Current treatment options for MUD are limited, as no pharmacotherapies have been approved by the FDA. Behavioral interventions, especially contingency management (CM), have emerged as effective alternatives. CM rewards individuals for maintaining drug-free behaviors, such as providing negative urine samples or attending therapy sessions. Despite strong evidence supporting its efficacy in reducing methamphetamine use and promoting health, CM faces significant implementation barriers. These include clinical challenges, such as a lack of comprehensive evidence and clinician involvement in program design, and political obstacles, such as concerns over the ethics of providing financial incentives in treatment.

We used a microsimulation model to evaluate the effectiveness and cost-effectiveness of CM in treating MUD.

3 - Incorporating Fairness In the Design and Evaluation of Capacity-Constrained Digital Health Interventions

Paul Dupenloup, Stanford University, Stanford, CA, United States, Margaret Brandeau, David Scheinker

The use of "just-in-time" digital health interventions is growing in clinical practice, however these are often deployed in pilot studies, rather than within a randomized clinical trial. The data collected in a pilot study can be used to optimize the intervention and a subsequent trial. However, in a capacity-constrained setting in which not all patients are eligible to receive a digital health intervention, there may be important tradeoffs between optimizing a clinical trial for predicted probability of success and health equity. Some patient populations could be left out of the study unintentionally if they are not expected to benefit significantly from the intervention, and may require an alternative or complementary intervention to achieve a greater treatment effect.

We leverage data from a remote patient-monitoring pilot study to design and compare interventions for a subsequent randomized clinical trial which balances predicted probability of success with health equity.

4 - Efficient Community Responder Crowdsourcing for TIME-Critical Medical Emergencies

Weiliang Liu, University of Chicago, Chicago, IL, United States, Timothy Chan, Zhisheng Ye

With the increasing prevalence of modern emergency response systems, crowdsourcing community responders near incident sites by sending alerts to them via mobile applications has become crucial for time-critical incidents like out-of-hospital cardiac arrest. An important decision under such circumstances is to determine the appropriate recipients of crowdsourcing alerts and the optimal timing for their dissemination. By far, there has been no systematic effort in developing analytical methods to understand the key trade-offs behind such decisions, which currently follow ad-hoc rules. This paper aims to help fill this gap, with the ultimate goal of providing analytically grounded responder alert strategies that achieve satisfactory response outcomes while minimizing excessive alerts.

1 - Span-Based Optimal Sample Complexity for Weakly Communicating and General Average Reward MDPs

Matthew Zurek, University of Wisconsin-Madison, Highland Park, WI, United States

We study the sample complexity of learning an ε-optimal policy in an average-reward Markov decision process (MDP) under a generative model. For weakly communicating MDPs, we establish the complexity bound SAH/ε^2 (ignoring constants and log factors), where H is the span of the bias function of the optimal policy and SA is the cardinality of the state-action space. Our result is the first that is minimax optimal (up to log factors) in all parameters S,A,H, and ε, improving on existing work that either assumes uniformly bounded mixing times for all policies or has suboptimal dependence on the parameters. We also initiate the study of sample complexity in general (multichain) average-reward MDPs. We argue a new transient time parameter B is necessary, establish an $SA(B+H)/\varepsilon^2$ complexity bound, and prove a matching (up to log factors) minimax lower bound. Both results are based on reducing the average-reward MDP to a discounted MDP, which requires new ideas in the general setting. To optimally analyze this reduction, we develop improved bounds for γ-discounted MDPs, showing that $SAHE^2/\varepsilon^2$ and $SA(B+H)E^2/\varepsilon^2$ samples suffice to learn ε-optimal policies in weakly communicating and in general MDPs, respectively, where $E =1/1-\gamma$ is the effective horizon. Both these results circumvent the well-known minimax lower bound of $SA E^3/\varepsilon^2$ for γ-discounted MDPs, and establish a quadratic rather than cubic horizon dependence for a fixed MDP instance.

2 - Random Graph Matching with Multiple Graphs

Taha Ameen, University of Illinois Urbana-Champaign, Urbana, IL, United States

This talk concerns fundamental limits for graph matching, i.e., recovering the underlying hidden correspondence among the nodes of multiple correlated random graphs. We identify a necessary condition for any algorithm to correctly match all nodes across all graphs and propose two algorithms for which the same condition is also sufficient. The first algorithm employs global information to simultaneously match all the graphs, whereas the second algorithm first partially matches the graphs pairwise and then combines the partial matchings by transitivity. We show that the second algorithm is an efficient and optimal bridge between 2-ary and m-ary graph matching, and that both algorithms work down to the information theoretic threshold. Our analysis reveals a scenario where exact matching between two graphs alone is impossible but leveraging more than two graphs allows exact matching among all the graphs. Along the way, independent results about the k-core of Erdős-Rényi graphs are derived.

3 - Strongly Tail-Optimal Scheduling in the Light-Tailed M/G/1

George Yu, Cornell University, Ithaca, NY, United States

We study the problem of scheduling jobs in a queueing system, specifically an M/G/1 with light-tailed job sizes, to asymptotically optimize the response time tail. This means scheduling to make P[T>t], the chance a job's response time exceeds t, decay as quickly as possible in the limit. For some time, the best known policy was First-Come First-Served (FCFS), which has an asymptotically exponential tail: P[T>t]~Ce−γt. FCFS achieves the optimal *decay rate* γ, but its *tail constant* C is suboptimal. Only recently have policies that improve upon FCFS's tail constant been discovered. But it is unknown what the optimal tail constant is, let alone what policy might achieve it. In this paper, we derive a closed-form expression for the optimal tail constant C, and we introduce *γ-Boost*, a new policy that achieves this optimal tail constant. Roughly speaking, γ-Boost operates similarly to FCFS, but it pretends that small jobs arrive earlier than their true arrival times. This significantly reduces the response time of small jobs without unduly delaying large jobs, improving upon FCFS's tail constant by up to 50% with only moderate job size variability, with even larger improvements for higher variability. While these results are for systems with full job size information, we also introduce and analyze a version of γ-Boost that works in settings with partial job size information, showing it too achieves significant gains over FCFS. Finally, we show via simulation that γ-Boost has excellent practical performance.

4 - A Hierarchical Approach to Robust Stability of Multiclass Queueing Networks

Feiyang Zhao, ExxonMobil, Houston, TX, United States

The focus of this research is on the robust stability of stochastic processing networks, under a wide class of control policies. A framework for robust stability is developed, in which the resources are given freedom to decide their own priority policy, under some general constraints. We offer a new approach for determining sufficient conditions to robust stability, which builds on, and makes connections to, suitable robust optimization problems, with the collection of priority policies as the uncertainty set. We also show how robust stability of a family of policies is inherited from the stability of some special policies, i.e., static-priority policies.

ML and Optimization Driven Fulfillment Operations Management

Invited Session

The Practice Section of INFORMS

Co-Chair: PREM KUMAR VISWANATHAN, Amazon, Seattle

1 - Warehouse Order Picking and Container Fill Optimization in Amazon Grocery Operations

Prem Kumar Viswanathan, Amazon, Seattle, WA, United States

This paper focuses on the problem of picking orders for Amazon Grocery with the twin objectives of lowering fulfillment costs and transportation costs. The fulfillment cost optimization is achieved by lowering travel distance between two picked items, while the transportation cost optimization is achieved by improving the fill rate on the containers used to haul these picked items, thereby increasing the cubic volume moved on trucks. We developed mathematical models utilizing the decomposition techniques and multi-stage solution approaches as well as variations of three-dimensional bin packing heuristics to solve the models. The integrated warehouse picking and container fill optimization problem has not been studied in the literature and we believe this seminal work will help pursue research in this area. Both mathematical models and heuristic approaches have been implemented and tested on over 700 problem instances. Mathematical models outperform the heuristic approaches for both fill-rate and travel time between picks.

2 - Visual-Assisted Approach to Optimizing Picking Operations in Fulfillment Centers

Akshay Kurapaty, Amazon, Bellevue, WA, United States, Abhisek Mukhopadhyay, SMA Bin Al Islam, Kay Zheng, Elcin Cetinkaya

In the dynamic landscape of e-commerce warehousing, optimizing picking processes is crucial for enhancing operational efficiency. Our research demonstrates that items with better visibility and accessibility significantly contribute to faster pick rates. Items that lack visibility or are obstructed by other items within a bin prove to be less suitable for fulfilling pick requests efficiently. We introduce a novel learning-based approach to assess pickability of an item. Pickability refers to the measure of how suitable an item is for being picked from a specific bin or shelf, within a given operational context. A high pickability score implies that an item is well-positioned, visible, and easily retrievable based on the state of a bin. This score encapsulates various factors, including item accessibility and visibility within bins, tailored to the specific operational context of the warehouse. By injecting pickability scores into the pick scheduling algorithm, we effectively guide the associates to bins containing items with shorter identification times. Consequently, this proactive approach leads to tangible improvements in overall pick time.

3 - Ergonomics Aware Stow Assistance

Abhisek Mukhopadhyay, Amazon, BELLEVUE, WA, United States, Andrew Johnson

In the Stow Process, associates at Amazon Robotics Sortable Fulfillment Centers are tasked with stowing individual items into bins in storage pods, from where pickers later retrieve them to fulfill customer orders. The pods are notably taller than an average human. Extreme locations within these pods pose ergonomic challenges during stowing and picking activities, with frequent bending and reaching movements correlating with an increased risk of Musculo-Skeletal Disorder (MSD) related injuries in associates. This paper presents Machine Learning and Simulation Model based solution to control MSD risk factors by guiding associates to stow fast-moving inventory in more ergonomic locations, while stowing slower-moving inventory to less ergonomic areas. Through experiments conducted in 5 fulfillment centers across North America, a 20-22% reduction in stows at the least ergonomic locations was observed, resulting in a statistically significant decrease in MSD risk. This study demonstrates that redistributing inventory over time enhances transaction frequency in ergonomically advantageous locations, contributing to a safer working environment for stow associates

4 - Error-Based Forecast Refinement: Bridging Past Mistakes to Enhance Future Predictions

Chinmoy Mohapatra, Amazon, Lake Stevens, WA, United States, Rohit Malshe, Abhilasha Katariya

Accurate forecasting is crucial for informed decision-making, yet discrepancies between forecasts and actual outcomes can lead to suboptimal plans and erode trust in predictive models. This paper presents a novel bridging methodology to analyze errors in any forecasting model and attribute them to specific input inaccuracies or model deficiencies using the Taylor approximation. We demonstrate its value for bridging last mile efficiency forecasts for Amazon Logistics. This scalable and automated error-attribution process has enhanced future planning and efficiency predictions by enabling targeted improvements. Since deployment in 2021, it has significantly improved Amazon's last mile planning process by identifying the best areas of opportunity to work on and has reduced the planning gap from by almost half through various science and data engineering efforts. This research aims to improve model explainability, enhance trust in predictive systems, and enable data-driven model refinement.

Machine Learning Methods for Large Population Games

Invited Session

TutORial

Chair: Jamol Pender, Cornell University, Ithaca, NY, United States

1 - Machine Learning Methods for Large Population Games

Gokce Dayanikli, University of Illinois Urbana-Champaign, Champaign, IL, United States, Mathieu Lauriere

In this tutorial, we provide an introduction to machine learning methods for finding Nash equilibria in games with large number of agents. These types of problems are important for the operations research community because of their applicability to real life situations such as control of epidemics, optimal decisions in financial markets, elec tricity grid management, or traffic control for self-driving cars. We start the tutorial by introducing stochastic optimal control problems for a single agent, in discrete time and in continuous time. Then, we present the framework of dynamic games with finite number of agents. To tackle games with a very large number of agents, we discuss the paradigm of mean field games, which provides an efficient way to compute approxi mate Nash equilibria. Based on this approach, we discuss machine learning algorithms for such problems. First in the context of discrete time games, we introduce fixed point based methods and related methods based on reinforcement learning. Second, we discuss machine learning methods that are specific to continuous time problems, by building on optimality conditions phrased in terms of stochastic or partial differential equations. Several examples and numerical illustrations are provided along the way.

1 - Does AI Technology Deployment Benefit the Owner of the Technology? Impact of GitHub Copilot Release on Microsoft

Poonacha Medappa, Tilburg University, Tilburg, Netherlands, Murat Tunc, Feiyang (Amber) Xu

The deployment of new AI technologies usually occurs in two phases: the technical preview, followed by the public release. These two phases differ in terms of access to AI technology. During the technical preview, access is limited to the organization that owns the technology, while it becomes widely available in the public release phase. This paper investigates the impact of these two deployment phases on the organization that owns the technology. Using a panel dataset spanning from 2020 to 2023, we examine the two-phase deployment of GitHub Copilot (as a technical preview in June 2021 and as a public release in June 2022) and how it impacts Microsoft's (the owner of GitHub) open-source software projects. Results show that during the technical preview, Microsoft projects experienced significant increases in development activity (commits, code additions, file changes) compared to the control group consisting of Google, IBM, and Meta. However, this advantage diminished after the public release. While the technical preview does not significantly impact project maintenance (issues reported, resolution time), the public release led to significant increases in both measures for Microsoft. The findings suggest that the technical preview of an AI technology benefits the owner organization's development productivity, but these gains are reduced, and maintenance activities emerge following the public release. Our study highlights the importance for organizations to develop curated deployment strategies for their AI technologies to maximize benefits and mitigate potential drawbacks associated with different phases.

2 - Strategic Behavior and AI Training Data

Jeremie Haese, University of Lausanne, Lausanne, Switzerland, Christian Peukert, Florian Abeillon, Franziska Kaiser, Alexander Staub

Human-created works represent critical data inputs to artificial intelligence (AI). Strategic behavior can play a major role for AI training datasets, be it in limiting access to existing works or in deciding which types of new works to create or whether to create any at all. We examine creators' behavioral change when their works become training data for AI. Specifically, we focus on contributors on Unsplash, a popular stock image platform with about 6 million high-quality photos and illustrations. In the summer of 2020, Unsplash launched an AI research program by releasing a dataset of 25,000 images for commercial use. We study contributors' reactions, comparing contributors whose works were included in this dataset to contributors whose works were not. Our results suggest that treated contributors left the platform at a higher-than-usual rate and substantially slowed down the rate of new uploads. Professional and more successful photographers had a stronger reaction than amateurs and less successful photographers. We also show that affected users changed the variety and novelty of contributions to the platform, which can potentially lead to lower-quality AI outputs in the long run. Taken together, our findings highlight the trade-off between interests of rightsholders and promoting innovation at the technological frontier. We discuss implications for copyright and AI policy.

3 - The Subtle Persuasion of Generative AI on Opinion Formation

Sterling Ceci-Williams, Cornell Tech, New York City, NY, United States, Maurice Jakesch, Advait Bhat, Kowe Kadoma, Lior Zalmanson, Mor Naaman

The talk presents an analysis of studies (n=3,024) that show the influence of AI-generated autocomplete suggestions on shaping views regarding various societal issues. Despite being exposed to biased AI suggestions, participants remained oblivious to how these biases shifted their expressed opinions. This phenomenon persisted even when individuals were forewarned about potential biases, underscoring the challenge of protecting human autonomy from the subtle yet powerful sway of AI.

These studies highlight the complex interplay between AI and human decision-making, showing a consistent inclination to defer to AI in cases of complex opinion formation, even against the backdrop of manifestly biased AI suggestions. The insights gathered call for a critical dialogue on the imperative to cultivate strategies that reinforce human autonomy, urging a deliberate and mindful integration of AI that safeguards independent human judgment in the face of expanding AI influence.

Artificial Intelligence and Digital Platforms

Invited Session

Social Media Analytics

Chair: Xue Tan, Southern Methodist University, Dallas, 75252, United States

1 - Patched Vulnerability Disclosure and Hacker Participation in Bug Bounty Programs

Ali Ahmed, Louisiana State University, Baton Rouge, LA, United States, Brian Lee, Amit Deokar

In cybersecurity, bug bounty programs (BBP) have emerged as an effective method of finding hidden vulnerabilities in a system. In this method, ethical hackers discover and report hidden vulnerabilities to the organizations. In return, these hackers receive rewards for their valid discoveries. The emergence of bug bounty programs has enabled the practice of Patched Vulnerability Disclosure (PVD), where firms disclose vulnerability information after they have been patched. Currently, there is little understanding of how PVD affects ethical hackers' participation in BBPs. We collected a dataset from a leading bug bounty platform and conducted empirical analyses to analyze the effect of PVD on hacker participation. Leveraging multiple specifications, including an instrumental variable approach, difference-in-differences, and data collected from third-party websites, our analysis reveals that as firms disclose more patched vulnerabilities, hacker participation in their programs decreases. To further explore the mechanism, we found that disclosing valid vulnerability reports discourages hacker participation, whereas disclosing invalid reports leads to more hacker participation. We found that PVD influences uncertainty in the bug bounty process, which can simultaneously impact the risk and ambiguity in hacking. Valid disclosures can escalate hackers' risk and discourage participation, whereas disclosing invalid submissions can reduce the ambiguity in the bug bounty process and increase the hacker's participation in BBP. We also found that reduced ambiguity is most salient for hackers with experience working with other firms on the platform. Overall, our study makes theoretical contributions to the literature on vulnerability disclosure, ethical hacking, and the management of bug bounty programs.

2 - Chaos is a Ladder: Artificial Intelligence and Employee Satisfaction

Yingying Chen, University of Washington, Seattle, WA, United States, Wenxin Huang, Tingting Song

This paper addresses the unresolved question of how artificial intelligence (AI) impacts human well-being. Employing textual analysis techniques, we develop a novel measure of AI exposure for jobs and create two dummy variables to distinguish between occupations likely to be complemented or substituted by AI technology, utilizing ChatGPT. We investigate the influence of AI exposure on employee satisfaction, finding that increased exposure correlates with higher levels of employee satisfaction, with self-esteem and social relatedness acting as partial mediators. Conversely, individuals in roles more susceptible to AI replacement exhibit signs of depression. Leveraging AI regulatory policy as a quasi-natural experiment, we employ various difference-in-differences methods to establish a causal relationship between AI and employee well-being, both within and beyond organizational boundaries. In summary, our findings suggest that the rise of AI makes most people better off, but those who may be replaced by AI technology are concerned about the future, which exacerbates the gap in employees' subjective well-being.

3 - AI-Powered Digital Streamers for Online Retail: Empirical Evidence and Design Strategies Through Experiments

Lei Wang, Pennsylvania State University, University Park, PA, United States, Yahui Liu, Yanwen Wang

Artificial intelligence (AI) advancements have sparked a rise in AI-powered digital streamers for live streaming, significantly transforming online retail. Despite their potential for cost-effective, customizable, and reliable product promotion, it remains unclear whether they can rival real human streamers in sales performance and what design features could boost their effectiveness. This study aims to address these questions by examining the impact of digital streamers on product sales and identifying design strategies to improve their performance. In the first study using a quasi-experiment with a leading fashion retailer, we discovered that the plain villa digital streamers had no significant increase in sales as compared to a baseline scenario without streaming. To understand how to enhance digital streamers' sales effectiveness, our second study, a randomized field experiment, examined various design strategies for digital streamers. Our findings indicate that scripts trained from expert human hosts do not significantly increase sales compared to plain villa digital streamers. In contrast, improvements in the streamers' appearance and voice lead to sales increases of 12% and 17%, respectively. Additionally, incorporating lottery boosts sales by 17%, and enhanced real-time Q&A interaction is the most effective strategy, with a 26% increase in sales. This performance is equivalent to the 31% sales increase achieved by real human counterparts. This study contributes to the literature by enhancing our knowledge of how design features affect consumer behavior and underscores the benefits of human-AI interaction in e-commerce. We also offer managerial insights for online retailers and digital streamer designers on optimal design strategies.

4 - Driver on Deck: Impact of Order Assignment in On-Demand Delivery Platforms

Caitlin Cunningham, University of Washington, Seattle, WA, United States, Leela Nageswaran

On-demand delivery platforms feature unique traits such as the possibility of stacking orders and communicating progress to consumers. Using data from a food delivery platform, we empirically study the impact of these traits on consumers. Our results provide guidance to platforms regarding the implications of order stacking on the order lifecycle.

Advancements in Time Series Analysis

Contributed Session

Contributed

Chair: Ming Luo

1 - Machine Learning for Time Series Analysis and Forecasting

Ming Luo, northeastern university , Boston, MA, United States

Time series data are prevalent and essential in decision-making. Author applies machine learning techniques to analyze time series data for classification, clustering, and forecasting. First, a new distance measure, value-added, is proposed in time series classification and clustering. Further, the author develops a novel framework in which decisions such as the number of clusters and prediction based on value-added are made using different techniques.

Moreover, forecasting in scale is a particular issue in business forecasting. A new approach reconciliation with neural network (R-NN) is proposed for hierarchical forecasting with the base forecasting from previous time series classification and clustering process, considering the non-linear relationship among time series for forecasting. Conventional techniques have yet to incorporate the relationship between series while making individual predictions and tend to lose information. In addition, computational costs can be exceptionally high due to model perplexity when using methods such as optimal reconciliation. The R-NN is straightforward to implement and fast to train without losing information.

The methods and procedures developed here can be applied in various business settings. Especially for companies with limited labor resources to make predictions on plenty of products, this approach can still generate a good prognosis for all the series. Likewise, the reconciliation with neural network (R-NN) can be used to forecast many time series simultaneously consistently. Then a coherent hierarchy of forecasts can assist subsequent supply chain decisions such as production and deployment.

2 - Unsupervised Anomaly Detection with Multivariate Time Series: Leveraging Mixture of Experts and Time Series Decomposition

Soomin Lee, Chungnam National University, Yuseong-gu, Daejeon, Korea, Republic of, Dongil Kim

Multivariate time series(MTS) is crucial in industries utilizing multiple sensors. Anomaly detection with MTS is one of the most important tasks. Anomaly detection typically employs unsupervised methods due to the absence of labeled data. A common approach is to train models solely on normal data and identify anomalies based on the degree of reconstruction. In this study, we propose an unsupervised anomaly detection method with MTS. Specifically, the proposed method considers adequate input data information through time series decomposition and adopts an idea of Mixture of Experts(MoE). Time series decomposition allows additional elements such as trend and differencing to be considered from the original time series. MoE consists of expert models and gate models, where the gate controls the weights of each expert model. By employing the idea of MoE, we expect the learning model to better adapt to various input patterns through decomposition and to utilize only necessary experts for reconstruction. Experiments involve comparing the proposed method with performance against more than ten baselines using five benchmark datasets. Based on experimental results, we will discuss the practical potentials.

3 - Noise-Resistant Anomaly Detection in Multivariate Time Series Using Feature Correlation

Hyungkwon Lee, Sungkyunkwan University, Suwon, Korea, Republic of, Jong-Seok Lee

Detecting anomalies within time series data is particularly challenging, especially in domains where anomalies have significant consequences. This task is further complicated by multivariate time series data, which often includes both noisy and noise-free observations due to inherent sensor inaccuracies or operational constraints. The presence of noisy data increases the risk of erroneous anomaly detection, especially in reconstruction-based approaches relying on generative models. To address this issue, we propose a new anomaly detection method based on TadGAN (Time Series Anomaly Detection Using Generative Adversarial Networks). By leveraging the correlation between noise-free and noisy features, our method aims to enhance anomaly detection accuracy and decrease false detection rates. This approach offers a robust solution for detecting anomalies in noisy environments by thoughtfully integrating insights from noise-free data. Numerical experiments demonstrate the effectiveness of our method in various time series data scenarios that include noisy data.

4 - Wavelet scattering for classification in health-related time-series datasets.

Jyotirmoy Nirupam Das, The Pennsylvania State University, State College, PA, United States, Yanling Li, Soundar Kumara, Sy-Miin Chow

Time series data in health-related studies are often characterized by non-stationaries in frequencies over time. Wavelet scattering is a class of machine learning methods that combines the strengths of wavelet transform and deep neural network to enable the use of deep learning for forecasting and classification purposes using features from wavelet analysis across different time and frequency scales within a single step. This work uses wavelet scattering to analyze and extract important features from two health datasets. In the first study, we used wavelet scattering to classify participants' facial electromyography (EMG) activities and self-reports into distinct categorical phases (during baseline, under positive and negative emotion induction procedures, and during recovery). In the second study, we use wavelet scattering on wearable device measures collected from individuals during the early phases of the SARS-CoV2 pandemic to classify individuals' infection status. In both cases, wavelet scattering provided robust feature generation to improve the performance of the deep learning model in discerning the hidden patterns in these health measures.

5 - A robust time series model with support vector regression

Chun-Yen Tsai, Department of Information Management, National Chi Nan University, Nantou, Taiwan, Puli, Taiwan, Jing-Rung Yu, Hao-Feng Deng, Donald Lien

This study incorporates error tolerance from support vector regression (SVR) into the Opt-ARIMA(fw) model, resulting in the SVR_ARIMA(fw) forecasting model tailored for fluctuating data. The Opt-ARIMA(fw) transforms the autoregressive integrated moving average (ARIMA) model using the Haar wavelet function to enhance performance. In addition, to address overfitting and reduce reliance on the subjective judgment in conventional ARIMA, the Opt-ARIMA(fw) simultaneously determines lagged terms, seasonal effect, and coefficients. The resulting SVR_ARIMA(fw) maintains a mixed-integer linear programming structure, inheriting the streamlined benefits of the Opt-ARIMA(fw), enhancing interpretability and efficacy for high-volatility datasets. From our evaluations comparing support vector regression, ARIMA, random forest, and GB, Opt-ARIMA(fw) excels in handling stable datasets but weak in dealing with fluctuating datasets from our preliminary test. Therefore, we employ support vector regression to enhance the Opt-ARIMA(fw), resulting in a more robust forecasting model, SVR_ARIMA(fw) which remains a linear mixed integer programming model to enhance the robustness and accuracy of the Opt-ARIMA(fw) by incorporating error tolerance in addition to automatic determination the seasonal effect and number of lags in MA and AR terms. We expand the training sample size and use the proposed SVR-ARIMA(fw) to forecast non-stationary datasets, such as high-frequency prices or returns of cryptocurrencies and composite stocks of NASDAQ 100 and S&P 500.

6 - Semi-Supervised Time Series Domain Adaptation Based On Contrastive Learning Using Momentum Encoder

Seonyoung Kim, Ewha Womans University, Seoul, Korea, Republic of, Dongil Kim

Machine learning models perform well on data from a particular domain, such as the data in training time. However, they are degraded when applied to data from a different domain. Many researchers have suggested alleviating these issues, as known as domain shift or discrepancy, in computer vision. Yet, time series has not been extensively studied in comparison to computer vision. These phenomena can be fatal in medical situations, but there are limitations due to the restricted data accessibility and high annotation cost. Likewise, we can easily face the conditions of just a few labeled target data, albeit given sufficient labeled source data in practice. Semi-supervised domain adaptation aims to reduce the discrepancy between the source and target distribution in the presence of limited labeled target samples. This study proposes a semi-supervised time series domain adaptation method using contrastive learning techniques with a momentum encoder to mitigate the domain shifts between the source and target domains and prevent collapse in the model. Additionally, we demonstrate the effectiveness of our method using multivariate bio-medical time series data.

Award Session

George B Dantzig Dissertation Prize Session

Chair: Ruth Beer, Baruch College, CUNY, New York, NY, United States

1 - Simulating Dynamical Systems from Data

Abdullah Alomar, MIT, Oakland, CA, United States

The availability of data from dynamical systems presents opportunities for automated decision-making, but challenges like high dimensionality, noise, sparsity, and confounding persist. We propose methods to leverage these datasets and address these issues in various inference tasks. Central to our approach is a key factorization of the dynamics, shared across related yet heterogeneous systems, into a linear combination of latent separable functions of state and action. This principled structure guides effective methods for time series forecasting, change point detection, reinforcement learning, and trace-driven simulation.

2 - Scalable, Efficient, and Fair Algorithms for Structured Convex Optimization Problems

Mehrdad Ghadiri, Georgia Institute of Technology, Atlanta, GA, United States

The thesis presents algorithms for fundamental optimization problems with theoretical guarantees on approximation quality and running time. These problems include linear programming (LP), tensor decompositions, and fair clustering. The focus is on developing efficient and scalable algorithms with provable approximation guarantees while incorporating ethical considerations such as fairness. Many industry applications motivate these problems. In particular, tensors are building blocks of deep neural networks, the workhorse of large language models (LLMs).

3 - Essays on Technology-enabled Social Impact

Alp Sungu, Wharton, Philadelphia, PA, United States

This thesis explores poverty alleviation policies in developing countries through an operational and technological lens. It sets up a research infrastructure in a low-income settlement in India to run field experiments. The first chapter places research assistants at food vendors to track nutrition for over 20,000 individuals and opens a subsidy program. It finds excessive junk food purchasing, especially among working parents. Staple food subsidies induce a shift from snacking out to home-cooked meals. The second chapter reveals low-income smartphone users binge on social media early in the month and are cut off from digital information later. A daily-capped data plan smooths data consumption and improves access to information.

4 - Analytics and Decision Making in Sustainable Operations

Leann Thayaparan, Johns Hopkins University, Baltimore, MD, United States

As we move towards more renewable resources, the ability to produce electricity in time with demand diminishes. Instead, rises a need for energy storage. Electric Vehicles (EVs) have been discussed as a way of providing a distributed energy storage resource to the electric grid. However, highly complex, non-linear driver behavior must be accounted for. In this dissertation we closely collaborate with a large American EV manufacturer to combine machine learning with optimization to model driver behavior in order to size the capacity of energy storage EVs can offer to the grid.

Nicholson Student Paper Competition II

Award Session

Nicholson Student Paper Competition

Chair: Siqian Shen, U of Michigan/NSF, Ann Arbor/Alexandria, 48109, United States

Co-Chair: Andrew Daw, USC Marshall Data Sciences and Operations, Los Angeles, CA, United States

1 - The Role of Level-Set Geometry on the Performance of PDHG for Conic Linear Optimization

Zikai Xiong, MIT OR Center, Cambridge, MA, United States

We analyze the performance of the restarted primal-dual hybrid gradient method (rPDHG) for general conic linear optimization problems, at the scale where matrix-factorization-free methods are attractive or necessary. We define three geometric condition numbers of the primal-dual level set: the diameter, the conic radius, and the Hausdorff distance to the optimal solutions, and we show how these condition numbers inform the convergence rate of rPDHG both in theory and in practice. We further show how central-path-based conic rescaling can markedly enhance the convergence rate of rPDHG.

2 - Optimizing Inventory Placement for a Downstream Online Matching Problem

Boris Epstein, Columbia University, New York, NY, United States

We study the inventory placement problem of splitting Q units of a single item across warehouses, in advance of an online matching problem. We compare the performance of two placement procedures based on optimizing surrogate functions: Offline and Fluid placement. We show that optimizing inventory placement for the Offline surrogate leads to an $\alpha (1-(1-1/d)^d)$-approximation for the joint placement and fulfillment problem under any demand model that admits an α-competitive fulfillment policy. We assume d is an upper bound on how many warehouses can serve any demand location.

3 - Causal Message Passing: A Method for Experiments with Unknown and General Network Interference

Mohamad Sadegh Shirani Faradonbeh, Stanford University, Stanford, CA, United States

Randomized experiments are a powerful methodology for data-driven evaluation of decisions. Yet, their validity may be undermined by network interference. This study introduces a new framework to accommodate complex and unknown network interference. Our framework, termed causal message-passing, is grounded in approximate message passing methodology. Utilizing causal message-passing, we introduce a practical algorithm to estimate the total treatment effect. We demonstrate the effectiveness of this approach across five numerical scenarios, each characterized by a distinct interference structure.

4 - The Cost of Impatience in Dynamic Matching: Scaling Laws and Operating Regimes

Angela Kohlenberg, Northwestern University, Evanston, IL, United States

We study two-sided matching queues with abandonment. We identify universal, non-asymptotic scaling laws for the matching loss due to abandonment (the “cost-of-impatience”). The scaling laws characterize how this cost depends on the arrival rates and mean patience of each side, and reveal four operating regimes. The scaling laws, specialized to each regime, reveal the fundamental structure of the cost-of-impatience and show that it is fully determined by (i) a “winner-take-all” competition between mean patience and utilization, and (ii) the ability to accumulate inventory on one side.

The Economics of eBusiness

Invited Session

eBusiness

Chair: Jisu Cao, Arizona State University, Tempe, AZ, United States

1 - The Effect of Law Enforcement's Participation on Online Platforms on User Engagement in Sharing Contributions

Jingyan Dai, University of Florida, Gainesville, FL, United States, Qili Wang, Shu He, Liangfei Qiu

Social media is being used by government organizations more and more to engage with the public they serve. It has rapidly become a significant focal point of government initiatives, quickly becoming an integral part of e-government efforts. The interactions between government and individuals could result in the broadening of government services, the emergence of new ideas, and improvements in decision-making and problem-solving capabilities (Bertot 2012). Nevertheless, increased involvement of government agencies in online activities could potentially alter the behavior of existing online users, particularly within communities where voluntary knowledge contribution is prevalent. To capture the impact of government involvement on users' voluntary knowledge contribution, we narrow our focus to the impact of the access of law enforcement to an online platform. The goal of connecting residents with public safety agencies through online communities is to cultivate safer and more well-informed communities. In this study, we investigate how law enforcement participation on online platforms affects users' voluntary contributions. Our results indicate that when a police agency joins the platform, users tend to decrease their voluntary posting activity. This cautious behavior likely leads to an improvement in the quality of online posts.

2 - Exploring Ar Interactions in the Industrial Metaverse: Effects on Information Search Efficiency and Learning Effectiveness

Runge Zhu, Tsinghua University, Beijing, China, People's Republic of, Ting Li, Cheng Yi

This study ventures into the industrial Metaverse to unravel the intricacies of Augmented Reality (AR) interactions and their effect on users’ information search efficiency and learning effectiveness. Through a large-scale online experiment and a field experiment involving real-world maintenance mechanics from one of the world’s largest airlines, we examined the differing impacts of multimodal and menu-based AR interactions, while also considering the moderating effects of task type, output multiplicity, and user experience. Our findings reveal that multimodal AR interaction is more efficient for information search, particularly for tasks with a higher search depth and less experienced users. However, this effect declines when multiple outputs are present. Regarding learning effectiveness, multimodal interaction hinders learning for tasks with a higher search depth and for experienced users, but facilitates learning when multiple outputs are available. These findings provide crucial insights for AR interaction designs in the emerging Metaverse, with significant implications for industrial training programs.

3 - Bias in Generative AI

Mi Zhou, University of British Columbia, Vancouver, BC, Canada, Vibhanshu Abhishek, Timothy Derdenger, Jaymo Kim, Kannan Srinivasan

This study analyzed images generated by three popular generative artificial intelligence (AI) tools - Midjourney, Stable Diffusion, and DALLE 2 - representing various occupations to investigate potential bias in AI generators. Our analysis revealed two overarching areas of concern in these AI generators, including (1) systematic gender and racial biases, and (2) subtle biases in facial expressions and appearances. Firstly, we found that all three AI generators exhibited bias against women and African Americans. Moreover, we found that the evident gender and racial biases uncovered in our analysis were even more pronounced than the status quo when compared to labor force statistics or Google images, intensifying the harmful biases we are actively striving to rectify in our society. Secondly, our study uncovered more nuanced prejudices in the portrayal of emotions and appearances. For example, women were depicted as younger with more smiles and happiness, while men were depicted as older with more neutral expressions and anger, posing a risk that generative AI models may unintentionally depict women as more submissive and less competent than men. Such nuanced biases, by their less overt nature, might be more problematic as they can permeate perceptions unconsciously and may be more difficult to rectify. Although the extent of bias varied depending on the model, the direction of bias remained consistent in both commercial and open-source AI generators. As these tools become commonplace, our study highlights the urgency to identify and mitigate various biases in generative AI, reinforcing the commitment for a more inclusive future.

4 - Learning to Adopt Generative AI

Lijia Ma, University of Washington, Seattle, WA, United States, Xingchen Xu, Yumei He, Yong Tan

ChatGPT, owing to its versatility, has garnered a substantial user base and has become a staple in many individuals' daily routines. Nonetheless, upon its introduction, potential adopters often face uncertainty regarding the technology. By accessing public information and engaging directly with ChatGPT, users can progressively discern its distinctions from traditional tools such as Google Search, thereby facilitating more informed decisions. However, individual differences—such as educational backgrounds and professional fields—may affect the speed at which users adapt, potentially impeding the adoption process and exacerbating the digital divide. Furthermore, users may derive varied utilities from the same tool based on their unique needs and contexts. To disentangle these mechanisms, we develope a comprehensive Bayesian Learning model incorporating multi-layer heterogeneities and calibrate it using detailed clickstream data. Utilizing the results from this model, we also crafte counterfactual policies aimed at enhancing user welfare.

5 - Bytes and Bets: How Online spORts Gamblers Navigate Risk and Return Through Online Forums

Jisu Cao, Arizona State University, Tempe, AZ, United States

Online forums, a virtual space where individuals can connect and share knowledge, have become a popular information source for users. While these forums provide valuable insights to help users make informed decisions, the quality of the content can vary significantly. Trusting misleading information can negatively impact forum participants, potentially leading to financial losses. In this paper, we try to understand how bettors seek information from online forums and its impact on their risk attitudes and returns. Collaborating with a leading online sports betting company in the United States, we collected a random sample of gamblers' web browsing history and their betting behaviors from 2019 to 2022 and conducted a set of empirical analyses. Our results show an increased risk attitude after the bettor participates in online forums. Specifically, bettors increase the amount of money they wager by 8\% for each additional post they read from the online forum. Surprisingly, these information-seeking behaviors do not improve betting outcomes but hurt bettors' financial returns. For every additional post read by the bettor, the net return decreases by $4.81. Our research underscores the importance of governance in online forums and discusses relevant managerial insights.

Operations Research Approaches to Wildfire Prevention and Management

Invited Session

Energy: Natural Resources

Chair: Tomas Lagos, The University of Sydney Business School, Sydney, 2000, Australia

1 - Fuel Treatment Planning Under Uncertainty Using a Bilevel Optimization Framework

Tomas Lagos, The University of Sydney, Sydney, Australia, Nam Ho-Nguyen, Dmytro Matsypura, Oleg Prokopyev

In this work, we develop a framework to minimize bushfires burned area resulting from adversarial attacks through strategic fuel treatment planning. Predicting fire ignition distribution is inaccurate due to the complexity of weather phenomena and the limited informativeness of historical data. Consequently, conservative approaches are sensible for protecting the landscape against worst-case scenarios, thereby ensuring baseline performance. We introduce a bilevel mixed-integer formulation with integer variables at both the upper and lower levels. For the general case, we propose an exact algorithm based on constraint generation, while under specific conditions, we propose a polynomial size MIP formulation that can solve the problem exactly. Through a real case study, we demonstrate the scalability and performance of our approaches, comparing them against heuristic procedures from existing literature.

2 - A Stochastic Programming Rolling Horizon Approach for Extended Attack for Extreme Wildfires

Lina Villa, Texas A&M University, College Station, TX, United States, Lewis Ntaimo

Wildfires pose significant threats to both human lives and the environment. In this study, we propose a pragmatic approach to wildfire management involving dynamic firefighting resource allocation under uncertainty for extreme wildfires. Our approach integrates a two-stage stochastic mixed-integer programming model with a rolling horizon strategy to dynamically allocate firefighting resources to a large-scale wildfire over time. We consider the construction of firelines, whereby combustible fuels are cleared by specific resources (in our case study, dozers), aimed at creating firebreaks to hinder fire growth. A fire manager identifies locations for fireline construction, and the model allocates resources to different points around the fire for fireline construction. The resources are dynamically reallocated at each stage. Decisions from the previous stage are incorporated into a fire behavior simulator to reflect the impact of the fireline construction at the next stage. Stochasticity is incorporated through weather scenarios, which in addition to resource allocation and fireline construction decisions, influence wildfire behavior. Therefore, we adopt a simulation-optimization approach within the rolling horizon framework. Through computational experiments conducted on simulated scenarios with real data, we demonstrate the efficacy of our approach in significantly reducing expected fire spread and impacts through optimized firefighting resource allocation.

3 - Forest Landscape Compartmentalization to Reduce Wildfire Risk

Denys Yemshanov, Natural Resources Canada, Sault Ste. Marie, ON, Canada, Ning Liu, Eric Neilson, Frank Koch

Wildfires is a dominant disturbance agent in North-American forests. A strategic removal of forest fuels to create landscape compartments has been deemed a viable strategy to reduce the wildfire spread risk. However, limited resources make it challenging to plan compartmentalization effectively. We consider a landscape compartmentalization problem to minimize the risk of wildfires under a resource constraint. We depict a forest landscape as a network of patches with flammable fuels and formulate a Critical Edge Removal problem to find a configuration of firebreaks that minimizes the risk of wildfire spread in the area of concern. We use a spatial fire growth model to generate a set of fire spread likelihoods between all pairs of locations in the landscape and use this set to guide the allocation of firebreaks. We compare the proposed problem with the critical node detection problem that removes a subset of nodes from a connected landscape fuel network to minimize its connectivity. We apply the approach to assist with the wildfire risk mitigation planning in the Red Rock-Prairie Creek area, Alberta, a complex, fire-prone landscape. Our solutions provide several strategies for reducing wildfire hazard in fire-prone landscapes and could assist strategic planning of wildfire mitigation activities in other regions.

Machine Learning for Optimization

Invited Session

Data Mining

Chair: Jay Rosenberger, University of Texas-Arlington, P.O. Box 19017, Arlington, TX, 76019, United States

Co-Chair: Yuan Zhou, University of Texas at Arlington, Arlington, TX, United States

1 - Developing a Composite Objective Function for Evaluating Chromatography Extraction Quality

Jaivardhan Sood, University of Texas at Arlington, Arlington, TX, United States, Jay Rosenberger, Victoria Chen, Kevin Schug, Niray Bhakta, Srividya Sekar

This research focuses on determining the weights associated with parameters that comprehensively capture the extraction science of a compound. We aim to create a composite objective function to evaluate compound extraction quality during chromatography, moving beyond single-metric assessments. Utilizing the Analytical Hierarchy Process (AHP) and linear programming, we derive these weights, which also account for the hierarchy of runs as evaluated by chemists. This method provides a holistic assessment tool that enhances decision-making in analytical chemistry. Our approach ensures a well-rounded evaluation of extraction processes, potentially improving the accuracy and reliability of compound extraction analysis in chromatography, thereby supporting better outcomes in analytical chemistry practices. Additionally, this composite function will be used in conjunction with the global optimization methodology QMARS-SUROPT to optimize parameters for SFS chemistry equipment, further enhancing the effectiveness of the extraction process.

2 - An Adaptive Framework for Continuous-State Stochastic Dynamic Programming

Huiyuan Fan, The University of Texas at Arlington, Arlington, TX, United States, Prashant Tarun, Victoria Chen

This presentation introduces a sequential state space exploration (SSSE) approach for approximate dynamic programming (ADP) inspired by reinforcement learning. The SSSE approach is coupled with an adaptive value function approximation (AVFA) algorithm that gradually grows the complexity of the statistical model as more data are observed. We refer to the novel SSSE-AVFA approach as an adaptive dynamic programming algorithm, as it automatically identifies the appropriate state space, sample size, and statistical model structure, thus, eliminating the need for time-consuming trial-and-error computational runs that were previously required. The new SSSE-AVFA algorithm is demonstrated using a nine-dimensional inventory forecasting problem and is compared with fixed structure runs in which the state space, sample size, and statistical model structure are assumed in advance. The implementation presented here employs neural networks and quasi-random, low-discrepancy sequence experimental designs. A single run of SSSE-AVFA algorithm takes longer than a single run of a fixed structure method. However, it must be recognized that if the SSSE-AVFA algorithm takes, for example, 20 times longer, that is still a significant improvement over many, many trial-and-error runs, as such a trial-and-error process could very easily go over 20 runs. As the newly proposed SSSE-AVFA algorithm is adaptive in determining the state space, sample size and statistical model structure, it has the potential to be more effective and efficient than the traditional methods in handling a wide range of real-world DP problems.

3 - Approximate Dynamic Programming with A Relu-Neuralnet for Temporary Healthcare Facilities

Vigneshwar Pesaru, University of Texas at Arlington, Arlington, TX, United States, Jay Rosenberger

The outbreak of coronavirus disease 2019 (COVID-19) has seriously affected the whole world, and pandemic research has attracted increasing amounts of scholarly attention. For instance, inappropriate patient allocation may result in unequal access and/or higher service costs in different regions at different time periods. Therefore, it is crucial to integrate capacity planning in healthcare system design while taking into consideration dynamic population requirements and uncertainties in patient demand, attrition, and death rates. In this research, we construct a mathematical model for a temporary healthcare facility problem that considers uncertainties in demand and attrition along with transferring patients between hospitals. We implement a future value approximation method with a ReLU-NeuralNet. We adopt a stopping criterion to effectively identify an optimally equivalent value function. Finally, we conduct numerical experiments to investigate the performance of the proposed method.

4 - Predicting Gas Phase Absorption Spectra in the Vacuum Ultraviolet Range through Molecular Feature Representations and Machine Learning Methods

Matine Ghasemloo, University of Texas at Arlington, Arlington, TX, United States, Victoria Chen, Jay Rosenberger, Kevin Schug, Shouyi Wang, Yujing Yang, Linh Ho Manh

Ultraviolet (UV) absorption spectroscopy stands as a widely employed technique for both quantitative and qualitative analysis of chemical compounds. Particularly in the gas phase, vacuum UV (VUV) and UV absorption spectra offer specific and diagnostic insights into numerous small molecules. Precisely predicting VUV/UV absorption spectra holds significant potential for characterizing novel or unidentified molecules across diverse fields such as fuels, forensics, and pharmaceutical research. Artificial intelligence emerges as a promising alternative to conventional quantum chemical methods for spectral prediction. In this study, diverse molecular feature representation techniques were explored and refined to encode chemical structures, facilitating the evaluation of three distinct machine learning models for predicting gas phase VUV/UV absorption spectra. Utilizing structure data files (.sdf) and VUV/UV absorption spectra from 1397 volatile and semi-volatile chemical compounds, the models were trained and tested. Novel molecular features (referred to as ABOCH) were introduced to better encapsulate pi-bonding, aromaticity, and halogenation effects. Incorporating these new features significantly enhanced spectral prediction accuracy, outperforming computationally-intensive molecular-based deep learning approaches. Among the machine learning methods examined, the Random Forest regressor demonstrated the highest accuracy score with the shortest training duration. Moreover, the developed machine learning prediction model surpassed spectral predictions relying on time-dependent density functional theory, underscoring its efficacy and practicality.

