all these challenges. Thus, this paper presents a recursive event-triggering point process to explicitly consider the error propagation based on the simulated data. The data are simulated from a proposed error injection framework, which can generate various errors from a sequence of interconnected stages in a perception system. The latent and probabilistic error propagation information is incorporated into a modified expectation-maximization (EM) algorithm for parameter estimation. The numerical and physics-based simulation case studies demonstrate the prediction accuracy and interpretability of the proposed modeling methodology.

Machine Learning and Artificial Intelligence for Advanced Manufacturing

Invited Session

Quality, Statistics and Reliability

Chair: Xiaoyang Song, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Wenbo Sun, University of Michigan Transportation Research Institute, Ann Arbor, United States

1 - Quality-Ensured in-Situ Process Monitoring Using Deep Canonical Correlation Analysis

Xiaoyang Song, University of Michigan, Ann Arbor, MI, United States, Wenbo Sun, Judy Jin

In-situ process monitoring is a key challenge in additive manufacturing. Different from conventional approaches that rely solely on real-time process data, this study proposes a novel method that integrates offline quality inspection data to enable more quality-oriented process monitoring. The core objective is to uncover nonlinear dependencies between in-situ process sensing signals and offline quality outcomes. To this end, Deep Canonical Correlation Analysis (DCCA) is employed to bridge the two data modalities—process signals and quality measurement data—by extracting highly correlated latent features that capture their shared representations. These learned features are subsequently used in an online monitoring algorithm for real-time process monitoring. The proposed method is supported through a series of statistical analysis and simulation studies. Last, the proposed method is applied to a real-world metal additive manufacturing process, where optical emission spectra and CT scans are the corresponding process signals and quality data, respectively. The superior performance in this case study demonstrates its effectiveness in enhancing in-situ monitoring capabilities.

2 - Multi-Fidelity Bayesian Optimization for Process Parameter Tuning in Additive Manufacturing

Chaoran Dou, Virginia Tech, Blacksburg, VA, United States, Raghav Gnanasambandam, Mihir Darji, Prahalada Rao, Zhenyu Kong

Laser Powder Bed Fusion (LPBF) is a key technique in metal Additive Manufacturing, enabling the fabrication of geometrically complex components with high precision. However, the quality and reliability of printed parts are highly sensitive to process parameters, particularly laser power and scan speed, which govern the thermal behavior during fabrication. A critical metric in this context is the end-of-cycle temperature, as it influences residual stress accumulation, microstructure evolution, and overall part integrity. Accurately predicting this temperature typically requires high-fidelity simulations, which are computationally expensive and make parameter optimization impractical. To address this challenge, a Multi-Fidelity Bayesian Optimization (MFBO) framework is proposed for efficient and accurate process parameter tuning in LPBF. The framework employs Multi-Fidelity Gaussian Processes to integrate data from both low- and high-fidelity thermal simulations, enabling the construction of a surrogate model that captures the complex relationship between input process parameters and thermal responses while significantly reducing computational cost. The proposed approach is applied to the optimization of laser power and scan speed, with the objective of controlling the end-of-cycle temperature to reach a specified target. Results demonstrate that the MFBO framework effectively identifies optimal parameter settings using substantially fewer high-fidelity evaluations than conventional methods, without compromising predictive accuracy. This work highlights the potential of multi-fidelity optimization strategies to accelerate process parameter optimization in LPBF and offers a generalizable methodology for other simulation-driven manufacturing applications.

3 - Human-in-the-Loop Convolutional Neural Network for Gas Tungsten Arc Welding Process Control

Shenghan Guo, Arizona State University, Mesa, AZ, United States, Yue Cao, Yuming Zhang

Gas tungsten arc welding (GTAW) process control is paramount to ensure the welding quality meets the industrial standard. Due to the uncertainty and volatility associated with GTAW processes, high-fidelity modeling and system controllers have been challenging. A human expert will monitor the thermal videos collected during a GTAW process, evaluate the weld pool size and shape, and then adjust the speed parameter based on his/her knowledge and experience in GTAW to influence the weld pool and ensure it stays close to the reference. This study conceptualizes manual GTAW control as a human-in-the-loop (HiL) system and investigates HiL machine learning to develop an AI-based GTAW system controller. Conventionally, AI models must be trained on given data and then taken to real-time implementations. The training data must be cleaned and preprocessed a priori to AI model training. In this study, we propose a human-in-the-loop Deep Learning (HiL-DL) model that feeds on the human-annotated GTAW thermal images of weld pools and fine-tunes its model weights in real-time. During a GTAW process, in-situ thermal images of weld pool will be annotated with the expert-suggested speed; a pretrained ResNet50 will be integrated with a Stacked Long Short-Term Memory to learn from the annotated images and fine-tune its model weights. Upon the completion of the process, the HiL-DL model will have updated its knowledge about GTAW weld pool size, shape, and their mapping to the desirable speed. By fine-tuning such a HiL-DL in multiple GTAW processes, we expect the model to automatically recommend speed adjustment.

4 - Learning-Based Optimization for Complex Physical Systems

Yinan Wang, Rensselaer Polytechnic Institute, Troy, NY, United States

Learning-based optimization (i.e., reinforcement learning) is known for its strength in generalizability and scalability. Generalizability indicates the knowledge learned in optimizing the training data can be directly applied to optimize the unseen testing scenarios without retraining. Scalability represents the capability of handling giant design space. In this talk, we will discuss the recent research work on developing learning-based optimization for complex physical systems. We select two cases as examples. One is the fixture layout design for reducing shape deformation of large-scale sheet parts in the assembly process. The other is optimizing the control parameters in the Brookhaven Alternating Gradient Synchrotron (AGS) to improve intensity and emittance preservation after the RF bunch merge.

5 - FedScope-Kd: Knowledge Distillation-Enhanced Federated Learning via Shared Composition and Personalized Exploration for Heat Emission Prediction in Additive Manufacturing

Rong Lei, Rutgers University, Piscataway, NJ, United States, Yuebin Guo, Weihong Guo

Additive manufacturing (AM) enables the production of customized and complex metal parts. However, maintaining consistent product quality for AM processes remains challenging, which makes predicting heat emissions become essential. Small- and medium-sized enterprises (SMEs) acquire limited and heterogeneous datasets due to unique printing configurations, making traditional centralized predictive model training paradigms impractical. Federated learning (FL) offers a solution, it enables collaborative learning across decentralized datasets while keeping data local and private. However, its performance may suffer under heterogeneous client data. This creates a need to address data heterogeneity while maintaining both global model performance and individual client personalization. We propose FedScope-KD, a novel heterogeneity-aware FL framework designed to balance the scope of global and personalized learning. Client heterogeneity level is quantified prior to the FL training, to improve the model weight aggregation during training. This is achieved through component decomposition and knowledge distillation. The framework decomposes client data into process-invariant representations, which capture the fundamental nature of the laser powder bed fusion (LPBF) process, and process-variant representations, which reflect local, client-specific configuration settings. This decomposition ensures that global models benefit from collaborative learning on the homogeneous data representations, while personalized predictions remain tailored to client-specific heterogeneous data representations. The variant components exhibit greater distances between clients, reflecting their inherent heterogeneity, while the invariant components are more closely aligned across clients. We demonstrate that FedScope-KD effectively addresses the challenges of data heterogeneity, providing a robust solution of predictive modeling for SMEs.

AI and Deep Learning for Supply Chains

Contributed Session

Contributed

Chair: Amir Kordijazi, University of Southern Maine, Portland, ME, United States

1 - Software Supply Chain: Investments in Cybersecurity by Firms in the Presence of Learning Cost

Siqi Li, School of Management, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Abhijeet Ghoshal, Chao Fang

The advent of AI facilitated the creation of several AI-powered tools by foundation firms, such as GitHub Copilot and Amazon Q Developer. However, these tools expose users to cybersecurity vulnerabilities passed on by the tool through the generated content due to poisoned data used during training by the foundation firm. Subsequently, the cyber criminals attack the user firm via the vulnerable code. In summary, the supply chain of AI tools passes on vulnerabilities to users via the AI tool, requiring efforts from both the foundation firm and the user to fight cybercrime. The users incur another type of cost while using AI tools, the AI tool learning cost, which is high initially and decreases with continued use. Knowing that the users face the cost of effort for fighting cyber threats and a learning cost, how much effort should the foundation firm expend on cybersecurity? Further, since it knows that the user's learning cost will eventually decrease, will it spend more or less effort than the user on cybersecurity? What happens to cybersecurity efforts when the user's learning cost decreases faster, enabling it to increase investment in cybersecurity, potentially? Are the efforts of the foundation firm and user substitutes? We answer such pressing questions in this paper using a game-theoretic model. We find that the efforts of the foundation firm and the user may be complementary under certain conditions when the users have a higher learning rate. Also, the foundation firm may invest more than the user under certain conditions.

2 - AI-Based Inventory Allocation with Fairness Constraints

Sirine Taleb, American University of Beirut, Beirut, Lebanon, Karmel Shehadeh

We present an AI-based inventory ordering and allocation system that integrates machine learning with an optimization model incorporating group-based fairness constraints. The system is designed to promote equitable decisions while providing explainable recommendations. We evaluate its performance using both synthetic and real-world demand data. Key performance metrics include cost efficiency, fairness violations, and model explainability under varying levels of demand uncertainty.

3 - Smart Retail Solutions Enabled by Generative AI and Computer Vision for Enhancing Customer Experience Management

Jongsawas Chongwatpol, NIDA Business School, National Institute of Development Administration, Bangkok, Thailand

Artificial Intelligence presents a significant opportunity to transform the retail industry. How can AI solutions be effectively designed and implemented to support and manage the in-store customer journey? This study presents a design journey for AI implementation aimed at understanding and improving the in-store customer shopping experience by integrating both Generative AI and Computer Vision AI. The design thinking process is adopted to ensure that challenges and potential failure factors in AI solutions are addressed during the proof-of-concept stage focusing on idea generation and testing.

This study presents several use cases demonstrating how Generative AI can be used to integrate the customer journey and point of view to gain insights into shopping behavior and preferences. Market analysts and store managers can then redesign the store layout by developing discrete-event simulation prototypes. The goal is to transform improvement ideas into experiments and, consequently, evaluate them through what-if scenarios.

The second objective of this study is to implement the “new store layout” prototype in a real-world setting by physically rearranging the store into different zones. Each zone is equipped with CCTV and video cameras, enabling the store to utilize data captured through Computer Vision AI to enhance information visibility. This includes tracking customer behavior at each touchpoint throughout their shopping journey—from the moment they enter the store until they make a purchase or leave. The goal is to leverage and integrate the wealth of information provided by facial recognition technologies into marketing strategies, enabling more effective personalized offers and follow-up campaigns.

4 - Lightweight Object Detection for on-Device Machine Vision

MINJONG SHIN, Kyung Hee University, Yongin City, Korea, Republic of, Seohyun Choi, Jae-Yoon Jung

The adoption of deep learning-based machine vision is rapidly advancing within the manufacturing sector. With the growing demand for real-time decision support, there is an increasing need for lightweight AI models capable of performing inference on edge devices. This study investigates the real-time object detection capabilities of a low-power device—specifically, the Raspberry Pi. The experimental setup consisted of a Raspberry Pi 5 and the Raspberry Pi Camera Module 3. A quantized YOLOv11n model was deployed on the Raspberry Pi for inference tasks. The evaluation dataset comprised images for detecting damaged areas on milling heads using machine vision techniques. TensorFlow Lite and OpenVINO served as the primary deployment frameworks for model quantization. Experimental results indicated that the average inference time was 163.5 ms in a GPU environment and 283.8 ms on the Raspberry Pi, demonstrating its suitability for real-time detection. These findings confirm that real-time vision processing is achievable on low-power platforms without significant loss in accuracy, supporting the feasibility of deploying smart vision systems under edge computing constraints.

5 - Agentic AI for Self-Refining Demand Forecasting in CPG Supply Chains

Sriram Sambasivam, Estee Lauder, EDISON, NJ, United States, Suneeth Sreedharan

The increasing complexity of Consumer Packaged Goods (CPG) supply chains—driven by product proliferation, regional heterogeneity, and omnichannel fulfillment—necessitates forecasting systems that are adaptive, modular, and capable of learning. This work presents an early-stage implementation of Agentic Artificial Intelligence (AI) within a statistical demand planning framework, wherein autonomous, goal-directed agents are employed to enhance system responsiveness and refinement.

Developed on a Databricks-native platform with a foundation in open-source libraries and composable components, the forecasting engine supports multiple planning horizons (execution, operating, strategic) and product scopes (e.g., Basic and New Product Launches). It leverages a diverse ensemble of models spanning statistical methods, tree-based algorithms, and neural networks. The introduction of agentic behaviors—such as automated forecast diagnostics, context-aware model selection, and anomaly detection—enables a progressive shift from static model execution to feedback-driven adaptation.

Rather than pursuing full autonomy, these agents emulate elements of human planning cognition: monitoring forecast performance, proposing targeted interventions, and iteratively improving based on historical signal patterns. Their decisions are explicitly linked to business-aligned performance metrics, including weighted forecast accuracy (WFA), plan attainment, completeness, and forecast bias.

This work outlines the modular architecture, key implementation considerations, and guiding design principles for embedding agentic intelligence within enterprise-scale forecasting systems. It represents a pragmatic, scalable approach toward intelligent automation in supply chain planning—one that balances technical rigor with operational viability.

6 - Explainable Graph Neural Networks for Anomaly Detection and Disruption Propagation in Supply Chain Networks

Samridhi Vats, Amazon, Bellevue, WA, United States, Swapnali Karvekar

Supply chains are inherently graph-structured systems, yet most anomaly detection models treat them as flat or time-series data—ignoring the cascading and relational nature of disruptions. This work introduces a novel application of **Graph Neural Networks (GNNs)** to detect and localize anomalies in complex, multi-tiered supply chain networks.

Unlike traditional models that rely on tabular inputs or sequential patterns, our framework captures the **relational dependencies** between entities—such as suppliers, distribution hubs, and logistics routes—by learning from both **node-level behaviors** and **edge-level interactions**. We evaluate our approach on publicly available datasets, including **SupplyGraph** and a synthetic anomaly-injected version of the **H&M Fashion** dataset. These graphs represent real-world supply networks where disruptions, delays, or abnormal flows can propagate in non-obvious ways.

To enhance interpretability and address industry concerns around deep learning black-box models, we incorporate **GNNExplainer-based modules** to generate node- and edge-level attributions for flagged anomalies. Our framework aims to bridge the gap between advanced AI techniques and practical, risk-aware supply chain operations.

This research contributes to the growing intersection of operations research and machine learning by proposing a scalable, explainable, and graph-native anomaly detection pipeline. It lays the groundwork for a new class of AI tools capable of **early warning, root-cause tracing, and proactive mitigation** in supply chain risk management.

7 - A Performance Comparison of State-of-the-Art Object Detection Algorithms and Their Sensitivity to Image Characteristics and Performance-Measuring Toolkits

Mehrsa Mashhadi, University of South Florida, Tampa, FL, United States, Nicolas Bustos, Susana Lai-Yuen, Sudeep Sarkar, Tapas Das

The task of object detection in computer vision is highly important for many applications including surveillance systems, autonomous driving, medical imaging, etc. Recently, multimodal object detection has gained significant attention due to its ability to maintain high accuracy under challenging environmental conditions, including adverse weather and low light scenarios by leveraging complementary information from multiple imaging modalities such as RGB and thermal images. However, evaluating the performance of these algorithms using varying custom datasets and metric tools has made consistent and fair comparisons challenging. In this research, we conduct a systematic evaluation of four state-of-the-art object detection algorithms—Detection Transformers, Faster R-CNN, YOLOv7, and YOLOv9—on the publicly available Aligned FLIR dataset, which provides aligned RGB and thermal image pairs. Each algorithm was trained and tested on RGB, thermal, and RGB-Thermal fused images, which were generated using TarDAL, a feature-level fusion algorithm. We investigated each model's detection performance and sensitivity to crucial factors including image modality, illumination conditions (day vs night), different object sizes, and image resolution variations. In addition, we analyze the impact of using different metric calculation frameworks on reported mean average precision (mAP). Our results indicate that YOLOv7 outperforms other detection algorithms in all the scenarios. Among different image modalities, thermal images yield the highest detection performance. Also, it highlights how the choice of evaluation toolkit can change the relative ranking of detectors. Our research proposes standardized evaluation guidelines to promote fair and reliable comparisons on future studies in the field of multimodal object detection.

8 - Accelerated Material Innovation: An AI-Driven Approach Using Bayesian Optimization

Amir Kordijazi, University of Southern Maine, Portland, ME, United States

This study examines how Bayesian Optimization (BO) can enhance materials design and manufacturing by guiding experimental processes to achieve specific optimal material properties. In materials design, achieving high-quality and consistent outputs involves navigating a vast parameter space, and BO offers a targeted approach to do this efficiently. By prioritizing experiments that yield the most valuable data, BO refines manufacturing settings iteratively, significantly reducing the time and resources needed to optimize results across diverse materials.

In addition to improving experiment selection with Bayesian Optimization, automation streamlines the testing process, helping researchers and manufacturers reduce hands-on tasks and enhance workflow efficiency. This study presents an adaptable, AI-driven framework that powers a self-driving lab, facilitating rapid and precise tuning of manufacturing parameters. This approach enhances productivity and accelerates the development of optimized material properties for specialized applications. It highlights the role of AI and automation in fostering faster innovation in manufacturing and advancing R&D in material design by simplifying the discovery of optimal configurations for high-performance, application-specific materials.

1 - The Impact of Accommodation Choices on The Feeling of Loneliness: a Surrogate Method for Measuring Association and Moderation for Discrete Choice Variables

Zhaohu Fan, Scheller College of Business, Georgia Institute of Technology, Atlanta, GA, United States, Shaobo Li, Lvy Liu, Philip S. Morrison, Dungang Liu

We propose a new residual-based method for regression models analyzing discrete choice outcomes. This work extends existing methodologies for discrete data analysis, building on frameworks introduced by Liu and Zhang (2018) and Liu et al. (2021). More recently, Li et al. (2024) developed a framework for quantifying and visualizing partial associations between mixed variable types. While their work has advanced our understanding of such relationships, the COVID-19 pandemic has intensified interest in examining how accommodation choices relate to loneliness, particularly in the context of remote learning among college students. Our study focuses on the association between accommodation types (e.g., student hall, home with parents, or renting) and the feeling of loneliness, an ordinal measure of emotional well-being. A key statistical challenge arises when one of the variables—such as accommodation—is a multinomial variable with no inherent order. To address this, we introduce a $[0,1]$ -scaled measure of association, where 0 indicates no association and 1 indicates perfect association. Our approach assigns orders to the unordered categories and computes the association measure T_i for each. The maximum of these values serves as the overall association measure. This framework also supports covariate adjustment, allowing us to estimate partial associations. Preliminary findings show that the method can effectively quantify the influence of a discrete choice variable on another outcome, offering a clear and interpretable summary measure. Our approach fills a methodological gap in analyzing associations involving unordered categorical variables and enhances interpretability in complex social science applications.

2 - Beyond Gdp: COVID-19'S Effects on Macroeconomic Efficiency and Productivity Dynamics in OECD Countries

Umit Saglam, East Tennessee State University, Johnson City, TN, United States

This study analyzes macroeconomic productivity dynamics across 37 OECD countries from 2018 to 2024, focusing on the impact of the COVID-19 pandemic and government response measures. Using a Slack-Based Measure Data Envelopment Analysis (SBM-DEA) and the Malmquist Productivity Index (MPI), we assess changes in total factor productivity (TFP) across pre-, during-, and post-pandemic periods. Our framework incorporates both desirable (GDP) and undesirable outputs (inflation, unemployment, housing price inflation, and interest rate distortions), offering a multidimensional view of macroeconomic efficiency. Results show broad but uneven productivity gains, with technological progress proving more resilient than efficiency during the pandemic. Post-COVID recovery trajectories diverged, reflecting differences in structural adaptability and innovation capacity. Regression analysis reveals that stringent lockdowns in 2020 were associated with lower productivity in 2023–2024, while more adaptive policies in 2021 supported long-term technological gains. These findings highlight the importance of aligning crisis response with forward-looking economic strategies and demonstrate the value of DEA-based methods for evaluating macroeconomic performance beyond GDP.

3 - Explaining Health Disparities via Accessibility: a Data-Driven Machine Learning Framework Using Shap

Jiewen Luo, university of Massachusetts Amherst, Amherst, MA, United States, Eric Gonzales

Understanding the impact of transportation access is pivotal for improving public health outcomes. However, the variety of transportation modes, community amenities, and the interactions between accessibility mode and opportunities often obfuscate the comprehensive understanding of the contributors to health disparities. This study clarifies the concept of accessibility and introduce a novel approach to measurement walking, biking, and public transportation accessibility by incorporating both mode

adoption probability for residents and built environment characteristics. We propose a framework employing three interpretable model (Elastic Net, XGboost, Geographical Random Forest (GRF)), enables detailed exploration of the relationship between accessibility and public health outcomes (obesity, diabetes, and heart disease) at both global and local scales. A case study has been conducted in Massachusetts. Key factors are interpreted using Shapley Additive Explanations (SHAP), which also facilitate the synthesis of multiple forms of accessibility into a single aggregated measure reflecting their contribution to health disparities. The proposed framework aims to provide more comprehensive insights into how improving access can enhance public health, identifies the types of accessibility most strongly associated with specific the health outcome, and explores how these relationships vary by demographic factors such as age, income, and car ownership. Results indicate that GRF outperforms other models when spatial autocorrelation (global Moran's I) is high and variable importance varies geographically. Obesity has a better fit on linear model, while hypertension and heart disease have non-linear relationship with accessibility. Findings suggest that targeted improvements in critical access through infrastructure planning can efficiently improve public health outcome.

4 - Exploring the Causal Inter-Relationships Among Arrests, Officers, and Crime Rates in the United States

Salma Shaik, University of Pittsburgh at Bradford, Bradford, PA, United States, Lakshika Kuruppuarachchi

The unexpected crime drop phenomenon in the early 1990s garnered increased interest to investigate the effects of various factors on crime but detailed studies analyzing the causal relationships between arrests, officers, and crime rates at different geographical levels are lacking. This study uses a comprehensive dataset from 1974-2020 to address this gap. Panel ARDL and Granger Causality techniques are utilized to estimate the short-run and long-run coefficients and to identify causal relationships by accounting for cross-section dependency, non-stationarity, slope heterogeneity, and co-integration. Analysis is carried out for violent crimes and property crimes separately for very large, large, and medium cities which are categorized based on the FBI guidelines. Results demonstrate the presence of both short-term and long-term relationships between arrests and crime across all agencies. Granger causality tests reveal that property arrests exhibit bidirectional causality with both property and violent crimes. Also, violent crimes drive violent arrests up especially in large and medium agencies while officers affect the outcome of crimes for all agencies. These results have significant policy implications since they show that though arrests and officers have deterrence effects on crime, they are not substantial. It is critical to ensure that everyone has access to good education, employment opportunities, and affordable housing so that the incentive to commit crime is reduced. Increased efforts should be made to reduce the rate of recidivism among repeat offenders. This study serves as a valuable resource for policymakers to understand the complex crime dynamics and to devise effective crime prevention strategies accordingly.

AI Reasoning and Behavioral Simulation

Invited Session

Artificial Intelligence

Chair: Marios Papachristou, Cornell University, Ithaca, NY, 14850, United States

Co-Chair: Caitlin Cunningham, University of Washington, Seattle, United States

1 - Agreeing to Disagree: Human-AI Collaboration in Ethical Decision-Making

Caitlin Cunningham, University of Washington, Seattle, WA, United States, Rebekah Baik, Leonard Boussieux, Leela Nageswaran

Though AI systems increasingly provide decision-support in subjective scenarios, their influence in ethically ambiguous decisions remains poorly understood. We conducted a lab experiment with participants evaluating ethical dilemmas grounded in real, everyday situations to examine how large language model (LLM) judgments, varying in decisiveness and justification, shape user agreement, confidence, and perceived helpfulness. We find evidence that users weigh AI input significantly more than their personal input, especially when reasoning is provided. Our findings also reveal that decisive AI recommendations increase user alignment and confidence, while justifications from a reasoning model enhance perceived helpfulness. These effects vary by the controversy level of the anecdote: minimal advice suffices in clearer dilemmas, while the added justification improves persuasion in more complex ones. Our findings offer actionable guidance for deploying LLMs in subjective human decision-making contexts where trust, deliberation, and user agency are at stake.

2 - Conversation Dynamics in Human-AI Collaborative Teams: Study of Group Decision-Making in Mixed-Agent Environments

Jiehui Luo, University of Notre Dame, Notre Dame, IN, United States, Margaret Traeger, Ahmed Abbasi

As generative AI systems enter collaborative environments, understanding their impact on team dynamics in complex decision-making tasks becomes crucial. While research has focused on one-to-one human-AI interactions, significant gaps exist in understanding how these dynamics extend to group settings. Our research examines human-AI collaboration in small groups (triads) performing complex evaluation tasks like essay grading. We vary generative AI interaction modalities and agency to study their influence on conversation patterns and outcomes. Using multi-method conversation analysis, we quantify how generative AI integration affects social dynamics.

Preliminary findings reveal that when generative AI systems engage in discussions containing negative emotional content, they produce larger evaluation gaps compared to human graders. This sensitivity to conversational affect creates generative AI judgment patterns that influence group evaluation processes and outcomes. Additionally, we observed that the cognitive processing level of generative AI contributions evolves across discussion rounds - initially displaying higher analytical complexity before gradually shifting toward simpler consensus-building language in later exchanges. Our data comparing final scores after pure generative AI setting discussions shows varying levels of alignment with human evaluators across different models. Our ongoing research examines various human involvement configurations, testing how expertise distribution, role clarity, and team composition influence evaluation processes and deference to generative AI judgments. These insights aim to provide guidance for designing generative AI systems that can be effectively deployed in educational assessment contexts while preserving the diversity and depth of human judgment.

3 - Too Much of a Good Thing? the Hidden Cost of Widespread AI-Generated Persuasion

Yan Leng, University of Texas at Austin, Austin, TX, United States

The rapid adoption of large language models (LLMs) has transformed digital communication, enabling users across commerce, fundraising, political campaigns, and other sectors to generate persuasive text at scale. While this AI-driven productivity boost appears beneficial, it introduces a novel platform-level externality: As users independently employ similar LLM prompts to optimize their content, messages increasingly resemble one another, leading to audience fatigue and diminished collective effectiveness. We term this phenomenon stylistic congestion. In a formal congestion model, users adopt overlapping stylistic "bits," whose persuasive value diminishes as usage increases. The resulting strategic environment forms a potential game in which uncoordinated LLM use generates substantial welfare losses that grow with user scale and adoption rates. This digital tragedy of the commons arises from the success and scale of generative AI. Our findings suggest that sustaining collective persuasive effectiveness and maximizing welfare will require platforms to shift from passively enabling AI delegation to actively governing it.

4 - Measuring Strategization in Recommendation: Users Adapt Their Behavior to Shape Future Content

Hannah Li, Columbia, New York, NY, United States

Most modern recommendation algorithms are data-driven: they generate personalized recommendations by observing users' past behaviors. A common assumption in recommendation is that how a user interacts with a piece of content is a reflection of the content, but not of the algorithm that generated it. Although this assumption is convenient, it fails to capture user strategization: that users may attempt to shape their future recommendations by adapting their behavior to the recommendation algorithm. We test for user strategization by conducting a lab experiment and survey. To capture strategization, we adopt a model in which strategic users select their engagement behavior based not only on the content, but also on how their behavior affects downstream recommendations. Using a custom music player that we built, we study how users respond to different information about their recommendation algorithm as well as to different incentives about how their actions affect downstream outcomes. We find strong evidence of strategization across outcome metric. For example, participants who are told that the algorithm mainly pays attention to "likes"/"dislikes" use those functions 1.9x more than participants told that the algorithm mainly pays attention to dwell time. A close analysis of participant behavior rules out experimenter demand as the main driver of these trends. Further, in our post-experiment survey, nearly half of participants self-report strategizing "in-the-wild," with

some stating that they ignore content they actually like to avoid over-recommendation of that content in the future. Our findings suggest that user strategization is common and that platforms cannot ignore the effect of their algorithms on user behavior.

5 - Llm Routing with New Models Through Active Learning

Alkiviadis Mertzios, Massachusetts Institute of Technology, Cambridge, MA, United States, Wei Sun, Georgia Perakis

LLM routing is an emerging area focused on selecting the best large language model for each query based on predicted cost and output quality. Prior work assumes a fixed pool of models and trains routing policies accordingly. We extend this setting to a more realistic scenario where new language models, such as domain-specific finetuned models, are introduced after the initial training phase. Since evaluating every query on the new model is expensive, we propose an active learning approach to selectively acquire the most informative queries. This enables efficient integration of new models with minimal evaluation cost.

1 - Cultural Dynamics in Online Consumer Behavior: Exploring Cross-Country Variances in Review Influence

Eunjung Lee, Lewis University, Romeoville, IL, United States

This study explores how cultural differences shape online consumer behaviors, specifically investigating how national cultural characteristics influence consumers' expressions in online reviews. Guided by Hofstede's Cultural Dimensions Theory, the research compares consumer reviews from two culturally distinct countries—the United States and South Korea—examining cultural dimensions such as Individualism vs. Collectivism, Power Distance, and Uncertainty Avoidance. A mixed-methods approach employing text mining, data mining, and topic modeling is utilized to analyze review data collected from popular platforms like Netflix and Agoda.com. This methodology allows the identification of culturally-specific patterns, such as individualistic consumers (U.S.) focusing on personal experiences and direct critiques, whereas collectivist consumers (Korea) emphasize communal experiences and group harmony. Furthermore, the study investigates whether high power-distance cultures show greater deference and politeness, compared to low power-distance cultures which display more openness to direct critique. To ensure accurate and culturally unbiased analysis, a two-way translation process is adopted, translating English reviews to Korean and vice versa. Ultimately, this research seeks to validate and extend Hofstede's cultural dimensions theory in digital consumer contexts. The findings will provide valuable insights for multinational companies, enabling them to tailor their marketing strategies, customer engagement, and review management systems effectively across different cultural markets. This contributes significantly to academic literature on cultural psychology and digital consumer analytics, offering actionable recommendations for businesses aiming to better resonate with culturally diverse global audiences.

2 - Between Originality and Popularity: How to Successfully Create Digital Content

Kang Lee, Fairfield University, Fairfield, CT, United States, Minjee Sun, Matthew Osborne

As digital content consumption becomes more routine, a range of content creators, from novices to professionals, are increasingly engaged in creating digital content. Despite the proliferation of digital content, few pieces of work achieve success and financial rewards. For a content creator to achieve a successful outcome, the content should follow a popular trend to capture the attention of potential customers, and also for algorithms to expose it to customer searches. At the same time, the content must have some originality: in other words, it must have some distinct features that ensure it can maintain customer attention in the long term. This research explores how content creators balance popularity and originality in their content creation. We utilize natural language processing (NLP) and text mining to identify popular and trending topics, then employ graph theory to construct network graphs for these topics, assessing the novelty and originality of content aligned with specific trends. Essential outcome measures, such as view counts and subscriptions, guide the determination of the optimal blend of popularity and originality. Our preliminary findings reveal that the emphasis on novelty varies significantly depending on the content's topic. Consumers exhibit preferences for stereotypical content in specific topics, lean toward balanced content in others, and seek highly distinctive content within each topic. Next, we plan to extend our findings to diverse digital content to ensure generalizability. Our research can assist content creators in developing more engaging and effective content and support digital platform managers in identifying and promoting promising content creators.

3 - Promotion Optimization for Durable Goods

Ronak Ramvishal Tiwari, WHU - Otto Beisheim School of Management, Vallendar, Germany, Arnd Huchzermeier

The profitability of promotions is often a concern for retailers. Management scholars have episodically studied the problem of determining profit-optimal promotional prices for CPG and fast-fashion sectors, much less so - empirically. We utilize data from an online bike retailer and study promotional pricing in the less-discussed durable goods context.

4 - Review Sentiment Analysis - Based Recommendation System

Soyeon Kim, Ewha Womans University, Seoul, Korea, Republic of, Dongil Kim

Recommendation systems are essential tools for delivering personalized experiences that enhance customer satisfaction and drive conversion rates. Existing conventional approaches that rely primarily on explicit rating data often fail to capture the nuanced emotional context behind user preferences. In contrast, user-generated reviews provide rich contextual information – sentiment and specific product-related preferences – that extend beyond numerical scores. This research employs natural language processing techniques to extract both emotional signals and product-related preferences with textual reviews. By incorporating these insights into the recommendation process, the research aims to develop a more context-aware that better reflects user intent, ultimately enabling more personalized and meaningful recommendations.

5 - Taste or Terminate? Understanding Business Competitiveness Through Consumer Cohort Reviews

Jie Li, University of Massachusetts Lowell, Malden, MA, United States, Asil Oztekin

For businesses with a significant offline presence, such as restaurants and hotels, understanding the role of competitive positioning in business survival is essential. However, assessing competitiveness remains challenging in today's dynamic market environment. This study examines key determinants of competitiveness—business feature proximity, geographical density, and consumer reviews—and their impact on restaurant survival. Through leveraging publicly available data from social media platforms which cover over 9,000 restaurants from 2005 to 2021, we apply survival analysis and panel regression framework to incorporate time-lagged consumer opinions and competitive attributes. The findings indicate that restaurants with less differentiation from their competitors face a higher likelihood of closure. Over time, consumer reviews have a long-lasting effect and continue to influence restaurant survival, contributing to accumulated reputational effects. Additionally, new customer reviews and sentiment have a stronger impact on competitive positioning than those from returning customers, highlighting the importance of first-time consumer experiences. These insights help inform competitive strategies and support industry practitioners in decision-making, emphasizing the role of consumer perception management and differentiation in maintaining business sustainability.

6 - As Transactions GO Social: Predicting User Engagement Through Language and Network Evolution with Dynamic Gnn

Hanyu Zhang, Emory University, Atlanta, GA, United States, Pantelis Loupos, David Schweidel

Venmo, the leading peer-to-peer payment platform, has profoundly transformed social and financial interactions by allowing users to observe friends' transaction activities within a social feed. By leveraging the diffusion of Venmo, we aim to examine the dyadic interactions among users, and unpack the impacts of network structure, content

(i.e., texts and emoji associated with transactions), and historical behaviors on consumer engagement in a dynamic network setting. We propose a theory-driven dynamic graph neural network (GNN) architecture that integrates both structural and communication data to effectively predict user engagement. The model leverages textual and emoji analyses to detect shifts in communication patterns and relational dynamics. It also adapts to changes in users' hidden statuses and enriches neighborhood message passing with data from social feeds. Evaluated within a live-update setting for dynamic link prediction, our GNN demonstrates that incorporating textual data significantly enhances performance, improving predictive accuracy by 7.72% compared to non-textual baseline models. This research provides a robust framework for understanding and predicting the complex behaviors of users on digital transaction platforms, highlighting the importance of integrating social feed dynamics into engagement strategies in evolving network environments.

1 - Advanced Machine Learning for 3D Polymer Structure Recognition with Explainable AI Analysis Advanced Machine Learning for 3D Polymer Structure Recognition with Explainable AI Analysis

Zhenyu Kong, Virginia Tech, Blacksburg, VA, United States, Amirul Islam Saimon, Soumil Joshi, Jihoon Chung, Sanket Deshmukh

Bottle Brush Polymers (BBPs), with their densely grafted side chains, show promise in applications like drug delivery, smart coatings, and advanced filtration. Their performance depends heavily on their 3D shape, typically captured through Molecular Dynamics (MD) simulations as point cloud data. Machine learning models, particularly 3D convolutional neural networks (CNNs), have been used to classify these shapes, but require computationally expensive voxelization of point clouds—both during training and inference. In response, this paper proposes a PointNet-based model that recognizes temperature-sensitive BBP shapes directly from raw point cloud data without the need for voxelization. Additionally, to make the shape predictions explainable to domain experts, we apply critical-bead method and gradient-based techniques that highlight the specific polymer beads most responsible for model's recognition decision. By combining model performance and explainability, we provide a practical tool that enables the rational design of advanced polymer materials.

2 - Causality-Informed Machine Learning in Manufacturing

Xubo Yue, Northeastern University, Jamaica Plain, MA, United States

The manufacturing world runs on data—sensors, logs, and real-time feeds—but are we really learning from it, or just drowning in noise? Machine learning (ML) has become the industry's favorite hammer, smashing through problems like predictive maintenance and quality control. But too often, these models chase correlations instead of *true causes*, leading to brittle solutions that fail when the real world throws a wrench in the gears.

Enter *causality*. Forget "good predictions"—what if we could uncover *why* a machine fails, *how* a process drifts, or *which* adjustments actually matter? A handful of bold researchers are already doing this, blending causal inference with ML to build models that don't just predict—they *understand*. Think Bayesian networks exposing hidden bottlenecks, or counterfactual simulations testing process changes before they're made. This isn't just academic fluff; it's the difference between a model that works on paper and one that survives the factory floor.

In this talk, we'll tear apart the hype, spotlight real-world wins (like causal ML slashing defect rates in automotive welding), and ask the hard question: *If causality is this powerful, why isn't every manufacturer using it?*

3 - PgcF-Net: a Prototype-Guided Causal Fusion Network for Interpretable Multivariate TIME-Series Anomaly Detection

Jahoon Jeong, Yonsei University, Seoul, Korea, Republic of, Hyunsoo Yoon

Time series anomaly detection often suffers from limited interpretability, as deep models typically operate as black boxes. We present PGCF-Net, a novel multivariate time-series anomaly detection (MTSAD) model that balances high detection performance with interpretability. The model extracts four types of anomaly evidence—predictive deviation, causal graph changes, contextual deviation, and spike magnitude—via a prototype-guided and causally-aware evidence extractor. These are adaptively fused by a learned evidence fusion network. Trained in two unsupervised stages, PGCF-Net achieves state-of-the-art results on five public benchmarks while providing rich, actionable explanations to support root cause analysis.

4 - Learning to Collect: a Two-Stage Data Collection Framework for Data-Efficient Personalization

Shuai Huang, University of Washington, Seattle, WA, United States, Feng Lin

Collaborative learning (CL) has been developed as a generic framework to develop personalized prediction models. Existing scope of CL focuses on learning from data collected from a heterogeneous collection of individuals, and has not considered how to improve the quality of the collected data. In this work, built on the foundation of CL, we propose Learning to Collect (LtC), a two-stage framework for efficiently collecting data from individual users. We theoretically and empirically demonstrate our design can induce personalized models to achieve competitive performance with less data compared to a full data design.

Co-Chair: Tonghun Lee, University of California, Berkeley, Berkeley, CA, United States

Co-Chair: Yiding Feng, Hong Kong University of Science and Technology, Hong Kong, Hong Kong

1 - Time-Based Contracts in Spatial Networks

Tonghun Lee, University of California, Berkeley, Berkeley, CA, United States, Ozan Candogan, Yiding Feng

Digital freight brokerages connect shippers and carriers through online platforms, but inefficiencies arise due to empty backhaul miles when return shipments are unavailable. These inefficiencies persist due to drivers' preference for cyclic routes that start and end at the same location, yet they often face difficulty securing return loads, potentially reducing their long-term participation on the platform. To address this, we propose a time-based mechanism design in which the platform assigns cyclic routes to drivers, who are compensated based on their on-duty time. We first characterize the driver equilibrium through a convex program formulation of a generalized population potential game and show its existence and essential uniqueness. Our approach to time-based mechanism design centers on a bi-level optimization problem, where the platform seeks to maximize its profits under driver equilibrium. To address the large-scale non-convex setting, we propose a first-order method that leverages a reformulation of the equilibrium characterization as a regularized optimization problem. Using this framework, we conduct numerical studies based on U.S. freight data to

assess the impact of time-based contracts on spatial supply-demand imbalances, platform profit, and driver surplus. We also examine how network expansion decisions influence platform profit.

2 - Information Design In Research Funding: Threshold Mechanisms and Performance Guarantees

Mengyang Lin, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Anran Li, Wenqi Lian, Zhe Liu

Research funding agencies must allocate limited funding opportunities among researchers who strategically disclose information about their projects' true quality, resulting in a novel mechanism design challenge. We model this scenario as an information design problem with multiple senders (the researchers) and a single receiver (the funding agency). Each project's value comprises a public component (θ), reflecting the researcher's track record, and a private component (η), representing the current project's quality. Beginning with a single-researcher setting, we characterize the researcher's optimal disclosure strategy under a threshold-based selection mechanism, which is shown to be optimal and achieves the full-information welfare.

Extending to the multi-researcher setting introduces competitive dynamics that render the threshold-based mechanism suboptimal in general. Moreover, identifying a truly optimal mechanism is computationally infeasible, and we demonstrate that funding projects purely based on the highest posterior values can fail to admit an equilibrium. Consequently, we refine the threshold-based policy to accommodate a capacity constraint of k maximum funding slots. Our policy guarantees a performance ratio of $\frac{1 - \sqrt{\frac{1}{k+3}}}{2}$ relative to the full-information optimum, inducing a simple equilibrium that efficiently allocates funding. The results provide actionable insights for designing research funding mechanisms under strategic information disclosure and limited resources.

3 - Learning and Dynamic Equilibria in Misspecified Duopoly Pricing

Feiyu Han, University of Chicago, Chicago, IL, United States, Ozan Candogan

We study a misspecified multinomial logit (MNL) duopoly Bertrand pricing model in which each firm treats itself as a monopolist. Firms use a stochastic gradient-based online learning algorithm with myopic monopoly pricing, following the approach in Goyal et al. (2023). While prior work shows convergence to the unique Nash equilibrium (NE) when price sensitivity in the utility is fixed, we relax the fixed price sensitivity assumption and allow it to vary over positive values. This flexibility introduces richer dynamics: the learning process does not necessarily converge to the NE. Instead, we introduce the notion of a dynamic equilibrium (DE): a pricing profile at which firms' expected decisions no longer change over time under the learning dynamics. We analyze the associated continuous-time ODE and show that multiple DEs may arise. Although the NE qualifies as a DE, it is not distinguished—it lies in the interior of the revenue set, defined as the set of all feasible revenue pairs. This implies the NE does not generally maximize revenue for either firm. Finally, we show that the NE is not a stable DE. These results highlight a gap between static equilibrium concepts and long-run outcomes under misspecified learning, and show that even small changes in utility specification can lead to qualitatively different dynamics.

4 - Learning a Stackelberg Leader's Incentives from Optimal Commitments

Yurong Chen, INRIA, Paris, France

Stackelberg equilibria, as functions of the players' payoffs, can inversely reveal information about the players' incentives. In this paper, we study to what extent one can learn about the leader's incentives by actively querying the leader's optimal commitments against strategically designed followers. We show that, by using polynomially many queries and operations, one can learn a payoff function that is strategically equivalent to the leader's, in the sense that: 1) it preserves the leader's preference over almost all strategy profiles; and 2) it preserves the set of all possible (strong) Stackelberg equilibria the leader may engage in, considering all possible follower types. As an application, we show that the information acquired by our algorithm is sufficient for a follower to induce the best possible Stackelberg equilibrium by imitating a different follower type. To the best of our knowledge, we are the first to demonstrate that this is possible without knowing the leader's payoffs beforehand.

5 - A System-Level Analysis of Conference Peer Review

Yichi Zhang, Rutgers University, New Brunswick, NJ, United States

Conference peer review involves three constituencies with different objectives: authors seek fast acceptance at prestigious venues, conferences want to present a program with many high-quality and few low-quality papers, and reviewers want to avoid excessive workloads. These objectives are far from aligned, primarily because paper evaluation is inherently noisy. Over the years, conferences have adopted various policies to manage these tradeoffs, such as adjusting acceptance thresholds, varying the number of reviews per submission, requiring prior reviews for resubmissions, and others. In this work, we investigate the effectiveness of these policies and the reasons behind their success or failure.

We model the conference-author interactions as a Stackelberg game: a conference commits to an acceptance policy; the authors best-respond by (re)submitting or not (re)submitting to the conference in each round of review, the alternative being a "sure accept" (such as a lightly refereed venue). Our analysis yields several insights. First, the conference should typically set a higher acceptance threshold than the actual desired quality --- creating a "resubmission gap". Second, the reviewing load is heavily driven by resubmissions of borderline papers - therefore, a judicious choice of acceptance threshold may lead to fewer reviews while incurring an acceptable loss in conference quality. Third, conference prestige, reviewer inaccuracy, and author patience increase the resubmission gap, and thus increase the review load for a fixed level of conference quality. For robustness, we further consider different models of paper quality and compare our theoretical results to simulations based on plausible parameters estimated from real data.

Chair: Hongseok Namkoong, Columbia University, New York, NY, United States

1 - Simulating and Experimenting with Social Media Mobilization Using LLM Agents

Mohsen Bayati, Stanford University, Stanford, CA, United States, Sadegh Shirani

Social networks have transformed the ways in which political mobilization messages are disseminated, raising new questions about how peer influence operates at scale. We develop an agent-based simulation framework that integrates real demographic data, Twitter network topology, and heterogeneous LLM agents to examine the effect of mobilization messages on voter turnout. This provides a controlled, reproducible environment for testing counterfactual designs in political mobilization research.

2 - AI and Operations: A View to the Future

Srikanth Jagabathula, NYU Stern School of Business, New York, NY, United States

This is a high level talk that covers how traditional research within operations interacts with transformative technologies, such as large language models, generative AI, and agentic systems. The focus will be on taking a view to the future and identifying interesting research opportunities.

3 - Discrete Optimization for Large Language Model Compression

Kayhan Behdin, LinkedIn, Mountain View, CA, United States

Large Language Models (LLMs) have demonstrated remarkable performance across a wide range of industrial applications, from search and recommendations to generative tasks. Although scaling laws indicate that larger models generally yield better generalization and performance, their substantial computational requirements often render them impractical for many real-world scenarios at scale. In this work, we present methods and insights for compressing LLMs into Small Language Models

(SLMs) that maintain the generalization performance of the LLM, while requiring less inference compute resources. Particularly, we focus on a key technique known as structured pruning, discussing algorithms rooted in discrete optimization. Additionally, we share the lessons we have learned from applying model compression techniques based on discrete optimization in a large-scale industry use case.

1 - Feedforward Neural Network (FNN) for Real-Time Packaging Strength Prediction

Supanart Sukrason, The Pennsylvania States University , Malvern, PA, United States, Animesh Agrawal, Rayat Noor

This study presents a Feedforward Neural Network (FNN)-based classification model for real-time strength prediction in corrugated box packaging, aiming to eliminate production latency caused by traditional quality assurance (QA) procedures. Conventional mechanical testing requires operators to halt production, extract sample boxes, and send them to a QA lab for compression testing—a process that takes approximately 10 minutes per lot. This delay results in machine idle time and throughput reduction, contributing to estimated annualized losses exceeding \$2.7 million.

In contrast, the proposed system enables inline, automated strength classification directly from live process parameters, eliminating the need for sample extraction or manual testing. The model is trained on industrial-grade data from SCG Packaging, incorporating multivariate features such as edge crush test (ECT) values, print cylinder gaps, additive formulation types, machine speed, box geometry, flute type, and etc. The model result is defined as binary outcomes (“Pass” or “Not Pass”) for supervised classification.

Five FNN architectures were developed and evaluated using performance metrics including accuracy, precision, recall, F1-score, and AUC-ROC. The optimal model (Model 0) achieved an AUC of 0.998 and accuracy of 98.6%, with minimal false positives/negatives.

Moreover, a real-time data pipeline integrates machine telemetry and raw material data via APIs and a middleware layer, supporting low-latency inference. This development enables continuous model predictive quality assurance, reducing downtime and improving operational efficiency.

This work highlights the role of deep learning and industrial AI in operations research, offering a scalable framework for intelligent, real-time quality control in packaging manufacturing.

2 - Causal Analysis for Congressional Trade - ML, Vector Db and AI Agents at Work

Hari Hara Prabhu Narayanan, dotData, Austin, TX, United States

We present a novel causal inference framework that integrates machine learning, hybrid vector search, and AI-driven investigative agents to evaluate the market impact of congressional stock trades. Our method identifies comparable control stocks using multi-modal embeddings (Vector DB), estimates counterfactual price trajectories through Bayesian structural time series (BSTS) modeling, and leverages LLM-based agents to autonomously investigate external policy or financial events that may validate causal relationships.

Analyzing over 10,000 congressional disclosures from 2022–2024, we find that 34% of trade clusters exhibit statistically significant post-trade deviations, often corroborated by AI-augmented external investigations. Our scalable and interpretable framework offers a new pathway for uncovering how political activity may causally influence financial markets, with implications for transparency, policy analysis, and investment strategy.

3 - Moveod: a Data Pipeline for Synthesizing Origin-Destination Demand Data Using U.S. Census Information

Rishav Sen, Vanderbilt University, Nashville, TN, United States, Samitha Samaranayake, Ayan Mukhopadhyay, Aron Laszka, abhishek dubey

Detailed, time-indexed origin–destination demand matrices provide the empirical foundation for transportation network optimization, vehicle-routing algorithm design, and congestion management studies in operations research. Unfortunately, publicly available OD data for the United States are usually coarse, mode-specific, or subject to disclosure limits that preclude detailed analysis. We present MoveOD, an open-source, fully automated pipeline that synthesizes time-stamped, building-level commuter flows for any United States county while exactly reproducing official Census marginals.