Roundoff-Error-Free Solutions of Optimization Problems

Invited Session

Computing Society

Chair: Christopher Lourenco, US Naval Academy, Annapolis, MD, United States

1 - Expediting Exact LP Solvers

Christopher Lourenco, US Naval Academy, Annapolis, MD, United States

Linear programming is the foundation of mathematical optimization; however, more than 20 years of research has shown that nontrivial round-off-errors can lead to incorrect solutions on a sizeable subset of real-world LPs. Currently, when exact or higher precision solutions are needed, the state-of-the-art LP solver is SoPlex which guarantees exactness via rational-arithmetic LU factorizations. This work accelerates the exact LP solver by replacing these rational factorizations and performing all KKT conditions via the exact LU factorizations of the SPEX software package. Altogether, the new interface increases the speed of SoPlex by a factor of 2.5 and 1.7 in average and geometric mean on a test set of real-world linear programs.

2 - Exact QR factorization

Erick Moreno-Centeno, Texas A&M University, College Station, TX, United States

We present the roundoff-error-free (REF) QR factorization framework comprising integer-preserving versions of the standard and the thin QR factorizations and associated algorithms to compute them. Specifically, the standard REF QR factorization factors a given matrix $A \in Z^{m \times n}$ as A = QDR, where $Q \in Z^{m \times m}$ has pairwise orthogonal columns, D is a diagonal matrix, and $R \in Z^{m \times n}$ is an upper trapezoidal matrix; notably, the entries of Q and R are integral, while the entries of D are reciprocals of integers. In the thin REF QR factorization, $Q \in Z^{m \times n}$ also has pairwise orthogonal columns, and $R \in Z^{n \times n}$ is also an upper triangular matrix. In contrast to traditional (i.e., floating-point) QR factorizations, every operation used to compute these factors is integral; thus, REF QR is guaranteed to be an exact orthogonal decomposition. Importantly, the bit-length of every entry in the REF QR factorizations (and within the algorithms to compute them) is bounded polynomially. Notable applications of our REF QR factorizations include finding exact least squares or exact basic solutions, $x \in Q^n$, to any given full column rank or rank deficient linear system Ax=b, respectively. In addition, our exact factorizations can be used as a subroutine within exact and/or high-precision quadratic programming. Altogether, REF QR provides a framework to obtain exact orthogonal factorizations of any rational matrix (as any rational/decimal matrix can be easily transformed into an integral matrix).

3 - Sparse Exact QR Factorization

Lorena Mejia Domenzain, Texas A&M University, College Station, TX, United States

The Gram-Schmidt process is most widely used for computing the QR factorization of a matrix. QR factorization is a widely used tool in mathematics, computer science, and engineering. For example, QR factorization is regularly used to solve least squares problems. Round-off Error Free (REF) QR was developed because the round-off errors incurred when factorizing can lead to a loss in orthogonality (thus incorrect solutions). REF QR factorization of matrix A is A=QDR, where Q is a left orthogonal matrix, R is a right triangular matrix, and D is a diagonal matrix. This talk presents an Integer-preserving Gram-Schmidt orthogonalization process (IPGS) and an efficient sparse IPGS-REF QR algorithm. IPGS is strongly grounded in exact linear algebra and every operation used in IPGS is integral; thus, the resulting vectors are guaranteed to be exact, integral and orthogonal to each other.

4 - An Early Termination Criteria For Dixon's Method

Kelsey Kitzmiller, Texas A&M University, College Station, TX, United States

Dixon’s p-adic lifting algorithm uses modular arithmetic to find exact solutions to systems of linear equations. Although this method is state-of-the-art for solving dense systems exactly, it often performs significantly more iterations than necessary to compute the solution. In order to avoid some of these unnecessary computations, a new early termination criteria is presented which is based on Cabay’s criteria for congruence technique algorithms. This stopping procedure is predicated on a new version of rational reconstruction which partially reconstructs the modular image found at each p-adic lifting iteration. The complete algorithm maintains the same worst-case complexity as Dixon’s original method but is more efficient in practice, as it performs only a small number of iterations beyond those which are necessary to compute the solution.

Statistical and Machine Learning in Healthcare

Invited Session

Data Mining

Chair: Xin Zan, University of Iowa, Coralville, IA, United States

1 - Muse-Net: Missingness-Aware Multi-Branching Self-Attention Encoder for Irregular Longitudinal Electronic Health Records

Zekai Wang, The University of Tennessee. Knoxville, Knoxville, TN, United States, Tieming Liu, Bing Yao

The era of big data has made vast amounts of clinical data readily available, particularly in the form of electronic health records (EHRs), which provides unprecedented opportunities for developing data-driven diagnostic tools to enhance clinical decision making. However, the application of EHRs in data-driven modeling faces challenges such as irregularly spaced multi-variate time series, issues of incompleteness, and data imbalance. Realizing the full data potential of EHRs hinges on the development of advanced analytical models. In this paper, we propose a novel Missingness-aware mUlti-branching Self-Attention Encoder (MUSE-Net) to cope with the challenges in modeling longitudinal EHRs for data-driven disease prediction. The MUSE-Net leverages a multi-task Gaussian process (MGP) with GPU acceleration for data imputation, a multi-branching architecture to address the data imbalance problem, and a time-aware self-attention encoder to account for the irregularly spaced time interval in longitudinal EHRs. We evaluate the proposed MUSE-Net using both synthetic and real-world datasets. Experimental results show that our MUSE-Net outperforms existing methods that are widely used to investigate longitudinal signals.

2 - Detecting Algorithmic Bias in Medical-AI Models Using Conformal Trees

Jeffrey Smith, Georgia Tech, Atlanta, GA, United States

With the growing prevalence of machine learning and artificial intelligence-based medical decision support systems, it is equally important to ensure that these systems provide patient outcomes in a fair and equitable fashion. This study presents an innovative framework for detecting areas of algorithmic bias in medical-AI decision support systems. Our approach efficiently identifies potential biases in medical-AI models, specifically in the context of sepsis prediction, by employing the Classification and Regression Trees (CART) algorithm with conformity scores. We verify our methodology by conducting a series of synthetic data experiments, showcasing its ability to estimate areas of bias in controlled settings precisely. The effectiveness of the concept is further validated by experiments using electronic medical records from Grady Memorial Hospital in Atlanta, Georgia. These tests demonstrate the practical implementation of our strategy in a clinical environment, where it can function as a vital instrument for guaranteeing fairness and equity in AI-based medical decisions.

3 - Heterogeneous Elasticity Moduli Estimation Based on Bone Mechanical Testing Data by Semi-Parametric Physics-Informed Neural Networks

Tatthapong Srikitrungruang, Texas A&M University, College Station, TX, United States, Sina Aghaee Dabaghan Fard, Jaesung Lee, Yuxiao Zhou

Estimation of bone stiffness is challenging, some research done previously uses physical experiments such as microtensile testing which is expensive and destructive. Simulation is also an option. But, it is still expensive and more suitable for response prediction whereas parameters estimation is limited. Physics-informed neural networks (PINNs) merge data-driven methodologies with laws of physics and have some effectiveness in parameter estimation. However, the estimation of heterogeneous physical parameters such as elasticity moduli is very challenging because one needs to estimate the parameter value at every given input location. Moreover, It is more challenging in three-dimensional space. In practice, we often have data of additional variables that have parametric relationships with heterogeneous parameters. For example, the parameter relations between bone stiffness and the bone mineral density measured from computed tomography (CT) data is studied in the literature. We leverage availability of such a variable and the parametric relationships by integrating them into PINNs framework. A novel Semi-parametric Physics-Informed Neural Networks is proposed to address challenges in optimization for parameter estimation. Our framework consists of two steps; in the first step, we optimize the objective function specially designed for the inverse linear elasticity model, where we incorporate slack variables to address noises in the data. Instead of using the boundary condition that exacerbates the optimization, we first find an unscaled parameter and rescale it. We demonstrate heterogeneous elastic moduli estimation based on the glenoid bone displacement data from mechanical testing coupled with CT images, and the result corresponds to the literature.

4 - A Dual-Granularity Bayesian Active Learning Framework with Uncertainty Quantification for Sleep Apnea Severity Estimation

Xin Zan, University of Florida, Gainesville, FL, United States

This work develops a dual-granularity Bayesian active learning framework with uncertainty quantification for automatically providing more reliable and accurate fine-grained apnea severity estimation. The proposed novel framework provides efficient manual annotations without remarkable diagnosis accuracy degradation by using available coarse-grained labeled data and actively querying instant-level labels at the fine granularity. In particular, the proposed framework employs a Bayesian deep learning architecture to systematically quantify the irreducible aleatoric uncertainty and reducible epistemic uncertainty embedded in acquired signal data and unknown model parameters, respectively. A novel integrated acquisition function, which combines the quantified epistemic uncertainty with knowledge misalignment, is designed to facilitate selecting the instants whose estimation contradicts clinical knowledge and with high epistemic uncertainty in instant-level active learning. A dual-granularity negative Gaussian log likelihood loss function is also designed and seamlessly integrated into the active learning framework to unify the model training process from iteratively updated training dataset with both initial coarse-grained labels and the additional queried fine-grained labels. An experiment is conducted using a real sleep dataset to demonstrate the superior accurate and reliable fine-grained apnea severity estimation of the proposed method.

5 - A Mutual Knowledge Distillation Framework for Alzheimer&Rsquo;S Disease Diagnosis Using Incomplete Multimodal Images

Min Gu Kwak, Georgia Institute of Technology, Atlanta, GA, United States, Lingchao Mao, Zhiyang Zheng, Yi Su, Fleming Lure, Jing Li

Early detection of Alzheimer's Disease (AD) is crucial for timely interventions and optimizing treatment outcomes. Despite the promise of integrating multimodal neuroimages such as MRI and PET, handling datasets with incomplete modalities remains under-researched. This phenomenon, however, is common in real-world scenarios as not every patient has all modalities due to practical constraints such as cost, access, and safety concerns. We propose a deep learning framework employing Mutual Knowledge Distillation (MKD) to model different sub-cohorts of patients based on their available modalities. In MKD, the multi-modality model (e.g., MRI and PET) serves as a teacher, while the single-modality model (e.g., MRI only) is the student. Our MKD framework features three components: a Student-oriented Multimodal Teacher (SMT) model designed through information disentanglement, a student model that learns from classification errors and SMT's knowledge, and the teacher model enhanced via distilling the student's single-modal feature extraction capabilities. Moreover, we show the effectiveness of the proposed method through theoretical analysis and validate its performance with simulation studies. In addition, our method is demonstrated through a case study with Alzheimer's Disease Neuroimaging Initiative (ADNI) datasets, underscoring the potential of artificial intelligence in addressing incomplete multimodal neuroimaging datasets and advancing early AD detection.

Optimization and Data Analytics for Agriculture Operations and Biomass Supply Chains

Invited Session

ENRE: Environment and Sustainability

Chair: Neng Fan, University of Arizona, Tucson

1 - Viability of Distributed Manufacturing for Chemicals from Biomass Using Local Renewable-Powered Electrochemistry

Sarah Ryan, Iowa State University, Ames, IA, United States, Motahareh Kashanian, Shayan Tohidi

A hybrid microbial electrochemical system (HMES) is a form of process intensification for converting biomass into chemicals, in which electrochemical reactions are done directly in the fermentation broth. Electrochemical reactors lack the economies of scale that characterize many types of chemical process equipment. This consideration, when combined with the cost of transporting feedstock and the potential for using local renewable energy, suggests that small-scale, spatially dispersed production could be economically and environmentally sustainable. We investigate this possibility in a two-step procedure to select sizes and locations of production facilities that minimize cost, including the social cost of carbon emissions. First, we use the REopt tool from the National Renewable Energy Laboratory to optimize capacities of wind and solar generation, at each potential facility location and size. Second, we solve a mixed-integer program to identify the optimal facility locations and sizes to meet a given demand for chemicals. Through detailed sensitivity analyses, we identify the economic, technical, and environmental factors that have the most significant impacts on the viability of distributed manufacturing for HMES. Lower economies of scale for the non-electrochemical processes, longer plant life and higher estimates of the social cost of carbon encourage a more distributed configuration of production facilities.

2 - Crop Yield Prediction for Semi-Arid Regions

Mahdi Mahdavimanshadi, University of Arizona, TUCSON, AZ, United States, Neng Fan

Predicting crop yields is complex due to various factors like crop genotype, environmental conditions, management practice, and their correlations. This research uses a deep learning approach combining convolutional neural networks (CNNs) and recurrent neural networks (RNNs) to forecast crop yields using environmental, soil, and management data. The proposed CNN-RNN model was compared with traditional methods like random forest (RF), deep fully connected neural networks (DFNN), SVM, and LASSO using historical data of wheat and cotton from Arizona for 1990-2023. Results show that the CNN-RNN model achieved significantly lower RMSE than other methods, indicating its superiority in yield prediction. In this paper, we demonstrate consistency in yield prediction across diverse environments and provide insights into the influence of weather, soil, and management practices on yield variability, especially in semi-arid regions compared to other areas.

3 - Identifying Sub-Communities in Intestinal Microbiome of Chickens

Mohammad Fili, Oklahoma State University, Stillwater, OK, United States, Guiping Hu, Lizhi Wang, Glenn Zhang

Eimeria maxima is a primary cause of coccidiosis in chickens and a significant predisposing factor for other economically important diseases, such as necrotic enteritis. Despite its impact, the intestinal microbiome's response to E. maxima infection remains inadequately understood. This study aimed to identify the sub-communities within the intestinal microbiome over a 14-day period following E. maxima infection. Bacterial 16S rRNA gene sequencing was conducted on ileal and cecal digesta samples collected from both mock-infected and E. maxima-infected chickens at various infection phases: prepatent (3 days post-infection [dpi]), acute (5 and 7 dpi), and recovery (10 and 14 dpi). By analyzing the abundance trajectories of the most frequent amplicon sequence variants (ASVs), we identified distinct sub-communities within the intestinal microbiome.

4 - Nationwide Optimization of Oilseed Supply Chain for Sustainable Aviation Fuel Production Under Uncertainties

Juliana Pin, North Carolina State University, Raleigh, NC, United States, Daniela Jones, Damon Hartley, Pralhad Burli, Matthew Langholtz, Chad Hellwinckel, David Thompson

The transition to sustainable aviation fuel (SAF) derived from non-petroleum sources is critical for reducing the environmental impact of aviation. The U.S. aims for 35 billion gallons per year (BGY) by 2050. Current studies focus on regional oilseed supply systems. Our research expands this by analyzing the nationwide feasibility of winter oilseeds—pennycress, camelina, and carinata—as viable feedstocks, identifying strategic locations for processing facilities and biorefineries to minimize costs. Using crop production predictions and a Mixed Integer Linear Programming model, we assess potential production volumes, costs, and logistical challenges. If all oilseed-producing counties contribute to SAF production by 2048, 1.12 billion gallons of SAF could be generated, achieving only 4% of the 2050 target at a biorefinery gate price of $0.68 per liter of bio-oil. This highlights the need to diversify feedstock sources. Also, considering meal credit as a co-product is crucial, otherwise costs could increase by 64-70%. We also modeled specific SAF demand levels for 2048 at 350, 700, and 1,050 million gallons—1%, 2%, and 3% of the 2050 target, respectively, with estimated bio-oil unit costs of $0.50, $0.57, and $0.65 per liter at the biorefinery gate. Our analysis addresses both the technical and economic aspects of SAF production and emphasizes the importance of scaling up infrastructure and exploring additional feedstocks to efficiently achieve the U.S. SAF production targets. Building on these results, our current work will enhance model flexibility with multi-capacity processors and biorefineries and include a stochastic model to incorporate uncertainties in oilseed production and SAF demand.

5 - Optimal Rice Cropping Patterns: Synergies in Water and Land Resources Management and Greenhouse Gas Reduction

Shiqi Tan, Sichuan University, Business School, Chengdu, China, People's Republic of, Jian Li, Liming Yao

This study examines optimal rice cropping patterns that effectively manage water and land resources and reduce CH_4 emissions. Rice cultivation stands as a primary source of methane emissions. Water-saving irrigation and optimized resource allocation are crucial for enhancing rice yield and quality while simultaneously reducing greenhouse gas emissions. However, achieving an economically viable yield from rice production is complex, influenced by market demands, constraints on land resources, and policy limitations. These factors form a dynamic decision-making environment. We study a two-stage stochastic dynamic optimization model that incorporates water rights and land allocation, and accounts for the uncertainties of rainfall and market prices, introducing economic incentives for methane reduction.

Industry-Research Analysis Partnerships to Inform Energy Infrastructure Decisions

Invited Session

ENRE: Energy-Climate

Chair: Stuart Cohen, National Renewable Energy Laboratory, ARVADA, CO, United States

1 - Hydropower Flexibility and Environmental Tradeoffs Analysis

Thushara De Silva, National Renewable Energy Laboratory, Golden, CO, United States

The importance of hydropower increases as the power grid evolves with the higher variable renewable contribution. As conventional thermal power plants are retired, the importance of hydropower contribution increases to balance the variability of solar and wind generation. However, reservoir water resources are constrained by multiple constraints, and variability of water inflow to the reservoirs creates limitations to dam water releases for power grid needs. Coordinating multiple tools, including water resources, ecological, and technical and economic power grid modeling, informs dam water releases. The case study, the Columbia River Basin multipurpose reservoir project, is operated for hydropower production and many other purposes considering the aquatic habitat of the river basin. Specifically, the river basin fish population is a vital element for the tribal community of the river basin. We integrated a production cost model, a water resource model, and decades of tribal knowledge to analyze the fish-friendly way of operating Columbia hydropower scheduling and grid impacts. We measure power grid impacts for various water resources planning scenarios in terms of total system operating cost, system reliability indicators, changes in wind and solar generation and curtailments, local marginal prices, and revenue for hydropower producers. The study results inform reservoir operating rules decisions from hydropower power producers, system operators, other water users, tribes, environmentalists, and other stakeholders.

2 - A Utility-National Lab Partnership to Value Pumped Storage Hydropower in an Evolving Grid

Stuart Cohen, National Renewable Energy Laboratory, Arvada, CO, United States

Accelerating deployment of variable renewable electricity from wind and solar technologies has created renewed interest in pumped storage hydropower (PSH) as an energy storage technology that can balance energy and maintain grid reliability and resiliency. The Tennessee Valley Authority (TVA) is an electric utility particularly interested in expanding its PSH fleet, but project advancement is challenged by high capital costs relative to internal economic value assessments using available market and analysis tools. That is why TVA partnered with three U.S. Department of Energy National Laboratories (NREL, ANL, and PNNL) to expand upon its internal PSH valuation studies by utilizing state-of-the-art lab capabilities and expertise in hydrological and electricity modeling. This presentation focuses on how the National Renewable Energy Laboratory (NREL) is using its suite of electric grid planning, operations, resource adequacy, and stability modeling tools to better understand the range of potential PSH system values under an uncertain and evolving grid. It will describe how laboratory capabilities are being adapted to a practical utility context and demonstrate preliminary results of PSH value and how it compares with TVA assessments.

3 - Extracting Insight from Unstructured Solar Operations and Maintenance Text Logs

Charity Sotero, kWh Analytics, Beaverton, OR, United States

As solar energy adoption grows, minimizing costly failures is critical. This presentation will detail a Department of Energy-funded analysis of unsupervised text data of over 60,000 O&M tickets from more than 700 U.S. utility-scale solar systems to identify trends in failure-driving equipment and possible resolutions. Natural language processing was used to categorize these unsupervised tickets, with an accuracy rate of 86.2% (F1=0.87). Analysis of the text data found that the top failures occurred in inverters (64.8%), modules (20.9%), trackers (4.7%), and transformers (2.0%). Root causes were often determined to originate much earlier in the PV system for failures originally associated with AC-side equipment. Our findings demand action with implications for each sector of the PV industry: increased on-site parts inventory, proactive maintenance protocols, and data transparency between operators and OEMs to pinpoint and prevent failures before they strike. This knowledge has further implications for PV lenders, insurers, and asset owners to move towards a "safe driver discount" for responsible developers. Overall, this research demonstrates both the richness of PV text data and the challenges associated with pre-processing O&M logs. Insights derived from cross-fleet analytics can help the industry as whole minimize downtime and improve availability.

Energy Systems Modeling and Optimization IV: Emerging and Distributed Energy Systems

Invited Session

ENRE: Other Energy

Chair: Alexandra Newman, Colorado School of Mines, Golden, CO, 80401, United States

1 - Analysis of Home Battery Energy Storage Systems for Affordable Housing

Andrew Aikman, Colorado School of Mines, Golden, CO, United States, Alexandra Newman, Paulo Cesar Tabares Velasco, Qiuhua Huang

We seek to evaluate the benefits of stationary and non-stationary home battery energy storage systems (BESS) combined with grid-enhancing solutions at the home level to reduce CO2–equivalent and other marginal emissions and to promote energy equity. BESS can be implemented in diverse and energy-burdened neighborhoods in order to support President Biden's Justice40 goals, in addition to reducing environmental impacts and increasing the flexibility and resilience of electric power systems. These disadvantaged communities are marginalized by underinvestment and overburdened by pollution, leading to worse living conditions and lower quality of life. However, BESS are still cost-prohibitive for most low- and middle-income (LMI) households. Thus, wide-scale BESS adoption requires the right mix of incentives and quantification of benefits for community acceptance.
We utilize NREL's REopt model to determine and compare the economic, environmental, and resiliency metrics of home systems consisting of different numbers of batteries . Increasing the system size allows homes to take advantage of time-of-use pricing schemes and periods of low marginal emissions for a reasonable cost tradeoff. Furthermore, we analyze the power outage durations, frequencies, and minimum critical loads that LMI households and communities are capable of handling. Preliminary results demonstrate that the inclusion of between 1 and 4 batteries per household results in 7% to 19% reduction in CO2 emissions, mitigating up to 35 tons of CO2 per year per community. In addition to life cycle cost comparisons, we explore economic incentives necessary to reach various emissions reductions targets.

2 - X Phase Change Material Heat Exchanger to Decarbonize Water Heating in Low-Income Housing

Chase Robinson, Colorado School of Mines, Golden, CO, United States

This project details the fabrication of a phase change material (PCM) heat exchanger for use in small-volume heat pump water heaters (HPWHs) to increase thermal storage capacity and overall performance. The design of the novel heat exchanger relies on additive manufacturing to produce complex geometries not possible via traditional manufacturing methods. This presentation describes efforts toward material processing and performance characterization for the 3D-printed PCM heat exchanger, as well as preliminary results showing the applicability of additive manufacturing for introducing thermal energy storage into a HPWH. Our PCM selection relies on those with low toxicity, high energy storage density, and an appropriate transition temperature for water heating applications. Based on preliminary HPWH modeling results, our work utilizes a material with a transition temperature of 55°C. A higher material content corresponds to a heat exchanger with a higher thermal energy storage density, thus providing greater benefit for small-volume HPWHs. This work presents a promising a path forward towards achieving superior HPWH performance in space-constrained, low-income housing.

3 - Estimating Resource Adequacy Contribution when Energy Storage Provides Frequency Regulation

HyeongJun Kim, The Ohio State University, Columbus, OH, United States, Ramteen Sioshansi

When energy storage capacity value is estimated, state-of-energy (SOE) is important as it determines availability of the storage to alleviate a loss of load. However, in case of providing frequency regulation, estimating the level of SOE becomes complicated and it may become intractable. Thus, we propose a three-step approach to estimate the capacity value of energy storage when it provides frequency regulation. First, discretized stochastic dynamic optimization is used to obtain optimal decision policy when multiple services are provided together. Second, these decision policies are used iteratively to derive actual optimal schedule for the energy storage operation using mixed integer optimization in a rolling-horizon fashion. As the last step, contribution from energy storage to resource adequacy of the power system is assessed using Monte Carlo simulation. Results of the case study are compared with the case when frequency regulation is not provided from energy storage. It shows that the capacity value decreases when there is no non-performance penalty for the capacity or storage duration is short.

4 - Leveraging Advanced Metering Infrastructure to Evaluate Energy Insecurity Demographics

Akua McLeod, Carnegie Mellon University, Pittsburgh, PA, United States, Destenie Nock, Amritanshu Pandey

Interrupted electricity access negatively impacts household resilience and can cause energy insecurity, by hindering households' ability to meet their energy demand. Households can experience an electric service interruption in the form of a power outage, or as an involuntary disconnection due to nonpayment. Often, electricity reliability is reported through system-level metrics and calculated only for only one type of service loss: power outages. These metrics overlook disconnections as a form of electric service loss, and obscure how energy access varies across the service territory. Advanced metering infrastructure (AMI) records sub-hourly electricity consumption at the household level, providing an opportunity to evaluate both forms of service loss and measure differences in access with greater spatial granularity. In this paper, we leverage extensive data from over 600,000 households in Illinois to build a classification model for disaggregating power outages from disconnections in residential electricity consumption smart meter data. We further evaluate how the duration and frequency of disconnections change across the service territory. Our analysis provides more granular metrics for electricity reliability, looking first at involuntary service loss, as well as the combined burdens of outages and disconnections. Ultimately, this analysis informs the identification of energy-insecure communities.

5 - The influence of regional geophysical resource variability on the value of single- and multi-storage technology portfolio

Anna Li, Princeton University, Princeton, NJ, United States, Edgar Virguez, Jacqueline Dowling, Alicia Wongel, Linda Covelli, Tyler Ruggles, Natasha Reich, Nathan Lewis, Ken Caldeira

A stylized macro-scale energy model of least-cost electricity systems relying only on wind and solar generation was used to assess the value individually and in combination of different storage technologies for the contiguous U.S. as well as for four geographically diverse U.S. load-balancing regions. For the contiguous U.S. system, at current costs, when only one storage technology was deployed, hydrogen energy storage produced the lowest system costs, due to its energy-capacity costs being the lowest of all storage technologies modeled. Additional hypothetical storage technologies were more cost-competitive than hydrogen (long-duration) only at very low energy-capacity costs, but they were more cost-competitive than Li-ion batteries (short-duration storage) at relatively high energy- and power-capacity costs. Moreover, in all load-balancing regions investigated, the least-cost systems that included long-duration storage had sufficient energy and power capacity to also meet short-duration energy and power storage needs, so addition of short-duration storage as a second storage technology did not markedly reduce total system costs. Thus, in electricity systems relying on wind and solar generation, contingent on social and geographic constraints, long-duration storage may be able to cost-effectively provide the services that would otherwise be provided by shorter-duration storage technologies.

Emerging Applications and Algorithms in Logistics and Urban Planning

Invited Session

Computing Society

Chair: Yiling Zhang, University of Minnesota, Minneapolis, MN, United States

1 - Accelerating Dynamic Programming via Dual Selection for Column-Generation-Based Exact Solution Framework

Zhengzhong You, University of Florida, Gainesville, FL, United States, Yu Yang

Column generation (CG) is a widely used exact solution approach for solving large-scale optimization problems such as vehicle routing problems (VRPs). However, the pricing subproblem, often formulated as a resource-constrained shortest path problem (RCSPP) and solved using dynamic programming (DP), can be computationally expensive. This paper proposes a novel dual selection strategy to accelerate the single iteration of DP in the context of CG. The authors introduce an abstract optimization program to find the "best" optimal dual solution that potentially minimizes the number of undominated labels in the labeling algorithm, a common DP technique for solving RCSPP. The paper presents a set of dual selection programs based on the abstract optimization program, along with a comprehensive theoretical analysis to determine the proper objective function for each program. Numerical experiments on the Capacitated Vehicle Routing Problem (CVRP) demonstrate that the proposed dual selection programs can eliminate up to a significant portion of the undominated labels, resulting in a substantial speedup of the labeling process, particularly for instances where pricing proves to be extremely challenging.

2 - Mobile Parcel Locker Scheduling with Customer Choices Under Uncertain Demand

Yin Can, University of Minnesota, Twin Cities, Minneapolis, MN, United States, Yiling Zhang

The movable unit equipped with a set of parcel lockers has been recently developed as a new mode to improve the efficiency of last-mile delivery. Mobile parcel lockers, different from traditional facility location problems placing permanent facilities in a specific region, can be relocated at any time, driven by the changing demand rate from location to location over time. This talk will present a scheduling problem of mobile parcel lockers under uncertain demand and customer choices. The problem is formulated as a distributionally robust two-stage stochastic programming model, where customer choices are captured by multinomial logit (MNL) models. The probability distribution of uncertain demand, although unknown for this new service, is characterized by the first moments and the support. Our models flexibly adapt different prior beliefs of spatial structures and pricing strategies. We obtain exact mixed-integer linear programming reformulations and derive valid inequalities used in decomposition algorithms.

3 - An Exact Approach for Solving Pickup-and-Delivery Traveling Salesman Problems with Neighborhoods

Cai Gao, University at Buffalo, San Jose, CA, United States, Ningji Wei, Jose Walteros

This paper studies a variant of the traveling salesman problem, called the pickup-and-delivery traveling salesman problem with neighborhoods, that combines traditional pickup and delivery requirements with the flexibility of visiting the customers at locations within compact neighborhoods of arbitrary shape. We derive two optimality conditions for the problem, a local condition that verifies whether a given tour is locally optimal at the visiting points and a global condition that can be used to cut off suboptimal regions of the neighborhoods. We model the problem as a mixed-integer nonlinear program and propose a generalized Benders decomposition to solve instances of the problem with convex and nonconvex neighborhoods. Finally, we conduct extensive computational experiments to demonstrate the efficacy of our solution framework.

4 - Solving the large-scale On-Demand Multimodal Transit Systems Design with Adoptions (ODMTS-DA) Problem

Hongzhao Guan, Georgia Institute of Technology, Atlanta, GA, United States, Beste Basciftci, Pascal Van Hentenryck

Capturing latent demand has a pivotal role in designing public transit services: omitting these riders can lead to poor quality of service and/or additional costs. This study introduces the On-Demand Multimodal Transit Systems (ODMTS) Design with Adoptions problem (ODMTS-DA) to capture the latent demand in on-demand multimodal transit systems. ODMTS-DA is a bilevel optimization problem that integrates a mixed-integer programming (MIP) model and a travel mode choice model. An exact combinatorial algorithm based on Benders decomposition can be applied to solve the problem. Unfortunately, this algorithm only finds high-quality solutions for medium-sized cities and is not practical for large metropolitan areas. To address these computational difficulties, this study proposes two new methods: (1) reformulating ODMTS-DA to a path-based single-level MIP (namely P-PATH) that can be solved to optimal in reasonable time and (2) five heuristic algorithms that rapidly find high quality solutions for large-scale instances. The computational benefits of both methods are demonstrated on two comprehensive case studies: the midsize transit system of the Ann Arbor – Ypsilanti region in Michigan and the large-scale transit system for the city of Atlanta. On the Michigan dataset, both methods can bring more than two orders of magnitude improvements compared with the exact algorithm. For Atlanta, the results show that P-PATH can solve large-scale ODMTS-DA instances optimally in a few hours or in a few days, and the heuristic algorithms can find high-quality solutions with even significantly less time (in a few minutes or in a few hours).

5 - Boosting Column Generation with Graph Neural Networks for Joint Rider Trip Planning and Crew Shift Scheduling

Tinghan Ye, Georgia Institute of Technology, Atlanta, GA, United States, Jiawei Lu, Wenbo Chen, Pascal Van Hentenryck

Optimizing service schedules is pivotal to the reliable, efficient, and inclusive on-demand mobility. This pressing challenge is further exacerbated by the increasing needs of an aging population, the oversubscription of existing services, and the lack of effective solution methods. This study addresses the intricacies of service scheduling, by jointly optimizing rider trip planning and crew scheduling for a complex dynamic mobility service. The resulting optimization problems are extremely challenging computationally for state-of-the-art methods.

To address this fundamental gap, this paper introduces the Joint Rider Trip Planning and Crew Shift Scheduling Problem (JRTPCSSP) and a novel solution method, called AGGNNI-CG (Attention and Gated GNN- Informed Column Generation), that hybridizes column generation and machine learning to obtain near-optimal solutions to the JRTPCSSP with the real-time constraints of the application. The key idea of the machine-learning component is to dramatically reduce the number of paths to explore in the pricing problem, accelerating the most time-consuming component of the column generation. The machine learning component is a graph neural network with an attention mechanism and a gated architecture, that is particularly suited to cater for the different input sizes coming from daily operations.

AGGNNI-CG has been applied to a challenging, real-world dataset from the Paratransit system of Chatham County in Georgia. It produces dramatic improvements compared to the baseline column generation approach, which typically cannot produce high-quality feasible solutions in reasonable time on both medium-sized and large-scale complex instances. AGGNNI-CG also produces significant improvements in service compared to the existing system.

A Tutorial on Automated Decomposition Methods for Optimization

Invited Session

Computing Society

Chair: Matthew Galati, Amazon, Glen Mills, PA, United States

1 - Introduction to Decomposition Methods

Rob Pratt, SAS, Cary, NC, United States

Large-scale practical optimization problems typically have structure that can be exploited to reduce the solve time. In particular, the constraint matrices for mixed integer linear optimization problems often have block-angular form. Problems for which a small percentage of constraints do not appear in the blocks motivate Dantzig-Wolfe decomposition. On the other hand, problems for which a small percentage of variables do not appear in the blocks suggest Benders decomposition. This presentation provides an elementary introduction to both of these classical decomposition methods.

2 - Automated Decomposition Software

Matthew Galati, Amazon, Glen Mills, PA, United States

For problems with decomposable structure, Dantzig-Wolfe and Benders decomposition often outperform state-of-the-art implementations of the traditional branch-and-cut algorithm for mixed integer linear programming. Implementation of either decomposition algorithm can be cumbersome for specific applications, especially in cases that have multiple natural block decompositions, and many critical implementation details are not obvious from textbook descriptions. This presentation describes generic software frameworks that fully automate these two decomposition algorithms while still enabling the user to easily specify the block structure if desired.

3 - Benders Decomposition for the Critical Node Detection Problem

Laszlo Ladanyi, SAS, Lakeville, CT, United States

For an undirected graph, the critical node detection problem is to find a small subset of nodes whose removal yields the maximum disconnectivity of the resulting graph. This presentation motivates the problem, describes a mixed integer linear programming formulation, and illustrates the application of automated Benders decomposition to solve the problem efficiently.

4 - Decomposing Problem Data Instead of Problem Formulation: An Application to Assortment Optimization

Taghi Khaniyev, Bilkent University, Ankara, Turkey, Kaan Cakiroglu, Ali Ilhan Haliloglu, Elif Sena Isik, Elif Rana Yoner

Most decomposition approaches in linear integer programming such as Dantzig-Wolfe (DW) and Bender's become efficient alternatives to branch-and-cut based approaches by exploiting an inherent decomposable (i.e., bordered block diagonal) structure in the constraint matrices of the problems. For well-known problems such as facility location and vehicle routing, a decomposable structure is readily available from the problem formulation where problem can usually be decomposed into subproblems based on one of the index sets (e.g., customer set or potential locations of facilities). Many problems, however, do not have such a decomposable structure in their constraint matrices when problem data can take arbitrary values. In this work, we study the consider-then-choose assortment optimization problem where the generic formulation is not amenable to classical decomposition techniques. Many realistic problem instances, however, have such problem data (consideration matrix, in this case) that has a bordered block diagonal structure which lends itself to a new reformulation that can be exploited with DW decomposition. We provide an algorithm that can automatically detect such a decomposable structure in the problem data and consequently apply DW decomposition automatically. We conduct computational experiments on synthetic datasets to illustrate the efficient performance of the proposed reformulation.

Sunday, October 20, 5:25 PM - 6:15 PM

Summit - Ballroom 3

2024 INFORMS UPS George D. Smith Prize Reprise Presentation: University of South Carolina

Plenary/Keynote Session

Keynote

Chair: Anne Robinson, Robinson Insights, Ottawa, ON, Canada

1 - 2024 INFORMS UPS George D. Smith Prize Reprise Presentation: University of South Carolina

Sanjay Ahire, University of South Carolina, Columbia, SC, United States, Mark Ferguson

The Management Science Department in the Darla Moore School of Business at the University of South Carolina supports both undergraduate and graduate programs in operations and supply chain and business analytics as well as a Ph.D. in operations management. The department couples classroom and real-world, experiential learning to produce top-notch graduates. The Operations and Supply Chain (OSC) Center, through which students have the opportunity to earn an industry-certified Lean Six Sigma Green Belt, plays a central role in this real-world experience and has, over time, become a focal point for identifying, developing and placing well-trained talent in many leading Fortune 500 multinational firms. The OSC Center faculty have executed 360+ capstone consulting student projects in more than 45 partner firms yielding more than 330 million dollars in recurring benefits.

The department is also home to the Moore School Data Lab, which assists students with statistics and data analytics courses, and to the Center for Applied Business Analytics, which provides training, academic challenges and curriculum support to students and faculty. Graduate programs include the Masters of Science in Business Analytics and concentrations in Operations and Supply Chain in the school's various MBA programs. The department's executive education programs have trained over 5,000 officers in the U.S. Army on the use of advanced data analytics.

Doctoral graduates from the Management Science Department are currently working as faculty members at institutions such as Penn State University, The Ohio State University, Florida State University, University of Colorado, and University of Tennessee, among others.

Summit - Ballroom 2

Smarter Decisions Towards Preventing, Controlling, and Eliminating Infectious Diseases

Plenary/Keynote Session

Keynote

Chair: Maria Mayorga, North Carolina State University, Raleigh

1 - Smarter Decisions Towards Preventing, Controlling, and Eliminating Infectious Diseases

Pinar Keskinocak, ISyE Georgia Tech, Atlanta, GA, United States

Advances in science, medicine, and public health significantly improved our understanding of infectious diseases as well as their prevention and control; however, infectious diseases continue to have a devastating impact on the lives and livelihoods of millions people around the world. Global and regional changes in climate, human behavior, contact between human and wildlife reservoirs, and technology may further exacerbate the risk of infectious diseases. There are tremendous opportunities for analytics and operations research in combatting infectious diseases, especially in resource-constrained settings. We will discuss examples of how operations research and analytics can inform decision-making related to disease prevention and control, improve equity in access to resources and outcomes, and support efforts towards eradication.

Summit - Ballroom 1

Philip McCord Morse Lectureship

Plenary/Keynote Session

Keynote

Chair: Anahita Khojandi, University of Tennessee, Knoxville, TN, United States

1 - OR and Analytics in Support of Democracy

David Shmoys, Cornell University, Ithaca, NY, United States

Computational tools can now address (at scale) a wide range of decision-making elements of the democratic process. Perhaps the most well-studied of these is to construct (and evaluate) legislative districts for each state, a process dictated by the United States Constitution to recur every 10 years. Sixty years have passed since the first attempts at using integer programming .

This talk will briefly discuss several large-scale approaches made possible by both advances in IP and in computational power. Although these methods are effective, they provide opportunities to both achieve notions of fairness and to thwart such objectives. Innovative Markov Chain Monte Carlo (MCMC) methods have been introduced to provide a mathematical perspective to detect attempts at undermining fairness in the resulting districting plans.

One counterproposal advocated by several "good government" NGO's is to modify the current system to a "multi-member" one, where each (larger) district elects, for example, 3 representatives through a process of using ranked-choice votes with a mechanism called single-transferable voting. IP can again be used to analyze the impact of such a modified system, and demonstrates (at least at the first cut) that this change would both help to facilitate fair outcomes, and limit the power of those attempting to undermine such fairness. Finally, we will highlight the notion of a citizens' assembly and sketch how OR tools can be (and are, in practice) employed to deliver on the promise of delivering a fair democratic system by this alternative approach.

Monday, October 21, 8:00 AM - 9:15 AM

Summit - 320

Scheduling, Bike Sharing and Other Supply Chain Issues

Invited Session

Scheduling and Project Management

Chair: Zhi-Long Chen, University of Maryland, College Park, MD, 20742, United States

Co-Chair: Zhi-Long Chen, University of Maryland, College Park, MD, United States

1 - Online Integrated Production and Distribution Scheduling

Zhi-Long Chen, University of Maryland, College Park, MD, United States

A growing number of applications can be modeled as online integrated production and distribution scheduling (IPDS) problems. We provide several application examples, give a state-of-the-art review of the online IPDS research, and point out several directions for future research.

2 - Integrated Production and Transportation Scheduling Problem Under Nonlinear Cost Structures

Feng Li, Huazhong University of Science and Technology, Wuhan, China, People's Republic of, Julong Wang, Zhixue Liu

We consider an integrated production and transportation scheduling problem arising in several make-to-order settings, where customer orders have release times and pre-specified delivery time windows. These orders are first processed in a plant and, thereafter, delivered to their customer sites by transporters (e.g., freight trains, ships, or air flights) with fixed departure times and nonlinear transportation cost functions. If the processing of an order is completed but not immediately delivered, it will be stored temporarily, incurring inventory holding costs. The objective is finding an integrated schedule for production and transportation such that the total cost of inventory holding and transportation is minimized. In this study, we consider the following two cases: one where partial delivery is not allowed, and the other where partial delivery is allowed. For each case, we propose an exact algorithm to find optimal solutions for small-scale instances, and a heuristic algorithm to find near-optimal solutions for large-scale instances. For the randomly generated test instances, the computational results reveal that the exact algorithms significantly outperform a commercial optimization solver in terms of the computational times and the number of instances solved within a specified time limit, and the heuristic algorithms are capable of generating near-optimal solutions within a reasonable computational time. Finally, we incorporate considerations of sequence-dependent setup time into the problem and apply the approaches for designing the algorithms to address the more general problem.

3 - Supply Chain Configuration and Its Applications

Haitao Li, University of Missouri - St. Louis, Saint Louis, MO, United States

Simultaneously optimizing the system-wide safety stock placement and the modes/options to execute supply chain functions is known as the *supply chain configuration problem* (SCCP). With its general and versatile modeling framework, the SCCP and its variants have a plethora of applications in various industries. In this presentation, I will start with an introduction of the basic SCCP with its mathematical programming formulation and connection with a project scheduling problem. Extensions and applications are presented next, including the SCCP with resource constraints (SCCP-RC), a variant of the resource-constrained project scheduling problem (RCPSP), for make-to-order (MTO) manufacturing, and the food supply chain configuration problem (FSCCP) that considers food loss and quality deterioration to configure an end-to-end agricultural/food supply chain.

4 - A Static Mixed Bike Repositioning Problem with Both Man-Powered Bikes and Electric Bikes

Jia Cui, Department of Civil Engineering, The University of Hong Kong, Hong Kong SAR, Hong Kong, Wai Yuen Szeto

The proliferation of bike-sharing systems has significantly facilitated travel convenience and the sustainability of urban development. An introduction of electric bicycles (e-bikes) to existing bike-sharing systems can enhance the cycling experience by covering longer distances with less physical exertion. However, managing a bike-sharing system with both man-powered bikes and e-bikes presents a complex challenge, consisting of addressing the imbalance between bike supply, dock supply, and user demand. Despite this, no research has yet been conducted on this topic. This study presents a novel static bike repositioning problem that considers both man-powered bikes and e-bikes while allowing low-battery e-bikes to be recharged at charging stations. A mixed-integer linear programming model is proposed that aims to minimize the deviation from the target inventory of man-powered bikes and e-bikes (opposite to the deviation from the target inventory of vacant docks), the fixed cost of vehicles, the travel cost, and the loading cost within the time budget. Numerical experiments are conducted by a commercial solver on small network instances to show the effect of introducing (low-battery) e-bikes into existing bike-sharing systems. Efficient algorithms are also designed to provide near-optimal solutions to the problem under large instances. Computational experiments based on real-world data validate the performance of the algorithm and provide practical implications.

5 - Robotic Mobile Fulfillment Systems: Frameworks for Performance Analysis

Chelliah Sriskandarajah, Texas A&M University, College Station, TX, United States, Kerim Uygur Kizil, Jon Stauffer

Motivated by the growing demand for efficient order fulfillment in e-commerce, our study investigates three interconnected problems arising in managing robotic mobile fulfillment (RMF) systems: *(i)* allocation of SKU inventories into pods, *(ii)* pod selection for picking operations, and *(iii)* pod scheduling for picking operations. We deploy two distinct methodological approaches, modular and integrated, to explore how the level of integration in addressing the three problems influences overall system performance. System performance is defined by two metrics: *(i)* the total completion time (TCT) to fulfill all orders assigned to a specific interval and *(ii)* the number of required robots (NRR) to support seamless picking operations. By investigating pod scheduling as a standalone problem, we show it is NP-hard with two pickers [resp., one picker] under the TCT minimization [resp., NRR minimization] objective. Our findings suggest that the modular approach achieves an overall performance level comparable to the integrated one. In particular, we show that managers could divide and conquer the three problems by considering intuitive objective functions for each rather than having to rely on complex models that simultaneously address all aspects of RMF system operations.

Summit - 321

Data Science in Wind Energy

Invited Session

Quality, Statistics and Reliability

Chair: Eunshin Byon, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Yu Ding, Georgia Institute of Technology, Atlanta, GA, United States

1 - Explainable Importance Sampling for Reliability Analysis of Wind Turbines

Chenfei Li, University of Michigan, Ann Arbor, MI, United States, Jaeshin Park, Eunshin Byon

We propose a new explainable multivariate importance sampling method in stochastic simulation. Importance sampling easily faces the curse of dimensionality, as the input dimension grows. This study devises a new method that identifies crucial input variables to effectively formulate a nonparametric instrumental density and explains the importance of each variable. The wind turbine reliability case study demonstrates the method’s efficiency.

2 - Large Scale Data Handling for Wind Turbines

Ahmadreza Chokhachian, Georgia Institute of Technology, Atlanta, GA, United States, Matthais Katzfuss, Yu Ding

Wind power curve models connect environmental input with wind power output. Wind industry arranges their operational data in a 10 minutes interval, implying over 50,000 data pairs per turbine per year. When terrain information is to be modeled, multiple turbines on a wind farm need to be used to capture the spatial variation. A recent study using 66 wind turbines on a wind farm handles over 3.4 million data pairs. Handling such large datasets presents the computational challenge for using machine learning methods like the Gaussian process models. This talk presents our recent effort in speeding out the computation for handling large datasets for wind energy applications.

3 - A Hierarchical Optimization Framework to Integrate Turbine Failure Risks and Accessibility Forecasts to Offshore Wind Farm Operations, Maintenance, and Logistics

Ceyhan Sahin, Wayne State University, Detroit, MI, United States, Feng Ye, Ahmed Aziz Ezzat, Onur Kilic, Murat Yildirim

This paper introduces an innovative hierarchical optimization framework to optimize operations, maintenance, and logistics decisions in offshore wind farms. Operating at multiple levels, the framework leverages a monthly dynamic programming model at a higher tier to determine optimal vessel rental strategies, as a function of turbine statuses and future accessibility conditions. At a more granular level, a detailed two-stage model is developed to optimize operations on an hourly basis over a 30-day timeframe. Integrating various data-driven predictions such as availability forecasts, production levels across wind farm locations, and turbine failure risks, this framework offers a comprehensive approach to asset management in offshore wind farms. The proposed approach provides significant advantages over the benchmark policies in terms of both efficiency and reliability.