MoveOD statistically fuses four data streams: (i) Longitudinal Employer–Household Dynamics OD flows (LODES), (ii) American Community Survey (ACS) departure-time histograms, (iii) ACS travel-time distributions, and (iv) building-level footprints from OpenStreetMap and Microsoft Buildings Footprint. An integer-linear program calibrates candidate trips so that three constraints hold simultaneously: origin–destination totals, origin by departure-block counts, and origin-specific travel-time histograms. The resulting synthetic commuters are spatially and temporally realistic yet privacy-preserving.

To illustrate MoveOD’s utility, we generate about one million synthetic trips for six southeastern U.S. counties, but the same pipeline applies to any county nationwide. These building-level, time-stamped data can feed directly into downstream studies such as benchmarking vehicle routing heuristics, evaluating congestion pricing, or stress testing multimodal network designs, analyses that are impractical with conventional zonal demand.

To facilitate adoption, we will release the complete, documented codebase with a web-based interactive interface through which practitioners select a county, set temporal parameters, and download calibrated OD tables together with the accompanying metadata and shapefiles. MoveOD enables rapid, reproducible experimentation for researchers, planners, and analysts across transportation, logistics, and public policy.

4 - Returns Consolidation and Outbound Freight Optimization: a Two - Stage MIP Model for Reverse Logistics

Sheetal Sheetal, University of Iowa, Iowa City, IA, United States

The convenience of e-commerce has led to a surge in online returns, introducing significant logistical and operational challenges for reverse logistics networks. Offline stores generate high volumes of returns that must be consolidated, sorted, and shipped back to merchants through multi-tier supply chains. Delays in consolidation, inefficient hub routing, and suboptimal freight mode choices can significantly increase operational costs. Designing coordinated shipment policies under stochastic return volumes and service-level constraints is thus a critical operational challenge.

We develop a mixed-integer programming model to optimize these operations for third-party logistics service providers managing e-commerce returns. The model captures consolidation at return drop-off stores, shipment routing to hubs, freight mode selection (parcel, LTL, and FTL) for dispatches to merchant warehouses, and information coordination between return points and hubs.

Our experiments simulate 100 days of operations across multiple stores, hubs, and merchants, with Poisson-distributed demand at each store. We test multiple scenarios involving box size flexibility, store-to-hub assignments, and hybrid shipping policies that combine quantity-based triggers with minimum service frequency guarantees.

Results show that hybrid policies —where shipments are triggered based on accumulated volume but must occur at least once a week—can yield cost savings of up to 30% over rigid time-based schedules while maintaining service levels. In contrast, allowing multiple box sizes for shipping from drop-off locations to hubs provides minimal additional savings. These findings highlight the importance of synchronization between returns consolidation and freight dispatch decisions, and offer practical insights for third-party providers designing scalable and cost-efficient reverse logistics systems.

5 - Strategic Placement of Drone Platforms in Out-of-Hospital-Cardiac-Arrest: A Case Study for Jefferson County, Louisville, Ky

Marziehsadat Rezaei, University of Louisville, Louisville, KY, United States, Monica Gentili

Each year, over 350,000 out-of-hospital cardiac arrests (OHCA) occur in the U.S., with survival rates as low as 8–10% due to delayed ambulance arrivals and limited use of publicly available Automated External Defibrillators (AEDs). Unmanned Aerial Vehicles (UAVs), or drones, present a transformative solution for rapid AED delivery to OHCA scenes, overcoming barriers like AED accessibility and bystander hesitation. Using Louisville's EMS data, this study identifies priority areas for drone delivery and potential launch sites in Jefferson County, Louisville, KY. These inputs inform an optimization model to determine the minimum number of launch platforms needed to cover a specified percentage of intervention calls within a desired service time. We present results of the optimization model under different scenarios, by varying the priority areas, the number and location of the platforms, and the drone flight parameters.

6 - A Roadmap to Sustainability for University Chemical Labs

Xinyue Zhang, Boston University, Boston, MA, United States, Xindi Liao, Chenxi Feng

This research developed a roadmap to help Boston University labs achieve My Green Lab Certification. Issues found in audit processes identified as duplicate purchases and data gaps. Recommendations include greener chemicals, optimized procurement processes, and equipment alternatives. A fluid dynamic model and energy efficiency estimates project sustainability improvements.

7 - Development of a Virtual Reality-Based Quadcopter Simulator for Immersive Training and Research in Rescue and Emergency Missions

Emre Eraslan, University of Illinois Urbana Champaign, Urbana, IL, United States, Avinash Gupta

Unmanned Aerial Vehicles (UAVs) are increasingly used in high-risk, time-sensitive scenarios such as search and rescue or disaster response. While autonomous UAVs have advanced, effective human oversight remains essential in complex, dynamic environments. Existing training tools often lack realism and fail to place the operator in immersive, decision-making roles. To address these limitations, this project introduces a digital twin-inspired virtual reality (VR) simulator for swarm-based UAV operations.

The system integrates MATLAB for control modeling and Unity for immersive visualization. Completed components include a nonlinear UAV dynamics model, closed loop reference model-based adaptive controllers for leader-follower formations, and autonomous obstacle avoidance via simulated sensors. A joystick interface enables real-time teleoperation of the leader UAV. A key technical achievement is the establishment of two-way data communication between MATLAB and Unity, allowing dynamic interaction and real-time feedback.

The ongoing work involves developing a VR environment with the XR Interaction Toolkit, terrain features, and embedded rescue mission scenarios. Human factors principles will inform interface design to reduce cognitive load and improve usability. The system will undergo pilot testing and structured usability evaluations.

This simulator offers a novel training and research platform that combines high-fidelity control, swarm dynamics, and immersive user interaction. Beyond operator training, it supports the study of human-system performance under mission-critical conditions. Long-term, this work lays the foundation for real-world UAV swarm deployment through VR-based interfaces. Potential applications include emergency response, digital mapping, and autonomous inspection, where coordinated autonomy and human oversight must seamlessly coexist.

8 - Dynamic Robust Integer Optimization with Cost Uncertainty

Pengyu Zhang, University of Michigan, Ann Arbor, MI, United States, Ruiwei Jiang, Guodong Lyu, Stanley Lim

We study a dynamic robust integer optimization model with cost uncertainties, characterized by stagewise Wasserstein balls. The model seeks to find a dynamic policy for discrete decisions, with an objective of minimizing the expected total cost under the worst-case distribution. We recast the model as a classical robust dynamic integer program by proving a minimax theorem and explicitly characterizing the worst-case distribution. In addition, we design a dual dynamic programming algorithm to solve this model, alongside lower and upper bounds that converge to the optimal value almost surely. Furthermore, we investigate value of multistage modeling (VMS) by benchmarking our model with popular alternatives, including a two-stage model and a myopic policy. In this analysis, we discover that VMS is particularly significant when the uncertainty has either a high variance or a high heterogeneity over time. The results from extensive numerical experiments in a real-world last-mile delivery and a route planning problem validate our findings.

9 - The Hidden Cost of Politeness: Evaluating The Environmental and Operational Costs of AI Prompt Design

Victoria Kehinde, Georgia State University, Atlanta, GA, United States, Mahira Begum, Lauretta Fagbuyi, Juliet Dokor, Nesreen El-Rayes, Wendy Roth

As artificial intelligence systems, particularly large language models (LLMs), become integral to daily digital interactions, seemingly benign user behaviors, such as adding polite phrases like “please” and “thank you,” may carry unexpected consequences for sustainability. This study investigates the relationship between prompt structure and energy consumption, examining how the inclusion of polite or verbose language affects processing time, compute intensity, and operational costs at scale. Using benchmark tests and industry energy use data, the research quantifies the marginal energy and cost increases associated with longer, more nuanced prompts and explores their cumulative environmental impact across millions of daily interactions.

The study also evaluates how prompt optimization strategies and user education might mitigate computational waste without sacrificing conversational quality. This study provides new insight into the intersection of human behavior, digital efficiency, and sustainability. It raises critical questions about the hidden costs of user interaction design in AI systems and suggests pathways for more energy-conscious AI use. The findings have implications for data center resource planning, responsible AI design, and digital sustainability practices, offering a novel lens through which to assess the societal and operational impacts of language in computational systems.

10 - Co-Optimizing Spacecraft Routing and Depot Location-Allocation in Cislunar Space

Mustafa Tanbir Kuhel, Texas State University, San Marcos, TX, United States, Tongdan Jin

The space industry is expected to grow at an exponential rate, reaching \$2.7 trillion by 2045, necessitating innovative supply chain frameworks to enable long-term deep space explorations. This research tackles the unique issues of space logistics by co-optimizing spacecraft routing, orbital depot placement, and rocket staging for human residence on lunar surface. Our Space Depot Location-Allocation (SDLA) model uses mixed-integer programming to reduce overall launch mass while maintaining depot capacity, flight route, propellant technologies, and orbital mechanics. The model evaluates single- and two-stage spacecraft design by applying the Tsiolkovsky rocket equation to compute fuel and structural mass for orbital depots and delivery routes from Earth to Moon.

Numerical experiments for Earth-Moon network of 6 candidate orbital depots, and 12 lunar bases reveal that two-stage rockets reduce total launch mass by 4,949 kg, equivalent to \$10.11M cost savings compared to single-stage systems, achieving a 5.05% fuel reduction. Sensitivity analysis identifies that raising specific impulse from 450s to 600s reduces mission mass by 23.3%, while lowering structural coefficients results in mass savings of up to 5.5%, emphasizing the importance of advanced propulsion and structural design. Siting depot at gravitationally stable nodes, such as Lagrange orbits, improves logistical efficiency in the cislunar network.

Future additions will include in situ resource utilization, additive manufacturing, and interplanetary flight time constraints in SDLA model. The framework offers valuable insights for reducing costs and improving logistics sustainability for lunar explorations in the next decade, aligning with global efforts to establish permanent human

habitats on the Moon.

11 - A Milp Approach for Multi-Period Order Allocation Under All-Unit Quantity Discounts and Blending Ratios

Fuhad Ahmed Opu, University of Texas at San Antonio, San Antonio, TX, United States, Moddassir Khan Nayeem, Hamid Najafzad, Yara Altarawneh, Omar Abbaas

This study addresses optimal order allocation under all-unit quantity discounts for manufacturing a single product requiring multiple ingredients with fixed blending ratios. Suppliers' quantity-based discounts introduce non-linearities, complicating multi-period cost minimization involving procurement, inventory holding, and fixed ordering costs under deterministic demand. We propose a MILP model based on a finite set of Critical Order Quantities (COQs) that preserves optimality and eliminates the need for nonlinear discount modeling. Mathematical propositions validate that ordering at these COQs efficiently minimizes total costs. This framework supports strategic procurement decisions, effectively balancing immediate cost savings and long-term inventory impacts.

12 - City Observation and Learning: a Map Tile Based Spatial Data Fusion Pipeline

Wing Au, Fujitsu Research of America, Santa Clara, CA, United States, Xiaojian Zhang

We present the pipeline to transform heterogeneous geospatial data into a common format and be combined or 'fused' for downstream tasks. Leveraging a convention that is used by Web Map technology, the format can be easily interpreted and controlled by laymen decision makers due to its uniform, intuitive representation. The mechanism addresses three main obstacles making geospatial data difficult to use in a widespread manner: multi-spectrum, generalizability and transferability. 2D/3D spatial images, 2D geometric shapes, 1D temporal data from various sources such as demographics, land-use, point-of-interest, weather, etc. are seamlessly assimilated as uniform features for the data pipeline. Observations in various social economics use cases such as traffic, public safety, city operation and environmental impact are analyzed within a generalized framework. Using global or national data sources as a basis, analyses and learnings performed on one locality can be transferred to a similar locality, where data may not be as abundance. A GUI-based application complements the data pipeline enhances usability by providing visual comparison of the various features and observations to produce the most statistically useful combination for downstream simulation or Machine Learning and Artificial Intelligence usage. Our goal is to target business and municipal operations, where a common framework can be applied anywhere, any problem with any data.

13 - Finite Time Analysis of the Natural Policy Gradient in Finite-Horizon Markov Decision Processes

Asha Barua, Virginia Polytechnic Institute & State University, Blacksburg, VA, United States, Sajad Khodadadian

The natural policy gradient is a well-known algorithm for finding the optimal policy in a Markov Decision Process (MDP). Variants of this algorithm, such as TRPO and PPO, have demonstrated remarkable performance in real-world applications. This success has sparked extensive research on the finite time analysis of these algorithms. In this work, we present the first finite time analysis of the natural policy gradient for finite-horizon MDPs where H is the length of the horizon and k is the iteration, establishing an $\mathcal{O}(H^2/k)$ rate of convergence.

14 - Growth of Income Funds and Death of Volatility : a Study in Inelastic Option Supply and Market Impact

Abdurrahman Kurucak, University of Texas at Dallas, Richardson, TX, United States, Taeyoung Park

Over the past decade, income funds employing the call overwriting strategy have emerged as one of the fastest-growing segments in the mutual fund industry. This study explores the consequential impact of their trading on the underlying assets and options. By using detailed option position data of all mutual funds from N-PORT disclosure, we find that the aggregate selling of call options by these income funds reduces subsequent monthly option implied and realized volatility. Its significance stems from income funds, which repetitively overwrite calls on a regular basis rather than engaging in informed selling for volatility timing. This reduces the endogeneity concern and bolsters the importance of the inelastic supply. In the context of demand-based asset pricing, this is a critical implication because this finding proves that asset prices can vary by inelastic supply of call options. In addition, in the context of investor protection, this study reveals that this activity can detrimentally impact potential profits, as lower implied volatility diminishes the option premium and consequently reduces the cash flow stream for investors of income funds.

15 - Next-Gen Grid Security Platform

Alaa Selim, University of Connecticut, Storrs, CT, United States

The rapid digitalisation of power distribution grids exposes millions of edge-connected devices to sophisticated cyber-physical threats. I introduce the **Next-Gen Grid Security Platform**, a closed-loop framework that first identifies the grid's most damaging attack surfaces, then detects ongoing intrusions, and finally responds with optimal corrective actions. A Bayesian optimisation engine emulates a non-cooperative adversary, learning worst-case ramp attacks that maximise voltage violations and loss of critical load on the IEEE-123 feeder, outperforming genetic algorithms and CMA-ES in both convergence speed and impact. For defence, two complementary controllers are trained: a deep-reinforcement-learning volt/VAr agent that dispatches DER reactive power in real time, and a Bayesian game-theoretic optimiser that co-ordinates topology reconfiguration with DER set-points under uncertainty. Together they restore up to ninety-five percent of lost load and return voltages to within ANSI limits in three 20-ms control cycles. Detection is handled by a hybrid large-language-model text validator that screens command streams and a lightweight ResNet classifier that flags anomalous SCADA waveforms with ninety-eight percent accuracy and only twenty milliseconds of latency, satisfying NIST CSF response timelines. All layers are validated through high-fidelity OpenDSS simulations and a hardware-in-the-loop microgrid at UConn's Center for Clean Energy Engineering. The talk opens with a concise survey of emerging cyber threats in active distribution networks and demonstrates how an optimisation-centric, machine-learning-driven framework embedded at the protective-relay layer can neutralise those threats, provide step-by-step deployment guidance for utilities, and chart future directions in robust optimisation, safe reinforcement learning, and trustworthy AI for critical-infrastructure security.

16 - An Analysis of AI-Based Methods for Visual Sensory Trigger Detection in Sensory Processing Disorder

Yara Altarawneh, The University of Texas at San Antonio - Department of Mechanical, Aerospace, and Industrial Engineering, San Antonio, TX, United States, Omar Abbaas, Leslie Neely, Moddassir Khan Nayeem, Fuhad Ahmed Opu, Hamid Najafzad

Sensory Processing Disorder (SPD) is a condition that causes difficulty in capturing, modulating, interpreting, or organizing sensory stimuli. Despite its impact on daily function, SPD continues to receive less attention in both research and practice compared to physical disabilities. Current assessments rely heavily on subjective tools, including checklists and observational reports. In this project, AI-based methods were reviewed and compared for their effectiveness in detecting visual sensory triggers, with the goal of improving sensory accessibility. A systematic review was conducted on 68 studies published between 2014 and 2025. A structured filtering process was followed, and models were evaluated based on four criteria: accuracy, processing speed, model complexity, and their ability to detect brightness, color, and contrast. The most effective techniques which outperformed traditional models in both detection capability and adaptability were identified and used in an example included in the project showing how AI can be used to process visual input by detecting visual triggers. Most of the reviewed work focused on classification and diagnosis, while visual trigger detection received limited attention. A noticeable overlap was found between studies on autism, neurodiversity, and accessibility, but direct attention to visual overstimulation in SPD remained limited. The results confirm that certain models are more suitable than others for detecting sensory triggers, and that detection-focused frameworks are still lacking. Future work should be directed toward building AI systems that detect and respond to visual overstimulation to support inclusive and adaptive environments.

17 - Who is the Better Bettor: a High School Student Using AI or a Professional Gambler?

Samuel Goldfeder, Highland Park High School, Highland Park, IL, United States, James DiLellio

This paper explores the performance of an AI-powered sports betting model compared to traditional market expectations and expert picks. Using machine learning—specifically, mass web scraping and gradient-based optimization—the model gathers a wide range of data to inform its decisions. Inputs include team efficiency metrics, historical betting lines, injury reports, public sentiment, and sharp money indicators, all used to generate probabilistic forecasts for NCAA men's basketball games.

The model learns from past results, gradually identifying which factors—like efficiency ratings, line movement, or injuries—have the greatest impact on outcomes. Over a five-week period, we tested the model on 68 games and compared its results to sportsbook closing lines and expert consensus.

The model consistently outperformed both sets of expectations, particularly in underdog and small-market matchups, where oddsmakers tend to be less accurate. It posted a 60.3% win rate, on against-the-spread (ATS) and total points scored (O/U) — well above the 50% market baseline and 57.5% expert average win rate—and returned a net gain of 12.91 units on total bets of 78.3 units. Importantly, bet size recommendations were dynamic, based on the model's confidence in each pick.

While its edge diminished closer to game time, aligning with market efficiency theory, the model proved especially effective in identifying early value. These findings suggest AI models can offer a measurable advantage in low-liquidity markets when powered by real-time data. This work adds to the growing field of algorithmic wagering and highlights the potential of adaptive, data-driven strategies in practical sports betting.

1 - Dual Decomposition for Coordinated Optimization of Coupled Traffic Power Systems with EV Charging and Queue Dynamics

Hamidreza Attari, University of California, Davis, DAVIS, CA, United States

The integration of electric vehicles (EVs) into urban systems has created a tightly coupled relationship between transportation and power infrastructures. We propose a dual decomposition-based optimization framework that models the coordination between these two subsystems, incorporating EV routing, queue-aware charging behavior, and distribution-level power constraints.

The model includes multiple types of shared information between subsystems, specifically, EV charging demand and charging station queue length, as coupling variables. Charging decisions are influenced by Locational Marginal Prices (LMPs), which are computed as dual variables of the nodal power balance constraints in the power model and passed iteratively to the traffic subsystem as real-time price signals. EV battery dynamics are captured through SOC update constraints, ensuring physical feasibility over time.

To evaluate the coordination mechanism, we implement a decentralized solution approach using dual decomposition, enabling iterative subsystem optimization with synchronized dual updates. Crucially, we assess the relative importance of each type of shared information by analyzing the magnitude and entropy of the associated dual variables. This allows us to quantify which information contributes most to system-wide coordination and cost reduction.

Numerical experiments on a multi-node coupled traffic–power testbed demonstrate the benefits of information-aware coordination, showing improved load balancing, reduced total cost, and mitigation of charging congestion. The proposed framework provides a scalable and interpretable foundation for operating interdependent infrastructure systems under high EV penetration.

2 - Hybrid Model for High-Precision Fake Account Detection on Social Media

Kimia Keshanian, University of Tampa, Tampa, FL, United States

Fake social media accounts on platforms like X and Instagram pose serious threats, spreading misinformation, malware, and scams. This study presents a multi-level model to detect such accounts with high precision, integrating deep learning and human feedback. Using the Cresci-2017 dataset of 6,825 accounts, our approach processes numerical metrics (e.g., follower counts), bio text, profile images, and tweets through distinct layers. The first layer extracts 7 numerical features and applies TF-IDF to bios, yielding 1,000 text features. The second layer employs a convolutional neural network (CNN) to analyze 2,024 profile images, generating 64 features. The third layer uses a long short-term memory (LSTM) model to evaluate 4,285 tweet sets, producing a probability score. Combining these 1,072 features, a Random Forest classifier achieves 99.77% accuracy in 5-fold cross-validation, outperforming a numerical-only baseline (99%). Feature importance analysis shows numerical metrics contribute 55%, images 29%, tweets 12%, and bios 4%. One uncertain account (59% fake probability) is flagged for human review, enhancing practical deployment. Unlike traditional machine learning methods, our multi-level framework leverages deep learning to address prior limitations, offering a scalable, robust solution. The model and features are archived for future research. This study highlights the effectiveness of layered, human-augmented modeling in identifying fake accounts, advancing trust and security in social media platforms.

3 - Trilevel Network Interdiction Game for the Minimum Cost Flow Problem with Input Dependence

Adam Rumpf, Florida Polytechnic University, Lakeland, FL, United States, Hemanshu Kaul

We consider a game theoretic network flow model for planning optimal fortifications to a collection of interdependent civil infrastructure networks against a targeted attack or worst-case natural disaster. The model consists of a three-stage sequential game played on a generalized minimum-cost flow network with binary input dependencies, wherein certain arcs within the network become unusable if there is shortfall in delivery of flow to certain nodes (for example, modeling links in a telecommunications network that require input from nodes in the electric power network in order to be usable). The game consists of a defender selecting a subset of arcs to protect, then an attacker selecting a subset of undefended arcs to destroy, and finally the defender optimizing the flow in the damaged network, with the overall goal of choosing the initial defensive strategy that minimizes the final flow cost over all possible attacks. The presence of binary interdependencies complicates the solution process due to the introduction of integer constraints and the possibility of cascading failures. We present exact and computationally efficient approximate solution algorithms for the resulting trilevel mixed integer-linear program, including algorithms that utilize a linear relaxation of the binary interdependencies.

4 - Large Language Models in Academia: Boosting Productivity but Reinforcing Inequality

YoungJin Kwon, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States, Agnes Yang

Large language models (LLMs) have garnered significant attention for their potential to enhance knowledge worker productivity. In this study, we provide the first large-scale empirical evaluations of LLMs' impact on academic research productivity. Leveraging a comprehensive dataset of 4,582 computer science scholars across 194 top U.S. universities and analyzing 251,124 research papers published between 2018 and 2024, we find that the introduction of LLMs is associated with about 8% increase in publication output—a gap that persists across alternative measures, including the first-author publications and top-tier conference papers. Our regression discontinuity in time (RDiT) analysis further reveals that LLMs not only shifted the average publication level but also accelerated the growth rate of productivity, rising to 3.2% in 2023 and 12.8% in 2024. Notably, junior scholars realize stronger gains than their senior counterparts, with the productivity benefit diminishing by roughly 1% for each additional year of experience. Recognizing that LLMs' benefits may not be uniformly distributed, we also investigate their impact on non-native English-speaking (NNEs) researchers, who have historically faced disadvantages in academic writing (Liao et al., 2024). Difference-in-differences and generalized synthetic control analyses indicate that, following LLM adoption, native English-speaking (NES) researchers produced more papers than their NNE counterparts. Overall, our findings indicate that while LLMs significantly boost scholarly productivity, they also exhibit dual effects, lowering barriers for junior scholars while potentially reinforcing linguistic inequities.

5 - Domain-Sensitive Opinion Leadership in Pandemic Communication: Identifying Influencers on Social Media

Aram Bahrini, University of Illinois at Urbana Champaign, Champaign, IL, United States, Behnam Malmir, Hossein Amini

Effective public health communication during pandemics is often hindered by misinformation and declining trust in official sources. This study proposes the Pandemic Opinion Leader Analysis (POLA) framework to identify domain-sensitive opinion leaders (OLs) in online social networks, enabling health authorities to strategically disseminate accurate and timely information. Leveraging both implicit and explicit data from X (formerly Twitter), the framework integrates social network analysis and topic modeling to uncover influential individual and organizational actors across thematic subdomains—such as vaccination, health policy, and community action.

The study identifies key leadership traits (trust, expertise, uniqueness, innovativeness, reputation) and quantifies their relevance via targeted surveys. Results reveal that OL influence is largely unidirectional, highlighting hierarchical dynamics in online discourse. The findings emphasize the importance of domain-specific OLs—individuals who exert targeted impact in niche pandemic topics—offering a nuanced approach to influencer engagement.

The POLA framework offers a scalable, data-driven tool for optimizing communication efforts in health crises and other public emergencies, contributing both theoretically and practically to information systems, digital leadership, and crisis management.

6 - Operational Design for Modular Transit Shuttle Systems During Pandemics

Xinke Cui, Drexel university, Philadelphia , PA, United States

Transit agencies need to control infection risks while maintaining service quality and lowering operational costs during global pandemics. To fulfil this need, various adaptation strategies have been proposed for transit operations under pandemic circumstances, but their reliance on fixed-capacity vehicles limits their effectiveness. In this study, we examine the use of Modular Autonomous Vehicles (MAVs) that enable variable capacity operations via autonomous docking and undocking maneuvers. To facilitate the design of transit operations with MAVs, we develop an optimization framework that simultaneously determines dispatch headways, vehicle formations, and onboard flow control levels. The consideration of both variable capacity operations and infection risks in this optimization framework poses tremendous computational challenges. To address these challenges, we reformulate the problem as a Mixed Integer Linear Programming Model for exact solution and propose a Continuum Approximation (CA) algorithm for near-optimal solution by decomposing the problem into a set of analytically and separately solvable subproblems. Numerical experiments using real traffic data from the Beijing subway system show that: (1) MILP was able to solve exact optimal solutions for small instances within 1831.11 sec; (2) the CA algorithm achieved near-optimal solutions for large instances with negligible error (0.52%) within only 5.9 sec. Results also demonstrate the potential of MAVs in reducing total system cost, despite the increase in the infection cost. Overall, the proposed model and algorithm offer transit agencies a practical decision-support tool for designing cost-effective and infection-aware operations under future pandemic conditions.

7 - Addressing Highly Imbalanced Clinical Data in Machine Learning for Cognitive Impairment Prediction Among Chronic Pain Patients

Do Kieu Trang Thoi, Virginia Tech, Blacksburg, VA, United States, Huaiyang Zhong

Chronic pain significantly impacts millions, often co-occurring with debilitating cognitive impairment. Early identification of patients at risk for cognitive decline is crucial for timely intervention and improved quality of life. This study aimed to develop and evaluate a model for predicting cognitive impairment in individuals with chronic pain. The dataset comprised electronic health records from Carilion Clinic, including demographic variables, medication history, diagnosis codes. We compared the performance of multiple classifiers, employing techniques to mitigate class imbalance. The findings demonstrate the feasibility of predictive modeling for early identification of cognitive impairment in chronic pain patients and underscore the importance of addressing data imbalance. Implementing such models in clinical decision support systems may facilitate timely interventions and improve cognitive health outcomes in this vulnerable population.

8 - Optimal Decision Support Systems for Adaptive Radiation Therapy

Fatemeh Nosrat, Rice University, Houston, TX, United States, Raul Garcia, Aysenur Karagoz, M. Soheil Hemmati, S. Mohammad Hosseinian, Andrew Schaefer, Clifton David Fuller

The purpose of this study was to determine personalized optimal timing for re-planning in adaptive organ-at-risk-sparing radiation therapy under limited re-planning resources in patients with head and neck cancer (HNC). A novel Markov decision process (MDP) model was developed using HNC patients treated at the University of Texas MD Anderson Cancer Center to determine optimal timing of re-plannings based on the patient's expected toxicity, characterized by normal tissue complication probability for four toxicities: xerostomia, dysphagia, parotid gland dysfunction, and feeding tube dependency at 6 months post-treatment. Optimal re-planning strategies were obtained when the permissible number of re-plannings throughout the treatment was to 1, 2, and 3. In contrast to prior work that relies on a single re-planning allowance or predetermined time intervals using a one-size-fits-all approach, the MDP model proposed in this paper offers a personalized, resource-aware, and scalable decision-making tool to identify optimal dynamic re-planning schedules, tailored to individual patients's needs.

9 - Information Sharing Strategies for Pharmaceutical Supply Chains

Kevin Carr, Northeastern University, Boston, MA, United States, Jacqueline Griffin

Pharmaceutical supply chains (PSCs) are critical healthcare infrastructure frequently compromised by fragmented information exchange, causing inefficiencies, stockouts, and patient safety risks. We introduce a comprehensive framework to address challenges to information sharing in PSCs through four interconnected aims. First, we identify and taxonomize unique barriers to information sharing, revealing that trust, transparency, and regulatory complexity present the most significant challenges. Second, we analyze information sharing practices from adjacent industries (e.g., retail, manufacturing, oil & gas) to identify transferable solutions. Our cross-industry matrix mapping demonstrates how specific practices can address different barrier dimensions, with the most successful solutions targeting trust and confidentiality issues. Finally, we explore modeling methods to examine how a multi-dimensional strategy addressing technical, behavioral, and organizational factors simultaneously, demonstrating that designing effective information-sharing platforms for PSCs may be less intractable than anticipated.

10 - Revitalizing Institutional Journalism: A Blockchain and AI-Driven Framework to Counter Digital Polarization

Mohamed Abouzahra, California State University, Monterey Bay, Seaside, CA, United States

The decline of traditional institutional journalism in the digital era has contributed to the rise of misinformation and the fragmentation of public discourse. This paper introduces a novel system that harnesses blockchain and artificial intelligence (AI) to restore the relevance, financial sustainability, and societal impact of institutional journalism. Leveraging a design science methodology, the study explores how blockchain-enabled smart contracts and AI-driven personalization can bridge the gap between legacy media and digital audiences on social platforms.

A large-scale analysis of over 80,000 tweets related to journalism revealed a strong correlation between users' political leanings and their preferred news sources, with content shared by individuals receiving greater engagement than posts from institutional outlets. This highlights the challenges traditional journalism faces in being perceived as external to online communities and its struggle to maintain audience trust and reach.

To counter these dynamics, we developed a system that personalizes news delivery via smart contracts on the Ethereum blockchain. AI agents analyze user interests to recommend and summarize content, which can then be purchased and shared seamlessly on social media. This community-centered approach increases article visibility, generates revenue for outlets, and reduces the barriers imposed by rigid subscription models.

The system was piloted with university students and demonstrated promising results in usability, engagement, and the fostering of democratic discourse. By embedding institutional journalism within the digital community fabric, this model presents a scalable, ethical pathway for combating polarization and revitalizing the role of journalism in democratic societies.

11 - A Three Stage Feature Selection Framework for Causal Inference

Tianyu Yang, Northeastern University, Boston, MA, United States, Alam Md Noor E

Feature selection is important in causal inference to obtain unbiased estimates of causal quantities. Selecting variables that achieve unbiased and robust causal estimation is pivotal. Recent research indicates that balancing treatment-associated variables alone introduces bias, while including spurious variables increases variance. Addressing this challenge, we propose a three-stage framework that significantly enhances feature selection compared to existing methods, yielding lower bias and variance in causal estimation while maintaining oracle property. Evaluation on synthetic datasets demonstrates superior performance across various scenarios, ensuring scalability for large datasets. Finally, we apply our methodology to real-world data, evaluating a key US healthcare policy on the causal link between opioid use disorder and suicidal behavior in the context of the opioid epidemic crisis.

12 - Sustaining the Future: A Model of Long-Term Environmental Investment in a Decentralized Supply Chains

Mukul Kaushik, University of Illinois Urbana Champaign, Urbana, IL, United States

This paper presents a model of pollution prevention in a supply chain where firms face environmental risks and increasing long-term costs from pollution. The supply chain consists of suppliers with different planning horizons – some focus only on short-term profits, while others consider medium or long-term outcomes. Pollution events occur randomly and lead to private penalties as well as externalities that grow over time, capturing rising reputational damage and regulatory compliance costs. Firms can choose to form an alliance to co-develop a pollution-reducing technology, adopt the technology by paying a licensing fee, or do nothing. Adoption decisions are not verifiable, allowing for the possibility of greenwashing. A downstream retailer sets wholesale prices and contract durations, which shape the incentives for upstream firms. The model captures how firm decisions depend on planning horizons, technology costs, pricing, and the accumulation of pollution-related compliance costs. It provides a structured way to analyze when and how decentralized supply chains invest in long-term environmental sustainability, even without strict regulation or enforcement.

13 - A Fairness Framework for Resource Substitution in Large Networks

Ved Mohan, Georgia Institute of Technology, Atlanta, GA, United States, El Mehdi Er Raqabi, Pascal Van Hentenryck

A major challenge for many organizations operating large-scale networks is ensuring that the right resource is available at the right location and at the right time. This is an NP-hard problem because uneven demand patterns and the subsequent asymmetric flow of resources across the arcs often create imbalances on the nodes of these networks. To deal with these imbalances, a cost-effective approach is to perform resource substitution among multiple, potentially composite and interchangeable, resource types. This leads to the resource substitution problem, a very challenging task in both theory and practice, which aims to find the minimum number of resource substitutions from the initial resource assignment in the network so that the overall imbalance is minimal. However, resource substitution cannot be satisfactory unless the preferences of various network schedulers are taken into consideration. This paper presents a generic framework that combines operations research (OR) and machine learning (ML) to ensure a fair resource substitution within large networks. The OR component allows modeling and solving the resource substitution problem under a fairness lens. The ML component leverages the historical data to learn schedulers' preferences, intelligently explore the decision space, and enhance the OR component's effectiveness. The framework outputs a portfolio of solutions from which the schedulers can pick satisfactory solutions. We apply our framework to the large network of a leading US parcel carrier, which motivated this research. Experimental results demonstrate the potential benefits of the developed framework against existing state-of-the-art approaches to resource substitution in the literature.

14 - Eliciting An Expert's Confidence in Their Chosen Model Construction Assumptions

Jennifer Pazour, Rensselaer Polytechnic Institute, Troy, NY, United States, Patrick Brewer

All models are wrong, some are useful. One reason even high-fidelity models are wrong is that they rely on humans to make translations from the system they are modeling to mathematical or computational form. While humans typically have some beliefs about which model construction assumptions are least like reality versus the assumptions in which they have the most confidence, this information is typically discarded once the model is put into use.

Thus, in this work, we explore how to design elicitation protocols to capture an expert's confidence in their chosen model assumptions and inputs. Grounded by a survey of existing expert elicitation protocols, this work identifies a portfolio of protocols that can elicit expert judgements and their confidence in their judgements at the model assumption-building stage. Follow on work translates this highly valuable knowledge into a method to quantify a predictive model's representative ability.

15 - Mindful Interactions with AI: a ChatGPT Case Study

Lu Xiao, Arizona State University, Tempe, AZ, United States, Marina Mitiaeva

Mindful communication involves being present, attentive, kind, and non-judgmental—expressed through ethical awareness, interpersonal sensitivity, and responsiveness. As generative AI systems like ChatGPT increasingly function as communication partners, a key question emerges: Can they engage in mindful communication—and does it matter? To explore this, we analyzed 48,000 real Human–ChatGPT conversations, examining how morality, politeness, and alignment—three core dimensions of mindful communication—unfold in practice. We also conducted a qualitative classroom study to investigate how prompt tone influences learning experiences.

Our findings reveal that while ChatGPT consistently employs moral and polite language, it lacks adaptive flexibility, limiting its responsiveness to user context and relational nuance. In contrast, human users demonstrate greater emotional and lexical variability, highlighting a gap in reciprocal adaptation.

We propose a layered framework of mindful AI communication: anchored in moral grounding, shaped by politeness, and realized through alignment. Crucially, these dynamics suggest that users increasingly perceive AI not merely as a tool, but as a social presence. Designing AI, therefore, is not just a technical endeavor—it is the crafting of social identity. This work offers both conceptual insight and practical guidance for developing AI systems that are socially intelligent, ethically grounded, and capable of nurturing trust, empathy, and sustainable human–AI relationships.

16 - Quick Recovery of Feasible MINLP Solutions from MILP Relaxations for Water Network Throughput Maximization

Sai Krishna Kanth Hari, Los Alamos National Laboratory, Los Alamos, NM, United States, Russell Bent

Determining the maximum demand a water distribution network can satisfy is crucial for ensuring reliable water supply and planning expansions. This maximum is computed by solving a mixed-integer nonlinear program (MINLP), which is computationally challenging. The challenge is typically addressed by solving mixed-integer linear program (MILP) relaxations obtained through variable domain partitioning with linear over- and under-estimators of the partitions. These MILPs provide useful bounds and are relatively easier to solve. However their solutions can violate nonlinear water flow physics. Thus, recovering feasible MINLP solutions from the MILP relaxations is crucial for enhancing MILP-based approaches.

In this presentation, we propose a robust solution recovery method that efficiently computes feasible MINLP solutions from MILP relaxations, regardless of partition granularity. Together with iterative partition refinement, our method produces feasible solutions that progressively approach the optimal solution. Through extensive numerical experiments, we demonstrate that the proposed method outperforms other recovery methods and direct MINLP solves by consistently recovering high-quality feasible solutions with significantly reduced computation times.

17 - Personalized Pathways to Discharge: Explaining What Matters, for Whom, and Why

Ha Na Cho, UC Irvine, Irvine, CA, United States, Kai Zheng, Bow Hansen, Alexander Lopez, Sairam Sutari

Efficient discharge planning is a critical challenge in surgical care operations, particularly for optimizing bed turnover and care coordination. We present a predictive framework to identify whether a patient who underwent surgery is likely to be discharged the following day, based on unstructured clinical notes. Leveraging data from a surgery department, we evaluated multiple machine learning (ML) models, including Logistic Regression, Random Forest, XGBoost, Support Vector Machines, and Naive Bayes, under class-balanced settings to address outcome imbalance. Among the models, XGBoost yielded the highest performance (accuracy: 0.81), followed closely by Random Forest and SVM (0.74-0.81). Logistic Regression demonstrated high recall (0.72) in detecting next-day discharges but exhibited lower precision.

To ensure transparency, we employed SHAP (SHapley Additive exPlanations) to analyze both global and patient-level feature attributions. SHAP summary plots revealed that certain textual features such as "home today" and "no acute distress" contributed positively to next-day discharge classification, while terms like "dressing change" and "dependent total" were more influential in predicting prolonged hospitalization. These results are not causal but offer interpretable operational proxies for discharge readiness.

At the individual level, SHAP waterfall plots highlighted significant heterogeneity in influential features, confirming that discharge decisions are highly personalized. Different features carried predictive weight for different patients, reflecting context-dependent pathways to discharge even within the same outcome class.

This study emphasizes the clinical value of explainable ML in supporting anticipatory discharge decisions. Our approach enables clinicians to trace the reasoning behind next-day discharge predictions, enhancing trust, and efficient resource planning.

18 - Navigating the Digital Footprint: a Cross-Cultural Analysis of Parental Information Disclosure on Social Media Platforms

Paras Bhatt, University of Alabama in Huntsville, Huntsville, AL, United States, Tripti Singh

The widespread practice of “sharenting,” where parents share their children’s information on social media, raises critical questions about how platform design and cultural norms jointly shape digital footprints and privacy risks. Although prior research has explored parental motivations for sharenting and examined individual platform features, such as content persistence (long-lasting, easily retrievable content) and ephemerality (temporary, short-lived content), a critical gap remains in understanding how combinations of platform-level affordances (e.g., algorithmic curation, privacy controls) interact with culturally embedded privacy norms to shape sharenting and associated privacy risks.

Using a mixed-methods study informed by affordance theory and social processing theory, we first map the platform’s key affordances, such as visibility, content persistence, editability, interactivity, algorithmic curation, and data governance, to analyze publicly available sharenting posts and demonstrate how these affordances shape parental disclosure. This includes a cross-platform analysis (YouTube, TikTok, and Instagram) across two different cultures: an individualistic, low-context culture (e.g., United States) that values direct and explicit communication, and a collectivist, high-context culture (e.g., Nepal), which emphasizes indirect cues, shared social norms, and group harmony. Next, we conduct a survey of parents in both cultures to assess how affordance-culture interactions drive parents’ oversharing versus protective behaviors.

Our findings will demonstrate 1) specific platform features and culture pairings that amplify children’s exposure and privacy risks, (2) reveal how cultural privacy norms moderate parental use of platform controls, and (3) generate actionable guidelines for designers to tailor affordances that encourage mindful sharing for safeguarding child privacy in diverse digital ecosystems.

19 - A Data-Driven Evaluation of Primary Care Utilization Across Pandemic Stages

Jennifer Mendoza-Alonzo, Department of Statistics, Franklin College of Arts and Sciences, University of Georgia, Athens, GA, United States

Primary care services are essential for preventive health and managing chronic conditions, influencing overall population health outcomes. Social determinants of health significantly influence individuals’ access to and utilization of primary care services. This cross-sectional study evaluates changes in primary care utilization across pre-, peak-, and post-pandemic periods by applying machine learning and traditional methods. Using Behavioral Risk Factor Surveillance System (BRFSS) data, we assess risk factors for adults receiving routine care based on social determinants of health and chronic conditions. We examine variable importance using machine learning and SHAP (SHapley Additive exPlanations), and incorporate the most relevant variables into traditional statistical models. Our findings offer insights into healthcare access patterns and demonstrate the value of combining interpretable machine learning algorithms and public health analytics to inform equitable health policy and strengthen health system resilience.

20 - Route Optimization for Electric Trucks in Solid Waste Collection: Impacts of Network Representations and New Solution Algorithms

Chinonso Okorie, FAMU-FSU College of Engineering, Tallahassee, FL, United States, Yanshuo Sun

Solid waste collection (SWC) is vital for environmental sustainability and public health. With the adoption of electric trucks (ETs), recent studies have begun to address ET routing optimization, but none has considered the realistic transportation network on which SWC occurs. This study bridges that gap by comparing two network representations: a real-world network with highway nodes and links, and an alternative network with virtual links. Comparative analysis shows the real-world network dominates when the network is sparse and most communities are visited, while the alternative excels when highways require multiple visits. Additionally, we propose two solution algorithms, namely column generation (CG) and sequential decomposition heuristic (SDH) to solve large-scale problems. Extensive computational experiments on synthetic and real-world case studies show their effectiveness in reducing computation time by up to 90%.

21 - Spatiotemporal Endemic&Ndash;Epidemic Modeling of COVID-19 Using Cluster-Aggregated Mobility Data During a Natural Disaster

Davison Tsekeni, Florida A&M University, Florida State University (FAMU-FSU) College of Engineering, Tallahassee, FL , Tallahassee, FL, United States, Arda Vanli

Understanding how mobility patterns influence infectious disease dynamics is critical for modeling epidemic spread, particularly during overlapping crises. We present an endemic–epidemic (EE) modeling framework by clustering ZIP codes using a k-means approach on geographic centroids and aggregating both COVID-19 infection case counts and origin-destination mobility data. Our study focuses on Florida’s Escambia, Santa Rosa, and Okaloosa counties from September 1 to September 30, 2020, encompassing the landfall of Hurricane Sally. To capture behavior-driven changes in mobility, we model inter-cluster movement rates using a multi-step changepoint approach. EE models are fit with distributed lag structures and Poisson likelihoods, and are evaluated using AIC, R^2 , and Residual Sum of Squares (RSS). The model estimates region-specific (cluster-specific) reproductive numbers and decomposes infection dynamics into self-driven, neighbor-induced, and environmental components. Results show that cluster-level variability in outbound mobility is strongly associated with neighbor-driven infection contributions. This modeling approach supports operational decision-making during public health emergencies by enabling local health agencies to identify high-risk regions, anticipate outbreak trajectories, and evaluate mobility-targeted interventions. By integrating real-world mobility disruptions into a scalable forecasting framework, this study contributes a practical tool for epidemic risk assessment, particularly in settings affected by concurrent public health and environmental hazards.

22 - A Two-Stage Stochastic Optimization Model for Equitable and Cost-Effective Food Distribution Under Multiple Uncertainties: A Case Study of Hays County Food Bank

Mukitil Islam, Texas State University, San Marcos, TX, United States, Clara Novoa

This poster presents a two-stage stochastic optimization model developed to support strategic and operational decision-making at the Hays County Food Bank (HCFB) located in Central Texas. The model incorporates practical complexities faced by the HCFB, including perishability of food, storage capacity limitations, restricted transportation resources, and uncertainty in donations, volunteers’ availability, and demands from food-insecure customers.

The model aims to minimize the total annual cost of food distribution while ensuring a weekly equitable distribution in six food categories and four cities. The model is solved using two methods, assuming discrete scenarios and employing sample-average approximation. The numerical results provided by these methods are validated against data and key performance indicators provided by HCFB. Through experimentation with the model, it has been found that the model is effective in assisting HCFB with future expansion plans, enhancing accessibility for vulnerable populations, and reducing food waste.

23 - Testing Optimization Models for Production

Francisco Zenteno Smith, American Airlines, Forth Worth, TX, United States, Jonathan Yu

Optimization models are deeply embedded in modern operational systems, powering decisions that move goods and people across the globe. In the commercial aviation industry in particular, these models play a central role in long range planning, day-to-day operations, and on-demand disruption recovery. For example, inclement weather in major hubs can cause cancellations that ripple across the network. Dependable and resilient models are the deciding factor in millions of dollars in savings, or loss.

While optimization models are mainly mathematical constructs, writing, deploying, and maintaining them is inherently a software engineering challenge. As business

needs evolve, so must the model, in lock-step with the code.

In this work we present a framework developed at American Airlines that enables large teams to collaboratively build and maintain optimization models efficiently, without compromising resiliency. The framework integrates continuous integration (CI) pipelines to automate both unit and integration testing of optimization models. Integration tests validate complete model snapshots against expected formulations, while unit tests verify individual model components (such as constraints, variables, and objective function terms) in isolation. This structured approach ensures alignment with business requirements, detects regressions early, and significantly reduces the need for time-consuming manual testing.

We show how this approach supports early detection of bugs, reduces deployment risk, and enhances trust in the optimization tools that support operational decision-making. By embedding rigorous testing into the development lifecycle, our framework improves reliability and accelerates the delivery of optimization-based solutions in production environments.

24 - An Adaptive Decision-Making and Environmental Monitoring System for Collaborative Robots Using Sensors

mahrou samizadeh, auburn university, auburn, AL, United States, Konstantinos Mykoniatis

As collaborative robots (cobots) become more prevalent in manufacturing, logistics, and service industries, their ability to adapt to dynamic environments is critical. Traditional cobots typically operate based on pre-programmed rules, which limit their flexibility and responsiveness in real-world conditions. This project presents a two-phase approach to improving cobot intelligence through real-time environmental sensing and decision-making.

In Phase 1, we developed a rule-based control system that integrates ultrasonic, infrared (IR), and DHT11 (temperature and humidity) sensors. These sensors were connected to an Arduino microcontroller, which processed sensor data and communicated binary signals to a Universal Robot (UR) arm. The robot responded in real time to object presence, executing pick-and-place actions. We evaluated sensor configurations under varying environmental conditions, and results from 40–50 experimental trials showed that ultrasonic sensors provided more stable and faster responses compared to IR sensors. ANOVA analysis confirmed the significance of sensor choice on robot performance, establishing a benchmark for real-time detection accuracy and task efficiency.

In Phase 2 (under development), the same sensor inputs will be combined with computer vision using YOLOv8 and a machine learning model to drive adaptive cobot behavior. The ML model will analyze multi-sensor patterns and YOLO detections to make context-aware decisions without relying on hard-coded rules.

This work contributes to the growing field of Human-Robot Interaction by proposing a scalable framework for building intelligent cobots. It supports the Industry 5.0 vision of human-centered automation by enabling cobots to make faster, smarter decisions in complex, changing environments.

25 - Convexification of Multi-Period Quadratic Programs with Indicators

Jisun Lee, UC Berkeley, Berkeley, CA, United States, Alper Atamturk, Andres Gomez

We consider a multi-period convex quadratic optimization problem with indicator variables, where the state evolves dynamically as an affine function of the current state and input (control) variables in each period. The affine function is determined by the indicator variables that denote the mode chosen in each period. This problem class has important applications in hybrid control and statistical learning. We study the complexity of the problem in various settings, demonstrating both polynomial-time solvable and NP-hard cases. For the polynomial-time solvable case, we present a compact convex hull description in an extended space with linear and conic quadratic inequalities. We also propose a polynomial-time algorithm that solves the problem as a shortest path problem for the unbounded case. Computational experiments with data from calcium imaging data deconvolution and hybrid-electric vehicle power management indicate promises and challenges.