4 - Spatio-Temporal Offshore Wind Energy Forecasting over Space, Time, and Height

Ahmed Aziz Ezzat, Department of Industrial & Systems Engineering, Rutgers University, Piscataway, NJ, United States, Feng Ye, Xinxi Zhang, Michael Stein

To unlock access to stronger winds, the offshore wind industry is advancing with significantly larger and taller wind turbines. Existing spatio-temporal forecasting methods compress the three-dimensional reality of the wind field (space × time × height) into a simpler, two-dimensional “world view” (space × time) which completely overlooks the vertical dimension of the wind field. Instead, we propose a multi-output spatio-temporal model with a multivariate, nonstationary, and state-dependent kernel that is is capable of adequately modeling the complex dependencies in local wind speeds across multiple heights. Embedded within the statistical model, an advanced deep learning architecture fully exploits the wealth of exogenous information available to the forecaster (typically in the form of high-dimensional image streams) in order to learn and update the kernel parameters. Experiments using real-world data from the offshore wind energy areas in the Northeastern United States show that the wind speed and power forecasts from the proposed model are of considerably higher quality than those from prevalent time series, deep learning, and space-time methods.

Co-Chair: Weihong Guo, Rutgers, The State University of New Jersey, Piscataway, NJ, United States

1 - Generative Model-Empowered Customized Metamaterial Design

Chenang Liu, Oklahoma State University, Stillwater, OK, United States, Ziyang Zhang, Yu Feng

This work presents a data-driven approach for designing customized metamaterial-structured shoe soles, tailored to individual plantar pressure using generative models. By integrating machine learning with finite element analysis, this work is expected to identify the optimal design based on user-specific biomechanical data. Specifically, our approach leverages plantar pressure measurements and preferences to adjust sole stiffness and cushioning, enhancing functionality and ergonomics while reducing development time and costs, thereby offering a scalable reverse design for personalized footwear.

2 - Robust Object Detection Using Unsupervised Multi-Domain Adaptation

Arpan Kusari, University of Michigan Transportation Research Institute, Ann Arbor, MI, United States, Hojun Son, Asma Almutairi, Venkata Sairam Polina, Jiahang Li

For learning based intelligent systems, the manual labeling process is labor intensive and costly. Transfer learning is an approach that enables cost-saving through use of other labeled datasets to train a neural network model and predict on our target dataset. However, it is challenging when confronted with significant distributional differences among datasets and noise in ground truth labels. To address these issues, an alternative which has been proposed in the domain adaptation realm is to learn from simulation and transfer onto a real environment, known as sim-to-real transfer. The simulation environment can produce infinite amount of data with large amount of control but lacks in variability which the real labelled datasets can provide. We devise a two-step domain adaptation approach towards object detection which takes into account the variability of multiple real datasets in learning a robust object detector model. We first train exhaustively on a photorealistic simulation environment, CARLA, altering the weather and daylight conditions along with the vehicle types seen on the road. Next, we simultaneously fine-tune on a number of real open-source object detection datasets in the automated vehicles domain. We provide some results on how the fine-tuning process can be applied, how the features of the background in the datasets can influence the foreground objects and the robustness of such object detection approaches as compared to learning from labeled examples. We show that such an approach can provide a very low-cost and powerful object detector.

3 - Plural: 3D Point Cloud Transfer Learning via Contrastive Learning with Augmentations

Michael Biehler, Georgia Institute of Technology, Atlanta, GA, United States, Jing Li, Jianjun Shi

Unlocking the power of 3D point cloud machine learning models can be a challenge due to the need for extensive labeled datasets, which presents a challenge when applying these models to new domains. Transfer learning can help overcome this challenge by utilizing data from related tasks to enhance model performance. However, traditional (2D) transfer learning methods struggle with 3D point cloud domain adaptation, due to differences in physical environments and sensor configurations. To address this issue, we propose PLURAL, a novel 3D point cloud transfer learning methodology based on contrastive learning with augmentations. Our approach is inspired by the notion that high-level shape features are more transferable than low-level geometry features. We propose a co-training architecture that includes separate 3D point cloud models with domain-specific parameters, as well as a module for learning domain-invariant features. Additionally, PLURAL extends the approach of contrastive instance alignment to 3D point cloud modeling by considering physics-informed hard sample mining. Our experiments on simulation and real-world datasets demonstrate that PLURAL outperforms state-of-the-art transfer learning methods by a significant margin, effectively reducing the domain gap.

4 - Heterogeneous Federated Learning via Generative Model-Aided Knowledge Distillation in the Edge

Chuanneng Sun, Rutgers University-New Brunswick, Edison, NJ, United States

Federated Learning (FL) has been popular recently as a framework for training Machine Learning (ML) models in a distributed and privacy-preserving manner. Traditional FL frameworks often struggle with model and statistical heterogeneity among participating clients, impacting learning performance and practicality. To overcome these fundamental limitations, we introduce Fed2KD+, a novel FL framework that leverages a set of tiny unified models and Conditional Variational Auto-Encoders (CVAEs) to enable FL training for heterogeneous models between network clients. Using forward and backward distillation processes, Fed2KD+ allows a seamless exchange of knowledge, mitigating data and heterogeneity problems of the model. Moreover, we propose a cosine similarity penalty in the loss function of CVAE+ to enhance the generalizability of CVAE for non-IID scenarios, improving the adaptability and efficiency of the framework. Additionally, our framework's design incorporates a codesign with Radio Access Network (RAN) architecture, reducing the fronthaul traffic volume and improving scalability. Extensive evaluations of one image and two IoT datasets demonstrate the superiority of Fed2KD+ in achieving higher accuracy and faster convergence compared to existing methods, including FedAvg, FedMD, and FedGen. Furthermore, we also performed hardware profiling on Raspberry Pi and NVIDIA Jetson Nano to quantify the additional resources required to train the unified and CVAE+ models.

5 - Estimation and Interpretation of the Effects of Process Variables in High-Temperature Superconductor tape manufacturing

Yisha Xiang, University of Houston, Houston, TX, United States, Yifan Huang, Zhigen Zhao

Improving the quality of the high-temperature superconductor (HTS) tapes is key to its commercialization. Identifying the significant process variables and interpreting their effects on the quality of the tape is important for the production. Stepwise linear regression is suggested to pinpoint the important predictors. Principal Component Analysis was employed to determine a few uncorrelated linear combinations of the process variables that account for most of their variation. There are some major drawbacks to these existing approaches, including the linearity assumption and underutilization of the response variable. To address these issues, we will develop a model-free screening and estimation method to identify critical process variables and find a sufficient low-dimensional representation for ultra-high dimensional data to assess the quality of the tapes.

1 - Physics-Informed Multi-Scale System Reliability Modeling and Digital Twins in Multi-Layered Smart Grid Networks

Phat Huynh, North Carolina A&T State University, Greensboro, NC, United States, Trung Le

Smart grid systems, characterized by their intricate multi-layered architectures and susceptibility to cascading failures, demand a novel approach to reliability modeling that incorporates both real-time data and comprehensive system dynamics. This study bridges significant gaps in existing methodologies by introducing a sophisticated, physics-informed multi-scale modeling framework that leverages the synergy between stochastic system dynamics models and digital twin technology. In our methodology, we first formulate the problem by identifying the stochastic nature of grid failures and the cascading effects that can result from interdependencies across different layers of the grid. We develop a set of differential equations that describe the physics of electrical flow and the conditions leading to system instabilities, informed by historical PMU data and failure logs. Using this foundation, we construct a physics-informed stochastic system dynamics model that simulates the interaction between different grid components and their failure mechanisms. This model quantitatively predicts the likelihood and impact of cascading failures by simulating various failure scenarios under different conditions. To dynamically integrate these simulations with real-time operational data, we implement a digital twin of the smart grid. This digital twin serves as a high-fidelity surrogate model, continuously updated with real-time PMU data. It not only simulates current grid conditions but also forecasts future states under potential stress scenarios. This study not only advances the field of system reliability but also sets a robust framework for the application of physics-informed modeling and digital twins in complex, interconnected energy systems.

2 - Adaptive Multi-scale Threshold Modeling for Intermittency Dynamics by Multivariate Koopman Spectral Analysis: A Case Study in Pathophysiological Processes of Obstructive Sleep Apnea

Viet Nguyen Ca Hoang, University of South Florida, Tampa, FL, United States, Ethan Kessler, Phat Huynh, Trung Le

This study introduces a comprehensive framework to address the intermittent and complex nature of obstructive sleep apnea (OSA). We propose a novel approach that integrates multivariate time series analysis with adaptive multi-scale dynamics to improve detection and prediction of intermittent physiological events characteristic of OSA. Our methodology begins with state space reconstruction using Takens' embedding theorem on high-dimensional physiological data to capture intrinsic system dynamics, including temporal interactions. We then implement multi-scale entropy analysis to quantify signal complexity across temporal scales, which is crucial for identifying transient dynamics and distinguishing between stable and unstable respiratory phases indicative of OSA episodes. Analyzing signal complexity at multiple scales provides a more nuanced understanding of OSA's intermittent nature, enabling precise identification of critical transitions in breathing patterns. Central to our framework is an advanced adaptive threshold model based on autoregressive techniques. This model dynamically adjusts detection thresholds in real-time, tailored to the multivariate and multi-scale physiological data, through an algorithm that forecasts future states of intermittency using linear and non-linear autoregressive models. This adaptive approach accommodates patient-specific variability and the non-stationarity nature of OSA-related signals. Our integrated approach, validated on a diverse dataset of OSA patients, demonstrated a 40% increase in detection sensitivity over traditional models and adaptability to evolving OSA dynamics. This research advances physiological monitoring and diagnostic analytics by providing a robust, scalable, and adaptive tool for managing OSA. It sets new standards in predictive modeling of complex health conditions, paving the way for innovations in medical technology and patient care.

3 - Longitudinal Survival Analysis in Traumatic Brain Injury Cohorts with Diverse Obstructive Sleep Apnea Endophenotypes

Tien Truong, University of South Florida, Tampa, FL, United States, Phat Huynh, Trung Le

Traumatic Brain Injury (TBI) and Obstructive Sleep Apnea (OSA) are significant public health concerns due to their high incidence and complex interdependencies which impact patient rehabilitation and outcomes. This study identifies OSA-TBI endophenotypes and analyzes their survival patterns and readmission factors to improve patient management and outcomes. Our methodology integrates innovative steps, utilizing advanced clustering algorithms to analyze clinical, physiological, and behavioral data, identifying unique patient endophenotypes with shared characteristics, and enhancing the precision and applicability of survival models for patients with combined OSA-TBI. Subsequently, employing state-space models, we develop a dynamic survival analysis framework that incorporates time-varying health states and continuous health monitoring data, allowing for real-time adjustments based on patient condition changes. We integrate hospital readmission data as a dynamic covariate within the survival model, examining its influence on patient outcomes across endophenotypes, and validate the models using advanced statistical techniques to ensure robustness and reliability. Preliminary results show significant variations in survival rates and readmission causes among OSA-TBI endophenotypes, with dynamic survival models outperforming traditional static models in predicting short-term and long-term patient outcomes. Integrating cluster analysis with dynamic modeling provides a comprehensive view of patient trajectories and risk factors, enabling tailored interventions, while the novel use of state-space models for real-time data integration advances predictive analytics for complex health conditions. This study advances survival analysis in complex clinical scenarios, providing tools to understand and predict TBI and OSA co-morbidity trajectories, and offering endophenotype-based insights to improve personalized care and reduce unnecessary readmissions.

4 - Tests for Homogeneity of Component Lifetime Distributions Based on System Lifetime Data

Tony Ng, Bentley University, Waltham, MA, United States, Jingjing Qu

In system reliability engineering, systems are made up of different components, and these systems can be complex. For various purposes, engineers and researchers are often interested in the lifetime distribution of the system as well as the lifetime distribution of the components that make up the system. In many cases, the lifetimes of an n-component coherent system can be observed, but not the lifetimes of the components. In recent years, parametric and nonparametric inference for the lifetime distribution of components based on system lifetime lifetimes has been developed. In this talk, we discuss the problem of testing the homogeneity of component lifetime distributions based on system lifetime data with known system signatures. Existing test procedures for the homogeneity of component lifetime distributions based on complete system lifetime data are reviewed. Then, several nonparametric testing statistics based on the empirical likelihood method are proposed for testing the homogeneity of two or more component lifetime distributions. Both complete and Type-II censored system lifetime data will be considered. The performance of the proposed empirical likelihood ratio tests is compared with other parametric and nonparametric tests in the literature. Finally, some concluding remarks and possible future research directions are provided.

Location Models

Invited Session

Location Analysis

Chair: Zvi Drezner, California State University Fullerton, Fullerton, CA, United States

1 - Optimizing Shape and Compactness

Alan Murray, University of California at Santa Barbara, Santa Barbara, CA, United States

Geographic shape has long been an intriguing feature of observed and defined facets of an area or region. Compactness reflects a critical element of shape with important practical and policy implications for urban form, trade and service provision, political representation and physical phenomena. While there has been much study of compactness and a wealth of measures and metrics derived to reflect nuances of geographic form, questions remain about their ability to characterize shape in a meaningful manner. This paper reviews representative measures compactness, examining both theoretical and practical issues as well as utilization in optimization.

2 - Locating Obnoxious Facilities With Variable Capacities

Zvi Drezner, California State University Fullerton, Fullerton, CA, United States

The problem of locating facilities that have a negative impact on surrounding communities was initiated about 50 years ago, and intensively analyzed in the literature. In the models proposed in the literature, it is assumed that all facilities have the same capacity (size). We propose to construct facilities of different capacities. Facilities located in open areas are far from communities and can be larger without impacting the most affected community. It allows facilities close to communities to be smaller without changing the total capacity and significantly reduces the negative impact on the most affected community. Such an important extension leads to a more complicated formulation that we were able to simplify. The simplified formulations resulted in much better solutions in shorter run times than the more complicated formulations. The specially designed algorithms proposed in this paper find much better configurations than those found for facilities that have the same capacities. In extensive computational experiments we found in some cases that the negative impact on the most affected community is reduced by more than 50% when facilities of different capacities are established.

3 - On Fairness-Efficiency Trade-offs in Service Network Design

mina torabi milani, University of Waterloo, Waterloo, ON, Canada, Hossein Abouee Mehrizi, Hamid Arzani, Saeed Ghadimi

In urban regions, budget-constrained service providers often face critical trade-offs between efficiency and fair access to service for individuals. In this paper, we study a service network design and resource allocation problem, where the service provider should serve the demand of customers residing along a line segment by deciding on the number of service facilities to locate, their locations, and the resources allocated to each, while adhering to budget constraints. Customers seeking service are self-interested, i.e., each aims to minimize their disutility, expressed as the sum of their travel and wait costs. We focus on two service providers: the efficient (i.e., utilitarian) provider, whose goal is to minimize the expected total disutility of customers, and the fair (i.e., egalitarian) provider, who aims to minimize the maximum disutility between the customers. We demonstrate that when the wait cost dominates the travel cost, the optimal fair policy closely follows the optimal efficient policy. In the regions where two policies disagree, we analyze the relative efficiency loss, namely the price of fairness (POF), associated with the fair provider. We derive analytical bounds on the POF for a broad class of demand distributions. We also examine how the spatial distribution of the population affects the POF, showing that a more dispersed distribution generally results in a lower POF.

Moreover, we observe that a population concentration near the urban center reduces the POF under some conditions. Conversely, in some cases, the POF decreases as the population concentration moves away from the center.

4 - Heterogeneous Directional Sensor Coverage Problem

Enbo Zhou, University of California, Santa Barbara, Santa Barbara, CA, United States, Alan Murray

Sensor network placement is critical for addressing a range of urban issues and concerns, including security surveillance, ecological observation, traffic monitoring, internet of things, and others. The appropriate deployment of a sensor network can increase system efficiency and reduce operation costs. Most existing studies assume identical sensors with isotropic coverage. However, sensors may be heterogeneous in practice because of different purchase time, budget limit and application requirements. Heterogenous sensors may have different specifications in viewing radius, field of view, operational spectrum and battery longevity, among others. It remains a question how to strategically select the sensor type, location, and orientation for a sensor network. To address these issues, a spatial optimization model is developed to simultaneously consider sensor type, location, orientation, and occlusion. Visibility analysis by sensor type is an important spatial component. Further, a finite dominating set can be derived for each sensor orientation, enabling linear integer program to be formulated. The proposed model is applied to a surveillance camera deployment case study on the UC Santa Barbara campus, demonstrating its effectiveness. The results highlight a holistic solution approach for sensor network planning, security surveillance, and emergency response.

5 - A Machine Learning Enhanced Column Generation in Location-Allocation with Equity Consideration for Efficient Vaccine Distribution

Kuangying Li, North Carolina State University, Raleigh, NC, United States, Hiruni Niwunhella, Leila Hajibabai, Ali Hajbabaie

This study presents a maximal covering location-allocation problem, formulated as mixed-integer linear model, that aims to minimize the total cost of vaccine distribution and maximize vaccine allocation to population blocks including equity constraints for age, race, and gender groups. A modified Voronoi diagram technique embedded in a Lagrangian relaxation framework is employed to solve the problem. A set of empirical case studies in Pennsylvania are conducted based on the real-world data obtained from the Centers for Disease Control and Prevention (CDC) and health department websites. The numerical experiments indicate that the proposed model can solve the problem effectively and outperform those of a benchmark column generation technique. While these methods effectively tackle the distribution problem, they both experience significant CPU times due to complex decision variables and extensive data. Therefore, this study proposes a machine learning-enhanced column generation method to improve computational efficiency while preserving solution quality, effectively reducing runtime and maintaining an acceptable optimality gap in vaccine distribution. The preliminary results indicate that the proposed approach can effectively solve the problem and outperform the solutions obtained from our prior work. The enhanced performance results from using predictive analytics within the machine learning process, which significantly improves the model’s capacity to manage the complexities associated with integer decision variables.

Optimization and Decision Models

Flash Session

Chair: Alex Savachkin, UNIVERSITY OF SOUTH FLORIDA, Tampa, FL, United States

1 - Forecasting Intermittent & Declining Demand in the End-of-Life Phase

Robyn Goldsmith, Lancaster University, Lancaster, United Kingdom, Anna-Lena Sachs

Across a number of sectors, after-sales services constitute a billion-dollar business. Final purchases are high stake decisions of particular importance for the aftermarket business. They are often made towards the end of the spare part life cycle and need to balance shortages and over-ordering so as to sustain demand for the rest of a part’s life. In the automotive industry, among others, this period can extend for as long as ten years.

Forecasting in order to make effective final purchase decisions is made difficult by the nature of the demand. A large majority of spare part inventories consist of items with intermittent demand structures, where in some periods no demand is observed at all. As a result, standard forecasting methods provide inaccurate forecasts for intermittent items. As final purchase decisions are frequently made to sustain demand several years into the future, modelling procedures should also be designed to include the decay in demand as time passes. A forecasting model that accounts for aspects of both decline and the intermittency of demand are the subject of this talk.

2 - Kondo

Ankit Jain, Amazon, Bellevue, WA, United States

Amazon's inventory is the result of complex stochastic decision-making processes that consider various economic, supply chain, and operational factors. These decisions are aimed at delighting customers by providing them with a wide range of selection at affordable prices with speedy delivery and lower cost to serve. However, until recently, there has not been a direct way to link the amount of inventory held with customer experience (delivery speed) and cost to serve the customers and audit these decision-making processes in a scalable way.

In our research, we focus on outbound shipping cost which is one of the main components of cost to serve. One of the key findings of our research is that inventory that optimizes for customer experience already captures most of the outbound shipping cost savings opportunity. Hence, from an inventory perspective, optimizing for customer experience is similar to optimizing for outbound shipping cost. Our approach is unique in that we use machine learning in combination with observational data patterns to uncover the relationship between inventory outcomes, customer experience and outbound shipping cost in a scalable way.

3 - A constraint programming approach to resource allocation for tour group travel planning

Xinran Ma, Mobi Systems, Somerville , MA, United States, Edmund Williams, Cheng Fang, Jacob Broida, Peng Yu

Tour and travel planning is one of the leading industries, accounting for approximately 10% of the world's GDP. The problem of tour group planning is particularly challenging for providers. Given an inventory of hotel rooms and restaurant places, the provider is required to allocate room and meal reservations to groups of travellers, and construct itineraries for places of interest consistent with timing constraints and travel routing times.

We decomposed the problem into two subproblems, one of allocating the resources, and one of itinerary construction given the chosen hotel and restaurants. At the top level, we map the resource allocation problem to one of bin packing. We then check for the feasibility of the resource allocation with respect to the travel time constraints, by formulating the itinerary creation problem as a vehicle routing problem with time windows. We iteratively generate resource allocations, guided by results of the bottom level, and use local search to improve solutions.

We will provide a detailed description of the encoding, as well as the solution method. We will provide an evaluation of the approach on datasets of hotels, restaurants, and places of interest inspired by real-world tour group travel destinations.

4 - Linear programming optimization model for repetitive prefabricated construction projects considering renewable resource categories

Dingfeng Yang, Huazhong University of Science and Technology, Wuhan, China, People's Republic of

Prefabricated construction refers to buildings where prefabricated components are produced in factories and then transported to construction sites for sequential assembly by lifting.The construction of multi-building, multi-story projects is a repetitive project. In traditional Resource-Constrained Project Scheduling Problems in repetitive activities projects(RCPSP-RA), renewable resources typically refer to those available for all tasks and units within the project. However, in prefabricated construction projects, due to resource complexity, their working scope needs consideration. For example, tower cranes are limited to tasks within their jib's reach, climbing frames and hoists operate within a single building. Therefore, this paper categorized renewable resources into four types: tower crane resources, building resources, crew resources, and global resources. Additionally, a new precedence relationship—spatial precedence relationship—was proposed to describe the relationship between different tasks on adjacent floors.Subsequently, a bi-objective linear programming model was constructed to schedule the start times of each activity, aiming to minimize both the project duration and the interruption time of crews, without violating feasibility constraints.The model was developed in three main phases: 1) identifying input data, 2) optimizing the constraints schedule of repetitive units by determining decision variables, formulating objective functions and constraints, and 3) visualizing output results.Finally,one case study of prefabricated building was analyzed to evaluate the model performance.Moreover,The model provided practitioners with a clear framework and could also serve as a guide for newcomers to understand and extend scheduling problems in prefabricated repetitive projects.

5 - Leveraging Smart Contracts to Improve Construction Supply Chain Agility During Emergencies

Zhujun Wang, School of Management, Xi’an Jiaotong University, Xi'an, Chile, Qin Su , Miroslaw Skibniewski

Construction projects belong to capital-intensive industries, and the structure of the construction supply chain is complex, making it susceptible to external factors. Typically, multiple stakeholders are involved in the construction supply chain, each with unique and sometimes overlapping business interests. Consequently, the supply chain often struggles to respond swiftly to emergencies, potentially leading to significant economic losses.

This paper introduces a smart contract prototype designed to enhance the agility of the construction supply chain during emergencies. This prototype, deployed on a blockchain, effectively links all stakeholders within the supply chain into a unified community. This integration significantly improves the efficiency and trust level of information transmission throughout the chain. Additionally, the prototype integrates with group decision-making models external to the blockchain platform, enabling all stakeholders in the supply chain to participate in decision-making. This integration fosters the alignment of stakeholder interests and facilitates the formation of well-consented decisions rapidly to manage emergencies effectively. The smart contract prototype can automatically execute decision results and log all transaction information for stakeholders to review. This paper employs Ethereum to simulate the prototype, demonstrating its practical viability.

This research contributes a novel smart contract-based solution to managing emergencies within construction supply chains, thus improving their collaborative efficiency and operational agility. Future studies are encouraged to explore the design of information transparency levels within the smart contract prototype to enhance its real-world applicability.

6 - Modeling Antiviral Resistance for Mitigating Pandemic Influenza Outbreaks

Alex Savachkin, University of South Florida, Tampa, FL, United States, Sandro Paz

The response to the next pandemic influenza will likely include extensive use of antiviral drugs, which will create significant selective pressure for the emergence of antiviral resistant strains. The existing literature has inadequate decision models to support mitigation of a pandemic influenza born by an antiviral resistant strain. We present a large-scale simulation optimization model for developing dynamic antiviral strategies including treatment of symptomatic cases and chemoprophylaxis of pre- and post-exposure cases. The model considers an oseltamivir-sensitive strain and a resistant strain with low/high fitness cost, induced by the use of the several antiviral measures. The model is tested on a hypothetical regional outbreak, involving more than one million people.

1 - Aircrew Scheduling Optimization

Coralys Colon-Morales, MIT Lincoln Laboratory, Woburn, MA, United States

Personnel scheduling is a well-known challenge across a wide variety of domains. Our work on Puckboard demonstrates a real-world application of personnel scheduling to flight crews in the U.S. Air Force. We utilize both linear & constraint optimization techniques to recommend air-crew based on factors such as legality, currency, and training history. Additionally, we encode a number of domain specific constraints such as flying time limits and instructor waivers. Using real personnel, mission, & training data, we provide optimal crew sets to the scheduler for review along with justification statements for explainability. As the application is used by schedulers, their assignment decisions are recorded alongside the recommendations of our algorithms, allowing for both refinement of the constraints and user workflow adjustments to ensure optimal and robust schedules.

2 - An Optimally Controlled Spatially-directed SIRS Epidemiology Model Driven by Multifractional Brownian Noise

Steven Kusiak, MIT Lincoln Laboratory, Lexington, MA, United States

The COVID-19 pandemic emphasized the important need for robust forecasting and advanced modeling frameworks that better describe the spread of highly contagious diseases in complex environments and under considerable uncertainty. Equally important, or more so, the pandemic revealed the need for tools that can leverage such models and determine the optimally balanced use of non-pharmaceutical interventions that can assist in controlling the spread of disease while simultaneously allowing for maximal in-class school engagement, in-office work, and worldwide production and delivery of critical goods and services. We present a novel analytical framework that casts generalized stochastic Susceptible-Infected-Recovered (SIR)-like compartmental disease models driven by time-dependent fractional Brownian noise into deterministic time evolutionary forward and backward partial differential equations whose solutions may be controlled. The model has allowed us to create an optimal control framework that provides the best tradeoff between an acceptable and controlled degree of disease spread with the largest amount of population interaction and migration between population centers. The model sheds much insight into the dynamic nature of diseases such as COVID-19 and provides a computational tool that determines optimal actionable policies in support of pandemic management under considerable uncertainty.

3 - The Backbone of Global Reach: Air Refueling Scheduling Algorithms for Air Campaign Modeling

Jesse Pietz, MIT Lincoln Laboratory, Lexington, MA, United States, Coralys Colon-Morales

In order to estimate the demand for refueling aircraft, U.S. Air Force planners must model air campaign scenarios. In each scenario refueling aircraft are scheduled to meet the fuel needs of receiver aircraft. This modeling effort leads to a difficult vehicle routing optimization problem that must be solved quickly as planners iterate through a large collection of scenarios. This presentation highlights key features of this refueling aircraft routing problem and describes a benchmark greedy algorithm that is used to compute high-quality solutions. In order to improve solution quality and decrease runtime, five algorithm variants are considered. Algorithms are tested against a library of 4,000 randomly-generated scenarios, and numerical results are presented to illustrate relative algorithm performance.

4 - Vehicle Routing Problem Approach for Improving Fuel Delivery Scheduling to Austere Sites

Brian Lemay, United States Air Force Academy, Colorado Springs, CO, United States, Jared Stewart, Kate Leonard, Gentry Lamb, Jack Heller, Sophie Allen

The 96th Logistics Readiness Squadron at Eglin Air Force Base, Florida conducts an average of 55 million gallons of annual refueling operations across the 464,000-acre Eglin Reservation. Currently, ground refueling operations plans generate suboptimal refueling routes, negatively affecting fuel consumption and operational costs. To improve the efficiency of the refueling operations, we created a data-driven scheduling tool inspired by the Vehicle Routing Problem. The study focuses on 20 sites across the reservation. When applying our scheduling tool to historical refueling operations, we find there are opportunities to significantly reduce mileage on refueling vehicles. The study aims to validate the effectiveness of the proposed tool by comparing suggested routes with current operations and offering actionable recommendations for future fuel distribution logistics. The analysis revealed an average of 6,650 miles saved per year. The scheduling tool's flexibility allows for adapted use on other installations and different operations.

1 - Digitized Indian Micro-Grocery Transactions Reveal that Grain Subsidies Reduce Junk Food Buying by Low-Income Shoppers

Kamalini Ramdas, London Business School, London, United Kingdom, Ali Aouad, Alp Sungu

What foods do people living on under :$2 a day buy? How do food subsidies affect their food shopping? The digitization of 39 micro-retail groceries and food vendors in a Mumbai settlement via installing point-of-sale scanners provides novel and objective data on individual shoppers' grocery transactions. Our data reveal that individuals residing in households with children {purchase} significantly more junk foods, and our experimental evidence suggests that staple food subsidies cause demand substitution towards a healthier diet. Based on over half a million food transactions made by 23,717 consumers, snacks, sugar and soft drinks represent 14.5 percent of food spending in our grocery stores, while rice and wheat combined are 15.6 percent. We randomized 1,255 settlement residents into a weekly rice-and-wheat subsidy disbursed via a government-like subsidy store – or none, for six weeks. Treated subjects substituted away from packaged snacks, sugar and soft drinks spending by 20 to 30 percent more than untreated subjects and increased spices and accompaniments spending by over 30 percent more, with strongest effects for those in households with children. Overall food spending, calories, and nutrients from purchased foods remained unchanged, indicating that the subsidy likely increased the total demand for food and total consumed nutrients.

2 - Load Estimation, Optimal Sizing, and Simulation of Micromobility-to-Microgrid Systems for Health Facility Electrification

Rebecca Alcock, University of Wisconsin–Madison, Madison, WI, United States, Justin Boutilier

Persisting energy poverty in healthcare facilities endangers patients and providers alike by limiting available services and creating poor working conditions. For clinics not yet connected to a traditional power grid, distributed clean energy solutions are the timeliest and most climate-resilient option. However, without accessible and relevant renewable energy design tools, these facilities must wait for grid connection or turn to carbon-based decentralized alternatives. Motivated by the urgent and widening nature of the energy-health crisis, we are developing a toolkit to optimally design a solar, storage, and e-vehicle network for never-before-electrified health facilities. The toolkit comprises three components: 1) predictive analytics for parameter generation, 2) prescriptive analytics to size the energy system, and 3) simulation to evaluate long-run performance under changing climate and healthcare conditions. We explore the results of the toolkit for a case study in rural Colombia.

3 - Estimating Heterogeneous Treatment Effects in Panel Data

Emily Zhang, Massachusetts Institute of Technology, Cambridge, MA, United States, Retsef Levi, Elisabeth Paulson, Georgia Perakis

This work addresses a core problem in causal inference: estimating heterogeneous treatment effects with complex intervention patterns using panel data. Motivated by our ongoing collaboration with the Massachusetts Department of Transitional Assistance (DTA), our methodology also extends to broader applications. Specifically, we make the following contributions. 1) We develop a novel causal inference method for this complex setting. 2) Our theoretical results establish the convergence of the resulting estimates. 3) We perform computation experiments on synthetic data, demonstrating that our method achieves superior accuracy compared to current state-of-the-art approaches. These analytical and computational findings reinforce our confidence in the method's reliability for real-world applications.

4 - Notifications and Social Media Activity: Evidence from a Field Experiment

Ananya Sen, Carnegie Mellon University, Pittsburgh, PA, United States, Alp Sungu, Saharsh Agarwal

Policymakers and social media platform managers coming to terms with digital addiction and its adverse societal consequences. Legislation (eg. SMART) being put forward that suggest design based interventions (eg no infinite scroll) to curb problematic social media use. We examine the impact of regulating people's access to social media notifications on their digital activity and well being. We focus on the behavior of teenagers, which has been the focus of policy conversations.

Notifications offer `intermittent variable rewards', and thus have all the necessary ingredients to trigger fear of missing out (FOMO). We implement a field experiment to analyze the impact of regulating notifications on real digital activity, including cross-app substitution. We recruit a large sample of teenagers in India that allows us to provide a rich understanding of the impact of such a policy recommendation. We also aim to benchmark these effects against session-specific time limits that aim to limit infinite scrolling. Individuals are heterogenous in their self-control and self-regulation abilities, and we also examine how these differences influence their susceptibility to the addictive effects of social media notifications. Not all notifications are the same, and we examine how the different types of social media notifications (e.g., likes, comments, direct messages) contribute to impulsive social media use. Finally, we look at the effect of treatment reversal by analyzing what happens to social media activity when the regulation on notification delivery is lifted. Answers to these questions will help quantify existing welfare losses driven by social media notifications.

Combinatorial Auctions / LLMs

Invited Session

Auctions and Market Design

Chair: Benjamin Lubin, Boston University, Boston, MA, 02215, United States

1 - Multidimensional Mechanism Design with Side Information

Siddharth Prasad, Carnegie Mellon University, Pittsburgh, PA, United States, Nina Balcan, Tuomas Sandholm

We develop a general tunable framework for multidimensional mechanism design with side information to boost revenue while preserving efficiency and incentives. Side information can come from a variety of sources— examples include advice from a domain expert, predictions from a machine-learning model trained on historical agent data, or even the mechanism designer's own gut instinct—and in practice such sources are abundant. We design a tunable mechanism that integrates input side information with an improvement of the classical VCG mechanism. The welfare, revenue, and incentive properties of our mechanism are characterized by a number of novel constructions we introduce based on the notion of a weakest competitor, which is an agent that has the smallest impact on welfare. When side information is of reasonably high quality and our mechanism is tuned well, it extracts welfare and revenue competitive with the total social surplus, and its performance degrades continuously and gradually as both the quality of the side information and the mechanism tuning worsens.

Time permitting, I will discuss computational challenges that arise when applying our approach to combinatorial auctions.

2 - Ad Auctions for LLMs via Retrieval Augmented Generation

Sébastien Lahaie, Google Research, New York, NY, United States, Suho Shin, Keivan Rezaei, MohammadTaghi Hajiaghayi

In the field of computational advertising, the integration of ads into the outputs of large language models (LLMs) presents an opportunity to support these services without compromising content integrity. This paper introduces novel auction mechanisms for ad allocation and pricing within the textual outputs of LLMs, leveraging retrieval-augmented generation (RAG). We propose a segment auction where an ad is probabilistically retrieved for each discourse segment (paragraph, section, or entire output) according to its bid and relevance, following the RAG framework, and priced according to competing bids. We provide a theoretical analysis of the efficiency, revenue, and incentive properties of various pricing rules, including a characterization of the incentive-compatible pricing scheme. An empirical evaluation validates the feasibility and effectiveness of our approach.

3 - Pricing Valid Cuts for Walrasian and Price-Match Equilibria

Robert Day, University of Connecticut, Storrs, CT, United States, Benjamin Lubin

In a combinatorial auction, there is often no vector of prices for the items being auctioned that constitutes a Walrasian equilibrium, in which all bidders prefer their allocated bundle and excess supply items are priced at zero. We use valid inequalities (cuts) of the binary integer program for winner determination as "artificial items" that can be interpreted intuitively and priced to generate an "Artificial Walrasian Equilibrium." We show that the lack of an integer programming gap is not a sufficient stopping criterion for cut generation to arrive at a "Price-Match Equilibrium" and provide examples where this refinement differs from natural Walrasian equilibrium. We prove the existence and characterize "Artificial Walrasian Equilibria" and prescribe "Minimally Artificial Price-Match" payments as a desirable equilibrium selection.

4 - Truthful Aggregation of LLMs with an Application to Online Advertising

Ermis Nikiforos Soumalias, University of Zurich, Zurich, Switzerland, Michael Curry, Sven Seuken

We address the challenge of aggregating the preferences of multiple agents over LLM-generated replies to user queries, where agents might modify or exaggerate their preferences. New agents may participate for each new query, making fine-tuning LLMs on these preferences impractical. To overcome these challenges, we propose an auction mechanism that operates without fine-tuning or access to model weights. This mechanism is designed to provably converge to the output of an optimally fine-tuned model as computational resources are increased.The mechanism can also incorporate contextual information about the agents when available, which significantly accelerates its convergence. A well-designed payment rule ensures that truthful reporting is the optimal strategy for all agents, while also promoting an equity property by aligning each agent’s utility with her contribution to social welfare, an essential feature for the mechanism's long-term viability. While our approach can be applied whenever monetary transactions are permissible, our flagship application is in online advertising. In this context, advertisers try to steer LLM-generated responses towards their brand interests, while the platform aims to maximize advertiser value and ensure user satisfaction. Experimental results confirm that our mechanism not only converges efficiently to the optimally fine-tuned LLM but also significantly boosts advertiser value and platform revenue, all with minimal computational overhead.

Logistics Optimization: Routing and Delivery

Flash Session

Chair: Dawei Chen, Eindhoven University of Technology, Eindhoven, 5612AH

1 - A Deep Reinforcement Learning Approach for the Dynamic Travelling Salesman Problem with Time-Dependent and Stochastic Travel Times

Dawei Chen, Eindhoven University of Technology, Eindhoven, Netherlands, Christina Imdahl, David Lai, Tom Van Woensel

We introduce a novel approach using deep reinforcement learning to tackle the Dynamic Traveling Salesman Problem with Time-Dependent and Stochastic travel times (DTSP-TDS). The main goal is to dynamically plan the route with the shortest tour duration and visit all customers while considering the stochastic nature of travel times. We employ a reinforcement learning approach to dynamically address the stochastic travel times to observe changing states and make decisions accordingly. Our reinforcement learning approach incorporates a Dynamic Graph Temporal Attention model (DGTA) that dynamically extracts information from the stochastic environment. We have tested the performance of our proposed approach on the simulation. Our approach can quickly provide high-quality solutions for all datasets using limited computing resources. The efficiency testing on different models demonstrates that new components in the DGTA model, such as the selection mechanism, dynamic attention component, and temporal pointer, can improve the performance. These findings highlight the importance of incorporating stochastic elements in the model to achieve better performance. Furthermore, the DGTA model with one set of trained parameters exhibits generalization capability to different instances with varying customer locations and uncertainty levels of travel times without requiring additional training time. Our work contributes to advancing the field of DTSP-TDS, with potential applications in various industrial and logistic problems.

2 - Equitable Routing - Rethinking the Multiple Traveling Salesman Problem

Kaarthik Sundar, Los Alamos National Laboratory, Los Alamos, NM, United States, Abhay Singh Bhadoriya, Deepjyoti Deka

The Multiple Traveling Salesman Problem (MTSP) with a single depot is a generalization of the well-known Traveling Salesman Problem that involves an additional parameter, namely, the number of salesmen. In the MTSP, several salesmen at the depot need to visit a set of interconnected targets, such that each target is visited precisely once by at most one salesman while minimizing the total length of their tours. An equally important variant of the MTSP, the min-max MTSP, aims to distribute the workload among salesmen by requiring the longest tour of all the salesmen to be as short as possible. The min-max MTSP appears in real-life applications to ensure a good balance of workloads for the salesmen. It is known in the literature that the min-max MTSP is notoriously difficult to solve to optimality due to the poor lower bounds its linear relaxations provide. In this paper, we formulate two novel parametric variants of the MTSP called the "fair-MTSP". One variant is formulated as a Mixed-Integer Second Order Cone Program, and the other as a Mixed Integer Linear Program. Both focus on enforcing the workloads for the salesmen to be equitable, i.e., the distribution of tour lengths for the salesmen to be fair while minimizing the total cost of their tours. We present algorithms to solve the two variants of the fair-MTSP to global optimality and computational results on benchmark and real-world test instances that make a case for fair-MTSP as a viable alternative to the min-max MTSP.

3 - Waste Collection Problem with Turn Penalty, Balanced Clustering, and Visual Attractiveness

Seungyeop Lee, Pohang University of Science and Technology (POSTECH), Pohang, Korea, Republic of, Byung-In Kim

The waste collection problem, a variant of the capacitated vehicle routing problem, involves vehicles making multiple waste disposal stops at landfills along their routes. Traditional objectives of waste collection, which focused solely on minimizing transportation costs, are often unsatisfactory to practitioners due to human perception factors. Acceptable solutions prioritize reducing turns, as garbage trucks spend more time maneuvering at intersections. It is also important to balance individual drivers' workloads and minimize route overlap to meet customer preferences of avoiding multiple visits by garbage trucks to the same locations. To address these challenges, we defined measures for a "nice" solution and proposed a cluster-first, route-second algorithm that considers turn penalties, balanced clusters, and visual attractiveness. We evaluate the algorithm's performance using benchmark datasets and real-world waste collection instances to demonstrate its effectiveness and practicality in waste management applications.

4 - Inbound-Outbound Load Plan Adjustments for Terminals in Parcel Delivery Service Networks

Ritesh Ojha, Georgia Institute of Technology, Atlanta, GA, United States, Alan Erera

The load planning problem is a critical challenge in service network design for parcel carriers: it decides how many trailers or loads to operate between terminals in the service network. The base load plan is usually fixed two weeks before the day of operations. Load planners at the terminals then locally modify the base load plan to adjust their outbound loads as the demand forecast changes over time; these local adjustments are often myopic in nature and result in operational inefficiencies. We consider the joint problem for a cluster of terminals where each terminal has planned inbound and outbound trailers and fixed capacity during each sorting periods. Load planners at each terminal need to decide (1) if they want to divert some of the inbound trailers at their terminal to nearby terminals and, (2) to cut some of the planned outbound trailers. The objective is to optimize outbound transportation cost and balance the sortation workload across the terminals in the cluster such that the flow balance, trailer capacity and sorting capacity constraints are satisfied. We propose a mixed-integer program for the inbound-outbound load planning problem. An extensive computational study demonstrates the utility of the model on real-life data for a cluster of three terminals in Atlanta provided by our research partner, a large U.S. parcel carrier. We provide evidence of the efficacy of our solution approach to generate near-optimal solutions that are implementable in practice.

5 - Electric vehicle milk-run scheduling optimization considering time of use pricing

ZHAO ZHAO, Tianjin University, Tianjin, China, People's Republic of, Yida Xu, Zhaofang Mao, Kan Fang

In manufacturing logistics systems, tow trains perform tasks according to a circular delivery, i.e., transporting goods from storage areas to assembly lines and commonly used among manufacturing companies. Unlike traditional vehicle scheduling problems, electric vehicle scheduling considers not only task assignment but also determines the timing and duration of charging. Additionally our study also considering the characteristic of peak-valley-flat electricity pricing in factory electricity usage, discussing electric vehicle scheduling and charging arrangements under time-of-use pricing, as well as balancing workload among vehicles to enhance fairness. To address these issues, an adaptive neighborhood simulated annealing algorithm is developed and compared with commercial solvers and tabu search algorithms. Experimental results demonstrate that the algorithm described in this paper performs well on medium and large instances. Moreover, the study conducts sensitivity analysis on the cost of vehicle usage, revealing insights into reducing the number of electric vehicles employed while maintaining efficiency. By optimizing both task assignment and charging strategies while considering time-of-using pricing and workload balance, manufacturing companies may achieve cost savings and operational improvements in their logistics systems.

1 - Integrating Human-Centric Approaches in Industry 5.0: A Dynamic Capability Perspective

Golnoush Javan, University of Toledo, Toledo, OH, United States, Benjamin George, Steven Wallace

The advent of Industry 5.0 introduces a transformative era in manufacturing, emphasizing a synergistic collaboration between human intelligence, advanced technological capabilities, and intelligent systems. This paper proposes a conceptual framework grounded in Dynamic Capability Theory to examine the adoption of Industry 5.0 from a high-level business perspective. Our study seeks to identify the essential technological and organizational characteristics required for embracing Industry 5.0, with a particular focus on the core principle of human-centricity and its influence on these characteristics. Utilizing systematic literature review and the Gioia methodology for qualitative research, we categorize and analyze various features of Industry 5.0 to construct a comprehensive understanding of the transition requirements. Our findings delineate three major components: technological features, organizational features, and human-centric features, each contributing to the reintegration of humans into the digital manufacturing process. We also explore the implications of these integrations on competitive advantage, emphasizing the role of dynamic capabilities that adapt and evolve in response to rapid technological advancements. This study contributes to the theoretical discourse by providing a structured analysis of how dynamic capabilities can facilitate a smooth transition to Industry 5.0, highlighting the pivotal role of human-centric approaches in enhancing operational effectiveness and innovation in modern manufacturing environments.

2 - AI capabilities and business value

Rajhans Mishra, Indian Institute of Management-Indore, Indore, India

Artificial Intelligence (AI) has become a popular buzzword in business and academia. Generative AI (GenAI) has further triggered a new dimension for the implementation and usage of AI technologies in business. Various techniques like natural learning processing (NLP), deep learning (DL), large language models (LLM), and computer vision are attributed and recognized as AI techniques. Many leading organizations like Microsoft and Google have come up with generic AI platforms (Azure AI & Copilot from Microsoft and Gemini from Google) that can be used by organizations to implement AI capabilities as their solutions. Besides that, several specific AI solutions are also developed and used in specific domains and functional areas. However, there is a lack in terms of the exact capabilities provided by AI solutions and how they can be used to enhance business value. The scope of AI solutions varies based on the capabilities offered, for example, Narrow AI and Strong AI solutions vary significantly based on their scope. This work will explore the various capabilities provided by AI technologies and how they can be mapped to the business value chain in different domains and functional areas. This exploration will be helpful in uncovering the requirements for AI solutions and the development of AI use cases in different business contexts.

3 - Ensuring the Safety of AI Systems

Young Lee, UL Solutions, Melville, NY, United States, Sudhi Sinha

AI systems offer remarkable benefits to society, including enhancements in wellness, convenience, productivity, efficiency, and innovation. However, if misused or malfunctioning, AI can cause significant harm, both unintentional and intentional. These systems are also vulnerable to malicious attacks that can manipulate their functionality or compromise sensitive data. Additionally, improperly trained AI systems can result in unethical outcomes, particularly impacting specific groups of people. Unsafe AI systems pose risks such as physical harm, financial loss, social disruption, and loss of public trust in AI technologies.

This talk introduces a comprehensive framework for evaluating AI application safety. The framework outlines key principles such as reliability, robustness, transparency, explainability, human oversight, fairness, bias mitigation, and data privacy. It defines essential requirements, guidelines, and procedures for each principle, ensuring AI applications align with the highest standards of safety, regulations, and industry best practices. The approach assesses data handling protocols, performance of machine learning algorithms, adaptive training methodologies, decision-making processes, and the overall integrity and reliability of AI systems.