26 - Modeling Mental Health Delivery via a Decentralized System

Candace Yano, UC Berkeley, Berkeley, CA, United States, Ricky Huang

Regional mental health services are often provided by a partially decentralized and capacity-constrained network of organizations operated by various government agencies and nonprofit entities, with the latter being supported by some combination of government subsidies, charitable contributions, and volunteer labor. In this setting, quantifying how the funding level or policy changes at one entity affects the overall value provided by the system in terms of improved health of its clients is difficult. We report on the initial development of a model to aid in understanding these relationships based on the underlying situation in one U.S. county.

27 - Inter-Airline Cooperative Disruption Management with TIME-Varying Cost Functions

Tolga Atabas, University of Michigan, Ann Arbor, MI, United States, Max Li, Brian Denton

Airlines regularly face delays due to disruptions that constrain airport capacities, such as adverse weather events. In response to these disruptive events, air traffic managers reschedule flights in order to balance the constrained airport capacities with the incoming demand of departing and arriving flights, leading to many flights being delayed. Airlines can create a cost of delay function that models the cost (e.g., dollars) for each flight as a function of the severity of delay (e.g., delay hours). These functions are then used in the optimization models to determine the optimal slot swaps that minimize costs for airlines. Recent methods use intra- and inter-airline slot swapping to reduce delay costs. However, the existing approach assumes fixed-rate cost functions that fail to capture real-world cost surges associated with missed connections, crew disruptions, and tail-propagated delays (i.e., delays for subsequent flights performed by the same aircraft). This study develops a novel, convex, stochastically-generated piecewise linear cost function that more accurately reflects time-varying delay costs. Using a Poisson process to model the times for cost rate surge events, we integrate these cost functions into the DELED framework and construct a Multi-Integer Linear Programming (MILP) optimization model. This enhancement improves the realism and robustness of airline delay management models, offering new insights into operational slot swap decision-making. We will show that incorporating time-varying cost structures can improve optimal delay assignments compared to fixed-rate cost assumptions.

28 - Enabling Collaborative Vehicle Routing by Mechanism Design

Jack Rissman, Northern Illinois University, Dekalb, IL, United States, Ziteng Wang

A fundamental question when looking at collaborative vehicle routing is whether the participating logistics providers will benefit from the coalition. These benefits can be in the form of cost reduction, efficiency improvements, environmental benefits, enhanced service levels, and room for innovation. This research aims to design an efficient mechanism for allocating cost savings in order to incentivize logistics providers to join the grand coalition. The research began with revealing Shapley value-based allocation and proportional allocation are not efficient because the core of the underlying cooperative game could be empty. Therefore, some outside source of support is necessary to enable the grand coalition. The next steps consist of optimizing the slack of each allocation savings to find a minimal value of necessary outside support. The research aims to find a mechanism to decide the outside support to better incentivize the collaboration of stakeholders. We will then generalize the results to collaborative vehicle routing problems involving any number of logistics providers.

29 - Average Distance of Random Bipartite Matching in Networks

Yuhui Zhai, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Shiyu Shen, Yanfeng Ouyang

The bipartite matching problem is widely applied in the field of transportation; e.g., to find optimal matches between supply and demand over time and space. Recent efforts have been made on developing analytical formulas to estimate the expected matching distance in bipartite matching with randomly distributed vertices in two- or higher-dimensional spaces, but no accurate formulas currently exist for one-dimensional problems. This paper presents a set of closed-form formulas, without curve-fitting, that can provide accurate average distance estimates for one-dimensional random bipartite matching problems (RBMP). We first focus on one-dimensional space and propose a new method that relates the corresponding matching distance to the area size between a random walk path and the x-axis. This result directly leads to a straightforward closed-form formula for balanced RBMPs. For unbalanced RBMPs, we first analyze the properties of an unbalanced random walk that can be related to balanced RBMPs after optimally removing a subset of unmatched points, and then derive a set of approximate formulas. Additionally, we build upon an optimal point

removal strategy to derive a set of recursive formulas that can provide more accurate estimates. Then, we shift our focus to regular discrete networks, and use the one-dimensional results as building blocks to derive RBMP formulas. To verify the accuracy of the proposed formulas, a set of Monte-Carlo simulations are generated for a variety of matching problems settings. Results indicate that our proposed formulas provide quite accurate distance estimations for one-dimensional line segments and discrete networks under a variety of conditions.

30 - Fitness Center Operational Improvements with Discrete Event Simulation

Junayed Pasha, Gannon University, Erie, PA, United States, Chenay Date Line, Jayed Pasha, Emilio Bell, Andres Esteban Florez

Fitness centers often deal with a large number of users. This may lead to frequent breakdowns of equipment and reduce the operational efficiency of the entire fitness center. Therefore, this research aims to analyze and improve the operations of a fitness center. Considering user flow and equipment utilization, this study seeks to identify bottlenecks, reduce wait times, and improve the overall user experience. In order to replicate the fitness center's operations, a simulation model is developed, which incorporates various features, such as user arrival patterns, equipment usage and popularity, queuing systems for high-demand equipment, as well as equipment reliability and downtime. Relevant data on usage, equipment layout, and failure rates is also collected. In order to improve the fitness center's operations, the simulation explores various scenarios (e.g., equipment rearrangement, maintenance strategies). Simulation results provide insights into peak usage times and the associated congestion, overall equipment utilization rates, impact of breakdowns on overall efficiency, and effectiveness of different layout configurations. Based on the simulation outcomes, this study provides some recommendations, including a redesigned equipment layout to reduce congestion, creating different strategies for managing high-demand machines, a modified maintenance schedule to minimize downtime, and resource allocation suggestions for popular equipment. These data-driven recommendations aim to enhance the fitness center's operational efficiency and user satisfaction, supporting informed decision-making for facility management.

31 - A Feature-Enhanced Capacity Prediction Method for Efficient Lithium-Ion Cell Grading Under Multi-Temperature Conditions

Shih Han Huang, Department of Industrial and Systems Engineering, Virginia Tech, Blacksburg, VA, United States, Kwok Tsui, Xinwei Deng

In battery pack assembly, cells are graded by measuring discharge capacity to enable consistent module performance. However, traditional grading tests often consider the capacity at a single temperature, which does not reflect the diverse environmental conditions for battery packs in real-world use. In this work, we present a data-driven grading method by utilizing features from the charging phase and the first half of the discharge phase to predict full discharge capacities under multiple temperature conditions. The proposed method enables early-stage prediction and supports grading based on the multi-temperature predictions and their uncertainties. Compared to conventional approaches, the proposed method reduces testing time and cost while improving grading robustness. The proposed method is validated across three major lithium-ion chemistries to demonstrate its merits. It also offers practical potential for quality control in battery pack manufacturing.

32 - Toward Smarter U-Net Architectures: A Systematic Review of Optimization Strategies for Tumor Segmentation

Omar Abueed, Binghamton University, BINGHAMTON, NY, United States, Yong Wang

Since its introduction in 2015, the U-Net architecture has become a foundational model in medical image segmentation, particularly for tumor delineation. However, challenges such as tumor heterogeneity, blurred boundaries, and partial volume effects continue to hinder precise segmentation outcomes. To address these limitations, a wide array of optimization strategies have been proposed to enhance U-Net's performance in segmenting CT and MRI images. This systematic review, conducted in alignment with the PRISMA guidelines, categorizes and critically analyzes the most recent advancements in U-Net optimization across seven major domains: backbone enhancements, bottleneck refinements, skip connection strategies, Transformer-based modules, metaheuristic algorithms, state space models (SSMs), and self-adaptive architectures. The review emphasizes how each technique contributes to overcoming the inherent challenges of the original U-Net design. Additionally, the significance of preprocessing methodologies in boosting segmentation effectiveness is thoroughly explored. This review not only synthesizes current optimization trends but also highlights persisting research gaps, offering valuable directions for future studies aiming to enhance U-Net's accuracy, robustness, and clinical utility in tumor segmentation tasks.

33 - Exploring Trust Dynamics in Stag-Hunt Games: a Simulation-Based Study

Mobin Zarreh, Arizona State University, Tempe, AZ, United States, Paul Grogan

From resource management to autonomous supply chains and other distributed systems, effective collaboration depends on trust among autonomous agents. These settings involve complex decision-making under uncertainty, where stakeholders must assess risks and anticipate others' actions, making them well-suited for decision analysis and game-theoretic modeling. Understanding how trust evolves and deteriorates can inform policy and the design of resilient multi-agent systems. This study introduces a novel dual-state agent-based model within the Stag Hunt game framework to investigate how trust evolves and shapes decision-making across diverse partner strategies. Unlike traditional scalar trust models, our framework explicitly separates two internal states: signal (the agent's perceived probability of partner cooperation) and trust (confidence in that expectation). This dual-state structure enables distinct, nuanced updating mechanisms. Trust updates depend on alignment between expected and observed partner behavior, whereas the signal evolves from observed collaboration frequencies weighted by recency. We evaluate the model against a range of partner strategies, including cooperative, adversarial, and particularly deceptive opponents such as an expectation-violation cheater who intentionally acts contrary to the agent's expectations. Results show that consistent cooperation fosters sustained collaboration, while predictable defection, despite building trust and confidence, leads to independent choices. Deceptive strategies notably erode trust, significantly reducing cooperation. Our findings highlight how expectation alignment, predictability, and learning dynamics shape strategic outcomes, offering valuable contributions to behavioral game theory and guiding the design of resilient multi-agent collaborative systems.

34 - Reconstructing and Predicting Driver's Routing Behaviour Under Incidents with Large Language Models

Haocheng Duan, Carnegie Mellon University, Pittsburgh, PA, United States, Sean Qian

Accurately forecasting network-wide impacts of traffic incidents demands a precise grasp of how drivers re-route when disruptions occur. Yet route choice emerges from a chain of context-dependent decisions that grow even more intricate once incident information and nonrecurrent network conditions enter the mix. Complicating matters, GPS traces that reveal these choices are both massive and sparsely sampled, making direct interpretation labor-intensive. To tackle these challenges, we employ a large language model (LLM) as an autonomous agent to preprocess extensive GPS datasets alongside a large-scale road network, obtain possible route information between, and complete trace subsets affected by disruptions. We then fine-tune a decision-making LLM on the small, carefully curated subset using supervised fine-tuning (SFT) and reinforcement learning from human feedback (RLHF), aligning its reasoning with human routing logic. By testing on real-world data collected in the Washington DC region in 2020, we found this two-stage pipeline substantially improves the model's ability to capture drivers' re-routing behavior and significantly boosts the accuracy of route-choice predictions during traffic incidents.

35 - Using Simple Math to Quantify the Impact of the Triangle Trade and Enslavement Practices on Familial Lines: A Case Study of Colonial Ayiti

Jovan Julien, Georgia Institute of Technology, Atlanta, GA, United States

Topic:

The impact of colonialism and enslavement practices on genetic diversity, cultural survival, and mortality in colonial Santo Domingue is not well documented. Due to the paucity of data on the enslaved population, mathematical modeling can serve as an effective way to explore the impact of these brutal regimes.

We leverage mathematical methods to quantify the impact of imperialism and colonialism between 1492 and 1804.

Methodology

Our goal is to explore the if(s). «Yo pa fe listwa avek les si» an memn tan jistis depandan sou « si ». This quantification of ifs is essential for justice, for the qualification of reparation and restitution, and to mark a historical tragedy such that generations might avoid its replication

We apply a semi-markov model framework to replicate and understand the creation process of a new population, Haitians, during the colonial period. Utilizing historical patterns of immigration and mortality we fit a model for family line and cultural community mortality and survival. Counterfactual analyses are conducted to quantify the impact if a revolution was not started and if French attempts to recapture the island had been successful.

Key arguments and results

Leveraging a land-based analysis allows for quantification of the crimes that occurred centuries ago. We offer a framework by which interested parties can explore the impact of colonialism.

Conclusion

While many would argue that mathematical models cannot capture the dreams unrealized, we offer a method by which a value can be generated for the many generations lost to Ayiti since colonization.

36 - Computer-Aided Analysis of Decentralized Optimization Algorithms

Ning Fang, Cornell University, Ithaca, NY, United States, Xin Jiang

Performance Estimation Problem (PEP) theory offers a rigorous framework to analyze the worst-case convergence rates of first-order optimization algorithms. We extend PEP to the decentralized optimization setting by developing a generalized primal formulation that accommodates both static and time-varying communication graphs, enabling systematic analysis of decentralized algorithms across different network scenarios. By encoding decentralized updates using Gram matrix representations, we systematically capture interpolation constraints involving function values, gradients, and consensus violations across agents. We apply this framework to analyze various decentralized gradient-based methods and present some intriguing results that are unlikely to be discovered without computer-aided analysis.

37 - Data-Driven Insights from Raccoon Eyes: Quantifying the Financial Impact of AI-Powered Food Waste Reduction at Georgia State University

Izuhunwa Amadasun, Georgia State University, Atlanta, GA, United States, Jennifer Wilson, Ivan Zou, Adetoun Adeleke, Mahira Begum, Lauretta Fagbuyi, Alexis Mathis, Tobi Oyeniran, Davron Dean, Chidimma Ihejirika, Wendy Roth, Nesreen El-Rayes

Food waste in institutional dining environments poses a significant financial and environmental challenge. This case study from Georgia State University's Panther Dining explores how the Raccoon Eyes AI dashboard (a computer vision and analytics platform) can drive data-informed decisions to reduce waste and associated costs. Drawing on over one million meal records, 42,000 pounds of waste data, and detailed breakdowns by food type, time, and plate count, the study identifies high-waste items and operational inefficiencies. By monitoring patterns such as overproduction and plate returns, and implementing targeted interventions (e.g., portion resizing, utensil adjustments, and menu optimization), the research quantifies both waste reduction and cost savings. Time series and intervention analyses demonstrate the platform's ability to guide waste mitigation strategies that improve efficiency and sustainability. The findings offer a replicable framework for other institutions to leverage AI tools like Raccoon Eyes to improve operational performance and reduce the financial burden of food waste. Key questions addressed include, but are not limited to: Which food items contribute most to waste and cost? What measurable savings result from intervention strategies? The results underscore the economic justification for adopting AI-powered waste tracking, highlighting its dual impact on institutional budgets and environmental outcomes.

38 - Mip Models for Searching---Bayesian Updates

Ransheng Guan, University of Wisconsin-Madison, Madison, WI, United States, Jeff Linderorth

Anti-Submarine Warfare (ASW) operations necessitate the strategic allocation of limited, often diverse, assets to locate elusive underwater threats. Foundational search theories leverage all information, including vital 'negative search evidence'—the absence of detection—to recursively refine probabilistic estimates of target locations using Bayesian inference. However, a primary challenge in dynamic operational environments is that the intelligence value and outcomes of future searches are not predetermined. Instead, they are significantly influenced by prior asset deployments and their results. This introduces complexities associated with Decision-Dependent Uncertainty (DDU), where actions actively shape the uncertainties faced in subsequent stages.

We introduce a mathematical programming framework to tackle ASW search problems where the information landscape evolves based on operational decisions. This approach combines established belief updating techniques with principles for handling DDU. It aims to formally model how search actions and their consequences dynamically alter the probabilistic assessments guiding future efforts. Recognizing that capturing these dynamic, often non-linear, interactions can lead to complex optimization challenges, this framework provides a structured methodology for incorporating decision-dependent information, including the impact of negative evidence, into ASW planning over a defined operational theater and time horizon.

39 - Harnessing Sentiment Analysis for Sustainable Dining: An AI-Driven Tool to Reduce Food Waste

Nesreen El-Rayes, Georgia State University, Atlanta, GA, United States, Jennifer Wilson, Ivan Zou, Izuhunwa Amadasun, Victoria Kehinde, Juliet Donkor, Alexis Mathis, Tobi Oyeniran, Wendy Roth

This study explores the role of consumer sentiment in shaping food waste outcomes within institutional dining environments, focusing on how qualitative feedback can inform sustainable decision-making. Leveraging a vision AI platform (Raccoon Eyes) that simultaneously tracks food waste metrics and captures students' feedback in the dining hall at Georgia State University, we apply natural language processing (NLP) and sentiment analysis to thousands of reviews collected across campus dining halls.

Integrating sentiment data with quantitative indicators such as waste volume, plate counts, and cost, the analysis highlights how AI-enabled tools can enhance responsiveness and sustainability in large-scale food service operations. By analyzing the sentiment polarity with waste patterns for specific food items, the research examines the sentiment as a leading indicator of high-waste meals. Additionally, we assess the impact of feedback-informed interventions on subsequent waste reduction and cost efficiency.

This research contributes to the growing intersection of AI, sustainability analytics, and operational efficiency in the food service sector, and has managerial implications that can be cascaded in similar setup in other organizations.

40 - Koopman Representations with Irregular TIME Intervals

Younghwan Cho, University of Illinois Urbana-Champaign, Champaign, IL, United States, Richard Sowers

Koopman operator theory has been widely applied in data assimilation problems of real systems governed by dynamical systems, as the theory allows for data-driven construction of modes of dynamical systems. In many modern problems, Koopman modes may have to be learned from data with irregular sampling intervals, as opposed to commonly used regular sampled data. We here propose a framework to recover Koopman eigenfunctions and eigenvalues for irregularly sampled data. We show that a Koopman eigenfunction and eigenvalue can be recovered via a natural optimization problem. We also provide technical remarks on the anticipated challenges in optimization and suggest a procedure to address them. Simulation studies under different irregular sampling scenarios verify the robustness of the proposed method in learning Koopman eigenfunctions.

41 - Exploring the Correlation Between Winter Severity Indices and Winter Maintenance Costs: Insights and Comparative Analysis from Nationwide Practices

Ardeshir Fadaei, Michigan State University, East Lansing, MI, United States, Farish Jazlan, Amirali Soltanpour, Hamid Mozafari, Ali Zockaie, Mehrnaz Ghamami, James Roath

Winter maintenance operations are essential for safe and efficient transportation, yet unpredictable weather introduces major challenges in cost and material planning. A single severe snowfall can deplete resources midway through the season, while milder-than-expected winters may result in unused surpluses. The Winter Severity Index provides a standardized measure of winter intensity, offering a promising tool to address these challenges. This study explores the relationship between WSIs and winter maintenance costs through a nationwide survey of state DOTs and Clear Roads Survey data. The Clear Roads survey analysis involves regression models, assessing the relationship between the AWSSI and winter maintenance expenditures across different U.S. climate divisions. AWSSI was used not as a recommended tool for operations, but as a nationally available and consistent index to investigate whether winter severity is statistically associated with cost trends at a broad scale. The study also assessed

non-linear regression models, which yielded similar results to linear models; therefore, the linear model was retained for its simplicity and interpretability. Results showcase significant correlation within various climate clusters, indicating that weather severity can explain cost variability. The study reveals that WSIs can improve winter maintenance budget management, but their effectiveness is regionally nuanced. Customized WSIs are essential for better cost and resource planning, as no single index, including AWSSI, works optimally in all geographic contexts. The study also identified best practices by state DOTs, such as integrating WSIs with real-time tools like Road Weather Information Service and Maintenance Decision Support System, to enhance planning accuracy and responsiveness.

42 - A Rose Given, Fragrance in Hand: Impact of Prize Draw Variation on Sales Change

Larry Cui, Portola High School, Irvine, CA, United States

Digital technologies are increasingly being adopted by companies to enhance various aspects of performance, including internal operations, financial management, marketing, and sales. This study utilizes prize draw and sales data from a publicly listed company that implemented digital technology to conduct consumer prize draws. By analyzing 8,872 observations across multiple cities in a large country, the study examines how variations in prize draw amounts influence changes in sales. The findings suggest that fluctuations in prize draw incentives can have a significant impact on product sales.

43 - Enhancing Energy Resilience of Data Centers Through Flexible-Load Strategies

Mohamed Abdelhady, Department of Multidisciplinary Engineering, Texas A&M University, College station, TX, United States, Eleftherios Iakovou, Stratos Pistikopoulos

Hyperscale data centers may face mounting reliability and cost challenges as power grids struggle to expand capacity under a volatile, uncertain, complex, and ambiguous (VUCA) environment. Traditional grid procurement strategies may no longer provide adequate resilience or cost-effectiveness in these challenging conditions. This study evaluates whether data centers should transition solely to reliance on the grid to integrating on-site self-generation portfolios that combine photovoltaic (PV), wind, gas turbines, nuclear, and battery energy storage systems (BESS).

We develop a two-stage stochastic programming framework to identify optimal technology portfolios under uncertainty. Our approach uses a scenario-generation algorithm that synthesizes fourteen years of historical wholesale price data, preserving critical patterns including seasonality and volatility. The first stage determines optimal capacity investments across technologies, while the second stage optimizes dispatch decisions to minimize expected costs while providing grid flexibility services. These services not only capture value from negative-price events and peak-shifting arbitrage but also provide rapid load support to relieve system stress and prevent grid blackouts. Under baseline conditions, PV and BESS emerge as the cost-optimal combination: PV panels provide low-marginal-cost energy during daylight hours, while BESS shifts energy to peak periods and captures value from negative-price events. However, when we incorporate explicit reliability constraints through chance-constrained programming—capping the probability of unmet load below specified thresholds—gas turbines re-enter the optimal mix to hedge against extreme price spikes and supply shortfalls from the grid.

These findings may offer data center operators and policymakers clear guidance on developing robust energy portfolios under power grid uncertainty.

44 - Optimizing and Deploying Schematic Bicycle Maps with Milp and User Input

Mohammed Abdalazeem, University of Massachusetts Amherst, Amherst, MA, United States, Jimi Oke

Schematic maps simplify network complexity and improve cognitive accessibility, principles widely adopted in public transit but rarely applied to bicycle infrastructure. This project proposes a complete pipeline for the development of schematic bicycle maps, including design rule synthesis, user-centered input via surveys, and an optimization-based automated layout engine. We begin by extracting design principles from existing bicycle maps and transit schematics, then synthesize a new set of constraints specific to cycling, accounting for elevation, stress level, infrastructure type, and the absence of fixed lines. We formalize these principles into a mixed-integer linear programming (MILP) model to generate schematic layouts. The optimization minimizes distortion and visual complexity while adhering to derived cyclist-centered design rules. To validate the usability of the proposed approach, we conduct a two-phase survey in the case study area to capture user preferences before and after exposure to generated schematics. We also develop a bicycle demand model using public and sensor-based count data, enabling future impact evaluation. The final map will be selected through focus group feedback and prepared for public installation. This work offers a replicable framework for schematic bike maps and a planning tool for cities aiming to expand cycling for sustainable, healthy, and accessible mobility.

45 - Fourier Learning Machines and Their Applications

Gabriel Nicolosi, Missouri University of Science and Technology, Rolla, MO, United States, Mominul Rubel, Adam Meyers

This work is concerned with the historical, computational and mathematical relationships between classic Fourier Series and Neural Networks. For five decades, numerous attempts to unify these two mathematical tools have been made by researchers in the most diverse yet often disconnected fields. In this work, a historical perspective on this endeavor is presented, alongside a new, straightforward and computationally efficient representation of Multivariable Finite Fourier Series as a Multi Layer Perceptron, referred to as a Fourier Learning Machine. Furthermore, we study a variation wherein integrality constraints over the frequencies are relaxed, and its relations to the Fourier Transform are investigated. Computational experiments and comparative performance evaluations in the context of Scientific Machine Learning and Numerical Optimal Control are presented.

46 - Why Do College Students Cheat?

Matt Dean, William & Mary, Williamsburg, VA, United States

Academic dishonesty among college students is commonplace. Building off a well-known article in the *Journal of Business Ethics* (Simkin and McLeod 2010), our study describes the status of college students cheating in 2024. We surveyed 171 business school students and analyzed their responses by applying partial least squares methodology on cheating behavior. Among cheaters in the previous 2010 study, a “desire to get ahead” was the most important motivating factor. Our study went deeper into this phenomenon to understand why college students are cheating by engaging with a focus group of survey participants. The results better describe when students choose to cheat and what professors and administrators should do to prevent such behavior.

47 - A Mitigation Strategy Against Cyberattacks on Distributed Optimal Power Flow

Mohannad Alkhrajah, National Renewable Energy Laboratory, Golden, CO, United States, Daniel Molzahn

Distributed optimization offers desirable features for power system operations by enabling coordination among multiple agents with minimal data exchange. However, distributed optimization's inherent reliance on communications among multiple agents potentially increases vulnerabilities to cyberattacks and communication failures. Leveraging concepts from robust optimization, this paper presents a mitigation strategy to reduce the impacts of cyberattacks and communication failures on distributed optimization for power systems. The proposed mitigation strategy involves a distributed solution of a bilevel *admissible bounds* problem. This problem bounds the maximum flows that can be achieved in branches connected to compromised areas without violating the local operational constraints of other areas. To solve this problem, this paper first introduces a decomposition method based on Kron reduction that uses a Power Transfer Distribution Factor (PTDF) formulation. The proposed method then reformulates the bilevel admissible bound problem using the weak duality theorem to reduce the problem into a single level. This paper demonstrates the proposed method using several test systems and compares the results with the global central solution. The results show the trade-off between solution quality and computation time when solving the admissible bounds problem.

48 - Improving Work Zone Safety: Assessing Law Enforcement Effectiveness with a Split-Plot Design in South Carolina

Mahyar Madarshahian, University of nebraska lincoln, Lincoln, NE, United States, Reka Howard, Nathan Huynh, Jackson Wegmet, Chowdhury Siddiqui

This study evaluates the impact of law enforcement presence on vehicle speeds in South Carolina work zones using a split-plot design with blocking, which offers greater precision compared to traditional factorial designs. Utilizing 2019 traffic data, eight alternative models are developed, examining two response variables: average speed

across the entire work zone and in the transition area. Each response variable is analyzed in two ways: (1) by calculating the difference between average speed and the temporary posted speed limit to assess compliance, and (2) by including traffic volume as a covariate to improve model accuracy. The findings reveal that the presence of state troopers significantly reduces vehicle speeds and enhances compliance with temporary speed limits in both zones. Seasonal variation was generally not a significant factor, with no effect observed in six of the eight models. Importantly, incorporating traffic volume as a covariate improves model precision, supporting its inclusion in future analyses.

49 - Keypoint-Aware Human Body Part Segmentation via a Dual-Discriminator Generative Adversarial Network

Shivam Shrivastava, University of Missouri, Columbia, MO, United States, Hyeong Suk Na

Accurate human pose estimation and body part segmentation are essential for various applications, including sports analytics, video surveillance, and security systems. While these two tasks have traditionally been addressed independently, they are inherently complementary and can be improved by joint learning. Existing studies mainly focus on leveraging segmentation to enhance pose estimation; however, very few models have exploited human pose keypoints to improve body part segmentation. To consider this gap, we develop a cross-domain learning framework to improve human body part segmentation by utilizing keypoints obtained from human pose estimation. Our model architecture is a dual-discriminator generative adversarial network, with one discriminator dedicated to keypoint detection and the other to body part segmentation. The generator has a shared convolutional backbone, followed by two task-specific branches. While the keypoint detection branch employs only the channel-attention module for keypoint regression, the segmentation branch integrates both channel-attention and spatial-attention modules. The channel-attention module is designed to enhance the regression of keypoint heatmaps across binary channels corresponding to each body joint. Additionally, the spatial-attention module aggregates concatenated features from the channel-attention module and the shared convolutional backbone to enhance spatial localization in segmentation. Then dual discriminators are employed to train these two modules individually, resulting in more accurate segmentation boundaries. The model is evaluated on the Look Into Person dataset, which includes annotations for 2D human pose estimation and body part segmentation. Our framework achieves a mean accuracy of 74% and a mean intersection over union of 60%, outperforming state-of-the-art methods such as SCHP.

50 - Cutting-Planes for Arc Flow Formulations from Path Flow Formulations

Anthony Karahalios, Carnegie Mellon University, Pittsburgh, PA, United States, Willem-Jan van Hoeve

An arc flow formulation is an integer linear program that has a variable for each arc in a network. For directed acyclic networks, there exists an equivalent path flow formulation with a variable for each path through the network. We give an example of a cutting-plane for a path flow formulation for which there does not exist an equivalent cutting-plane in the arc flow formulation. We introduce a method that takes as input a cutting-plane in a path flow formulation and alters the network to permit an equivalent cutting-plane to be formulated in the arc flow formulation. We demonstrate the alteration method for Chvátal-Gomory rank-1 cuts derived from the path flow formulation. We give experimental results that show how the alteration method can translate such cutting-planes to improve the linear programming relaxation of an arc flow formulation for the capacitated vehicle routing problem.

51 - Food Detection from Continuous Glucose Monitoring Sensors Using Pretrained Transformer-Based Models

Abhimanyu Kumbara, WellDoc Inc., Columbia, MD, United States, Junjie Luo, Mansur Shomali, Anand Iyer, Gordon Gao

Healthy eating is a critical self-management behavior for a number of chronic health conditions such as diabetes and obesity. Manually logging meals is burdensome, and individuals with health conditions often do not consistently track their meals. Sporadic meal entries lead to sparse data, which may hinder data analysis, clinical decision support, and patient coaching. In this study, we present a novel approach for automatically detecting recent food intake solely based on continuous glucose monitoring (CGM) data.

We created three transformer encoder-based food event detection models: CGMEncoder, CGMEncoder+Time, and CGMEncoder+Time+Pretraining. The input to the models is a full 24-hour CGM trace, and the output is a discrete label indicating the hour (within a specified range) when a food event occurs. Our dataset consists of over 90,000 input-output pairs, partitioned into training, validation, and test sets. Each instance for the model includes CGM token sequences, hour-minute positional identifiers, and auxiliary time-related features capturing dietary event frequency and recency. The test accuracy increases from 63.0% with CGMEncoder model to 71.4% and 77.8% for the CGMEncoder+Time and CGM+Time+Pretraining models, respectively. These results demonstrate the importance of temporal encoding and pretraining for building robust and generalizable food event detection models using CGM data alone. These types of food event detection models can be embedded in digital health tools to automatically collect valuable food data, which can then be used for clinical applications.

52 - Decarbonizing Freight Transportation: Joint Optimization of Intermodal Cargo Routing, Scheduling, and Service Networks

Zeyu Liu, West Virginia University, Morgantown, WV, United States

Intermodal transportation, which exploits the strengths of alternative modes of transpiration, such as rail and water, offers a promising solution for the growing freight transportation sector to reduce carbon emissions and operating costs. Optimization of the intermodal transportation system has been widely studied in the literature, but conventional approaches typically focus on the broad averages of emission and cost statistics or rely on existing inflexible timetables that lead to suboptimal results. In this study, we optimize the U.S. intermodal system consisting of highway, railway, and waterway freight transportation. We construct a mixed integer programming model on a multi-layered transportation network to jointly optimize freight routing, scheduling, and service network design decisions. The model minimizes intermodal operating costs, carbon emission costs as carbon taxes, and late penalties for delayed freight arrival. The complexity of the intermodal system imposes great computational challenges on state-of-the-art solution methods. To address this, we investigate mathematical properties of the model to explore structural benefits. We further propose a vehicle scheduling decomposition approach that expands the Lagrangian cutting plane methods towards nonlinear linking constraints. Structural properties are integrated into the decomposition to derive novel algorithms. Real-world intermodal infrastructure, cost, and freight projection data are collected to validate the model and the algorithms through comprehensive experiments. Carbon emission data from combinations of vehicle engines and fuel types are utilized in large-scale case studies to provide insights on intermodal decarbonization, targeting a carbon-neutral U.S. freight transportation sector by 2050.

53 - Collaborative New Product Development: the Implications of Long-Term vs. Short-Term Contract Choice on Cost-Sharing in Vertical Channels

Abhishek Roy, Temple University Fox School of Business, Philadelphia, PA, United States, Ganesh Balasubramanian

Problem Definition: It is well known that a buyer expects price commitment from upstream supplier when they collaborate to improve the product quality. This insight is based on the notion that an upfront price commitment from the supplier allows the buyer to confidently co-invest without having to worry about the supplier exploiting the buyer with a future price rise. Existing research on supplier-buyer co-creation has not addressed the impact of the buyer's ability to influence the supplier's demand in multi-period selling environments by carrying strategic inventory. We investigate how the possibility of strategic inventory influences buyer's co-creation effort, product quality, and the supplier's contract choices between short-term transactional and long-term commitment contracts.

Methodology/Results: Using a stylized game-theoretic model, we consider the collaborative interactions between a supplier and a buyer over a two-period horizon in which demand is deterministic. Our analysis reveals that the buyer does not benefit from price commitment, and its collaboration effort decreases with price commitment for sufficiently low values of holding cost. In addition, we find that the supplier may prefer a long-term commitment contract despite losing the flexibility to vary prices.

Managerial Implications: Considering the impact of short-term dynamic contracts on supplier-buyer collaboration efforts in a multi-period setting, we contribute to the literature on collaborative product development and strategic contracting. Our research enables suppliers and buyers who engage in collaborative product development to optimally determine their effort and contract choices.

54 - Uncertainty-Aware Large Language Models for Risk-Sensitive Motion Planning in Autonomous Driving

Yuming Chang, Georgia Institute of Technology, Atlanta, GA, United States, Yongyang Liu, Ruining Yang, Nastaran Moradloo, Srinivas Peeta

Autonomous vehicles (AVs) operate in highly dynamic environments where accurately identifying and interpreting surrounding vehicles and human behavior is critical for their safety. Current models predominantly focus on spatial-temporal data, often neglecting nuanced contextual and interpretive reasoning required to handle uncertainties effectively. This research addresses critical gaps in quantifying environmental and behavioral uncertainties using Multimodal Large Language Models (MLLMs). We propose a multimodal contextual reasoning framework that uses MLLMs to detect, classify, and semantically interpret the behaviors and intentions of surrounding vehicles and humans by utilizing multimodal environmental data including camera, LiDAR, and radar. Our probabilistic prediction framework employs MLLM-driven reasoning to explicitly quantify uncertainties by providing predictive entropy and confidence scores, which are crucial for navigating uncertain and dynamic driving scenarios. **Further, Thenmore**, we develop a Bayesian decision-making system explicitly integrating these quantified uncertainties to enhance real-time, safety-critical decision-making. The effectiveness of this approach is validated through extensive simulation and evaluation, employing metrics such as time-to-collision and collision rates within simulated environments, demonstrating its usability and reliability in improving the safety of autonomous vehicles.

55 - Rethinking Risky Portfolio Allocation as An Online Mixed Integer Stochastic Bandit Problem

Jeffrey Varner, Cornell University, Ithaca, NY, United States

This paper presents a framework for online portfolio construction by redefining the mean-variance allocation problem as an online mixed-integer stochastic multi-armed bandit problem. Each arm represents a binary vector representing a candidate asset subset, with rewards computed via Cobb–Douglas utility maximization under budget constraints. Historical market data and a risk-aversion parameter inform the exponents in the utility function, which measure investor preference. We employed an ϵ -greedy algorithm with a decaying exploration rate and an analytical solution for the utility maximization problem, to compute the expected utility (reward) from each arm. This approach computes the optimal subset of assets to include in a portfolio and the number of shares of each asset to hold in the portfolio as a function of time.

We tested our approach on static and dynamic rebalancing problems with portfolios from S&P 500 constituents and ETFs during a 2024 out-of-sample period. Static analyses showed the bandit-driven maximum-utility portfolios approximate the efficient frontier, achieving over 90% similarity to the nearest mean-variance optimal weights while excluding non-preferred assets. By adjusting the risk-aversion parameter, we traverse the frontier: lower risk-aversion leads to risk-seeking allocations with higher expected returns, while higher risk-aversion favors portfolios composed of lower-risk assets. Finally, the algorithm identified optimal portfolios despite noisy market parameter estimates, demonstrating robustness against model uncertainty.

This bandit formulation offers an adaptive online learning approach to portfolio construction, integrating investor preferences for responsive portfolio management. Our findings highlight its potential for real-time personalization and suggest paths for enhanced context models and utility specifications.

56 - A Data-Driven Graph Model Approach to Critical Care Patient Clinical Trajectory Prediction

Honglin Du, University of Florida, Gainesville, FL, United States, Muxuan Liang, Xiang Zhong

The advent of increasingly available patient health data has created opportunities for critical care medicine to embrace modern data-driven decision support. However, existing methods, such as rule-based scoring systems or machine learning-based classification models, often focus on uni-dimensional patient outcomes such as mortality, lacking the granularity necessary to understand a patient's overall health during their hospital stay. This research focuses on predicting a patient's clinical trajectory, described by key health indicators readily accessible through electronic health records, by estimating correlations and causal relationships among these health indicators over time. To overcome the challenges associated with multi-dimensional, longitudinal, and heterogeneous patient data, we develop an analysis pipeline that first identifies distinct patient clusters with similar clinical trajectories through temporal pattern analysis. Then, for each cluster, we implement a structural equation model (SEM) to capture both immediate and time-lagged dependencies among variables, which offers a deeper understanding of the dynamic relationships. Directed acyclic graphs (DAGs) are used to visualize causal and correlative relationships, providing intuitive insights into how vital health indicators interact and form a patient's clinical trajectory. This integrated approach, which combines clustering, SEM, and DAG visualization, enables more refined modeling of patient clinical trajectories, yielding predictive insights tailored to specific patient groups. The approach has the potential to guide personalized interventions, ultimately improving patient outcomes in critical care settings.

57 - From Liquidity to Legacy: Designing Value-Centric Tokenomics for Sustainable Blockchain Innovation and RealFi

Ruizhe Jia, Stanford University, Palo Alto, CA, United States

The rapid liquidity available in cryptocurrency markets presents a double-edged sword: while facilitating access to capital, it often creates incentive structures that favour short-term gains over sustainable, long-term innovation. This "incentive-liquidity mismatch," particularly prevalent in current token financing models, can lead to premature exits by founders and investors, hindering the development of robust products—a critical challenge for ambitious goals like RealFi which require sustained effort and real-world integration.

This project seeks to address this fundamental problem. We argue for a **paradigm shift away from simplistic, time-based token vesting towards novel tokenomic models intrinsically linked to verifiable, real-world value creation, such as protocol revenue or user adoption metrics**. Our core objective is to design and analyze new crypto-native corporate finance and governance structures that effectively incentivize long-term commitment and reward the delivery of tangible, impactful products.

Employing a dual approach, we will first **empirically analyze** existing crypto projects to quantify the shortcomings of current models. Second, leveraging **mechanism design and game theory**, we will **develop and theoretically validate** these new value-centric tokenomic frameworks.

58 - Critical Configurations: Unraveling the Emergence of Outlier Technology Entrepreneurship in Crowdfunding

Xuanye Li, New Mexico Institute of Mining and Technology, Socorro, NM, United States, Christopher Crawford

Outlier technology entrepreneurship (TE) represents an extraordinary yet underexplored phenomenon within the broader study of superstar entrepreneurial success. This study examines the critical configurations of endowments and engagement that drive outlier outcomes in reward-based crowdfunding.

A robust dataset of 39,908 observations from 2014 to 2022, scraped from the population of Kickstarter.com campaigns, serves as the empirical foundation for this research. To uncover the generative mechanisms of outlier outcomes, we utilize three analytical methods, including fuzzy-set qualitative comparative analysis (fsQCA), Machine Learning—Word Embedding Models, and the analysis of heavy-tailed distributions.

Among the five significant findings, campaigns that receive a platform endorsement (i.e., identified by Kickstarter as 'Projects We Love') and post frequent interactions with backers via frequently asked questions (FAQs) emerged as key drivers of outlier success. We explicate the four other critical configurations that lead to outlier funding outcomes in the findings section.

Our findings reveal distinct configurations of factors for prioritizing resource accumulation that significantly enhance the likelihood of achieving exceptional funding success, offering actionable insights for entrepreneurs, and extending the theoretical understanding of outlier dynamics in entrepreneurial ecosystems.

59 - Adaptive Intelligence in Service Operations: Reinforcement Learning vs. Traditional Staffing Heuristics

Shenghan Xu, University of Idaho, Moscow, ID, United States

Effective service operation staffing is critical in managing fluctuating demand and ensuring high service quality, particularly in call centers. Traditional staffing strategies—**level, chase, and mixed approaches**—are widely adopted due to their simplicity and compatibility with spreadsheet-based planning tools. However, these rule-based heuristics may fail to adapt dynamically to real-time and nonlinear demand patterns, leading to suboptimal performance.

This study examines the application of **reinforcement learning (RL)** as a data-driven approach to staffing decision-making in service operations. Using two years of call center operational data, we evaluate the performance of RL-based staffing policies against conventional level, chase, and mix strategies. The RL model is trained to optimize staffing decisions by learning from historical call volume patterns and agent performance metrics, with the objective of minimizing cost while maintaining service level targets.

To ensure practical relevance, we develop an **Excel-based simulation framework** to emulate call arrival processes, agent availability, and customer service levels under each strategy. We further demonstrate how RL policies can be approximated and operationalized in Excel using rule extraction and scenario mapping, bridging the gap between advanced AI techniques and managerial implementation tools.

Results indicate that RL-based staffing consistently outperforms traditional heuristics across multiple demand scenarios, especially under high-variance or peak-load conditions. Moreover, we highlight a feasible pathway to integrate RL insights into existing Excel-based planning systems, providing a scalable solution for service operations that seek to leverage AI without overhauling their legacy infrastructure.

60 - Beyond Binary Classification: a Comprehensive Multi-Criteria Assessment System for Programming Assignments

Dan O'Leary, Auburn University, Auburn, AL, United States

The effective assessment of coding assignments presents several pedagogical and practical challenges. Traditional automated assessment systems reduce various educational objectives into a binary classification problem. The result fails to assess implementation quality and lacks actionable feedback, both essential to improving learning outcomes.

We present a hybrid system addressing the fundamental trade-off between assessment throughput and educational quality control. By integrating code execution tests with structured LLM analysis, it enables multi-criteria evaluation while improving operational efficiency. Declarative rubric statements designed for True/False evaluation focus on implementation logic and structural requirements, while correctness is verified through output comparisons and unit tests. A threshold-based scoring mechanism requires submissions meet minimum competence requirements to receive partial credit, enforcing learning outcomes with more nuance than any binary approach.

The framework automatically flags submissions for human review when confidence is low or anti-patterns are detected. This separation of concerns positions the LLM as a structured, rubric-aligned evaluation assistant rather than an open-ended judge, preserving human control over educational standards.

Empirical validation using nearly 1,000 programming submissions demonstrates significant improvements in assessment consistency, depth of feedback, and grading efficiency. Students receive detailed, actionable feedback covering both correctness and implementation improvements, even when code execution fails.

While developed for introductory Python courses, the framework is readily extensible within software engineering education by adjusting the number, granularity, and abstraction level of rubric items. Moreover, this approach shows broader promise for assessment applications that are similarly concrete and rule-governed, in domains where systematic criteria can be clearly defined.

61 - Linear Transformers as Vector Autoregressive Models

Jiecheng Lu, Georgia Institute of Technology, Atlanta, GA, United States, Shihao Yang

Autoregressive attention-based time series forecasting (TSF) has gained growing attention, with mechanisms such as linear attention sometimes outperforming standard attention. However, deeper Transformer architectures often conflict with autoregressive objectives, obscuring the vector autoregressive (VAR) structure inherent in linear attention and limiting their ability to model the underlying data-generating processes. In this work, we first demonstrate that a single linear attention layer can be interpreted as a dynamic VAR model. We then show that classic multi-layer Transformers introduce structural mismatches that reduce both interpretability and generalization. To overcome this, we propose a rearranged architecture, modifying the order of MLPs, attention modules, and data input, that allows multi-layer linear attention to align with a VAR structure. Building on this insight, we introduce Structural Aligned Mixture of VAR (SAMoVAR), a linear Transformer variant that incorporates interpretable, dynamic VAR weights for multivariate TSF. By structurally aligning the model with autoregressive objectives, SAMoVAR achieves superior performance, interpretability, and computational efficiency compared to state-of-the-art TSF methods.

62 - Disclosing AI, Questioning Authenticity: How Transparency Shapes the Value of AI-Generated Professional Work

Angel Hsing-Chi Hwang, University of Southern California, Los Angeles, CA, United States

This work presents two series of studies that examine how knowledge workers and their audiences perceive AI-generated content and how these perceptions shape professional outcomes. In the first series, we invited professional writers to use AI-assisted tools in their writing process and reflect on their experiences. Writers generally reported that their AI-assisted work still felt authentic. However, they expressed concern that clients or audiences might devalue their output upon learning that it contained AI-generated content. We analyzed data from 9,149 freelancers across two major online platforms to understand this tension. We found that disclosing AI use had divergent effects across domains: in creative fields, disclosure was associated with lower pay, while in non-creative fields, such disclosure correlated with higher compensation, suggesting that AI was seen as a value-add in most domains but a threat in creative ones. We also observed that freelancers who disclosed AI use were often novices with limited platform experience. To further investigate how disclosure interacts with the reputation of workers, we ran online experiments using synthetic freelancer profiles that varied by disclosure and popularity. Results showed that participants strongly preferred hiring popular freelancers regardless of AI disclosure; for less popular freelancers, disclosing AI use significantly reduced their likelihood of being hired. Together, these findings highlight the complex, context-dependent nature of AI disclosure and raise critical questions for designing transparent yet equitable systems for AI-mediated work.

63 - Do You Reason like Me? Evaluating Chain-of-Thought Alignment with Linguistic Personas in LLMs

Kezia Oketch, University of Notre Dame, South Bend, IN, United States

Chain-of-thought (CoT) prompting has emerged as a powerful method for eliciting structured reasoning from large language models (LLMs). Yet little is known about whether these reasoning paths align with users' sociolinguistic identities, particularly in multilingual, low-resource settings. This paper investigates whether persona-aware prompting can improve both the accuracy and epistemic quality of LLM-generated CoT explanations.

Using a Swahili-language dataset of 2,170 free-text health responses annotated with demographic and linguistic features, we define speaker personas based on *Sheng* (urban vernacular) usage, tribal lexicons, code-mixing, and loanwords. We prompt three instruction-tuned LLMs (GPT-4o, Llama 4-Scout, Qwen3-32B) to score each response and generate an accompanying explanation under five conditions: (1) no CoT (score-only), (2) standard CoT, (3) persona-tuned CoT, (4) misaligned CoT (incorrect persona cues), and (5) few-shot persona-primed CoT.

We evaluate performance using Δ Score (Human – LLM), and introduce a multi-layered analysis of CoT explanations, assessing semantic relevance, hallucination rates, tone appropriateness, and stylistic alignment with each persona. Our results reveal that persona-tuned prompting improves alignment for marginalized linguistic profiles and yields explanations that are more culturally respectful and contextually grounded. However, these benefits vary by model and task (trust in doctor, numeracy, subjective literacy, and anxiety visiting a doctor), and misaligned prompts can degrade reasoning quality or amplify stereotypes.

This study contributes a new fairness diagnostic at the reasoning level and offers persona-aware prompting as a lightweight, deployable strategy to enhance epistemic inclusion and cultural sensitivity in LLM explanations.

64 - Determining the Optimal Material Cost Threshold and Its Corresponding Time for Battery Plant Investment

K Jo Min, Iowa State University, Ames, IA, United States, Olivia Bujak, Eli Sallis, Gazi Nazia Nur, Mohammad Ahnaf Sadat, John Jackman

Due to substantial increases in electric vehicle (EV) demand, when to invest in battery plants for EV's has become an economically critical and much strategic business decision. A key reason that such decision-making is challenging is that the costs of the essential materials such as Lithium and Nickel are highly volatile over time. Under

these circumstances, we investigate how the optimal material cost threshold and its corresponding time for the battery plant investment can be determined based on a class of stochastic optimal controls with geometric Brownian motion processes representing the price evolution of Lithium or Nickel. By solving resulting second order stochastic differential equations, we demonstrate the optimal timing of such investment decisions and the value of the corresponding option to invest. Through a combination of empirical and simulated data, we provide numerical examples in the context of cost fluctuations of Lithium or Nickel. Economic implications and managerial insights are also presented.

65 - Analysis and Discussion of the Wga Strike of 2023

Lara Inci Kullu, Georgia Tech , Atlanta, GA, United States

In this paper, we study the Writers Guild of America strike of 2023. Writers are critical suppliers of the entertainment industry, which is a major service industry in the U.S. The strike affected not just the movie and television studios, but also the whole economies of California, Georgia, and New Mexico, placing the economic cost at more than 6 billion dollars. We look at the problem with analytical tools from labor economics and discuss equitable solutions for the industry as a whole and future research directions.

66 - Scale-Aware Mosaic Games for Multi-Level Strategic Risk and Resilience Design

Quanyan Zhu, New York University, New York, NY, United States

Evaluating strategic risks in large-scale complex systems poses significant challenges due to expansive attack surfaces, evolving threat models, and intricate interdependencies. Traditional risk assessment techniques often fail to scale or adapt effectively in the face of such complexity. Game theory offers a rigorous foundation for modeling adversarial behavior, enabling analysts to anticipate and mitigate threats through equilibrium concepts and incentive-aligned strategies. Yet, applying these tools directly to high-dimensional systems, such as cybersecurity infrastructures or interdependent critical infrastructures, frequently encounters computational and representational bottlenecks.