The framework evaluates the conformance of AI systems with international standards like ISO/IEC JTC 1/SC 42 and IEEE-SA, as well as compliance with emerging regulations such as the U.S. AI Executive Order and the EU AI Act. By bridging the gap between rapid technological innovation and safety standard development, this work ensures AI systems are not only innovative and efficient but also safe, ethical, and trustworthy. Establishing AI system safety is vital for building public trust and ensuring the responsible adoption of beneficial AI technologies.

4 - Emotion vs. Information: Understanding the Effect of AI-powered Call Systems on Potential Customers from A Field Experiment

zhe jing, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Xin Xu, Yong Jin, Jie Shen

Emerging technologies such as neural networks, cloud computing, and big data have paved the way for the development of artificial intelligence (AI), enabling AI to facilitate business operations. However, AI-human interaction tends to fall short of expectations in real-world settings due to the difference between humans and AI from emotional and informational perspectives. To better understand the mechanism resulting in the different impacts on customer behavior between humans and AI, we conducted a randomized field experiment at a call center within a large securities company. Our study focuses on the differences in customer behavior between AI and human agents when initiating outbound calls to potential customers to encourage them to complete the complex process of opening a financial transaction account. The results show that the AI group and human agent group perform similarly but have different effects on customers from different sources and potential customers who are at different stages of the account opening process due to the differences between emotional support and informational support. The findings of this study contribute to the literature on the application of technology in organizations and provide guidance to organizations on how to implement AI systems effectively.

5 - AIoT Service Adoption and Selling Mode Selection Strategies

Bingxuan Wang, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Jun Lin

With the rapid development of information technology across various fields, many enterprises are seeking to harness Artificial Intelligence of Things (AIoT) technology to enhance their operations and bolster profits. This study constructs a game-theoretic model within the e-commerce domain, involving a manufacturer and an e-commerce platform providing AIoT service. We explore the strategic interplay regarding the adoption of AIoT service by the manufacturer under scenarios where the selling mode is determined either independently by the manufacturer and the platform or both of them.Our focal concerns encompass: (1) whether the manufacturer will adopt the AIoT service provided by the e-commerce platform to transform conventional product into smart one, thereby utilizing consumer data to enhance product utility, and(2) how the information value of the collected data impacts the platform, the manufacturer, and societal welfare. Our study reveals that in certain circumstances, the option for the manufacturer to use the platform's AIoT service, will lead to a better performance of the manufacturer, the platform, and the channel. This insight prompts a reassessment of AIoT integration strategies within the supply chain, offering valuable guidance for e-commerce platforms, manufacturers, and policymakers who aim to optimize societal benefits while maintaining operational excellence.

6 - Untangling the Impact of Artificial Intelligence Innovation on Firm's Market Power

Jiawei Xu, College of Economics and Management, China agricultural university, Beijing, China, People's Republic of, Jianjun Lu, Yi Yang

Artificial Intelligence (AI) technology is reshaping the competitive landscape of the market. Consequently, firms are increasingly focusing on AI-related innovation to enhance their market performance. However, existing research has not fully elucidated the market utility of AI innovation. In light of this gap, this study empirically examines the mechanism by which AI innovation impacts firm's market power, through an analysis of data from Chinese listed companies from 2011 to 2022. The results of regression analysis indicate that AI innovation significantly enhances firm's market power. The impact of AI innovation on market power is moderated by industry heterogeneity, with AI innovation exerting a greater market utility in industries characterized by high concentration and non-technological intensity. The mediation effect test results show that AI innovation can elevate market power by increasing positive media attention, alleviating financial constraints, and reducing internal cost stickiness within firms. Furthermore, the results of response surface analysis reveal that radical AI innovations have a more significant effect on market power than incremental AI innovations. This study not only enriches the theoretical research framework of AI innovation but also provides practical insights and theoretical basis for managers to formulate relevant market strategic decisions.

1 - How Does Uncertainty Reduction Increase User Welfare in Cryptocurrency Transaction Market? An Empirical Study on Eip-1559

Guangzhi Shang, Florida State Unviersity, Tallahassee, FL, United States, Xi Zhao, Zhichao Wu, Peilin Ai

Transaction fee is fundamental in maintaining the stability and decentralization of a permissionless blockchain, the infrastructure underlying major cryptocurrency networks such as Ethereum and Bitcoin. Like Bitcoin, Ethereum started with a name-your-own-price style fee mechanism. Under this Legacy mechanism, we demonstrate that, surprisingly, only three quarters of the transaction fee is necessary for users to attain the service quality they receive; the remaining one-quarter thus constitutes welfare loss. In August 2021, Ethereum implemented a fee mechanism change. Together, the Legacy methods and the new scheme, which we call Cap-Tip, describe the two most widely used fee mechanisms in all major permissionless blockchains. We explain the innovations embedded in the Cap-Tip mechanism through the lens of information quality and task decomposition. Collecting over 123 million transactions covering the change period, we estimate the causal impact of Cap-Tip on welfare improvement using a doubly robust difference-in-difference estimator that accommodates heterogeneity across timing of and exposure after adoption. The result is an astounding 80% reduction in welfare loss, achieved by users only six days after adoption. Interestingly, we also find that adoption benefits small users more than large ones, alleviating fee disparity and improving fairness. We theorize this difference through user experience and the overconfidence bias. Our study offers a novel operational perspective to unpack how the arguably most significant fee mechanism change in the blockchain space affects user welfare.

2 - Market Fragmentation in Cryptocurrency Exchanges

Wei Chen, University of Connecticut, Stamford, CT, United States, Xiaofeng Liu, Kevin Zhu

This research delves into the repercussions of cryptocurrency exchange market fragmentation. We focus on the effects of new market entrants, both CEXs and DEXs, on the aggressiveness of token pair orders and the resultant price impact. Our findings reveal distinct influences exerted by CEXs and DEXs. While both augment trade volume (in USD) and elevate order submission aggressiveness, the underlying mechanisms diverge. CEXs see an uptick in the number of trades without a corresponding rise in trade size. DEXs, conversely, often report larger individual trades without a surge in their frequency, possibly attributed to substantial blockchain transaction fees and the inherent price predictability due to automated pricing on DEXs. Notably, CEX fragmentation broadens the overall spread, whereas DEXs do not exhibit a significant sway. Furthermore, we find that order aggressiveness increases more for the token pairs with lower pre-entry fragmentation levels, lower trade volume, and linking to non-fiat currencies, while the effects on price impacts are more homogeneous. Moreover, we further extend the analysis to the token level. The results show order aggressiveness is mainly significant at the token pair level, while price impacts from primary tokens also influence associated secondary pairs.

3 - Battle of the Bots: Flash Loans, Miner Extractable Value and Efficient Settlement

Alfred Lehar, University of Calgary, Calgary, AB, Canada, Christine Parlour

Settlement on decentralized ledgers is transparent and batched. The settlement also allows settlement agents to expropriate profitable arbitrage trades. Arbitrage may be socially beneficial or wasteful. We model the effect of an alternate, private settlement on arbitrage. We document payments from arbitrageurs to private settlers that exceed 2 million USD per day.

4 - The Effects of Margin Requirements in Defi Lending Markets

Qiang Wang, Penn State University, State College, PA, United States

This paper investigates the effects of relaxing margin requirements on borrowing decisions in Decentralized Financial lending (DeFi lending) markets. Margin requirements impose leverage constraints by dictating the maximum loan amount relative to the pledged collateral. Using

account-level data, I find that borrowers increase loan balances by 1.6% and collateral holdings by 1.2% in response to a 1% relaxation in margin requirements. Margin requirements disproportionately impact borrowers closer to their leverage constraints. These borrowers take higher leverage following the relaxation. Overall, this paper highlights the role of margin requirements in a credit market without centralized intermediaries.

Revenue Management and Marketplace Operations

Invited Session

Revenue Management and Pricing

Chair: Dmitry Mitrofanov, Boston College, Chestnut Hill, MA, United States

1 - Assortment Optimization with Replacement Options for Retail Platforms with Stockout Risk

Yuheng Wang, Cornell University, USA, NY, United States, Dmitry Mitrofanov, Huseyin Topaloglu

There has been a notable surge of online platforms that operate as market facilitators without having direct control over the inventory of the products they sell. This usually leads to potential out-of-stock situations during order fulfillment. Therefore, such online platforms often prompt the customers to pick not only a preferred option, but also a replacement option. We study assortment optimization problems when the customers are offered assortments of products among which they pick their preferred and replacement options. If the preferred option is available, then they are provided with the preferred option. If the preferred option is not available, but the replacement option is, then they are provided with the replacement option. Otherwise, the customers are provided with no products. We use a version of the multinomial logit model to capture the choice process of the customers. We consider two variants of the problem. In the non-adaptive variant, we compute one assortment of products among which the customers pick their both preferred and replacement options. In the adaptive variant, the assortment of products among which the customer chooses her replacement option depends on the preferred option she picked. We show that both variants are NP-hard. Our main technical contributions are a polynomial-time approximation scheme for the adaptive variant and a fully polynomial-time approximation scheme for the non-adaptive variant. Using data from Instacart, we demonstrate that explicitly modeling the presence of a replacement option and using an adaptive strategy to offer assortments for the replacement option can provide significant revenue benefits.

2 - Anti-Competitive Effects of A Dominant Retailer's Guaranteed Profit Margin and Low-Price Contracts

Aditya Jain, Baruch College, Zicklin School of Business, New York, NY, United States, Leela Nageswaran, Haresh Gurnani

A retailer can insist on a guaranteed margin contract with its supplier, wherein they require a margin on each sale. In addition, they may want to have the lowest selling price in a market with competing retailers, and if this strategy of offering the lowest price reduces their margin, the supplier must pay up the difference. There has been recent debate on whether this approach is anti-competitive leading to higher prices and reduced product access. We analyze a game-theoretic model involving a supplier and two retailers where the focal retailer adopts either the guaranteed margin contract, or the guaranteed margin contract with lowest price guarantee. We show that when product category competition is intense, the guaranteed margin contract is anti-competitive: the supplier forms an exclusive distribution with the focal retailer leading to higher prices and reduced product access in comparison with when they both adopt a wholesale price contract. However, if the intensity of competition is low, consumers benefit by paying lower prices with wider access as long as the supplier sets identical wholesale prices, but prices remain higher when they set differentiated wholesale prices. The guaranteed margin contract with lowest price guarantee, however, is always anti-competitive as it leads to higher prices by dampening competition. As such, the ability of the focal retailer to choose the contract type and the intensity of product category competition leads to outcomes that can either benefit or hurt consumers. Our results help inform policy makers on the necessary interventions to alleviate anti-competitiveness.

3 - Personalized Promotion Planning with Strategic Customers

Ozge Yapar, Indiana University, Kelley School of Business, Bloomington, IN, United States, Chloe Glaeser

We study a dynamic personalized promotion problem for a consumer goods retailer facing strategic, repeat customers. We introduce a modified contextual bandit algorithm with a heterogeneous cost term in the reward estimate to reflect how promotions influence future demand. Validated with proprietary data from an online grocer, our approach highlights the need for personalized pricing strategies that consider strategic customer behaviors like stockpiling. Our algorithm, based on Thompson Sampling, offers a computationally efficient method to navigate the complexities of personalized promotion planning. Through numerical simulations using real-world data, we show that considering strategic behaviors through our modified reward function significantly boosts revenue, particularly when many customers are strategic. This work extends the personalized dynamic pricing literature by integrating strategic consumer behavior with effective promotion strategies.

4 - Online Combinatorial Optimization with Group Fairness Constraints

Kumar Kshitij Patel, Toyota Technological Institute at Chicago, Chicago, IL, United States, Negin Golrezaei, Rad Niazadeh, Fransisca Susan

As digital marketplaces and services continue to expand, it is crucial to maintain a safe and fair environment for all users. This requires implementing fairness constraints into the sequential decision-making processes of these platforms to ensure equal treatment. However, this can be challenging as these processes often need to solve NP-complete problems with exponentially large decision spaces at each time step. To overcome this, we propose a general framework incorporating robustness and fairness into NP-complete problems, such as optimizing product rankings and maximizing sub-modular functions. Our framework casts the problem as a max-min game between a primal player aiming to maximize the platform's objective and a dual player in charge of group fairness constraints. We show that one can trace the entire Pareto fairness curve by changing the thresholds on the fairness constraints. We provide theoretical guarantees for our method and empirically evaluate it, demonstrating its effectiveness.

5 - Bundling and Pricing Decisions for Ancillary Products

Tong Xie, The University of Chicago Booth School of Business, Chicago, IL, United States, Rene Caldentey

Service companies are increasingly using ancillary products as a strategy to enhance their core offerings, increase customer satisfaction, and grow their revenue. Broadly speaking, ancillary products are additional products or services offered to consumers alongside their primary purchase. In many cases, there is a separation between the time a customer purchases a core product (e.g., buys an airline ticket or books a hotel room) and the time of its consumption, most ancillary services can be offered and purchased within this time window. This gap introduces an inter-temporal component to Ancillary Revenue Management, simultaneously creating new opportunities and obstacles for firms aiming to implement it effectively.

We study Ancillary Revenue Management in the presence of consumer risk aversion, focusing on scenarios where there is a temporal gap between the purchase and consumption of products or services. We assume that consumers' valuation for an ancillary product is stochastic and evolves over time, becoming more predictable as the time of consumption approaches. We characterize firm's optimal bundling decisions when every ancillary is either sold in a big bundle or sold separately.

Under constant absolute risk aversion (CARA) utility functions, we demonstrate that as consumers become more risk-averse, a firm's optimal policy shifts from selling ancillaries as a bundle to offering them separately. Furthermore, when multiple ancillary products are involved and the valuations of these ancillaries are independent, the optimal bundling policy for each ancillary can be determined independently. We also examine both myopic and strategic purchasing behaviors on the part of consumers.

Co-Chair: Jinglong Zhao, Boston University, Boston, MA, United States

1 - A Maximum Likelihood Approach to Randomized Trees

Zhiyuan Sun, UCLA, Los Angeles, CA, United States, Velibor Misic

Randomized trees, unlike traditional deterministic trees, offer a novel framework for predictive modeling by splitting data points with a probability that is determined by their feature vectors and specific parameters at each node. This paper introduces a smooth non-convex estimation problem for learning the parameters of randomized trees from data. We establish that optimizing over randomized trees is theoretically equivalent to optimizing over deterministic trees. We develop generalization guarantees for the log likelihood of randomized trees and proved the convergence of the randomized tree MLE problem. We further showed that the problem is NP-hard. Motivated by this, we develop a heuristic algorithm to efficiently optimize the parameters of randomized trees. Our numerical experiments demonstrate the effectiveness of our method in improving predictive performance over classical top-down induction methods such as CART over a variety of binary and multiclass classification datasets.

2 - Bidding in Uniform Price Auctions for Value Maximizing Buyers

Sourav Sahoo, Massachusetts Institute of Technology, Cambridge, MA, United States, Negin Golrezaei

We study the problem of bidding in uniform price auctions, which are widely used in practice. Although uniform price auctions are non-truthful for bidders with quasilinear utility, empirical findings suggest that this auction format induces truthful bidding. We attribute this difference in theory and practice to the assumption of the behavioral model of the bidders. In this pursuit, we study these auctions in a repeated setting from the perspective of a value-maximizing buyer who aims to maximize their cumulative value across T rounds, subject to per-round return-on-investment (RoI) constraints.

For a RoI-constrained value-maximizing buyer, we study a generalized version of the uniform bidding format, commonly used in practice, which we term as m-uniform bidding. To characterize the optimal m-uniform bid, we introduce and study the notion of universally feasible (UF) bidding policies, which are robust, meaning that RoI feasibility is obtained regardless of the competitors' bids. We show that the optimal class of UF bidding policies is essentially a generalization of truthful bidding policies, which depends only on the valuation curve of the bidder and target RoI. To measure the performance of UF bidding policies against the optimal bidding policy that is not necessarily UF, we introduce a metric called the Price of Universal Feasibility (PoUF) and establish that PoUF<2, irrespective of m and show that the upper bound is tight. We compare the m-uniform bidding interface to the classical uniform bidding (m=1), and show that the total value under m-uniform bidding increases by at most a factor of m.

3 - Online Estimation and Inference for Robust Policy Evaluation in Reinforcement Learning

Yichen Zhang, Purdue University, W Lafayette, IN, United States, Weidong Liu, Jiyuan Tu, Xi Chen

Our work places emphasis on statistical inference for the parameter estimates computed using reinforcement learning algorithms. While most existing analyses assume random rewards to follow standard distributions, we embrace the concept of robust statistics in reinforcement learning by simultaneously addressing issues of outlier contamination and heavy-tailed rewards within a unified framework. In this paper, we develop an online robust policy evaluation procedure, and establish the limiting distribution of our estimator, based on its Bahadur representation. Furthermore, we develop a fully-online procedure to efficiently conduct statistical inference based on the asymptotic distribution. This paper bridges the gap between robust statistics and statistical inference in reinforcement learning, offering a more versatile and reliable approach to policy evaluation.

4 - Diversity-Fair Online Selection

Tongwen Wu, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Ming Hu, Yanzhi Li

Selection problems, such as representative democracy, employee recruitment, and task delegation on crowdsourcing platforms, often involve candidates with multiple attributes and unknown arrival. Traditional models, which assume decision-makers (DMs) have complete knowledge of single-attribute value distributions, fall short in these complex real-world scenarios. Our research addresses this gap by focusing on the diversity-fair online selection problem, where the DM must make decisions with limited information and multiple constraints.

We introduce a general online selection model where each candidate's profile is represented by a binary vector across d dimensions, and the selection unfolds over n rounds with a size constraint K. The DM aims to maximize the minimum expected utility across all dimensions, a challenge compounded by the lack of joint distribution knowledge and the need to rely only on marginal information.

Our main contribution lies in developing a linear program-based policy that balances selection probabilities for candidates contributing to multiple dimensions, guided by marginal information. We apply our framework to both a stationary scenario—where an adversary distributes d of ones across candidates in each round—and a general scenario with distinct marginal information. In the stationary case, our method achieves a CR of $\Omega(1/d$^0.75), while in the general scenario, we attain $\Omega(1/(d\log d))$. In addition, we demonstrate that our approach can matches the upper bound for the CR in the general sicario up to a polynomial factor, underscoring the effectiveness of our proposed solutions.

Predictive and Constraint Based Learning Techniques with Business Applications

Invited Session

Artificial Intelligence

Chair: Neta Rabin, Tel-Aviv University, Tel-Aviv, Israel

Co-Chair: Gonen Singer, Bar-Ilan University, Ramat-Gan, Israel

1 - Design for Explainability: A New XAI Method Based on Design of Experiments

Irad Ben-Gal , Tel-Aviv University , Tel-Aviv, Israel

We propose a new Design for Explainability (DFX) methodology that for a given trained Machine Learning (ML) model; a feature training set; and a list of potential features interactions generates a Design of Experiments (DOE) plan to measure the importance or the effect of features, while estimating selected high-order features' interactions, with a lower computational cost than the SHAP.Experiments show that DFX and SHAP are equivalent in approximately 80% of the cases in identifying the top 10% of the most affecting features, while the DFX utilize on average 1.05% of the number experiments that are required by SHAP.

2 - The Skill-Fit Model: Utilizing Skills to Advance Machine Learning based Job Recommendation Systems

Hila Chalutz-Ben Gal, Bar-Ilan University, Ramat Gan, Israel

The growing practice of utilizing Machine Learning based Job recommendation systems (JRS) has become a major component in talent management. However, recent disruptions in the labor force (e.g. flexible work, freelancing, gig work) result in the need to adopt a Skill-Fit Model. For this purpose, we present an analysis of the ML based JRS literature and propose a synthesized approach to analyze and model skills. Our results indicate that some JRS features may benefit from the Skill-Fit Model thus may be adopted by ML-enabled JRS in order to achieve improved performance. This study contributes to the understanding and systematically developing skills - based JRS to support the new world of work.

3 - A Hybrid Cost-Sensitive Machine Learning and Optimization Models for the Resource-Constrained Classification Problem

Gonen Singer, Bar-Ilan University, Ramat-Gan, Israel, Danit Shifman, Chen Ben-Mayor, Itay Margolin

Resource-constrained classification tasks are common in real-world applications such as allocating tests for disease diagnosis, hiring decisions when filling a limited number of positions, and defect detection in manufacturing settings under a limited inspection budget. We propose a comprehensive analytic framework for scenarios that, in addition to including multi-class classification problems with misclassification costs, also has constraints on the number of classified samples of classes due to resource limitations. To classify samples under the constraints, the framework uses a probability matrix generated by a trained cost-sensitive classifier as the input for an optimization model with a minimum cost objective and resource allocation constraints. To demonstrate how useful and versatile it can be, the framework utilizing a cost-sensitive neural network and decision tree was implemented in two case studies: one focused on allocating medical resources, and the other on allocating customer service resources. The proposed framework performs significantly better than the alternative common approaches. Our results show that the proposed framework is capable of providing an effective limited-resource allocation for misclassification cost problems.

4 - Spatio-Temporal Time-Series Forecasting Using an Iterative Kernel-Based Regression

Neta Rabin, Tel-Aviv University, Tel-Aviv, Israel

Spatio-temporal time-series forecasting is relevant in various domains like epidemiology or economics. Kernel based regressions, which capture non-linear data-function relationships, provide simple and efficient forecasting models. In this work, we propose a kernel-based iterative regression model that utilizes multiscale kernels to fuse data from various spatial locations and improve the accuracy of time-series forecasting. The model resembles deep learning ideas but is easy to implement and effective for small datasets. Experimental results for forecasting solar energy, epidemiology infections, and fire event forecasts show that the proposed model outperforms existing techniques.

5 - An Approach for classifying Tracheal Stenosis based on EMG signals utilizing an Adaptive Cost-Sensitive Learning method with Asymmetric Misclassification Errors

Sara Naftali, Afeka Tel Aviv Academic College of Engineering, Tel Aviv, Israel, Ohad Volk, Anat Ratnovsky, Gonen Singer

Respiratory disorders, such as asthma, can cause upper airway obstruction, leading to abnormal airway structure. Early detection of this obstruction is crucial in avoiding health deterioration. This study aimed to identify early-stage tracheal stenosis non-invasively by analyzing electromyography (EMG) signals from inspiratory muscles. The classification of tracheal stenosis has been defined as an asymmetric misclassification cost problem. A ResNet-like architecture for tabular data, coupled with an Adaptive Cost-Sensitive Learning (AdaCSL) algorithm, was employed to address this. EMG signals from the external intercostal muscles of four healthy individuals were recorded as they breathed through tubes simulating narrowed and normal airways. Two experimental approaches were developed: one focused on classifying tracheal stenosis in a specific subject by training the model on data from other subjects, mimicking diagnosing a new patient. The other aimed to classify tracheal stenosis by merging data from all subjects to reduce inter-subject variations. The ResNet-like architecture with AdaCSL significantly outperformed other methods, achieving 43%, 48%, and 59% reductions in the first experiment approach across different misclassification cost values. It also demonstrated lower costs in the second approach setting compared to alternative classifiers. These experiments underscore the potential of utilizing EMG signals from inspiratory muscles for respiratory disease diagnosis and highlight the efficacy of the AdaCSL algorithm for personalized monitoring.

Revenue Management and Pricing

Chair: Faidra Monachou, Yale University, New Haven, CT, United States

1 - Implications of Worker Classification in on-Demand Economy

Zhoupeng (Jack) Zhang, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Ming Hu, Jianfu Wang

How should gig workers be classified, as employees or as contractors? We study this policy question by highlighting the difference between full- and part-time gig workers and focusing on the welfare of full-timers, who do gigs to earn primary incomes. We develop a multi-period game-theoretic queueing model to study market outcomes in different worker classification scenarios. We show that being classified as independent contractors is not always harmful to full-timers; they can end up with high surpluses thanks to a positive *incentives de-pooling* effect of part-timers' market entry. As such, when all gig workers are reclassified as employees (as per, e.g., Assembly Bill No. 5 in California) and part-timers exit the market, full-timers can be *undercut* (underhired or underpaid) by their platform employer and end up with lower surpluses. When all are reclassified as "contractors^{+}," a UK practice that provides incomplete employee benefits but still gives workers flexibility, additional part-timers incentivized may *overcrowd* the platform and hinder the improvement in full-timers' welfare. We propose two policy alternatives: (1) a Hybrid Mode that classifies full-timers as employees but part-timers as contractors, and (2) a Priority Mode that prioritizes matching full-timers with customers over part-timers. We verify that these differentiated schemes can benefit full-timers as well as other stakeholders in the market. We calibrate the parameters in our model using real-world data and illustrate our insights with simulations of Uber's market over 137 cities in California.

2 - Swap: a New System for Facilitating Resource Sharing Among Nonprofits Through Market Design and Mathematical Optimization

Weixiao Huang, Worcester Polytechnic Institute, Worcester, MA, United States, Carlos Morel Figueroa, Arjun Venat, Elise Deshusses, Yunus Telliel, Sarah Stanlick, Jennifer Pazour, Alexander Teytelboym, Andrew Trapp

Nonprofit organizations (NPOs) face significant challenges in service delivery due to resource scarcity and an inability to scale talents and tangible assets effectively, which is compounded by mismatches between available resources and temporally shifting service demands. Motivated by these observations, we propose a novel resource sharing system, SWAP, what we believe to be the first auction-based resource sharing system designed and implemented in the nonprofit sector. SWAP facilitates resource exchanges through a process of offering-their-own and bidding-upon-others' resources, integrated with virtual currency (re-)distribution mechanisms. The multilateral resource exchange outcomes are determined by integer optimization models accounting for both efficiency and fairness. Empirical and simulated experiments demonstrate that SWAP can address temporal resource needs in the real world. Our custom-built SWAP Hub platform has already facilitated dozens of resource exchanges among tens of pilot NPOs since its initial April 2023 deployment. More NPOs are joining and forming SWAP groups beyond the pilot group, enhancing collective impact on the NPO community and demonstrating strong potential for future expansion.

3 -

Increasing Engagement on Ed-Tech Platforms Through Personalized Nudges: Evidence from the Field

Alex Akira Okuno, New York University, New York, NY, United States, Divya Singhvi, Somya Singhvi

In this study, we collaborate with one of India's leading non-profits focused on catalyzing Early Childhood Education. We run a series of large-scale experiments to evaluate the impact of personalized behavioral nudging using WhatsApp messages. Results demonstrate the significant positive effect that data-driven techniques can have on parents' engagement.

4 - Ecological Inference with a Markov Discrete Choice Model

Charles Thraves, University of Chile, Santiago, Chile

We study a Markov Discrete Choice model in an Ecological Inference setting in a political election context. Specifically, at each ballot box, we observe (i) the total number of votes for presidential candidates and (ii) the total number of votes for house representative candidates' parties, while the number of votes for each combination is unknown. Additionally, each ballot box, depending on the region, has a subset of parties for the House of Representatives. We use the EM algorithm to formulate likelihood maximization with missing data to estimate the model parameters that govern voters' actions. Results from simulated instances show that the original parameters can be accurately identified with the model.

Sequential Decision Making Under Uncertainty

Invited Session

Revenue Management and Pricing

Chair: Min-hwan Oh, Seoul National University, Seoul, Korea, Republic of

1 - Nearly Minimax Optimal Regret for Multinomial Logistic Bandit

Joongkyu Lee, Seoul National University(SNU), Gwanak-gu, Korea, Republic of, Min-hwan Oh

In this paper, we study the contextual multinomial logit (MNL) bandit problem in which a learning agent sequentially selects an assortment based on contextual information, and user feedback follows an MNL choice model. There has been a significant discrepancy between lower and upper regret bounds, particularly regarding the maximum assortment size K. Additionally, the variation in reward structures between these bounds complicates the quest for optimality. Under uniform rewards, where all items have the same expected reward, we establish a regret lower bound of $\Omega(d\sqrt{T/K})$ and propose a constant-time algorithm, **OFU-MNL+**, that achieves a matching upper bound of $\tilde{O}(d\sqrt{T/K})$. Under non-uniform rewards, we prove a lower bound of $\Omega(d\sqrt{T})$ and an upper bound of $\tilde{O}(d\sqrt{T})$, also achievable by **OFU-MNL+**. Our empirical studies support these theoretical findings. To the best of our knowledge, this is the first work in the contextual MNL bandit literature to prove minimax optimality --- for either uniform or non-uniform reward setting --- and to propose a computationally efficient algorithm that achieves this optimality up to logarithmic factors.

2 - Improved Algorithms for Multi-period Multi-class Packing Problems with Bandit Feedback

Wonyoung Kim, Columbia University, New York, NY, United States, Garud Iyengar, Assaf Zeevi

We consider the linear contextual multi-class multi-period packing problem (LMMP) where the goal is to pack items such that the total vector of consumption is below a given budget vector and the total value is as large as possible. We consider the setting where the reward and the consumption vector associated with each action is a class-dependent linear function of the context, and the decision-maker receives bandit feedback. LMMP includes linear contextual bandits with knapsacks and online revenue management as special cases. We establish a new estimator which guarantees a faster convergence rate, and consequently, a lower regret in LMMP. We propose a bandit policy that is a closed-form function of said estimated parameters. When the contexts are non-degenerate, the regret of the proposed policy is sublinear in the context dimension, the number of classes, and the time horizon T when the budget grows at least as $T^{1/2}$. We also resolve an open problem posed in Agrawal & Devanur (2016) and extend the result to a multi-class setting. Our numerical experiments clearly demonstrate that the performance of our policy is superior to other benchmarks in the literature.

3 - Lasso Bandit with Compatibility Condition on Optimal Arm

Taehyun Hwang, Seoul National University, Seoul, Korea, Republic of, Harin Lee, Min-hwan Oh

We consider a stochastic sparse linear bandit problem where only a sparse subset of context features affects the expected reward function. To exploit the sparse structure in the unknown reward parameter, existing algorithms for sparse linear contextual bandit use Lasso as an estimator for the reward parameter. The compatibility conditions together with additional diversity conditions on the context features are imposed to achieve regret bounds that only depend logarithmically on the ambient dimension d. In this paper, we demonstrate that even without the additional diversity assumptions, the compatibility condition *only on the optimal arm* is sufficient to derive a regret bound that depends logarithmically on d, and our assumption is strictly weaker than those used in the existing literature. We propose an algorithm that adapts the forced-sampling technique and prove that the proposed algorithm achieves O(*poly*log dT) regret under the margin condition. To our knowledge, the proposed algorithm requires the weakest assumptions among high-dimensional linear bandit algorithms that achieve O(*poly*log dT) regret. Through the numerical experiments, we confirm the superior performance of our proposed algorithm.

4 - Noise-Adaptive Confidence Sets for Linear Bandits and Application to Bayesian Optimization

Kwang-Sung Jun, University of Arizona, Tucson, AZ, United States

Adapting to a priori unknown noise level is a very important but challenging problem in sequential decision-making as efficient exploration typically requires knowledge of the noise level, which is often loosely specified. We report significant progress in addressing this issue in linear bandits in two respects. First, we propose a novel confidence set that is `semi-adaptive' to the unknown sub-Gaussian parameter σ_*^2 in the sense that the (normalized) confidence width scales with $\sqrt{d\sigma_*^2 + \sigma_0^2}$ where d is the dimension and σ_0^2 is the specified sub-Gaussian parameter (known) that can be much larger than σ_*^2. This is a significant improvement over $\sqrt{d\sigma_0^2}$ of the standard confidence set of Abbasi-Yadkori et al. (2011), especially when d is large. We show that this leads to an improved regret bound in linear bandits. Second, for bounded rewards, we propose a novel variance-adaptive confidence set that has a much improved numerical performance upon prior art. We then apply this confidence set to develop, as we claim, the first practical variance-adaptive linear bandit algorithm via an optimistic approach, which is enabled by our novel regret analysis technique. Both of our confidence sets rely critically on `regret equality' from online learning. Our empirical evaluation in Bayesian optimization tasks shows that our algorithms demonstrate better or comparable performance compared to existing methods.

Co-Chair: Rojin Rezvan, University of Texas at Austin, Austin, TX, United States

1 - Response-Adaptive Clinical Trials with Many Treatments

Jingyi Yan, Duke University, Durham, NC, United States, David Brown

Clinical trials are traditionally designed to be non-adaptive, ensuring the identification of a well-performing treatment by the end of the trial with low bias. However, this approach may result in the inefficient allocation of medical resources to underperforming treatments. In contrast, response-adaptive designs enable the decision maker to alter the number of patients assigned to a treatment given its previous performances. Using an approach based on Lagrangian relaxations, we develop feasible policies and performance bounds. In a simplified model employing beta-binomial belief updates, we establish bounds for the performance loss of the feasible Lagrangian policies and show that these policies are asymptotically optimal when the number of patients and treatments grow at the same rate.

2 - Targeted Policy Learning

Gaoqian Xu, University of Washington, Seattle, WA, United States, Yanqin Fan, Alice Qi

This paper proposes an optimal individualized treatment rule (ITR) targeting the average welfare of a subpopulation of the post treatment outcome population. Operationally we adopt the CVaR of the outcome induced by a binary treatment rule as the objective or welfare function. It interpolates between the average welfare function used in empirical welfare maximization (EWM) and the Rawlsian welfare. It can also be interpreted as distributionally robust EWM allowing for the target population to have a different distribution than the study population. Using the dual formulation of the CVaR welfare function, we propose a debiased estimator of the optimal ITR and establish its regret bounds. In addition, we establish asymptotic normality of the debiased estimator of the optimal welfare facilitating Wald inference. The finite sample performance is studied via simulation and an empirical application is presented.

3 - Reinforced Social Learning

Thanawat Sornwanee, Stanford University, Stanford, CA, United States

I present a knowledge-free mechanism to ensure the zero asymptotic average regret in a sequential social learning framework with binary state of the world and homogeneous preference. This mechanism also ensures that the state of the world can be asymptotically learned, regardless of the choice of Nash equilibrium employed. The asymptotic optimality of the mechanism will also shown to be preserved under different economic scenarios, such as when each agent may be blinded from the history of actions and/or received a utility shock.

4 - A Multi-Dimensional Online Contention Resolution Scheme for Revenue Maximization

Rojin Rezvan, University of Texas at Austin, Austin, TX, United States

We study multi-buyer multi-item sequential item pricing mechanisms for revenue maximization with the goal of approximating a natural fractional relaxation – the ex ante optimal revenue. We assume that buyers' values are subadditive but make no assumptions on the value distributions. While the optimal revenue, and therefore also the ex ante benchmark, is inapproximable by any simple mechanism in this context, previous work has shown that a weaker benchmark that optimizes over so-called "buy-many" mechanisms can be approximable. Approximations are known, in particular, for settings with either a single buyer or many unit-demand buyers. We extend these results to the much broader setting of many subadditive buyers. We show that the ex ante buy-many revenue can be approximated via sequential item pricings to within an O(log2 m) factor, where m is the number of items. We also show that a logarithmic dependence on m is necessary. Our approximation is achieved through the construction of a new multi-dimensional Online Contention Resolution Scheme (OCRS), that provides an online rounding of the optimal ex ante solution. For the welfare objective, constant-factor approximations have been demonstrated for a wide range of combinatorial constraints on item allocations and classes of buyer valuation functions. Our work opens up the possibility of a similar success story for revenue maximization.

Advanced Decision Strategies: Integrative Approaches from Machine Learning to Practical Applications

Invited Session

Decision Analysis Society

Chair: Yifan Xie, Adelphi University, Garden City

1 - A Defect Classification Model for Pick and Place Machines using Parallel Neural Network

Yuqiao Cen, Binghamton University, Binghamton, NY, United States

Surface Mount Technology (SMT) involves directly mounting components onto printed circuit boards (PCBs), making it a popular method for low-cost, high-density electronic assemblies. Within the SMT process, the pick-and-place (P&P) step is crucial for placing components after solder paste printing. Automated Optical Inspection (AOI) machines are commonly employed in production lines to detect assembly defects. However, the machines lack the ability to identify the root causes of failures or provide reliable maintenance guidance. With the advent of Industry 4.0, machine learning methods can be applied to improve production line maintenance efficiency. Therefore, the traditional human interact check-out process can be changed into a data-driven and condition-based maintenance process. This paper conducts experiments on initial machine errors and gathers investigative data. It proposes a parallel neural network-based multi-output defect classification model to identify the root causes by leveraging patterns uncovered from experimental data. Compared to traditional root cause identification models, the developed model offers greater flexibility for adjustments.

2 - Enhancing Content Marketing Decisions with Social Media Text Mining: A Case Study of Instagram Fashion Brands

Xiaoru Gao, Northern Illinois University, DeKalb, IL, United States

In order to communicate brand concepts and values to the young generations, many brands are highly active on social media platforms such as Twitter, Facebook, and Instagram. Brand-Generated Content has already become the most common marketing strategy for fashion brands and plays a significant role in influencing consumers' purchase intention. However, not all social media posts successfully yield positive outcomes for brands, as some may attract a notable percentage of negative comments. In this paper, we develop (1) a methodology to detect anomaly of posts that have unusually high percentage of negative user comments and (2) interpret the reason behind anomaly posts. based on Instagram design variables, including semantic text meanings, facial expressions, color scheme and background of photos, and post timing, among others. We collected a data set of brand-generated Instagram posts from ten fashion brands. The data covers the image, text, and user comments posted between 2019 and 2020. Image features were extracted using Convolutional Neural Network, and text topics were generated through Latent Dirichlet Allocation. Our results will help managers design Instagram posts to reduce negative consumer reactions.

3 - Enhancing Feature Interpretability and Reducing Data Costs: Sparse Group PCA with Elastic Regularization

Tianhui Wang, Rutgers University, Piscataway, NJ, United States, Geonseok Lee, Dohyun Kim, Myong Kee Jeong

In modern production environments, the utilization of sensors for monitoring manufacturing processes generates large amounts of data, which offers chances to improve production efficiency and quality by using machine learning models. However, challenges arise in processing raw data and constructing predictive models. Principal component analysis (PCA) is a widely used statistical technique for dimensionality reduction, extracting a low-dimensional subspace in which the variance is maximized (or the reconstruction error is minimized). To improve the interpretability of learned representations, several variants of PCA have recently been developed to estimate the principal components with a small number of input variables. However, existing sparse dimensionality reduction methods only focus on the sparsity in terms of variables or groups of variables, neglecting the simultaneous consideration of sparsity in both variables and groups to enhance feature interpretability and reduce data acquisition costs. To address these challenges, we propose a sparse group PCA method with elastic regularization, integrating sparsity constraints into the objective function to account for both within-group and between-group sparsities. Our approach efficiently uncovers sparse principal loading vectors, eliminating the need for prior assumptions about feature sparsity patterns. We propose an alternating direction method of multipliers for efficient distributed optimization of the non-smooth regularized problem. Experiments conducted on synthetic multi-group data and a semiconductor manufacturing dataset demonstrate the superiority of our proposed method over existing sparse group PCA approaches. Our method exhibits enhanced within-group and between-group sparsities, significantly improving feature interpretability while effectively reducing data acquisition costs.

4 - Optimizing Active Distribution Grids with Weather- and Decision-Dependent Reliability

Gejia Zhang, Rutgers University, Piscataway, NJ, United States, Robert Mieth

The reliability of power systems is critically influenced by weather conditions, which directly affect the operational integrity of physical infrastructure and electricity consumption patterns. Emerging smart grid technology enables system operators to react to temperature fluctuations, but tools to quantify and internalize failure risk on a component-level in operative decisions are still lacking. In this work we develop a distribution system model to optimize the control set-points of distributed generation units, battery energy storage systems, and demand response resources, that explicitly considers weather- and decision-dependent system reliability. Through decision-dependent reliability, our model captures how operational decisions and ambient temperature impact the likelihood of component failures, allowing operators to directly balance cost efficiency and reliability. To address the non-linear and non-convex optimization challenges of the model, we develop an iterative optimization strategy using linearization techniques around initial reliability estimations derived from a baseline scenario. We demonstrate our model and methodology using numerical case studies on IEEE test systems.

5 - Think Like an Organism: Strategies for Low-Surprise Decision-Making via Active Inference

Yulin Li, Rutgers University, New Brunswick, NJ, United States

This presentation explores an innovative strategy for low-surprise decision-making through active inference, inspired by biological organisms. Active inference, based on the free energy principle, posits that organisms minimize discrepancies between internal models and external sensory inputs. This theoretical framework offers a novel approach to developing robust, adaptive algorithms that make meaningful decisions and evaluate the value of those decisions in complex systems, with significant implications for artificial intelligence and automation.

Methodologically, we implement active inference in a simulated robotic control environment. The robot pushes a ball from point A to point B across surfaces of varying friction levels, mimicking dynamically changing conditions. There is no reward unless the ball reaches point B. The robot continuously updates its internal model based on sensory input and makes subsequent decisions to reduce uncertainty. Compared to reinforcement learning approaches, results show that active inference allows the robot to learn and adapt to new conditions more efficiently, requiring fewer trials to train the model, leading to more stable and reliable operations.

The findings underscore the potential of active inference to enhance the adaptability and resilience of autonomous systems across diverse applications, including robotics and autonomous vehicles. By effectively learning world models and making decisions that minimize surprise, active inference offers a promising alternative to conventional RL techniques. Future research will focus on scaling these methods to more complex, real-world scenarios, further validating their practical benefits and applicability.

1 - Impacts of Smart Vending Machines in Different Urban Settings: Tensor Completion with Spatiotemporal Data

Mingrui Zhang, University of Washington- Michael G. Foster School of Business, Seattle, WA, United States, Wanning Chen, Yong Tan, Xusen Cheng

We investigate the treatment effect of deploying smart vending machines (treatment) compared to traditional vending machines (control) across various urban settings. Based on our result, we discuss potential changes in consumer purchasing behavior due to the introduction of technologically enhanced smart vending machines across diverse settings. The dataset we use spans 25 cities, 20 distinct urban settings, and 81 weeks. We employ tensor completion algorithms to predict over 70\% missing sales outcomes in both control and treatment outcomes. Benchmarked against traditional regression models and matrix-based approaches, the tensor completion methods demonstrate superior predictive accuracy. The predictions for the unobserved and non-existent region-setting-time combinations shed light on how to strategically plan and optimize for smart vending machine deployments. More broadly, our analysis underscores the value of leveraging spectral algorithms such as tensor completion to conduct causal analysis on high-dimensional spatiotemporal data, empowering more informed decision-making.

2 - Causal Inference When Controlling for Unstructured Data

Sikun Xu, Washington University in St. Louis, St. Louis, MO, United States, Dennis Zhang, Zhenling Jiang

As unstructured data (e.g., images, and videos) become increasingly available, more empirical research relies on them to derive business and economics insights. Inevitably, this also means that unstructured data have been an important source for empirical researchers to model confounders and control for confounding effects. To control for unstructured data, many studies follow an embedding-then-inference framework: Researchers train a representation learning model to generate lower-dimensional embeddings of the unstructured data, which are then included in the causal inference model. In this paper, we first demonstrate that such a framework can lead to highly biased causal estimates because most representation learning models are not trained to extract relevant confounders from the unstructured data for a particular causal model. We also show that an end-to-end double/debiased machine learning model can avoid arbitrary bias but it requires abundant data to achieve satisfying results. We then propose a debiased embedding framework that effectively and efficiently incorporates unstructured data as confounders. This method extracts low-dimensional embeddings that capture the relevant confounding information from unstructured data and can be easily implemented with other pretrained deep-learning models. Finally, we demonstrate the effectiveness of our proposed method in obtaining accurate causal effect estimates compared to other methods using extensive simulation experiments and a real world dataset.

3 - Learning from User Experience: A Deep Learning Approach to User Embedding for Engagement Prediction and Policy Learning in Online Gaming Platforms

Yu Qin, Arizona State University, Tempe, AZ, United States, Kan Xu, Olivia Liu Sheng

In the competitive online gaming industry, accurately predicting user engagement is essential for maintaining platform vitality and driving strategic decisions. Traditional methods, focusing on demographics and gameplay statistics, fail to fully capture the intricate dynamics of user behavior and interaction. This limitation highlights the need for a more evolved analysis that provides crucial insights into changing engagement and interaction patterns, which are vital for accurate engagement forecasting and effective policy customization. To overcome these challenges, we propose a novel deep learning framework that integrates user match-related data into user embeddings. Our framework leverages diverse data, including game outcomes, in-game dialogue, and paralinguistic elements like emojis, employing multi-task learning to encompass both gaming outcomes and player interactions. This approach offers a comprehensive view of user engagement, addressing the shortcomings of traditional analytics and enhancing the understanding of complex behavior patterns. The anticipated result is an improvement in long-term engagement prediction accuracy and policy learning, enabling targeted promotions and interventions. This research aims to advance user engagement analytics and policy learning, serving as a decision-support tool to optimize business strategies for online gaming platforms.

4 -

An Operational Perspective to Online Content Moderation

Tingrui Shi, University of Chicago, Chciago, IL, United States, Rene Caldentey, Amy Ward, Amir Alwan

The rapid growth of social media users in recent years has led to an increase in the prevalence of harmful content on social media platforms, making online content moderation more important than ever. Content moderation systems nowadays highly rely on artificial intelligence (AI) due to the unprecedented scale of such systems. However, human reviewers are still essential for moderating ambiguous content and providing labels for the training of AI models. We use a Bayesian learning framework to model the AI's classification accuracy as a function of the labeling activities conducted by human reviewers. We derive a diffusion approximation for our model and investigate the operational problem of optimally allocating the capacity of the human reviewers in order to minimize long-term misclassification and holding costs.

Multi-objective Optimization: Methods and Applications

Invited Session

Multi Criteria Decision Making

Chair: Ozlem Karsu, Bilkent University, Ankara, Turkey

Co-Chair: Banu Lokman, University of Portsmouth, Portsmouth, United Kingdom

1 - Using Equitable Optimization for the Hazmat Transport Network Design Problem

Özlem Karsu, Bilkent University, Ankara, Turkey, Yunus Çakır

The shipment of hazardous materials is challenging due to the risk that the population centers face during transportation. The policy makers often have concerns for ensuring a balanced allocation of the risks to the population centers. We structure this problem as an equitable optimization problem with multiple objectives aiming to minimize the risk exposure of different neighborhoods. The resulting multiobjective mixed integer linear programming problem is solved to provide the policy makers equitably nondominated options, each with different levels of efficiency (total risk) and fairness (allocation of risk).

2 - Optimising Sampling Plans for MRI-Guided Prostate Biopsies: a Multi-Objective Approach

Banu Lokman, University of Portsmouth, Portsmouth, United Kingdom, Sara Saadatmand, Utku Lokman

We develop a multi-objective optimization-based approach to optimise sampling plans for MRI-guided prostate biopsies. The aim is to generate personalised sampling plans that minimize the number of biopsy cores whilst maximizing the probability of detecting cancer and coverage.