This talk introduces Mosaic Games, a multi-resolution dynamic game framework designed to overcome these limitations. Mosaic Games enable analysts to dynamically “zoom in” to examine local subsystems with fine-grained precision, or “zoom out” to evaluate global, systemic interactions. The framework supports hierarchical modeling, composability, and modular computation, facilitating scalable learning and real-time strategic adaptation. It provides a principled means to bridge local agent behavior and emergent global phenomena within a unified strategic architecture.

We illustrate this framework through its application to cybersecurity risk assessment, demonstrating how Mosaic Games facilitate both threat quantification and the design of resilient network architectures. Moreover, this approach generalizes to other domains characterized by nested or distributed decision-making, and it offers novel tools to capture systemic risks, where small perturbations yield cascading failures, and holonic risks arising from interactions among layered subsystems. By integrating granular and panoramic views of strategic behavior, Mosaic Games offer a compelling new lens for understanding and managing risk in today's adversarial, interconnected environments.

67 - Federated Short-Run Process Monitoring

Alina Gorbunova, Georgia Institute of Technology, Atlanta, GA, United States, Zihan Zhang, Kamran Paynabar

Short-run productions are common in manufacturing systems which require customization and flexibility under limited demand and resources. However, traditional statistical process control charts cannot handle such scenarios, since they either ask for data transformation or have strict assumptions which misalign with real-world applications. To address these limitations, we propose a federated framework to collect process parameters across multiple distributed product lines and create process monitoring baseline models for each line. Specifically, a Gaussian Mixture Model uses the gathered local information to estimate each line's parameters at the global server. By running the clustering algorithm, local sites receive the process parameters. Next, we personalize the local model based on the random effect model. Finally, we validate the model by using simulations and a case study.

68 - Graph Network-Based Transmission Line Screening for the Unit Commitment Problem

Farhan Hyder, Rochester Institute of Technology, Rochester, NY, United States

Solving the transmission-constrained unit commitment (TC-UC) problem efficiently for high quality solutions is one of the biggest challenges faced by independent system operators today. One way to achieve this is by removing superfluous network constraints from the problem. Several approaches have been used to identify such constraints. However, these methods are either too conservative or fail to maintain solution feasibility. In this work, a graph network-based approach is developed to identify the subset of transmission lines that can be safely removed from the TCUC problem. The idea is to capture the spatiotemporal relationship between past line loading levels, nodal demands, and future line loading levels to identify superfluous network constraints. To achieve this, a novel regression-based classification approach is developed, where the regression model is used to predict line loading levels, and different thresholds are applied to classify transmission line capacity constraints as necessary or not for the TC-UC problem. In addition, different classification thresholds are applied for peak and off-peak hours. The major advantage of this approach is that once trained, the model can be used under different classification thresholds. Numerical results on the RTS-96 and the Polish-2383 bus systems show that the proposed approach significantly improves computational efficiency without compromising the solution quality.

69 - Acquire, Build, OR Partner? An Agent-Based Framework to Facilitate Decision-Making on Companies Entry Strategies to Incorporate a Disruptive Technology in Current Operations

Yingzheng Liu, University of Virginia, Charlottesville, VA, United States, Zhen Liu, Shun Cao

Decision-making regarding the adoption of new technologies has become increasingly challenging. For example, a recent literature review finds that 70% of digital transformation projects ultimately fail to meet their goals, resulting in wasting trillions of dollars in global investment. Although firms must evaluate strategic options—internal development, acquisition, and partnership—when disruptive technologies arise, existing decision-support tools often overlook the dynamic interplay between legacy and emerging markets under conditions of high uncertainty and frequently require extensive data to yield actionable insights, limiting their real-world applicability. The model does not only capture interactions between a legacy market (the industry in which the firm is well-established) and a emerging market (the industry the firm is considering) by integrating firm-level attributes such as technological capability, adaptability, market-share dynamics, investment behavior etc., but also captures interactions including competition and cooperation within markets. Simulation results demonstrate the framework's effectiveness in replicating real-world firm behaviors and reveal behaviors such as how market volatility and resource endowments shape optimal entry strategies: high uncertainty conditions favors partnerships, whereas stable or low uncertainty conditions support internal development. Acquisition is also shown to be a versatile strategy across both high- and low-uncertainty environments. More interesting behaviors are to be explored since the model is designed to allow users to calibrate parameters to ensure replicability. This tool has the potential to empower decision-makers and policy-makers across different functional sectors to systematically anticipate market evolution and evaluate entry strategies, and ultimately make informed decisions with the help of enhanced strategic foresight.

70 - Modeling Port-Centric Supply Chain Disruptions: Lessons from the Francis Scott Key Bridge Collapse

Ziping Wang, Morgan State University, Baltimore, MD, United States, Di Yang, Qiannong Gu

The sudden collapse of the Francis Scott Key Bridge on the I-695 Baltimore Beltway in March 2024 presents an unprecedented disruption scenario, as it simultaneously severed a major regional transportation artery and obstructed maritime access to the Port of Baltimore, a vital international logistics hub. This event offers a rare and impactful opportunity to examine the cascading effects of critical infrastructure failure on multimodal supply chains.

This research investigates the collapse as a case study to model supply chain disruption dynamics at both the port operations level and across the broader logistics network. We develop analytical models to assess how logistics systems adapt in the face of compound transportation interruptions. Key objectives include predicting

response patterns, quantifying resilience gaps, and identifying mitigation strategies to enhance future disaster preparedness.

The findings of this study are intended to provide actionable insights for port authorities, logistics organizations, and policymakers in the development of more resilient and adaptable supply chain systems capable of withstanding rare yet high-impact disruptions. The research contributes to the growing discourse on infrastructure resilience and port-centric risk management.

71 - Supporting EV Tourism Trips Through Intermediate and Destination Charging: A Case Study of Lake Michigan Circuit

Sajjad Vosoughinia, Michigan State University, East Lansing, MI, United States, Amirali Soltanpour, Alireza Rostami, Mehrnaz Ghamami, Ali Zockaie

This research proposes a comprehensive framework for optimizing Electric Vehicle (EV) charging infrastructure along the Lake Michigan Circuit (LMC) to support ecotourism, incorporating both destination-based slow charging and corridor-based fast charging. The framework identifies the optimal locations and capacities of Level 2 chargers at key tourist destinations, as well as Direct Current Fast Chargers (DCFCs) along major travel corridors. Infrastructure planning is evaluated based on two primary objectives: (1) minimizing overall charging infrastructure costs, and (2) minimizing user inconvenience. It also identifies the most cost-effective allocation of a given budget between Level 2 and DCFC installations under different budget limits. By integrating the Level 2 and DCFC networks, the framework reallocates any unserved Level 2 demand at destinations to nearby DCFC stations while remaining within budget constraints. To address the optimization problem, the study employs Simulated Annealing (SA) and the Nondominated Sorting Genetic Algorithm II (NSGA-II), comparing their performance and solution efficiency. The case study focuses on two states along the LMC, Wisconsin and Michigan, and compares their results in terms of regional travel behavior and charging demand patterns. The results demonstrate that the proposed interconnected infrastructure meets EV demand across the LMC region under various budget scenarios. Overall, the findings highlight the importance of balancing investment between Level 2 and DCFC chargers to achieve optimal infrastructure outcomes. This balanced strategy supports EV adoption and ecotourism by ensuring reliable and accessible charging options, while also offering a foundation for future research on dynamic planning and broader regional applications.

72 - Integrating Structured and Unstructured Data to Estimate Baseline Status After Stroke: a Hybrid Machine Learning Model Enhanced by Language Models

Chung-Kai Chou, Hofstra University, Hempstead, NY, United States, Amir Gandomi, Bo Yang, Joseph Ohara, Jeffrey Katz, Jason Wang, Maria Sanmartin, Pina Sanelli

Accurately estimating a patient's baseline functional status at the time of stroke admission is critical for retrospective research and for risk adjustment in outcome prediction models. The modified Rankin Scale (mRS), a standardized measure of functional disability, is commonly used for this purpose. However, mRS scores are often missing or inconsistently documented in structured electronic health records (EHRs). This study presents a hybrid machine learning model designed to estimate baseline mRS scores by integrating structured EHR data with unstructured clinical text.

To address incomplete or missing data, we apply large language models (LLMs) to extract and impute mRS-related information from free-text clinical notes. Thus, LLMs are not used for prediction but serve as data augmentation tools, supporting missing data imputation and feature enrichment. This enables the creation of a high-quality dataset for supervised learning.

The final hybrid model combines structured variables with BERT-encoded clinical narratives and achieves significantly improved performance. Compared to structured-only models, the hybrid approach increases mRS classification accuracy from 80.2 percent to 94.5 percent using a random forest classifier.

This study shows how LLMs can enhance clinical datasets and support robust modeling of baseline functional status in stroke patients. The proposed framework offers a scalable solution for improving predictive performance in healthcare applications involving both structured and unstructured data.

73 - Contract-Based Multi-Agent Deep Reinforcement Learning for Integrated Timber Supply and Carbon Offset Management

Sorna Javadi, Department of Industrial and Systems Engineering, Mississippi State University, Starkville, MS, United States, Mohamad Dehghan Bonari, Bruno Kanieski Da Silva, Mohammad Marufuzzaman, Shaun Tanger

The coexistence of timber harvesting and forest-based carbon offset programs presents a growing challenge for managing supply chain decisions across multiple parties with conflicting objectives. Hence, this study investigates a competitive timber supply chain involving forest landowners, a wood-consuming mill, and a carbon aggregator. Modeled as a decentralized approach, each party in this supply chain aims to optimize its own objective without considering others' benefits. The landowners set stumpage price offers for their timber stands to maximize their land expectation values, while the mill plans to minimize its operating costs by purchasing from eligible landowners (i.e., only landowners with mature stands are selected). Meanwhile, the carbon aggregator offers carbon credit contracts to the landowners targeted by the mill, convincing them to defer harvesting to meet a carbon sequestration objective. Moreover, we extend this model by introducing a reservation-based option contract between the mill and landowners, modeled as a Stackelberg leader-follower game (mill as leader, landowners as followers). Under this contract, the mill pays an upfront premium for the right to buy timber at a predetermined future price, securing future supply. Landowners decide whether to accept the option by comparing the option-enhanced value of their forest (the immediate payment plus guaranteed future price) against potential future market returns or carbon payments. Both proposed models are solved and compared using a Multi-Agent Deep Reinforcement Learning (MADRL) framework, where each agent can learn a policy to optimize their long-term objectives.

74 - Dynamic Parking Pricing and Curb Space Allocation for Enhanced Urban Mobility Using Bayesian Optimization Approach

Prakash Ranjan, University of Connecticut, Storrs, CT, United States, Fatemeh Fakhroosavi, Krishna Murthy Gurumurthy, Abdelrahman Ismael, Nazmul Khan

Parking scarcity in downtown areas presents a major challenge for commuters seeking convenient spaces near their destinations. This study proposes a dynamic pricing optimization framework for garage parking in downtown Chicago, aiming to balance the often-conflicting objectives of parking authorities (i.e., maximizing revenue) and users (i.e., ensuring affordability especially relative to other choices). The framework incorporates a minimum occupancy constraint to promote efficient resource utilization while dynamically adjusting prices based on temporal demand variations. We employed simulated data from POLARIS activity-based transportation simulator, within a Bayesian optimization framework to determine optimal garage prices for both peak and off-peak periods. These optimized prices were then reintroduced into POLARIS to evaluate key performance metrics, including temporal and spatial demand distribution, occupancy rates, and revenue over a 24-hour period. The results show that reducing off-peak prices significantly increased demand by making garage parking more attractive and accessible, while higher peak-hour prices effectively aligned user demand with available capacity. The proposed approach improved peak-hour occupancy from approximately 70% to over 90% and increased overall utilization with a marginal reduction in revenue, demonstrating the effectiveness of the pricing strategy. Additionally, this study highlights the influence of allocating a portion of parking spaces to reserved users or specific vehicle types in enhancing curb space management and guiding travelers' parking choices. The findings support policy formulation aimed at reducing cruising behavior and alleviating traffic congestion, contributing to a more sustainable urban environment where parking is both accessible and affordable for a broader range of users.

75 - A Robust Approach to the Fleet Composition Problem with Truckload and Less-than-Truckload Shipping Options

Jiazheng Ling, The University of Arizona, Tucson, AZ, United States, Yue Wang

We investigate a two-stage robust optimization framework for the fleet composition problem under uncertain demand for multiple products, which integrates both dedicated truckload (TL) and supplemental less-than-truck (LTL) shipping options, with the objective of minimizing total costs. In the first stage, the model determines the composition of a dedicated fleet from a set of vehicle types with heterogeneous capacity, fixed costs, and dispatching costs, prior to any demand realization. In the second stage, once the demand is realized, the model optimizes dispatching strategies using a mix of TL and LTL services. To manage the complexity arising from the demand uncertainty, we approximate the problem by adopting its associated K-adaptability formulation, which partitions the uncertainty set into K subsets and identifies the best dispatching strategy for each subset. To solve the K-adaptability problem, we implement a scenario-based branch-and-bound algorithm that recursively solves a sequence of relaxed problems and identifies violating scenarios through a separation problem, branching when necessary to iteratively refine the solution. Our numerical

experiments demonstrate the effectiveness of this method in solving the fleet composition problem. Results from a comprehensive parametric analysis provide valuable managerial insights into the trade-offs among fleet investment, service flexibility, and robustness to demand variability.

76 - Waste-to-Energy Solutions in the Indonesian Energy System: Comparing Net-Zero CO₂ Alternatives in Electric Power Generation

Qoriatul Fitriyah, North Carolina State University, Raleigh, NC, United States, Matteo Nicoli, Ranji Ranjithan, Anderson de Queiroz

As one of the largest CO₂ emitters in the world (532 MtCO₂ in 2020), Indonesia ratified the Paris Agreement to reach zero CO₂ by 2050. In this work, we evaluate options to achieve zero CO₂ emissions in the country by 2050 in the power generation sector. We use Tools for Energy Modeling Optimization and Analysis (TEMOA) to explore four scenarios: Business as Usual (BaU), Net Zero (NZ), Net Zero with Waste-to-Energy (NZ+W) scenario, and Net Zero with WTE and Solar (NZ+W+S). The BaU scenario has the lowest cost (\$50.7 billion) but fails to eliminate CO₂ emissions at 451 Mt in 2050. The NZ scenario achieves zero CO₂ emissions by 2050 at a cost 13.4% higher than BaU. The NZ+W and NZ+W+S scenarios achieve zero CO₂ by 2050 at a higher cost (16.9% and 20.5% above NZ, respectively). However, NZ+W provides early emissions reductions and addresses Indonesia's 27.6 Mt annual waste problem by eliminating open pits, while NZ+W+S helps the government increase the renewable share. Our findings suggest that Indonesia can combine renewables and WTE to achieve zero CO₂ by utilizing combustible waste that would otherwise be disposed of in open pits.

77 - Short-Term Forecasting of Residential Energy Demand Using Machine Learning and Transformer-Based Deep Learning Models

Mohammad Hzayen, Binghamton University, Vestal, NY, United States, Yong Wang

The precise prediction of electricity demand is essential for maintaining stable power systems while enhancing their operational efficiency and sustainability. ARIMA and SARIMA models have gained popularity because they are straightforward to understand and require minimal computational power. Yet, they fail to effectively model the non-linear and seasonal patterns of real-world energy systems. Modern machine learning and deep learning techniques have developed stronger models that detect intricate time-based patterns while integrating weather data for prediction purposes.

This research compares various forecasting approaches, including Random Forest, XGBoost, and LightGBM from the ML family, as well as Long Short-Term Memory and Transformer architectures from DL. Real-world electricity load datasets are enriched by adding weather data variables and engineered temporal variables including lag terms, rolling averages, and time-based encodings.

The evaluation uses RMSE, MAE, MSE, MAPE, sMAPE, and R^2 as standard metrics for assessment. The results show that XGBoost and Transformer outperform other models in long-horizon and capturing high-variability.

This research develops a flexible and scalable forecasting framework incorporating weather data and time-aware modeling to enhance prediction accuracy. The study provides practical applications for grid planning, demand-side management, and renewable energy integration.

78 - Temporal Decomposition and Sensitivity-Driven Optimization of Stochastic Power System Capacity Expansion Using Distributed Computing

Keith Holliday, Michigan Technological University, Longmont, CO, United States, Ana Dyreson

Temporal Decomposition and Sensitivity-Driven Optimization of Stochastic Power System Capacity Expansion Using Distributed Computing

Solving high-resolution capacity expansion problems (CEPs) under deep uncertainty remains computationally intensive due to the scale and complexity of modeling long-term operations across multiple scenarios. This work proposes a scalable solution framework that combines scenario decomposition with temporal decomposition to improve tractability and parallel efficiency.

We begin with a sensitivity analysis to identify dominant sources of computational bottlenecks, revealing that storage dynamics, renewable portfolio standards (RPS) constraints, and inter-temporal linkages significantly impact solve time. Motivated by these findings, we extend the Progressive Hedging Algorithm (PHA) with a novel, cloud-based, distributed dual-axis decomposition strategy, where subproblems are partitioned by scenario and time blocks—enabling finer-grained parallelization.

Using a custom implementation built on Dask's distributed framework, we orchestrate concurrent solutions of scenario-time subproblems while preserving global feasibility through augmented coordination steps. Empirical results on the California Test System (CATS) test system and a modified CEP model demonstrate that this approach offers a favorable trade-off between reduced wall-clock time and minimal optimization loss compared to traditional scenario-only decomposition.

This work highlights the practical benefits of sensitivity-driven reformulation and distributed temporal decomposition in stochastic optimization for energy planning. Our findings support the broader adoption of dual decomposition approaches in high-performance cloud computing environments and lay the foundation for future extensions involving asynchronous coordination and adaptive decomposition schemes.

79 - Enhancing Last Mile Delivery Through Network-Aware Clustering

Wenda Zhang, ESRI, Redland, CA, United States, Mingdong Lyu, Heather Moe, WeeLiang Heng, Mingyi He

Last mile delivery is a critical and costly component of logistics, often hindered by urban congestion, geographic obstacles, and strict delivery schedules. Conventional clustering methods, such as k-means, rely on geometric proximity and neglect the complexities of real-world transportation networks, leading to inefficient routing. This study evaluates a network-aware clustering approach using the ArcGIS Pro Last Mile Delivery Solver, which incorporates actual road networks, travel times, and operational constraints. Comparative analyses demonstrate that network-based clustering significantly improves route compactness, reduces travel time and distance, and minimizes constraint violations. Additionally, it enhances route balance and fairness, addressing common issues such as fragmented service areas and overlooked geographic barriers. Through spatial analyses including Thiessen polygons, we show that clustering is not merely a preprocessing step but a strategic component that shapes route quality and operational performance. Our findings advocate for a shift from traditional geometric heuristics to GIS-informed clustering for more realistic and equitable logistics planning.

80 - Hallar: a New Low-Rank Solver for Solving Huge SDPs: Theory and Computation

Arnesh Sujanani, University of Waterloo, Atlanta, GA, United States, Renato D C Monteiro, Diego Cifuentes

This talk presents a new first-order method, HALLaR, for solving large-scale semidefinite programs (SDPs) with bounded domain. It is an inexact augmented Lagrangian (AL) method where the AL subproblems are solved by a hybrid low-rank method. In contrast to the classical low-rank method, the new method finds a near-optimal solution (with provable complexity bounds) of SDP instances satisfying strong duality.

The main computational workhouse of HALLaR is sparse matrix-vector multiplications, making it especially suitable for solving large-scale SDPs and GPU programming. Computational results comparing HALLaR to state-of-the-art CPU-based solvers on several large SDP instances show that the former finds higher accurate solutions in substantially less CPU time than the latter ones. For example, in less than 20 minutes, our method can solve, on the CPU of a personal laptop, a maximum stable set SDP with 1 million vertices and 10 million edges within $1e-5$ relative accuracy. Finally, we also briefly discuss that the GPU version of HALLaR is even faster than the CPU version, often achieving speedups of 50 to 100 times.

81 - Using Machine Learning Models to Understand the Factors Affecting Individuals Mode Choice for Health Care Visit

Md Sami Hasnine, Virginia Tech, Blacksburg, VA, United States, Tasnim Abbasi, Xiaomin Chen

Transportation systems, including healthcare facilities, are crucial in individuals' access to fundamental needs. Lack of transportation access is often a significant obstacle when visiting a doctor for scheduled appointments or when urgent care is needed. Public transportation accessibility is limited in many rural communities in the USA, where driving or ride-hailing is the only available option. There is a lack of studies which looked at how access to transportation choices impact individuals' access to healthcare facilities. To address this gap, this study developed various machine learning models (i.e., Random Forest, XGBoost, etc.) and AI models (i.e., Neural Network) to understand which factors impact the mode choice decision during their health care visits. This study uses the National Household Level Travel Survey (NHTS) 2022, the largest national household-level survey in the USA. Using this rich dataset, we particularly looked at individuals whose went for medical or dental care facilities and the modes for those visits. The model results show that individuals' access to cars, number of members in the household, income, home location, and a few land-use factors affect individuals' choice of mode while visiting medical or dental facilities. The model result suggests that subsidized transportation services should be available for low-income individuals to visit their healthcare facilities even if they do not have access to private cars. The findings have significant implications for making our transportation and healthcare systems more affordable and accessible.

82 - A Quantum Inspired Bilevel Optimization Framework for Bus Route Accessibility Improvement Using QAOA

Daniel Udekwe, Florida State University, Tallahassee, FL, United States

As quantum computing transitions from theory to application, its ability to address complex optimization challenges has attracted significant attention. In transportation planning, classical algorithms often struggle with the combinatorial complexity of large-scale problems, particularly in contexts like bilevel optimization, where strategic and operational decisions interact hierarchically. Hybrid quantum-classical algorithms, such as the Quantum Approximate Optimization Algorithm (QAOA), offer a promising alternative.

This study introduces a hybrid optimization framework that integrates QAOA into a bilevel model for bus route planning aimed at improving accessibility for seniors. The upper-level model (ULM), solved using a classical optimizer, minimizes average walking distances for residents in age-restricted communities. The lower-level model (LLM), responsible for optimizing route structure under practical constraints, is reformulated as a Quadratic Unconstrained Binary Optimization (QUBO) problem and solved using QAOA via IBM Qiskit.

Simulations on a grid-based scenario demonstrate that the quantum-enhanced approach can identify new stop placements that bring all target communities within a 400-meter walking radius, while keeping total route length within acceptable limits. This confirms the potential of QAOA to effectively handle combinatorial subproblems that are otherwise computationally intensive for classical methods.

By embedding quantum algorithms within a classical planning framework, this work advances scalable, equity-aware urban transit design. It showcases the feasibility of applying quantum techniques to real-world infrastructure challenges, offering a template for future integration of quantum computing into smart city planning.

83 - Nash Equilibrium of Codeshare Strategy and Flight Frequency Optimization in Airline Alliances

Ko-Wen Lin, National Tsing Hua University, Hsinchu, Taiwan, Yu-Ching Lee, Chun-Han Wang

This study develops a nonlinear optimization model to jointly determine codeshare cooperation levels and flight frequency decisions among airlines in an alliance. The model accounts for market demand, seat capacity, airport slot constraints, load factors, and revenue-sharing mechanisms between marketing and operating airlines. To capture strategic interactions in a competitive market, equilibrium outcomes are derived using Karush-Kuhn-Tucker (KKT) conditions within a Nash equilibrium framework. The objective is to maximize total alliance profit while balancing cooperation and competition among allied and non-allied carriers. Our results offer quantitative insights into partner selection, codeshare intensity, and frequency adjustments under shared operations. The model provides a theoretical foundation to support airline alliance decision-making and profit optimization, and can be extended in future work with numerical analysis or empirical validation.

84 - Network-Aware Contextual Bandits for Distributed Decision-Making

Chyun Deng, University of California, Berkeley, Berkeley, CA, United States, Huiwen Jia

We study dynamic decision-making in distributed environments and propose contextual bandit algorithms that leverage both inter-node similarities and heterogeneity to enable scalable learning. Motivated by multi-city pricing applications, we introduce two network-aware online learning algorithms: NetLinUCB, which maintains local parameter estimates and aggregates information via adaptive network weights, and Net-SGD-UCB, which performs local stochastic gradient updates and then constructs the confidence interval to perform uncertainty-aware exploration. Both methods decompose learning into global and local components. We establish theoretical regret bounds and show that our methods reduce the regret associated with the shared feature space from linear scaling in the number of cities $O(N)$ to sub-linear $O(\sqrt{N})$, significantly improving sample efficiency. We conduct extensive experiments and show that the proposed algorithms consistently outperform standard LinUCB, particularly in high-dimensional feature setting.

85 - Public Chargers for Electric Semis: a Bi-Level Optimization Approach

Mansimran Singh, University of Iowa, Iowa City, IA, United States

Electrifying long-haul freight hinges on deploying high-power chargers where fleets actually travel, yet most carriers cannot individually justify the capital or utilization risk of dedicated infrastructure. We model the required coordination as a bi-level principal-agent framework tailored to the I-10 corridor. In the upper level, a third-party developer (principal) selects candidate hub locations, sizes each site's charger array, and sets location-specific energy tariffs subject to contractual service guarantees on congestion and availability. In the lower level, multiple fleet operators (agents) solve continuous route-and-charge decisions that embed state-of-charge dynamics, heterogeneous values of time, and queueing-based waiting times. The principal's investment and pricing choices and the agents' operational responses are mutually dependent through congestion and energy demand, producing an optimization that links infrastructure decisions with day-to-day logistics behavior.

To navigate this coupling, we design an iterative bilevel decomposition: the principal's discrete-continuous planning problem is solved, holding congestion surrogates fixed; agents then independently update their optimal routing and charging strategies given the current hub design and prices; refined congestion estimates feed back to the principal stage, and the process repeats until decisions and congestion estimates stabilize. This approach preserves tractability while capturing the essential feedback loop among facility sizing, tariffs, and fleet routing.

The framework reveals how service-level guarantees, differentiated pricing, and modest charger utilizations can jointly align developer profitability with fleet welfare, thereby enabling coalition-based charging hubs without requiring each participant to bear full capital risk. Though calibrated to I-10, the model readily extends to broader corridor networks and evolving megawatt-scale technologies.

86 - Evaluating Discretization Effects in Bayesian Networks for Multi-Hazard Risk Assessment in Java, Indonesia

Himanshu Rana, NA, Kirkland, WA, United States, Rolf De By

Java, Indonesia is highly susceptible to multiple natural hazards, including earthquakes, volcanic eruptions, and tsunamis. These hazards often occur in interconnected sequences, forming disaster chains that significantly amplify environmental and societal impacts. Understanding the relationships among these hazards is essential for accurate risk assessment and mitigation. Hence, this study proposes a Bayesian Network (BN) based framework to model the probabilistic dependencies within these multi-hazard systems, with a focus on disaster chains involving volcanoes, earthquakes, and tsunamis. A key challenge in developing accurate BNs is the discretization of continuous geospatial and hazard data. While discretization is a common preprocessing step in BN modeling, it often leads to information loss, introducing bias into inference and decision-making. This study evaluates the influence of different discretization algorithms on model performance, which is frequently overlooked in environmental BN applications. The classification performance of the BN was assessed through Receiver Operating Characteristic (ROC) curve analysis, comparing discretization strategies to identify optimal methods for preserving data integrity. Additionally, spatial hazard mapping is conducted using ArcGIS to visualize the conditional hazard levels across the Java coastline. Results of the study demonstrate that the BN effectively captures the relationship of cascading hazards and that

discretization methods significantly influence predictive accuracy. The generated hazard maps reveal variable risk levels along the southern coastline, ranging from moderate to high. This study highlights the need for careful selection and documentation of discretization methods in BN-based hazard modeling to enhance reliability in disaster chain prediction and risk-informed decision-making.

87 - Automation and Robotics: the Future of the Warehouse

Cylia Blackmon, Kean University, Union, NJ, United States

Robotics and automation have revolutionized the way many supply chains and warehouses operate worldwide. They are increasing operational speed, decreasing order fulfillment time, and enhancing inventory management. This research explores the role of robotics and automation in warehousing and distribution, focusing on history, the variety of systems available, and associated advantages and disadvantages.

Automation dates back to the late 19th century with early innovations such as conveyor belts and barcode scanning, which optimized workflow. Modern advances in technology have companies considering automation's addition because of their ability to increase productivity as well as their high efficacy and efficiency. Modern systems such as autonomous guided vehicles (AGVs) and automated storage and retrieval systems (AS/RS) have been invented adopted. These findings suggest that by modernizing many of the repetitive and labor-intensive warehouse tasks, robots can assist in streamlining many processes, helping manage inventory, reducing associated costs, and delivering on consumer demand faster.

Even though automation has numerous advantages, including increased efficiency, higher profits, and continuous operation, it also has significant challenges. High initial costs, maintenance requirements, and the physical size of these systems often limit adoption, especially for smaller businesses. Additionally, the potential for job displacement concerns raises ethical issues about automation, prompting companies to consider retraining employees to include working with the new technology. Despite these challenges, automation is crucial in addressing warehouse labor shortages and meeting the increasing consumer demand. By understanding both the benefits and their associated challenges, organizations can make informed decisions about integrating robotics into their operations.

88 - The Unintended Consequence of Hawk-Eye Challenge

Shengshuo Xu, University of Science and Technology of China, Hefei, China, People's Republic of

The Hawk-Eye (HE) Challenge is widely adopted in sports when players dispute an umpire's call. Intuition suggests HE improves final call correctness by reviewing umpires' decisions, but this overlooks potential reputation loss for umpires when HE overrules their judgments. This study examines how HE influences umpires' strategic decisions, players' challenge behavior, and call correctness. Without HE, umpires prioritize maximizing correctness: those with high signal accuracy follow their received signals, while those with low accuracy rely on prior beliefs. With HE, umpires balance correctness gains against reputation loss from overruling. In this case, high-accuracy umpires still follow their signals despite possible HE overruling, but low-accuracy umpires may intentionally make decisions to trigger or avoid challenges, depending on reputation costs and players' challenge tendencies. Interestingly, we find HE can unintentionally lead relatively high-accuracy umpires to avoid challenges, undermining correctness compared to scenarios without HE. This work clarifies how interactions between umpire signal accuracy, reputation loss, and challenger signal accuracy affect game correctness—providing managerial insights for optimizing HE Challenge adoption in sports.

89 - A Stochastic and Equity-Aware Framework for Fare-Free Transit Zoning and Scheduling

Jiaqing Lu, Florida State University, Tallahassee, FL, United States, Qianwen Guo

This paper proposes the first analytical stochastic framework for optimizing the design and implementation of fare-free transit services. Focusing on a transportation corridor with two primary travel modes (auto and bus) the model divides the corridor into two sections: an inner zone offering fare-free transit and an outer zone maintaining a fare-based system. To capture the uncertainty in transit demand, a Geometric Brownian Motion process is used to represent the stochastic evolution of demand density, improving the model's realism. In the static model, we optimize the length and service frequency of the fare-free zone to maximize total social welfare. Results show that fare-free transit increases ridership, reduces automobile use, and enhances social equity. Joint consideration of social welfare and equity objectives leads to longer optimal fare-free zones than optimizing for social welfare alone. The dynamic model adopts a real options approach to address fare policy switching over time, offering closed-form solutions for optimal timing thresholds to activate or terminate fare-free service. These thresholds vary under social welfare-aware and equity-aware regimes and account for switching costs. Application to the Utah Transit Authority (UTA) Blue Line demonstrates that dynamic policies yield higher performance than static policies, with earlier implementation and longer fare-free periods under social welfare objectives.

90 - A Joint Design of Redundancy, Spares, and Trajectory for Permanent Lunar Habitats

Ahsanul Abedin, Texas State University, San Marcos, TX, United States, Tongdan Jin

Problem definition: This study addresses the challenge of designing sustainable lunar habitats by tackling two key questions: How can system reliability, spare parts, and spacecraft trajectory be co-optimized for deep-space habitation on the Moon? Is it feasible to minimize total launch mass while meeting stringent reliability and availability goals? **Practical relevance:** We present a novel Redundancy-Sparing-Trajectory Allocation (RSTA) model, integrating reliability optimization with space logistics theory. This integrated approach is crucial for space agencies and commercial entities aiming for cost-effective, sustainable lunar presence. **Methodology:** To address the combinatorial optimization, the RSTA model is solved in two phases: in Phase 1, allocating redundancy and spare parts for the lunar habitat's Environmental Control and Life Support System to minimize mass using two metaheuristic algorithms; in Phase 2, optimizing spacecraft trajectory, rocket staging, and propellant mass with Dijkstra's Algorithm to reduce launch mass in a cislunar network of 9 orbital nodes and 23 velocity changes.

Results: Experiments show strong interdependence between rocket staging, launch mass, mission duration, resupply lead time, and spacecraft trajectory. Longer missions favor spares inventory, and shorter durations prioritize component redundancy. A three-stage rocket design is optimal for balancing launch mass and cost effectiveness. High specific impulse propellants and optimized structural ratios significantly reduce launch mass. **Managerial implications:** The RSTA model represents an integrated approach for deep-space mission planning. It allows for building reliable, cost-effective lunar habitats by optimizing reliability-redundancy, spares stocking, and costly logistics. Future works can extend the model to interplanetary missions, including crewed flight to Mars.

91 - An Integrated Study of Data-Driven Thermal Modeling and Identification of Lithium-Ion Battery Packs

Saima Alam, University of Alabama in Huntsville, Huntsville, AL, United States, Rahul Bhadani

Accurate real-time temperature prediction is critical for ensuring the safety, longevity, and efficiency of lithium-ion battery (LIB), particularly under dynamic electric vehicle (EV) operations. Our work advances the electro-thermal modeling of LIBs by formulating a nonlinear state-space framework that captures cell-to-cell heat exchange, integrating a two-RC equivalent circuit model with polynomial approximations of heat generation based on state of charge (SOC). A comprehensive parameter identification pipeline is developed using experimental data from the open-source NASA battery dataset showing that unlike traditional approaches Neural ODEs not only predict the thermal behavior of LIBs from data, but also learn the underlying thermal dynamics, achieving sub-degree accuracy with RMSE as low as 0.007°C, and simultaneously identify parameters with high precision, reducing estimation error from 0.0052 to 0.0017 under constraints. Traditional approaches e.g. ordinary least squares (OLS) provides a fast, interpretable baseline through explicit weight coefficients, yet their linear nature cannot capture the battery's non-linear dynamics. Transformer models address part of this gap by modeling long-range temporal dependencies and lowering peak-temperature errors during high C-rate, but still treat the system as a black-box. In contrast, neuralODE offer high predictive power and dynamic interpretability, generating deeper insight into the thermal behavior and guaranteeing consistency with the governing physical laws. We demonstrate that neuralODE can uncover internal dynamics of the LIBS while maintaining a stable prediction of temperature over time. For application, these findings will be important moving forward for temperature management and tracking battery health through parameter estimation from the derived dynamic equations.

92 - Privacy-Preserving Automated Vulnerability Detection: Enhancing Organizational Security Through Federated Learning and Integrated Code Analysis

Ronia Arabian, University of South Florida, Tampa, FL, United States, Motahareh Pourbehzadi, Giti Javidi

Software vulnerability detection is crucial for safeguarding organizational assets and ensuring the reliability of complex systems. While recent advances in deep learning have shown promising results for automated vulnerability identification, many existing approaches overlook critical privacy and security concerns, particularly when leveraging data from multiple organizations. This research investigates privacy-preserving methods, specifically federated learning, that enable collaborative model training across organizations without sharing raw code data. By preserving data privacy, federated learning allows access to larger and more diverse datasets, addressing a significant barrier in vulnerability detection. Additionally, this research provides a comprehensive evaluation of various vulnerability detection techniques by analyzing source code, comments, and graph-based code representations to understand their individual and combined impacts on detection effectiveness. This study will also explore privacy challenges posed by potential adversarial attacks on federated frameworks and analyze defense mechanisms to enhance organizational software security. Through empirical evaluation on real-world datasets, this study aims to improve risk management strategies and advance privacy-aware vulnerability detection systems within enterprise environments.

93 - Appreciating the Complexity: A Systems Thinking Framework for Strategic Decision-Making and Performance Enhancement with Actionable Strategies that Align with the Organization's Operational Realities

Anwer Muhammad, Mount & peak media consultancy services LLC, Dubai, United Arab Emirates

The application of systems thinking in complex organizational environments, emphasizing the transition from soft systems methodologies to hard system modelling in real-world decision-making contexts. Soft systems thinking (SST), with its roots in interpretive paradigms, is crucial for navigating unstructured, human-centric problems involving multiple stakeholder perspectives and values. It enables appreciation, dialogue, and ideation in early problem definition stages. In contrast, hard systems thinking (HST) offers structured, quantitative approaches to model defined problems and optimize solutions through tools like simulation, system dynamics, and decision analytics. The integration of SST and HST fosters a bigger approach to change in a context of rich picture, where systems are not only modelled but deeply understood in their power and influence structures. Through this awareness, we used the methodology that supports iterative learning, adaptive change, and sustainable decision-making responses by breaking down actions into short- and long-term objectives. This concludes by examining how this continuum can guide enterprise transformation initiatives, enhance stakeholder engagement, and deliver Context-sensitive situation to solutions within complex, evolving ecosystems. Simulation modelling further enhances decision-making by providing dynamic foresight into complex systems, enabling organizations to align strategic objectives with operational realities.

94 - Risk Disclosure Premium in the Cross-Section of Stock Returns: a Generative Topic Modeling Approach

Beichen Zhang, Stevens Institute of Technology, Hoboken, NJ, United States, Shanshan Yang, Steve Yang

We examine the pricing implications of financial risk disclosures by applying generative topic modeling to Section 1A of 10-K risk factor filings for S&P 1500 firms from 2010 to 2023. Using embeddings from FinBERT, GTE-Qwen, and SFR-Mistral, we quantify firm-level exposure to specific risk narratives and compute corresponding risk scores. These scores are used to construct narrative-based risk factors through a two-step empirical asset pricing framework. First, we test the return predictiveness of these factors using the Fama-French 5 factor model via long-short portfolio sorts. Second, we implement Fama-MacBeth cross-sectional regressions to evaluate their risk premia alongside the standard market, size, value, profitability, and investment factors. Our results reveal a robust risk premium in operational risk disclosure - which remains statistically significant even after applying the Bonferroni correction for multiple tests. In addition, several other disclosure factors, such as funding risk, intellectual property risk, and infrastructure risk, also show some level of significance. These findings suggest that firm-disclosed forward-looking risks, as identified through generative embedding model on firm risk disclosures, offer economically meaningful and statistically robust insights into cross-sectional return variation.

95 - Volatility-Aware Deep Recurrent Neural Network: Integrated Garch-Gru

Jingyi Wei, Stevens Institute of Technology, Hoboken, NJ, United States, Steve Yang, Zhenyu Cui

We introduce a novel Volatility-Aware Deep Recurrent Neural Network for financial volatility modeling and forecasting. The model integrates the Generalized Autoregressive Conditional Heteroskedasticity (GARCH(1,1)) formulation directly into the Gated Recurrent Unit (GRU) architecture. It yields a unified recurrent unit, integrated GARCH-GRU, that jointly captures both traditional econometric properties and complex temporal dynamics. This hybrid structure leverages the strengths of GARCH in modeling 'stylized facts' of volatility, such as clustering and persistence, while utilizing the GRU's capacity to learn nonlinear dependencies from sequential data. Empirical evaluations across multiple financial datasets demonstrate that the integrated GARCH-GRU model consistently outperforms classical GARCH-type models, standard neural networks, and alternative hybrid architectures in terms of MSE and MAE. Compared to a GARCH-LSTM counterpart, the proposed model achieves average MSE reductions of 21.55%, 11.91%, and 23.85% for 1-day, 3-day, and 7-day ahead forecasts, respectively. Notably, the GARCH-GRU exhibits faster adaptation to sharp changes in realized volatility, resulting in more accurate real-time adaptation to volatility shocks. As a practical application, we compute daily Value-at-Risk (VaR) forecasts for the S&P 500 index and observe lower violation ratios, further validating the model's effectiveness in dynamic financial risk management.

96 - A Hierarchical Bayesian Modeling Approach to Predict Upper Extremities' Fatigue Using Wearable Sensors in A Dynamic Order-Picking Task

Setareh Kazemi Kheiri, University of Pittsburgh, Pittsburgh, PA, United States

Predicting upper extremities' fatigue in dynamic tasks is crucial for human reliability analysis and system safety in warehouses and distribution systems. New nonintrusive technologies, such as wearable sensors, can facilitate worker safety monitoring. This study proposes a hierarchical Bayesian modeling approach that incorporates random slopes, intercepts, and nonlinear terms to enhance prediction accuracy for upper extremities' fatigue. Data were collected from a laboratory experiment involving 14 participants who performed order picking tasks over four days under varying load and pace conditions. Inertial Measurement Unit sensors attached to the wrist, trunk, and upper arm recorded accelerometer and gyroscope signals. The proposed hierarchical model utilized task conditions, individual characteristics, and signal features, with prior distributions of parameters continuously updated over time with new observations. The results demonstrate that incorporating random effects alongside fixed effects significantly improves the prediction accuracy. Updating prior distributions over time reduced prediction errors for subjective fatigue indicators, thus supporting proactive interventions. Our approach enables more precise and individualized fatigue prediction in dynamic tasks, contributing to improved system safety in smart warehouses.

97 - Optimizing Distributed Bio-Based Chemical Production with Stochastic Modeling and Scenario Analysis

Motahareh Kashanian, Iowa State University, Ames, IA, United States, Sarah Ryan

This poster presents a stochastic optimization framework for designing distributed manufacturing systems for biomass-based chemicals powered by electrochemistry and renewable energy. To address key uncertainties, such as renewable energy availability, process productivity, and the social cost of carbon, we use a two-stage stochastic programming model to support investment and operational decisions under diverse future conditions.

Scenario generation plays a central role. Renewable energy output is modeled using location-specific solar and wind data from NREL's System Advisor Model (SAM). Process productivity is treated as a stochastic variable reflecting technological uncertainties, while carbon pricing scenarios are drawn from recent climate-economic models. These scenarios inform second-stage decisions such as electricity sourcing and facility utilization.

The model identifies robust supply chain configurations that balance cost and emissions under uncertainty. Compared to deterministic models, the stochastic approach results in more flexible infrastructure decisions and highlights the trade-offs between up-front capital investment and long-term operational adaptability.

This work demonstrates how scenario-based planning and stochastic modeling can improve the resilience and sustainability of distributed chemical manufacturing systems.

1 - Dynamic Watermarking for Cybersecurity of Closed- and Open-Architecture Machine Tool Controllers**Abhishek Hanchate, Texas A&M University, College Station, TX, United States, Satish Bukkapatnam**

Modern manufacturing systems are recognized as highly vulnerable to cybersecurity threats, with Machine Tool Controllers (MTCs) representing a key point of risk on the factory floor. Undetected cyber intrusions can jeopardize safety, disrupt productivity, and undermine system integrity. In response to these challenges, Dynamic Watermarking (DWM) has recently gained attention for its ability to provide provable security assurances across diverse domains such as energy systems and autonomous vehicles. This paper presents the first implementation of DWM tailored for manufacturing MTCs. The method is designed to detect cyberattacks in real-time, protecting MTCs from malicious interference while maintaining formal performance guarantees. Validation was conducted on both a proprietary (Siemens Sinumerik 828D emulator) and an open-source (Servo controller) control platform. Experimental results demonstrate that the DWM approach can reliably detect injection, replay, and flip attacks with an average latency of just 22 milliseconds, all while introducing less than 2 micrometers of deviation in the toolpath.

2 - Maintenance Modeling, Journey Control Charting, and Classification for Vulnerability and Blockchain Management**Theodore Allen, The Ohio State University, Main Campus, Columbus, OH, United States, Mohammad Abdullah, Vimal Buck, Zhizuo Chen**

We describe roles for security infrastructure relating to using a new type of "journey" control chart to monitor new cyber vulnerabilities and crumbs from blockchains. Also, we explore the roles of Markov Decision Processes in creating improved cyber-physical maintenance plans. Data from current systems is used to illustrate the methods.

3 - Stealth-Constrained Strategic Attack Generation in Integrated Cyber-Physical Systems via Reinforcement Learning**Navid Aftabi, University of Wisconsin-Madison, Madison, WI, United States**

Cyber-Physical Systems (CPS) are widely used in critical infrastructures and face cyberattacks that can inflict physical damage. In a CPS, attackers exploit vulnerabilities to compromise sensors and controllers, with the explicit goal of causing such damage. Consequently, novel mitigation strategies and anomaly-detection mechanisms must be developed under adversarial conditions. To expose weaknesses in current defenses, we propose a holistic attack-modeling framework that generates stealth-constrained adversarial policies in integrated CPS using reinforcement learning. Our framework serves as a tool for cyber-risk assessment of existing systems and for evaluating detection algorithms. It also enables automated, strategic adversary emulation in CPS, with direct applications to red-team testing and the design of more resilient detection mechanisms. We model the attacker's challenge as a Markov decision process (MDP) with stealth enforced via a cumulative detection-cost budget, incorporated into the reward through a Lagrangian relaxation. The resulting constrained MDP is solved by a Soft Actor-Critic algorithm augmented with dual ascent on the Lagrange multiplier, producing a policy that maximizes expected physical damage while minimizing detectability. Our results demonstrate that these strategic attacks can inflict severe damage on CPSs while remaining undetected, underscoring the urgent need for more advanced detection algorithms and further research in cyber-physical security.

1 - Dynamic Matching with Post-Allocation Service and Its Application to Refugee Resettlement**Soonbong Lee, Yale university, New Haven, CT, United States, Kirk Bansak, Vahideh Manshadi, Rad Niazadeh, Elisabeth Paulson**

Motivated by our collaboration with a major refugee resettlement agency in the U.S., we study a dynamic matching problem where each arrival (a refugee case) must be matched immediately and irrevocably to one of the static resources (a location with a fixed annual quota). In addition to consuming the static resource, each case requires post-allocation service from a server, such as a translator. Given the time-consuming nature of service, a server may not be available at a given time, thus referred to as a dynamic resource. Upon matching, the case waits to avail service in a first-come-first-serve manner. Bursty matching to a location may result in undesirable congestion at its corresponding server. Consequently, the planner (the agency) faces a dynamic matching problem with an objective that combines matching reward (pair-specific employment outcomes) with costs for congestion at dynamic resources and over-allocation of static ones. Motivated by observed fluctuations in refugee composition across years, we design algorithms without relying on distributional knowledge from past years' data. We develop learning-based algorithms that are asymptotically optimal in certain regimes, interpretable, and computationally fast. Our design is based on learning the dual variables of the underlying optimization problem; however,

the main challenge lies in the time-varying nature of dual variables associated with dynamic resources. To address this, our theoretical development draws on Lyapunov analysis, adversarial learning, and stochastic optimization. When tested on real data from the partner agency, our method outperforms existing ones, making it a viable candidate for replacing current practices upon experimentation.

2 - The Power of Static Pricing for Reusable Resources

Jiaqi Shi, Columbia University, New York, NY, United States, Adam Elmachtoub

We consider the problem of pricing a reusable resource service system. Potential customers arrive according to a Poisson process and purchase the service if their valuation exceeds the current price. If no units are available, customers immediately leave without service. Serving a customer corresponds to using one unit of the reusable resource, where the service time has a general distribution. The objective is to maximize the steady-state revenue rate. This system is equivalent to the classical Erlang loss model with price-sensitive customers, which has applications in vehicle sharing, cloud computing, and spare parts management. With general service times, the optimal pricing policy depends not only on the number of customers currently in the system but also on how long each unavailable unit has been in use. We prove several results that show a simple static policy is universally near-optimal for any service rate distribution, arrival rate, and number of units in the system. When there are multiple classes of customers, we prove that static pricing guarantees 78.9% of the revenue of the optimal dynamic policy, achieving the same guarantee known for a single class of customers with exponential service times. When there is one class of customers who have a monotone hazard rate valuation distribution, we prove that a static pricing policy guarantees 90.4% of the revenue from the optimal inventory-based policy. Finally, we prove that the optimal static policy can be easily computed, resulting in the first polynomial-time approximation algorithm for the multi-class problem.

3 - Data-Driven Stochastic Modeling Using Autoregressive Sequence Models: Translating Event Tables to Queueing Dynamics

Daksh Mittal, Columbia University, New York City, NY, United States, Shunri Zheng, Jing Dong, Hongseok Namkoong

While queueing network models are powerful tools for analyzing service systems, they traditionally require substantial human effort and domain expertise to construct. To make this modeling approach more scalable and accessible, we propose a data-driven framework for queueing network modeling and simulation based on autoregressive sequence models trained on event-stream data. Instead of explicitly specifying arrival processes, service mechanisms, or routing logic, our approach learns the conditional distributions of event types and event times, recasting the modeling task as a problem of sequence distribution learning. We show that Transformer-style architectures can effectively parameterize these distributions, enabling automated construction of high-fidelity simulators. As a proof of concept, we validate our framework on event tables generated from diverse queueing networks, showcasing its utility in simulation, uncertainty quantification, and counterfactual evaluation. Leveraging advances in artificial intelligence and the growing availability of data, our framework takes a step toward more automated, data-driven modeling pipelines to support broader adoption of queueing network models across service domains.

4 - Equity vs. Efficiency in Service Systems with Differentiated Demand

Hamid Arzani, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Ming Hu, Hossein Abouee-Mehrizi

In service systems, the pursuit of efficiency by prioritizing certain groups often raises concerns about equity toward those who are being prioritized. We study the efficiency-equity trade-off for a queueing system with two customer classes, distinguished by their arrival rate, urgency level (measured by per-unit-time delay cost), and initial well-being at the time of arrival to the system. We examine two types of policies among all work-conserving and non-preemptive priority policies: the efficient policy, which maximizes the system's overall expected utility by prioritizing the urgent customers, and the equitable policy, which maximizes the minimum expected utility of individual customers. We fully characterize the equitable policy and show that it agrees with the efficient policy when the system utilization is lower than a threshold and disagrees otherwise. We analyze the relative efficiency loss associated with the equitable policy, namely the price of equity (PEQ), and the relative equity loss associated with the efficient policy, namely the price of efficiency (PEF). We show that a slight increase in service capacity can lead to significant improvements in both the PEQ and PEF. We further show that the PEQ is significant when there is a moderate gap in delay cost rates and neither arrival rate significantly outweighs the other. In contrast, the PEF is significant when the delay cost rates are close, and the arrival rate of the urgent class significantly dominates that of the nonurgent class. Our results challenge the perception that efficiency and equity lie at the opposite ends of the spectrum.

Chair: Hyeontae Jo, POSTECH, Pohang, N/A, Korea, Republic of

1 - Mean Vector Shrinkage Estimation

Vali Asimit, Bayes Business School, London, United Kingdom, Ziwei Chen, Nathan Lassance

Shrinkage is a statistical method that was propelled by the *Stein's Paradox*, which showed that the standard *Maximum Likelihood Estimator* is not the estimator with the lowest estimation error. Shrinkage estimators have been used with great success in multivariate estimation such as multiple linear regression, mean vector and covariance matrix estimation, portfolio weights etc. The shrinkage tool combines two estimators, the most common choice and a low-variance target estimator, so that the combined estimator is more stable than the common/natural estimator. We provide four distribution-free shrinkage estimators for mean vectors and show their consistency properties under the most general setting where both the sample size and vector dimension get large. Such a setting is of great importance in practice, for example in portfolio theory, when the sample size is often smaller than the number of assets. We illustrate that such theoretical guarantees are reflected in synthetic and real data experiments, but we also show that our novel solutions outperform all existing methodologies. We choose some portfolio theory applications to explain the advantages of our estimators.

2 - Systematic Liquidity Risk Management: A Novel Perspective on Derivatives

Joseph Yi, Mizuho Financial Group, New York, NY, United States, Baeho Kim

Systematic liquidity risk poses a critical challenge in financial risk management, particularly during periods of market stress when liquidity suddenly dries up, as experienced during the Great Financial Recession. Liquidity shocks can propagate rapidly across asset classes, including derivatives, and exhibit persistence that undermines traditional risk models. This paper presents a novel risk management framework that bridges the gap between theory and practice by incorporating aggregate liquidity risk into derivatives pricing and risk assessment. Our approach integrates both physical and risk-neutral asset return dynamics to enable consistent risk pricing and measurement. We model systematic liquidity risk as a linear combination of two mean-reverting stochastic processes: a diffusive component and a jump component, using a double-exponential jump diffusion model. To demonstrate the tractability and applicability of our model in equity market, we propose a two-step calibration procedure for empirically capturing volatility skew. The first step estimates 'common' liquidity risk parameters using S&P 500 option prices, while the second step calibrates 'key' asset-specific parameters. We apply our framework to price a path-dependent contingent claim hedged with vanilla options and simulate idiosyncratic asset returns to generate a stressed P&L distribution for Value-at-Risk (VaR) estimation. Our findings validate the model's effectiveness, highlighting how the separation of common and idiosyncratic parameters enhances interpretability and practical implementation. This research offers both a theoretical foundation and a practical toolset for incorporating systematic liquidity risk into derivatives risk management policy to set risk limits, providing clearer insights into stress testing, pricing, and hedging in potentially illiquid market environments.

3 - High-Dimensional Portfolio Optimization Under Heavy-Tailed-Ness

Amirmohammad Ebrahimi, University of Florida, Gainesville, FL, United States, Hamed Amini, Hongcheng Liu

Portfolio selection under realistic market conditions often involves complex, non-smooth objectives and high-dimensional, heavy-tailed return distributions. We study the sample complexity of portfolio selection problems formulated via the Sample Average Approximation (SAA) method, including a regularized variation. We consider general convex composite objectives (possibly non-smooth) and derive non-asymptotic high-probability bounds on the optimality gap between the SAA solution and the true population-optimal solution. Our analysis uses a decomposition framework that yields bounds that are dimension-free with respect to the feasible region. The results

provide new theoretical insight into the reliability of data-driven portfolio construction under limited sample settings and offer practical guidance for model selection in high-dimensional, heavy-tailed environments.

4 - Advancing Yield Curve Forecasting: Deep Learning Nelson-Siegel Models and Macroeconomic Insights

Hyeontae Jo, POSTECH, Pohang-si, Korea, Republic of, youngju Ahn, MYUNGJUN KIM, Bong-Gyu Jang

This study empirically examines whether incorporating macroeconomic information into a Deep Learning Nelson–Siegel (DLNS) framework improves yield-curve forecasts, using monthly U.S. Treasury data. The benchmark DLNS model and its macro augmented variant, DLNS-X, both outperform the traditional dynamic Nelson–Siegel (DNS) model across all forecast horizons. Integrating CPI inflation and M2 money supply into the DLNS-X model further enhances medium-term and long-term predictive accuracy during periods of elevated short-term interest rates, indicating that these variables convey incremental information beyond that contained in the yield curve. In contrast, the performance gap narrows in certain economic regimes, lending support to the macro-spanning hypothesis that key macroeconomic news is already embedded in the curve. These findings confirm that deep-learning term-structure models can capture complex nonlinear dynamics while preserving economic interpretability, identify the conditions under which macro factors most improve forecast performance, and establish a foundation for the development of more refined forecasting methodologies.

1 - Platform Economics and Piracy Control: when Supply-Side Enforcement Backfires

Guangjun Huang, Central South University, Changsha, China, China, People's Republic of, Fuqiang Wang, Yunchuan Liu

The rise of digital platforms has fundamentally changed content distribution in the digital economy. In contrast to previous findings favoring supply-side measures, we discover that supply-side enforcement unintentionally reduces discovery system investment and weakens network externalities, diminishing product quality. Our results suggest a reconsideration of anti-piracy strategies in platform-dominated markets.

2 - Does Smart Contract Add Value to a Retailer with Buyback Risk?

Ao Zhuo, Renmin University of China, Beijing, China, People's Republic of, Wanshan Zhu, Zhengping Wu

Retailers face buyback risk in supply chains when manufacturers fail to honor their buyback commitments, as documented in litigation records. A smart contract can mitigate this risk by functioning as escrow to reserve a portion of the manufacturer's wholesale revenue in a dedicated account exclusively for buyback purposes. We focus on this escrow role of the smart contract to examine the value it brings to the retailer under both exogenous and endogenous buyback risk. Intuitively, the smart contract benefits the retailer by directly reducing buyback risk and hurts the manufacturer by posing extra financial constraints. Under exogenous buyback risk, which arises from uncontrollable external events, our analysis shows a counterintuitive result that the smart contract adds value to the retailer only if she is risk-averse, while always benefiting the manufacturer. In risk-neutral cases, the retailer suffers from the implementation of a smart contract because it allows the manufacturer to charge a higher wholesale price to extract profit. If risk aversion is above a threshold, a smart contract can create significant value for both the retailer and the manufacturer, leading to a "win-win" outcome. Under endogenous buyback risk, which stems from the manufacturer's financialization, the smart contract may lead to a "lose-lose" situation when an attractive investment opportunity exists, as the smart contract prevents the manufacturer from pursuing the more lucrative opportunity. Our research highlights the significant potential value of smart contracts, while advising supply chain managers how to avoid its pitfalls.

3 - Decentralized Platforms: Governance, Design, and Information Asymmetry

Wenxin Zhang, Syracuse University, Syracuse, NY, United States

In the decentralized platform economy, platforms often support two primary modes for distributing service providers' offerings to end users: service fee channel and reselling channel. This paper investigates the implications of platform channel design when a service provider possesses service quality information unknown to the decentralized platform. We analyze a signaling game between a service provider and a decentralized platform, in which the better-informed service provider first sets the service price, which it may use to signal private quality information. Based on the service price, the platform decides what units of service to deliver through the reselling channel. Finally, if the platform opens its service fee channel, the service provider decides what units of service to deliver through the service fee channel. We find that the effects of platform channel design on the service provider and the platform depend on three model parameters: the commission rate, the degree of channel substitution, and the degree of quality differentiation. Interestingly, using smart contract may narrow the region of the win-win outcome in which dual channel mode benefits both platform and service provider. Moreover, the platform cannot always induce the service provider to share quality information through smart contract; similarly, dual channel mode may even decrease the value of using smart contract for the decentralized platform.

4 - Smarter Games: AI Adoption in Video Game Development

Linghui Feng, Boston University, Boston, MA, United States, Qi Wang, Marcus Bellamy

We investigate how video game developers adopt and disclose the use of artificial intelligence (AI) in their production processes. Leveraging a large-scale dataset of games, developers, and publishers, we examine which organizational and collaborative characteristics influence developers' likelihood of disclosing AI use and how AI tools are applied across different aspects of game creation. Our findings highlight the determinants and visibility of AI adoption in creative industries, offering insights into how transparency and technological capabilities shape innovation in digital content development.

5 - Information Sharing and Channel Structures In Live Streaming Commerce

Xin Liu, Renmin University of China, Beijing, China, People's Republic of, Jianghua Wu

In recent times, online platforms have established live streaming channels through which manufacturers can advertise their products by paying the platforms service fee for live streaming. Manufacturers with direct channels consider utilizing live streaming channels through agency selling or reselling formats. The live streaming channel offers a comprehensive product introduction and an immediate purchasing experience for consumers, which can mitigate product uncertainty and enhance demand on the platform. As a consequence of the expansion of the brand, live streaming has the spillover effect of increasing demand in the direct channel. A game-theoretic model is constructed for the purpose of examining equilibrium pricing and live streaming efforts, as well as studying the interaction between selling format and information sharing. The results demonstrate that information sharing confers benefits to both the manufacturer and the platform in the context of agency selling. Conversely, under reselling, it is always beneficial to the manufacturer but harmful to the platform when the cost coefficient of live streaming is high. Furthermore, the manufacturer is inclined to pursue agency selling with a low commission rate. When the service fee increases, the manufacturer accepts a lower commission rate for agency selling. Furthermore, the platform has the ability to exert influence on the manufacturer to select the platform's preferred selling format by modifying the service fee. The findings of this study offer valuable insights to managers seeking to identify optimal strategies for selling formats and information sharing, with consideration of live streaming.

1 - From Thrill to Theft: the Unintended Consequences of Online sports Betting**Ecem Basak, Baruch College, New York, NY, United States, SHAGUN TRIPATHI, Yi-Jen (Ian) Ho**

In 2018, in a landmark legislation, the U.S. Supreme Court ended a federal ban on sports betting, allowing individual states to regulate the activity. This prompted rapid adoption and fueled a surge in online, platform-mediated gambling. However, accessibility provided by online betting platforms raises growing concerns about broader societal impact. In this short paper, we examine whether the legalization of sports betting is associated with increases in crime—specifically burglary and robbery, offenses closely tied to financial strain and opportunity. Using a panel dataset covering U.S. states and the District of Columbia from 2018 to 2023, we employ staggered difference-in-differences models to estimate causal effects. We find that legalization is associated with statistically significant increases in both crime categories. Theoretically, we extend Routine Activity Theory and Strain Theory to digitally mediated environments. Our findings surface overlooked societal costs of legalization and platformization of gambling, and the expansion of digital markets.

2 - Multi-Agent Framework for AI Debiasing Human Creation in Commercial Practices**Chen Liang, The University of Illinois at Chicago, Chicago, IL, United States**

Concerns over fairness and accountability in content creation have surged with the rapid integration of artificial intelligence and human activities in the commercial usage scenario. Our study aims to design a multi-agent framework to debias human narratives using AI implementation, incorporated human-in-the-loop-evaluation, for detecting and mitigating bias in human-created commercial content. We also seek to investigate the alignment between AI models and human examinations to address if the perception gap exists between two subjects and thus broaden the understanding of human-AI hybrid creation and create a more feasible debiasing guidelines toward such collaboration.

3 - The Role of AI-Generated Links in Reshaping Collaboration Networks: Evidence from An Oss Platform**Zifeng Cheng, University of Illinois Chicago, Chicago, IL, United States, Yuheng Hu**

Open-source software (OSS) development plays a pivotal role in driving digital innovation, yet its progress is increasingly hindered by community fragmentation and weak cross-project connectivity. Emerging technologies such as Generative AI offer new opportunities to reshape developer interactions through their autonomy and creative capabilities. Among these, AI-generated conversational links—such as ChatGPT links—may enable more connected and decentralized collaboration by fostering transparent, interpretable, and participatory knowledge sharing. Unlike static documentation, these links dynamically externalize users' cognitive processes and illuminate the rationale behind decisions. We conceptualize these links as a novel form of social learning that reduces information asymmetries and promotes broader knowledge diffusion across developer communities. Empirically, we find that the use of AI-generated links reduces collaborator deep engagement and contributes to a more decentralized network structure. Moreover, our results suggest that users who adopt AI-generated links tend to occupy stronger bridging positions within the network, which serves as a driving factor in reshaping network structure. Overall, our findings contribute to the emerging literature on AI-generated content by shifting the focus from individual performance to relational and structural outcomes. At the same time, we introduce a network-based perspective on OSS innovation and highlight the potential of AI-enabled tools to reduce fragmentation and strengthen community connectivity.

4 - The Impact of Generative AI on Collaborative Open-Source Software Development: Evidence from GitHub Copilot**Fangchen Song, University of Texas at Austin, Austin, TX, United States, Ashish Agarwal, Wen Wen**

Generative artificial intelligence (AI) enables automated content production, including coding in software development, which can significantly influence developer participation and performance. To explore the impact on collaborative contributions and coordination dynamics, we investigate the role of GitHub Copilot, a generative AI pair programmer, in open-source software development where multiple distributed developers voluntarily collaborate. Using GitHub's proprietary Copilot usage data, combined with data from open-source repositories and a generalized synthetic control method, we find that Copilot use increases project-level code contributions by 5.9%. This gain is driven by a 2.1% increase in individual code contributions and a 3.4% rise in developer participation. However, these benefits come at a cost as coordination delays increase by 8% due to higher communication demands. Specifically, Copilot use is associated with more discussion volume, broader participation in discussions, and greater discussion intensity. This reveals a trade-off. While AI expands who can contribute and how much they contribute, it simultaneously slows coordination in collective development efforts. Despite this tension, the combined effect of these two competing forces remains positive, indicating a net benefit from using AI pair programmers. Interestingly, we also find the effects differ across developer roles. Peripheral developers show smaller gains in project-level code contributions but face greater coordination delays than core developers, likely due to limited project familiarity. In summary, our study underscores the dual role of AI pair programmers in augmenting contribution volumes and reshaping coordination dynamics in open-source communities and suggests potential implications for both practice and the broader open-source ecosystem.

AI Transforming Platforms and Society

Invited Session

Information Systems

Chair: Zhechao Yang, George Mason University, Fairfax, VA, United States

1 - Labeling AI-Generated Content: Implications for Platforms, Creators, and Consumers**Yan Zhu, The University of Texas at Dallas, Richardson, TX, United States, Jianqing Chen, Srinivasan Raghunathan**

With the rapid evolution of generative AI, the line between human generated content and AI generated content has become increasingly blurred. To ensure transparency and trust, some social-media platforms, such as Facebook and Instagram, have introduced AI labels to inform users. However, the impact of such labels on different creators' creation effort remains unknown. At the same time, social-media content has become a valuable source of training AI models. Platforms have either directly monetized the content on the platform or used it to train their own AI models, creating a new revenue source besides advertising. This adds complexity to a platform's profit maximization problem, as it must balance user engagement and content quality. In this project, we study the impact of AI labels on platforms, content creators, and consumers using a stylized game-theoretic model.

2 - Pay Transparency and Workforce Dynamics: Evidence from It Labor Market**Haofei Qin, Georgia Institute of Technology, Atlanta, GA, United States, Jiayu Yao, Mingfeng Lin**

While proponents of pay transparency policies argue that disclosing salary ranges can reduce information asymmetry and promote equity in labor markets, the broader implications for employer behavior and workforce dynamics remain understudied. This paper explores how mandatory wage disclosure influences hiring and retention in the IT labor market by exploiting the implementation of a regional pay transparency law. We show how wage disclosure mandates reshape recruitment strategies and employee retention in high-skill labor markets.

3 - (How) Can LLMs Enhance Privacy Research?**Xiang Cheng, University of Maryland College Park, College Park, MD, United States, Wen Wang**

Understanding consumer privacy preferences and decision-making is central to how businesses and policymakers approach data governance, personalized services, and regulatory compliance. This study explores the potential of Large Language Models (LLMs) as scalable substitutes for human subjects in privacy research. We first assess whether LLMs exhibit a *privacy mindset*—human-like privacy preferences and decision-making—by benchmarking their responses against those of human subjects. Our findings reveal that LLMs not only demonstrate clear privacy preferences but also make reasonable, context-aware decisions. Interestingly, LLMs show higher privacy concerns than humans yet are more willing to share information in real-world scenarios. They also reflect both the *privacy calculus* (balancing risks and benefits) and the

privacy paradox (expressing concern while compromising privacy). These results suggest that LLMs possess a coherent privacy mindset, supporting their use as foundational tools for simulating human subjects in privacy research. To enhance alignment with human privacy behavior, we introduce a methodology that combines multi-persona modeling, Generative Adversarial Networks, and interpretable machine learning. This enables the generation of synthetic human subjects that closely mirror real-world privacy preferences. Extensive experiments show that our method significantly improves alignment between LLM and human responses across datasets and decision contexts. By establishing LLMs as viable proxies for privacy research, our study offers a scalable, cost-effective methodology for studying privacy behavior, with broad implications for academia, industry, and policy.

4 - Is Consumer AI Really Beneficial to a Firm?

Yue Li, Tianjin University, Tianjin, China, People's Republic of, Jianqing Chen, Srinivasan Raghunathan, Yan Zhu

Consumer AI, which is becoming increasingly prevalent in practice, significantly alters consumer purchasing behavior. A question that warrants further investigation is whether the adoption of consumer AI truly benefits the firm. We examine the optimal strategy for firms adopting consumer AI in a market where a manufacturer sells a product to consumers. We find that the manufacturer should adopt consumer AI (i.e., consumer AI is beneficial to the manufacturer) if the product base value is moderate, and otherwise, not adopting AI is the optimal choice (i.e., consumer AI hurts the manufacturer). Our findings provide guidance for the adoption of consumer AI by firms.

5 - Backfire of AI Marketplace Entry? Empirical Evidence from Start-Ups' Gpts Adoption

Xinyu Li, The Chinese University of Hong Kong, Shatin, Hong Kong, Wen Wen, Keongtae Kim

In the post-ChatGPT era, startups are increasingly entering the AI application market to launch their own bot services, seeking to attract investors and achieve long-term success. However, the majority of AI products and services being released appear to be of poor quality and fail to achieve product-market fit. This may even negatively impact investor and customer perceptions of these startups, given the increasingly crowded market. We study AI marketplace adoption to understand startups' strategies for launching AI complement products and their subsequent performance outcomes. Our preliminary findings suggest that launching AI bot services may actually harm funding performance.

1 - Coexistence of Competition? Platform Entry Effect on Third-Party Sellers on Retail Platforms

Zohre Yahyaee, the University of Kansas, Lawrence, KS, United States, Anurag Garg, Arvind Tripathi

Hybrid e-commerce platforms—where marketplaces operate as both retailers and hosts to third-party (3P) sellers—have reshaped online competition. While platform entry can benefit or harm 3P sellers, empirical evidence remains inconclusive. This study examines the impact of first-party (1P) entry by JD.com on 3P seller performance, with a focus on product popularity. Using proprietary JD.com data and a Difference-in-Differences design with SKU- and day-level fixed effects, we find that 1P entry expands market size and increases 3P sales, but through different channels. For popular products, 1P presence reduces consumer uncertainty and raises conversion without increasing product views. For unpopular products, it boosts visibility but not sales. Prices remain stable across both segments. These findings clarify the heterogeneous effects of platform entry, highlighting the role of baseline demand and platform structure. The study offers strategic insights for platform operators, third-party sellers, and policymakers navigating competition in hybrid marketplaces.

2 - Supply, Demand OR Policy Driven? An Empirical Examination of Data Center Location Strategies in the United States

Chen Tian, Emory University, Atlanta, GA, United States, Ramnath Chellappa, Jonathan Gomez Martinez

The growth of cloud-based IT has fueled the rapid expansion of data center construction, raising questions about the determinants of digital infrastructure location. We examine the importance of market fundamentals—specifically supply-side and demand-side factors—as well as local government tax policies in influencing data center entry across U.S. counties. Using a panel dataset from 2000 to 2023 and a staggered difference-in-differences design, we find that state-level tax incentives significantly increase data center entry, particularly for public cloud and large colocation facilities. Additionally, data center entry continues to be shaped by supply and demand factors, including proximity to the information industry, land costs, and broadband access. However, time-varying results suggest that improvements in network latency and cloud technology have diminished the importance of demand-side considerations in data center location decisions. Our findings suggest a growing decoupling between data center location and digital demand, reflecting broader shifts driven by technological change and policy interventions.

3 - Investigating the Impacts of IT Outages on Firms' Service Operations In Digital Platforms

Huai-Tzu Cheng, Montana State University, Bozeman, MT, United States

IT outages create major challenges for firms, causing economic and operational setbacks and challenging information system resilience. These outages lead to the prevention of normal operations, lost revenue, reduced customer trust, and higher costs from downtime and recovery efforts, weakening a firm's competitive position in the market. Operationally, unexpected outages cause service delays and strain resources. Customer service is key to managing these impacts, but traditional support channels often get overwhelmed during the crisis, pushing firms to use digital platforms like X.com, Facebook, or Instagram for real-time customer communication. During crises, more firms increasingly rely on these platforms to connect and engage with customers and provide support. This shift requires fast responses and careful handling of misinformation to prevent negative word-of-mouth.

This study analyzes recent IT outages to quantify their impacts on customer service operations and evaluate information systems resilience, focusing on operational delays, customer service challenges, and recovery strategies. In this study, we find that customer complaints increase significantly during outages, and firms' slow responses worsen dissatisfaction. These findings advance academic understanding of IT outage impacts and provide practical strategies for firms to manage disruptions, enhance a firm's customer service, and optimize service recovery during crises in digital platforms, ensuring operational stability and customer satisfaction. This study contributes to the literature on information systems, crisis management, and service operations.

4 - Competition Through Recommendations

Robin Ng, Mannheim, Mannheim, Germany

Consumers rely on platform recommendations when purchasing products. I examine a platform's decision to design recommender systems to be informative of value. Informative recommendations generate two effects: screening effect, where lower-quality firms exit the platform; and ranking effect, among remaining firms, consumers interact more with higher-quality firms. Screening benefits higher-quality firms while ranking benefits only the highest-quality firms. Both effects improve consumer surplus, attracting more consumers to the platform. However, the ranking effect intensifies price competition as firms want to provide more value to attract demand. Hence, a platform designing its recommender system balances between stimulating price competition to attract consumers and per-transaction ad-valorem fees from firms. When platforms compete, recommendations become more informative when the competitor has a more informative recommender system. I connect these results to the evolution of recommender systems, showing how regulatory policies and the competitive environment lead platforms to prioritise trust-building or engage in enshittification.

1 - Data-Driven Optimization for Meal Delivery: a Reinforcement Learning Approach for Order-Courier Assignment and Routing at Meituan

Ramon Auad, Amazon, Santiago, Chile, Tomas Lagos, Felipe Lagos

The rapid growth of online meal delivery has introduced complex logistical challenges, where platforms must dynamically assign orders to couriers while accounting for demand uncertainty, courier autonomy, and service efficiency. Traditional dispatching methods, often focused on short-term cost minimization, fail to capture the long-term implications of assignment decisions on system-wide performance. This paper presents a novel hybrid framework that integrates reinforcement learning with hyper-heuristic optimization to improve sequential order assignment and routing decisions in meal delivery operations. Our approach combines n-step SARSA with value function approximation and a multi-armed bandit-based hyper-heuristic incorporating seven specialized low-level heuristics. Our approach explicitly models the evolving system state, enabling dispatching policies that balance immediate efficiency with future operational performance. By employing scalable linear value function approximation, we enhance policy learning in high-dimensional environments while maintaining generalization across states and actions.

Using real operational data from the food delivery platform Meituan, we develop a comprehensive simulation environment that captures order dynamics, courier behavior, and service times. Through extensive computational experiments, we demonstrate that our framework significantly outperforms traditional benchmark policies, achieving 12% cost reduction through strategic order postponement. Our results reveal that the largest improvements occur during high-demand periods with courier shortages, and that a 10% increase in courier availability yields greater benefits than algorithmic improvements alone.

The proposed methodology effectively balances immediate operational efficiency with long-term performance, while providing valuable insights for meal delivery platforms regarding courier fleet management and order assignment strategies.

2 - Dispatch OR Hold? An Offline Learning and Online Optimization Approach for on-Demand Delivery

Long He, George Washington University, Washington, DC, United States, Yihua Wang, Zhengling Qi, Stefan Minner

In large-scale on-demand food delivery systems, dynamic order dispatching needs to balance immediate dispatch and order holding amid competing objectives, including delivery efficiency, service timeliness, and courier utilization. While holding orders may improve route consolidation, it also increases the risk of delayed delivery. Real-time decisions must determine both when to dispatch and how to group orders for efficient delivery.

We propose a hierarchical offline learning and online optimization framework that integrates inverse optimization with deep reinforcement learning. The framework first determines which orders to dispatch immediately and which to hold, then consolidates the dispatched orders by solving a multi-objective weighted set covering problem. To estimate the trade-off weights between objectives, we develop a cutting-plane-based inverse optimization method that learns from real-world dispatch data. The inferred cost structure is embedded in a Markov decision process, and a dispatch policy is trained with Proximal Policy Optimization to optimize long-term performance.

Empirical results on real-world data from a major food delivery platform show that the learned policy significantly improves operational outcomes, reducing travel distance and courier usage while improving on-time delivery. Analysis reveals key behavioral insights: strategic order holding increases grouping opportunities and improves delivery efficiency, particularly in periods or regions with low order arrival rates. However, long-distance orders are less suited for holding due to limited consolidation potential and higher delay risk.

3 - The Meal Delivery Routing Problem with Courier Behavior and Graph Neural Networks

Niels de Jong, University of Groningen, Groningen, Netherlands, Ilke Bakir, Kees Jan Roodbergen

We address the Meal Delivery Routing Problem (MDRP) faced by online food delivery platforms, where customer orders arrive dynamically and must be assigned to autonomous couriers. Each courier picks up orders from merchants and delivers them to customers. The platform must handle several challenges: couriers have varying behaviors and capabilities; courier-to-order assignment decisions must balance immediate and future costs; decisions must be made in seconds; multiple orders can be efficiently bundled; some assignments can be delayed; and there is inherent uncertainty in food preparation times, travel speeds, and order delivery locations. To address these challenges, we develop a scalable, polynomial-time heuristic using Graph Neural Networks (GNNs) to estimate future assignment costs in a rolling horizon assignment framework. We test our approach using a modular, open-source digital twin that simulates millions of deliveries in seconds and is validated on real data from Meituan. Our GNN-based heuristic is trained using Twin Delayed Deep Deterministic Policy Gradient (TD3). Results show our method reduces average delivery time (click-to-door) by 11.6% and order rejections by 2% compared to a myopic benchmark. It also adapts to varying courier behaviors and changing spatio-temporal demand, enabling real-time, efficient decision-making for food delivery and related applications like ride-sharing.

4 - Mixed-Type Courier Dispatch for Online Food Delivery Platforms

Junlin Chen, Tsinghua University, Beijing, China, People's Republic of, Manxi Wu, Chiwei Yan, Zhanhao Zhang

Many online food delivery (OFD) platforms employ a combination of full-time couriers, who operate on fixed schedules, and part-time couriers, who enter and exit the system dynamically. Despite their distinct operational characteristics, existing dispatch policies often overlook how to best allocate orders between these two groups. Using a large-scale dataset from Meituan—China's largest OFD platform, we identify systematic differences in courier behavior and performance, and develop a mathematical optimization model to improve dispatch efficiency. Our model reveals a spatial cutoff distance to guide order allocation: full-time couriers are prioritized for deliveries within this range, while part-time couriers handle orders beyond it. We develop analytical models for both single-cluster and multi-cluster settings, where each restaurant cluster has its own order arrival rate, distribution and dedicated full-time fleet, and part-time couriers operate across clusters. In both cases, we derive closed-form solutions for the optimal cutoff distance that maximizes system throughput. Furthermore, we allow the platform to allocate its total full-time couriers across clusters, formulate the resulting joint courier allocation and dispatching problem as a convex program, and provide an efficient algorithm. Our numerical experiments calibrated by real-world data confirm the practical value of our approach, noticeably improving on-time performance and throughput compared to benchmark policies.

Coordinated Planning in Complex Transport Networks

Contributed Session

Contributed

Chair: Bhargav Ganguly, Amazon

1 - Designing Platooning Hub Networks Under Cost Uncertainty

Elif Zeynep SERPER, TED University, Ankara, Turkey, Sibel Alumur Alev

Platooning offers promising cost and environmental benefits for full truckload transportation by enabling trucks to travel in close convoys using vehicle-to-vehicle communication. This study addresses the design of hub networks that support platoon formation and dissolution, with the goal of transporting truckload shipments from their origins to destinations within the required delivery time while minimizing total costs.

We first develop a deterministic optimization model to identify optimal hub locations and routing decisions under known cost parameters. Each shipment can either be delivered directly or routed via two hubs to benefit from platooning. To account for real-world uncertainties in platoon cost savings, we then propose a two-stage

stochastic programming model. The Sample Average Approximation (SAA) method is employed to solve the stochastic model efficiently.

Using real-world data from 1,253 shipments among 39 U.S. cities, our computational results show that platoon-enabled networks significantly reduce transportation costs and improve delivery performance. The stochastic model provides improved performance under uncertainty, offering quantifiable gains over deterministic planning. These results offer practical insights for designing reliable and cost-effective platoon-based freight systems.

2 - A Game-Theoretic Model of Code-Sharing Between Marketing and Operating Airlines Based on Nash Bargaining and Second-Order Cone Programming

Bing-Hsin Sun, National Tsing Hua University, Hsinchu, Taiwan, Yu-Ching Lee, Chun-Han Wang

As the airline market matures, airlines have shifted from pure competition to strategic cooperation. Code-sharing is a common collaborative strategy that allows a marketing airline to sell seats on flights it does not operate, while the operating airline conducts the actual service. The revenue from such flights is distributed based on a profit distribution parameter. This strategy helps enhance network coverage, reduce operational costs, and improve overall market efficiency. Under a code-sharing arrangement, airlines compete on flight frequency while simultaneously collaborating on profit and market share distribution, forming a complex, multi-player game with strategic interdependence. Despite its strong practical relevance, current literature lacks a mathematical model that integrates both code-sharing agreements and frequency competition. To address this gap, this study proposes a game-theoretic model formulated as a second-order cone programming (SOCP). Using the Karush-Kuhn-Tucker (KKT) conditions, we derive a system of primal, dual, and complementarity slackness constraints. The model's objective is to maximize the product of airline profits, thereby obtaining a stable Nash bargaining solution (Nash, 1950). We further analyze how different profit distribution parameter affect airline profits, flight frequencies, passenger volumes, and the operational characteristics of code-sharing segments. Empirical results show that code sharing not only increases total industry profit and aircraft utilization but also allows airlines to serve more passengers without increasing the number of flights. The proposed model thus offers practical decision support for airlines formulating code-sharing strategies. Moreover, the findings confirm that code sharing can significantly enhance both profitability and service quality in the airline industry.

3 - Optimization of Hydrogen Refueling Facility Locations Under Dynamic Market Share Scenarios Leveraging Large Language Models

Mina Kim, Georgia Institute of Technology, Atlanta, GA, United States, Benoit Montreuil

The decarbonization of freight transportation has accelerated interest in hydrogen as a sustainable fuel alternative for heavy-duty trucks. A key barrier to large-scale adoption is the lack of adequate hydrogen refueling infrastructure. Static assumptions regarding vehicle market shares fails to capture the evolving nature of technology adoption and policy-driven market shifts. This study proposes a novel framework for optimizing hydrogen refueling facility placement by leveraging Large Language Models (LLMs) to generate dynamic market share scenarios for hydrogen fuel-cell electric heavy-duty trucks (FCEV HDTs). In contrast to conventional models, our approach anchors facility deployment on the Physical Internet (PI) regional hubs, which serve as strategic nodes in a hyperconnected logistics network. LLMs are used to synthesize plausible regional adoption patterns that reflect future uncertainty and heterogeneity in FCEV HDT uptake. These scenarios are integrated into an optimization model that selects hydrogen refueling facility locations to minimize emissions and cost while maximizing network coverage. Leveraging real-world freight data and the PI network, our method reveals deployment strategies that offer new perspectives beyond the reach of static models. The results highlight the potential of combining LLM-driven market forecasting with infrastructure planning to support resilient and future-ready hydrogen ecosystems.

4 - Consolidation of Urban Freight Delivery and Public Transit Systems

Mohammadhosein Pourgholamali, Purdue University, West Lafayette, IN, United States, Mohammad Miralinaghi, Samuel Labi

The demand in urban freight delivery systems is increasing, and freight agencies try to expand their delivery fleet to accommodate this demand. This is due to the expansion of e-commerce sales and online shopping over the past decades. The expansion in logistics fleet and last-mile delivery operation, however, caused many negative impacts on the community, such as traffic congestion. Therefore, having a more efficient and sustainable urban freight delivery system is necessary. Regarding the public transit, however, the demand has decreased. Therefore, the loss of ridership in recent years caused a loss of revenue for transit agencies and made the transit infrastructure underutilized. Public transit networks tend to be extensive, covering a large fraction of any metropolitan area, thereby offering wide coverage for small-freight collection and delivery. This study proposed a consolidated transportation system (CTS) in which the public transit fleet is used to transport passengers and packages in an urban area. A mathematical decision-making framework is developed to identify optimal transit lines, transit stations, and service zones that should be used to form a CTS. The analytical framework is formulated as an optimization problem that minimizes the total delivery cost and is solved by an Adaptive Large Neighborhood Search algorithm. The numerical results show promising benefits for freight agencies by saving delivery costs and for transit agencies by generating more revenue, respectively. Furthermore, the results show the important roles of different cost components in the feasibility of the CTS.

5 - Dynamic Fleet Allocation for Last-Mile Delivery Networks

Bhargav Ganguly, Amazon, Seattle, WA, United States, John Phelix, Andre Snoeck, Jin Ye, Daniel Merchan

Vehicle capacity represents a critical constraint in last-mile delivery optimization, as both physical cargo limitations and battery capacity influence route productivity. While increased vehicle capacity offers greater delivery potential, it increases the cost of operations, both in direct operational expenses and indirect logistical challenges such as urban parking constraints. We present a novel dynamic fleet allocation algorithm that optimizes the distribution of vehicle resources among Delivery Service Providers (DSPs) based on geographical service areas, demand forecasts, and anticipated weather. The proposed framework demonstrates improved vehicle utilization and cost efficiency compared to static allocation methods, particularly in the context of electric vehicles where effective capacity is highly temperature dependent.

1 - Stochastic Shockwave Dynamics in First-Order Traffic Flow

Yanlin Zhang, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Alireza Talebpour

First order continuum models, including the Lighthill-Whitham-Richards (LWR) model, have been studied extensively in the literature. The traditional formulation of these models assumes deterministic inputs, leaving a gap in our ability to describe how random upstream fluctuations propagate and interact with downstream traffic. In this work, we propose a novel framework for solving the LWR model with stochastic boundary conditions, where the upstream density evolves as a Markov process with only upward jumps, representing shock-inducing fluctuations.

Assuming a strictly concave fundamental diagram, this setting leads to a conservation law, where solution evolves according to a closed-form kinetic equation. This equation describes the statistical dynamics of traffic density over space and time, accounting for shockwave dynamics in a unified way.

We validate our approach through numerical experiments under both triangular and other smooth fundamental diagrams, and compare the statistical shock dynamics predicted by our kinetic model against high-resolution results from multiple discretization methods, including the Cell Transmission Model (CTM) and other Godunov schemes. Results show that our framework accurately reproduces shockwave statistics with significantly reduced computational cost and without the need for space-time discretization.

This framework provides an analytical tool for modeling traffic under uncertainty and opens the door to more robust strategies for congestion prediction and control, particularly in environments with varying driving behaviors.

2 - Multicommodity Trade, Tariffs, and Rerouting

Anna Nagurney, University of Massachusetts Amherst, Amherst, MA, United States, Samirasadat Samadi

The concept of “equilibrium” is fundamental to many disciplines, including economics and operations research. The theory of variational inequalities continues to provide a rich methodological framework for the formulation, analysis, and solution of a wide range of equilibrium problems with many recent applications, because of their relevance, including policies associated with the trade of commodities. In this paper, we add to the literature on multicommodity trade by constructing a spatial price equilibrium model with tariffs that allows for the investigation of rerouting of commodities to evade tariffs, as has been happening for several years now, along with “trade wars.”

3 - Causal Evidence on Economic Consequences of Maritime Shipping Disruptions

Shahnawaz Akhtar, IESE Business School, Barcelona, Spain, Mihalios Markakis, Geert Mesters

This article provides the first comprehensive evidence on the causal impact of maritime shipping delays on firm-level output and supply chain networks. Using a novel instrumental variable approach based on weather-induced port disruptions, we isolate the causal effect of delays on firm sales, leveraging a unique dataset that integrates firm financial data with detailed shipping records. We find that firms experiencing severe shipping delays suffer significant output declines. Moreover, these shocks propagate beyond the initially affected firms, leading to measurable contractions in output among their upstream suppliers and downstream customers. Industries heavily reliant on maritime trade, such as manufacturing and wholesale trade, are particularly vulnerable. These findings offer critical insights into the economic risks posed by shipping disruptions and underscore the urgent need for resilient supply chain strategies to mitigate their impact.

4 - Optimizing Truck Parking Infrastructure Using a Bi-Objective Flow-Based Model

Aida Riahifar, University of Nebraska-Lincoln, Lincoln, NE, United States, Nathan Huynh, Li Zhao, Zhenghong Tang

The shortage of safe and adequate truck parking capacity poses a critical challenge to improving freight transportation safety across the United States—a challenge exacerbated by the enforcement of Electronic Logging Device (ELD) regulations and Hours-of-Service (HOS) requirements. These mandates compel drivers to stop within defined time intervals, yet limited access to designated rest areas increases crash risk, driver fatigue, and disrupts supply chain operations. This raises an essential research question: how can truck parking locations and capacities be optimally planned to address safety requirements while remaining financially feasible?

To answer this question, this study develops a bi-objective facility location model that jointly optimizes the placement and scale of truck parking infrastructure. The novelty of the approach lies in modeling crash risk as a spatial-temporal probabilistic flow and infrastructure cost as a reverse flow within a graph-theoretic flow network framework. A multi-objective optimization strategy, supported by scenario-based and sensitivity analyses, is used to evaluate trade-offs between safety and investment cost. The model is applied as a case study to Interstate 80 (I-80) in Nebraska—a heavily trafficked and strategically vital corridor for east-west freight movement in the U.S.

The findings identify high-priority investment zones and offer a decision-support framework for policymakers and logistics planners. By leveraging a data-driven and scalable approach, this framework enables strategic alignment of parking infrastructure with dynamic freight demand, enhancing safety, regulatory compliance, and the overall resilience of freight transportation networks.

5 - Analysis of Throughput Properties of A Max-Pressure Based Ramp Metering Control

Simanta Barman, University of Minnesota, Minneapolis, MN, United States, Abdullah Farabi, Michael Levin, Ali Hajbabaie

Ramp metering is proven to be an effective strategy for improving freeway traffic operations. Previous studies have focused on optimizing various objectives such as freeway throughput, speed, waiting time, and capacity utilization. While these methods effectively manage freeway operations in different scenarios, most ramp metering controls lack theoretical guarantees of performance. In this study, we propose a novel ramp metering control framework based on max-pressure principles, aiming to maximize freeway flow rate. We provide a mathematical proof that the proposed control can serve nearly all of the feasible demand that any control method can handle. Additionally, we present a simple, efficient algorithm for implementing the proposed control. Numerical and simulation results demonstrate the significant effectiveness of our approach. Numerical analysis shows that under realistic conditions, the proposed control can serve more than 99% of the maximum theoretical demand. In a case study, we implemented our Max-Pressure Ramp-Metering (MPR) control in a microsimulation environment and benchmarked its performance against no metering control and the state-of-the-art ALINEA method. Simulation results show that the proposed control outperforms both benchmarks, reducing delay by up to 56% and average travel time by up to 20%.

Innovations in Mobility Services

Contributed Session

Contributed

Chair: Breno Serrano de Araujo, Technical University of Munich, Munich, Germany

1 - Optimizing Curb Space Management Through Dynamic Pricing

Tien Nguyen, University of Michigan-Dearborn, Dearborn, MI, United States, Armagan Bayram

With the growth of new mobility services and increased needs for goods delivery, curb spaces, and their use have evolved very rapidly. Especially after COVID-19, active travel has increased and delivery rates have skyrocketed, creating a great need to ensure safe and efficient curb management. With delivery trucks, ride-sharing vehicles, private cars, and pedestrians all needing curb space, cities need a better way to manage these areas to keep them safe and efficient. One way to handle this is by using flexible pricing for various curb uses that adjust based on demand and available curb spaces. Hence, in this study, we developed a pricing model that sets curb prices dynamically for different uses by considering the uncertain demand, to maximize the revenue cities earn while supporting a fair and organized use of curb space for everyone. Our model aims to create straightforward pricing strategies that city planners can put into action quickly. This approach helps cities adapt to the fast-changing needs of curb spaces, supporting smoother, safer, and more organized city streets for everyone.

2 - Estimating Consumer Willingness-to-Pay for Time Saving Using Maas: Contingent Valuation Method Approach

Stephen Park, University of Goettingen, Goettingen, Germany, Hyungbin Moon, Yasemin Boztug

Mobility as a Service (MaaS) platforms offer innovative solutions by integrating various transportation modes into a single, user-friendly service. While MaaS is widely recognized for its convenience and sustainability benefits, the social benefit of time savings—an essential metric for urban transportation efficiency and productivity—remains underexplored. This study addresses this gap by estimating consumers’ willingness to pay (WTP) for time savings on MaaS platforms. Using the Contingent Valuation Method (CVM), we analyze personal preferences towards different time savings from a diverse urban sample, incorporating covariates such as gender, age, income, residency, commuting status, and access to mobility services. Based on the analysis, various consumer clusters that have homogeneous WTP for travel route search and travel time savings are identified, allowing for segmentation of urban mobility market. Characteristics of different clusters are examined to determine if seamless integration of different mobility services or reducing searching time is more valued by different consumer segments. The results reveal that consumers place significant economic value on search time reduction, with frequent commuters and urban residents with limited mobility alternatives exhibiting a higher WTP. These findings provide valuable insights for policymakers and service providers, underscoring the economic benefits of streamlining route-planning interfaces and supporting the

development of pricing models and platform features that prioritize time-saving aspect of the platform. Looking ahead, future research will extend this framework to analyze WTP for actual travel time reduction, enabling a more comprehensive understanding of the value proposition of MaaS across all phases of urban mobility.

3 - Optimizing Customized Bus Lines Considering Users' Transfer Willingness Under Cooperative and Competitive Relationship Between Metro and Online Car-Hailing

Beibei Wang, School of Economics and Management, Southeast University, Nanjing, China, People's Republic of, Xinyi Qi

In the context of 'carbon peak' and 'carbon neutrality', coordinating individual travel demand through multi-modal transportation and guiding travelers towards new shared public transport options is increasingly important. In this paper, we analyze the competitive and cooperative relationship between online car-hailing (OCH) services and metro systems in Nanning, China, and conduct a survey among different types of OCH users. A mixed choice model that considers psychological latent variables is constructed to investigate OCH users' attitudes and cognitions toward customized buses (CBs). An improved adaptive Density-Based Spatial Clustering of Applications with Noise (DBSCAN) algorithm is proposed to identify potential carpooling station sets, and a hybrid genetic-ant colony algorithm (GACA) is designed to solve bi-level programming model for CB line optimization. Additionally, a case study in Nanning indicates an 83.8% overall transfer rate from OCH users to CBs, with the optimized scheme achieving a 69.68% reduction in carbon emissions.

4 - Joint Optimization of Emerging Mobility Infrastructure and Services with Considerations of Accessibility and Fairness

Lindsay Graff, Carnegie Mellon University, Pittsburgh, PA, United States, Katherine Flanigan, Peter Zhang, Sean Qian

Cities are integrating new mobility modes into their transportation networks to improve route options and increase accessibility. Strategically co-locating mobility infrastructure and services is consequently of pivotal importance. This work introduces a bi-level, bi-objective mixed-integer program to jointly select the locations of bikeshare stations and microtransit service zones. The upper-level objective is a weighted sum of a system-level accessibility metric and the minimum value of the accessibility metric computed for any origin. The lower level solves the combined mode split and traffic assignment problem for a multimodal system with shared mobility. Since the relationship between the lower- and upper-level decision variables cannot be expressed in closed form, an iterated local search heuristic is used. A case study in Allegheny County, PA illustrates the benefit of joint optimization. When bikeshare and microtransit investments are optimized together, system-level accessibility increases by 4.0% relative to the transit-only baseline, and minimum-level accessibility rises by 8.7%. A key insight is that bikeshare and microtransit individually provide limited improvements for the most disadvantaged area, but their impact magnifies when deployed together. Experiments reveal diminishing marginal returns of the bikeshare budget on the combined objective value due to diminishing returns on the minimum-level accessibility metric. This suggests that the constraints of the existing public transit network limit the extent to which shared mobility can improve accessibility in the worst-off areas. Finally, Pareto optimization illustrates the importance of balancing system and fairness objectives to ensure that disadvantaged areas are not left behind in pursuit of broader system-wide gains.

5 - Optimizing a Ride-Hailing System with a Mix of on-Demand and Pre-Booked Customers Under Distributional Shift

Breno Serrano de Araujo, Technical University of Munich, Munich, Germany, Alexandre Jacquillat, Stefan Minner, Maximilian Schiffer

We consider a mixed-service ride-hailing system that offers customers the option to request a ride on-demand or to pre-book it in advance. For time-sensitive customers, pre-booking provides a service guarantee at a price premium. From the operator's perspective, pre-booking allows for planning ahead with higher certainty but may incur the duty to operate unfavorable trips that may even induce a shift in the demand distribution, e.g., in low-demand suburban neighborhoods. Against this background, we develop an optimization framework for a mixed-service ride-hailing system, allowing us to study the trade-offs between higher planning certainty and the rise of unfavorable rides due to shifts in the demand distribution. We propose a two-stage stochastic optimization formulation in which the first-stage problem consists of deciding which pre-booking requests to accept, while the second-stage problem involves assigning vehicles to requests and planning routes with uncertain on-demand requests. We present a sample average approximation formulation and a scalable solution algorithm that approximates the second-stage subproblems using a polynomial-time algorithm. We conduct experiments based on yellow taxi trip data from New York City. We show that greedily accepting all pre-booking requests leads to a 14.5% profit reduction compared to a purely on-demand baseline in environments with strong distributional shifts. In contrast, our proposed solutions lead to profit increases between 6.5% and 7.7%, in settings with weak and strong distributional shifts, respectively, while satisfying customer pick-up time windows. Additionally, we provide managerial insights to assist operators in making informed design choices to counteract the effects of distributional shifts.

Urban Logistics Network Design and Operations

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Dipayan Banerjee, Loyola University Chicago, 220 W Illinois St, Chicago, IL, 60654, United States

1 - Service Network Design in Intra-City Express Delivery

Tirui Cao, Tsinghua University, Beijing, China, People's Republic of, Lei Zhao, Yixiao Huang, Alexandre Jacquillat, Alexandria Schmid

Intra-city express delivery is an emerging service that enables customers to send and receive packages in the same city within a short delivery window. Its time- and cost-efficiency relies on a dedicated intra-city service network, where packages are transported between and consolidated at a number of satellite stations located in the city. A key challenge in designing and operating such service networks lies in the limited docking capacity to unload/load packages at satellite stations, which often leads to congestion and delays. Besides increasing docking capacity at certain satellite stations, one may also reroute a subset of intra-city packages using the spare capacity of the inter-city service network (independently designed for inter-city express delivery). This mitigates congestion at the satellite stations and shortens the delivery time for the remaining packages, yet introduces extra detour and sorting time for the rerouted packages. We show in a theoretical model that, when these trade-offs are properly balanced, leveraging the inter-city service network can shorten average delivery time and reduce total operational cost. Further, we formulate the intra-city express delivery service network design problem as an integer programming model and explore two solution algorithms: a column generation-based algorithm and a multi-arc generation-based algorithm.