3 - Cutting-Edge Algorithms for Multi-Objective Portfolio Optimization

Pubudu Jayasekara, The University of Tennessee at Chattanooga, Chattanooga, TN, United States, Dilhani Marasinghe

Multi-objective portfolio optimization (MOPO) is an advanced financial strategy that transcends traditional portfolio optimization by integrating multiple investment goals beyond mere return maximization and risk minimization. This approach considers a broader set of factors including liquidity, risk, return, and other relevant investment criteria, reflecting a more holistic view of portfolio management. The development and application of cutting-edge algorithms in MOPO have been propelled by significant enhancements in computational power and algorithmic sophistication. These modern algorithms are adept at managing the intricate trade-offs inherent in diverse investment objectives, making them essential tools in today's complex financial landscape. Consequently, MOPO enables investors to achieve a balanced portfolio that aligns with their multifaceted investment objectives, leveraging state-of-the-art computational techniques to navigate the complexities of modern financial markets.

4 - Aquanutriopt V2.0: A Bi-Objective Multi-Period Optimization Tool for Controlling Harmful Algal Blooms (Habs)

Ashim Khanal, University of South Florida, Tampa, FL, United States, Hadi Charkhgard

We present AquaNutriOpt Version 2.0, an upgraded version of previously published user-friendly Python package designed to tackle a complex combinatorial optimization problem aimed at optimizing nutrient management for the control of harmful algal blooms. This optimization process involves the identification of optimal Best Management Practices (BMPs) and Treatment Technologies (TTs). AquaNutriOpt Version 2.0 boasts two significant enhancements over its predecessor. Firstly, it now accommodates multiple time periods, broadening its scope for comprehensive analysis. Secondly, it empowers users to handle up to two objective functions using a novel custom-built solution approach that factors in diverse budget scenarios and delivers recommendations aligned with the specified objective functions. We demonstrate the efficacy of the package through a real-world case study aiming to control harmful algal blooms in Lake Okeechobee, located in Florida, by simultaneously minimizing both Phosphorous and Nitrogen.

5 - Utilizing Local Upper Bounds for Solving Convex Vector Optimization Problems

Firdevs Ulus, Bilkent University, Ankara, Turkey

There are existing outer approximation algorithms for convex vector optimization problems (CVOPs) that use supporting half Spaces of the upper image to update the polyhedral convex outer approximations. The extreme points of the updated outer approximation are computed by solving a vertex enumeration problem, which gets challenging as the dimension of the objective space increases. On the other hand, local upper bounds (LUBs) are efficiently used to generate approximation algorithms to solve (mixed) integer Mult objective optimization problems. We show that LUB can be used to solve CVOP efficiently under some assumptions on the ordering cone.

Optimization Techniques in Network and Scheduling

Contributed Session

Chair: Christopher Montez, OpsLab, Austin, TX, United States

1 - Practical Challenges and Considerations for Network Modeling of a Scheduling Problem

Christopher Montez, OpsLab, Austin, TX, United States

Many scheduling problems may naturally be modeled using a network, with vertices representing a particular event occurring and edges representing a decision of going from one event to another in chronological order. We may then construct an integer program using such a network to find a desirable schedule. However, depending on how the network is constructed, the resulting integer program may prove to be too computationally intense for practical purposes. In this talk, we present our journey for selecting a network for a scheduling problem for the U.S. Air Force. We discuss the various challenges along the way and how we resolved them in order to reduce solve times from the order of hours to seconds.

2 - Stochastic Dynamic Machine Scheduling with Interruptible Set-up Times

Dongnuan Tian, Lancaster University, Lancaster, United Kingdom, Rob Shone, Kevin Glazebrook

We consider a problem in which a machine is scheduled dynamically within a network to process jobs at different demand points. Costs are accumulated as jobs wait to be processed. The time needed for a machine to travel between two nodes in the network represents the “set-up time” needed to switch from processing one type of job to another. By using a network formulation, we can model complex relationships in switching times between different types of activity and also allow the switching times to be interrupted. The problem can be formulated as a Markov decision process in which arrival times, service times and switching times are uncertain and the objective is to minimize the expected long-run average cost. However exact solutions using dynamic programming are not possible due to the complexity of the state space. Heuristics for certain special cases of the problem have been proposed in the literature and in this talk we discuss how to adapt these heuristics to our problem. We also discuss how forward-thinking strategies can be used to develop improved heuristics and show the results obtained by applying these methods to networks of various different configurations.

3 - An outer approximation method for finding exact solutions to the discrete network design problem

Michael Levin, University of Minnesota, Minneapolis, MN, United States, David Rey

The problem of network design under user equilibrium route choice behavior appears in many specific contexts, but is difficult to solve because user equilibrium is itself a convex program resulting in a bi-level optimization problem. We specifically focus on discrete network design focusing on binary decisions to open or not open new links. Despite its introduction by Leblanc in 1975 and broad relevance, progress on exact solution methods has been limited. We develop a path-based outer approximation method for the system optimal discrete network design problem, and extend it to the bi-level problem with user equilibrium route choice. A path-based approach is used because link-based formulations do not scale well with network size. The idea behind outer approximation is to solve a sequence of relaxed master problems with system optimal traffic assignment that approximate the convex objective function by linear underestimators from points corresponding to subproblem solutions obtained at integer link design solutions. The subproblems are system optimal and user equilibrium traffic assignment problems with fixed design variables. Outer approximation is applicable because when the integer decision variables are fixed, network design becomes a convex traffic assignment problem. The system optimal problem is used to obtain lower bounds, whereas upper bounds are obtained through user equilibrium traffic assignment. Branching on relaxed binary design variables is used, and system optimal-based lower bounds are used to eliminate some branch nodes.

4 - Ant Colony Optimization for Path Planning in Search and Rescue Operations

Michael Morin, Department of Operations and Decision Systems, Université Laval, Québec, QC, Canada, Irène Abi-Zeid, Claude-Guy Quimper

In search and rescue operations, an efficient search path is a path maximizing the probability of finding survivors. Maximizing this objective quickly enough and with sufficient realism can have a substantial positive impact in terms of human lives saved. In this presentation, we address the problem of efficiently optimizing search paths in the context of the optimal search path problem with visibility, based on search theory. To that end, we develop and evaluate ant colony optimization algorithm variants where the goal is to maximize the probability of finding a moving search object with Markovian motion, given a finite time horizon and finite resources (scans) to allocate to visible regions. Our empirical results, based on evaluating 96 variants of the metaheuristic with standard components tailored to the problem and using realistic size search environments, provide valuable insights regarding the best algorithm configurations. Furthermore, our best variants compare favorably, especially on the larger and more realistic instances, with a greedy heuristic and a state-of-the-art mixed-integer linear program solver. With this research, we add to the empirical body of evidence on the configuration and application of ant colony optimization algorithms, and pave the way for search path optimization in operational decision support systems for search and rescue.

5 - Proving an Approximation Ratio by Mathematical Programming

Insoo Park, POSTECH, Pohang, Korea, Republic of, Kyungduk Moon, Kangbok Lee

The identical parallel machine scheduling problem, aimed at minimizing the makespan, is a central topic in scheduling theory. Among the various approximation algorithms, MULTIFIT stands out for its significance and theoretical impact. Despite being proposed approximately 45 years ago, the approximation ratio of the MULTIFIT algorithm remains unproven for specific numbers of machines. In this work, we introduce a new methodology that utilizes mathematical programming-based analysis to determine the approximation ratio for these unresolved cases. Our approach not only addresses this long-standing question but also offers a promising framework for analyzing other algorithms that can be encoded as mathematical programming models.

Gurobi/Nextmv

Invited Session

Technology Showcase

1 - One Goal, Multiple Paths: Understanding Gurobi's Python APIs for Efficient Model Construction

Maliheh Aramon, Gurobi Optimization, North Vancouver, BC, Canada

Discover the versatility of Gurobi’s Python APIs in our workshop, “One Goal, Multiple Paths.” We’ll explore three key approaches to model building:

1. Term-based modeling involves constructing models with individual variables and constraints for detailed control.
2. Matrix-based expressions utilize linear algebra for efficient, large-scale model construction.

3. Data-first methods leverage pandas DataFrames and Series, integrating seamlessly with data-centric workflows.

In this workshop, we will walk you through the principles, best practices, and practical examples for each method. By the end of the workshop, you will be equipped to choose and implement the most suitable approach for your optimization projects. Join us to master Gurobi's powerful Python APIs and enhance your modeling skills.

2 - The What, why, and how of DecisionOps: It's not just about what you run, but how you run it

Carolyn Mooney, Nextmv.io Inc, Philadelphia, PA, United States

Optimization is founded upon the promise of efficiency and improving solutions. While it's common to believe success starts and ends with an algorithm's runtime, there are tremendous gains to be had beyond those bounds.

While continued optimization model and solver development is important, the next chapter of optimization will be defined by how teams deploy, test, and operate these solutions. Whether you implement a trustworthy sedan or F1 racer of optimization tech, there are key (and often overlooked) efficiencies to be realized in how teams test, tune, troubleshoot, and operate their solutions.

Operations research and decision science teams balance the demands of budgets, headcount, revenue, timelines and success metrics, building and improving DecisionOps practices will save time, money, and headache in pursuit of optimization efficiency. This session will explore how through real-world applications and storytelling.

Advanced Network and Optimization Techniques for Resilient Systems

Contributed Session

Chair: Sarper Aydin, Harvard University, 150 Western Ave, Allston, MA, 02134, United States

1 - Building Back Better: Decentralized Recovery Modeling in Sociotechnical Systems using Strategic Network Dynamics

Negin Maddah, Northeastern University, BOSTON, MA, United States, Babak Heydari

The ability of sociotechnical systems to recover from disruptions through decentralized, bottom-up processes is a crucial element of their overall resilience, which is also among the most overlooked in resilience research. This study proposes a computational framework leveraging dynamic multi-agent networks to conceptualize, model, and quantify decentralized recovery processes building upon strategic network formation methods. This innovative approach addresses limitations in conventional strategic network formation models by accounting for the fluidity of structural shifts induced by the strategic behaviors of individual agents, and by acknowledging the inherent heterogeneity within agent populations. The central objective of this research is to highlight the critical role of bottom-up recovery and present a systematic, adaptable framework for modeling these processes in diverse real-world scenarios. We achieve this through four key elements: modeling post-disruption responses, exploring their interdependencies, accommodating multiple equilibria, and generating metrics for scenario comparison and forecasting. Our dynamic strategic network formation model offers valuable insights into crucial trade-offs in decentralized recovery processes and facilitates the integration of both bottom-up and top-down resilience strategies. Furthermore, it could serve as a predictive tool informing initial network architectural decisions by estimating likely post-disruption equilibrium states based on the initial network structure. Ultimately, this study provides a robust platform for analyzing network efficiency and resilience trade-offs, setting the stage for more informed decision-making in complex sociotechnical systems.

2 - Federated Optimization of the Integrated Transportation Distance by Dual Subgradient Methods

Zhengqi Lin, Rutgers University, Piscataway, NJ, United States, Andrzej Ruszczynski

The Integrated Transportation Distance is a novel metric in the space of stochastic kernels. We identify its usefulness for addressing several federated learning problems, such as the Wasserstein barycenter problem under the privacy-preserving setting and federated clustering. We propose efficient federated dual subgradient algorithms for optimizing the Integrated Transportation Distance without violating the privacy restrictions. Owing to the absence of any matrix-vector operations, the algorithms exhibit very low complexity of each iteration and significant scalability. We illustrate their virtues on several examples.

3 - Learn-to-Construct Cuts for Nested Benders Decomposition in Multi-stage Stochastic Network Optimization Problems

Shima Mohebbi, George Mason University, Fairfax, VA, United States, Babak Aslani, Ran Ji

The temporal propagation of uncertainty and the sequential decision-making nature of large-scale network optimization problems in different application areas, such as flow-based restoration of interdependent infrastructure networks, have not been investigated extensively from a multi-stage stochastic formulation point of view in the literature. While Nested Benders Decomposition (NBD) has emerged as a promising solution algorithm to tackle such multi-stage stochastic problems, the method suffers certain computational bottlenecks and fails to be considered a scalable solution algorithm. Having shed light on these computational deficiencies, we utilize machine learning algorithms to embed accelerating components into the NBD framework to provide a scalable solution algorithm for large-scale network optimization problems. Specifically, we collect the training data from the NBD and train a fast regression with a customized loss function to construct outer-approximated Bender's cuts. In addition, we use an end-to-end learning component for the forward pass of NBD to reduce the computational time. Even though we use approximated Benders cuts, the proposed framework maintains the exactness of the NBD, as we solve the sub-problems and the master problem in the backward pass with such cuts in an exact approach. We evaluate the proposed Learn-to-

Construct Cuts framework in randomly generated networks and a case study to show the computational improvements in terms of the number of cuts, the number of iterations, and the convergence rate.

4 - Reduced-Basis Method for Fast Solutions of Traffic Flow Problems

Ali Pirmohammadi, New York University, New York, NY, United States, Daniel Vignon

Obtaining repeated and/or real-time solutions of traffic flow equations in a network is computationally prohibitive, especially when historical information on traffic flow and travel demand patterns is not suitable (e.g: disaster response scenarios). Even though model order reduction methods exist to address this issue, their application is limited in this context due to the hyperbolic nature of the partial differential equations (PDEs) describing the system. In this study, we investigate the reduced-basis (RB) method for fast solution of first-order macroscopic traffic flow models both at the link and network level. The RB approximates the solution manifold of the PDE system with a linear basis, allowing rapid construction of the solution for given time horizon, boundary, and initial conditions. This is accomplished through an offline and an online stage. In the offline stage, we obtain the reduced basis functions through an effective greedy sampling method. We overcome the inherent reduction challenge for hyperbolic PDEs by relying on cumulative density, rather than density, for the construction of the basis. In the online stage, we solve a specific instance of the problem with the aid of the Empirical Interpolation Method (EIM). Applied at the link and network levels, our method shows promising computational improvement.

5 - Multi-Agent Resilient Consensus under Intermittent Faulty and Malicious Transmissions

SARPER AYDIN, Arizona State University, Tempe, AZ, United States, Orhan Eren Akgun, Stephanie Gil, Angelia Nedich

In this work, we consider the consensus problem in which legitimate agents share their values over an undirected communication network in the presence of malicious or faulty agents. Different from the previous works, we characterize the conditions that generalize to several scenarios such as intermittent faulty or malicious transmissions, based on trust observations. As the standard trust aggregation approach based on a constant threshold fails to distinguish intermittent malicious/faulty activity, we propose a new detection algorithm utilizing time-varying thresholds and the random trust values available to legitimate agents. Under these conditions, legitimate agents almost surely determine their trusted neighborhood correctly with geometrically decaying misclassification probabilities. We further prove that the consensus process converges almost surely even in the presence of malicious agents. We also derive the probabilistic bounds on the deviation from the nominal consensus value that would have been achieved with no malicious agents in the system. Numerical results verify the convergence among agents and exemplify the deviation under different scenarios.

Models of Entrepreneurship and Innovation

Invited Session

Technology, Innovation Management and Entrepreneurship

Chair: Tian Chan, Emory University, Atlanta, GA, United States

Co-Chair: Zhi Chen, National University of Singapore, Singapore, Singapore

1 - A Market for Lemons? Guidelines for A Vigilant Application of Artificial Intelligence in Entrepreneurship Research

Moren Levesque, York University, Toronto, ON, Canada, Martin Obschonka

The rapid expansion of AI applications is transforming entrepreneurship scholarship. Due to potential information asymmetries, especially between authors and reviewers, the field could suffer from unproductive knowledge exchanges. Notably, if newly published, low-quality articles supported by AI go undetected in academic journals, they could create a ‘market for lemons.’ If the field can avoid such unintended and inaccurate knowledge exchange, then the AI revolution could potentially usher in a new golden era for the field. We discuss actions necessary to elevate the field to a higher level of AI resilience, while steadfastly updating its foundational principles and core values.

2 - Meet Our Friendly Virtual Assistant! the (Many) Hurdles to Chatbot Adoption in Customer Service

Brett Hathaway, Brigham Young University, Provo, UT, United States, Evgeny Kagan, Maqbool Dada

Despite recent advances in large language models, chatbot technology continues to face adoption hurdles. We report the results of four studies (a retrospective survey and three incentivized experiments) that examine the choice between the chatbot channel and the live agent channel in customer service. We show that people respond positively to improvements in chatbot performance; however, the chatbot channel is utilized less frequently than expected time minimization would predict. This underutilization is caused by two separate behaviors: gatekeeper aversion (aversion to any service format that may involve a transfer to a different server) and algorithm aversion (aversion to an algorithmic service provider). Among the two factors, gatekeeper aversion is the more dominant one, accounting for 73% to 86% of behavior. In contrast, algorithm aversion is a weaker factor, and is only present for those aged 40 and older in our data. We further unpack gatekeeper aversion and show that it is driven in roughly equal parts by two factors: risk aversion and acclimation (an aversion to obstacles that slow down progress towards service completion).

3 - How Funding Incentives at Lean Startups Distort Product Experiments and Innovation

Onesun Yoo, UCL School Of Management, University College London, London, United Kingdom, K Sudhir, Zihou Zhou

The lean startup method (LSM) is an experimentation-driven approach to learn about product-market fit for improving startup success, but it abstracts away from the financing incentives of the entrepreneur. This paper models the LSM process in the presence of an investor that seeks to learn about entrepreneur's private type while the entrepreneur seeks to learn about the consumer. We show that the investor cannot infer the entrepreneur's type based on the entrepreneur's actions, and therefore must rely on the product test outcome to do so. This can create an incentive for the high-type entrepreneur to distort the experimentation strategy. Our analysis identifies two possible types of distortions relative to the LSM without financing need: one that prioritizes funding at the expense of learning, and the other that prioritizes minimizing the risk of false positive test outcome at the expense of leaving potential innovation ideas wasted. Overall, the information asymmetry about the entrepreneur's type leads to misallocation of funds, wherein the low-type entrepreneurs may get funded and under low investor confidence when the high-type entrepreneurs may not be funded. A noteworthy implication from our model is that entrepreneurs facing negative investor stereotypes (e.g., women, minority entrepreneurs) endogenously sacrifice learning for funding, launching overall less successful ventures and obtaining lower payoffs than those not facing such negative stereotypes. Thus, investor stereotypes on entrepreneurs can become self-reinforcing, accentuate payoff inequality and hurt welfare.

4 - Learning by Failing: the (Unintended) Consequence of Test Reporting on Autonomous Vehicle Training

Zhi Chen, National University of Singapore, Singapore, Singapore, Wenjie Xue

The success of autonomous vehicles (AVs) depends on its access to various real-world driving scenarios. To improve AVs' algorithms, firms send testing vehicles to discover unknown scenarios. While these scenarios are valuable for AVs' future improvements, they trigger failures. We study how a test reporting regulation affects firms' testing strategies.

5 - Experience and Pivoting in Entrepreneurial Product Development

Janne Kettunen, The George Washington University, Washington, DC, United States, Karthik Ramachandran

Pivoting is a significant shift from the current product under development to an alternative opportunity. Pivoting is strongly advocated in the popular press and commonly used in entrepreneurial product development. However, not all pivots are fruitful. Several practical examples and our conversations with early-stage entrepreneurs suggest that a high fraction of pivots do not succeed. We explore the entrepreneurs' experience level, which manifests itself in reduced overconfidence, as a mechanism that drives the pivoting decision. We aim to answer how the entrepreneurs' experience level impacts their pivoting decisions. We develop a decision-theoretic model to analyze the entrepreneurial choice regarding whether to pivot or persist while accounting for the overconfidence and market and pivot opportunity uncertainties. We show that lack of experience, i.e., higher level of overconfidence, can result in systematic overutilization or underutilization of pivoting. Furthermore, we show that novice (more overconfident) entrepreneurs are likely to make radical risky pivots, whereas experienced (less overconfident) entrepreneurs are more likely to make safe pivots. Our results suggest how, depending on the experience level of the founders and their likely pivoting behavior, entrepreneurs should set the duration of their supply chain contracts, choose the type of employees to hire, and select mentors. For government and educators, our results indicate what type of training programs to provide for novice and experienced entrepreneurs. For venture capitalists, the results imply different approaches for evaluating startups with novice and experienced founders.

Quantum Computing and Optimization (Part 1)

Invited Session

OPT: Linear and Conic Optimization

Chair: Zeguan Wu, Lehigh University, Bethlehem

Co-Chair: Mohammadhossein Mohammadisiahroudi, Lehigh University, Bethlehem, PA, 18015, United States

1 - A quantum dual logarithmic barrier method for linear optimization

Zeguan Wu, Lehigh University, Bethlehem, PA, United States

Quantum computing has the potential to speed up some optimization methods. One can use quantum computers to solve a linear system of equations via the Quantum Linear System Algorithm (QLSA). Quantum Linear System Algorithms (QLSAs) can be used as an oracle for algorithms that require solving a linear systems of equations at each iteration. The dual logarithmic barrier method is used to solve linear optimization problems. This method , at each iteration, requires the solution of a linear system to compute Newton directions. In this paper, we use QLSA to solve the linear system at each iteration of the dual logarithmic barrier method. Due to the noise in contemporary quantum computers, the output of QLSA is noisy. Hence, we need to work with the inexact variant of the dual logarithmic barrier method. Thus, this paper proposes an inexact feasible dual quantum logarithmic barrier method for linear optimization. Convergence properties of the method are studied and we show that this method has $\mathcal{O}(\sqrt{n}L)$ iteration complexity, where L is the bit length of the input data.

2 - Arbitrary state preparation via quantum walks

Igor Gaidai, The University of Tennessee Knoxville, Knoxville, TN, United States, Alvin Gonzales, Rebekah Herrman, Colin Campbell, Ji Liu, Teague Tomesh, Zain Saleem

In this talk, I will introduce the concept of continuous time quantum walks on dynamic graphs and show how these walks can be used to prepare an arbitrary quantum state in O(nm), where n is the number of qubits and m is the number of non-zero amplitudes in the state. Then I will show how the walks can be converted to a circuit model and demonstrate performance comparison between different methods of state preparation.

3 - Quantum Algorithms and Software for Nonconvex Continuous Optimization

Xiaodi Wu, University of Maryland, College Park, College Park, MD, United States, Jiaqi Leng, Ethan Hickman, Joseph Li, Yufan Zheng, Samuel Kushnir, LEI Fan

Identifying efficient quantum algorithms for nonconvex optimization would be appealing for both theoretical and practical applications. A conventional approach to achieving quantum speedups in optimization relies on the quantum acceleration of intermediate steps in classical algorithms while maintaining the overall algorithmic trajectory and solution quality unchanged. We propose Quantum Hamiltonian Descent (QHD), which is derived from the path integral of dynamical systems corresponding to certain classical optimization algorithms, as a genuine quantum approach to nonconvex optimization. Specifically, we prove that QHD can efficiently solve a family of nonconvex continuous optimization instances, each characterized by exponentially many local minima. Meanwhile, a comprehensive empirical study suggests that representative state-of-the-art classical optimization algorithms/solvers, including Gurobi, would require super-polynomial time to solve such instances. We also propose several implementation techniques that enable us to run QHD on today's analog quantum computers for solving large-scale non-convex quadratic programming (QP) problems. Based on the QHD algorithm and its real-machine implementation, we have developed a user-friendly software package named QHDOPT, specifically designed for nonconvex optimization.

4 - The quantum central path algorithm: improvements and extensions

Brandon Augustino, JPMorgan Chase, New York, NY, United States

We propose a novel quantum algorithm for solving linear optimization problems by quantum-mechanical simulation of the central path. While interior point methods follow the central path with an iterative algorithm that works with successive linearizations of the perturbed KKT conditions, we perform a single simulation working directly with the nonlinear complementarity equations. Combining our approach with iterative refinement techniques, we obtain an algorithm that avoids dependence on condition number and exhibits polylogarithmic dependence on precision. We then discuss how our approach can be extended to semidefinite optimization and convex quadratic optimization problems.

5 - Quantum optimization with local counterdiabatic driving

Jiayu Shen, JPMorgan Chase, New York City, NY, United States, Changhao Li, Ruslan Shaydulin, Zichang He, Marco Pistoia

Recent advancements in quantum computation including quantum control have significantly broadened its applicability in addressing complex optimization problems. One of the key challenges in quantum optimization is the preparation of a target ground state with high fidelity from an easy-to-prepare ground state. Traditionally, quantum adiabatic evolution, the standard technique used for such tasks, requires slow driving, which translates to impractically long evolution times for many applications. This work introduces the application of local counterdiabatic (LCD) driving as an efficient shortcut to adiabaticity, aimed at overcoming these limitations in quantum ground state preparation. Focusing on applications including portfolio optimization and the transverse-field Ising model, our results reveal that the proposed LCD driving protocols can substantially outperforms traditional adiabatic techniques with simple accessible quantum control. This demonstration of LCD methods paves the way for preparing the ground state of complex systems using readily available controls. Our study highlights the potential of local control-based quantum shortcut to adiabaticity to advance quantum optimization by providing faster and more efficient solutions to real-world problems.

Interplay Between Optimization, Statistics, and Learning - Part I

Invited Session

OPT: Machine Learning

Chair: Lijun Ding, University of California San Diego, La Jolla, CA, 77843, United States

Co-Chair: Liwei Jiang, Georgia Institute of Technology, Atlanta, GA, United States

1 - Reinforcement Learning in Latent Environments: Online Guarantees via off-Policy Evaluation

Jeongyeol Kwon, Wisconsin Institute for Discovery, Madison, WI, United States, Yonathan Efroni, Mannor Shie, Constantine Caramanis

In many real-world decision problems there is partially observed, hidden or latent information that remains fixed throughout an interaction. Such decision problems can be modeled as Latent Markov Decision Processes (LMDPs), where a latent variable is selected at the beginning of an interaction and is not disclosed to the agent initially.
In last decade, there has been significant progress in designing learning algorithms for solving LMDPs under different structural assumptions. However, for general LMDPs, there is no known learning algorithm that provably matches the existing lower bound~\cite{kwon2021rl}. We effectively resolve this open question, introducing the first sample-efficient algorithm for LMDPs without *any additional structural assumptions*.
Our result builds off a new perspective on the role off-policy evaluation guarantees and coverage coefficient in LMDPs, a perspective, which

has been overlooked in the context of exploration in partially observed environments. Specifically, we establish a novel off-policy evaluation lemma and introduce a new coverage coefficient for LMDPs. Then, we show how these can be used to derive near-optimal guarantees of an optimistic exploration algorithm.
These results can be of interest beyond the LMDP class, and especially, for partially observed environments.

2 - 1-bit Matrix Completion for Causal Panel Data Models under Binary Outcomes

Jianzhi Xu, University of Southern Carlifornia, Los Angeles, CA, United States

In this paper, our main focus is to introduce 1-bit matrix completion to address the problem of predicting average and individual causal effects when dealing with binary outcome panel data. The core idea of this approach is to adopt a convex optimization approach to recover the control/treated potential outcome matrix based on the observed 1-bit (binary) outcomes. By doing so, we can more accurately predict causal effects under such a binary setting.

3 - Proximal Random Reshuffling Under Local Lipschitz Continuity

Xiaopeng Li, Columbia University, New York, NY, United States, Cedric Josz, Lexiao Lai

We study proximal random reshuffling for minimizing the sum of locally Lipschitz functions and a proper lower semicontinuous convex function without assuming coercivity or the existence of limit points. The algorithmic guarantees pertaining to near approximate stationarity rely on a new tracking lemma linking the iterates to trajectories of conservative fields. One of the novelties in the analysis consists in handling conservative fields with unbounded values.

4 - Algorithms for Budget-constrained D-optimal Design

Weijun Xie, Georgia Institute of Technology, Atlanta, GA, United States, Jiaqi Wang, Ilya Ryzhov

D-optimal experimental design is a classical statistical problem in which one chooses a collection of data vectors, from some available large pool, in order to maximize a measure of predictive quality. In the classical formulation, the only constraint is on the cardinality of the collection, i.e., the number of vectors chosen. We study a more general budget-constrained variant in which vectors have heterogeneous costs, and develop four new algorithms (two deterministic, and two randomized) with approximation guarantees. Our methods handle heterogeneous costs using a novel exchange rule that interchanges packs of data vectors whose total costs are similar (up to some controlled amount of rounding error). The algorithms outperform the only existing method for this problem from both theoretical and empirical standpoints.

Recent Advances in Online Decision Making

Invited Session

OPT: Optimization Under Uncertainty

Chair: Jiashuo Jiang, Hong Kong University of Science and Technology, Hong Kong, N/A

Co-Chair: Yilun Chen, CUHK Shenzhen, Shenzhen, N/A

1 - High-Dimensional Prediction for Sequential Decision Making

Georgy Noarov, University of Pennsylvania, Philadelphia, PA, United States, Ramya Ramalingam, Aaron Roth, Stephan Xie

We study the problem of making predictions of an adversarially chosen high-dimensional state that are unbiased subject to an arbitrary collection of conditioning events, with the goal of tailoring these events to downstream decision makers. We present efficient algorithms for solving this problem, as well as a number of applications that stem from choosing an appropriate set of conditioning events.

For example, we can efficiently make predictions targeted at polynomially many decision makers, giving each of them optimal swap regret if they best-respond to our predictions. We generalize this to online combinatorial optimization, where the decision makers have a very large action space, to give the first algorithms offering polynomially many decision makers no regret on polynomially many subsequences that may depend on their actions and the context.

Further, we develop a novel transparent alternative to conformal prediction for building valid online adversarial multiclass prediction sets. We produce class scores that downstream algorithms can use for producing valid-coverage prediction sets, as if these scores were the true conditional class probabilities. We show this implies strong conditional validity guarantees including set-size-conditional and multigroup-fair coverage for polynomially many downstream prediction sets. Moreover, our class scores can be guaranteed to have improved L2 loss, cross-entropy loss, and generally any Bregman loss, compared to any collection of benchmark models, yielding a high-dimensional real-valued version of omniprediction.

2 - Online Local False Discovery Rate Control: a Resource Allocation Approach

Hongyu Chen, Massachusetts Institute of Technology, Cambridge, MA, United States, Ruicheng Ao, David Simchi-Levi, Feng Zhu

We consider the problem of sequentially conducting multiple experiments where each experiment corresponds to a hypothesis testing task. At each time point, the experimenter must make an irrevocable decision of whether to reject the null hypothesis before the next experimental result arrives. The goal is to maximize the number of discoveries while maintaining a low error rate at all time points measured by local False Discovery Rate (FDR). We formulate the problem as an online knapsack problem with exogenous random budget replenishment. We start with general arrival distributions and show that a simple policy achieves a $O(\sqrt{T})$ regret. We complement the result by showing that such regret rate is in general not improvable. We then shift our focus to discrete arrival distributions. We find that many existing re-solving heuristics in the online resource allocation literature, albeit achieve bounded loss in canonical settings, may incur a $\Omega(\sqrt{T})$ or even a $\Omega(T)$ regret. With the observation that canonical policies tend to be too optimistic and over claim discoveries, we propose a novel policy that incorporates budget safety buffers. It turns out that a little more safety can greatly enhance efficiency --- small additional logarithmic buffers suffice to reduce the regret from $\Omega(\sqrt{T})$ or even $\Omega(T)$ to $O(\ln^2 T)$. We extend the policy to the scenario with continuous arrival distributions as well as time-dependent information structures. We conduct both synthetic experiments and empirical applications on a time series data from New York City taxi passengers to validate the performance of our proposed policies.

3 - Stochastic subgradient descent for high-dimensional stochastic control

umur cetin, Cornell, ithaca, NY, United States, Yilun Chen, David Goldberg

We employ a convex optimization framework and demonstrate that stochastic subgradient descent leads to a simulation-based PTAS for optimal stopping and multiple stopping, as well as certain generalizations thereof. Our approach establishes novel connections between high-dimensional stochastic control, convex optimization, and simulation, enabling PTAS for a broad range of high-dimensional control problems. Our work builds on Chen and Goldberg's recent iterative simulation-based PTAS for optimal stopping.

4 - Optimistic Q-learning For Average Reward and Episodic Reinforcement Learning

Priyank Agrawal, Columbia University, New York, NY, United States, Shipra Agrawal

We present an optimistic Q-learning algorithm for regret minimization in average reward reinforcement learning under an additional assumption on the underlying MDP that for all policies, the expected time to visit some frequent state s_0 is finite and upper bounded by H. Our setting strictly generalizes the episodic setting and is significantly less restrictive than the assumption of bounded hitting time {\it for all states} made by most previous literature on model-free algorithms in average reward settings. We demonstrate a regret bound of $\tilde{O}(H^5 S\sqrt{AT})$, where S and A are the numbers of states and actions, and T is the horizon. A key technical novelty of our work is to introduce an $\overline{L}$ operator defined as $\overline{L} v = \frac{1}{H} \sum_{h=1}^H L^h v$ where L denotes the Bellman operator. We show that under the given assumption, the $\overline{L}$ operator has a strict contraction (in span) even in the average reward setting. Our algorithm design then uses ideas from episodic Q-learning to estimate and apply this operator iteratively. Therefore, we provide a unified view of regret minimization in episodic and non-episodic settings that may be of independent interest.

Efficient Methods for Large-scale Optimization Using Inexactness I

Invited Session

OPT: Optimization Under Uncertainty

Chair: Robert Baraldi, Sandia National Laboratories, Seattle, WA, 87123, United States

Co-Chair: Johannes Milz, Georgia Institute of Technology, Atlanta, GA, United States

1 - Structure Utilization for Reducing Dimensional Dependency for Nonsmooth Derivative-Free Optimization

Ching-pei Lee, Institute of Statistical Mathematics, Tokyo, Japan, Geovani Grapiglia

Deterministic methods for derivative-free optimization that use finite difference to approximately conduct first-order updates usually have an evaluation cost per iteration proportional to the problem dimension, making these methods prohibitively expensive for high-dimensional problem.
In this work, we consider a regularized setting of minimizing the sum of a smooth function and a nonsmooth regularization term, where we only have access to the function value of the smooth term but assume full knowledge of the regularization. By identifying the structure at the point of convergence induced by the regularization using an inexact proximal gradient method constructed through finite difference, we propose an acceleration method whose per-iteration evaluation cost locally depends on the rank of the structure instead of the original problem dimension, and thus making the algorithm much more efficient without harming the convergence guarantees. We discuss how the structure can be found under a general error bound condition, and cover related convergence properties.
We further consider a progressive identification strategy that gradually decreases the estimated rank of the structure through an approximate Riemannian proximal gradient method by confining to the manifold that represents the structure at the current point, and discuss how it could potentially improve the convergence speed.

2 - A Stochastic Trust Region Method for Nonsmooth Optimization

Aurya Javeed, Sandia National Laboratories, Albuquerque, NM, United States

This talk is about minimizing a smooth term plus a convex nonsmooth term. We present a stochastic proximal Newton trust region algorithm that assumes models and estimates of the objective are sufficiently accurate, sufficiently often. Like previous stochastic trust-region algorithms such as STORM, which handles stochastic optimization with random models, we use martingale theory to prove our algorithm is globally convergent with probability one.

3 - Risk-averse optimization using randomized quasi-Monte Carlo methods

Olena Melnikov, Georgia Institute of Technology, Atlanta, GA, United States, Johannes Milz

We establish epigraphical and uniform laws of large numbers for sample-based approximation. Our sample-based approximation schemes include Monte Carlo (MC), quasi-Monte Carlo (QMC), and certain randomized quasi-Monte Carlo integration (RQMC), such as scrambled net integration. Our results can be applied to the approximation of risk-averse stochastic programs and stochastic variational inequalities. Finally, we empirically compare the performance of MC, QMC, and RQMC approximations for high-dimensional risk-averse stochastic optimization problems. We find that RQMC approaches based on Halton and Sobol sequences yield smaller variance than MC and QMC methods.

4 - Adaptive Randomized Sketching for Nonsmooth Dynamic Optimization

Robert Baraldi, Sandia National Laboratories, Seattle, WA, United States

Dynamic optimization problems are used for control and modeling of many applications, including optimal flow control, full waveform inversion, and medical imaging. Notably, these applications are plagued by significant computational challenges; namely, memory is a limiting factor on problem size. Evaluation and storage of the entire state trajectory is required for both cost function and derivative computation. Additionally, nonsmooth regularizers or auxiliary constraints on the optimization variables that arise via physical or user-desired features can prohibit usage of traditional smooth optimization techniques. We introduce a trust-region algorithm for minimizing the sum of a smooth, nonconvex function and a nonsmooth, convex function that addresses these two challenges. Our trust-region algorithm employs randomized sketching to store a compressed version of the state trajectory and adjoints, and adaptively learns the rank of the state sketch. We prove convergence of our method with near optimal memory requirements and demonstrate the efficacy of our method on PDE-constrained optimization problems.

Advances in Continuous Optimization Algorithms

Invited Session

OPT: Nonlinear Optimization

Chair: Tianjiao Li, Georgia Institute of Technology, Atlanta, GA, United States

Co-Chair: Zhe Zhang, Georgia Tech, Atlanta, GA, United States

1 - Smoothing approach for nonconvex-nonconcave minimax problems

Yangyang Xu, Rensselaer Polytechnic Institute, Troy, NY, United States, Hari Dahal, Wei Liu

We consider nonconvex-nonconcave minimax problems and present a smoothing framework to solve the problem. Convergence results and numerical results will both be presented. Compared to existing works, our algorithm can work without assuming concavity-like structure or PL-like condition on the dual part.

2 - Hyperparameter Tuning via Trajectory Predictions: Stochastic Prox-Linear Methods in Matrix Sensing

MENGQI LOU, Georgia Institute of Technology, ATLANTA, GA, United States

Iterative algorithms are the workhorses of modern signal processing and statistical learning, and are widely used to fit large-scale, complex models to random data. While the choice of the hyperparameters of an algorithm determines both the efficiency and fidelity of the learning pipeline, it is common for this choice to be made heuristically, usually either guided by upper bounds on error convergence or by expensive trial-and-error.

Motivated by these issues, we study an important iterative stochastic algorithm——the mini-batched prox-linear method——for a canonical nonconvex model-fitting problem—rank-1 matrix sensing with random data. We derive a low-dimensional deterministic recursion that predicts the error of this method and show, using a non-asymptotic framework, that this prediction is accurate for any batch-size and a large range of step-sizes. In particular, our analysis reveals that this method, though stochastic, converges linearly from a local initialization with a fixed step-size to a statistical error floor. Our analysis also exposes how the batch-size, step-size, and noise level affect the convergence rate and the eventual statistical estimation error. Notably, our convergence guarantees are sharp, in the sense that we provide matching upper and lower bounds on the error trajectory. We also demonstrate how to use our deterministic predictions to perform hyperparameter tuning (e.g. step-size and batch-size selection) without ever running the method.

3 - Policy Dual Averaging for General State and Action Space

Caleb Ju, Georgia Institute of Technology, Atlanta, GA, United States, Guanghui Lan

We first present a substantial generalization of the recently developed policy mirror descent method to deal with general state and action spaces. We introduce new approaches to incorporate function approximation into this method, so that we do not need to use explicit policy parameterization at all. Moreover, we present a novel policy dual averaging method for which possibly simpler function approximation techniques can be applied. We establish linear convergence rate to global optimality or sublinear convergence to stationarity for these methods applied to solve different classes of RL problems under exact policy evaluation. We then define proper notions of the approximation errors for policy evaluation and investigate their impact on the convergence of these methods applied to general-state RL problems with either finite-action or continuous-action spaces. Finally, our presentation includes preliminary numerical results of policy dual averaging applied to various problems in optimal control and sequential decision making.

4 - Conditional gradient methods for smooth functional constrained optimization

Yuyuan Ouyang, Clemson University, Clemson, SC, United States, Yunheng Jiang, Zhe Zhang

We propose new projection-free algorithms for solving functional constrained optimization problems. For convex functional constrained optimization problems, we show that a straightforward extension of conditional gradient (CG) method, called the constrained CG (CCG) method, can solve an ε-approximate solution while the gradient evaluation complexity and the linear objective optimization complexity are both of order $O(\varepsilon^{-1})$. Further, by incorporating a sliding procedure in CCG, we show it could obtain a better $O(\varepsilon^{-1/2})$ gradient evaluation complexity while maintaining the $O(\varepsilon^{-1})$ linear objective optimization complexity. Moreover, we show that CCG with a linesearch strategy can also be adapted for solving nonconvex functional constrained optimization problems. If the objective function is nonconvex but the constraints are convex, our proposed method has an $O(\varepsilon^{-2})$ complexity to compute an approximate stationary point. If both the objective and constraint functions are nonconvex, our proposed method has an $O(\varepsilon^{-2})$ complexity to compute an approximate Fritz-John point.

Summit - 427

Amazon Flexible Under-the-Roof Capacity Planning

Invited Session

Transportation Science and Logistics (TSL)

Chair: Roman Levkin, Amazon, Seattle, WA, United States

1 - Associate Capacity Prediction

Esra Sisikoglu, AMAZON, Seattle, WA, United States, Jeronimo Callejas

Effective short-term labor and capacity planning at Amazon hinges on accurately predicting the capacity to flex-up or flex-down the labor supply. From hiring decisions at the planning level to shift offering at the execution level, all models leverage predicted associate capacity to optimally match demand with labor supply. This presentation discusses the design of an capacity prediction service that identifies the associate capacity – how much we can flex up or down – within a given time horizon, at a given surge rate, with a given associate pool. The strength of this design lies in its flexibility to provide predictions for various use cases at different granularity, enabling coordination between planning and execution levers.

2 - Labor Capacity Management with Surge

Dev Das, Amazon.com, Seattle, WA, United States

Amazon uses additional surge pay incentive to associates to accept shifts where the demand of associate hours is high and acceptance rate of shifts is low. Optimizing surge pay recommendations involves understanding associate responsiveness to surge pay that requires measuring the acceptance rate of surge shifts for various surge amounts, the time when shifts start, and how close to the shift start time is the surge offered. This presentation will discuss scientific approaches developed to address this problem. The approaches range from cost-neutral, fair-pay-adherent randomized control experimental design to fully-automated continuous learning approaches using multi-armed bandit models that are used across multiple Last Mile operations.

3 - Integrating Associate Preference into Labor Planning: Sentiment Analysis

Rachel Rutkowski, Amazon, Seattle, WA, United States, Jeronimo Callejas, Roman Levkin, Thomas Fillebeen, Martin Savelsbergh

Labor planning often relies on capacity predictions generated from observable labor data. These data are useful in predicting broad capacity trends but are insufficient in capturing the nature, directionality, and magnitude of the causal capacity relationship between the labor context and associate labor behavior. Thus, we leverage associate listening tools (e.g., surveys) to capture associate-generated sentiment data that are synthesized to recover latent factors that inform associate labor behavior. These data are used to refine model specification selection (e.g., complexity, assumptions, features) which results in more durable models that capture the broader, nuanced labor context within which associates operate.

4 - Integrating Associate Preference into Labor Planning: Structural Modeling

Jeronimo Callejas, Amazon, Seattle, WA, United States, Rachel Rutkowski, Roman Levkin, Thomas Fillebeen, Martin Savelsbergh

Labor planning often relies on capacity predictions generated from observable labor data. These data are useful in predicting broad capacity trends but are insufficient in capturing the nature, directionality, and magnitude of the causal capacity relationship between the labor context and associate labor behavior. Thus, we leverage associate listening tools (e.g., surveys) to capture associate-generated sentiment data that are synthesized to recover latent factors that inform associate labor behavior. These data are used to refine model specification selection (e.g., complexity, assumptions, features) which results in more durable models that capture the broader, nuanced labor context within which associates operate.

5 - Enhancing Associate Capacity via Shift Reservations

Evan Wyse, Amazon.com, Inc., Seattle, WA, United States

While Amazon's flexible workforce claims the majority of their shifts proactively, the company has recently begun to experiment with pushing specific opportunities out to associates. A propensity-matching experiment indicates that associates who are given specific, guaranteed shift opportunities work more hours on average, as well as working more hours at night. This presentation will discuss specific algorithms used to identify the shifts that associates would be most likely to claim using a recommender system. Further, we will also articulate the methods used to ensure that shift opportunities are allocated fairly and optimally to all associates.

6 - Amazon Flexible Under-the-Roof Capacity Planning

Thomas Fillebeen, Amazon, Seattle, WA, United States, Roman Levkin

Overview of flexible Under-the-Roof (UTR) capacity planning across Amazon operations, its unique challenges and opportunities for Science to make impact. The objective is to minimize hiring, attrition, productivity loss and costs while maintaining capacity reliability and introducing capacity flexibility to structurally respond to changes in customer demand. To accommodate demand volatility cost effectively, many high-speed fulfillment operations started with slack capacity. However, as this specialty business matured and capacity constraints became top of mind, these businesses started shifting towards maximizing throughput. In this environment, it is crucial to predict capacity to adapt and respond to disruptive changes and deploy labor execution levers. This in turn requires a holistic approach - from machine learning to qualitative research.

Dynamic Decision-Making in Last-Mile Fulfillment

Invited Session

TSL: Freight Transportation

Chair: Sara Reed, University of Kansas, Lawrence, KS, United States

Co-Chair: Dipayan Banerjee, Loyola University Chicago, Chicago

1 - Continuous-TIME Dynamic Yield Management: near-Optimal Policies and Applications to Multichannel Fulfillment

Dipayan Banerjee, Georgia Institute of Technology, Atlanta, GA, United States, Alan Erera, Alejandro Toriello

Motivated by multichannel retailers using in-store inventory to fulfill both in-store demand and rapid delivery requests from online customers, we study the finite-horizon continuous-time dynamic yield management problem with stationary arrival rates and two customer classes. We consider a class of linear threshold policies proposed by Hodge (2008), in which each online (i.e., less desirable) customer is accepted if and only if the remaining inventory at the customer's arrival time exceeds a threshold that linearly decreases over the selling horizon. Using a discrete-time Markov chain representation of sample paths over inventory-time space, we show that a range of such linear threshold policies achieve uniformly bounded regret. We then generalize this result to analogous policies for the same problem with arbitrarily many customer classes. Numerical simulations demonstrate linear threshold policies' competitiveness with existing heuristics and illustrate the effects of the linear threshold's slope. We discuss other potential applications of these results to rapid e-retail fulfillment.

2 - Smart Parking in Last-Mile Delivery

Sara Reed, University of Kansas, Lawrence, KS, United States, Michael Lash

Parking poses a challenge in last-mile delivery, particularly in urban environments. One way to mitigate this challenge may be to provide the driver with real-time parking information to assist with driver decision-making. We introduce the Dynamic Parking Delivery Problem with Real-Time Information (DPDP-I) to model en-route decisions regarding where the delivery person should park and which customers to serve from each parking spot. We formalize the DPDP-I as a Markov Decision Process and develop a dynamic solution approach. Our computational results shows that our heuristic policy successfully leverages historical and real-time parking information as well as the interdependencies between parking availability and customer density to reduce route completion times.