Based on real world instances from a major express delivery carrier in China, our preliminary numerical experiments demonstrate the scalability of the proposed algorithms and validate the value of leveraging the inter-city service network to improve service quality and reduce operational cost in intra-city express delivery.

2 - Stochastic Fleet Coordination in Disaster Relief: a Model for Integrated Evacuation and Supply Delivery

Mina Samiei Nasab, University at Buffalo, Buffalo, NY, United States, Rajan Batta

This research addresses a dynamic transportation planning problem in the context of post-disaster humanitarian logistics, an area that lies at the heart of the Transportation Science and Logistics (TSL) domain. Specifically, we develop an integrated model to coordinate a heterogeneous fleet of vehicles to serve victims with evolving and time-sensitive needs. Victims are classified into two groups: those requiring immediate evacuation (Category A) and those initially needing critical supply delivery (Category B). However, Category B victims can deteriorate with time, creating cascading demand on already limited evacuation resources. Most existing models treat evacuation and delivery as separate problems, overlooking the synergistic potential of joint coordination. Our research bridges this gap by introducing a unified optimization framework where different vehicle types work in coordination to handle both evacuation and delivery operations, expanding operational reach and enabling more flexible, adaptive operations. The core problem involves the simultaneous routing of multiple vehicle types, selection of service points, and real-time reassignment based on endogenous uncertainty in service times and victim deterioration.

3 - Joint Bus Trip Scheduling and Vehicle Assignment: A Scalable Iterative Framework for Time-Dependent Travel Times

Yuhan Tang, Massachusetts Institute of Technology, Cambridge, MA, United States, Charlie Liu, Chonghe Jiang, John Attanucci, Haris Koutsopoulos, Jinhua Zhao

This research addresses the inefficiencies in traditional bus scheduling systems that rely on fixed runtime estimates, which fail to capture delay propagation—where delays on one trip adversely affect subsequent trips served by the same bus—and passenger demand variability. To overcome these shortcomings, we develop an integrated optimization model that simultaneously determines bus trip departure times and bus assignments using a mixed-integer quadratic programming framework. The model also incorporates robust optimization to handle travel time uncertainty, ensuring effective scheduling under real-world operational conditions.

Our approach features a network flow formulation for bus assignment that yields a notably tight linear relaxation, enhancing both solution quality and computational efficiency. To improve scalability and tractability, we employ Benders decomposition to decouple the problem into two stages: a trip scheduling phase focused on minimizing total passenger waiting time, and a bus assignment phase formulated as a minimum path cover problem in an acyclic graph.

Numerical experiments and a case study on Chicago Transit Authority's Route 22 demonstrate that the integrated model significantly reduces passenger waiting times and improves operational efficiency compared to conventional methods. Academics benefit from an advanced theoretical framework that integrates delay propagation and robust optimization. Transit practitioners gain a data-driven tool for enhancing service reliability, while policy makers receive quantitative insights supporting sustainable urban mobility and informed resource allocation.

4 - Service Network Design of Modular Vehicles on General Road Networks Considering Passengers' Turning Choices

Xiaolei Wang, Tongji University, Shanghai, China, People's Republic of, Jiahui Yu, Lei Guo, Zhibin Chen, Zhe Liang

The emergence of modular vehicles (MVs) opens the avenue to an entirely new urban transit system, in which a fleet of modular vehicles circulating within the road network constitute a dynamic MV service network, and transit passengers can freely and stop-lessly choose where they go at each intersection by transferring to the appropriate pod. Provided feasible MV circulation patterns on the road network, this paper develops a novel mathematical model to depict passengers' turning choices at user equilibrium in the MV service network. We establish the equivalence of this model to a linear optimization problem, which can be further transformed into a multi-commodity network flow problem on a revised network. Taking passengers' turning choices as the lower-level problem, we then propose a bi-level problem to optimize the MP circulation pattern. We show that this bi-level problem can be transformed into a single-level problem with bi-convex property, and employ a multi-start alternating minimization (AM) algorithm to solve it by iteratively solving two convex subproblems. The convergence of the AM algorithm is theoretically established, and tailored algorithms are developed for solving each subproblem efficiently in large-scale networks. Numerical experiments are conducted to validate the model and algorithm, and demonstrate the computational efficiency on large-scale networks.

5 - Optimal Batching and in-Building Delivery Routing with Capacitated Residential Parcel Lockers

Dipayan Banerjee, Loyola University Chicago, Chicago, IL, United States, Ignacio Erazo

In this work, we optimize the operations of a parcel delivery firm that has access to a residential parcel locker (RPL) in the lobby of a high-rise building. We assume that the number of parcels to be delivered on a particular day exceeds the number of available RPL compartments; parcels that cannot be delivered to the RPL must be delivered to residents' doorsteps on upper floors of the building. Given certain building features, such as floor layouts and elevator waiting time distributions, we seek to determine the optimal subset of parcels to deliver to the RPL. For the remaining parcels, we seek to optimize the driver's travel route within the building; when the number of non-RPL packages exceeds the driver's carrying capacity, we additionally seek to determine an optimal separation of the non-RPL packages into batches. Our objective is to minimize the expected time to deliver all of the building's parcels. Under mild assumptions, we first derive a polynomial-time algorithm for determining the optimal sequence of floor visits given a set of parcels to deliver at residents' doorsteps. We then leverage this algorithm to develop a branch-and-price solution approach capable of solving realistically sized instances of the full problem to optimality.

Striking the Balance of Innovation and Responsible Ethical AI

Panel Session

Practice Track

Co-Chair: Archi Pandurangi, ISpot TV, Alpharetta, United States

1 - Moderator Panelist

Archi Pandurangi, ISpot TV, Alpharetta, GA, United States

As artificial intelligence reshapes industries and decision-making at scale, the tension between rapid innovation and responsible governance grows ever sharper. This panel explores how leaders and technologists can drive cutting-edge advancements while upholding ethical standards that protect individuals, communities, and democratic values. From algorithmic transparency and bias mitigation to compliance frameworks and long-term societal impacts, panelists will examine real-world trade-offs and decision points. With perspectives spanning enterprise analytics, product development, and regulatory oversight, the discussion will highlight pragmatic approaches for embedding ethics into scalable AI systems—ensuring that innovation doesn't outpace accountability.

2 - Panelist

1 - Optimal Pure Strategies for a Discrete Search Game**Thuy Bui, Rutgers University, New Jersey, NJ, United States**

Consider a two-person zero-sum search game between a Hider and a Searcher. The Hider chooses to hide in one of n discrete locations (or “boxes”) and the Searcher chooses a search sequence specifying which order to look in these boxes until finding the Hider. A search at box i takes t_i time units and finds the Hider—if hidden there—independently with probability q_i , $i = 1, \dots, n$. The Searcher wants to minimize the expected total time needed to find the Hider, while the Hider wants to maximize it. It is shown in the literature that the Searcher has an optimal search strategy that mixes up to n distinct search sequences with appropriate probabilities. This paper investigates the existence of optimal pure strategies for the Searcher—a single deterministic search sequence that achieves the optimal expected total search time regardless of where the Hider hides. We identify several cases in which the Searcher has an optimal pure strategy, and several cases in which such optimal pure strategy does not exist. An optimal pure search strategy has significant practical value because the Searcher does not need to randomize their actions and will avoid second guessing themselves if the chosen search sequence from an optimal mixed strategy does not turn out well.

2 - A Prioritized 2-D Packing Model for Military Combat Loading**William Kirschenman, North Carolina State University, Raleigh, NC, United States, H. Sebastian Heese, Michael Kay, Russell King, Brandon McConnell**

Rapid and accurate combat loading of personnel and equipment is critical to success in large-scale, contested military operations. Existing tools like the Integrated Computerized Deployment System (ICODES) Single Load Planner assist with generating load plans but rely heavily on manual item placement and constraint checks performed by the user interface’s built-in “agents.” This research introduces a prioritized two-dimensional bin packing (2D-BPP) approach to automate and optimize these decisions. We formulate the problem as a mixed-integer linear program (MILP) minimizing a weighted rectilinear distance objective capturing multi-level tactical priorities for item placement relative to each other and access points. The MILP model integrates essential constraints including non-overlap, fixed obstacle avoidance, minimum item separation, and critically, global load balancing via center-of-gravity limits.

While smaller instances are solvable directly using commercial solvers (e.g., Gurobi), we utilize a two-stage framework. Stage 1 uses a sliding-window decomposition method for an initial plan optimized for the prioritized distance objective. Stage 2 applies a post-processing MILP adjustment to meet load balancing constraints. This MILP performs minimal modifications targeting center-of-gravity limits for load balance, preserving Stage 1 tactical priorities. Compared to alternatives like in-stride penalization during Stage 1’s iterative subproblem solves, this post-processing MILP adjustment within the two-stage framework is the most promising approach for effectively balancing competing objectives.

Results with realistic military equipment data show this two-stage decomposition framework rapidly generates high-quality, balanced, tactically sound load plans, significantly improving upon current methods. We analyze performance trade-offs between the exact MILP and this two-stage approach.

3 - Comparing Milp Formulations for Medevac Mission Planning**Armin Fugenschuh, Brandenburg University of Technology, Cottbus, Germany**

Rapid and reliable air- or ground-based medical evacuation (MEDEVAC) remains a core operational challenge in military missions. We introduce and compare two mixed-integer linear programming (MILP) models that automate MEDEVAC dispatching while explicitly accounting for escort vehicles, mission safety, and limited resources.

The first model is a **time-expanded network** formulation that discretizes the planning horizon into successive layers, tracking vehicle movements, patient transfers, and escort assignments on a replicated battlefield graph. The second, a **path-and-time** formulation, couples binary routing decisions with continuous departure and arrival times, thereby avoiding full time discretization while preserving all precedence and risk constraints.

A common set of benchmark instances will evaluate runtime, solution quality, and scalability, revealing the conditions under which each formulation excels or struggles. Beyond this comparative analysis, we outline avenues for integrating multicriteria objectives—such as balancing safety and speed—and for incorporating real-time information. These insights aim to guide practitioners in selecting and tuning optimization engines for next-generation, AI-assisted MEDEVAC planning tools.

4 - Strengthening Secure Communications: Addressing Operational Risks in Messaging Platforms**David Gurzick, Hood College, Frederick, MD, United States, Jonathan Shaw Wood, Gerard Werner**

Secure messaging applications like Signal offer end-to-end encryption, yet recent events have exposed significant operational risks when these tools are used improperly. A high-profile case involving a senior US official’s misuse of Signal highlighted how even strong encryption cannot prevent operational security failures without strict access controls. Drawing from these vulnerabilities and lessons learned, we propose a novel framework for secure communications built around three key principles: (1) isolated session-based communications, (2) ephemeral keying, and (3) continuous real-time access validation. In this model, each communication session forms a temporary, encrypted peer-to-peer tunnel established only after multi-factor authentication and dynamic authorization checks. Encryption keys are generated for single use and destroyed immediately after the session ends, leaving no persistent access points. Continuous endpoint monitoring ensures that any change in authorization status results in instant revocation of access, even during active sessions. Unlike traditional messaging platforms, this approach ensures that unauthorized individuals cannot join, monitor, or retroactively access sensitive exchanges. The design addresses gaps exposed by incidents like the Signal case, providing stronger operational resilience by embedding zero trust and dynamic control into the core of session management.

5 - Are More Competitive Supply Chains More Resilient? Evidence from Defense Industrial Base (DIB) Supply Chains**Yiseon Choi, The Ohio State University, Columbus, OH, United States, Noah Dormady, Ruhaimatu Abudu**

This paper explores the resilience of supply chains within the Defense Industrial Base (DIB), a critical infrastructure sector designated under Presidential Policy Directive 21 (PPD-21). We surveyed domestic and international firms involved in the supply chains of critical materials such as small arms munitions and eight DIB-critical metals, several of which are classified as strategic or rare. We collected data on resilience tactics (e.g., input substitution, resource isolation) employed by firms in response to disruptions and assessed the economic avoided losses that would have occurred in the absence of these tactics using a unique survey methodology. Through firm and tactic-level analyses, we evaluate the cost-effectiveness of resilience tactics and compare the severity of supply chain disruptions. This paper takes a novel approach to explore how firm size influences resilience and traces the pathways through which input substitutability affects firm resilience. We use Structural Equation Models (SEM) to estimate both the direct and indirect effects of having a larger pool of input suppliers on the magnitude of losses a firm can avoid by leveraging resilience tactics. Specifically, we trace the pathway from the size of the supplier pool through the expected duration of the disruption, and ultimately to the firm’s resilience outcome. The findings show that access to a larger pool of potential suppliers is associated with longer disruption durations, which in turn allows firms to avoid greater losses, particularly when operating under fixed-price supply contracts.

6 - Army Officer Rebranching: A Multicriteria Optimization Model for Rebalancing Officer Inventories**Matthew Ferguson, United States Army Human Resources Command, Elizabethtown, KY, United States**

The U.S. Army’s officer career fields are divided into branches with varying personnel needs; some require a surplus of junior officers, while others need more senior officers. Historically, the Army corrected these imbalances through a branch detailing process. However, the recent transition to a voluntary branch detail system has diminished the effectiveness of this approach, leading to projected mismatches in officer inventory that could negatively impact professional military education, career development and unit readiness. To address these challenges, the Army developed the Officer Rebranching Process (ORP) allowing an opportunity for junior Army officers another opportunity to voluntarily transfer branches as junior officers. The Army elicits ordinal and possibly incomplete preferences from junior officers eligible to transfer branches over a set of branches that are projected to require additional officers, and capacities for each branch, as well as limitations on transfers, are defined. We present the development and implementation of an optimization model supporting the ORP. The model employs a multicriteria lexicographic framework from the

literature to balance Army readiness requirements with officer preferences. This approach balances several objectives defined by stakeholders and resulted in rapid stakeholder agreement. The model was initially developed and utilized in 2024 and a revised version of the model used in 2025 to voluntarily reassign Army officers among branches while accounting for both Army readiness requirements and individual officer preferences.

7 - Time-Constrained Sample Average Approximation for Port Selection in Lateral Transshipment with Stochastic Travel Time

Lennon Conson, U.S. Air Force, Urbana, OH, United States, Brian Lunday, Matthew Robbins

This presentation introduces both a model and a time-constrained solution algorithm for port selection in lateral transshipment with stochastic travel times. In our problem, roll-on/roll-off equipment is dispersed across the continental United States. An emergency deployment order directs that a portion of the equipment be shipped to a single overseas seaport of debarkation (SPOD). The equipment must be moved first by rail to selected seaports of embarkation (SPOEs) and then shipped to the SPOD. Because only a limited number of SPOEs can be activated, a first-stage decision—which ports to open—must be made within a set amount of time.

We formulate the problem as a large-scale two-stage stochastic mixed-integer program that captures rail-to-ship synchronization, processing limits at each SPOE, and stochastic rail and ship travel times. Because the first-stage decision must be made within a limited amount of time before transshipment begins, we propose a Time-Constrained Sample Average Approximation (TC-SAA) framework. TC-SAA has two distinct phases: pre-deployment metamodeling and emergency-deployment. During the pre-deployment metamodeling phase, planners solve a representative set of SAA instances created with a space-filling design over plausible demand profiles. In the emergency deployment phase, the algorithm utilizes the first-phase metamodeling to choose an appropriate SAA sample size that allows for enough replications to reduce the predicted estimated optimal gap.

8 - Simulation-Supported Decision Analysis of Command Structures Under Contextual Uncertainty

Murat Balci, Old Dominion University, Norfolk, VA, United States

This research introduces a decision analysis framework supported by simulation to compare the effectiveness of centralized and decentralized command structures, under varying operational conditions. The framework is grounded in a rational inductive approach, combining conceptual modeling with discrete-event simulation to analyze decision performance under uncertainty.

Using Lanchester-based attrition modeling, the simulation explores scenario variations such as force imbalance, reinforcement timing, and decision latency. The outcomes are measured using two core decision objectives: mission effectiveness and resource efficiency. The framework is applied to compare how structural command constraints, unity of command versus decentralized responsiveness, affect outcome robustness in both deterministic and stochastic environments.

Rather than focusing on doctrinal correctness, this study treats command styles as decision architectures, each offering different trade-offs in flexibility, coordination, and risk exposure. The results provide structured insights into when and why particular decision frameworks outperform others depending on the operational context. The study contributes to the decision analysis literature by offering a generalized approach to evaluating organizational decision structures in complex, dynamic environments.

Strategic Interactions in Service Systems

Invited Session

Applied Probability Society

Chair: Ran Snitkovsky, Collier School of Management, Tel Aviv University, Tel Aviv - Jaffa, Israel

1 - On the Value of Service Age Information

Ricky Roet-Green, Simon Business School, University of Rochester, Rochester, NY, United States

Sharing service age information with customers has become a common practice among electric vehicle (EV) charging companies. This information plays a crucial role in customers' waiting decisions, as charging times can range from 30 minutes to several hours. To reduce uncertainty and improve drivers' willingness to wait, many companies now disclose service age details. The vast majority of papers in the literature ignore service age information because they assume an exponential service time distribution. However, this Markovian service assumption, which is intended to simplify the analysis, is less common in real-life settings. In cases of general service distributions where the memoryless property does not hold, service age becomes crucial for helping customers better estimate their waiting time and plays an important role in their decision to join the queue. While recent research has highlighted that disclosing queue-length information to customers may improve system performance, the value of revealing the service age information remains unaddressed. Our work aims to close this gap.

2 - Preemption Pays: Optimal Preemptive Priority Pricing in M/G/1 Queues

Binyamin Oz, Hebrew University of Jerusalem, Jerusalem, Israel, Moshe Haviv, Elisheva Zur

In an M/G/1 queueing model where the mean residual service time is larger than the mean service time itself, preemption improves the performance of the system. One way to utilize this idea is by granting customers preemptive priority via a lottery. We derive the optimal probabilities of this lottery for any preassigned number of priority classes. In particular, the optimal probabilities define a truncated geometric distribution with a parameter which is a function only of the system's traffic intensity and the number of priority classes. Then we show how these probabilities can be implemented via the introduction of various prices across the priority classes, while the customers, who select and pay for a priority class, are engaged in a non-cooperative game among themselves. These probabilities define a mixed Nash equilibrium. Finally, we identify a range for the system's traffic intensity where, regardless of the number of priority classes, this equilibrium is unique and the (generalized) avoid the crowd (ATC) property prevails.

3 - Information Asymmetry In Queues with Strategic Customers

Shunan Zheng, University of Texas at Austin, Austin, TX, United States

In this work we study information asymmetry in an unobservable single-server queueing system. While system managers have knowledge of the true arrival rate, customers may lack this information and instead form arbitrary beliefs. We propose a three-tier hierarchy of information asymmetry with increasing levels of information disclosure. Within this framework, the effects of the belief distribution, which is assumed to be general with minimal restrictions, are analyzed in terms of equilibrium joining probabilities, revenue, and social welfare. Furthermore, strategies for information disclosure are proposed for system managers to regulate the queue.

4 - From Baseline to Boost: Optimizing and Re-Optimizing Price and Capacity in Response to Marketing-Driven Demand Growth

Levent Kocaga, Sy Syms School of Business, New York, NY, United States

Many service firms optimize pricing and capacity to serve customers who are sensitive to both price and congestion. In such settings, the endogenous demand is influenced by both price and capacity which leads to a complex equilibrium with no closed-form expression for the arrival rate. This challenge is further complicated when firms undertake marketing promotions, such as advertising, which expand the market size over time. In response, firms must re-optimize pricing, capacity, or both to effectively leverage this increased demand. We study this joint pricing and capacity problem in the context of a large-scale service provider modeled as an unobservable M/M/C (Erlang-C) queue. Customers have heterogeneous valuations and choose to purchase if their valuation exceeds the sum of the price and expected delay cost. This strategic behavior induces an endogenous equilibrium arrival rate, and the provider aims to maximize profit—defined as revenue minus linear capacity costs—based on this equilibrium. We distinguish between initial optimization, which targets a baseline market size, and re-optimization, which occurs post-promotion. Depending on operational flexibility, the provider may adjust both price and capacity or only one. Because exact equilibrium analysis is intractable, we use an asymptotic approach: letting market size grow while holding individual preferences fixed. This yields tractable, near-exact expressions for optimal decisions and profit. Our results show that

substantial gains from market expansion can be captured by adjusting capacity alone. We also account for marketing costs and provide guidance for designing near-optimal promotions that align with operational capabilities and profit goals.

Learning in Dynamic Environments

Invited Session

Applied Probability Society

Chair: Moise Blanchard, Georgia Tech, Somerville, MA, United States

1 - Sequential Learning Under Distribution Shifts

Samory Kpotufe, Columbia University, New York, NY, United States

We consider sequential learning, e.g., ‘online learning’ and ‘bandits’, under distribution-shifts settings that interpolate between fully adversarial and stochastic (i.e. where observations are i.i.d.). The main questions of interest revolve around the types performance possible under relevant notions of performance, e.g., dynamic or adversarial regrets, and elucidating conditions on intervening distributions that affect such performance.

2 - Conformal Prediction Under Levy-Prokhorov Distribution Shifts: Robustness to Local and Global Perturbations

Julie Zhu, MIT, Cambridge, MA, United States, Liviu Aolaritei, Oliver Wang, Michael Jordan, Youssef Marzouk

Conformal prediction provides a powerful framework for constructing prediction intervals with finite-sample guarantees, yet its robustness under distribution shifts remains a significant challenge. This paper addresses this limitation by modeling distribution shifts using Levy-Prokhorov (LP) ambiguity sets, which capture both local and global perturbations. We provide a self-contained overview of LP ambiguity sets and their connections to popular metrics such as Wasserstein and Total Variation. We show that the link between conformal prediction and LP ambiguity sets is a natural one: by propagating the LP ambiguity set through the scoring function, we reduce complex high-dimensional distribution shifts to manageable one-dimensional distribution shifts, enabling exact quantification of worst-case quantiles and coverage. Building on this analysis, we construct robust conformal prediction intervals that remain valid under distribution shifts, explicitly linking LP parameters to interval width and confidence levels. Experimental results on real-world datasets demonstrate the effectiveness of the proposed approach.

3 - Tackling Transfer Learning Problems Optimally: Methods for Regression Under Covariate Shift

Liviu Aolaritei, UC Berkeley, Berkeley, CA, United States, Michael I. Jordan, Reese Pathak, Annie Ulichney

Modern machine learning methods are often deployed in scenarios where the training and test data distributions differ. Motivated by these distribution shifts, in this work, we study linear regression under a form of distribution shift known as covariate shift. When the covariance matrix of the training distribution is appropriately bounded by the covariance matrix of test distribution, we derive computationally efficient and statistically optimal estimators. Our work quantifies how the interaction between constraints on the underlying regressors and the level of discrepancy between the training and test distributions determine the statistical complexity of such learning problems.

4 - Learning in a Changing World: Perspectives from Abstention and Relaxed Benchmarks

Abhishek Shetty, Massachusetts Institute of Technology, Cambridge, MA, United States

Though modern machine learning has been highly successful, as we move towards more critical applications, many challenges towards building trustworthy systems, such as ensuring robustness, privacy, and fairness, arise. Ad hoc and empirical approaches have often led to unintended consequences for these objectives, thus necessitating a principled approach. Traditional solutions often require redesigning entire pipelines, come with a significant loss in quality or typically make strong assumptions on the data. In this talk, we will look at principles towards incorporating important desiderata into existing pipelines without significant computational and statistical overhead. Towards addressing this, we look at two perspectives on prediction on arbitrary data sequences: abstention and relaxed benchmarks. We will show that using these perspectives allows us to circumvent impossibility results regarding prediction. Further, we will convey connection between these perspectives and other perspectives on beyond worst case analysis of learning. The talk will be based on joint works with Surbhi Goel, Steve Hanneke, Shay Moran, Omar Montasser and Nikita Zhivotovsky.

5 - Improved Rates for Online Calibration

Noah Golowich, MIT, Cambridge, MA, United States, Yuval Dagan, Constantinos Daskalakis, Maxwell Fishelson, Robert Kleinberg, Mehryar Mohri, Princewill Okoroafor, Jon Schneider

A set of probabilistic forecasts is calibrated if each prediction of the forecaster closely approximates the empirical distribution of outcomes on the subset of timesteps where that prediction was made. In this talk we discuss the fundamental problem of online calibrated forecasting, in which an adversary chooses the outcomes which are revealed to the forecaster in a sequential manner.

We begin by studying the setting where the predictions are binary, which was initiated by Foster & Vohra (1998). They derived an algorithm with $T^{2/3}$ calibration error after T time steps, and showed a lower bound of $T^{1/2}$. We give the first improvement to the $T^{2/3}$ upper bound on calibration error of Foster & Vohra. To do so, we study a combinatorial game called sign preservation recently introduced by Qiao & Valiant (2021) and show new upper bounds on the value of this game.

In the second half of the talk, we move to the problem of high-dimensional calibration, where the forecasts belong to an arbitrary convex subset of Euclidean space. We connect this problem with that of regret minimization for online linear optimization, showing that upper bounds for regret minimization imply the existence of efficient calibrated algorithms. In the special case that the convex subset is the simplex, our result recovers a recent result of Peng (2025). Moreover, we establish a lower bound showing that our result is near-optimal, significantly improving a corresponding lower bound of Peng for this problem.

Electrification of Urban Transportation

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Dongyang Xia, Delft University of Technology, Delft, N/A, Netherlands

1 - A Bilevel Optimization for Electric Vehicles Charging Stations Placement

Mobina Nankali, University of Minnesota, Minneapolis, MN, United States, Michael Levin

Planning electric vehicle (EV) charging infrastructure requires balancing economic goals with user convenience and demand patterns. A bilevel optimization framework is developed to capture the strategic decisions of network planners, who aim to maximize revenue through optimal station placement, and the responsive behavior of EV users, who seek to minimize travel time and charging costs. A solution method is proposed, combining High Point Relaxation, Value Function Cuts, and Outer Approximations to refine the solution space systematically. A Branch-and-Price-and-Cut (BPC) algorithm further enhances computational efficiency by integrating column generation, allowing the model to scale with large user path sets. Results demonstrate that explicitly modeling user behavior leads to more efficient and profitable infrastructure outcomes, improving station utilization and reducing investment waste.

2 - First-in-first-out (FIFO) or highest-energy-first-out (HEFO)? A tale of two electric vehicle (EV) battery swapping policies

Mengyi Sha, Tsinghua University, Beijing, China, People's Republic of

3 - Data-Driven Battery Swapping Routing Methods for E-Bike Sharing Systems

Xinyu Jiang, Tsinghua University, Beijing, China, People's Republic of, Wei Qi

Shared e-bike systems have emerged as a vital component of sustainable urban mobility. Efficiently managing their battery swapping operations, specifically the routing of service staff, is paramount for ensuring e-bike availability and overall system viability. However, current approaches often optimize limited short-term metrics and compromise long-term value. They struggle with dynamic adaptation, fairness integration and scalability due to inflexible parameter setting. This paper presents a novel data-driven framework to address these challenges through the integration of continuous-time Markov chains (CTMCs) and reinforcement learning (RL). A CTMC is proposed to model the state of e-bikes in each sub-region. Based on the states of sub-regions, a spatio-temporal network model is established to capture the decision process of battery swapping routing, with the objective of maximizing the long-term value of regional operations. Adaptability and human-centricity are enhanced via a feedback mechanism that leverages large language models to interpret staff input. The optimization of routing model parameters is achieved through an RL method guided by a comprehensive reward function which incorporates efficiency, fairness and service metrics. Collaborating with one of the leading shared e-bike operators in China, we validate the proposed method using both synthetic data and test instances built on their real operational dataset. Extensive experiments across multiple scenarios demonstrate that our approach outperforms existing strategies in terms of computational efficiency, battery swapping performance, fairness and scalability. This research contributes an advanced artificial intelligence-assisted methodology for battery swapping routing and offers practitioners an adaptive solution to improve operational performance in shared mobility systems.

4 - Robust Charging Station Location and Routing-Scheduling for Electric Modular Autonomous Units

Dongyang Xia, Delft University of Technology, Delft, Netherlands, Lixing Yang, Yahan Lu, Shadi Sharif Azadeh

Motivated by global electrification targets and the advent of electric modular autonomous units (E-MAUs), this paper addresses a robust charging station location and routing-scheduling problem (E-RCRSP) in an inter-modal transit system, presenting a novel solution to traditional electric bus scheduling. The system integrates regular bus services, offering full-line or sectional coverage, and short-turning services. Considering the fast-charging technology with quick top-ups, we jointly optimize charging station locations and capacities, fleet sizing, as well as routing-scheduling for E-MAUs under demand uncertainty. E-MAUs can couple flexibly at different locations, and their routing-scheduling decisions include sequences of services, as well as charging times and locations. The E-RCRSP is formulated as a path-based robust optimization model, incorporating the polyhedral uncertainty set. We develop a double-decomposition algorithm that combines column-and-constraint generation and column generation armed with a tailored label-correcting approach. To improve computational efficiency and scalability, we propose a novel method that introduces super travel arcs and network downsizing methodologies. Computational results from real-life instances, based on operational data of advanced NExT E-MAUs with cutting-edge batteries provided by our industry partner, indicate that charging at both depots and en-route fast-charging stations is necessary during operations. Moreover, our algorithm effectively scales to large-scale operational cases involving entire-day operations, significantly outperforming state-of-the-art methods. Comparisons with fixed-composition buses under the same fleet investment suggest that our methods are able to achieve substantial reductions in passengers' costs by flexibly scheduling units. Our approach is appealing to operators, providing entire-day solutions with enhanced service quality.

5 - National Electric Truck Charging Network Planning with Cluster-Based Optimization and Temperature Sensitivity

Hanieh Rastegar Moghaddam Bajestani, University of Illinois at Chicago, Chicago, IL, United States, Xi Cheng, Xueqi Zeng, Amir Shafiee, Jialu Yang, Chi Xie, Jane Lin

This study develops a scalable optimization framework for electric truck (ET) charging infrastructure planning, explicitly incorporating temperature-dependent battery efficiency and network-wide flow patterns across the United States. Unlike previous approaches, which address the problem on a national scale as a monolithic network, we propose a novel hierarchical decomposition approach that enables computational tractability over the U.S. national interstate highway network. The proposed method first applies spatial clustering to partition the national highway network into several geographically coherent regions based on freight flow density and spatial proximity derived from and Federal Highway Administration (FHWA)'s Freight Analysis Framework (FAF) data. Within each cluster, a bi-level optimization model is solved to jointly optimize charging station location, sizing, and long-haul ET routing, while capturing user equilibrium under local temperature variations and queuing delays using a convex combinations algorithm embedded with a multi-criterion label-correcting method. To address inter-cluster flows, a corridor-based routing strategy is proposed to optimize key long-haul connections between clusters. These sub-network solutions are then integrated to form a comprehensive charging infrastructure plan that balances intra-regional efficiency and national connectivity. By decomposing the full-scale problem and capturing both local operational constraints and cross-regional interactions, our approach provides a practical and flexible planning framework for nationwide ET deployment. The updated model will be validated with the FAF commodity and truck flows. This research offers policy insights into regionalized infrastructure investment, adaptive planning under environmental constraints, and scalable frameworks for decarbonizing freight transportation at the national level.

Processes and Algorithms on Networks

Invited Session

Applied Probability Society

Chair: Souvik Dhara, Purdue University, West Lafayette, IN, United States

1 - Testing a Planted Matching in a Random Graph at the Critical Threshold

Cheng Mao, Georgia Institute of Technology, Atlanta, GA, United States

To study inference of hidden information in statistical networks, researchers have been working extensively on random graph models with planted structures in recent years. In this work, we focus on testing the presence of a planted matching in a random graph. Our results not only identify the statistical threshold for this problem but also establish the asymptotic normality of the log-likelihood ratio at the critical threshold. To achieve this, we provide two approaches, one based on an orthogonal decomposition of the likelihood ratio and the other based on the cluster expansion of the log-likelihood ratio. Either approach shows that the likelihood is dominated by the signed wedge count, a simple statistic that is both statistically optimal and computationally efficient.

2 - Propagation of Shocks on Networks: Can Local Information Predict Survival?

Souvik Dhara, Georgia Institute of Technology, Atlanta, GA, United States

Complex systems are often fragile, where minor disruptions can cascade into dramatic collapses. Epidemics serve as a prime example of this phenomenon, while the 2008 financial crisis highlights how a domino effect, originating from the small subprime mortgage sector, can trigger global repercussions. Similarly, a massive power outage in eastern North America was seemingly set off by a localized fault. The mathematical theory underlying these phenomena is both elegant and foundational, profoundly shaping the field of Network Science since its inception. In this talk, I will present a unifying mathematical model for network fragility and cascading dynamics, and explore its deep connections to the theory of local-weak convergence, pioneered by Benjamini-Schramm and Aldous-Steele.

3 - Mixing Phases and Metastability for the Glauber Dynamics on the P-Spin Curie-Weiss Model

Somabha Mukherjee, National University of Singapore, Singapore, Singapore, Ramkrishna Samanta, Jiang Zhang

In this talk, we will analyze the mixing behavior of Glauber dynamics for the p-spin Curie-Weiss model with an external field. By examining the structure of a related negative free-energy function, we will identify three disjoint regions in the parameter space, each corresponding to a different order of mixing time. These regimes depend on the number and nature of local maxima: fast mixing occurs when there's a unique, strongly concave maximum; exponentially slow mixing arises in the presence of multiple local maxima (metastability); and a critical regime with a flat maximum leads to polynomially slower mixing. We give a near-complete geometric characterization of these regions and show that the remaining portion of the space—a one-dimensional boundary curve—corresponds to an unresolved case involving

stationary inflection points, where one can establish a polynomial lower bound for the mixing time. Finally, we will demonstrate that even in the metastable regime, one can define a restricted version of the original Glauber dynamics that mixes rapidly within a single local basin.

4 - The DeGroot Model on Complex Networks

Fuwei Yu, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

The DeGroot model is a popular model for opinion formation on directed networks, where at each time-step individuals update their opinions by taking a weighted average of their neighbors' opinions, either synchronously or asynchronously. Provided the matrix of weights is irreducible, the model under synchronous updates is known to converge to the Perron-Frobenius eigenvector times the vector of initial opinions, resulting in consensus. In this talk we study the limiting opinions in the DeGroot model when the underlying network is generated through a random graph model having as a local weak limit a Galton-Watson process (single or multitype) and characterize the limit in terms of an associated weighted branching process.

1 - Optimal Immutable Series Selection in Forecast Reconciliation for Hierarchical TIME Series

Wai Yin Leung, Monash University, Melbourne, Australia, Shanika Wickramasuriya

Hierarchical time series (HTS) represent collections of time series organized according to aggregation constraints, such as geographical or product-based hierarchies. Forecasts for individual series in an HTS are typically generated independently, resulting in incoherence. Forecast reconciliation refers to the process of adjusting these base forecasts to ensure coherence. In standard reconciliation approaches, all forecasts are adjusted. However, in many practical settings, it may be necessary—or even beneficial—to keep certain forecasts unchanged. These are referred to as *immutable series*. Currently, the choice of which series to designate as immutable is often heuristic or based on domain expertise. This paper proposes a novel mathematical formulation and an iterative cutting plane algorithm to optimise the selection of immutable series in forecast reconciliation. We assess the scalability of the method via simulation and demonstrate its superior performance using Australian domestic tourism data.

2 - Ad Assignment with Social Influence: A Scalable Optimization Approach

Reyhaneh Kharazmi Pour, University of California, Irvine, Irvine, CA, United States, John Turner

In digital advertising, some advertisers prefer to show their ads to viewers who are socially connected, such as friends. The idea is that when friends are exposed to the same ad, it can increase influence and lead to higher engagement and conversion. Allowing for this kind of targeting creates new opportunities for publishers to generate more revenue, but it also makes the ad allocation problem more complex. We study an ad delivery setting where the value of assigning an ad to a viewer depends not only on the individual but also on whether their friends are assigned the same ad. This creates a need to jointly consider individual impact, social influence, advertiser budgets, and constraints across the entire viewer network. To address this, we develop an efficient algorithm that produces high-quality ad assignments while accounting for social connections. The algorithm is designed to scale to large instances and to find near-optimal solutions without requiring excessive computational resources.

3 - Optimal Forecast Reconciliation for Quantiles

Anastasios Panagiotelis, Monash University, CAULFIELD EAST, Australia, Hossein Alipour, George Athanasopoulos, Nam Ho-Nguyen

A new methodology is developed for reconciling probabilistic forecasts where the objective is to obtain accurate forecasts for a given quantile level. This is achieved by minimizing expected pinball loss, a challenging problem which we propose to overcome in two ways. First, to allow for full generality of base forecasts, expectations are approximated by drawing a sample from the base forecast. Second, to allow for optimization via first order methods, pinball loss is approximated by a smooth function. Theoretical results are developed proving that the minimizer of the objective function that employs these two approximations converges to the minimizer of expected pinball loss in the limit. The newly developed methodology is then applied in a simulated and real-world empirical setting and shown to significantly outperform the very competitive MinT benchmark.

4 - Dynamic Pricing Strategy for Perishable Products Considering Price and Age-Dependent Logit Demand Function

Moddassir Khan Nayeem, University of Texas at San Antonio-Department of Mechanical, Aerospace, and Industrial Engineering, San Antonio, TX, United States, Hamid Najafzad, Fuhad Ahmed Opu, Yara Altarawneh, Omar Abbaas

Effective pricing strategies are critical for managing perishable products due to their limited shelf life and declining consumer appeal as they age. This study introduces a comprehensive framework for dynamic pricing optimization, combining an exact algorithm, inflection point-based analysis, and six discount policies. The exact algorithm identifies revenue-maximizing prices for each product age by solving a logistic demand function using the Lambert W function, providing a precise solution. Building on this, the inflection point-based algorithm pinpoints ages where consumer sensitivity to price is highest, guiding price adjustments that sustain demand and enhance revenue. Six discount policies, including uniform, age-specific, threshold-driven, and lifecycle-based approaches, are proposed to address varying market dynamics. These policies target specific stages of the product lifecycle to balance inventory turnover and profitability. Results demonstrate significant demand and revenue improvements compared to baseline inflection point-based pricing. Uniform discounts at inflection points maximize total revenue, while lifecycle-based strategies achieve balanced performance across all ages. Policies tailored to specific stages, such as threshold-driven and uniform discounts for younger or older products, excel in inventory clearance or early profitability. This research offers actionable insights into aligning pricing strategies with consumer behavior and product lifecycle dynamics, equipping retailers with data-driven tools to optimize revenue, reduce waste, and enhance inventory turnover for perishable products.

5 - Auto-Calibration and Biconvex Compressive Sensing: Theory and Applications to Parallel MRI

Yuan Ni, University of California Davis, Davis, CA, United States, Thomas Strohmer

We study a class of blind inverse problems in which a transform-sparse signal is measured by multiple sensors with unknown system parameters. This setup naturally arises in a range of applications, including imaging, wireless sensing, and biomedical signal acquisition, where explicit calibration is difficult or impractical. The problem leads to a biconvex formulation involving simultaneous recovery of the signal and unknown sensing operators — a setting that is typically challenging due to the lack of theoretical recovery guarantees.

We address this challenge by reformulating the problem as a convex optimization task using the 'lifting' technique. By leveraging the signal's sparsity structure and the redundancy introduced by multiple sensors, we solve a mixed-norm minimization problem to jointly recover the signal and sensing parameters. We derive robust and stable recovery guarantees under noise and sparse deficiencies.

As a key application, we demonstrate the approach on self-calibrated parallel MRI (pMRI), where explicit coil sensitivities are often unavailable. Our method enables auto-calibrated imaging with theoretical guarantees and closes a longstanding theoretical gap, aligning with empirical findings reported in the pMRI literature.

6 - Parametric Workload Distribution for Balanced Optimization: Theory and Application

Abhay Singh Bhadoriya, Los Alamos National Laboratory, Los Alamos, NM, United States

Workload distribution is a fundamental challenge across various operations research applications, including multi-agent path planning, task assignment, and facility location. In general, workload balancing in all of these applications can equivalently be formulated as a problem of minimizing the dispersion of a vector of decision variables. In this talk, we will present a general parametrized family of constraints to control the dispersion of a vector of decision variables. We introduce a parameter to control the amount of dispersion and show that, in certain special cases, these constraints reduce to a single second-order conic constraint or a set of linear constraints. We will also discuss some theoretical properties for the same. Finally, we demonstrate the efficacy of the proposed formulations using off-the-shelf or existing methods on a few practical examples from vehicle routing, multi-agent task allocation and power grids.

7 - Linx Double-Scaling: An Enhanced Relaxation with Efficient Algorithm for the Maximum-Entropy Sampling Problem

Lingqing Shen, Carnegie Mellon University, Pittsburgh, PA, United States, Fatma Kılınc-Karzan

In this work, we study convex relaxations for the Maximum-Entropy Sampling Problem (MESP), a key problem in experimental design. We first use majorization theory to derive convex relaxations for a general class of principal submatrix selection problems, which recover the state-of-the-art DDFact [Li and Xie, 2024] and linx [Anstreicher, 2020] relaxations. We further analyze the majorization-based relaxations by establishing convex hull properties and equivalent representations. Next, we introduce a new double-scaling technique for the linx relaxation and prove that it admits a convex-concave saddle point formulation. In addition, we address two open questions posed by Chen et al. [2024], showing the convex-concavity of g-scaling for the DDFact relaxation and proving its equivalence to the original DDFact relaxation. Building on these results, we reveal a new connection between the DDFact and linx relaxations, both in their original and scaled forms, which, in particular, yields the first known bound on the integrality gap for linx. Finally, to efficiently solve the scaling relaxations as saddle point problems, we propose parameter-free variants of the extragradient algorithm with adaptive stepsize schemes and prove a non-ergodic convergence rate of $O(1/\sqrt{T})$. Our experimental results highlight the improved quality of the proposed linx double-scaling compared to g-scaling and o-scaling from the literature, and demonstrate the practical efficacy of our algorithm.

Statistical and Algorithmic Foundations of Reinforcement Learning

Tutorial session

Tutorials

Chair: Yao Xie, Georgia Institute of Technology, Atlanta, GA, United States

1 - Statistical and Algorithmic Foundations of Reinforcement Learning

Yuxin Chen, University of Pennsylvania, Philadelphia, PA, United States, Yuejie chi, Yuting Wei

As a paradigm for sequential decision making in unknown environments, reinforcement learning (RL) has received a flurry of attention in recent years. However, the explosion of model complexity in emerging applications and the presence of nonconvexity exacerbate the challenge of achieving efficient RL in sample-starved situations, where data collection is expensive, time-consuming, or even high-stakes (e.g., in clinical trials, autonomous systems, and online advertising). How to understand and enhance the sample and computational efficacies of RL algorithms is thus of great interest. In this tutorial, we aim to introduce several important algorithmic and theoretical developments in RL, highlighting the connections between new ideas and classical topics. Employing Markov Decision Processes as the central mathematical model, we cover several distinctive RL scenarios (i.e., RL with a simulator, online RL, offline RL, robust RL, and RL with human feedback), and present several mainstream RL approaches (i.e., model-based approach, value-based approach, and policy optimization). Our discussions gravitate around the issues of sample complexity, computational efficiency, as well as algorithm-dependent and information-theoretic lower bounds from a nonasymptotic viewpoint.

Network Design

Invited Session

TSL: Freight Transportation

Chair: Christian Truden, University of Klagenfurt, Klagenfurt, 9020, Austria

1 - Cost-Effective and Speedy Fulfillment for a Large Assortment to a Large Number of Customers

Kenneth Kuhn, Walmart, Seattle, WA, United States

Walmart would like to reduce fulfillment costs and increase delivery speeds for a large and increasing assortment of items to hundreds of millions of customers in the United States in the next five years. To accomplish this, we first forecast future demand, in time and space and by item group. We identify clusters of dense demand. Such areas can be cost-effectively served using delivery vans from a nearby Walmart facility. We go on to find optimal sets of Fulfillment Centers, Sortation Centers, and Delivery Stations to serve the demand clusters. We solve a four-layer transshipment optimization problem to produce an optimal fulfillment policy. Finally, we solve prototype vehicle routing problems to construct models of Delivery Station operations and analyze unit economics. We find that no single-layer Fulfillment Network or single delivery method or mode is capable of achieving our desired results. The lowest per package costs are achieved by using relatively full delivery vans in areas of dense demand. It makes sense for these vans to pick up packages at Sortation Centers and Delivery Stations that collect shipments from multiple Fulfillment Centers. Third-party express delivery services are particularly useful for last-mile deliveries in areas with sparse demand. We set out to identify the optimal, near-future, multi-layer Walmart Fulfillment Network and network flows of goods within this network and to customers. We needed to develop formulations of network design and network flow problems tailored to the Walmart use case. We needed to define solution search strategies that scale well.

2 - Hydrogen Refueling Station Location Problem Considering Pipeline Delivery

Jane Lin, University of Illinois Chicago, Chicago, IL, United States, Jialu Yang, Bo Zou

Hydrogen Fuel Cell Trucks (HFCTs) are promising alternatives to Diesel Trucks (DTs) for long-haul freight transportation in reducing greenhouse gas emissions while maintaining similar operational characteristics to DTs. Despite continued advancement in hydrogen technologies, investigation into strategic deployment of Hydrogen Refueling Stations (HRS) along the U.S. interstate highway network remains limited. Thus, this study considers an optimal hydrogen refueling station network design problem that minimizes the total cost of HRS construction and hydrogen delivery. In particular, we consider a hybrid hydrogen delivery method that utilizes the existing natural gas pipeline network throughout the country to deliver hydrogen from the production hubs to the storage facilities (reservoirs) and then trucks to delivery hydrogen from reservoirs to HRS. The problem is formulated as a Mixed-Integer Linear Program (MILP) that satisfies interstate highway freight demand using the Freight Analysis Framework (FAF) for 2050. A Lagrangian Relaxation-based decomposition algorithm is proposed and its performance is evaluated against Gurobi in terms of solution quality and computational efficiency. Our results highlight the predominance of HRS construction costs, constituting over 70% of total cost. Furthermore, pipeline-based hydrogen transport exhibits outstanding economic advantages over truck-based hydrogen delivery, underscoring the strategic importance of leveraging existing pipeline infrastructure and advocating for a dedicated hydrogen pipeline network in the future. The findings provide valuable policy implications for targeted governmental support in hydrogen distribution and refueling infrastructure building to facilitate economically viable adoption of HFCTs for long haul freight transportation.

3 - A Continuous Approximation Approach for Designing Collection and Delivery Point Networks

Benjamin Rojas, Pontificia Universidad Católica de Chile, Santiago, Chile, Homero Larrain, Mathias Klapp

Collection and delivery points (CDPs) are facilities where customers can pick up their online purchases, enabling logistics operators to consolidate multiple deliveries into a single stop and reduce distribution costs. However, the choice of the customer depends on factors such as personal preferences, proximity to the CDP network, and

economic incentives offered by logistics providers in the form of discounts or cashback. In this study, we propose a strategic model for designing a cost-efficient next-day last-mile distribution system that incorporates CDP pickups, balancing infrastructure investments, transportation costs, and customer incentives. Using a continuous approximation approach, we estimate total costs and determine the optimal number of CDPs and incentive levels. Key findings highlight that optimal CDP installation significantly reduces costs, especially in high-density demand areas. Additionally, incentives are especially effective in low-density areas, encouraging customers to travel further and reducing the need for additional CDPs. Our experiments also suggest that CDPs, without incentives, can reduce costs by 16.9%, while adding incentives increases savings to 28.1%. This research offers a comprehensive framework for understanding and designing cost-efficient urban parcel distribution systems.

4 - A Framework for Measuring Maritime Port System Capacities with Limited Input Data

Debojjal Bagchi, The University of Texas at Austin, Austin, TX, United States, Kyle Bathgate, Stephen Boyles

We present a framework to estimate the “operating capacity” and “ultimate capacity” of a multimodal maritime freight system. Accurately determining the capacity of a port aids stakeholders in making informed decisions about infrastructure investment and resource allocation. Traditional methods for port capacity assessment often rely on data-driven simulations, which can be difficult to calibrate due to complex interactions among port systems and the large volume of data required. We present a data-efficient alternative to estimate port capacities by demonstrating that anchorage queueing behavior and channel entry patterns serve as effective indicators of port performance. We develop a novel queueing-theory-based formulation to define the operating capacity of a port system as the maximum vessel arrivals that can be sustained for an extended period of stable operations. To capture the port’s performance beyond stable operations, we propose a dynamic model to estimate the ultimate capacity, or the maximum throughput that the port can handle in saturated conditions. Our approach requires minimal data, which can be readily obtained from archival automatic identification system (AIS) vessel trajectories, making implementation robust and efficient. We validate our framework using a discrete-event simulation of the Port of Houston and archival AIS data. Our model estimates that the port’s operating capacity is about 5% above current levels, while ultimate capacity is approximately twice that of the operating capacity. Anchorage wait times predicted by our model closely match historic vessel tracking data with errors in the range of 0.35% to 17%, indicating the viability of the proposed model.

5 - A Heuristic Approach for the Service Network Design with Fleet and Emissions Management

Christian Truden, University of Klagenfurt, Klagenfurt, Austria, Mike Hewitt

Less-than-truckload (LTL) carriers often operate transportation networks covering vast geographic areas - frequently spanning the entire contiguous United States - and deploy large fleets of trucks. In these networks, resource prices vary significantly from region to region, especially between states as well as between urban and rural areas. The complexity increases further when carriers consider introducing sustainable power-train technologies such as battery-electric or hydrogen-electric heavy-duty tractors. The Service Network Design problem with Fleet and Emissions Management (SND-FEM) accounts for these factors by including multiple power-train technologies and incorporating spatial variations in fuel prices and Scope 2 emissions associated with the energy sources used by these tractors. However, LTL carriers face very large SND-FEM instances, making exact solution methods inapplicable. To address this challenge, we propose a path-based heuristic that constructs and explores alternative routes between network terminals. Our approach employs a two-level representation of the underlying road network, which simplifies resource-related considerations during path construction. We present initial results demonstrating the effectiveness of our heuristic in solving realistic SND-FEM scenarios.

Building A Level 4 A412

Metamodeling and Design of Experiments

Invited Session

Simulation

Chair: Wei Xie, Northeastern University, Boston, MA, United States

Co-Chair: Qiong Zhang, Clemson University, Clemson, SC, United States

1 - Space-Filling MOFAT Designs

Roshan Joseph, ISyE Georgia Tech, Atlanta, GA, United States, Difan Song

Space-filling designs are commonly used for metamodeling. They ensure that the testing points are not too far from the training points and thus provide a robust prediction performance. However, they cannot quickly identify the important factors from the set of factors used in the simulation. Screening designs such as the maximum one-factor-at-a-time (MOFAT) designs do a much better job for identifying the important factors. This talk will explain an improvement to MOFAT designs that aims at both prediction and screening.

2 - Enhancing Underutilized Bus Routes with Semiflexible Routing

Ye Chen, Bowling Green State University, Bowling Green, OH, United States, Md Hishamur Rahman, Shijie Chen, Yanshuo Sun, Muhammad Siddiqui, Matthew Mohebbi, Nikola Markovic

We explore improving an underutilized conventional bus route by converting it into a semiflexible transit system where passengers provide advance notice of their intended stops, allowing buses to skip downstream stops without demand by taking shortcuts. This approach increases stop density, reduces walking distances to and from bus stops, and maintains operational efficiency. To design this system, we develop optimization models that maximize the number of stops while adhering to tour duration and arrival time constraints. Then, a Bayesian framework is established to analyze the sequential simulation experiment outputs, so that we can (i) reduce the number of simulation experiments needed for assessing violation of constraints, and (ii) decrease the duration of individual simulation runs by aborting them immediately once the bus tour duration surpasses the desired upper bound.

3 - Sequential Experimental Design for Adaptive Reduced-Order Modeling

Jingyi Feng, Georgia Institute of Technology, Atlanta, GA, United States, Xiao Liu

Projection-based Reduced-Order Modeling requires generating data from full-order systems (through numerical methods). Because a full-order system is often parameterized by a set of parameters, challenges immediately arise when one needs to (sequentially) determine the parameter settings, from the parameter space, under which the full-order system is solved and data are generated. In this talk, we present some preliminary results on the sequential experimental design for constructing reduced-order models that well capture the system behavior over the parameter space (needed in design, control, uncertainty quantification and real-time operations). This talk consists of two major parts. In the first part, we describe a Projected Gaussian Process (pGP) that establish the relationship between parameters and reduced-order models. In the second part, we share some early results on a sequential design framework that enables us to sequentially construct or update the pGP model by collecting data from the optimal experimental conditions (i.e., parameter settings).

4 - Bioprocess Mechanism Bayesian Learning and Monitoring

Wei Xie, Northeastern University, Boston, MA, United States

While biomanufacturing plays an increasingly significant role in supporting public health and fighting pandemics, it faces critical challenges including high complexity, high variability, and very limited historical process experiment runs. Driven by these challenges, we propose a novel Bayesian learning framework on bioprocess multi-scale mechanistic and hybrid model in the form of stochastic differential equations (SDEs). The proposed framework can integrate heterogeneous and sparse data, facilitate the learning of underlying regulatory mechanisms and support monitoring latent state trajectories.

5 - Surrogate-Based Contextual Simulation Optimization: A Divide-and-Conquer Approach with Application to Distribution Inventory Systems

Junkai Zhao, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Weiwei Fan, Jun Luo, Tong Wang, Xiaowei Zhang

Distribution inventory system management plays a pivotal role in modern retail supply chains, directly influencing operational efficiency and market responsiveness. However, these systems confront critical challenges stemming from inherent high stochasticity, high context-dependency, and computational intensity. To address these limitations, we propose a contextual simulation optimization framework employing surrogate modeling. Our methodology utilizes Gaussian processes (GPs) to construct a metamodel that captures the joint dependence of cost functions on inventory policies and contextual variables, enabling data-driven policy optimization. To resolve computational bottlenecks associated with inverting large covariance matrices in conventional GP implementations, we develop a parallelizable divide-and-conquer

algorithm. This approach strategically partitions datasets into subsets for localized GP training, subsequently aggregating predictions through ensemble averaging. We derive asymptotic bounds for convergence rate of the optimality gap in our algorithm. Extensive numerical experiments validate the ability of our method to handle industrial-scale inventory problems and demonstrate its consistent effectiveness and efficiency across various inventory networks.

Computing Society

Chair: Susanne Heipcke, FICO, Xpress Optimization, Birmingham, United Kingdom

Co-Chair: Robert Fourer, AMPL Optimization Inc., Evanston, IL, United States

1 - Recent New Features of Fico Xpress APIs and Xpress Mosel

Susanne Heipcke, FICO, Xpress Optimization, Birmingham, United Kingdom

This talk gives an overview of recent updates to the FICO Xpress APIs. Primary focus will be on the Python API for Xpress that has been reworked to align it more closely with the other APIs (see <https://github.com/fico-xpress/python-notebooks>), and new features of Xpress Mosel, including its tools and components (see <https://github.com/fico-xpress/mosel>).

We also shortly outline updates to the object-oriented APIs (C++, C#, Java) and to the recently published Julia API for Xpress that is provided open-source on Github (see <https://github.com/fico-xpress/XpressAPI.jl>) and through the official Julia registry.

2 - Efficient Data Exchange in Amplpy via Apache Arrow Integration

Jurgen Lentz, AMPL Optimization Inc., Mountain View, CA, United States

AMPLPy is the most popular Python API for AMPL, a powerful algebraic modeling language for large-scale mathematical optimization. As modern optimization workflows increasingly integrate with data-intensive environments, efficient data handling becomes critical. To address this, AMPLPy now incorporates support for Apache Arrow, an open-source, columnar in-memory data format designed for high-performance analytics.

By leveraging Apache Arrow, AMPLPy enables rapid, zero-copy data transfer between AMPL models and Python data structures such as Pandas, Polars and many more data frames. This integration minimizes data transfer overhead and significantly improves the speed and scalability of data exchange in optimization pipelines. Users can seamlessly pass large datasets from Python into AMPL for model instantiation and retrieve results back into Python with minimal latency. Arrow's cross-language and cross-platform capabilities enhance interoperability with other systems and data science tools, and will also be used to transfer data to and from other AMPL APIs, such as those in Go and Rust, in the future.

The use of Arrow aligns AMPLPy with modern data engineering practices, ensuring compatibility with distributed data processing frameworks and in-memory analytics platforms. This development makes AMPLPy an even more attractive tool for both researchers and practitioners looking to embed optimization within data-centric and performance-critical applications.

3 - Beyond the Solver: Designing Uis that Empower Decision-Makers

James Laramore, FICO, Hillsborough, NC, United States

Large-scale optimization models generate tremendous value, but their real-world impact often hinges on how easily end-users can interact with, deploy, and act on the model's results. This session explores how thoughtfully designed user interfaces (UIs) bridge the gap between optimization experts and decision-makers, enabling faster, more confident operational decisions.

We'll highlight best practices for creating model-driven applications and show how integrating generative AI and large language models (LLMs) enhances user engagement through practical, natural language explanations and interactive decision support. Attendees will learn strategies for building trust, accelerating adoption, and decreasing time-to-value through interactive, decision-ready user interfaces.

4 - Exploring the Interplay Between LLMs and Mathematical Optimization Model Building

Erik Halseth, Gurobi Optimization, Los Angeles, CA, United States

Generative AI based tools are being positioned to transform the workflows surrounding mathematical optimization. At Gurobi, we want to leverage new opportunities in this space while still honoring the importance of studying and practicing classical model development techniques. In this presentation, we'll walk you through some of our recent work aimed at equipping users with knowledge and tools for leveraging LLMs to develop and deploy optimization models with gurobipy. We will hone in a hypothetical workflow that will serve to highlight key aspects on bridging together LLMs and mathematical optimization models. Whether you're starting your optimization journey or fine-tuning your skills, discover how these innovative AI resources can streamline your workflow and unlock new levels of efficiency.

Advances in Multimodal Learning for Healthcare

Invited Session

Computing Society

Chair: Matthew Peroni, MIT, Cambridge, MA, United States

1 - When is More Better? Efficient Personalized Modality Selection

Matthew Peroni, MIT, Cambridge, MA, United States

The ultimate goal of multimodal learning is to combine disparate and complementary information from multiple data modalities, such as images, text, sensors, and audio, to create more robust, generalizable, and accurate models. However, incorporating many modalities can increase costs and introduce additional complexity into deployed ML systems. Previous work has investigated modality selection at the population level, selecting a subset of modalities that provide the best balance of performance and costs. In this work, we go beyond the population level, introducing the idea of personalized modality selection, which adaptively selects modalities to acquire based on some contextual information about the sample. We characterize this problem setting and its challenges and introduce efficient algorithms for scaling personalized modality selection to scenarios where the total number of modalities is very large. Applying this approach to clinical decision support tasks, we achieve improved performance over baselines while reducing the total cost of data acquisition substantially.

2 - Multimodal Machine Learning for Clinical Trajectory Prediction in Psychiatric Care

Jiayi Gu, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas

Predicting prognostic outcomes—such as length of stay, relapse, and risk of admission—remains a critical challenge in clinical psychiatric care. Many psychiatric conditions, including psychosis, mood disorders, and anxiety disorders, are characterized by fluctuating courses, where relapse is often preceded by subtle but detectable symptom changes weeks or even months in advance. However, current methods have limited predictive power and often fail to support timely intervention. This study leverages multimodal electronic medical record (EMR) data to develop machine learning algorithms that predict clinical trajectories and outcomes across a range of psychiatric diagnoses. By integrating diverse data modalities—including structured clinical data, unstructured clinical notes, and treatment histories—our approach aims to improve prognostic accuracy. The ultimate goal is to enhance patient outcomes, reduce the economic burden on health systems, and demonstrate the value of predictive models in enabling proactive, personalized mental healthcare.

3 - Multi-Class Diagnosis of Left Ventricular Systolic Dysfunction from Electrocardiograms

Catherine Ning, MIT, Cambridge, MA, United States, Dimitris Bertsimas, Yu Ma, Cindy Wang

A reduced left ventricular ejection fraction (LVEF) serves as an essential diagnostic and prognostic marker for heart failure and risk of sudden death. Traditionally, the estimation of ejection fraction has relied on time-consuming and expensive imaging techniques. In contrast, the standard 12-lead electrocardiogram is much faster, more affordable, and is the most widely used complementary exam for heart evaluation, yet does not allow for a direct human interpretation of the LVEF. Therefore, we believe that an accurate AI-enabled diagnosis system is most acutely needed and can be further improved by analyzing large amounts of available patient information. This can be of immense value especially in outpatient or resource-limited settings, e.g., in low- and middle-income countries, where individuals often do not have access to trained cardiologists.

Most AI models for cardiac diagnosis proposed in the literature have focused on unimodal, binary classification from ECGs, often limited to identifying moderately or severely reduced LVEF while unable to capture mildly reduced LVEF. In contrast, we predict more granular levels of LVEF ranges, specifically, normal, mildly, moderately, or severely reduced ejection fraction. Additionally, we leverage both ECG tracings and patient electronic health records, thereby offering a cost-effective diagnostic tool that can be readily integrated into the EHR data processing systems in primary care offices, emergency units, and hospitals alike.

4 - A Multiomics Approach to Cancer Detection

Beini Wang, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas

Recent advances in high-throughput sequencing technologies have catalyzed a shift in cancer research toward multiomics. Cancer diagnosis traditionally relies on the visual inspection of histopathology slides (which are obtained from biopsies), while molecular testing is often done as a follow-up test for treatment planning and when histopathology results are inconclusive. Hence, in this work, we present a machine learning framework for robust cancer detection through a multiomics, molecular approach. Specifically, we developed parsimonious XGBoost models that integrate signals from DNA methylation profiles, miRNA expression, and gene expression (via mRNA) to distinguish tumor from normal tissue (binary classification) and identify cancer tissue of origin (multiclass classification), across diverse tumor types. Our models were trained on data from The Cancer Genome Atlas (TCGA), and validated on two datasets, namely: (i) A held-out subset from TCGA which was not used for training, and (ii) an external dataset from Phase III of the Clinical Proteomic Tumor Analysis Consortium (CPTAC-3). Multiomics models outperformed single-omics models, with the methylation-and-gene expression model yielding the highest validation AUCs. Notably, models retained strong performance using only a small number of features, enhancing explainability and potential clinical utility.

Transmission Planning: Aligning Academic Advances with Industry Needs

Invited Session

ENRE: Energy

Chair: Weihang Ren, University of Florida, Gainesville, FL, United States

Co-Chair: Yongpei Guan, University of Florida, Gainesville, FL, United States

1 - A Review of Optimization Models and Challenges in Transmission Expansion Planning

Weihang Ren, University of Florida, Gainesville, FL, United States, Alinson Xavier, Yongpei Guan, Feng Qiu

Transmission expansion planning is vital in ensuring power system reliability and efficiency. Despite extensive research on optimization models for transmission planning, the lack of unified mathematical formulation and the growing complexity of academic models pose challenges for both new researchers and practical implementation. This paper reviews and synthesizes existing optimization models, proposing a unified base formulation with modular extensions to address practical considerations such as AC power flow, unit commitment, policy requirements, and uncertainty. Additionally, we survey industry technical reports to identify current planning objectives, tools, and challenges, aiming to bridge the gap between academic research and industry practice.

2 - Community-Level Optimization of Solar and Storage Investments with Energy Sharing Mechanisms

Basim Aljohani, University of Florida, Gainesville, FL, United States

In this paper, we investigate coordination and collaboration among residential property owners within a community to maximize both individual and collective profits. Recognizing that some homes may be unsuitable for solar panel installation due to factors such as tree shading, roof age, and other constraints, we propose a community-shared energy storage model. We develop three mathematical formulations (solar-only, solar with individual storage, and solar with shared community storage) and implement an ADMM-based distributed optimization framework. To handle discrete decision variables in the shared storage model, we develop a linearized reformulation with branch-and-bound algorithm. Theoretical proofs establish that solar with individual storage achieves costs no greater than solar-only systems, while shared community storage further improves upon individual storage due to economies of scale. Case studies on a 140-household Florida community demonstrate the effectiveness of the proposed approaches, with shared storage achieving cost reduction in the baseline scenario and even more improvement with Investment Tax Credits. Scalability analysis shows that cost advantages become more pronounced as community size increases and storage costs decline.

3 - Coordinated Resilience Investments for Proactive Consumers and the Supplying Utility

Tu Feng, The Ohio State University, Columbus, OH, United States, Antonio Conejo

Power grids increasingly face resilience challenges due to extreme weather and the growing penetration of weather-dependent renewable energy sources. In electricity distribution systems, both the utility and consumers seek high supply resilience. An increasing number of proactive consumers with solar panels and battery storage now enables power backups for them during utility outages. This creates a trade-off: if the utility achieves high resilience for the whole distribution system, individual consumers have little incentive to invest in their own resilience. Conversely, low utility resilience encourages more consumer investment. To address this, we propose two modeling approaches: (1) an equilibrium model, suitable when proactive consumers and the utility have comparable influence, and (2) a hierarchical bi-level model, which identifies optimal solutions for both the leading entity—the electric utility—and the responding agents, including proactive and non-proactive consumers, that react to the decisions of the leading agent. Resilience improvements are achieved through battery investment. The proposed technique can be helpful for distribution system planners to optimally coordinate resilience investments between the electric utility and proactive consumers. The complementarity models can be transformed to single-level models, although nonconvex, are still computationally tractable. We demonstrate the effectiveness of our models through case studies based on realistic distribution systems.

Electricity Storage Issues: Batteries, Integration, Microgrids, and Planning

Invited Session

ENRE: Electricity

Chair: Dirk Lauinger, MIT, Cambridge, MA, United States

1 - Evaluating Energy Storage Integration Under Uncertainty: a Real Options Analysis**Gazi Nazia Nur, Iowa State University, Ames, IA, United States**

Renewable energy sources like wind power are crucial for a sustainable energy future, but they are inherently uncertain. One key challenge is the mismatch between electricity demand and wind availability: high wind generation during periods of low demand can cause grid instability and wasted wind power, while low wind during high-demand periods can lead to unmet electricity needs. The integration of energy storage systems (ESS) with wind energy farms offers a promising solution to this problem. Our study investigates the economic feasibility of integrating ESS into existing wind farms. By adding ESS, surplus energy can be stored during periods of low demand and discharged during peak hours, effectively redistributing electricity supply throughout the day and reducing peak electricity demand. This approach relieves grid congestion and lowers the locational marginal price (LMP) of electricity, ultimately reducing electricity bills for consumers. However, the high capital investment and technology costs, combined with market uncertainties, present significant challenges. To address these, we apply a real options analysis (ROA) framework, which is able to consider uncertainty and capture the value of flexibility in investment decisions. Our objective is to assess whether the benefits of electricity bill reduction justify the investment in ESS, incorporating key uncertainties such as electricity demand and storage costs. The findings aim to provide actionable insights for stakeholders considering energy storage integration in renewable energy systems under uncertain market conditions.

2 - Improved TIME-Series Clustering for Long-Term Grid Planning Using Approximate Solutions**Theodore Dahl, Massachusetts Institute of Technology, Cambridge, MA, United States, Ruaridh Macdonald**

"Energy grid planning models use time-series clustering to identify representative periods which lead to the same investment and dispatch decisions as the original, full timeseries. This reduces computational complexity and has become essential in the past few years given research showing that grid planning optimizations are only robust when they consider several decades of weather and demand data. One limitation of existing time-clustering methods is that it is difficult to know a priori how many representative periods are required to produce an accurate answer, or how long each period should be. Recently, a new clustering method was proposed which uses fast-to-produce approximate solutions as another clustering feature. This was shown to better guarantee the accuracy of the final optimization result. However, the total runtime was longer than state of the art methods and there was no way to incorporate state variables across representative periods. In this work, we build upon this recent output-based method to improve its computational efficiency while maintaining accuracy in planning outcomes. Specifically, we demonstrate that additional pre-processing steps and a second clustering step lead to fewer approximate solutions being required. We also extend the method to incorporate inter-representative period state variables, allowing long duration storage and similar technologies to be modeled. We implement the improved clustering strategies in a Julia based open-source capacity expansion model (GenX). Our results demonstrate that the optimized clustering framework can achieve promising reduction in solver runtime with only minimal deviations in investment decisions and reliability relative to the full-resolution benchmark."

3 - Infrastructure-Defining Lows In Wind and Solar Energy Resources**Shannon Hwang, Massachusetts Institute of Technology, Cambridge, MA, United States, Micah Ziegler, Jessika Trancik**

Rare, severe periods of low wind and solar resource availability could pose challenges for a transition to an electricity system that depends on substantial proportions of these variable resources. Here we examine the nature of rare but sizable resource lows to characterize the space of possible solutions for providing reliable power even during these periods. Our analysis considers the effects of variability in wind and solar energy resources over a 40-year period across the coterminous United States. We demonstrate how resource lows drive sizing of system components. For example, we show that these resource lows occur irregularly and infrequently over decadal timespans and accumulate resource deficits over timescales of days to months, heavily impacting the required capacities and utilization of energy storage, supplemental energy, and demand management infrastructure. Consequently, technologies proposed to help mitigate low resource availability, such as energy storage and supplemental (i.e., neither wind nor solar) generation, would likely operate at full capacity very infrequently, with capacity factors reaching 0.06 or less in systems with very high renewables penetrations. Resource lows can cover large geographical areas—up to hundreds of kilometers—which suggests that geographical aggregation of generation resources through transmission infrastructure expansion must be at least similarly large to be most effective. Additionally, resource lows occur during predictable seasons, which may be beneficial for the development of demand-side management strategies. Such understanding of the capacities and operations required of reliable, high-renewable energy systems is essential for informing system planning and technological innovation to address climate change.

4 - Consumer Acceptance of Second-Life use for End-of-Life EV Batteries: Evidence from a Discrete Choice Experiment in Korea**Myongji Cho, Seoul National University, Seoul, Korea, Republic of, Jungwoo Shin**

The expansion of Battery Electric Vehicles (BEVs) is regarded as a key strategy for achieving carbon neutrality and promoting energy transition. As EV adoption accelerates, the large-scale emergence of end-of-life (EOL) batteries has become an urgent environmental and societal issue. In response, two approaches have gained significant attention for their environmental and economic potential: second-life use—repurposing used batteries for applications such as energy storage systems (ESS) or low-speed electric vehicles—and resource recovery, which involves extracting valuable materials like lithium and cobalt through recycling. However, evaluating the market feasibility of these technologies requires not only technical validation but also a quantitative understanding of consumer acceptance. This study empirically examines consumer preferences and acceptance of second-life battery applications in the Korean market. A Discrete Choice Experiment (DCE) was designed to present respondents with hypothetical vehicle choice scenarios that varied in attributes such as carbon emissions, vehicle price, and battery reuse potential. A Mixed Logit Model was applied to capture heterogeneity in individual preferences. Additionally, scenario-based simulations were conducted to predict changes in demand under varying policy and information conditions. The results provide data-driven insights to support the development of demand-oriented policies and private-sector business strategies aimed at promoting sustainable management of EOL batteries in alignment with circular economy principles.

5 - From Energy Consumer to Grid Partner: Co-Designing Data Centers for System Flexibility**Wei Wang, Pacific Northwest National Laboratory, Richland, WA, United States, Himanshu Sharma, Bowen Huang, Thiagarajan Ramachandran, Shaolei Ren, Timothy Salsbury**

The rapid advancement of artificial intelligence and digital infrastructure has significantly increased the demand for data centers (DCs), which are pivotal in supporting the digital economy. Widely known for their high energy consumption, data centers now present new opportunities: with advancements in workload management strategies and appropriately sized energy storage technologies, optimally operated DCs can provide flexibility to support power grid needs. Data center developers in the early system design stage require decision-making tools that simultaneously consider design and operational decisions while accounting for workload uncertainties, ensuring demand response capabilities that meet power grid requirements. This work introduces a multi-time-scale, multi-stage stochastic control co-design framework that optimizes both design and operational decisions under uncertainty. We demonstrate our framework's application by optimizing energy storage sizing and demand response strategies for data center operations, utilizing price signals from day-ahead and real-time energy markets under uncertain workload conditions. The framework addresses operational, planning, and economic considerations, providing comprehensive solutions to co-design large loads such as data centers to enhance grid flexibility and improve resilience.

Adapting Electric Distribution Systems to Climate Extremes

Invited Session

ENRE: Energy-Climate

Co-Chair: Aviadv Navon, University of Michigan, Ann Arbor, 48104, United States

Co-Chair: Michael Craig, University of Michigan, Ann Arbor, MI, United States

1 - Impacts of Rising Temperatures on Overloading and Long-Term Degradation in Electric Distribution Systems

Aviad Navon, University of Michigan, Ann Arbor, MI, United States

This work investigates how rising ambient temperatures, driven by climate change, affect the performance and longevity of electric distribution systems. Using high-resolution climate and demand data, combined with a weather-dependent network model, we quantify the increased risk of line and transformer overloading under future temperature scenarios. We also model the long-term degradation of infrastructure components due to sustained thermal stress, highlighting potential reductions in equipment lifetime and reliability. These insights support utility decision-making by helping to balance infrastructure upgrade costs with the growing risks of thermal overloading and accelerated aging.

2 - Navigating Uncertainty Through Flexibility, Resilience and New Technologies in Future Low-Carbon Power Systems**Rodrigo Moreno, University of Chile, Santiago, Chile, Mathaios Panteli**

As our energy systems face an era of unprecedented complexity driven by climate volatility and rapid decarbonization, resilience has become not just a design principle, but a necessity. This presentation explores the evolving landscape of power system resilience, highlighting key insights from global projects and groundbreaking research. Drawing on real-world applications, it will examine how integrated, risk-based, and digitally enabled strategies are redefining the way we design, operate, and plan future energy systems. From probabilistic security assessments to resilient microgrid networks, this talk makes the case for resilience not just as an add-on, but as a vital planning and operation criterion of future energy systems.

3 - Robustness and Extensibility Tradeoffs for Grid Reliability**Mikhail Chester, Arizona State University, Tempe, AZ, United States, Ryan Sparks, Nathan Johnson, Daniel Eisenberg**

Modernizing power grids while accommodating emerging technologies and confronting climate hazards necessitates new decision support frameworks that balance robustness (hardening and redundancy) and extensibility (microgrids, storage, distributed generation, etc). We introduce a novel decision support framework that: i) simulates regional grid operations during peak demand; ii) creates mechanisms for stressing the grid due to myriad hazards; iii) estimates the likelihood of cascading failures and resulting outages across transmission systems (lines and substations); iv) characterizes the marginal reliability benefits of redundancy (e.g., the addition of transmission capacity to protect critical demand nodes). The framework uses publicly available information for transmission and estimates line parameters for power flow modeling. Transmission is disrupted considering multiple hazards including wildfires and extreme heat. When disruption occurs, we rebalance power flow revealing both high likelihood low consequence and low likelihood high consequence failures at substations. We build and test this network using NERC reliability subregions. The results reveal several critical insights. First, the reliability impact to transmission systems when subjected to climate hazards and the specific vulnerabilities (as infrastructure assets and operational challenges) of these hazards. Second, the potential drivers of so-called black swan (low probability high consequence) events, as both network configuration and operational dynamics. Third, robustness and extensibility tradeoffs are captured by evaluating the marginal benefits of redundancy; portions of the grid benefit greatly from additional transmission capacity and others do not. Where the marginal benefits of additional transmission capacity are low then critical assets should be protected with extensibility strategies.

4 - Sociotechnical Modeling of Steel Electrification Interactions with Electricity Grids**Rebecca Ciez, Purdue University, West Lafayette, IN, United States, Hanwen Qin, Anindya Nath, Abhinand Ayyaswamy, Partha Mukherjee**

Steel production is one of the largest sources of industrial greenhouse gas emissions globally, and Indiana is home to most of the steel production in the United States. Many of these emissions are associated with the use of blast furnaces, which convert iron ore into steel using fuels like coal, coke, and natural gas. Electrification of the steel industry, through the use of electric arc furnaces, in conjunction with direct reduction of iron ore via hydrogen, can significantly reduce the GHG emissions per unit of steel produced. However, both electrification and the production of hydrogen by electrolysis are significant consumers of electricity.

Here, we conduct a process-based cost model to consider the tradeoffs between minimizing the cost of producing steel via electrified manufacturing, the costs to workers associated with adapting production to electricity prices, and the environmental impacts of different manufacturing strategies. To answer these questions, we use a two-stage optimization model to design and dispatch the manufacturing capacity. We use this framework to conduct scenario analysis with different grid futures and weighting of different objectives in a multicriteria decision analysis. The grid future scenarios considered are based on future technology costs, and include business-as-usual, high renewable adoption, high solar adoption, high wind adoption, and high adoption of nuclear and CCS technologies. The results of this analysis allow us to understand the appropriate size of electrified steel production facilities to reach economies of scale in steel production, and how capital, labor, and energy costs can trade-off to minimize these costs.

Building B Level 2 B206

Optimization and Impact Study of Next-Generation Energy Decarbonization Solutions

Invited Session

ENRE: Energy-Climate

Chair: Bolun Xu, Columbia University, New York, NY, United States

Co-Chair: Zhiyuan Fan, Columbia University, New York, NY, 10027, United States

1 - Consumer-Driven Climate Mitigation: An Analytical General Equilibrium Framework**Benjamin Leibowicz, The University of Texas at Austin, Austin, TX, United States**

Consumer-driven climate change mitigation strategies reduce greenhouse gas (GHG) emissions through decisions by many individual consumers to use less energy and choose less carbon-intensive products. Concrete examples include commuting by walking or cycling instead of driving, reducing air travel, living in a smaller home in a more central and walkable neighborhood, or adopting a vegetarian diet, to name just a few. The literature contains numerous studies that assess and quantify the direct GHG reduction potentials of specific consumer-driven mitigation actions, but most of this work does not consider the general equilibrium effects of these changes in final consumption and their implications for the net, economy-wide GHG impacts of the mitigation strategies. In this paper, I formulate a stylized general equilibrium model and solve it analytically to investigate the net, economy-wide GHG impacts of a shift in consumer preferences that favors less carbon-intensive final consumption. The analysis primarily serves to highlight the general channels through which changing consumer preferences influence aggregate emissions. These channels include upstream spillovers within supply chains that tend to amplify the GHG-reducing effects of climate-friendly consumption choices, as well as horizontal spillovers across sectors that tend to offset direct emissions reductions as consumers reallocate spending and prices adjust throughout the economy.

2 - Carbon-Aware Scheduling: a Framework for Integrating Intermittent Renewable Energy into Grid Operations**Walid Hanafy, UMass, Amherst, MA, United States**

The rising demand for computing, largely driven by AI applications, raises significant concerns regarding the carbon footprint of computing and the ability of the current electricity grid to accommodate this demand. Renewable energy presents a viable solution to both challenges due to its cost-effectiveness and high carbon efficiency. The widespread adoption of renewable energy sources has substantially reduced carbon intensity, measured in terms of carbon emissions per unit of energy. Nonetheless, the intermittent nature of renewable energy sources undermines their overall effectiveness as the share of renewables in an electricity grid increases. One way to enhance the effectiveness of added renewables is through demand adaptations, which align energy demand with the availability of renewable energy.

Fortunately, computing workloads have temporal and spatial flexibility that facilitates demand adaptations based on the availability of renewable energy. Carbon-aware scheduling is a framework that leverages the flexibility of computing workloads and the availability of low-carbon energy to optimize the carbon efficiency of computing. For instance, batch workloads, such as machine learning (ML) training jobs, offer substantial temporal flexibility, allowing execution to be suspended during periods of high carbon periods and scaled up again during periods of low carbon periods. Additionally, the diversity of energy sources across grids has motivated the use of spatial

shifting, which involves moving workloads according to the availability of low-cost and low-carbon energy.

In this talk, I provide an overview of the opportunities and challenges of carbon-aware scheduling, highlighting multiple use cases in batch scheduling and AI model serving systems.

3 - Optimization for Direct Air Capture System Operation and Design from Electric and Thermal Energy Perspectives

Zhiyuan Fan, Columbia University, New York, NY, United States

Direct air capture (DAC) systems are promising for large-scale carbon dioxide removal but are limited by their high electricity and thermal energy demands. This study develops a mixed-integer linear programming (MILP) framework to optimize DAC system design and operation from both power and thermal energy perspectives. We analyze two complementary strategies: (1) grid-connected DACs that dynamically respond to wholesale electricity prices, and (2) solar-thermal DACs that use concentrated solar power coupled with low-cost sand-based thermal energy storage. Grid-connected DACs can significantly improve profitability—up to a tenfold increase—by operating during low-price electricity windows, though this may reduce capacity factors. Solar-thermal DACs, in contrast, achieve high utilization (over 80%) and cost-effective CO₂ removal (\$160–\$200 per ton), particularly in regions with high solar potential and sandy terrain. Short-cycle sorbents play a critical role in both configurations by enhancing responsiveness to intermittent energy supply and ambient conditions. Together, these approaches highlight the need for integrated design strategies that leverage both grid and renewable thermal resources. Our results show that coordinated optimization of energy supply, sorbent dynamics, and policy incentives—along with careful consideration of ambient temperature and humidity sensitivity, which plays a non-trivial role in DAC performance—is essential to scale DAC systems sustainably and affordably.

4 - Underground Hydrogen Storage Opportunities Under Legacy Natural Gas Infrastructure Constraints

Wei Ai, University of Michigan, Ann Arbor, MI, United States, Jacqueline Dowling, Michael Craig

As energy systems transition to net-zero emissions, declining dispatchable fossil generation and rising variable renewable generation intensify the firming benefit of long-duration energy storage. Underground hydrogen storage (UHS), leveraging geologic formations, has extremely low energy-capacity capital costs and offers a promising solution, but its deployment is constrained geographically by resource availability. On the other hand, UHS and its supporting pipeline network can expand at lower costs and with less development efforts by leveraging existing natural gas infrastructure. To fully understand the opportunities of UHS in decarbonizing the energy system and to maximize its potential, it is essential to consider legacy natural gas infrastructure and retrofit dynamics.

We develop a coordinated energy system planning model coupling electricity, natural gas, and hydrogen sectors across the contiguous U.S. by adding a full representation of the hydrogen sector to PyPSA-USA. Modeled at the facility level, UHS and hydrogen pipeline expansions are constrained to existing natural gas infrastructures and their capacities. Energy demands for electricity, natural gas, and hydrogen are exogenously defined at the state level. The planning optimization is sequenced over multiple decision periods to capture the evolution of the energy system and UHS deployment. We also include alternative long-duration energy storage technologies to assess competition under UHS constraints.

Results will show how regional differences in subsurface resource availability and infrastructure retrofit pacing influence UHS and alternative long-duration energy storage deployment. These insights will inform strategic planning for deploying UHS under legacy natural gas infrastructure constraints.

Health Policy Modeling: Advancing Decision Making for Healthcare

Invited Session

Health Applications Society

Chair: Sze-chuan Suen, University of Southern California, Los Angeles, CA, United States

Co-Chair: Yiwen Cao, University of Southern California, Los Angeles, CA, United States

Co-Chair: Citina Liang, University of Southern California, Los Angeles, CA, United States

1 - Risk-Sensitive Optimal Acceptance for Marginal Kidneys

Yili Wang, University of Michigan, Ann Arbor, MI, United States, Mariel Lavieri, Amirhossein Moosavi

Despite nearly 90,000 patients on the US transplantation waitlist, about 25% of lower-quality (marginal) kidneys are discarded annually. To improve the utilization of these organs, an out-of-sequence allocation policy has been implemented for marginal kidneys. Motivated by this policy, this research focuses on developing decision-support models to assist patients and clinicians in making informed acceptance decisions, accounting for varying levels of risk aversion. By applying Conditional Value at Risk (CVaR) within a Markov Decision Process (MDP) framework, we capture risk sensitivity and analyze its impact on acceptance policies for marginal kidney transplants. We also demonstrate key properties of the CVaR-MDP model in determining optimal acceptance policy.

2 - Alternative Payment Models for Active Surveillance of Prostate Cancer

Sogand Soghrati Ghasbeh, University of Michigan, Ann Arbor, MI, United States, Brian Denton, Mark P. Van Oyen, Vahakn Shahinian, Arnab Srivastava

Prostate cancer is the most commonly diagnosed cancer among men in the United States aside from skin cancer. For men with low-risk prostate cancer, active surveillance (AS), a strategy that involves routine monitoring to avoid unnecessary treatment, has become the standard of care. While AS can spare patients from adverse side effects of surgery or radiation, such as incontinence and erectile dysfunction, overtreatment remains widespread. A key driver of this issue lies in the prevailing fee-for-service payment model, which incentivizes curative interventions over long-term observation. Although bundled payments have been introduced in other episodic care settings to encourage value-based treatment, such alternative payment models (APMs) do not currently exist for chronic care pathways like AS.

In this study, we develop a novel payment model to address this gap using a hidden Markov model (HMM) to characterize the natural progression of low-risk prostate cancer. Leveraging rich longitudinal data from the Michigan Urological Surgery Improvement Collaborative (MUSIC), we estimate our HMM on a contemporary cohort of patients under AS in community settings. The model captures the stochastic nature of disease evolution and treatment decisions, enabling us to simulate reimbursement distributions under current and proposed payment frameworks. We propose a payment redesign that introduces incremental reimbursements aligned with AS care timelines, aiming to make healthcare providers financially indifferent to treatment modality. This approach reduces overall healthcare spending while maintaining compensation for individual urologists, offering a promising pathway for aligning financial incentives with evidence-based care.

3 - Dynamic Assignment of Stochastic Service Requests in Mobile Public Health Operations

Jing Jin, University of Southern California, Los Angeles, CA, United States, Sze-chuan Suen, Maged Dessouky, Fernando Ordonez

For many on-site service providers, requests arrive stochastically and often must be scheduled before the following requests are observed. This is the case for on-site visits by the Mobile Vaccination Team (MVT) at the Los Angeles County (LAC) Department of Public Health. These visits provide service to a geographically disperse area with potentially long travel times. To address this problem, we formulate a finite-horizon Markov Decision Process (MDP) model where service requests arrive sequentially from random locations within the service area. Weekly nurse team schedules are built dynamically as services are requested to minimize total travel time for the next week. We study properties of the optimal policy and design heuristics for large-scale problems suitable for real-world instantiation.

4 - Strategic Influence of Household Attitudes on Hpv Vaccination in Kenya: a Network-Based Optimization Approach

Sze-chuan Suen, University of Southern California, Los Angeles, CA, United States, Suyanpeng Zhang, Corrina Moucheraud

Dissemination of health information through social networks may be an effective avenue to influence attitudes towards health interventions, as information may be received from trusted social sources. However, existing network models often neglect the possibility of heterogeneous influence and receptiveness of individuals. We

study a model to maximize the influence of Human Papillomavirus (HPV) vaccination information disseminated through a social network. Our directed network uses an extended linear threshold model to capture the dynamics of attitude spread in the presence of heterogeneous influence and receptiveness of individuals, and we provide structural observations on the equilibrium state and convergence of network outcomes. We then formulate a mixed-integer linear program (MILP) that selects a subset of nodes within the network for information dissemination to maximize the number of nodes with positive attitudes after information spreads through the social network within the analysis period. To illustrate our process, we parameterize our network model using a 2022 dataset from Kenya on household HPV vaccine attitudes. We find that the nodes selected generally consider both initial HPV attitudes and centrality measures, suggesting information on both should be included in future surveys to inform health information dissemination campaigns.

5 - Data-Driven Cohort Stratification for Markov Disease Progression Models

Nana Xia, University of Southern California, Los Angeles, CA, United States, Sze-chuan Suen

Traditional Markov models of disease progression stratify populations into cohorts by risk, demographic characteristics (age, etc.), or other factors based on data availability or ad hoc rules—practices that lack consistency, objectivity, and reproducibility. We introduce a data-driven framework that simultaneously partitions individuals into groups and estimates group-level transition probabilities in a Markov model. We formulate a mixed-integer program that minimizes the sum of squared errors between true and cohort-predicted sick-state probabilities using observed health-status trajectories. Assuming heterogeneous incidence probabilities, we solve this nonconvex problem via a coordinate-descent algorithm that alternates between optimizing individual assignments and updating group parameters. Experiments on synthetic data demonstrate that our method accurately recovers group assignments, yields interpretable transition rates, and ensures full reproducibility. This framework provides a principled, automated approach for constructing cohorts in disease-progression models, with applications in chronic disease management.

Generative AI: Alignment, Reasoning and Interpretability

Invited Session

OPT: Machine Learning

Chair: Tianyi Lin, Columbia University, New York, NY, United States

1 - The Value of Imperfection: LLMs Post-Training on "Trash" Data

Peter Chen, Columbia University, New York, NY, United States

In this talk, I will discuss how to utilize "trash" data in LLM post-training. Specifically, I will focus on two areas: preference alignment and reinforcement learning (RL) for reasoning. For preference alignment, I will introduce ComPO, a framework designed to extract useful signals from "noisy" preference pairs that Direct Preference Optimization (DPO) fails to utilize effectively. ComPO employs a zeroth-order method to directly extract comparison information from the preference data and incorporate it into the model. For RL reasoning, I will present Spectral Policy Optimization (SPO), a new framework based on AI feedback that addresses the challenge of handling all-negative-sample groups in Group Relative Policy Optimization (GRPO). SPO demonstrates that reasoning mistakes can be valuable and should not be discarded in GRPO.

2 - Discrete Diffusion Models: Inference, Post-Training and Application

Hanyang Zhao, Columbia University, New York City, NY, United States

Discrete Diffusion Models is an emerging but capable family of non-autoregressive models which showcases great promise in modeling categorical distributions like language. In this talk, we propose a discrete analogue of DDIM algorithm as generalizations, which results to faster inference and improved techniques in post-training discrete diffusion models for alignment and enhanced reasoning. We also investigate the applications of discrete diffusion models for recommender systems.

3 - On Reinforcement Learning for Better Scientific Reasoning

Ming Yin, Princeton University, Plainsboro, NJ, United States

We investigate how to teach large language models (LLMs) to perform scientific reasoning by leveraging expert discussions as a learning signal. Focusing on the genomics domain, we develop an automated pipeline to extract trainable data and introduce Genome-Bench, a new benchmark constructed from over a decade of scientific forum discussions on genome engineering. Our pipeline transforms raw interactions into a reinforcement learning-friendly multiple-choice questions format, supported by 3000+ high-quality question-answer pairs spanning foundational biology, experimental troubleshooting, tool usage, and beyond. We fine-tune an LLM using RL with a rule-based reward signal derived from the synthetic MCQ dataset to enhance domain-specific reasoning.

4 - Goedel-Prover-V2

Shange Tang, Princeton University, Princeton, NJ, United States, Yong Lin, Chi Jin

We introduce Goedel-Prover-V2, an open-source language model series that sets a new state-of-the-art in automated formal proof generation. Built on the standard expert iteration and reinforcement learning pipeline, our approach incorporates three key innovations: (1) Scaffolded data synthesis: We generate synthetic proof tasks of increasing difficulty to progressively train the model, enabling it to master increasingly complex theorems; (2) Verifier-guided self-correction: The model learns to iteratively revise its own proofs by leveraging feedback from Lean's compiler, closely mimicking how humans refine their work; (3) Model averaging: We combine multiple model checkpoints to improve robustness and overall performance.

Our small model, Goedel-Prover-V2-8B, reaches 83.3% on MiniF2F test set at Pass@32, matching the performance of prior state-of-the-art DeepSeek-Prover-V2-671B while being nearly 100 times smaller in model size. Our flagship model, Goedel-Prover-V2-32B, achieves 88.1% on MiniF2F at Pass@32 on standard mode and 90.4% on self-correction mode, outperforming prior SOTA DeepSeek-Prover-V2-671B and concurrent work Kimina-Prover-72B by a large margin. Additionally, our flagship model with self-correction solves 64 problems on PutnamBench at Pass@64, securing the 1st on the leaderboard surpassing DeepSeek-Prover-V2-671B's record of solving 47 problems by Pass@1024.

1 - A Novel Adaptive Testing Scheme for Multi-disease Testing

Merve Bodur, University of Edinburgh, Edinburgh, United Kingdom, Douglas Bish, Ebru Bish, Berk Gorgulu

Testing for multiple diseases is essential for both diagnosis (when diseases share symptoms but require different treatments) and screening, but is highly costly. Two cost-saving strategies are multiplexing (a single assay detects multiple diseases) and pooling (a single assay tests multiple subjects, with individual re-testing if positive). While laboratory automation enables a flexible integration of these strategies, optimal testing designs that fully exploit this potential remain underexplored. Existing approaches restrict re-testing to the same multiplex used in the initial pooled test (Dorfman testing), often leading to inefficiencies. To address this gap, we introduce a novel adaptive testing design that tailors each subject's re-test based on pooled test outcomes, using only the diseases that tested positive. This leads to a complex partition-type optimization problem that is considerably more difficult to solve than the Dorfman testing designs previously studied. We derive a closed-form cost function, characterize structural properties of optimal designs, and develop effective solution methods. A case study involving 18 respiratory diseases demonstrates substantial savings: 59.8% and 53.5% relative to two current practice benchmarks, and 36.2% compared to previously studied non-adaptive Dorfman testing designs.

2 - Data-Driven Facility Layout for Enhancing Walk Appeal in Walkable Neighborhoods.

Haoran Guo, Tsinghua University, Beijing, China, People's Republic of, Sentao Miao, Wei Qi, Jian Cui, Zhenning Dong

In response to the challenges posed by car-centric urban development, there is growing global advocacy for walkable neighborhoods that promote public health and urban sustainability. To support the design of such neighborhoods, this paper studies the optimal layout of facilities (e.g., retail and service establishments) to enhance walk appeal. Unlike conventional designs that rely primarily on distance metrics, our approach focuses on pedestrian choices. We use a latent class logit model to estimate how facility layouts influence individuals' propensity to walk, accounting for heterogeneous travel purposes. This model is calibrated with a city-wide dataset from our industry collaborator, a leading Chinese map service provider. Building on this model, we develop a choice-based optimization framework to determine facility layouts that maximize the aggregate walking probability of residents. We first analyze its structural properties to derive analytical insights into optimal layout patterns. To find optimal layouts for this NP-hard problem, we reformulate it as an exponential cone program. To address the computational challenges this poses for large-scale applications, we further develop efficient greedy algorithms and establish their performance guarantees via submodularity ratio analysis. A case study in Beijing shows that our approach significantly improves walk appeal compared to traditional methods, with minimal impact on facility accessibility. Our results also reveal a "wisdom of crowds" effect in existing layouts and emphasize the importance of neighborhood context in shaping optimal design patterns. Specifically, we find that dispersed layouts are preferable in already walkable environments, while more challenging walking conditions benefit from spatially concentrated facilities.

3 - Retailers' Informational Role in an Informal Circular Economy

Amrita Kundu, McDonough School of Business, Georgetown University, Washington, DC, United States, Erica Plambeck, Qiong Wang

This paper reveals the strategic behaviour of small retailers in providing personalized prices and (mis)information about the durability of goods in an informal circular economy. Their behavior puts poor customers at an informational and economic disadvantage, and perpetuates a lemons market. These retailers sell new lead-acid batteries for electric vehicles, buy back batteries at end of life, and thus directly observe the life of batteries of various brands. Customers want long life so, in theory, a retailer will guide customers to the longest-lasting brand for which the marginal cost is well justified, to build reputation and attract a stream of repeat customers. To observe how retailers actually behave, we covertly audit 261 retail shop owners. Posing as five different types of customer across 1,122 visits, we learn that retailers provide inconsistent information about battery life and which brand is longest-lasting. For poor customers, a retailer exaggerates the life and sets a higher price (net of used battery trade-in value) for a given brand of battery. More frequently with poor customers, a retailer promotes as longest-lasting the brand that offers him the best incentive. A retailer gives the lowest price for a given brand of battery to a wealthy customer who owns multiple vehicles. The retailers do not create a secondary market for well-performing used batteries. Instead, retailers offer to buy used battery for about 1/2 the price of new battery, regardless of its age or performance, and most retailers simply sell the used batteries to informal battery scrapers.

4 - Improving Basic Retail Coverage in Africa: Modeling Geographic Disadvantage Among Farmers in Senegal

Mark Brennan, Rutgers University, Camden, NJ, United States, Stephen Graves, Peter Zhang, Babacar Ndiaye, Jonars Spielberg, Bish Sanyal

African consumers rely on 10 million retail points for essentials: medicine, schoolbooks, and farming equipment, among others. The lack of accessibility and competitiveness of the retail landscape for significant portions of the population is a salient policy concern. Due to a historical lack of data, the questions in African capitals today are basic: where does and should retail exist relative to disadvantaged customer segments? We use an original census of 1,100 irrigation-equipment shops along the 600-kilometer Senegal River Valley, combined with satellite imagery that identifies where demand for irrigation products lies. We find that farmers need to travel an average distance of 31 kilometers to buy any irrigation equipment, and half of these farmers lack a shop in their nearest city. The retail sector is particularly sparse in areas where the state also delivers fewer public services. However, we find that if policymakers were to induce just five more shops to open in prescribed locations, the farmers' mean travel distances to buy most equipment types would be lessened by one-third—and especially improved for farmers underserved by the state. Our results provide policymakers with direction to locate new retail irrigation equipment shops and to encourage more prevalent repair shops to also sell equipment. Our approach of combining field and satellite data can be applied in other contexts to inform retail-policy decisions. Our hope is that this work generates awareness about geographic disadvantage that African farmers face and demonstrates that modest policy action can correct much of this disadvantage.