3 - In-Store Order Picking for E-Grocery

Charlotte Köhler, European University Viadrina, Frankfurt (Oder), Germany, Jan Fabian Ehmke, Ann Campbell

E-grocers struggle to create profitable business models, and careful planning is needed to balance tight margins with high customer expectations. Although numerous studies emphasize optimizing customer acceptance and efficient delivery, the costs and resources required for picking orders are less examined despite their significant influence on profitability.

In this presentation, we delve into in-store picking costs within the e-grocery context and introduce a cost evaluation function designed to give retailers a precise assessment of the resources needed for picking orders, thereby assessing feasibility and maximizing the number of accepted orders. For e-groceries, the time taken to pick items is a critical determinant of costs and use of resources, as longer picking times directly translate to increased labor expenses and fewer orders that can be picked.

We are conducting a comprehensive assessment of the proposed cost evaluation function, utilizing real-world data to ensure accuracy and relevance for different order picking strategies. Our assessment employs a detailed analysis of store layouts like those of REWE in Germany, combined with historical data from a former German e-grocer involving over 400,000 order baskets. This data provides insights into typical order compositions and the resources needed for various basket types, enhancing our understanding of critical costs in e-grocery picking. The insights from this study will provide valuable input for a comprehensive analysis of both picking and delivery processes in the e-grocery sector.

4 - Gamifying the Vehicle Routing Problem with Stochastic Requests

Justin Goodson, Saint Louis University, Saint Louis, MO, United States, Nicholas Kullman, Nikita Dudorov, Martin Cousineau, Jorge Mendoza

Do you remember your first video game console? We remember ours. Decades ago, they provided hours of entertainment. Now, they’ve been repurposed to solve dynamic and stochastic optimization problems. With deep reinforcement learning techniques posting superhuman performance on a wide range of Atari games, we consider the problem of representing a classic logistics problem as a game. Then, we train agents to play it. We consider several game formats for the vehicle routing problem with stochastic requests. We show how various design features impact agents’ performance, including perspective, field of view, and minimaps. With the right game design, general purpose Atari agents outperform optimization-based heuristics, especially as problem size grows.

Emerging Topics in Transportation and Logistics

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Hai Wang, Singapore Management University, Singapore, Singapore

1 - Pricing Shared Rides

Yifan Shen, University of Washington, Seattle, WA, United States, Chiwei Yan, Julia Yan

Propelled by high rates of personal car ownership (91.5% of American households in 2020, Davis and Boundy 2022) and low vehicle occupancies (1.54 passengers per car in 2017), shared rides have been envisioned as a means of transporting compatible riders together in a carpool-type service, thereby reducing vehicle miles and carbon emissions. However, major ridesharing platforms have long struggled to maintain a healthy and profitable shared rides product. To understand why shared rides have struggled, we analyze procedures commonly used in practice to set static prices for shared rides, and discuss their pitfalls. We then propose a pricing policy that is adaptive to matching outcomes, dubbed match-based pricing, which varies prices depending on whether a rider is dispatched alone or to what extent she is matched with another rider. Analysis on a single origin-destination setting reveals that match-based pricing is both profit-maximizing and altruistic, simultaneously improving cost efficiency (i.e., the fraction of cost saved by shared rides relative to individual rides) and reducing rider payments relative to the optimal static pricing policy. These theoretical results are validated on a large-scale simulation with hundreds of origin-destinations from Chicago ridesharing data. The improved efficiency of match-based pricing drives a reduction in vehicle miles while also benefiting riders and platforms. In addition, these effects are especially pronounced under high-cost, low-demand settings, expanding access to shared rides where they have historically been most challenging.

2 - The Value of Flexibility in Last-Mile Delivery

Haoqing Wang, Department of Logistics & Maritime Studies, Faculty of Business, Hong Kong Polytechnic University, Hong Kong, Hong Kong, Sheng Liu, Shuaian Wang

In on-demand last-mile delivery, it is common to assign each driver to serve a designated area, which enhances the driver's familiarity with the region but limits the overall flexibility of the delivery system. By analyzing the real-world delivery data provided by a food delivery platform, we identify imbalanced capacity among regions. Motivated by this phenomenon, we investigate the value that driver flexibility can bring to last-mile delivery. With the objective of improving service level, i.e., reducing the expected wait time of customers, we consider three mechanisms: (i) full flexibility between two (neighboring) regions, (ii) one-side partial flexibility between two regions, and (iii) two-side partial flexibility between two regions. We find that (a) full flexibility can improve the service level to the greatest extent; (b) partial flexibility also enhances the service level, and under optimal configurations, it can achieve a significant proportion of the service level improvement attained by full flexibility. Moreover, we analyze the impact of region size on the results and expand the analysis to multiple orders and regions.

3 - Navigating Algorithmic Disparity in Ride-Hailing: Examining Spatial-Temporal Disparate Impacts of Transportation Network Company Algorithms in New York City

Hanyong Xu, Massachusetts Institute of Technology, Cambridge, MA, United States

With the rise of Transportation Network Companies (TNCs) like Uber and Lyft, examining their pricing and matching algorithms becomes crucial. Previous studies have shown that these algorithms can discriminate against certain demographic groups. However, the specific spatial-temporal distributions and the associated demographic characteristics have not been thoroughly explored. Understanding the development of such algorithmic discrimination is essential. It enables platform users to be aware of potential pricing volatility and helps decision-makers advocate for better industry regulations.

Under these conditions, the presentation will cover three parts. First, it demonstrates that there are spatial disparities in pricing and service availability caused by the algorithms of Transportation Network Companies (TNCs) in New York, while controlling for socio-demographic factors and trip characteristics. Second, it reveals how these disparities and their relationship to socio-demographic factors have evolved over the course of the pandemic. Lastly, the presentation introduces a method that leverages socio-demographic awareness in the demand prediction model to improve prediction fairness.

4 - Assessing and Explaining Urban Transportation Network Efficiency

Hai Wang, Singapore Management University, Singapore, Singapore

Urban transportation networks are critical infrastructures ensuring the mobility of people and goods while having a significant influence on the environment. To assess the service quality and environmental impact of current and emerging transportation services, a critical challenge for service providers and policymakers is to measure and understand the efficiency of urban transportation networks. Existing transportation network efficiency metrics either do not address the efficiency of service trips beyond two demand points or do not provide large-scale efficiency assessments on real networks. In this paper, leveraging network optimization insight and modern transportation data, we introduce a network efficiency metric capable of assessing the efficiency of multi-demand vehicle routing based services on urban transportation networks at scale, while accommodating different service modalities and demand distributions. Furthermore, to understand what makes a network efficient, we identify primary micro/macroscopic network properties explaining the network efficiency. By deploying our methodology, we construct a new dataset to measure and explain network efficiency for 200 cities worldwide. Through case studies, we show that our method can assess the network efficiency under diverse transportation service modalities. Specifically, we examine the efficiency of multimodal urban transportation services, the time evolution of the efficiency of New York City's subway network, and the efficiency of a last-mile delivery service.

5 - Multi-Criteria Decision Making in Transportation Planning

Hongyi Jiang, Cornell University, Ithaca, NY, United States, Samitha Samaranayake

In transportation planning, decision-making often involves navigating complex tradeoffs between various competing objectives. In this talk, I will discuss the development and application of multi-criteria decision-making methods to address some of the key challenges in this domain. The discussion will cover the theoretical foundations and practical implementations of optimization models and algorithms designed to balance factors such as efficiency, cost, sustainability, and reliability in transportation systems. The insights gained from our work can inform ongoing and future research in advancing multi-criteria decision-making approaches, both in transportation and other areas facing similar complexities.

Air Transport Operations

Invited Session

Aviation Applications

Chair: Jan-Rasmus Kunnen, Wing Labs, Hamburg, Germany

1 - Deriving strategic ATM regulations from network-optimal routing via decision trees

Jan-Rasmus Kunnen, Wing Labs, Hamburg, Germany

We use decision tree methodology to develop applicable and effective ATFM regulations for strategic planning of air traffic flows in Europe in times of capacity shortages.

The methodology was developed as part of an industrial project to upgrade the planning tools for the European Network Manager. It consists of 3 parts: First, we determine the best flight-to-route assignment for all flights given capacity restrictions and pre-determined trajectory options. Second, use decision trees to derive individual regulations (RAD measures) from the resulting trajectories by aggregating individual trajectories on selected criteria (Origin, Destination, sector entry time). Finally, we combine the individual measures for each Area Control Center (ACC) by selecting the most effective set of non-overlapping measures.

We apply the method on a real-life case study of 10,000 flights, where we determine the most effective ATFM measures for a week-long capacity reduction in two Paris ACCs in November 2024.

3 - The Airport of Future: Prescriptive AI Integration for Optimizing Delta Air Lines' Worldport Operations

Ash Omidvar, Delta Air Lines, Inc., Atlanta, GA, United States, Ruhollah Heydari, Dayana Cope

Efficient airport operations hinge upon seamless coordination among diverse resources, both above and below the wing, to ensure on-time and high-quality flight experience. The envisioned "Airport of Future" endeavors to amalgamate subject matter expertise with advances in artificial intelligence (AI) technologies to attain optimal operational outcomes. In this presentation, the Delta Decision Science team elucidates the deployment of prescriptive AI methodologies at the Worldport to enhance the efficiency of both above-wing (crew and customer-related) and below-wing (ground operations-related). Through a synergistic integration of advanced algorithm and real-time data analytics, the practiced AI framework facilitates proactive decision-making, resource allocation, and scheduling optimizations. By harnessing the power of prescriptive AI, the Airport of Future further elevates operational performance, enhances customer experience, and ensures safety and welfare for team Delta.

4 - Distributionally Robust Integer Programming and Air Traffic Management

Max Li, University of Michigan, Ann Arbor, MI, United States, Haochen Wu, Alexander Estes

The airport ground holding problem seeks to minimize flight delay costs due to reductions in the capacity of airports. However, the critical input of future airport capacities is often difficult to predict, presenting a challenging yet realistic setting. Even when capacity predictions provide a distribution of possible capacity scenarios, such distributions may themselves be uncertain (e.g., distribution shifts). To address the problem of designing airport ground holding policies under distributional uncertainty, we formulate and solve the airport ground holding problem using distributionally robust optimization (DRO). We address the uncertainty in the airport capacity distribution by defining ambiguity sets based on the Wasserstein distance metric. We propose reformulations which integrate the ambiguity sets into the airport ground holding problem structure, and discuss dicretization properties of the proposed model. We discuss comparisons (via numerical experiments) between ground holding policies and optimized costs derived through the deterministic, stochastic, and distributionally robust airport ground holding problems. Our experiments show that the DRO model outperforms the stochastic models when there is a significant difference between the empirical airport capacity distribution and the realized airport capacity distribution. We note that DRO can be a valuable tool for decision-makers seeking to design airport ground holding policies, particularly when the available data regarding future airport capacities are highly uncertain.

5 - Natural Disaster-Resilient Spaceport Network Planning

Haochen Wu, University of Michigan, Ann Arbor, Ann Arbor, MI, United States

In recent years, the United States commercial space launch sector has experienced unprecedented growth, driven by companies such as SpaceX and Blue Origin. Geohazards, such as landslides, flooding, and erosion have long caused challenges to transportation systems in the US. In particular, hurricanes have caused significant challenges to spaceport operations at Cape Canaveral Space Force Station and Kennedy Space Center. Our motivation aligns with the strategic goals of the USSF to address the problem of creating a spaceport network that not only handles the demand of space access but is also resilient for natural disasters that will inevitably arise. Given historical data of natural disasters' annual frequencies (such as those obtained from, we apply the Chance-Constrained SPFL model (CC-SPFL). The idea behind the CC-SPFL is that we generate samples of the random variable based on the annualized frequency data, and for at least some percentage of all samples the demand of all types of missions are satisfied. We will also apply importance sampling technique into CC-SPFLP to deal with rare but significant events such as earthquake, and thus generating potential spaceport locations under uncertainties of different types of natural disasters.

6 - Flight Timetabling under Context-dependent Choice Model

Yufeng Cao, Shanghai Jiao Tong University, Shanghai, China, People's Republic of

Flight timetabling impacts an airline's operating profit. We consider a joint flight timetabling and revenue management problem with passengers choosing among multiple itineraries. The classic multinomial logit (MNL) choice model does not well depict the interaction between parallel itineraries. So, we introduce a context-dependent MNL model where the attraction value of one product is contingent on the offer set. The context-dependent MNL model extends common choice models and provides alternative explanations to several empirical observations. We formulate the joint flight timetabling and revenue management problem as a mixed integer programming model. We present a two-stage decomposition framework to compute the network timetable within a practical time budget. Numerical results suggest that the combination of the formulation and the solution approach leads to profit improvement for airlines.

Operations Research and Analytics at BNSF Railway

Invited Session

Railway Applications

Chair: Andrea Arias, BNSF Railway, Keller, TX, United States

1 - Real time optimization and sequential decision making in railroad hump yard operations

Avnish Malde, BNSF Railway, Fort Worth, TX, United States, Paul Kuhn

The hump yards are the large merchandise terminals in the railroad that assist in classifying cars belonging to common outbound blocks. Every hump yard consists of sub-yards, i.e., arrival yard, classification bowl, and departure yards. The arriving railcars that must be classified are stored on arrival yard tracks. The outbound block for every railcar that needs classification is known. Every railcar requiring classification is then sent over the hump, also known as the hill, according to the hump order of the arrival yard tracks and the sequence of the railcar on the arrival yard track. Classification tracks are preassigned for every outbound block that needs to be built. The switches and retarders aid in routing the railcar to the correct classification track. When all the required cars of the outbound trains are humped and its build time has approached, the train is built by gathering all the railcars parked on corresponding classification tracks. The cleared classification tracks can now be assigned to construct a new outbound block. This research studies the multi-period sequential decision-making problem for optimal outbound block assignment to classification tracks by considering the operational constraints of every sub-yard so that we maximize the overall performance of the hump terminal. We model this problem as a multi-objective program and solve it using a combination of hierarchical and blended objective approaches.

2 - Multi-period network optimization for railroad intermodal networks

Hedieh Ashrafi, Southern Methodist University, Dallas, TX, United States, Paul Kuhn

This project introduces an integrated recommendation tool for *Condition-Based Gate Management* (CBGM) throughout BNSF intermodal network. The proposed recommendation system is comprised of two steps. First, we develop a mathematical formulation to optimally orchestrate the intermodal unit flow such that the total number of penalized blocked ingates is minimized subject to yard inventory, lift (ramp and deramp) and offspot capacities. The proposed model connects major operations including ingate, ramp, pipeline, deramp and outgate within and between the intermodal hubs. A solution to the model involves the number of units to ingate, allocate, ramp, not-ramp, deramp, offspot and outgate at origin, destination, domestic/internation and load/empty levels over an 11-day planning horizon. In the second stage, we design a what-if algorithm to automatically drill down into the obtained solution and identify the underlying reasons for possible undesirable events such as allocations and offspots.

3 - Dual-stream, time-space network optimization for resource allocation at railroad intermodal hubs

Vishal Badyal, BNSF Railway, Fort Worth, TX, United States, Dasaradh Mallampati

Railroad intermodal hub facilities are logistical marketplaces where customers drop off individual units (i.e. in-gate) to be shipped to various destinations serviced by the railroad, and collect units brought in by the railroad for them. This process is resource-intensive in the sense that it involves chassis, parking lots, lifting equipment, hostlers, hub personnel, crew, rail equipment, and so on. Units trickle in as customers bring in, and railroad needs to aggregate and assign them to an outbound train that can deliver them on time at the intended destination. Similarly, an inbound train brings in a large batch and railroad operations need to deramp (i.e. unload) and store the units in right parking spot in the hub before customer could pick them up, without hampering the fluidity of the hub facility.

This initiative employs two time-space networks – one for the in-gate traffic and the other inbound- to represent hub operations and process events as nodes, and unit flow between them as edges. The flow of units through both the networks is governed by resource availability and complementary and competitiveness between them. This dual-stream, time-space network model synchronizes the unit flow between ingate and inbound streams and facilitates resource exchange and allocation, and identifies scenarios where additional resources are needed from external sources to address the ebbs and flows of intermodal traffic through the hub facilities.

4 - Resource and capital planning for railroad automotive facilities using simulation

Andrea Arias, BNSF Railway, Fort Worth, TX, United States, Rajon Pantha, Justin Taylor

Efficient resource and capital planning are critical for railroad automotive facilities to maintain operational excellence and meet customer demands. In this presentation, we show how simulation can be leveraged to make data-driven decisions, optimize resource utilization, and strategically plan capital investments to enhance operational efficiency, customer satisfaction, and financial performance.

5 - A Dynamic Programming Algorithm for Intermodal Load Planning

Wenjie Li, BNSF, Fort Worth, TX, United States, April Kuo

In load planning, containers and trailers (i.e. units) from intermodal facilities are assigned to railcars on tracks with many operational considerations, such as characteristics of units, and other load compliance rules. Each unit has its service priority. Basically, units with low service priority cannot be assigned if units with high service priority have not been assigned. Thus, this load planning problem aims to satisfy service level agreements and follow compliance rules. A dynamic programming algorithm is designed to find optimal solutions in intermodal load planning.

Empirical Research in Healthcare Operations

Invited Session

Behavioral Operations Management

Chair: Bing Bai, McGill University, Montreal, QC, Canada

Co-Chair: Nicholas Clyde, Washington University in St. Louis, St. Louis, MO, United States

1 - The Impact of Ridesharing Platforms on Healthcare Access

Nicholas Clyde, Washington University in St. Louis, St. Louis, MO, United States, Bing Bai, Dennis Zhang

The vast majority of people in the United States do not access the recommended healthcare services, and missed opportunities for prevention are costing the country an estimated $55 billion annually. This is particularly important for older patients, who face a higher risk of adverse health outcomes if potential issues are not detected early. Unfortunately, this population is also prone to transportation barriers because of mobility issues and driving limitations. Our paper uses a natural experiment to empirically investigate the impact of ridesharing platforms on healthcare access. We specifically focus on Medicare patients since healthcare access for them has the most potential to improve health outcomes and reduce spending for this population. We employ a difference-in-differences specification to show that ridesharing platforms have a negative impact on healthcare access for Medicare patients. We further show that this negative impact is mitigated by access to public transportation. Finally, we show evidence for two potential mechanisms: the re-entry of ridesharing platforms causes an increase in traffic and a negative impact on non-profit organizations which provide transportation services to older people and people with disabilities. Our results suggest that ridesharing platforms increase the inconvenience and financial cost of going to healthcare appointments.

2 - Contractors in Nursing Homes: How Contractors Influence the Quality of Care

Minyu Ye, University of Illinois Urbana-Champaign, Champaign, IL, United States

Contractors have become a ubiquitous presence in the operations of nursing homes, playing a pivotal role in shaping the delivery of care to residents. To explore the intricate relationship between the utilization of contractors and the quality of care provided in nursing homes, we employ an Instrumental Variable (IV) method to uncover the causality between the two and examine the underlying mechanisms driving these effects. Understanding the nuanced interplay between contractor usage and care quality is essential for enhancing the overall standards of care in nursing homes and ensuring optimal outcomes for residents. By utilizing the public holiday as the instrumental variable that are exogenous to the quality of care but influence contractor usage, we find that with higher usage of contractors in nursing homes, there are more residents experiencing accidental falling. However, there is no significant effect on Urinary Tract Infection (UTI). Furthermore, we find that the usage of contractors may lead to inconsistent working schedule of staff, which harms the familiarity between nurses and residents, eventually causing the worse quality of care in nursing homes.

3 - Does Team Familiarity Harm the Care Delivery Quality? Evidence from Cardiac Interventional Procedures

Xiaohan Chen, Xiamen University, Xiamen, China, People's Republic of

Managers are often advised to strive for high team familiarity to increase team coordination and thus improve team performance. However, long-term partnerships may reduce learning effectiveness. To explore the potential negative effects of team familiarity on the quality and efficiency of teamwork, we use data from emergency percutaneous coronary intervention (PCI) procedures to estimate the impact of team familiarity on the incidence of major adverse cardiovascular events (MACE) and the duration of each procedural stage. We find U-shaped effects of familiarity both on cooperative quality and efficiency, and these phenomena vary with the requirements of coordination in different task stages. We observe that cross-hierarchical relationships are the source of these negative effects. Finally, we test the moderating effect of leader authority on the negative effect of familiarity. We contribute to adding the evidence and mechanisms by which familiarity negatively affects team performance, particularly in the healthcare field. We discuss that the application of collaborative strategies lies in a dynamic focus on familiarity rather than always strengthening partnerships.

4 - All Horn and No Halo: Explaining Safety-Net Hospitals Underperformance on Patient Experience

Ankita Shirahatti, Boston University, Boston, MA, United States, Anita Carson

Safety-net hospitals play a critical role in the American healthcare ecosystem but face chronic financial challenges - especially on pay-for-performance programs like HCAHPS. Our study takes advantage of the expanse of publicly available information on hospital quality and financial performance to assess how accurately patient-satisfaction is measured for safety-net hospitals. We first examine whether a horn effect --- the opposite of a well-documented cognitive bias known as the halo effect --- distorts patient perceptions of safety-net hospital experiential quality. We also use the growing volume of online reviews of Massachusetts hospitals to identify dimensions of safety-net care that, while deeply important to their patients, are not included as patient experience measures on HCAHPS. We find evidence that safety-net hospitals are subject to a horn effect in which they lose up to two points on the best possible scores for patients' overall ratings and willingness to recommend their hospital. Our results are supported by an alternate empirical specification that examines the effect of newly assigned safety-net status on HCAHPS performance. Our textual analysis of online hospital reviews reveals that ratings are dependent on several features of care not measured by HCAHPS, including a hospital's wait times, diagnostic testing, accommodations, billing process, staff communication, and staff attention levels.

Machine Learning for Queueing Model Discovery and Control

Invited Session

Applied Probability Society

Chair: Vahid Sarhangian, University of Toronto, Toronto, ON, Canada

Co-Chair: Berk Gorgulu, McMaster University, Hamilton, ON, Canada

1 - Admission Decisions Under Imperfect Classification: An Application in Criminal Justice

Zhiqiang Zhang, The University of Chicago Booth School of Business, Chicago, IL, United States, Pengyi Shi, Amy Ward

We study the decision of admitting individuals eligible for probation to incarceration diversion treatment programs, whose aim is to reduce the chance an individual re-offends. The admission decisions are made based on the outcome of a machine learning (ML) algorithm. We model the diversion program as a queueing loss model with reneging during service, and calibrate the model using data from Illinois. Using fluid optimization, we show that the optimal policy has a simple prioritization scheme when the ML algorithm's prediction is sufficiently accurate, but is suboptimal otherwise. We provide a finite sample bound for an imperfect prediction in tabular mixture models and propose guidelines for potential interventions such as collecting more data and involving human judgement. Finally, we investigate the fairness issues among different subpopulations. We explore various fairness criteria from ML and operations perspectives, and discuss the impact of each fairness criterion on admission decisions and corresponding outcomes.

2 - Data-Driven Stochastic Modeling Using Autoregressive Sequence Models: Translating Event Tables to Queueing Dynamics

Daksh Mittal, Columbia University, New York, NY, United States, Shunri Zheng, Jing Dong, Hongseok Namkoong

While powerful, stochastic modeling of service systems demands significant human resources and extensive expertise. To scale and democratize these benefits, we propose a new data-driven paradigm based on prediction models, leveraging recent advances in autoregressive sequence modeling in AI such as transformers. We utilize the rich operational data typically stored in the form of event tables, which record sequences of event types and inter-event times. We propose a meta-learning framework that leverages autoregressive sequence models trained on historical event tables to learn the underlying dynamics of the system. Our main theoretical insight justifies how next-token prediction enables stochastic modeling through autoregressive generation, by drawing connections between partial exchangeability of Markov chains and De Finetti's predictive view of Bayesian inference. As a proof of concept, we substantiate our approach on event tables generated from queueing networks, and demonstrate its benefits in simulation and uncertainty quantification. Our proposed framework lays the groundwork for scaling the impacts of stochastic modeling by leveraging engineering advances in AI and ease of training prediction models.

3 - Approximate Dynamic Programming for Multiclass Scheduling Under Slowdown

Berk Gorgulu, McMaster University, Hamilton, ON, Canada, Jing Dong, Vahid Sarhangian

In many service systems, service times of customers can be correlated with waiting times. Scheduling under such dependency is challenging as a Markovian state description requires keeping track of all customers' waiting history. We propose an approximate dynamic programming algorithm for multi-class scheduling with wait-dependent service times. Our algorithm can generate policies with simple structures and achieve strong performance which we illustrate in a healthcare setting using real data.

4 - Scalable Learning in Weakly Coupled Markov Decision Processes

Chen Yan, The University of Michigan, Ann Arbor, Ann Arbor, MI, United States, Weina Wang, Lei Ying

We explore a general model of Markov decision processes (MDPs) consisting of a large number N of independent sub-MDPs, linked by global constraints. The complexity of finding optimal policies is known to grow exponentially with the number of components N.

In the non-learning scenario, when the model satisfies a specific non-degenerate condition, efficient (i.e., polynomial in N) Linear Programming (LP)-based algorithms exist, achieving a performance gap smaller than $\sqrt{N}$ relative to the LP upper bound value. Conversly, without this non-degenerate condition, any existing heuristics results in a gap of $\sqrt{N}$, and this Central Limit Theorem-type order is generally tight.

In this talk we will improve our current understanding of the order in terms of N for these bounds and then discuss the implications in the learning scenario, considering both the degenerate and non-degenerate settings.

Large-Scale Stochastic Systems

Invited Session

Applied Probability Society

Co-Chair: Debankur Mukherjee, Georgia Tech, ISyE, Marietta, GA, United States

1 - Mean-Field Approximations for Stochastic Population Processes with Heterogeneous Interactions

Anirudh Sridhar, MIT, Cambridge, MA, United States, Soummya Kar

This work studies a general class of stochastic population processes in which agents interact with one another over a network. Agents update their behaviors in a random and decentralized manner according to a policy that depends only on the agent's current state and an estimate of

the macroscopic population state, given by a weighted average of the neighboring states. When the number of agents is large and the network is a complete graph (has all-to-all information access), the macroscopic behavior of the population can be well-approximated by a set of deterministic differential equations (the classical mean-field approximation). For incomplete networks such characterizations remained previously unclear, i.e., in general whether a suitable mean-field approximation exists for the macroscopic behavior of the population. The present work addresses this gap by establishing a generic theory describing when various mean-field approximations are accurate for \emph{arbitrary} interaction structures.
Our results are threefold. Letting W be the matrix describing agent interactions, we first show that a simple mean-field approximation that incorrectly assumes a homogeneous interaction structure is accurate provided W has a large spectral gap. Second, we show that a more complex mean-field approximation which takes into account agent interactions is accurate as long as the Frobenius norm of W is small. Finally, we compare the predictions of the two mean-field approximations through simulations, highlighting cases where using mean-field approximations that assume a homogeneous interaction structure can lead to inaccurate qualitative and quantitative predictions.

2 - Invariance Principles and Mckean-Vlasov Limits for Randomized Load Balancing In Heavy Traffic

Rami Atar, Technion, Haifa, Israel, Gershon Wolansky

A load balancing model is considered where service time distribution possesses a finite second moment (otherwise general). A small fraction of arrivals pass through the power-of-choice algorithm while the remaining ones are assigned to queues chosen uniformly at random. The system is analyzed at the many-server limit in heavy traffic. It is proved that the hydrodynamic limit exists and is characterized as the unique solution of a parabolic PDE with nonlocal coefficients. The PDE has an explicit stationary solution.

Next, two forms of an invariance principle are proved, one under a rather general initial distribution and another under exchangeability. The latter is given by a McKean-Vlasov SDE, a result closely related to limit results for Brownian particles interacting through their rank. However, an entirely different set of tools is required because of the non-Markovian nature of the queue length processes.

3 - A Large-Scale Particle System with Self-Propulsion and Distributed Synchronization

Alexander Stolyar, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Yuliy Baryshnikov

A system of n particles, moving forward in jumps on the real line, is considered. Each particle can make both i.i.d.-sized "independent" jumps and "synchronization" jumps, allowing it to join a randomly chosen other particle if the latter happens to be ahead. System state is the empirical distribution of particle locations. The mean-field asymptotic regime, where n becomes large, is considered. Our results include: (a) convergence of the process to the mean-field limit (MFL); (b) MFL propagation speed (depending on the initial state) and existence of traveling wave solutions; (c) proof of a "minimum speed selection principle," stating that the limit of steady-state propagation speeds is the minimum possible speed of a traveling wave MFL.

4 - Characterizing Rare Events for Interacting Markov chains on Sparse Graphs

Kavita Ramanan, Brown University, Providence, RI, United States, Sarath Yasodharan, I-Hsun Chen, Ivan Lee

Many phenomena in operations research and engineering can be modeled as interacting processes whose instantaneous evolution is governed by an underlying interaction graph. While there has been a lot of attention devoted to the case when the underlying graph is dense, in many real-world applications this underlying interaction graph is sparse. We develop a framework for describing probabilities of rare events, or large deviations probabilities, in such systems on sparse graphs. We also illustrate, via specific examples, how this framework can be applied to gain insight into how rare events occur, and how they are influenced by the underlying graph topology. The talk is based on various joint works with I-Hsun Chen, Ivan Lee and Sarath Yasodharan.

Multiserver & Preemptive Scheduling

Invited Session

Applied Probability Society

Chair: Izzy Grosof, Northwestern University, Evanston, IL

1 - New Lower Bounds on Optimal M/G/k Scheduling

Isaac Grosof, Northwestern University, Chicago, IL, United States, Ziyuan Wang

A well-designed scheduling policy can significantly improve the performance of a queueing system, without requiring any additional resources. While scheduling is well-understood in the single-server setting, much less is known in the multiserver setting. Results are particularly sparse in moderate load settings, outside of the asymptotic regimes of heavy traffic and light traffic. Lower bounds are particularly sparse outside of these settings, limited to the M/G/1/SRPT and M/G/infinity lower bounds, which are only tight in these asymptotic limits.
We seek to prove tighter lower bounds on mean response time in the M/G/k, especially under moderate load. We introduce the WINE lower-bounding framework, allowing multiple lower bounds to be combined into a single, stronger lower bound. Moreover, we introduce and analyze the Increasing Speed Queue, which captures the variable-service-speed nature of the M/G/k system, and use it to further strengthen our lower bound on M/G/k scheduling.

2 - Simple Policies for Multiresource Job Scheduling

Zhongrui Chen, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Isaac Grosof, Benjamin Berg

Workloads in data centers are composed of multiresource jobs requesting a variety of computational resources including CPU cores, memory, disk space, and hardware accelerators. In general, a data center server can run multiple jobs in parallel, but a set of jobs can only run in parallel if the server has sufficient resources to satisfy the demands of each job. It is generally hard to find sets of jobs that perfectly utilize all server resources, and choosing the wrong set of jobs can lead to underutilization of the server. This raises the question of how to allocate resources across a stream of arriving multiresource jobs to minimize the mean response time across jobs — the mean time from when a job arrives to the system until it is complete.

Current policies for scheduling multiresource jobs are complex to analyze and hard to implement. We propose a class of simple policies, called Markovian Service Rate (MSR) policies. We show that the class of MSR policies is throughput-optimal, in that if a policy exists that can stabilize the system, then an MSR policy exists that stabilizes the system. We derive bounds on the mean response time under an MSR policy, and show how our bounds can be used to choose an MSR policy that minimizes mean response time.

3 - Transform Analysis of Preemption Overhead in the M/G/1

Shefali Ramakrishna, Cornell University, Ithaca, NY, United States, Ziv Scully

We present the first transform analysis of the M/G/1 queue under preemptive priority scheduling with preemption overhead. Preemptive scheduling allows high-priority jobs to interrupt low-priority ones, but such interruptions involve overhead costs that are often overlooked in queueing literature. Our work incorporates these overheads, accounting for stochastic delay each time a job is paused or resumed. We also analyze preemptive policies that could minimize overhead by making jobs "resistant" to preemption. Such adjustments could potentially balance the costs and benefits of preemption.

Along the way, our analysis develops a number of new tools for studying preemption overhead in queues. For example, one of the main technical challenges is that a low-priority job's service time is dependent on how many high-priority arrivals occur during it. We develop a method based on multivariable Laplace transforms to capture this dependence. The tools we develop are flexible enough to be useful beyond the specific model of preemption overhead we consider.

This research lays the groundwork for further theoretical exploration into preemptive scheduling with overhead, encouraging subsequent studies to incorporate overhead considerations into more complex scheduling policies.

4 - Transform methods for Markov-modulated queues

Daniela Hurtado-Lange, Kellogg, Northwestern University, Evanston, IL, United States, Isaac Grosof

The Transform Method based on the Drift Method has been developed in the last four years for heavy-traffic analysis in a variety of queueing systems, including the single-server queue, load-balancing system, input-queued switch, generalized switch under complete resource pooling, and ride-sharing. These are studied in discrete time under i.i.d. arrival and potential service process. In this talk, I will introduce a generalization to the Transform Method, where we allow a Markov-modulated arrival and service process. The key is in carefully designing the test function, which includes the queue length and a correction due to the Markov-modulated nature of the arrival process. In this talk, I will present a simple case, but the methodology can be generalized to more complex queueing networks.

5 - Heavy-traffic Optimal Known Size Scheduling in Generalized Switches

Runhan Xie, University of California, Berkeley, Berkeley, CA, United States, Isaac Grosof, Ziv Scully

We study the problem of known-size scheduling in generalized switches. The scheduler has available the size and class information of each job in the system and chooses which jobs to enter service. We give the first scheduling policy that provably minimizes mean response time in heavy traffic. Our results apply to two important classes of queueing models: multiserver-job systems and queues with compatibilities. We remove the server need restrictions, such as power-of-two, in prior study of multiserver-job scheduling and offer insights into scheduling in queues with compatibilities. Our result is a novel combination of ideas from load-balancing guardrails, approximate WINE, and MaxWeight policy.

Summit - 436

Simulation and Generative AI

Invited Session

Simulation Society

Chair: Zeyu Zheng, University of California, Berkeley, Berkeley, CA, United States

1 - Contractive Diffusion Probabilistic Models

Hanyang Zhao, Columbia University, New York, NY, United States, Wenpin Tang

Diffusion probabilistic models (DPMs) have emerged as a promising technology in generative modeling. The success of DPMs relies on two ingredients: time reversal of Markov diffusion processes and score matching. Most existing works implicitly assume that score matching is close to perfect, while this assumption is questionable. In view of possibly unguaranteed score matching, we propose a new criterion -- the contraction of backward sampling in the design of DPMs, leading to a novel class of contractive DPMs (CDPMs). Our key insight lies on the illustration that the contraction in the backward process can narrow score matching errors as well as discretization errors, thus our proposed CDPMs are theorectically robust to both sources of error. For practical concerns, we further show that CDPM does not require any retraining and can leverage pretrained existing DPMs by a simple transformation. We corroborated our proposal by experiments on synthetic 1-dim experiments, Swiss Roll, MNIST and CIFAR-10 dataset: notably, CDPM shows the best performance among all known SDE-based DPMs in terms of W_2 error and smallest FIDs for CIFAR10 unconditional generation, surpassing VE SDE based on NCSN++ \cite{Song20} architecture and the same predictor-corrector sampler.

2 - Learning to Generate Heavy-tailed Conditional Distribution via Diffusion Model

Tingyu Zhu, University of California, Berkeley, Berkeley, CA, United States, Haoyu Liu, Zeyu Zheng, Jinghai He

Emerging applications of conditional generative models in the domain of service queueing systems, supply chain, healthcare and revenue management often witness data with heavy-tailed distribution. Despite the importance of adequately learning heavy-tailed distributions for these applications, we theoretically show that existing conditional generative models, such as diffusion models, encounter challenges in addressing the tail distribution in both model training and data generation. To address these challenges, we develop a method to effectively capture the heavy-tailed distribution patterns, and propose a new framework for conditional generation of heavy-tailed data. We further design synthetic experiments to efficiently evaluate generative models for conditional distributions. Via the experiments, we demonstrate that our method shows superior performance in learning and generating heavy-tailed distributions. Our code is provided in supplementary materials.

3 - Supply Chain Financing Risk Management through a Quantile-regression-based Generative Model

Qingkai Zhang, City University of Hong Kong, Hong Kong, China, People's Republic of, Jeff Hong, Houmin Yan

Supply chain finance is an effective solution for addressing the financing challenges encountered by small and medium cross-border e-commerce enterprises. This study focuses on the crucial risk management issue of supply chain finance. In contrast to conventional approaches, this paper proposes an innovative application of generative models to effectively manage the risk associated with supply chain finance. Specifically, we propose employing a quantile-regression-based generative model to learn the probability distribution of e-commerce product sales, especially the left tail of the distribution which plays a crucial role in risk management. Once the generative model is constructed, any interested risk measure can be easily calculated. Building upon the unique characteristics of supply chain issues, we also derive the convergence and convergence rate of the generative model and corresponding loss of the loan under linear quantile regression assumptions. Moreover, in order to capture non-linear relationships and complex combination characteristics between sales and covariates, we enhance the linear model using deep neural network and factorization machine techniques. Numerical experiments conducted on synthetic and real-world data validate that our proposed generative model can accurately predict the target distribution and facilitate subsequent risk management.

4 - A class of grey-box diffusion models

Haoyu Liu, University of California, Berkeley, Berkeley, CA, United States, Tingyu Zhu, Zeyu Zheng

Diffusion models, which aims at learning a diffusion process that generates a probability distribution for a given dataset from random noises, have been shown to be successful in generation tasks of many areas, including but not limited to audio, graphs, text, time series, and general tabular data. The generation process starts from random noises from a known distribution (usually Gaussian distribution), and iteratively denoise until we obtain new samples from the target distribution. It requires a neural network based model that takes noisy sample as input and predicts the noise. For different kind of tasks, properly designed architecture of the noise prediction model is crucial for the success of the method. Commonly used architectures include U-Net and transformer-like blocks. However, most of the current networks are still black-box that are evaluated only on end-to-end performance. In this work, we propose some preliminary methods to obtain grey-box diffusion models, whose architecture has higher interpretability and allows for more control in the generation process.

Economics of Pharmaceutical Markets

Invited Session

Health Applications Society

Chair: Qinquan Cui, UCL School of Management, University College London, London, United Kingdom

Co-Chair: Kenan Arifoglu, UCL School of Management, University College London, London, E14 5AA, United Kingdom

1 - The Role of Partnerships in Clinical Trials

Feryal Erhun, University of Cambridge, Cambridge, United Kingdom, Lidia Betcheva Haris, Houyuan Jiang, Efthymia Kostaki, Nektarios Oraiopoulos

Drug discovery and development is a lengthy and costly process which, on average, takes 10 to 15 years and costs $2.6 billion per drug, with the majority of R&D costs resulting from clinical trials. Meanwhile, the cost of running a trial has been increasing annually by at least 10%. The importance of launching new drugs to the market quickly, exacerbated by climbing R&D costs, has prompted pharmaceutical companies to strive to conduct clinical development in a more efficient manner. One direct way a pharmaceutical company can extract more value from a drug is by reducing the trial duration. In this talk, we explore how pharmaceutical companies do that with different models.

2 - Mitigating the U.S. Drug Shortages: Evaluating Quality Reward and Other Interventions

Hui Zhao, The Pennsylvania State University, University Park, University Park, PA, United States, Sergey Naumov, In Joon Noh

Drug shortages have been persistent in the U.S. for over a decade, posing serious threats to public health and the healthcare system. While previous research has investigated the causes and effects of drug shortages, there is a dearth of research exploring potential solutions to mitigate this problem. Using a system dynamics model of the U.S. generic drug market, we evaluate the long-term effectiveness of two existing policy interventions (expediting drug approvals and nudging manufacturers to ramp-up their production) and the "quality reward" initiative that is being actively explored by the FDA and industry. Our results indicate that while the effect of the existing policy interventions is limited, quality reward can mitigate drug shortages in a sustainable way. However, a potential caveat of quality reward is the emergence of a monopolistic supply market with negative consequences. We suggest that a carefully designed quality disclosure mechanism can address *this issue. To the best of our knowledge, this is the first study to quantitatively and comparatively evaluate long-term effectiveness of quality reward and other interventions on drug shortages and provide structural explanations for their performance.*

3 - The Role of Information Asymmetry Between Brand-Name and Generic Firms in Pharmaceutical Markets

Qinquan Cui, UCL School of Management, University College London, London, United Kingdom, Kenan Arifoglu, Dongyuan Zhan

Brand-name firms, leveraging their extensive resources and patent protection, possess more information about consumers compared to generic firms. This *information asymmetry* plays a crucial role in shaping pharmaceutical markets. Moreover, following the entry of their generic alternatives, some brand-name drug prices experience a paradoxical increase (i.e., the *Generic Competition Paradox (GCP)*). However, existing research overlooks the information asymmetry between brand-name and generic firms, failing to provide a comprehensive understanding of pharmaceutical markets. To bridge this gap, we develop a game-theoretic model with signaling to analyze interactions between a brand-name firm and a generic firm over two periods (signaling and full-information). We find that the brand-name firm can use *limit pricing* during the signaling period to deter generic entry by charging below its monopoly price, then increase its price and allow entry in the full-information period, leading to the GCP. Consequently, under information asymmetry, limit pricing may arise from the brand-name firm's *anticompetitive* practices, offering an *alternative* explanation for the GCP. While typically resulting in higher drug prices and reduced consumer choice, limit pricing and the GCP can sometimes *benefit* consumers and society. This challenges the prevailing belief that information asymmetry and the GCP are always detrimental, highlighting their nuanced impacts.

4 - Surprise! The Relative Effectiveness of Preannounced and Unannounced Inspections

Zach Wright, Ohio State University Fisher College of Business, Columbus, OH, United States, John Gray, In Joon Noh, George Ball

FDA is the sentinel for ensuring the quality of pharmaceuticals sold in the U.S. For decades, FDA has utilized its facility inspections program to perform periodic process inspections of drug manufacturers. Such inspections in the U.S. are nearly always unannounced, while inspections in foreign countries are preannounced, up to three months in advance. This study examines whether this variation in FDA inspection strategy may impact inspection and product quality outcomes. We employ FDA inspection data, which include two unannounced-inspection pilots performed in India. Using a coarsened exact matching (CEM) matching approach designed to mimic the FDA's inspection Site Selection Model, we examine both inspection outcomes and post-inspection serious adverse events for drugs made at the plant. We find no difference between the likelihood of the most extreme inspection outcomes occurring when comparing all inspections. However, when comparing unannounced inspections in India to pre-announced inspections in the US, we find that inspections in India are several times more likely to receive the egregious (e.g., poor quality) inspection outcomes, suggesting that preannouncing inspections may incentivize "window dressing behavior" by foreign pharmaceutical manufacturers. Further, we find evidence of decreases in serious adverse events following extreme inspection outcomes in India, pointing to the importance of accurate assessments of foreign drug facilities in inspections. Our findings highlight the importance of using unannounced inspections to improve drug outcomes.

AI in Healthcare

Invited Session

Health Applications Society

Chair: Mehmet Ayvaci, The University of Texas at Dallas, Richardson, TX, 75287, United States

1 - What People Think of Machines as Doctors: Unveiling the Value of Gen-AI for E-Health

Dicle Yagmur Ozdemir, Erasmus University, Rotterdam, Netherlands, Mehmet Ayvaci, Alejandro Zentner

Large language models (LLMs) generate human-like text from vast data, enabling natural language communication even for tasks demanding expert knowledge. As LLMs increasingly become an alternative for experts, understanding how non-experts perceive and respond to automated responses by machines (in this case, LLMs) is crucial. Framed within the context of patient-physician communication, we investigate how non-experts (typical patients) perceive LLM responses versus physician responses and explore the factors influencing their perception. In a survey-based experiment, we compare non-experts' (survey participants) evaluations of responses from physicians and ChatGPT, a Chat Generative Pretrained Transformer, to patient queries. Our findings reveal that non-experts overwhelmingly prefer ChatGPT responses over responses by physicians, even when machine responses are of low quality (as judged by a blinded panel of experts). Two key factors influencing this preference emerge from our study: longer prose from ChatGPT heightens non-experts' preference for machines, while disclosing the response source diminishes this preference, especially when the ChatGPT response quality is lower. Our study indicates the need for a careful use of LLMs when responding to laypersons, particularly patients, in their search for answers to health-related questions.

2 - AI Orientation of Online Influencers: Evidence from A Fitness Platform

Fanruo Wang, University of Rochester, Rochester, NY, United States, Hongfei Li, Weiguang Wang

The influencer economy has flourished over the past decade, driven by social media marketing, endorsements, and product placements. While it could be cooperative or competitive among influencers, artificial intelligence (AI) is revolutionizing the landscape of the influencer economy. On one hand, AI can be cooperative with influencers by streamlining and enhancing content creation, spanning from idea generation to content writing. On the other hand, AI has the potential to challenge or replace influencers by producing high-quality content at scale and delivering timely, personalized responses. With the unprecedented change in the influencer economy, however, influencers' attitudes towards AI are unexplored. In this study, we conduct a large-scale field experiment by sending a fitness-related question in a private message to the influencers that contains the different activation information of value orientation towards human and AI peers and analyze their responses. Our findings indicate that influencers exhibit a greater inclination to respond when prompted with the activation of social value orientation, whereas they display reduced responsiveness when primed with the activation of AI value orientation. We further explore the heterogeneous attitudes towards AI and observe that influencers are less willing to contribute with the AI cooperative activation.

3 - Technological Interventions to Combat Social Stigma in Mental Health Support

Zhichen Chen, Boston University, Boston, MA, United States, Gordon Burtch, Bin Gu, Chrysanthos Dellarocas

Many individuals in the United States face mental health challenges but do not seek professional help. Besides cost and accessibility, stigma is a significant barrier. This study explores how telehealth and conversational artificial intelligence (AI) can reduce stigma and encourage individuals to seek mental health support. We conducted a controlled online experiment with over 1,000 participants who reported mental health challenges. Participants were randomly assigned to two independent treatments: one manipulated their expectations of stigma, employing a social norm intervention, while the other presented them with alternative bundles of mental health service offerings (combinations of offline services, online telehealth services, and a ChatGPT-like conversational AI agent with varying data privacy assurances). Results showed that participants had greater intention to engage with mental health services when telehealth and conversational AI options were provided, especially when they were treated with high stigma concerns. However, when treated with low stigma concerns, participants' intention to engage with offerings involving conversational AI depended on strong data privacy commitments. Weak privacy assurances reduced interest in using offerings involving conversational AI. These findings highlight the potential of telehealth and conversational AI to increase engagement with mental health services. They also underscore the need for strong data privacy policies to address the tension between social stigma and privacy concerns. Implications for designing and implementing conversational AI for mental health support are discussed, considering data privacy and demographic factors.

4 - Between Learning and Practicing: Investigating Labeling Availability related AI Fairness in Predicting Diabetes Progression from Prediabetes

Junjie Luo, Johns Hopkins School of Medicine, Baltimore, MD, United States, Ritu Agarwal, Gordon Gao

AI fairness is increasingly crucial as AI technologies are implemented in critical areas. Current research often presumes that data in practical settings are of full labeling availability as those in learning settings. This assumption can be flawed, as not all individuals from practical settings return for follow-up to generate the label to be learned by models. This discrepancy in feature and labeling distributions between learning and practicing settings is underexplored in the context of AI performance and fairness evaluations. Addressing this, we examine the impact of labeling availability on model fairness, using diabetes progression prediction from prediabetes as a case study. Our analysis reveals that only 37.09% of data points in practical settings are labeled for model training. Furthermore, there is a significant racial disparity in labeling availability: 40.33% for White individuals compared to 35.26% for Black individuals. This discrepancy not only affects dataset construction but also extends to model performance, where the prediction accuracy for Black individuals is 2% lower than for White individuals. To tackle these issues, we designed a model that evaluates labeling availability for each data point. Our findings show that data points with higher labeling availability scores generally yield better prediction performance, with accuracy improving by 0.26% for a 1% increase in labeling availability. Most importantly, controlling for labeling availability eliminates racial disparities in prediction performance, highlighting the necessity of considering labeling availability in both model training and application phases. This paper calls attention to labeling availability for more equitable AI outcomes.

OR and Other Analytical Approaches for Healthcare Systems

Invited Session

Health Applications Society

Chair: Ankit Bansal, State University of New York, Binghamton, Binghamton, NY, United States

1 - Data-Driven Robust MDPs: an Application to Clinical Treatment Decisions

Angela Lin, Massachusetts Institute of Technology, Cambridge, MA, United States, Gavin Findlay, Dessislava Pachamanova, Georgia Perakis

We propose an approach for solving empirically-learned Markov Decision Processes (MDPs) which addresses two important goals in the context of clinical decision-making: robustness to estimation errors and risk-aversion. Since the optimal treatments (policies) are heavily dependent on the empirically-estimated transition probabilities of the MDP, we leverage statistical tools and observed data to construct appropriately conservative uncertainty sets for our robust MDPs and obtain robust treatment policies. These treatment policies not only protect against estimation errors but also provide a risk-aware decision-making lens. We test our robust/risk-aware MDP methodology on a sepsis treatment problem using data from a Boston area hospital.

2 - Equitable Vaccine Allocation through a Dynamic Epidemic-Supply Chain Model

Kimiya MohammadiJozani, Virginia Tech, Blacksburg, VA, United States, Esra Buyuktahtakin Toy

We present an optimization framework that integrates epidemic compartmental models with vaccine supply chains, incorporating equity considerations. Our model offers a proactive vaccination strategy that effectively controls disease spread by anticipating disease waves based on real data and planning mitigation efforts in advance. It serves as a dynamic decision-support tool for policymakers, optimizing vaccine distribution with various definitions of equity to ensure fairness. We introduce a new decomposition and cutting plane algorithm designed to address the computational complexities of our large-scale NP-Hard problem. This approach is demonstrated through its application to COVID-19 vaccine allocation in the US, showcasing its effectiveness in managing the complications of vaccine allocation challenges.

3 - Personalized Prediction and Control of Blood Glucose Levels using Dynamic System Modeling

Anjolaoluwa Popoola, Georgia Institute of Technology, Atlanta, GA, United States, Pooyan Kazemian, Kamran Paynabar

Patients with diabetes in the ICU typically rely on two methods to monitor their blood glucose levels: blood tests analyzed in the laboratory and fingerstick tests. While fingerstick tests offer a cost-effective and convenient approach, they sacrifice accuracy, providing only approximate measurements. In this paper, we propose a dynamic system model combining deep learning models and Kalman filtering to accurately predict blood glucose trajectory and assist with personalized glucose control over time. The resulting model, called a deep Kalman filter (Deep-KF) model, can be applied in the ICU and other healthcare settings. We validate our model using randomized real-world glucose and insulin clinical data. We demonstrate how our model can deliver precise blood glucose forecasts and insulin delivery recommendations and be used as a decision-support tool for healthcare providers, hence making glucose monitoring more efficient and patient-centric.

4 - *A Branch-and-Price Approach for Resource Allocation in a Pre-admissions Testing Clinic*

Mohammad Al Syouf, Binghamton University, Binghamton, NY, United States, Ankit Bansal, SALIGRAMA AGNIHOTHRI

Pre-admissions testing (PAT) clinics are hospital units serving pre-operative patients and performing tests to prepare patients for surgery. Patients may need multiple tests, each performed by a specialized nurse. Once a patient is taken to one of the limited exam rooms available, the patient stays in the room until all the required tests are completed. This research introduces a new modeling framework for optimizing the allocation of resources, such as room time and nurse time, in a PAT clinic. Efficient allocation of these resources is vital for patients, healthcare providers, and administrative personnel. The study proposes a novel routing-based modeling approach for resource allocation within PAT scheduling and presents a Branch-and-Price algorithm to address the problem. Computational results, based on real instances, are presented to demonstrate the effectiveness of the proposed approach.

5 - Minimizing Nurse Anesthetist Intraoperative Handovers

Abhishrut Sinha, State University of New York, Binghamton, Binghamton, NY, United States, Ankit Bansal, Osman Ozaltin, Michael Russell

Intraoperative handovers between Certified Registered Nurse Anesthetists (CRNAs) during surgeries pose a significant risk of medical errors, potentially leading to adverse health consequences. To address this, we introduce a two-stage stochastic optimization model that assigns CRNAs to operating rooms. The model aims to minimize intraoperative handovers while accounting for system operational constraints and uncertainties in surgery durations. We present computational results using data from a hospital system to showcase the effectiveness of our proposed approach.

Topics in Platform Economy

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Dan Zhang, University of Colorado, Boulder, CO, United States

Co-Chair: Chengyi Lyu, University of Colorado Boulder, BOULDER, CO, 80309, United States

1 - Platform Entry and Vendor Competition in on-Demand Economy

Xiaotang Yang, University of Toronto, Toronro, ON, Canada, Arseniy Gorbushin, Ming Hu, Yun Zhou

We examine the impact of introducing a delivery platform on vendor competition. We consider an on-demand delivery system with n vendors competing for customers on the *full price*, which includes both the food price and the delivery fee. Vendors are strategic; each must decide whether to participate in the platform or build its dedicated delivery fleet (i.e., employing in-house delivery) to maximize its profit, or not offer any delivery option (i.e., only serving local customers). Vendors who participate in the platform set their food prices while the platform sets the delivery fee and takes a commission from the vendors' revenue. Vendors who build their own dedicated delivery fleets decide on both the food prices and delivery fees. To operate in the market, both the platform and vendors that build dedicated delivery fleets must ensure that their delivery times do not exceed the maximum allowable delivery time. We solve for the equilibrium of the underlying system and benchmark against the system without the platform. Our findings indicate that the introduction of the platform can either intensify vendor competition by subsidizing the delivery service (i.e., charging a delivery fee lower than the marginal delivery cost), leading to lower vendor profits and higher customer surplus, or conversely alleviates vendor competition by deriving profits from the delivery service, leading to higher vendor profits and lower customer surplus. Hence, the platform enabled sharing of couriers improves delivery efficiency, lowers delivery cost, but may intensify vendor competition and hurting vendors as in a prisoner's dilemma.

2 - Does Size Matter for Loyalty Points Redemptions?

Yang Chen, Smith School of Business, Queen's University, Kingston, ON, Canada, Anton Ovchinnikov, Nicole Robitaille

Prior research finds that redeeming loyalty points is generally associated with increased customer loyalty. However, does the size of a redemption impact loyalty? Numerous economic, behavioral, and psychological theories suggest that size might matter, but their specific predictions are often conflicting. Furthermore, whether a reward redemption feels small or large may be individual and context-dependent. With a large longitudinal proprietary dataset from a major loyalty program (LP) capturing its highest earners, our study investigates the effect of reward redemption size and consumer "type" on long-term behavioral loyalty. We find that size does matter in reward redemptions, and so does the operationalization of size and prior reward redemption behaviors. Small redemptions are sometimes associated with increased loyalty, whereas medium redemptions are most consistently associated with increased loyalty. With large redemptions, however, we sometimes observe a decrease in loyalty. Our findings suggest that encouraging the optimized redemption size has the potential to increase LP revenue significantly. That is, rather than passively letting reward redemptions happen, firms may want to actively manage them and treat redemptions as a new control lever in LP revenue optimization.

3 - Optimizing and Learning Assortment Decisions in the Presence of Platform Disengagement

Mika Sumida, Marshall School of Business, University of Southern California, Los Angeles, CA, United States, Angela Zhou

We consider a problem where customers repeatedly interact with a platform. During each interaction with the platform, the customer is shown an assortment of items and selects among these items according to a Multinomial Logit choice model. The probability that a customer interacts with the platform in the next period depends on the customer's past purchase history. The goal of the platform is to maximize the total revenue obtained from each customer over a finite time horizon. First, we study a non-learning version of the problem where consumer preferences and return probabilities are completely known. We formulate the problem as a dynamic program and prove structural properties of the optimal policy. Next, we provide a formulation in a contextual episodic reinforcement learning setting, where the parameters governing contextual consumer preferences and return probabilities are unknown and learned over multiple episodes. We develop an algorithm based on the principle of optimism under uncertainty for this problem and provide a regret bound. Previous approaches that address user disengagement often constrain exploration. However, in our model with non-permanent disengagement with assortments, the optimal solution simply offers larger assortments at the beginning of the horizon and exploration is unconstrained during the learning process. We numerically illustrate model insights and demonstrate regimes where our algorithm outperforms naively myopic learning algorithms.

4 - Customer Reward Programs for Two-Sided Markets

Chengyi Lyu, University of Colorado Boulder, BOULDER, CO, United States, Dan Zhang

Some two-sided markets have been spending billions of dollars on customer reward programs every year. Yet, there is little research on the rationale and impacts of such programs, despite the large literature on customer reward programs in traditional markets. This paper examines the rationale and impacts of customer reward programs in two-sided markets, investigating the efficacy of such programs and highlighting their interplay with matching schemes. We adopt an analytical model for a platform that interacts with customers and service providers over an infinite time horizon. Under a customer reward program, a customer earns a cash reward for every purchase with a finite expiration term, which can be used to offset the selling price in a subsequent purchase within the expiration window. Customers are heterogeneous in their request probabilities and valuations, while providers differ in their service costs. The platform maximizes its profit by setting the service compensation for providers, and the price and reward program parameters for customers. We show that adopting a customer reward program can often dramatically improve the platform's profit. Importantly, matching schemes play an important role -- customer reward programs are much more lucrative under priority matching schemes than a random matching scheme. Our results rationalize the heavy investments made by many two-sided markets in customer incentives and demand/supply matching. Overall, we conclude that customer reward programs can be an even more important profit-boosting tool for two-sided markets than for traditional one-sided markets. We also discuss the welfare implications of our findings.

Applications of Stochastic Models in Service Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Demet Batur, University of Nebraska-Lincoln, Lincoln, NE, United States

1 - Curbing the Opioid Crisis: Optimal Dynamic Policies for Preventive and Mitigating Interventions

Sina Ansari, Driehaus College of Business, DePaul University, Chicago, IL, United States, Shakiba Enayati, Raha Akhavan-Tabatabaei, Julie Kapp

This paper addresses the challenge of effectively responding to the opioid epidemic stemming from prescription pills through a public health lens. It centers on the strategic distribution of resources across diverse interventions aimed at preventing and mitigating the consequences of opioid use disorder (OUD) and overdose occurrences.

This paper proposes a decision aid tool built on the expected utility theory that leverages a Susceptible-Infected-Removed compartmental model to simulate the dynamics of the epidemic in a population. This model then feeds into a Markov Decision Process (MDP) model to generate optimal policies upon the current state of the epidemic. The optimal policies allocate the intervention budget to primary preventive and mitigating interventions in each decision period by minimizing the cost of fatal overdoses relative to the population's number of individuals with OUD, considering the impact magnitude of each intervention, based on the current state of the epidemic. A 10-year simulation of the epidemic's progression is conducted to assess the dynamic efficacy of the proposed decision tool.

The findings reveal an average reduction of 29% in total costs compared to the scenario without interventions and a decrease of 12% in total costs on average compared to the scenario with a 50-50 allocation. This study provides practitioners with a tool to effectively address the opioid epidemic and enhance public health by deciding how to allocate their budget to various levels of intervention.

2 - Dynamic Capacity Sharing in Wireless Networks

Demet Batur, University of Nebraska-Lincoln, Lincoln, NE, United States, Jennifer Ryan, Mehmet Vuran

A Markov Decision Process (MDP) model is proposed to study the decision problem faced by the operator of a private 5G network, known as a private cell, who must allocate available capacity to meet the resource needs of the primary user of the network, but who may also make excess capacity available to external secondary users to generate additional revenue. Private cells are privately owned wireless networks independent of commercial or public 5G networks. Industries such as manufacturing and transportation utilize private cells to prevent downtime for their automated operations. Private cells provide dedicated wireless connectivity, which enables enhanced security, reliability, and cost-effectiveness. They make use of network slicing, a technological advancement made available by 5G, to meet differentiated needs across applications. The network and its resources can be segmented through slicing to support specific applications. We study the problem faced by a private cell operator whose main responsibility is to serve the slice instances of the private cell's primary user but who can also lease excess resources to a secondary user to generate revenue. Slice instances require a slice with a specific combination of resources, such as spectrum, computation, or storage. The operator must manage the network's operations to determine which instances will be admitted to the network for service and which resources can be leased to the secondary user. We use an MDP model to formulate this problem and characterize the optimal admission and leasing decisions, which must be made in real-time based on the private cell's state.

3 - The Interplay Between Customer Feedback Solicitation and Product Innovation: a Dynamic Solution

Izak Duenyas, University of Michigan-Ann Arbor, Ann Arbor, MI, United States, Hanqi Wen, Joline Uichanco

Nowadays customers are becoming important partners of product/service innovation, with firms using customer feedback to guide product quality improvements. Soliciting customer feedback not only supports product innovation, it also cultivates loyalty among customers who feel that their voice can lead to change. However, soliciting informative feedback could be costly, leading to complicated tensions in the decision of whether to solicit feedback or not. In this paper, we analyze the dynamic policy for soliciting feedback that is informative for product quality improvement under two different settings where (i) the firm continually invests and (ii) the firm jointly decides when to invest in product quality improvement respectively. In setting (i), we find that the optimal policy has a monotone-threshold structure, which suggests the firm should initially engage in soliciting customer feedback, until either the amount of solicited feedback is sufficient or the product quality reaches a certain level, indicating the termination of solicitation. The policy is very easy to implement in practice. In setting (ii), the problem is extended to be the joint optimization of feedback solicitation and quality improvement, where we propose a simple but effective heuristic that only needs three thresholds. We run numerical experiments to verify the performance of the heuristic. Our numerical experiments reveal the importance of ensuring adequate customer engagement before committing resources to product innovation, where just a little coordination between feedback solicitation and product innovation can go a long way.

4 - Stability of Fork-Join Systems with Redundancy under Flexible Capacity Allocation

Chutong Gao, Northwestern University, Evanston, IL, United States, Seyed Iravani, Ohad Perry

We consider the stability problem of fork-join systems with redundancy under flexible capacity allocation. In this setting, a job consists of multiple tasks, each of which is sent to a different queue, and the service of a job is completed once some of its tasks are processed by the servers (so that the rest of the tasks are redundant). Further, servers can collaborate in processing tasks, thus increasing the rate at which they are processed. In the case when two tasks for each job must be completed, we establish the necessary and sufficient condition for systems under any static capacity allocation policy to be stable, and characterize the maximal stability region among all static policies. We then show that a static allocation policy achieves the maximal stability region if and only if the capacity allocated to each queue does not exceed one half of the total capacity. Next, we consider dynamic allocation policies, which allow for reallocation of capacity at any time. We show that dynamic policies achieve the same maximal stability region as the static policies, but under a milder condition, which only requires that the capacity allocated to the shortest queue does not exceed half of the total capacity at any time.

Advances in Empirical Healthcare Operations

Invited Session

MSOM: Healthcare

Chair: RJ Niewoehner, Kelley School of Business, Indiana University, Bloomington, IN, United States

Co-Chair: Maria Ibanez, Kellogg School of Management at Northwestern University, Evanston, IL, United States

1 - E-Access Versus Physical Access: An Examination of Telehealth Adoption

Eric Xu, Mississippi State University, Mississippi State, MS, United States, Kevin Linderman

As interest in telehealth has expanded in recent years, it is more important than ever to understand the tradeoffs patients make when deciding about whether to use in-person services or telehealth services. Therefore, we examine the impact of telemedicine adoption on primary care use, specifically examining the conditions by which telehealth consultations become a substitute for in-person care or a compliment to in-person care. Using a unique dataset of insurance claims for primary care visits, we examine in-person, asynchronous, and synchronous primary care visits.

2 - From Full-TIME to Flexi: Examining the Outcomes of Workforce Changes in Primary Healthcare Delivery

Harshita Kajaria-Montag, Indiana University, Bloomington, IN, United States, Michael Freeman

Primary care practices have responded to the workforce crisis by altering the
composition of their workforce, specifically, by hiring more part time and locum physicians. But, this is counterproductive as research suggests that providing continuity of care is productivity-enhancing, which is difficult to offer with such a fragmented workforce. Consequently, the trend suggests that continuity of care has been declining over the past decade. This paper examines this question from an operations management perspective by exploring the relative importance of workforce composition related operational factors that may explain variation in rates of COC between practices and over time.

3 - Machine Learning-Guided Cancer Screening: The Benefits of Proactive Care

Minje Park, The University of Hong Kong, Hong Kong, Hong Kong, Carri Chan, David Vawdrey, Elliot Mitchell, Abdul Tariq

With the advance of data analytics, many disease prediction models have been developed with the intent of detecting diseases earlier and improving patient outcomes. The operationalization of interventions and care based on these predictive models is critical to attaining these goals. We study the effects of a machine learning-guided colorectal cancer screening program. Using a regression discontinuity design based on the predicted risk score for having cancer, we find that the program increases the likelihood of colonoscopy uptake in three and six months by 6.8 percentage points (243% increase relative to the control sample within the bandwidth) and 9 percentage points (184% increase), respectively. Importantly, we also find significant effects on mortality. We estimate that the program decreases 2-year mortality by 7.2 percentage points (49% decrease). Our finding suggests that a machine learning-guided cancer screening program could significantly improve patient outcomes in addition to higher disease detection rates.

4 - The Impact of Batching Behavior in Emergency Department Prescription Orders

Yong Xia, University of California, San Diego, La Jolla, CA, United States, Danqi Luo

This study investigates the batching behavior of emergency department (ED) physicians in placing prescription orders and its impact on healthcare delivery quality. Batching behavior is defined as the practice of placing orders for multiple patients within a brief time interval immediately after seeing these patients. Understanding this behavior is crucial as it provides insights into workflow practices that influence healthcare outcomes and inform policy and operational improvements. Data from two comprehensive sources were analyzed: a large teaching hospital in Southern California over three years and a central hospital in China over seventeen months. The analysis reveals that physicians engaging in batching behavior order more tests, particularly lab tests, but fewer imaging tests. Furthermore, batching behavior is associated with a reduction in patient length of stay (LOS) but an increase in readmission rates. These findings suggest that while batching can improve workflow efficiency, it may adversely affect the quality of care. Thus, hospitals must consider the tradeoff between operational efficiency and maintaining high healthcare standards.

Summit - 443

NFT and Platform Innovation

Invited Session

MSOM: iForm

Chair: Yao Cui, Cornell University, Ithaca, NY, United States

Co-Chair: Jingchen Liu, Renmin University of China, Beijing, 100872

1 - Nft Market Design

Jingchen Liu, Renmin University of China, Beijing, China, People's Republic of, Yao Cui

In this paper, we study two NFT platforms that compete in a two-sided market over two periods. Period 1 corresponds to the primary sale period, where the creators mint and sell the NFTs to speculators on one of the two platforms. Period 2 corresponds to the resale period, where speculators resell the NFTs to collectors on the platforms. Under both centralized and decentralized royalty policies, we study the impact of platforms' adoption of interoperability on the competition between platforms and the welfare of other stakeholders.

2 - Unveiling the Scalping Factor: An Empirical Analysis of Nft Market Dynamics and Operational Insights

Wenbin Wang, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of, Shanshan Guo, Yue Qiu, Tian XIE

This paper explores the dynamic relationship between scalping activities and market returns in the non-fungible token (NFT) market. Central to our approach is the development of a theoretical model that elucidates the interaction between consumer and scalper behaviors, examining their impact on NFT pricing and market dynamics. Complementing the theoretical insights, our empirical analysis is anchored in a one-period-ahead regression model, utilizing the common correlated effect (CCE) estimation method. This method is crucial for identifying and quantifying an unobserved 'scalping factor', significantly influencing NFT returns. Analyzing the data on 16 Ethereum-based NFTs from OpenSea, we uncover a varying impact of scalping on various market segments.

Our research uncovers that while scalping negatively correlates with returns for larger-cap NFTs, it benefits smaller-cap NFTs, exhibiting immediate yet transitory effects in the dynamic NFT market. This research highlights the complexity of the NFT market and emphasizes the importance of the CCE methodology in unraveling the nuanced effects of scalping, offering key insights for investors and platform developers in this rapidly evolving sector.

3 - Information Good Pricing Under Unit Costs: Impact of Lazy Minting on Pricing Strategies In Nft Marketplaces

Giannis Kanellopoulos, Tilburg University, Tilburg, Netherlands, Dominik Gutt, Murat Tunc, Ting Li

Non-fungible tokens (NFTs) represent a new category of information goods, and unlike others, their marginal costs per additional unit are non-negligible. To alleviate the upfront financial costs typically borne by creators, NFT platforms introduced the "lazy minting" approach. Lazy minting introduces a new cost structure for information goods by deferring the minting fee until the point of sale and transferring the responsibility from the creators to the initial buyer. This shift has the potential to reshape the pricing dynamics of information goods, where production cost is no longer the primary factor guiding creators' pricing decisions. To explore this, we empirically examine the impact of lazy minting on NFT prices. Our findings reveal that creators' pricing decisions are influenced by their trading experience (i.e., the risk premium effect) and the duration they own and hold their NFTs (i.e., the endowment effect). Our results contribute to the pricing and valuation of information goods in response to the changes in production costs.

4 - When Crowdsourcing Meets Crowdfunding: The Work-Donation Interplay and Its Implications for User Engagement

Xue Tan, Southern Methodist University, Dallas, TX, United States, Rowena Gan, Kyunghee Lee

When platforms integrate crowdsourcing and crowdfunding, users play a dual role of both workers and donors. Understanding the interplay between individuals' work and donation behavior helps enhance user engagement on and contribution to the platform. We examine the interplay between users' decisions in a Web 3 community both analytically and empirically. Our empirical context was a digital platform (GitCoin) that offers both grants (a crowdfunding service) and bounties (a crowdsourcing service). While our economic model predicts that people will behave in a consistency-seeking way such that those who used to donate more would donate more in the future and those who used to earn more would work more in the future, our empirical analysis identified variety-seeking behavior in the short run. That is, workers who have recently earned incomes would be more likely to donate, and they would be most likely to donate when they have earned income from traditional projects. They would be least likely to donate when they earned the income from contests. In the long run, our prediction of consistency-seeking was validated in the data.

Operational Decision-Making Under Uncertainty

Invited Session

MSOM: Service Operations

Chair: Milad Armaghan, Southern Methodist University, Dallas, United States

Co-Chair: Eojin Han, University of Notre Dame - Mendoza College of Business, Notre Dame, IN, United States

1 - Optimal Control of In-store Inventories for Omnichannel Retailing

Joohyun Kim, University of North Carolina at Charlotte, Charlotte, NC, United States, Sila Cetinkaya

We investigate the problem of optimizing the omnichannel inventories of a firm that owns and operates multiple retail stores in a stochastic dynamic setting. We consider the case where the relationship between online and in-store demands is considered explicitly and propose a new mean-field control model. We compute the closed-form solution characterizing the optimal control policy.

2 - Relative Monte Carlo for Reinforcement Learning

Audrey Bazerghi, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Sebastien Martin, Garrett van Ryzin

We introduce relative Monte Carlo (rMC), a new general purpose policy gradient algorithm for reinforcement learning with discrete action space. The policy is improved in real time using relative returns between a root sample path and counterfactual simulated paths instantiated by taking a different action from the root. The method is compatible with any differentiable policy, including the leading choice of neural network parametrization. It is guaranteed to converge for episodic and average reward tasks. Unlike traditional Monte Carlo, rMC policy gradient steps are performed throughout the rollout using a memory-efficient update decomposition, inspired by eligibility traces. Strong couplings between root and counterfactual paths further contribute to low data generation and memory requirements. We test rMC with a policy network in a two-tiered inventory fulfillment problem. Numerical results show it performs well compared to related algorithms.

3 - Predicting demand for wildfire suppression resources

Yasser Zeinali, University of Alberta, Edmonton, AB, Canada, ILBIN LEE, Mostafa Rezaei

Wildfires, as a global threat, pose significant damage recently in North America, where Canada reports over 8,000 wildfires annually, burning millions of hectares. The situation escalated in 2023, with Canada facing wildfires over an unprecedented 18.5 million hectares. Wildfire management agencies are under intense pressure to devise an effective resource allocation strategy. In this work, as a collaboration with the Alberta government, we integrate machine learning, queuing theory, and robust mixed integer programming to develop a predictive and prescriptive system for deploying wildfire suppression resources. This system estimates both the total daily resource-hours and the number of wildfires requiring each resource type, which together help us in determining the optimal number of resources to be deployed. Although our case study focuses on Alberta, our methodologies are adaptable and can potentially be tailored to meet the challenges of wildfire management in any region.

4 - A Competitive Newsvendor Problem under Limited Information

Milad Armaghan, Southern Methodist University, Dallas, TX, United States, Eojin Han, Sila Cetinkaya

We study a newsvendor game involving substitutable products. The industry demand is random and unmet demand for a retailer may spill over to competition. The retailers set their inventory levels with limited information about the industry demand distribution. Our goal is to characterize the distributionally robust inventory policies of the retailers. We discover the conditions under which it is optimal to disregard or consider the spill-over demand when setting optimal stocking levels. We also compare and contrast our problem setting to a monopoly under limited-information, and we investigate the conditions under which competition increases or decreases the industry inventory.

Co-Chair: Lei Li, Hong Kong Polytechnic University, M507n, The Hong Kong Polytechnic University, Hong Kong, N/A

1 - Transfer Learning, Cross Learning and Co-Learning Across Newsvendor Systems with Operational Data Analytics (Oda)

Lei Li, Hong Kong Polytechnic University, Hong Kong, Hong Kong, Qi Feng, J Shanthikumar

Decision making with limited statistical characterization and limited data is challenging. The typical statistical-machine-learning approaches would call for migrating the experience of a related system with ample data through transfer learning or leveraging the similarity of multiple systems with limited data through data pooling. We, instead, develop new solution concepts to learn across related systems by adapting the parametric Operational Data Analytics (ODA) framework for non-parametric decision making. We demonstrate that transfer learning can, indeed, improve decision performance in the focal system by utilizing a model pre-trained using ample data in a related system. In contrast, the ODA cross-learning approach utilizes the ample data from the related system to mimic the stochastic environment of the focal system. When the data from the old system are sufficiently large, the cross-learning solutions derived outperform any transfer-learning solution, and they are shown to asymptotically approach the parametric ODA solutions. When there are multiple related systems with limited data, we aggregate the data from different systems to create a generic stochastic environment for the decision-making problem. We show that the derived co-learning solutions are asymptotically optimal for the aggregate system and for each sub-system. This approach outperforms the existing data-pooling techniques in the sense that the latter focuses only on the aggregated performance, and the chosen solution may be (asymptotically) suboptimal for individual sub-systems. Our results underscore the roles of domain knowledge and the structural relationships between the data and the decision in designing efficient learning solutions with limited data.

2 - Conformal Contextual Optimization with a Smart Predict-Then-Optimize Method

Paul Grigas, UC Berkeley, Berkeley, CA, United States, Hyungki Im

We study an extension of contextual stochastic linear optimization (CSLO) that, in contrast to most of the existing literature, involves inequality constraints that depend on the uncertain parameters that are predicted by the machine learning (ML) model. Building on previous work that develops the “Smart Predict-then-Optimize (SPO)” loss and its tractable SPO+ surrogate loss in the case of a known deterministic feasible region, and work that develops robust variants of contextual optimization using conformal prediction methods, we propose a “Conformal Smart Predict-then-Optimize (CSPO)” approach for addressing uncertainty in the constraints. Specifically, we first propose the CSPO loss – a direct extension of the SPO loss – that measures the decision error, or regret, induced by following a robust predict-then-optimize approach that uses a conformal prediction method to produce an uncertainty set. We then propose a convex surrogate loss function called the CSPO+ loss – a direct extension of the SPO+ loss – to tractably train a prediction model in our CSLO setting. To train the model, we employ a data filtering procedure to address issues of infeasibility whenever the predicted uncertainty set fails to cover the true parameters. Furthermore, we utilize importance sampling when training to address the distribution shift induced by the data filtering step. Theoretically, we establish statistical consistency of the CSPO+ loss relative to the CSPO loss and provide finite-sample convergence guarantees for the CSPO loss with importance sampling under mild assumptions. Experimentally, we demonstrate strong performance of the CSPO+ loss on several different CSLO problem classes.

3 - A Single-Index Contextual Bandit Problem

Xi Zheng, University of Washington, Seattle, WA, United States, Gaoqian Xu, Wanning Chen

The Multi-Armed Bandit with Covariates (MABC) framework is a simple yet powerful approach for online decision-making under uncertainty. It has proven valuable in various fields, including online advertising, dynamic pricing and personalized medicine. Traditional MABC frameworks based on parametric and non-parametric models have been well studied. Parametric models are limited by structural assumptions and therefore lack flexibility, while non-parametric methods face significant challenges when the covariate dimension is high. Semi-parametric formulations offer an attractive middle ground between parametric and non-parametric estimation. In this paper, we consider a semi-parametric contextual bandit problem where the conditional expectation of the reward for each arm follows a single-index model. We propose two algorithms for this bandit problem and conduct a finite-time regret analysis. Additionally, we explore the inference properties for finite-dimensional parameters in the semi-parametric model. Numerical experiments based on synthesized and real-world datasets demonstrate that the practical performance of both methods aligns with the theoretical guarantees.

4 - Unraveling Temporal and Spatial Dynamics: An Interpretable St-Ode Method for Predicting Delivery TIME

Hao Wang, UC Berkeley, Berkeley, CA, United States, Junyu Cao, Yan Leng

We develop a new interpretable deep learning method by modeling continuous time on spatial networks to enhance the accuracy of delivery time prediction in home appliance retail sector. Driven by the operational complexities observed at RiRiShun Logistics, a prominent company in China’s home appliance delivery and installation industry, we introduce a novel model that integrates spatial network data within a continuous-time dynamic framework. This model is tailored to capture: (1) the irregular and sporadic patterns of dynamic order placements; (2) the time-dependent relationships within the spatial delivery network; and (3) the varying influences of different delivery centers. Through detailed numerical experiments on RiRiShun’s comprehensive dataset, we demonstrate that our model achieves superior accuracy in delivery time prediction compared to the current best-performing benchmarks. Our ablation study dissects the contribution of individual model elements, revealing how the variability in order flow, the dependencies within the delivery network, and the distinct roles of origin and destination centers can significantly influence predictive performance. The results indicate improvements up to 44.2% for different components, underscoring the efficacy of our motivation and model. These findings not only enhance the reliability of delivery predictions in the retail sector but also contribute a new perspective to the literature on dynamic prediction models, particularly highlighting the benefits of integrating continuous-time analysis with spatial network data.

1 - The Differing Impact of Female Technical Leaders vs. Female Operational Leaders on Product Quality in the Medical Device Industry

George Ball, Operations and Decision Technologies, Kelley School of Business, Indiana University, Bloomington, IN, United States, Donggyu Jeon, Owen Wu, Gil Souza

Examining the influence of gender diversity in general, and female leadership in particular, on product quality performance in firms is a burgeoning research domain. While limited studies have examined if or how female leadership impacts product quality, no studies of which we are aware have differentiated between female technical leaders and female operational leaders. We do so in the highly technical medical device industry, in which product quality outcomes are primarily influenced by one of two underlying firm functions: design or manufacturing. Along those lines, we examine all publicly traded medical device firms in the U.S., and measure the proportion of female leadership team members that hold technical leadership positions, such as research, design and engineering vice-presidents, as well as the proportion of female leadership team members that hold operational leadership positions. These include roles such as manufacturing, supply chain and purchasing vice-presidents. We find that while in aggregate, adding more female leaders to a medical device firm reduces future serious product quality adverse events, this effect is completely explained by female technical leaders; female operational leaders appear to have no measurable impact on product quality complaints. Further, we employ detailed firm-level time-variant culture measures using Glassdoor.com, and discern that the impact of female technical leaders on quality is most prominent when a firm has a relatively negative overall culture, compared to a positive culture. Our study thus helps inform firms as to both when to add female leaders and in what roles to add them.

2 - A Moment For Reflection: De-biasing Service Evaluations

Hallie Cho, Vanderbilt University, NASHVILLE, TN, United States, Dawson Kaaua

This study examines different types biases in the evaluation of a service. Service evaluations typically come in two types--quantitative ratings and qualitative written feedback. Although ratings are typically collected before the written feedback, we propose that switching this order to ask for written feedback first can mitigate any bias present in star ratings as the process of writing provides time and space for reflecting on the evaluator's experience and analytical thinking. We conducted an experiment on Amazon Mechanical Turk where 4261 participants interacted with a server and evaluated their performance quality. We do not find strong effects of common biases toward servers (such as race and gender) in our setting but find strong effects of operational bias--sequence of good or bad experiences leads to biased star ratings. Most importantly, we find that collecting written feedback prior to star ratings effectively mitigates the detected sequence bias in subsequent star ratings. Our paper shows that most widely used quantitative feedback (i.e., average star ratings) can be biased if collected in the traditional manner and that this bias can be reduced if qualitative feedback is collected first. This work has major implications for any firm that collects quantitative and qualitative feedback and bases strategic decisions on aggregated quantitative feedback.

3 - The Impact of Political Polarization on Restaurant Reviews: Evidence from Yelp.Com

Rajan Mishra, California State University, Northridge, CA, United States, Sugato Chakravarty, Wreetabrata Kar

This study examines the influence of political polarization on online reviews and consumer behavior, using Yelp restaurant reviews from the 2016 election cycle. The bedrock of the Social Identity Theory is used to hypothesize that political shifts of a region from Democratic to Republican results in fewer, shorter reviews with simpler language and less praise. Our findings confirm these hypotheses, indicating that political polarization significantly impacts consumer behavior and online review language. Our research makes at least three important contributions. It empirically demonstrates the effect of political polarization on consumer behavior and language use; it underscores the potential impact of political polarization on the quantity and quality of online reviews; and it stresses the need for policymakers and online platform administrators to consider these effects and develop mitigation strategies. In as much as shorter reviews can convey less relevant/important information to the millions of consumers of online reviews, our study provides a timely wakeup call for all stakeholders.

4 - Decoding Biases: Unraveling Fairness and Discrimination in Human and Algorithmic Decision-Making

Arunima Chhikara, University of Kansas, Lawrence, KS, United States, Anurag Garg, Naveen Kumar, Liangfei Qiu

Decision-making exerts a profound influence on both individual destinies and broader societal trajectories. The advent of AI has been driven by the need for assistance in navigating intricate choices. While algorithmic systems promise heightened accuracy, they can inadvertently inherit biases from their underlying rules or training data, thereby engendering inequitable results. Discrimination becomes apparent when protected attributes, including race and gender, sway decisions, perpetuating a cycle of injustice. Despite the presence of numerous laws and policies designed to mitigate discrimination, both human and AI decision-making processes continue to grapple with biases. Our study delves into bias and discrimination in the context of online deception detection (ODD). We explore how gender and race bias affect the detection of fake reviews by AI systems and humans. Moreover, we conduct a randomized experiment to investigate taste-based and statistical discrimination in human decision-making in ODD and establish causal inference. Discerning various forms of discrimination can inform platform policies, bolstering trust. We draw on observational data from Yelp, complemented by randomized experiments, to offer a robust multi-method validation and glean valuable insights. Our research carries significant implications for platforms, policymakers, and businesses, advocating for fairness in online decision-making.

5 - Coping Through Precise Labeling of Emotions: A Deep Learning Approach to Studying Emotional Granularity in Consumer Reviews

Ali Faraji-Rad, University of Maryland, College Park, MD, United States, Ali Tamaddoni, Atefeh Jebeli

When describing their emotions, people may demonstrate *emotional expertise* by differentiating between emotions when using emotional labels or use emotion labels interchangeably to indicate a general valence. The authors develop a novel deep-learning-based method to measure the granularity with which people describe their emotions via language. They investigate the role of emotional granularity in consumer decision making, specifically in relation to coping with negative consumption experiences described in online reviews. Granularity in describing negative emotions is associated with more successful coping with negative experiences. Therefore, especially when the overall experience is negative, in which case coping is most relevant, greater granularity in describing *negative* emotions predicts more *positive* ratings of the business. Furthermore, in line with the view that the ability to granularly describe negative emotions is a skill, reviewers progressively become more granular when describing their negative emotions as they write more reviews. Consequently, reviewers progressively provide more positive ratings for negative experiences as they write more reviews. Finally, a greater temporal distance between the consumption experience and the writing of the review predicts greater granularity in describing negative emotions. Consequently, when the overall experience is negative and coping is relevant, a greater temporal distance predicts more positive ratings.

1 - Impact of Collaborative Food Rescue Initiatives on Food Waste Reduction

Ricky Owusu, North Carolina A&T State University, Greensboro, NC, United States, Lauren Davis

In the current food systems landscape, the concept of food rescue has become a powerful force due to concerns about waste and its effects on the environment and society. This paper explores the collaborative efforts of various stakeholders, such as retail donors, food banks, for-profit organizations, and waste management entities, in addressing the complex challenges of food security, sustainability, and waste reduction. Through a comprehensive framework, surplus food is rescued from various stages of the supply chain and redirected towards meaningful purposes, which helps mitigate the environmental impact of food waste. However, despite these efforts, the global paradox of food waste alongside increasing food insecurity continues to exist. This study examines the dynamics of how food is allocated among stakeholders through Monte Carlo simulation in order to identify disparities and optimize the use of resources. By addressing disparities and improving collaboration, the paper aims to enhance the efficiency and sustainability of food rescue initiatives, ultimately reducing food waste and improving societal well-being. Key research questions explore the impact of for-profit food rescue on non-profit organizations, the influence of optimized food allocation on sustainability, and the role of contracts in fostering collaborative efforts to combat food waste.

2 - A Disaster Management Digital Twin Framework for Resilient Electric Power Restoration

Abdullah Braik, Texas A&M University, College Station, TX, United States, Maria Koliou

Efficient and rapid restoration of electric power following natural hazards is crucial for community resilience, playing a pivotal role in emergency response, economic recovery, and the functionality of essential lifeline and social infrastructure systems. However, previous frameworks available in the literature have focused either on uncertainty modeling for pre-hazard mitigation and preparedness or on post-disaster data analysis for continuous learning and improvement. This study introduces a novel digital twin framework for immediate and rapid post-hurricane electric power restoration. The framework uses a hybrid approach that combines physics-based and data-driven models by utilizing a dynamic Bayesian network. By capturing the complexities of power system dynamics and incorporating the influence of the road network, the proposed framework provides a holistic approach to address restoration challenges. A discrete event simulation is conducted to showcase the framework's efficacy, demonstrating how the electric power restoration digital twin can be monitored and updated in real-time to reflect changing conditions, thereby facilitating risk-informed adaptive decision-making. Moreover, the framework's flexibility enables decision-makers to prioritize essential residential and business infrastructure and compare different restoration plans, assessing their potential impact on the community. In conclusion, the proposed framework holds the promise to revolutionize disaster recovery strategies, leading to faster recovery, improved emergency response, and enhanced community resilience.

3 - Exploring Interconnected Infrastructure Restoration and Resilience with Reinforcement Learning

Ribhu Sengupta, University of Washington, Seattle, WA, United States

With the Pacific Northwest falling along the Cascadia Subduction Zone fault running from Vancouver Island, Canada to Northern California, there is an increased probability that within the next 50 years, a disaster on the scale of a Magnitude 9 earthquake will occur. For a disaster of this magnitude, contingency plans for critical infrastructure networks will have to be developed for restoration efforts to help society recover. We model infrastructure restoration processes through Agent Based Simulation modeling at various levels of awareness/preparedness of interconnected infrastructure systems utilizing a sample setting with six subareas within a city sharing four infrastructure systems (Water, Ground Transportation, Electricity, and Telecommunications). To help guide the development of restoration plans for such networks, we explore the insights various Multi-Agent Reinforcement Learning (MARL) formulations can glean for infrastructure management officials in their planning efforts for the various levels of awareness. These MARL based approaches are benchmarked against theoretical optimal solutions for performance and validated using well known case study examples from the natural hazards resilience modeling platform IN-CORE. The findings from the MARL formulations are translated into actionable items for critical infrastructure managers to incorporate into their contingency planning.

4 - Mitigating Natural Hazard Impacts on Network Systems

Himadri Sen Gupta, University of Oklahoma, Norman, OK, United States, Andres Gonzalez, Charles Nicholson

Enhancing the resilience of utility networks against natural hazards is crucial for maintaining essential services during and after such events. This research presents a stochastic programming model to optimize the resilience of critical utility networks, specifically focusing on power grids and water supply systems. By incorporating the uncertainties associated with natural hazard occurrences and their impacts, the model generates probabilistic scenarios to assess potential disruptions. These scenarios are then used to optimize network configurations and response strategies, aiming to minimize service interruptions and expedite recovery times. The model is tested with data from Joplin, MO, a city severely impacted by natural hazards such as tornadoes. Preliminary results demonstrate significant improvements in network reliability and service continuity, validating the effectiveness of the proposed approach. This study contributes an optimization-based framework for enhancing the resilience of utility networks in hazard-prone areas.

Healthcare Decision Models

Invited Session

Health Applications Society

Chair: Kimia Ghobadi, Johns Hopkins University, Baltimore, MD, United States

1 - Supervised Inverse Optimization with Exogenous Decision Information

Felix Parker, Johns Hopkins University, Baltimore, MD, United States, Kimia Ghobadi

There are many potential practical settings of Inverse Optimization in which the typical strong assumptions on the forward problem structure and near-optimality of observations do not hold because the decision-making process was not optimized exactly, but exogenous information about the performance of observed decisions exists.

We propose Supervised Inverse Optimization (SIO), which aims to meld existing approaches for IO with supervised machine learning by incorporating scores for each observation to learn the objective function parameters through a model that optimizes both IO and regression objectives. The observation scores represent partial information about the objective function, which is often available, and reduces the reliance on assumptions, thereby improving performance. The model is highly flexible and can model problems with linear or non-linear objectives, objectives with unknown structure, multiple scores per observation, and many other problem settings.

SIO is valuable in real-world applications including diet recommendation, hospital capacity management, and finding shortest paths in traffic networks, among others. We demonstrate this with empirical results for the data-driven diet recommendation problem and for inferring and improving hospital capacity management strategies.

2 - Precision Staffing for Float Nurses Integrating AI and Optimization

Jonathan Helm, Indiana University, Bloomington, IN, United States

This talk describes an academia industry collaboration to design and execute a new internal travel nursing program at IU Health that moves flexible nurses between the 16 system hospitals to respond short term geographic fluctuations in demand. For adoptability, we developed decision support to create an on-call list of how many nurses will move and where 2 weeks in advance and deployment decisions 24-48 hours in advance. This required developing a machine-learning-based occupancy forecasting model that accounts for different levels of patient acuity and outputs distributional information that can be used to characterize stochastic nurse demand across the network that feed a stochastic optimization. Implemented in May 2023, subsequent 8 months indicates reductions of 17% understaffing, and 5% overstaffing. Annual savings >$750K.

3 - Neural Combinatorial Contextual Bandit Under Constraints for Sequential Resource Allocation

Ha Bui, Johns Hopkins University, BALTIMORE, MD, United States, Anqi Liu, Kimia Ghobadi

We study the Sequential Resource Allocation (SRA) problem, i.e., how to find an optimal decision of a fixed budget to minimize the allocation cost over time. We formalize this problem under the Combinatorial Multi-Armed Bandit (CMAB) setting. Then, we propose the Neural Combinatorial Upper Confidence Bound Resource Allocation (Neural-CUCB-RA) algorithm, a neural-network-based model to improve the allocation performance by learning from observed data over time. We show our method can work in the healthcare domain with a real-world COVID-19 dataset, in which the model allocates COVID-19 patients to different hospitals with different numbers of available ICU beds so that can save as many patients as possible.

4 - Enhancing Radiotherapy Selection through Predictive Modeling of Treatment-Induced Toxicities

Ibrahim Chamseddine, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States

Radiation therapy is essential for over half of all cancer patients, requiring careful selection of treatment modalities based on patient-specific needs and available technologies. Photon therapy, the more common option, often exposes normal tissue to harmful radiation, making it less suitable for patients at high risk of side effects. On the other hand, proton therapy offers better protection for healthy tissues but is not as widely available. To optimize the allocation of proton therapy, we developed a deep learning model that predicts the risk of radiation-induced toxicities by incorporating patient-specific characteristics and radiation dose distributions in critical non-tumor tissues, referred to as organs-at-risk. The model, applied initially to liver cancer, was trained at Massachusetts General Hospital and validated with an external cohort from MD Anderson Cancer Center. This model has proven superior to traditional risk assessment methods, which typically rely on the average radiation dose delivered to the liver. By achieving high sensitivity in detecting high-risk patients and high specificity in confirming low-risk cases, the model facilitated the creation of personalized decision maps that aim to assist clinicians in selecting the most appropriate treatment modality. We further integrated the model directly into the treatment plan optimization process, through which we were able to adjust dose constraints in the liver based on the patient predicted risk, thereby personalizing treatment plans. Applied similarly to prostate cancer, our model demonstrated its ability to stratify patients into photon versus proton therapy based on their risk of rectal toxicity.