Recent Advances in Stochastic Nonlinear Optimization I

Invited Session

OPT: Nonlinear Optimization

Chair: Miaolan Xie, University of Chicago, Chicago, IL, United States

Co-Chair: Sen Na, Georgia Institute of Technology, Atlanta, 30339, United States

1 - Advanced, Adaptive and Flexible Algorithms for Decentralized Optimization

Albert Berahas, University of Michigan, Ann Arbor, MI, United States, Raghu Bollapragada

Decentralized optimization problems come in diverse shapes and forms, and could have very different characteristics. In this talk, we discuss novel flexible approaches for solving decentralized optimization problems that adapt to problem characteristics. We discuss the rationale behind our proposed techniques, convergence in expectation and complexity guarantees for our algorithms, and present encouraging numerical results. This is joint work with Raghu Bollapragada, Wanping Dong, Shagun Gupta, Suhail Shah and Jiahao Shi.

2 - Reducing Sample Complexity in Stochastic Derivative-Free Optimization via Tail Bounds and Hypothesis Testing

Luis Nunes Vicente, Lehigh University, Bethlehem, PA, United States

We introduce and analyze new probabilistic strategies for enforcing sufficient decrease conditions in stochastic derivative-free optimization, with the goal of significantly reducing sample complexity and simplifying convergence analysis. In particular, we propose two complementary approaches. First, we develop a new tail bound condition imposed on the estimated reduction in function value, which permits flexible selection of the power used in the sufficient decrease test—greater than 1 but arbitrarily close to it. This approach allows us to reduce the number of samples per iteration from the standard $O(\delta^{\alpha-4})$ to $O(\delta^{\alpha-2-\epsilon})$, where $\epsilon > 0$ can be made arbitrarily

small, under mild noise assumptions. Second, we formulate the sufficient decrease condition as a sequential hypothesis testing problem, in which the algorithm adaptively collects samples until the evidence suffices to accept or reject a candidate step. This test provides statistical guarantees on decision errors and can further reduce the required sample size, particularly in the Gaussian noise setting, where it approaches $O(\delta^{-2})$ when the decrease is far from the "forcing function". We incorporate both techniques into stochastic direct-search and trust-region methods for potentially non-smooth, noisy objective functions, and establish their global convergence properties.

3 - Fast, Adaptive, and Scalable Methods via Hessian Averaging and Adaptive Gradient Sampling Strategies

Raghu Bollapragada, The University of Texas at Austin, Austin, TX, United States, Thomas O'leary Roseberry

In this talk, we discuss minimizing finite-sum and expectation objective functions using Hessian-averaging-based subsampled Newton methods. These methods accommodate gradient inexactness and maintain fixed per-iteration Hessian approximation costs. Recent work (Na et al. 2023) showed that Hessian averaging achieves fast $\mathcal{O}(\sqrt{\frac{\log k}{k}})$ local superlinear convergence for strongly convex functions, but requires gradient exactness and strong convexity, limiting practical use. To address this, we propose Hessian-averaged methods with adaptive-sampling strategies allowing gradient inexactness. For finite-sum problems, we use deterministic sampling, yielding global linear and sublinear convergence for strongly convex and nonconvex functions. We derive an improved local superlinear rate of $\mathcal{O}(\frac{1}{\sqrt{k}})$. For expectation problems, we use stochastic sampling and derive global linear/sublinear rates and a local superlinear rate of $\mathcal{O}(\frac{1}{\sqrt{k}})$. Additionally, we introduce scalable methods like the diagonally-averaged Newton (Dan) method for large-scale problems. Numerical results show that Hessian averaging enhances convergence and achieves state-of-the-art performance on challenging tasks like CIFAR100 classification with ResNets.

4 - Variance-reduced First-order Methods for Stochastic Optimization with Deterministic Constraints

Zhaosong Lu, University of Minnesota, Minneapolis, MN, United States, Sanyou Mei, Yifeng Xiao

We consider stochastic optimization problems with deterministic constraints. Existing methods typically focus on finding an approximate stochastic solution that ensures the expected constraint violations and optimality conditions meet a prescribed accuracy. However, such an approximate solution can possibly lead to significant constraint violations in practice. To address this issue, we propose variance-reduced first-order methods that treat the objective and constraints differently. Under suitable assumptions, our proposed methods achieve stronger approximate stochastic solutions with complexity guarantees, offering more reliable constraint satisfaction than existing approaches.

Ongoing Advances in Decision-Aware Learning

Invited Session

OPT: Optimization Under Uncertainty

Chair: Michael Huang, CUNY Baruch College, New York, NY, United States

1 - Statistical Comparative Analysis of Data-Driven Optimization Algorithms

Haofeng Zhang, Morgan Stanley, New York, NY, United States, Adam Elmachtoub, Henry Lam, Haixiang Lan

Data-driven optimization aims to translate a machine learning model into decision-making by optimizing decisions on estimated costs. Such a pipeline can be conducted by fitting a distributional model which is then plugged into the target optimization problem. While this fitting can utilize traditional methods such as maximum likelihood, a more recent approach uses estimation-optimization integration that minimizes decision error instead of estimation error. Although intuitive, the statistical benefit of the latter approach is not well understood yet is important to guide the prescriptive usage of machine learning. In this paper, we dissect the performance comparisons between these approaches in terms of the amount of model misspecification. In particular, we show how the integrated approach offers a "universal double benefit" on the top two dominating terms of regret when the underlying model is misspecified, while the traditional approach can be advantageous when the model is nearly well-specified. Our comparison is powered by finite-sample tail regret bounds that are derived via new higher-order expansions of regrets and the leveraging of a recent Berry-Esseen theorem.

2 - Decision-Focused Bias Correction for Fluid Approximation

Can Er, University of North Carolina-Chapel Hill, Chapel Hill, NC, United States, Mo Liu

Staffing decisions in large-scale service systems, such as call centers and healthcare networks, are typically formulated as a two-stage stochastic optimization problem: the first stage determines the capacity of each server, and the second stage dynamically allocates different types of customers to each server. These decisions are generally made in two steps: estimating future demand for different customer types and optimizing capacity accordingly. Due to the unknown joint distribution of demand, a common approach is to use fluid models that consider average arrival rates to solve the two-stage problem. Despite the widespread use of the fluid approximation (FA), employing the mean (or conditional expectation) as the arrival rate has been the conventional practice.

In our paper, we show that the traditional FA approach, which uses the sample mean of the arrival rate, does not generally yield the optimal staffing decision. This motivates a corrected approach that directly minimizes the expected cost. We characterize the resulting predictor and show that it can be computed as the minimizer of a convex function. We then analyze how this predictor can be estimated from data and establish convergence guarantees for gradient-based optimization, along with generalization error bounds under finite samples. Finally, numerical experiments demonstrate the effectiveness of our bias correction approach for FA under various settings.

3 - Decision-Aware Training of Spatiotemporal Forecasting Models to Select a Top K Subset of Sites for Intervention

Kyle Heuton, Tufts University, Medford, MA, United States, F. Samuel Muench, Shikhar Shrestha, Thomas J. Stopka, Michael C. Hughes

Optimal allocation of scarce resources is a common problem for decision makers faced with choosing a limited number of locations for intervention. Spatiotemporal prediction models could make such decisions data-driven. A recent performance metric called fraction of best possible reach (BPR) measures the impact of using a model's recommended size K subset of sites compared to the best possible top-K in hindsight. We tackle two open problems related to BPR. First, we explore how to rank all sites numerically given a probabilistic model that predicts event counts jointly across sites. Ranking via the per-site mean is suboptimal for BPR. Instead, we offer a better ranking for BPR backed by decision theory. Second, we explore how to train a probabilistic model's parameters to maximize BPR. Discrete selection of K sites implies all-zero parameter gradients which prevent standard gradient training. We overcome this barrier via advances in perturbed optimizers. We further suggest a training objective that combines likelihood with a decision-aware BPR constraint to deliver high-quality top-K rankings as well as good forecasts for all sites. We demonstrate our approach on two where-to-intervene applications: mitigating opioid-related fatal overdoses for public health and monitoring endangered wildlife.

4 - Decision-Aware Learning with Feature-Space Clustering Constraints

Golbagh Roghaniaraghi, Baruch College, NEW YORK, NY, United States, Michael Huang

In many real-world decision-making tasks, such as bank marketing, fraud detection, and customer churn, predictive models are trained on high-dimensional data that often contain weakly informative or noisy features. These features may not harm prediction accuracy but can mislead downstream decision-making when predictions are used in combinatorial optimization. We propose a decision-aware learning framework that addresses this challenge by using unsupervised clustering to denoise the feature space in a way that improves decision quality. Specifically, we introduce clustering constraints into the optimization layer, requiring that similar instances, grouped via hierarchical clustering, are treated consistently in downstream decisions. Unlike traditional clustering approaches, we do not fix the clusters in advance. Instead, we tune the clustering structure based on its impact on decision loss, as measured by the Perturbation Gradient (PG) loss. Empirical results across all three domains show that our method leads to improved decision quality compared to standard predict-then-optimize models, as well as PG-trained models without clustering constraints. By integrating

unsupervised clustering into a decision-aware optimization pipeline, our approach enables more reliable policies in settings where noisy features would otherwise obscure important structure in the data.

5 - Bandit-Powered Adaptive Decision Making

Huiwen Jia, University of California, Berkeley, Berkeley, CA, United States, Haoming Shen

We study adaptive decision-making problems under uncertainty, where decisions unfold in stages and the decision-maker selects a primary discrete decision followed by an auxiliary linear or mixed-integer decision in each stage. A key aspect of this setting is that the distribution of the uncertain parameters depends solely on the primary decision. To address this structure, we propose a bandit-based framework that guides exploration over the primary decision and leverages observed feedback to optimize the auxiliary decision. This approach enables effective learning in layered decision settings with decision-dependent uncertainty. We establish theoretical guarantees on the performance of the proposed method.

Derivative Free and Simulation Optimization

Invited Session

OPT: Computational Optimization and Software

Chair: Juliane Mueller, National Renewable Energy Laboratory, Golden, CO, United States

Co-Chair: Yunsoo Ha, National Renewable Energy Laboratory, Raleigh, United States

1 - Remu: Regional Minimal Updating for Model-Based Derivative-Free Optimization

Pengcheng Xie, Lawrence Berkeley National Laboratory, Berkeley, CA, United States, Stefan Wild

Derivative-free optimization (DFO) problems are optimization problems where derivative information is unavailable or extremely difficult to obtain. Model-based DFO solvers have been applied extensively in scientific computing. Powell's NEWUOA (2004) and Wild's POUNDERs (2014) explore the numerical power of the minimal norm Hessian (MNH) model for DFO and contributed to the open discussion on building better models with fewer data to achieve faster numerical convergence. Another decade later, we propose the regional minimal updating (ReMU) models, and extend the previous models into a broader class. This talk shows motivation behind ReMU models, computational details, theoretical and numerical results on particular extreme points and the barycenter of ReMU's weight coefficient region, and the associated KKT matrix error and distance. Novel metrics, such as the truncated Newton step error, are proposed to numerically understand the new models' properties. A new algorithmic strategy, based on iteratively adjusting the ReMU model type, is also proposed, and shows numerical advantages by combining and switching between the barycentric model and the classic least Frobenius norm model in an online fashion.

2 - Adaptive Sampling-Based Bi-Fidelity Stochastic Trust Region Method for Derivative-Free Stochastic Optimization

Yunsoo Ha, National Renewable Energy Laboratory, Golden, CO, United States, Juliane Mueller

Bi-fidelity stochastic optimization is increasingly favored for streamlining optimization processes by employing a cost-effective low-fidelity (LF) function, with the goal of optimizing a more expensive high-fidelity (HF) function. We introduce ASTRO-BFDF, a new adaptive sampling trust region method specifically designed for solving unconstrained bi-fidelity stochastic derivative-free optimization problems. Within ASTRO-BFDF, the LF function serves two purposes: first, to identify better iterates for the HF function when a high correlation between them is indicated by the optimization process, and second, to reduce the variance of the HF function estimates by Bi-fidelity Monte Carlo (BFMC). In particular, the sample sizes are dynamically determined with the option of employing either crude Monte Carlo or BFMC, while balancing optimization error and sampling error. We demonstrate that the iterates generated by ASTRO-BFDF converge to the first-order stationary point almost surely. Additionally, we numerically demonstrate the superiority of our proposed algorithm by testing it on synthetic problems and simulation optimization problems with discrete event simulations.

3 - A Large-Scale Benchmarking of Deterministic and Stochastic Black-Box Optimization Algorithms

Donghyun Oh, Georgia Institute of Technology, Atlanta, GA, United States, Nikolaos Sahinidis

We present a systematic benchmarking of state-of-the-art black-box optimization algorithms. Using a diverse and extensive set of test problems, ranging from smooth and convex to nonsmooth and nonconvex, we evaluate optimization performance with metrics including solution quality, convergence rate, and sensitivity to initialization. In addition to customary stochastic methods such as Bayesian optimization, we consider a variety of modern deterministic approaches like the recently proposed branch-and-model algorithm. We report trends in performance and scalability, highlighting the strengths and limitations of different algorithms across multiple problem classes.

4 - Global Multi-Objective Simulation Optimization: An Upper Bound on the Error with Convergence Analysis for a Simple Algorithm

Susan Hunter, Purdue University, West Lafayette, IN, United States, Burla Ondes

Consider the context of solving a multi-objective simulation optimization problem with two or more simultaneous and conflicting continuous objective functions to global optimality on a compact feasible set. If computing resources are plentiful or the simulation model runs quickly, one might implement a simple algorithm which consists of selecting m feasible points in the decision space using a space-filling design, expending n simulation replications per point to estimate the objective function values, and returning the discretized estimated efficient and Pareto sets. In this context, we define a mathematically tractable optimality gap for assessing the algorithm convergence as the total simulation budget $b=mn$ tends to infinity, derive probabilistic upper bounds on the optimality gap of the returned solution, and determine how best to trade off the number of feasible points m with the number of simulation replications per point n to ensure convergence of the optimality gap to zero at a fast rate.

5 - The Derivative-Free Fully-Corrective Frank-Wolfe Algorithm for Optimizing Functionals over Probability Spaces

Di Yu, Purdue University, West Lafayette, IN, United States, Shane Henderson, Raghu Pasupathy

The challenge of optimizing a smooth convex functional over probability spaces has recently generated much attention due to its relevance in important contexts such as experimental design, emergency response, and variations of the problem of moments. For solution, the fully-corrective Frank-Wolfe (FCFW) first-order recursion has emerged as a viable and provably efficient algorithm. We propose an FCFW recursion that rigorously handles the oft-encountered zero-order setting, where the derivative of the objective is known to exist, but only the objective at a specified probability measure is observable. The main ingredient of our proposal is an estimator for the objective's influence function, which can be viewed as a function providing the directional derivative of the objective function in the direction of point mass probability distributions, constructed via a combination of Monte Carlo, and a projection onto the orthonormal expansion of an L2 function on a compact set. An analysis of the bias and variance of the influence function estimator guides step size and Monte Carlo sample size choice, and leads to a characterization of the recursive rate behavior on smooth non-convex problems.

Exploiting Math Structure for Faster Solve Times on Practical Problems

Invited Session

OPT: Integer and Discrete Optimization

Chair: Alexandra Newman, Colorado School of Mines, Golden, CO, United States

1 - Improvements and Enhancements to Modeling Optimized Steel Coil Production Schedules Under Continuous Casting and Hot Rolling

Jennifer McClary, Colorado School of Mines, Colorado Springs, CO, United States, John Cox, Alexandra Newman

In continuous steel casting, heats of molten steel are alloyed, cast into slabs, and hot-rolled into coils in a tightly coordinated process. Building on a previous mixed-integer programming model for daily scheduling in a 100% direct-charge steel mill with two casters and one hot rolling mill, we present an enhanced model that improves

computational scalability while preserving solution quality. The extended model explicitly defines penalty parameters for violating operational best practices and introduces three constraint categories: intercaster gauge differences, gauge change, and double trim operations. Three innovations further enhance efficiency: (1) learned cuts derived from production insights to tighten the formulation, (2) coil clustering to reduce sequencing complexity, and (3) iterative solving that prioritizes critical penalties for faster convergence via warm starts. Computational experiments demonstrate that the model solves large instances with thousands of variables significantly faster than the original, enabling real-time scheduling and future planning in steel mills. These advances leverage state-of-the-art solvers and domain-specific insights, addressing the combinatorial complexity of large-scale schedules while maintaining strict safety and logical constraints

2 - Optimizing Freight Logistics for Mining Operations Under Infrastructure Constraints

Yongchen Wu, Colorado School of Mines, Golden, CO, United States, Kevin Bamwiso, Steph Shiferaw, Hojun Choi, Alexandra Newman

We analyze an integrated freight logistics system for mining operations in the United States. Our study focuses on optimizing the fleet size and cost over multiple years at monthly fidelity, within a constrained multi-modal (truck and rail) transportation network.

We formulate and solve a multi-commodity, time-expanded network flow model that minimizes transportation operational costs while satisfying material needs for mining and processing operations. The model captures dynamic supply and demand, transport capacity constraints, storage limits, and commercial market purchases.

We provide quantitative trade-offs between transport modes and offer recommendations on acid transloading, storage policies, and routing protocols for the time horizon of interest.

3 - Tightening Bilinear Relaxations with Geometric Rotations

Jaivardhan Sood, The University of Texas at Arlington, Arlington, TX, United States, Jay Rosenberger

Bilinear terms are crucial in nonlinear optimization, presenting considerable challenges due to their non-convexity. While traditional techniques use McCormick envelopes to form convex relaxations, they often result in loose bounds, particularly when variable limits create an elongated rectangular shape. This research introduces a new geometric approach to improve these relaxations. By analyzing the feasible region's geometry, we propose a 45-degree rotation of the coordinate system when one edge of the bounding rectangle is significantly larger than the other. This rotation facilitates the derivation of directional bounds that consistently surpass the upper bounds given by conventional McCormick envelopes. Instead of relying on the typical axis-parallel cuts from McCormick relaxations, our method develops 45-degree cuts that more efficiently tighten the relaxation. We show that this approach yields better upper bounds in all scenarios, representing a notable improvement for global optimization solvers, especially within spatial branch-and-bound frameworks.

4 - A Branch-and-Price Algorithm to Solve the Two Dimensional Cutting Stock Problem with Length Tolerances

Serkan Urkmez, Ozyegin University, Istanbul, Turkey, Erhun Kundakcioglu

The Two-Dimensional Cutting Stock Problem (TDCSP) poses a critical optimization challenge in industries such as flat steel, textile, glass, paper, and wood processing, where maximizing material utilization is essential for minimizing waste and reducing costs. This study introduces a mixed-integer linear programming model for TDCSP with guillotine cuts, incorporating industry-specific constraints such as order specifications defined by length intervals, precise width requirements, and total demanded lengths. Given the exponential growth in computational complexity, we employ column generation as the primary solution approach, systematically generating and integrating cutting patterns to improve efficiency. To further enhance performance, we incorporate a branch-and-price algorithm, applying heuristics and warm-start strategies to accelerate convergence. Computational experiments on large-scale instances demonstrate that column generation with branch-and-price outperforms the direct solution of the standard formulation, significantly reducing material waste while ensuring practical applicability. These results highlight the superior scalability, adaptability, and effectiveness of the proposed approach, delivering both economic and environmental benefits for the industry.

5 - Mixed-Integer Optimization for Causal Learning with Unknown Interventions

Tong Xu, Northwestern University, Evanston, IL, United States, Simge Kucukyavuz, Armeen Taeb, Ali Shojaie

Causal discovery is an important problem in many areas such as biology, social sciences, and economics. There have been a lot of methods using observational and interventional data to learn the Bayesian network that represents the interaction network among a complex system. Current methods for causal discovery often face one or more of the following limitations: (i) reliance on known intervention targets, restricting their applicability to specific scenarios (e.g., GIES); (ii) lack of scalability and dependence on restrictive parametric assumptions, often yielding only partial causal structures; (iii) reliance on test-based approaches that require large sample sizes, making them impractical for data-scarce settings; and (iv) inconsistency in their results. These shortcomings underscore the need for more scalable, flexible, and consistent methods for causal discovery.

We propose a novel mixed-integer programming formulation for causal structure learning that unifies observational and interventional settings, accommodating known, partially known, and unknown intervention targets while incorporating structural information. We develop an efficient alternating optimization algorithm with guaranteed convergence to a coordinate-wise minimum. Empirical results demonstrate that our method achieves superior scalability and accuracy compared to state-of-the-art algorithms, bridging a critical gap in causal discovery and providing a robust foundation for future research on scalable DAG learning.

1 - Work-from-Home and Its Implications for Firm Performance

Yu Wang, Binghamton University, Vestal, NY, United States, Rory Eckardt

With the advancement of technologies and the outbreak of COVID-19, work-from-home (WFH) has transitioned from an alternative to a dominant work mode. While extensive extant literature has emphasized individual-level outcomes of it, this study investigates its actual effects on the organizational level, focusing on how different levels of WFH intensity (in-office, hybrid, fully remote) influence productivity and profitability in professional service firms.

Drawing on resource based view and social exchange theories, we propose that WFH can enhance firm performance by reducing operational costs, increasing autonomy, and expanding access to a broader talent pool and a wider clients base. In addition, we further examine three moderators that shape this relationship: the gender of strategic leaders, the firm's leverage ratio (i.e., number of associates per partner), and the level of AMO human resource systems. Female leaders may amplify WFH benefits through relational leadership styles; high leverage ratios—associated with structured workflows—may support more efficient remote collaboration; and strong AMO systems enhance employee performance under remote settings.

Based on archival data from ALM 200 law firms, we empirically test these relationships by using OLS and moderated hierarchical regression analyses. This research offers new insights into when and for whom WFH is most effective, advancing theoretical understanding of remote work and providing actionable guidance for strategic decision-making in professional service firms.

2 - Contract Design for Professional Services

Jiayu Tian, Washington State University, Pullman, WA, United States, ting lu

Professional service contracts often face expertise asymmetry. We develop a performance-based contract framework, which improves alignment between client and provider incentives and enhances contract efficiency. This study advances our understanding of contract theory and practice.

3 - Queue-Length Information in a Tiered Service System with Referrals and Imperfect Customer Perceptions

Shrutivandana Sharma, New York University, Brooklyn, NY, United States, Yufeng Zhang

In this work we investigate implications of queue-length information provision on strategic customers' choice between tiered service providers, where customers are heterogeneous in terms of their service needs and the generalist tier refers urgent customers to the expert tier, but where customers' choices are made under imperfect perceptions of their urgency (need for referral). We present an analytical framework based on queueing games to investigate these issues. We prove existence of equilibrium for this system, and characterize structure of equilibrium strategies. Based on this structure we conduct numerical experiments to further analyze equilibrium properties, and implications of queue-length information on social cost for customers. We also compare this system with one without real time queue-length information, and identify conditions under which queue-length information provision is beneficial.

1 - Assessing the Applicability of Large Language Models in the Multi-Attribute Healthcare Decision Making

Mohammad Alipour Vaezi, Virginia Tech, Blacksburg, VA, United States, Sajad Khodadadian, Kwok-Leung Tsui

The growing complexity of healthcare decision-making has underscored the necessity for robust, scalable, and interpretable decision-support systems. Multi-Attribute Decision-Making (MADM) techniques have been widely employed to facilitate structured decision processes, enabling the evaluation of alternatives across multiple, often conflicting criteria. Traditionally, these methods rely heavily on expert judgment to define decision criteria, assess attribute importance, and rank alternatives. Recent advancements in Large Language Models (LLMs) offer a promising avenue to augment or enhance MADM applications in healthcare by leveraging their natural language processing capabilities to synthesize information, generate structured decision matrices, and provide analytical insights. This study proposes a novel framework that integrates LLMs into MADM processes, aiming to assess their efficacy in replicating expert-driven decision-making tasks. The framework includes prompt-tuning strategies and meta-learning techniques to adapt LLM outputs to MADM requirements, enabling automated identification of decision criteria, construction of decision matrices, and application of established MADM methods. To evaluate this approach, three case studies are designed to benchmark LLM-driven decision-making against expert-based evaluations, focusing on key performance metrics such as consistency, interpretability, biasness, and alignment with ethical guidelines. Preliminary findings suggest that LLMs possess the capacity to enhance decision consistency and scalability while maintaining interpretability within MADM frameworks. This study contributes to the discourse on AI-driven decision-support in healthcare, offering insights into the practical integration of LLMs in expert-based decision-making environments.

2 - Toward the Effectiveness and Efficiency of LLM Reasoning in Healthcare

Liang Zhao, Emory University, Atlanta, GA, United States

As medical AI systems increasingly support high-stakes decisions, it is no longer sufficient for models to be accurate—their decision process must also be transparent, reasonable, adaptable, and resource-efficient. In this talk, I will introduce a roadmap on enhancing AI reasoning, covering techniques like explanation supervision, distillation, and retrieval-augmented generation (RAG). First, explanation supervision allows models to learn not just *what* to predict, but *why*, using human or saliency-based guidance to align model reasoning with clinical intuition. Building on this, we will introduce the reasoning of large language models (LLMs) and how to improve its quality and efficiency on the fly. Then, we extend to the topic on how large language models (LLMs) can act as mentors in an *explanation-guided distillation* process—actively correcting the reasoning flaws of smaller, deployable models, while minimizing annotation costs. Finally, we address the need for comprehensive context in clinical decision support by extending RAG methods to go beyond isolated documents and tap into richly connected patient data, biomedical literature, and knowledge graphs. Together, these approaches move us toward a future where medical AI is not only performant, but also interpretable, scalable, and grounded in structured clinical knowledge. This integrative strategy opens new doors for trustworthy AI applications in diagnosis, imaging, and real-time decision-making in the clinic.

3 - Paging Dr. GPT: Extracting Information from Clinical Notes to Enhance Patient Predictions

David Anderson, Villanova School of Business, Villanova, PA, United States, Margret Bjarnadottir, Stephen Mahar, Shriyan Reyya

In healthcare, there is a long tradition of using information from electronic medical records (EMRs) for outcome prediction in support of hospital operation and to support clinical decision making. Most prior work uses tabular data from EMRs and overlooks the unstructured clinical notes typically written by doctors. These notes capture key aspects of the patient's hospital stay, including diagnosis, treatment, progress, medications and care plans, which are factors important to the patient's health and prognosis that may contribute to prediction accuracy. Despite their potential, these notes remain underutilized in predictive modeling, even though large language models (LLMs), with their strengths in text summarization and analysis would seem well suited for extracting insights from them. Here we introduce an intuitive, physician-driven approach that integrates LLMs into standard machine learning pipelines, and show that a model using an LLM's answers to simple clinical questions from discharge notes can outperform models built on available tabular data. We further show that combining the LLM's answers with tabular data significantly improves predictive performance. Our results reveal that LLMs are capable of extracting and distilling the information contained in discharge notes to quantify patient risks, and illustrate a way that AI tools can complement human workers. This approach highlights the potential for transparent and expert driven prompt engineering to combine the strengths of human expertise and machine intelligence, and is broadly applicable in any field with underutilized textual data sources, where LLMs can be guided with expert questioning.

1 - Regression Discontinuity in Time: Evaluating the Impact of Evolving Digital Health Interventions

Isha Thapa, Stanford University, Stanford, CA, United States, Pierre-Amaury Laforcade, Franziska Bishop, Johannes Ferstad, Manisha Desai, David Maahs, Priya Prahalad, Dessi Zaharieva, David Scheinker, Ramesh Johari

Background: Clinics continue to adopt digital health interventions (DHIs) in which algorithms analyze data to help direct patient care. Changes to these algorithms are rarely evaluated rigorously, despite their potential to affect patient outcomes. The regression discontinuity in time (RDT) design may be used to estimate the causal effect

of such changes but has received little attention in medical literature.

Methods: We conducted a retrospective study of continuous glucose monitor (CGM) data from youth with type 1 diabetes in the 4T Program from November 2020 to March 2022. In 2020, the clinic used an algorithm that directed patients for provider review based on the number of glucose targets not met (e.g., time in range (TIR) < 65%). In September 2021, the clinic adopted a new algorithm that prioritized the review of patients experiencing level 2 hypoglycemia (glucose < 54 mg/dl). We evaluated the validity of the RDT framework in this setting and estimated the impact of this change in directed care on weekly TIR.

Results: There were 247 patients with 11,297 weekly TIR observations. Robustness checks supported the validity of the RDT design. Patients with level 2 hypoglycemia were prioritized for review, with no significant change to population-level TIR (-0.2% points; 95% CI: [-4.8, 3.5]).

Conclusions: We demonstrate the feasibility of using the RDT framework to estimate the impact of algorithmic changes to a DHI on patient care. As algorithm-directed care increases in clinical practice, this approach can serve as a diagnostic tool to measure how operational changes impact outcomes.

2 - Evaluating Secure Messaging Workflows to Improve Healthcare Delivery

Sean Tsung, Stanford University, Stanford, CA, United States, Jisun Lee, Yue Hu, Song-Hee Kim, Vijaya Parameswaran

Secure messaging is widely used for asynchronous patient-provider communication, yet the effects of messaging workflows on both operational and patient outcomes remain understudied. We analyze secure messaging data from Stanford primary care clinics to assess how message routing strategies and varying levels of resource flexibility (e.g., increased involvement of medical assistants) influence key operational outcomes such as response times and resolution rates, along with downstream patient outcomes. While greater provider flexibility may be associated with shorter response times, it can also be linked to lower resolution rates. Our findings offer guidance for designing secure messaging workflows and managing provider workloads to improve system performance without compromising care quality.

3 - Personalized Health Check with Joint Screening: a Data-Driven Approach with Pomdp

Guohua Wan, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Haotian Li

Regular health check is critical in personal health management, with over 250 million conducted annually in China. Despite its widespread use, designing an efficient health check policy remains a challenge. Existing clinical guidelines often fail to offer personalized recommendations and overlook the influence of disease correlations on joint disease screening.

We address this issue by developing a stochastic modeling framework based on Partially Observable Markov Decision Processes to personalize health check decisions. The model decides optimally when and how to select a subset of screening items for an individual, explicitly accounting for correlations between diseases. To estimate the parameters of the decision model, particularly the joint progression of multiple diseases, we introduce a modified Baum-Welch algorithm and apply it to real-world health check data. The results are validated against medical literature in our numerical studies. In the case study, we demonstrate the application of our personalized health check strategy by designing a joint screening strategy for chronic kidney disease (CKD) and diabetes. The proposed policy is projected to save 628 million CNY annually in China compared to current guidelines and 558 million CNY compared to single-disease analysis. Additionally, it could save up to 6.828 quality-adjusted life months for the stratified population compared to existing screening benchmarks. Our findings highlight that the proposed personalized health check policy offers more efficient and cost-effective recommendations, with significant potential for improving health outcomes and resource allocation.

4 - Telehealth's Double-Edged Sword: The Hidden Costs of Expanding Access to Virtual Care

Masoud Kamalahmadi, University of Miami, Coral Gables, FL, United States, Jong Myeong Lim

Leveraging variation in telehealth adoption across specialties during the COVID-19 pandemic within a major health system, we find that the expanded access offered by telehealth may come with significant trade-offs, including increased physician workload, reduced patient time, and financial strain on healthcare organizations.

1 - Auditing Strategies in Trade Credit Contracts

Paola Martin, Indiana University, Bloomington, IN, United States

In a trade credit contract, the supplier may not observe the retailer's marketing efforts and resulting sales. Verification of the retailer's sales is possible, but costly. Furthermore, the supplier may not accurately learn the true sales. The supplier may choose to perform an early audit, which is less costly and inaccurate, and/or a late audit, which is more costly but reveals the actual sales of the retailer. In either audit, the supplier does not learn the retailer's marketing effort. This talk explores the supplier's choice of auditing strategies and their impact on trade credit contract terms. In particular, it will address the following questions. Will the supplier exercise the option to perform an early audit? Given the results of the early audit, for what parameter values will the supplier forego a second audit? How does the auditing strategy affect the retailer's order quantity, as well as the total supply chain profit? How does the asset level of the retailer affect the supplier's trade credit terms?

2 - Clean-Tech Adoption and Risk Hedging

Liao Wang, The University of Hong Kong, Hong Kong, Hong Kong, David Yao

We develop a model for manufacturers who are considering switching from existing technologies to clean technologies that generate fewer carbon emissions. Such a switch requires upfront fixed investment cost. For instance, in cement manufacturing, investment in Carbon Capture and Storage (CCS) is needed for cleaner production. Another example is the paper and pulp industry, where cleaner production technologies entail replacing the fossil-based heaters with heat pumps. Clearly, such investments, given their upfront nature, are risky, so risk-averse producers may not want to switch to the clean technologies. Our objective is to develop risk hedging strategies for such producers, by trading carbon emission permits in a secondary market, such as the EU Emissions Trading System (ETS) market, as well as other relevant financial assets that impact product demand (for example, stock index as a proxy of the general economy). We jointly optimize hedging strategy, capacity decision and technology choice to maximize Conditional Value at Risk (CVaR) objective. The solutions are completely characterized analytically. We find that risk hedging facilitates the clean technology adoption by allowing for larger upfront investment cost, compared to the production-only model.

3 - AI Algorithmic Pricing and Collusion

Yuze Li, Questrom School of Business, Boston University, Boston, MA, United States, Jussi Keppo, Gerry Tsoukalas, Nuo Yuan

The increased use of algorithmic pricing agents poses significant challenges for markets and regulatory oversight. This paper provides a theoretical and experimental investigation into algorithmic pricing agents based on Large Language Models (LLMs). We find that (1) LLM-based agents can autonomously achieve optimal pricing, and (2) they engage in pricing collusion without explicit communication. To investigate the underlying mechanisms, we develop a two-period stylized model that motivates an extensive simulation exploration into various factors influencing the rate of pricing collusion among LLM-based agents, including (1) the number of agents,

(2) heterogeneity in algorithmic and computational capabilities, (3) variability in the agents' information environment, and (4) the degree of platform competition. Our findings uncover the dynamics underpinning algorithmic collusion, providing unique insights into regulating LLM-based pricing agents and algorithmic market behavior.

4 - Costless Multi-Party Signaling with Buyback Contracts in Supply Chain Finance

Wenqiang Xiao, New York University, New York, NY, United States, Fangruo Chen, Guoming Lai, Chuanshuai Ru

We investigate an innovative financing scheme in which large suppliers use buyback clauses to help downstream resellers secure favorable loan terms. A key question is how buyback contracts can operate effectively when external lenders have less knowledge about a product's prospects than supply chain parties. We develop a multi-party signaling framework involving three parties: a supplier, a financially constrained reseller, and a lender, to examine the value of buyback contracts as an information-revelation instrument. In our model, while offering buyback terms can reduce loan interest rates by sharing default risk, it does not inherently improve supply chain performance under symmetric information. In contrast, under asymmetric information, the choice of buyback terms becomes critical. Sufficient differentiation between contracts—such as lower wholesale prices or higher buyback prices under the optimistic product prospect compared to the pessimistic one—combined with aligned procurement quantities, allows the supply chain to credibly signal the product's prospects to the lender in a costless way. The supplier's access to information proves pivotal in facilitating efficient signaling. Our findings underscore the powerful capacity of buyback contracts as both risk-sharing and signaling tools, providing practical insights for large suppliers on contract design and information management. These benefits are unattainable through standard wholesale-price contracts. Additionally, the multi-party signaling framework offers a generalizable solution methodology applicable to similar signaling scenarios, extending its relevance beyond supply chain finance.

1 - Optimal Pricing and Date Labeling Strategies for New and near-Expiry Food Products: Implications for Food Waste Reduction

Shuxian Xiao, University of Northern Iowa, Cedar Falls, IA, United States, Charles Wang, Mike Wei

In this paper, we study three common retail practices for communicating expiration dates to consumers: (1) **Strategy DN**, which involves displaying and selling only new products; (2) **Strategy DB**, which involves displaying date labels and offering different prices for new and near-expiry products; and (3) **Strategy M**, which involves mixing new and near-expiry products while charging a uniform price. Our research is guided by the following questions: *How do consumers behave under these three approaches? What are the retailer's optimal prices, profits, and resulting food waste under each approach? Which strategy performs best in terms of financial outcomes and food waste reduction?*

We develop a Stackelberg game in which the retailer first determines its date-labeling and pricing strategy to maximize profit. Consumers then decide whether to purchase a new product, a near-expiry product, a product from the mixed batch, or not to purchase at all.

We analytically examine how these date-labeling strategies influence consumer purchasing behavior, retailer pricing decisions, profit outcomes, and food waste. Our analysis identifies optimal strategies and the conditions under which mixing new and near-expiry products can simultaneously reduce food waste and enhance retailer profitability. We also develop an infinite-horizon model in which the retailer replenishes the inventory of new products at the beginning of each period. The results and insights from the infinite-horizon model are qualitatively consistent with those from the single-period setting.

2 - Inventory Competition, Stockouts and Food Waste

Timothy Richards, Arizona State University, Mesa, AZ, United States, Stephen Hamilton, Elliot Rabinovich

The economic cost of lost or wasted food at the grocery-retail level is well documented. We analyze how much of this loss results from grocers competing in both price and inventory as these retailers overorder to avoid stockouts. We use grocery retail data to estimate a model of spatial demand, and competition in prices and inventories, among competing retailers to examine stockout costs and retail food loss. We find that prices and inventories are strategic complements in the sense that when retailers increase inventory levels to avoid stockouts, doing so softens price competition so prices rise accordingly in Bertrand-Nash equilibrium. Moreover, because we account for the reverse effect as well -- the feedback effect between prices and inventories -- we find that higher prices in turn lead to higher inventory levels. We find that, at the Bertrand-Nash equilibrium, retailers over-order relative to their baseline demand so that they waste some 13% of retail sales, on average, over multiple categories. We also find higher stockout costs than in the prior literature, and excess ordering of some 17% relative to noncompetitive-retailer levels. Retail competition in inventory appears to be an important driver of excess food stocks and an overlooked market failure contributing to overall food waste in the supply chain. This explains why retailers waste so much food, as holding excess inventories is profit-maximizing when there is a low-cost way of moving excess inventories out the back of the stores without incurring tipping fees.

3 - Profitability and Food Waste in Buffet Restaurants

Yuwen Hu, University of Michigan, Ann Arbor, MI, United States, Ekaterina Astashkina, Izak Duenyas

All-you-can-eat buffets are often criticized for generating excessive food waste. We build a stylized model of a profit-maximizing buffet operator facing cost-minimizing consumers with uncertain appetites. First, we examine how improvements in food accessibility (i.e., enhanced convenience in a buffet) affect consumer plate waste and the buffet's profitability. Contrary to conventional wisdom, we find that greater convenience can lead to lower plate waste and results in higher profits, as easier plate refills encourage diners to take smaller food portions. We then compare two common strategies buffet restaurants use to reduce plate waste: (i) imposing penalties for leftovers and (ii) educating consumers about the environmental and social implications of waste. We find that imposing an optimal penalty consistently boosts profits, whereas consumer education may sometimes lower profits, particularly in buffets with low unit production costs. Furthermore, optimal penalties outperform consumer education in terms of profitability, but education can be more effective in reducing plate waste in buffets with moderate unit production costs. Our findings remain robust even in environments where consumers do not perfectly learn their demands, as well as in the presence of insatiable or environmentally conscious consumers.

4 - Governance Strategies Targeting the 'Hidden Middle' to Reduce Food Loss and Health Risks in China's Food Supply Chain

Cangyu Jin, Zhejiang University, Hangzhou, China, People's Republic of

The untraceability challenges posed by the often overlooked "hidden middle"—small- and medium-scale entities within complex agricultural supply chains—exacerbate food losses and health risks. However, the impact of the "hidden middle" within the food supply chain, from the perspective of cross-regional food safety risk transfer, and the effectiveness of governance, remain uncertain. Leveraging over 300,000 aquatic product tests from 247 prefectures between 2015 and 2022 in China, we developed a data driven framework examines food loss and health risks associated with antibiotic residues in aquatic supply chains, and proposes optimization strategies within the framework of the existing food sampling schemes. First, we found that widespread contamination by antibiotic residues exceeding maximum residue limits (MRLs) throughout China by conditional probability model. Second, we employed the conditional probability model with dose-response relationships revealed an average food loss of 44,200 tons per province and health risks exceeding warning thresholds in six provinces. Third, Integer Programming (IP) was used to optimize the allocation of food safety monitoring resources for aquatic products along the supply chain, aiming at maximizing the probability of detecting contaminated products. The optimization leading to an average mitigation of 14,702 tons of food loss and a 77% reduction in health risks from antibiotic residues in the national aquatic supply chain—improvements of 6,951 tons and 17% compared to the baseline monitoring approach. Our findings highlight the importance of the "hidden middle" in food safety governance along complex agricultural supply chains, which plays a critical role in reducing food loss and health risks.

5 - A Joint Optimization Model for Storing and Transporting A Perishable Product in A Cold Chain

zahra Hossein Pour, University of Arkansas, Fayetteville, AR, United States, Haitao Liao

One of the most challenging tasks in the food industry is controlling product quality throughout the cold chain. In this research, we consider two key stages in the cold chain for a perishable product: storage and transportation. For a given demand with a specific delivery window, a joint optimization model for storing and transporting the product is developed considering a potential loss due to product decay during the two stages. The objective is to determine the optimal order quantity, the start time of transportation process, and the storage and transportation conditions—particularly temperature settings—to minimize the total cost while satisfying the customer demand. The total cost includes the storage cost, transportation cost, and the cost of wasted units. To address this problem, the life distributions of the product due to decay during both the storage and transportation are jointly considered. We employ the cumulative exposure model to formulate product quality deterioration over time and its dependency on temperature settings. The proposed joint optimization model is applied in an illustrative case study to demonstrate its practical applicability. This model can serve as a valuable tool for designing and operating food distribution relying on a cold chain, offering an effective approach for balancing food quality preservation, delivery time, and cost across the cold chain.

Building B Level 3 B305

Topics in Empirical Operations Management

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Caleb Kwon, The University of Texas At AUstin, Austin, United States

1 - Racial and Gender Biases in Customer Satisfaction Surveys: Causal Evidence from An American Restaurant Chain

Yong-Pin Zhou, University of Washington, Seattle, Seattle, WA, United States, Masoud Kamalahmadi, Qiuping Yu

We study racial and gender biases in customer satisfaction surveys using 1.5 million transactions and 260,000 customer surveys from a casual-dining restaurant chain in the US. We find that customer ratings are biased against racial minorities, and strikingly female servers despite them being the majority. We explore the mechanisms of discrimination and propose mitigation strategies.

2 - First Impressions Matter: Task Frictions and Retention on a Crowdfork Platform

Martin Gonzalez Cabello, University of California, Los Angeles, Los Angeles, CA, United States, Auyon Siddiq, Charles Corbett, Andrew Gordon

Crowdfork platforms are central to the data supply chains that power AI systems, particularly through large-scale data labeling. Yet the dynamics of worker engagement on these platforms remain poorly understood. We study fairness and worker engagement on a large online crowdfork platform. Leveraging a comprehensive dataset that records every task completed during a full calendar year, we focus on workers that recently joined the platform and analyze how their early experiences shape subsequent platform activity. We examine several dimensions of procedural fairness and how they influence workers' future engagement with the platform. We link submission records, study metadata, and dashboard data to reconstruct what each worker saw before choosing a task. Using this information, we assess how early exposure to mismatched or returned tasks affects long-term engagement. Our findings have direct implications for platform design and policy: improving early task experiences may promote retention and build trust among new workers.

3 - 2004--2024: Unpacking Two Decades of Food Date Labeling in the US and UK

Fiorentia Zoi Anglou, University of Texas at Austin, Austin, TX, United States, Robert Bray, Robert Sanders, Ioannis Stamatopoulos

Food date labels---e.g., "best by," "use by," "sell by"---are widely believed to influence consumer behavior and therefore contribute to food waste. Based on these beliefs, policymakers have taken action: California will soon implement date-label changes, a date-label-standardization bill is pending in Congress, and five of the top-10 UK retailers have switched from "use by" to "best by" labels. Our research provides the first large-scale, field study assessing the impact of date labels on consumer purchasing behavior. We combine data from 40,000-60,000 households across the US with state-level policy variation for dairy products' date labels in four states between 2005--2021. Using an event-study design and placebo inference, we find no evidence of change in consumer behavior in response to changes in date labels. These findings directly challenge prevailing assumptions among policymakers and regulators about the relationship between date labeling and food waste.

4 - The Digital Hustle: Can After-Hours Work Emails Shape Career Success

Priscilla Rodriguez, INSEAD, Fontainebleau, France, So Yeon Chun, Jurgen Mihm

Today's professionals have unprecedented access to digital communication tools that enhance connectivity and control over work-related tasks. However, these tools can be a double-edged sword: employees may be pressured to remain constantly available, creating an 'always on' work culture. In the past, clear boundaries limited the amount of work employees could do outside scheduled hours, but now these boundaries have blurred. Thus, employees may feel compelled to engage in after-hours work, defined as work beyond scheduled work hours. Yet a critical question remains: does this even pay off? This question has far-reaching implications not only for individual career trajectories but also for family dynamics, mental health, and broader workplace culture.

In this study, we empirically examine the impact of after-hours work on performance evaluations using proprietary, anonymized data from over 3,000 desk job employees at a Fortune 500 company. This dataset integrates granular digital traces of work behavior, including email and meeting records with timestamps and participant details, individual performance evaluations, and HR metadata on role, seniority, and demographics. To mitigate potential endogeneity, we use a novel instrumental variables approach that leverage both formal reporting relationships and informal collaboration networks. We investigate whether and how after-hours work influences evaluations, propose a potential mechanism, and provide supporting empirical evidence. Our findings offer insights into how after-hours work patterns may influence career outcomes while highlighting that the effects vary across individuals.

Simulation and Modeling

Invited Session

Decision Analysis Society

Chair: Kamelia Sepanloo, Purdue University, West Lafayette, IN, United States

1 - Multimodal Evaluation of Nurse Trainees in Extended Reality

Kamelia Sepanloo, Purdue University, West Lafayette, IN, United States, Young-Jun Son, Janine Hinton

This presentation examines the use of eye-tracking and physiological response analysis to assess cognitive load and stress in nursing trainees during simulation-based education in extended reality environments. The study utilizes a custom-designed training system that operates in both mixed reality (MR), using the HoloLens 2 headset, and virtual reality (VR), using the Meta Quest Pro. Nurses interact with digital patient and digital medical equipment in MR, and within a fully immersive digital environment in VR. Throughout the simulation, participants' eye movements are continuously recorded to capture metrics such as fixation duration, saccade frequency, and gaze distribution, offering insight into visual attention and task engagement. In parallel, physiological data are collected using the Empatica Embrace plus wristband, capturing heart rate, electrodermal activity (EDA), and skin temperature. These measures serve as indicators of stress and arousal during high-stakes clinical scenarios, including moments when the patient's condition deteriorates due to hypotension and hypoxia. The training simulation is segmented into six time-based stages, allowing for

detailed temporal analysis of both gaze behavior and physiological responses as the scenario evolves. Preliminary findings indicate notable differences in cognitive load and stress responses between MR and VR environments, with implications for the design of adaptive training systems. By combining eye-tracking and physiological data, this research provides a multidimensional understanding of trainee experience and offers a pathway toward more responsive, personalized simulation-based education. Ultimately, these insights aim to enhance the preparedness of healthcare professionals by optimizing learning environments based on real-time cognitive and emotional feedback.

2 - Real-Time Digital Twin Development and Augmented Environment Generation for Multi-Agent Robotic Systems

Seonho Woo, Purdue University, West Lafayette, IN, United States, Seung Ho Woo, Young-Jun Son

This study focuses on the development of a real-time bidirectional digital twin framework utilizing the NVIDIA Isaac Sim platform. Current robotic systems struggle with effective decision-making in dynamic environments due to limited sensory input, data inaccessibility from occluded regions, and resource constraints. Our study addresses these challenges through the proposed interaction framework, leveraging a generative model, where physical and digital twins continuously exchange information to enhance situational awareness and generate environmental knowledge.

Our system constructs high-fidelity virtual environments using multimodal sensor data from LiDAR, cameras, and IMU sensors mounted on robotic platforms. The bidirectional communication enables real-time experiment planning where the digital twin can simulate navigation scenarios and path optimization strategies while the physical twin validates and refines these predictions through actual execution. A key innovation involves developing generative AI models that create comprehensive environmental representations using limited real-time data without relying on extensive historical datasets or pre-defined knowledge bases.

The current implementation focuses on perfecting single-agent digital twin interactions of UGV, with planned expansion to multi-agent systems that demonstrate collaborative decision-making through distributed sensing and coordinated task execution. This approach optimizes resource utilization and maintains data integrity through privacy-preserving frameworks. The system's scalability positions it for large-scale digital twin modeling, which would be a practical approach for existing challenges in manufacturing facility and warehouse automation that can expand to support efficient decision-making in dynamically changing environments.

3 - Properties of Two-Stage Stochastic Multi-Objective Linear Programs

Akshita Gupta, Purdue University, West Lafayette, IN, United States, Susan Hunter