5 - A Network-Flow Approach to Increasing Inter-Facility Transfers for Nova Scotia Health Long-Term Care

Peter Vanberkel, Dalhousie University, Halifax, NS, Canada, Amelia Lane, Claver Diallo

Due to access and flow challenges within acute care, nearly 3,000 long-term care residents in Nova Scotia, Canada are on a waitlist to be transferred to their preferred facilities. Reasons for transferring include moving closer to families, cultural communities, and to reunite with a life partner in a different facility. We developed a new method to identify an optimal series of transfers which considers residents' care needs (i.e. required bed type, smoking, life partner), priority level, facility preferences, and the features of a vacant bed. We model this by generating a network of every resident on the waitlist and solving it as an elementary path problem, generating a chain of transfers starting with a vacancy. We use dynamic programming to solve this problem in practice. In this talk, the mathematical models and algorithms used to generate these chains, as well as an overview of their potential impact, will be discussed.

Amazon Last-Mile Resource Optimization

Invited Session

The Practice Section of INFORMS

Chair: Liron Yedidsion, Amazon, Redmond, WA, United States

1 - Optimizing Tour Slicing via Shortest Path Formulations

Michael Wagner, University of Washington, Seattle, WA, United States, Dipal Gupta, Rohit Malshe

We present a novel method for slicing a Traveling Salesman tour into sub-tours that correspond to capacitated (both in time and space) vehicle routes. The slicing is guided by an optimization objective related to business metrics such as volume and time utilization as well as cost. Our key contribution is formulating the partitioning problem as a shortest-path problem on an induced network. When the metrics are non-negative, we demonstrate that the fast Dijkstra's algorithm can be used to solve the shortest path problem. Even when metrics can be negative, the slower Bellman-Ford algorithm can be applied. This shortest path approach is shown to be significantly faster than existing deterministic dynamic programming solutions. The methodology is general and can be applied to other sequence-slicing applications beyond vehicle routing.

2 - Logistics Operations with Combined Deliveries and Pickups

Rohit Malshe, Amazon.com, Kirkland, WA, United States, Abhilasha Katariya, Ram Thiruveedhi, Chinmoy Mohapatra

Combined deliveries and pickups are a logistics challenge. Highlighting the significance of the issue, we address the complexities faced in achieving optimal efficiency while ensuring customer satisfaction through shipper experience, promise, speed, and cost-effectiveness. Key sub-problem includes strategizing around the time lag between route planning and pickup windows to prevent over or under planning across multiple horizons under uncertainty.

3 - Newsvendor Model for Capacity Planning.

Liron Yedidsion, Amazon, Redmond, WA, United States, Rohit Malshe

The Newsvendor (NV) model calculates the target volume for each station that would minimize the cost expectancy under stochastic demand. The model considers the costs and capacities of each overage and underage scenario, In most cases, expected overage costs are higher than the expected underage costs, and thus the optimal target volume is usually smaller than P50. Using a segmented newsvendor logic, more volume is allocated to flexible means of delivery even though they are costlier per package.

4 - Essential components of capacity planning under uncertainity

Ram Thiruveedhi, Amazon, Leander, TX, United States, Abhilasha Katariya

Effective capacity planning of resources necessitates accurate estimates of demand and resource utilization: demand forecasting, resource usage forecasting, and capacity planning. We describe various processes to monitor and improve the effectiveness of the overall capacity planning process. These processes include tracking the accuracy of capacity forecasts, attributing errors to various forecast components, and continuous monitoring. Furthermore, we will explore the impact of underage and overage situations, where resources are either insufficient or excessive, respectively. These imbalances can lead to significant inefficiencies, such as lost revenue opportunities or unnecessary expenses. We will discuss solutions to address the imbalance and minimize the associated costs.

5 - Cycle Optimization Engine: Maximizing Last Mile Delivery Performance

Wen Chong, Amazon, Kirkland, WA, United States, Marc Anderson, Yimin Liu

Amazon orders are are fulfilled at a Fulfillment Center (FC) and shipped to a Delivery Station (DS) via line haul trucks. At the station, arriving packages are processed in a sequence of "cycles" -- operating shifts -- where packages are inducted and sorted into routes before dispatching to drivers for last mile delivery. Because packages bound for possibly faraway geographies arrive randomly throughout the day, with no cycle planning we potentially create inefficient routes with low delivery density and packages per route. Furthermore, some packages have high delivery sucesss rates at certain times of day (e.g. locker deliveries in the morning), which would be compromised if we neglect their time affinities. Finally, oversized (OV) packages are challenging to deliver, and we want to avoid repeatedly concentrating them in certain cycles/routes.
The novel Cycle Optimization Engine (COE) uses a MIP algorithm to compute the optimal cycle for each arriving package based on its delivery location, time-of-day preference and attributes such as OV, locker, business/residential. The algorithm maximizes each cycle's delivery density while respecting the station's complex processing constraints. It also prescribes the optimal use of buffering capacities for delaying packages to later, more favorable cycles. OV packages are dispersed both across different cycles and also geographically to avoid concentrating them on a small number of routes. In simulations, we show improvements in last mile delivery performance and financial savings.

Food Bank Operations: A U.S. Perspective on Humanitarian Food Assistance

Invited Session

TutORial

Chair: Jamol Pender, Cornell University, Ithaca, NY, United States

1 - Food Bank Operations: A U.S. Perspective on Humanitarian Food Assistance

Lauren Davis, North Carolina A&T State University, Greensboro, NC, United States, Irem Sengul Orgut, Steven Jiang, Eric Aft, Charlie Hale, Larry Morris, Jean Rykaczewski

Food banks are non-profit organizations with the primary mission of providing food

assistance to the communities they serve. This assistance occurs through the collec[1]tion, storage, and distribution of food to people in need through a complex supply

chain network of donors and charitable agencies. Distribution of food is challenging

in this environment, given the many resource constraints experienced at the finan[1]cial, human, and material levels. Furthermore, the COVID-19 pandemic highlighted

the important role these organizations play as demand for food assistance surged,

while sources of supply were constrained. This tutorial provides an overview of food

bank operations from a supply chain perspective. We specifically characterize the key

stakeholders, product, and information flows within the food bank supply chain and

draw from our prior experience with several U.S. food banks to delineate structural

differences that exist among these supply chain networks. We further elucidate the

influence of the supply chain network design on the organizations' operational deci[1]sions and strategic direction with respect to equity, efficiency, effectiveness, diversity

and inclusion. We present several studies that illustrate the role of descriptive, pre[1]dictive, and prescriptive analytics in improving the distribution of food and reducing

food waste, as well as provide insights for future research in this area.

1 - Helping Oneself by Helping a Rival: Effects of a Social Media Platform & Rsquo;S Decision to Enable Features that Help Influencers

Yan Zhu, University of Texas at Dallas, Richardson, TX, United States, Jianqing Chen, Srinivasan Raghunathan

Social-media platforms and influeners have long been seen as collaborators. However, the fact that both of them make money through advertising services adds a competitive dimension to their relationship. While some platforms have adopted an antagonistic approach, other have adopted a friendly approach in allowing the influencers to use features that are available to the platform. We develop a game-theoretic model to study the platform's decision to enable a feature for influencers' use. The influencer's service becomes more effective and more efficient if she uses the feature. We show that the platform would be better off enabling the feature if the advertisers' valuation of the platform's service is not too low compared to that of the influencer, if the feature's valuation-enhancement effect is not too low nor too high, and the cost-reduction effect is not high. Under those conditions, while the platform loses market share when it enables the feature, the loss is offset by the higher price the platform charges. Our results imply that whether the platform should provide help hinges critically on the nature and extent of the help. Additionally, while giving the influencer access to the feature could be a win-win situation for both the platform and the influencer, their gains are at the expense of some advertisers, suggesting the platform's helping the influencer can lead to a collusive outcome and can act as a advertiser surplus extraction strategy, despite the price competition between them for advertisers.

2 - Competing with Generative AI: Does It Hurt Creative Content Producers?

Zhen Yan, University of Texas at Dallas, Richardson, TX, United States, Jianqing Chen, Srinivasan Raghunathan

This study investigates the impacts of Generative Artificial Intelligence (GenAI) on the creative industry, focusing on the competition between the expert and nonexpert creators. Based on a game-theoretic model, we examine how GenAI reshapes creators' strategic allocation of budget with respect to the routine technical-execution dimension and the nonroutine originality dimension. GenAI has two main impacts: automating the routine tasks and augmentation creators in doing nonroutine tasks. We find whether the expert could benefit from GenAI depends critically on whether the expert's capability advantage over the non-expert is greater on the originality dimension or the execution dimension. If the capability advantage is greater on the originality dimension, the expert is always better off with GenAI. On the other hand, if the capability advantage is greater on the execution dimension, the expert benefits from GenAI only when consumers' appreciation of originality vis-à-vis execution is not significant, and GenAI's augmentation effect dominates the automation effect.

3 - Flexible Estimation of Network Models

Ye Liu, University of Washington, Seattle, WA, United States

The curse of dimensionality issue is at the center of analysis with network data, where traditional empirical models either resort to aggregated measures at the node level or require extraordinary computational effort as the size of the network grows. Recent developments in machine learning have introduced numerous neural network structures essential for network analysis, such as Graph Convolutional Networks (GCN). However, these neural networks typically treat network links and node characteristics as separate inputs, failing to capture the interplay between node characteristics and network structure. In this paper, we propose a scalable, yet simple neural network structure as a non-parametric method to estimate models with network data as input. We demonstrate through extensive simulations that our proposed functionals can flexibly capture the underlying interplay between the network links and node characteristics in a completely data-driven fashion. We also apply our method to a real-world dataset to demonstrate the practicality of our method, showing its ability to handle large-scale networks efficiently.

4 - Win-Curves in Real-TIME Bidding: a Micro-Foundation

Shailender Joseph, University of Texas at Dallas, Richardson, TX, United States, Ganesh Janakiraman, Milind Dawande, Vijay Mookerjee

The emergence of digital media has transformed the advertising landscape. Real-time bidding (RTB) has become an important avenue for selling the digital ad space that is generated in these media outlets. The RTB process is a set-up where the publishers can auction off each impression via the supply-side platform (SSP), and the demand-side platform (DSP) can make bids for these impressions so that they can complete the ad campaigns on behalf of the advertisers. The interactions between the SSP and DSP are facilitated by an ad exchange.

A win-curve in this context is a function that tells the amount to bid in order to achieve the win (i.e., the probability of winning for a given bid) probability that the bidder desires. A sizable number of previously published works that studied the RTB process assumed the existence of such a curve to derive their results. Our work provides a formal and rigorous framework on how such a win-curve emerges in an RTB setup. This work is a step in this direction where we attempt to understand the microstructure of RTB that helps in the characterization of the equilibrium in this setup, and the emergence of win-curve is a part of this characterization. We also provide a method to compute this win-curve and implement this method on some numerical examples to understand its shape.

Social Media Analytics on E-Commerce

Invited Session

Social Media Analytics

Chair: Jae Hong Park, Kyung Hee University, Dongdaemun-gu

1 - Impact of Financial APIs on the Trade Outcome of Retail Investors

Bongjin Sohn, Korea University, Seoul, Korea, Republic of, Ziru Li, Gunwoong Lee

This research investigates the impact of financial Application Programming Interfaces (APIs) on retail investors' trading behavior in the stock market. Traditionally, accessing financial information necessitated extensive manual procedures. The advent of financial APIs, however, has remarkably simplified the retrieval and analysis of corporate data for investors. Initially exclusive to institutional investors, financial APIs now grant retail investors access to the same data. This study aims to examine the impact of financial APIs on retail investors, leveraging the introduction of the OpenDART service in South Korea. OpenDART provides company disclosure information via APIs. Analyzing trading volume, net-buying trends, and stock returns of retail investors around OpenDART' launch, we find an increase in retail investors' trading volume and a decrease in the trade quality post API introduction. For lesser-known stocks, moreover, we observe a more pronounced increase in abnormal trading volume and a notable decline in trade quality. The findings contribute to the literature on electronic disclosure systems, financial technologies, and the behavior of retail investors, offering managerial implications for both retail investors and policymakers in the stock market.

2 - Performance after Reward, Penalty, and Break-Even: Empirical Study with mHealth App under Reward-Penalty Incentive Structure

Kyung Pyo Kang, Kyung Hee University, Seoul, Korea, Republic of, Seungwook Jin, Keumseok Kang, Jae Hong Park

The reward-penalty structure is a composite incentive system used in mobile health platforms, requiring users to deposit money before starting goal-oriented activities. At the end of the activities, users can receive rewards, face penalties, or get refunds depending on their performance. Previous research suggests that rewards and penalties can positively motivate users by encouraging them to seek rewards or avoid penalties. However, their effects may extend beyond a current activity, influencing performance in subsequent activities either positively or negatively. For example, individuals might either improve performance after facing penalties to recover losses or perform poorly due to decreased motivation from negative experiences. Understanding the effects of rewards and penalties on users' subsequent activities is essential for platform managers, because the primary goal of mobile health platforms is to maintain user motivation throughout their goal-oriented activities. Nevertheless, previous studies have mainly focused on the effects of incentive structures on single activity, overlooking the long-term incentive effects on performances with respect to the continuous stream of goal-oriented activities. While previous research on financial incentives has explored the sole effects of either rewards or penalties, scant literature examines how the reward-penalty composite structure works. This study addresses the literature gaps by examining the dynamics of goal achievement within the reward-penalty incentive structure, specifically in the context of a mobile health (mHealth) application. We investigate how rewards, deposit refunds, and penalties influence users' subsequent short-term and long-term goal achievement rates. We expect this paper will enhance understanding of the mechanisms underlying reward-penalty incentive structure.

3 - The Substitution Effect of YouTube Videos on Netflix Viewership: An Empirical Study on the Impact of Video Length and Popularity

Seungwook Jin, KAIST College of Business, Seoul, Korea, Republic of, Keumseok Kang

In the era of digital content, user-generated content (UGC) in the form of video has become an important source of information for consumers. While previous literature has primarily focused on the promotional aspect of UGC, this study extends the conventional view by examining the substitution effect of video UGC on over-the-top (OTT) service. Drawing on Uses and Gratifications Theory (UGT), we hypothesize that the gratifications derived from video UGC can substitute for the utility of consuming original content on OTT platforms, ultimately cannibalizing its viewership. We investigate the impact of video UGC on the viewership of Netflix's top 10 movies by analyzing a dataset of 315 movies and their associated weekly view hours and ranks, as well as related video UGC posted on YouTube. We find that while the overall effect of weekly UGC volume on movie viewership is positive, suggesting a promotional effect, this relationship is negatively moderated by video length, likeability, and number of views. These findings suggest that as video UGC becomes longer, more liked, and more viewed, it provides consumers with a higher level of satisfaction, leading to a substitution effect on viewership of the original film on the OTT platform. Our findings have important implications for content creators and OTT platform managers, highlighting the need to strategically manage video UGC to optimize its promotional benefits while mitigating its potential substitution effects on viewership.

Power of LLMs in the Analytics Classroom: The Good, the Bad, and the Inevitable I

Invited Session

INFORMS Committee on Teaching and Learning

Chair: Sourav Chatterjee, University of North Texas, 1155 Union Circle, #311160, Denton, TX, 76203, United States

Co-Chair: Gabriela Gongora-Svartzman, Carnegie Mellon University, Pittsburgh, United States

1 - Beyond Search: How LLMs are Transforming Informal Learning and Code Development

Erin Trochim, University of Alaska Fairbanks, Fairbanks, AK, United States

Large Language Models (LLMs), the technology powering conversational AI tools like ChatGPT and Gemini, are changing how we learn and create. While early experiences with chat boards and search engines often required iterative strategies to find applicable information, modern LLMs have unlocked a new era of possibilities. As LLMs are reshaping the landscape of informal learning, we will focus on implications for creating materials for and learning coding and analytics.

We'll explore how LLMs can enhance code standards by generating clear examples, optimizing existing code, and providing insightful explanations. This approach offers the opportunity to refine code accessibility and enhance understanding. We will compare models with specific custom instructions and examples versus using a prompt engineering chat approach. We'll also examine how these tools can support self-guided learning, offering on-demand explanations, tutorials, and problem-solving assistance.

2 - How ChatGPT can support learning from a student's perspective

Zoe Long, University Of Florida, Gainesville, FL, United States, Elif Akcali

ChatGPT is one of, if not, the most used natural language processing tools in many industries. With ChatGPT's increasing popularity, it is important to integrate it into the educational system to prepare students for the workforce. Students need to be able to understand how and when to use large language processing models to be successful in their careers. An assignment was created for students in an upper-level industrial and systems engineering class during the spring 2024 semester. For the assignment, students were asked to prompt ChatGPT to create an essay with multiple references about ABC analysis and then to analyze each sentence of the essay for correctness of the technical information and the relevance of references cited. At the end of the semester, students were asked to reflect on their experience with the assignment and how it impacted their learning. Of the 38 students in the class 31 consented to have their ChatGPT generated essays, their analysis of their text, and their responses to reflection prompts used for research purposes. These student responses to the reflection prompts

were qualitatively analyzed using open and axial coding. This presentation will focus on some preliminary insights on how students feel using ChatGPT can be used to support their educational experience, and how it impacts their understanding of technical concepts.

3 - Beyond Spreadsheets: Embracing ChatGPT in Business Analytics Education

Mustafa Hayri Tongarlak, Ivey Business School, London, ON, Canada, Mehmet Begen, John Wilson

Analytics courses on decision-making are popular in business schools. Most such courses use spreadsheets and add-ins as their modelling tools. Recent developments in large language models (LLM), such as ChatGPT, can allow instructors to use LLM agents instead of spreadsheet-based tools to enhance student interaction and learning and focus more on Decision-Making with Analytics (DMA) skills. We critically analyze the implications of this adoption in terms of benefits and challenges, in addition to ethical considerations, potential pitfalls, and practical recommendations. Through case studies and feedback from pilot implementations, we aim to showcase the tangible benefits and encourage a broader discussion on optimizing AI integration in DMA education.

4 - The challenges and opportunities of integrating LLMs in classrooms

Hayley Falk, University of Michigan, Ann Arbor, MI, United States

Large language models (LLMs), powered by artificial intelligence (AI), have existed for decades, but were not widely known outside of academic circles. However, the launch of ChatGPT (Chat Generative Pre-Trained) in November 2022 by Open AI catapulted the field from the research community to the general public. Since November 2022, a significant number of LLMs have been developed with seemingly endless capabilities. Here we present a comparative analysis of teaching practices employed in teaching a Python programming curriculum to high school students pre- and post-ChatGPT. Our analysis will highlight some potential challenges and opportunities of incorporating AI language models in classrooms and in reshaping educational paradigms.

AI in Mining and Mineral Processing

Invited Session

Artificial Intelligence

Chair: Bart Maciszewski, Imperial Oil, Calgary, AB, Canada

1 - Offline Reinforcement Learning for Chemical Process Control with a Digital Twin

Dhavalkumar Patel, University of Toronto, Toronto, ON, Canada, Stefano Scaini , David Molina Concha, Chi-Guhn Lee

The application of Reinforcement Learning (RL) for process control has attracted much attention in process-driven industries. RL is an area of machine learning that is focused on learning optimal decisions through experience. Given that RL is traditionally an online paradigm, that is, data-based experiences are gained by interacting with real processes in real time, its adoption for uses that are prohibitively dangerous or costly has been limited. The chemical processing industry in particular is an industry defined by highly controlled and risk-intensive extraction and manufacturing processes which do not lend themselves naturally to the use of RL, despite the great potential for unlocking value that RL offers to many chemical processing applications. The field of Offline Reinforcement Learning (Offline RL) has emerged largely as an answer to this difficulty, with the goal of learning being redirected to fixed batches of recorded data. This eliminates the need to interact with live processes directly, and when combined with supplemental models of the process environment—digital twins—this approach can lead to strong outcomes. The talk will focus on the use of Offline RL in combination with process simulation modelling to develop an optimal control policy for pH stability.

2 - Enhance Mine Operations Through Analytics

Hannah Zhao, Imperial Oil Limited, Calgary, AB, Canada, Rahul Raman, Saied Afshari, Andrew Milne, Dmitry Yakunin, Farah ElMallah, Anuraj Grewal, Jessica Pickel, Richard Leger, Freeman Lin

In the dynamic landscape of mining operations, leveraging data analytics and machine learning has become paramount for productivity and operational reliability gains and informed decision-making. At Imperial's Kearl oil sands mine, we've harnessed these technologies to drive meaningful improvements.

By analyzing shovel sensor data, we've gained insights into effective shovel operation. Our custom dashboard breaks down shovel operators' performance, aiding targeted training, ultimately helping increase productivity, and lower operating and maintenance costs.

We've tackled shovel crowd cylinder failure analysis using anomaly detection techniques. Hydraulic crowd cylinder failure can be costly and causes unplanned downtimes, so understanding when failure happens is essential. Our approach, utilizing autoencoders, provides valuable insights for maintenance strategies and component longevity.

Furthermore, we currently have a manual process to infer tracked vehicle undercarriage components replacement timing. We are developing models to aid in predictive maintenance by analyzing historical data, usage patterns, and wear rates.

3 - Applications of Artificial Intelligence for Advancing Short-Term Mine Planning Leveraging Real-TIME Sensing Technologies

Zachary Levinson, AIRL Technologies, North Vancouver, BC, Canada, Julien Keutchayan

At large-scale mining operations worldwide, sensors play a crucial role by providing rich data on orebody characteristics and equipment performance. Leveraging this data, an optimization framework is developed to enhance short-term production plans by learning to adapt to real-time operating conditions over time. This framework is tested at a copper mine, where it demonstrates significant improvements in productivity and more efficient extraction of valuable materials. These results underscore the potential of integrating sensing data into production planning to boost overall operational efficiency and resource utilization.

4 - Reinforcement learning for optimizing underground mine planning and design considering geotechnical, geological, and grade uncertainty

Jeff Boisvert, University of Alberta, Edmonton, AB, Canada, Roberto Noriega, Yashar Pourrahimian

Uncertain geological and mineral grade estimates due to scarce drill-hole data present a key challenge in the design and strategic planning of underground mining projects. Geological complexities and variations in mineral grades undermine the reliability of mine plans and designs, often leading to suboptimal production strategies, heightened financial risks and missed opportunities. Numerous geostatistical techniques have been developed to assess uncertainty in mineral estimates and provide multiple simulated scenarios based on the current level of knowledge of the deposit, however, incorporating these simulated models within a mine planning and design framework remains a major challenge. In this work, the application of Reinforcement Learning (RL), an Artificial Intelligence (AI) technique that deals with the problem of decision-making in uncertain environments, is explored to incorporate an ensemble of simulated mineral deposit scenarios in the generation of underground reserves and mine extraction plans. A risk-discounted strategy is presented that penalizes the financial risk of the mine design and allows a user specified attitude towards risk, a trade-off between expected profit and financial risk over the ensemble of geological and grade scenarios. A case study based on the extraction of a gold deposit using sublevel stoping method is presented to highlight the impact of geological and grade uncertainty on the financial performance of an underground mining asset. The proposed methodology incorporates an ensemble of mineral resource realizations in the design and extraction planning, respecting operational and geotechnical constraints, to aid practitioners make informed choices in the face of uncertainty.

5 - Fault-tolerant Autonomous Control System

Mahmut Tatlici, University of Alberta, Edmonton, AB, Canada, Oguzhan Dogru, Biao Huang

Primary Separation Cells (PSCs) are crucial in bitumen extraction, separating oil sands slurry into bitumen froth, middlings, and coarse tailings. Optimizing the froth-middling interface is vital for maximizing recovery and minimizing environmental impact. However, designing an autonomous control system for PSCs presents challenges like operating-point optimization, interface tracking, and fault tolerance. To address these challenges, we propose a machine learning-based fault-tolerant control system using three reinforcement learning (RL) agents to enhance a model predictive controller (MPC)-based control loop. The first agent uses camera images for accurate interface tracking, the second tunes the MPC for optimal set-point tracking, and the third optimizes the set-point for maximum recovery and minimal environmental impact. The MPC controller, supervised by these agents, calculates optimal control actions and completes the feedback loop. Despite these improvements, faults such as actuator issues, sensor failures, and communication errors can necessitate human intervention. To address this, we implement a sensor fusion approach with a Kalman filter-based prediction model to correct interface measurements during faults. Experimental validation on a pilot-scale PSC demonstrates the approach's effectiveness. Our results show the potential of machine learning, combined with fault-tolerant techniques, to achieve autonomous control in complex systems. This research advances control algorithms in nonlinear systems, providing a general solution for optimizing bitumen extraction and other similar environments requiring fault-tolerant autonomous control.

AI in Financial Ethics and Fraud Detection

Contributed Session

Contributed

Chair: Xingying Wu, Xi'an JiaoTong university, 西安市, N/A

1 - Perspectives on Artificial Intelligence Integration in Accounting

Shari Fowler, Indiana University East, Richmond, IN, United States, Marcy Jance

The presentation discusses a survey that will be sent to accountants to gauge accountants’ views on how artificial intelligence is impacting current and future accounting jobs and how artificial intelligence can be used to prevent fraud, financial reporting misstatements, tax evasion, and other ethical violations.

2 - Using Artificial Intelligence and Analytics Techniques to Combat Accounting Fraud

Marcy Jance, Indiana University East, Richmond, IN, United States, Shari Fowler

The presentation discusses the types of accounting fraud that may be uncovered by using artificial intelligence techniques. The presentation then discusses how artificial intelligence and analytics can be used to help companies detect accounting fraud in financial statements.

3 - Firm-level AI Ethics Awareness Measurement and Effects: A Machine-Learning Approach

Xingying Wu, Xi'an JiaoTong university, 西安市, China, People's Republic of, Shan Liu

Recent years have witnessed the rapid development of artificial intelligence (AI) and its pervasive impacts on business and society. However, the deployment of AI also brings ethical challenges regarding beneficence, privacy, and security. A thorough understanding and effective management of AI ethics issues are imperative to ensure the socially beneficial development of AI. Drawing on the AI ethics frameworks outlined by the National Overall Group for Artificial Intelligence Standardization, we employ textual analysis techniques to develop a novel firm-level, time-varying measure of AI ethics awareness (AIEA), which captures the attention management devotes to AI ethics related issues. We validate AIEA through content analysis, variance decomposition, and by considering the time series and cross-industry variations, which ensures that the measure is specifically indicative of the intended construct. Subsequently, we identify its determinants and reveal that firms with larger size, greater Environmental, Social and Governance (ESG) commitment, and managers with higher educational levels, can improve firms' AIEA level. We investigate how AIEA affect firms' innovation behavior, revealing that firms with higher AIEA have higher digital innovation. We also discover that firms with higher AIEA enjoy lower audit pricing and positive market reactions, suggesting that the disclosure of AIEA serves as a signal of firms' ethical management and mitigates the perceived business risk of the auditor and investors. Our research contributes to the AI ethics literature by developing a novel AIEA measure with broad applicability and offers practical implications for firms to enhance their awareness and voluntary disclosure on AI ethics issues.

Hydrogen Production and Emission Strategies

Contributed Session

Chair: Rui Zhou, University of Tennessee, Knoxville, knoxville, TN, United States

1 - DRI Operation, Costs, and CO_2 Emissions under Different Energy Markets

Simon Kamerrer, TU Dortmund, Dortmund, Germany, Elina Hoffmann, Valerie Karplus, Chris Pistorius, Christian Rehtanz

In response to the climate crisis, steelmakers have increasingly turned to direct reduction (DR) to achieve their CO_2 emissions reduction targets. This study explores the operational flexibility and economic viability of three DR technologies under different economic conditions to investigate how variation in local energy markets may drive technology choice. Hydrogen direct reduction (H-DR) eliminates fossil fuel use but requires robust hydrogen supply chains or onsite hydrogen electrolysis, whereas natural gas direct reduction (NG-DR) leverages existing natural gas infrastructure and can be coupled with carbon capture and sequestration (CCS) for deeper decarbonization. Hybrid-DR allows flexibility between hydrogen and natural gas fuels based on economic factors and availability. Our time-series based optimization incorporates detailed material balances to simulate the costs and emissions of these different DR processes, economically optimizing the operation of each plant layout and quantifying the costs associated with CO_2 avoidance. We find that the NG-DR with CCS and Hybrid-DR plants offer cost advantages through flexible operation, minimizing the use of their decarbonization technologies, whereas the H-DR plant achieves consistently low CO_2 emissions but is highly sensitive to electricity prices. We find that the NG-DR with CCS and H-DR plants are able to achieve lower mean costs at higher emissions reduction targets, with H-DR dominating in regions of low electricity prices and high natural gas prices. This research underscores the importance of examining market environments, operational strategies and technological flexibility to inform investment and policy decisions for decarbonizing the steel industry.

2 - Advancing the Technology Adoption for an Effective Scale Up of Green Hydrogen

Jingwei Chen, University of Tennessee, Knoxville, Knoxville, TN, United States, Mingzhou Jin

Green hydrogen represents a promising frontier in sustainable energy, offering a zero-emission alternative to fossil fuels crucial for decarbonization efforts worldwide. Despite its potential, scaling up green hydrogen production faces numerous challenges, including high costs of electrolyzer technologies, substantial renewable energy requirements, integration complexities within existing energy infrastructures, and regulatory hurdles. Market dynamics and technological uncertainties further complicate the adoption process. To address these issues effectively, we introduce a novel approach using stochastic programming to develop an optimization model tailored to manage uncertainties. This model aims to navigate cost variability, fluctuating energy supplies, and evolving policy landscapes, providing practical solutions to enhance the capacity and scalability of green hydrogen production, thus accelerating its integration into the global energy mix.

3 - Hydrogen Logistics Network Design for Hydrogen Fuel Cell Electric Long-haul Trucks

Rui Zhou, University of Tennessee, Knoxville, knoxville, TN, United States

With the growing emphasis on reducing carbon emissions and transitioning towards sustainable transportation solutions, hydrogen fuel cell electric long-haul trucks have emerged as a promising alternative to conventional diesel-powered vehicles. This study addresses the critical need for designing effective hydrogen delivery networks for long-haul trucks under different demand. Through the utilization of advanced modeling techniques and optimization algorithms, we seek to identify optimal configurations for hydrogen delivery technologies (compressed gas, liquid hydrogen, and ammonia) and refueling infrastructure. The outcomes of this research are expected to provide valuable insights into the strategic planning of hydrogen logistics networks, thereby facilitating the widespread adoption of hydrogen fuel cell electric long-haul trucks and contributing to the decarbonization of the transportation sector.

Digital Technologies in Business

Invited Session

eBusiness

Chair: Kai Sun, University of Texas at Dallas, Richardson, TX, United States

1 - How Do Human Mental Health Care Providers React to Their AI Counterparts? a Study of An Online Counseling Forum

Gujie Li, University of Maryland, College Park, MD, United States, Jui Ramaprasad, Lauren Rhue

Mental health care has become a concern globally, and the challenges of providing and accessing appropriate care is only magnified by a dearth of available counselors. At the same time, Large Language Models (LLMs) are anticipated to hold transformative potential for numerous industries including healthcare. LLM's exceptional capacity to offer individually-tailored recommendations derived from massive medical knowledge can facilitate access to affordable mental health services. Naturally, an inquiry arises regarding how human counselors respond to the emergence of AI counselors. We focus on an online counseling platform in China wherein professional counselors and peers offer support to mental health care seekers through question-and-answer (Q&A). In February 2023, an LLM-powered chatbot was integrated into the platform to address inquiries from seekers, providing an excellent context for us to study changes in behavior of incumbent human counselors in the presence of an AI counselor. Specifically, leveraging the (unanticipated) introduction of the chatbot as a natural experiment, we investigate how human counselors react to the AI counselor in terms of the level of engagement, quality of assistance and counseling strategies.

2 - Visibility OR Capability: An Economic Analysis of Livestreaming Adoption

Xiang Ji, University of Science and Technology of China, Hefei, China, People's Republic of, Qingning Cao, Min Chen

Livestreaming marketing is increasingly becoming a popular strategy to promote, market, and sell products in online retailing. This study uses a game-theoretic framework to provide insights into the firm's livestreaming strategy.

3 - An Economic Analysis of Regulation on Clinical Algorithmic Fairness

Zhe Wang, City University of Hong Kong, Hong Kong, Hong Kong, Dengpan Liu

In the context of healthcare, employing a game-theoretical model, we examine the impact of algorithmic fairness regulation on key market outcomes, including patient surplus, healthcare providers' payoffs, and social welfare. Our analytical results show that, when healthcare algorithm fairness regulations become stricter, the performance of algorithms among majority patient groups worsens, leading to a decrease in utility for majority patient groups. Meanwhile, surprisingly, when fairness regulations for algorithms are overly stringent, further reinforcing fairness restrictions may even worsen the performance of algorithms among minority patient groups and potentially reduce the utility of minority patient groups. Additionally, our research findings indicate that as fairness regulations become stricter, healthcare service providers initially increase and then decrease their healthcare service fees. Considering the impact of fairness regulations on diagnostic accuracy for different groups and healthcare service fees, we find that appropriately emphasizing algorithmic fairness can improve overall diagnostic accuracy and potentially enhance overall patient utility and societal welfare, however, excessively emphasizing algorithmic fairness can reduce overall diagnostic accuracy and harm overall patient utility and societal welfare. Based on this, our analysis further addresses how to regulate healthcare algorithm fairness policies. Specifically, our research results suggest that for policymakers aiming to maximize social welfare, the optimal algorithm fairness constraints should relax as effort cost parameters increase or co-insurance rates increase, but tighten as the baseline diagnostic accuracy of minority patient groups increases or the severity of symptoms increases.

4 - Using Optimization to Augment Structural Estimation: a Reinforcement Learning Approach

Kai Sun, The University of Texas at Dallas, Richardson, TX, United States, Wangsheng Zhu, Vijay Mookerjee

Structural Models have been used in many business domains including Information Systems, Finance, Marketing, and Operations Management. One advantage of structural models is that they can be used to perform counterfactuals or policy simulations that predict what would happen if certain elements of the economic environment were to change. However, the validity of these predictions critically depends on the assumptions made to build the model. We could have competing models that fit the observed data but make different predictions. Re-enforcement learning (RL) allows us to find near-optimal solutions to complex problems without making structural assumptions. We demonstrate using this property of RL to choose between different models that statistically fit the data.

Power Systems on the Road Between Optimization and Learning

Invited Session

ENRE: Electricity

Chair: Vladimir Dvorkin, University of Michigan, Ann Arbor, 48104

1 - Value-Oriented Renewable Energy Forecasting

Yuanyuan Shi, University of California San Diego, La Jolla, CA, United States, Yufan Zhang, Honglin Wen, Yuexin Bian

Energy forecasting is an essential task in power system operations. Operators usually issue forecasts and leverage them to schedule energy dispatch ahead of time. However, forecast models are typically developed in a way that overlooks the operational value of the forecasts. To bridge the gap, we design a value-oriented forecasting approach for sequential energy dispatch problems with renewable energy sources. Specifically, the forecast model parameter estimation is formulated as a bilevel program, optimizing the forecast model parameter at the upper level and the operation decisions are determined at the lower level. The DA and RT market clearing problems are solved at the lower level, with the RES forecast from the upper level serving as the input. Theoretically, we derive the exact form of the loss function for training the forecast model that aligns with such a goal. For market clearing modeled by linear programs, this loss function is a piece-wise linear function. Additionally, we derive the analytical gradient of the loss function with respect to the forecast, which inspires an efficient training strategy. Numerical study shows our forecasts can bring benefits of the overall cost reduction compared to quality-oriented forecasting.

2 - Dynamic Optimal Power Flow: Real-TIME Stochastic Predictive Control Through Constrained Reinforcement Learning

Anna Scaglione, Cornell University, New York, NY, United States, Tong Wu

Traditional Deep Reinforcement Learning (DRL) techniques have shown promise in addressing control challenges within power systems that are associated with the volatility and stochasticity introduced by high penetration of renewable resources and responsive demand. However, vanilla DRL does not ensure compliance with crucial physical constraints like power flow equations and voltage limits. Existing approaches typically project actions onto feasible sets, potentially leading to sub-optimal solutions. In this presentation we introduce a novel primal-dual method to train constrained DRL policies tailored for real-time stochastic dynamic optimal power flow control. We also prove the convergence of critic and actor networks and showcase the effectiveness of our approach through case studies on IEEE standard systems, highlighting its ability to identify near-optimal actions while maintaining safety compliance.

3 - Learning Context-Aware Security Prescriptions in Optimal Power Flow

Robert Mieth, Rutgers University, Piscataway, NJ, United States

The massive roll-out of stochastic resources (e.g., wind and solar power) in the power system complicates its operations and challenges established regulatory and economic paradigms. Yet, while novel and provably effective decision-making techniques can internalize parameter stochasticity efficiently, they are often complex and deviate too much from existing approaches for a timely implementation in practice. This talk discusses approaches on how optimal power flow, a central tool for power system operations and planning, can be enriched with few interpretable parameters that are prescribed such that its performance is as close as possible to a fully stochastic approach. We briefly survey the state-of-the-art and present a novel data-driven approach to learn an efficient parameter prescription for robust optimal power flow.

4 - Diffusion Based Electric Vehicle Charging Modeling

Yize Chen, University of Alberta, Edmonton, AB, Canada

Recent proliferation of electric vehicle (EV) charging load has imposed vital stress on power grid. The stochasticity and volatility of EV charging behaviors render it challenging to manipulate the uncertain charging demand for grid operations and charging management. Charging scenario generation can serve for future EV integration by modeling charging load uncertainties and simulating various realistic charging sessions. To this end, we propose a denoising Diffusion-based Charging scenario generation model coined DiffCharge, which is capable of yielding both battery-level and station-level EV charging time-series data with distinct temporal properties. In principle, the devised model can progressively convert the simply known Gaussian noise to genuine charging demand profiles by learning a parameterized reversal of the forward diffusion process. Besides, we leverage the multi-head self-attention mechanism and prior conditions to capture the unique temporal correlations associated with battery or charging station types in actual charging dynamics. Moreover, we validate the superior generative capacity of DiffCharge on a real-world dataset involving ample charging session records, and attest the efficacy of produced charging scenarios on a practical EV operation problem in the day-ahead electricity market.

5 - Regression Nash Equilibrium in Electricity Markets

Vladimir Dvorkin, University of Michigan , Ann Arbor, MI, United States

We argue that the economic efficiency of renewable-dominated electricity markets improves if stochastic producers coordinate on their forecast models. To support this argument, we introduce the ***regression equilibrium***—a state of the electricity market where no profit-seeking stochastic producer benefits by unilaterally deviating from their respective forecast model. While the equilibrium aims to maximize the private welfare, i.e., the profit of each market participant, it also proves to align with the socially optimal solution that minimizes the average electricity cost across the day-ahead and real-time stages, thus improving temporal market coordination. We base the equilibrium analysis on the theory of variational inequalities, providing results on the existence and uniqueness of such an equilibrium in energy-only markets, and deriving two methods for equilibrium computation.

Developing Machine Learning Methods for Complex Data Distributions and Structures

Invited Session

Data Mining

Chair: Yanjun Qian, Virginia Commonwealth University, Glen Allen, VA, United States

1 - Machine Learning-Based Risk Adjusted Cusum Control Chart for Monitoring Surgery Readmission Rate

Yanjun Qian, Virginia Commonwealth University, Glen Allen, VA, United States

Percutaneous Transhepatic Biliary Drainage (PTBD) Catheter Placement is known to suffer from a high readmission rate. This work focuses on monitoring the change in readmission rate after a new clinical paradigm for post-procedural care is implemented for the PTBD procedures. The Risk-Adjusted CUmulative SUM (RA CUSUM) chart, considering the preoperative risk of patients, is widely used for similar tasks. However, the popular logistic regression model for RA CUSUM charts in the literature shows a weak discriminant ability for the readmission prediction of the PTBD procedures. To overcome these limitations, we incorporate RA CUSUM charts with other machine learning methods for modeling the patients' risks based on their characteristics. We use data retrospectively and prospectively collected before and after the paradigm change from the medical college of Virginia Commonwealth University to evaluate the performance of the proposed method. The RA CUSUM charts based on tree-based models show better discriminant ability and faster detection than the logistic regression one.

2 - Optimal Supervised Data Splitting

Samuel Paul Gyamfi, Virginia Commonwealth University, Richmond, VA, United States, Sujay Mudalgi, Anh Bui

Data splitting is an important step in predictive modeling. State-of-the-art data splitting methods accomplish this via minimizing the energy distance between the split and original data. However, they do not specifically consider the relationship between the response and predictor variables. In this article, we propose Alyke, a supervised data splitting method that aims to minimize the energy distance while considering this relationship. We demonstrate that Alyke can help improve predictive power in simulation and real examples. Alyke is also much faster than the state-of-the-art data splitting methods, making it a more viable solution for big data applications. We also discuss the application of Alyke in supervised data compression problems.

3 - Predicting Dengue Incidence in the Dominican Republic Using Climate Data

Sahil Chindal, Virginia Commonwealth University, Richmond, VA, United States, Demian Herrera, Manuel Colome Hidalgo, Helena Sofia Rodrigues, Yanjun Qian, Michael Robert

Dengue is a mosquito-borne disease prominent in tropical and subtropical regions of the world and has been emerging in temperate areas. Dengue is endemic to the Dominican Republic, where outbreaks have been occurring for the last four decades. Most provinces in the

Dominican Republic have a tropical climate with abundant rainfall during rainy seasons, providing ample resources for mosquito proliferation and growth, which creates an environment favorable for dengue transmission. Using climate data and dengue case data, we aim to determine which climate factors are associated with dengue cases. Additionally, due to the potential lags between climate and dengue trends, we seek to characterize the lags between variables associated with climate and cases. Using machine learning methods, we analyze the temporal dynamics of dengue spread by estimating the parameters of the SIR-type model framework. We validate our model using the historical data for dengue cases in the Dominican Republic. We will use our results as part of a predictive model to forecast the spread of dengue cases between various provinces of the Dominican Republic and integrate our model into an early warning system that predicts outbreaks and informs public health and mosquito control policies in the Dominican Republic.

4 - Out-of-Distribution Learning with Gaussian Process Boundaries

Wenbo Sun, University of Michigan Transportation Research Institute, Ann Arbor, MI, United States, Yang Chen, Chih-Li Sung, Arpan Kusari

Deep neural networks (DNNs) are usually constructed under the closed-world assumption, which is violated in real-world tasks, due to presence of out-of-distribution (OOD) samples. This leads to DNNs outputting highly overconfident wrong predictions and can lead to disastrous consequences in safety-critical applications. All existing OOD detection methods rely on curating a set of OOD samples to train the models or perform hyperparameter tuning to separate the in-distribution (InD) samples from the OOD, failing to achieve a high detection accuracy without exposure to OOD samples in the training phase. Given that humans can reason about what they do not know through a process called Metacognition, we propose a Gaussian-process-based OOD detection method to establish a detection boundary based on InD samples only. The basic idea is to perform uncertainty quantification of the unconstrained softmax scores via a clustered Gaussian process, and then define a score function to separate InD and OOD samples based on their fundamental differences in the posterior predictive distribution from the Gaussian process. The method is shown to have good statistical properties. The comparison study results demonstrate that the proposed method consistently outperforms the state-of-the-art OOD detection methods.

5 - Riemannian Manifold Approach to Time Varying Mixture Models of Object Shapes

Rifat Hasan, Florida State University, Tallahassee, FL, United States, Chiwoo Park

Geometrical forms of products are important quality characteristics in advanced manufacturing, e.g., geometries of 3D printed products and morphology of nano-manufactured products. Hence, the importance of quantifying the distribution of the geometric forms of objects along with evaluating the quality and variation of related manufacturing processes. Here, we present a new time varying mixture model for the probability distribution of geometrical forms in 2D. Based on Riemannian geometry, an appropriate space of shapes and proper metric over the space is defined. After that, we present the time varying mixture model with Gaussian-type distributions. Here, we consider that only mixture proportions will change along with time; the other parameters like mean and covariance will be constant. Finally, the numerical result of the algorithm is provided with applications to modeling the time varying mixture models of nano-products.

Machine Learning for Heterogeneous Data Fusion

Invited Session

Data Mining

Chair: Hyunsoo Yoon, Yonsei University, Seoul, Korea, Republic of

1 - Balanced Cross-Domain Fault Diagnosis Method in Rotating Machinery with Imbalanced Data

Yongmin Kim, Yonsei University, Seoul, Korea, Republic of, Hyunsoo Yoon

Traditional unsupervised domain adaptation-based bearing fault diagnosis research assumes that the source machine and target machine data have the same label distribution. However, in real-world manufacturing process, most of the data from the target machine is normal, with few or no labeled fault classes, and even unlabeled fault classes often have only a few samples. This class imbalance leads to poor performance since unsupervised domain adaptation models tend to overfit to the abundant normal data and do not effectively learn from the limited defect data. Thus, class imbalance makes it challenging for typical unsupervised domain adaptation methods to generalize for diagnosing faults on the target machine. To address this issue, we propose an unsupervised domain adaptation technique to tackle the problem of class imbalance in target machine data. Our approach aims to prevent overfitting to normal data and enhance the model's learning capability from insufficient defect data. As a result, the proposed method improves fault diagnosis performance, ensuring more reliable and accurate identification of bearing faults in real-world manufacturing scenarios.

2 - Fine-Tuning Run-to-Run Process Control Method Using An Autoencoder for Chemical Mechanical Polishing

HYEONGGU LIM, Yonsei University, Seoul, Korea, Republic of, Chang Ouk Kim

In the chemical mechanical polishing (CMP) process of semiconductor manufacturing, run-to-run (R2R) process control is critical for consistently producing high-quality products. R2R process control involves optimizing the process parameters of equipment to maintain high-quality products despite process noise such as equipment aging. In this paper, we propose a novel method to overcome two limitations of existing R2R process control algorithms when applied to CMP processes. The first limitation is that ratios between control variables are not considered, despite being essential. The second is that it is not possible to prioritize between control variables when there are multiple ways to reach a target. The proposed method can update the control variables while maintaining the ratios between the control variables, enabling continuous process control even in severe noise. The cost of process control can be reduced by setting priorities among the control variables to reach the target. In addition, the proposed method estimates the changes in the process environment with an autoencoder, achieving better performance on several process control metrics than other R2R algorithms.

3 - Leveraging Deep Domain Adaptation for Improved Estimation of Remaining Useful Life

Youngje Oh, Yonsei University, Seoul, Korea, Republic of, Hyunsoo Yoon

Prognostics and Health Management (PHM) is extremely important in industrial environments. In particular, the prediction of Remaining Useful Life (RUL) has gained significant attention due to its impact on equipment operating costs and safety. While most studies employ supervised learning models for training and evaluation, relying solely on training data from specific domains can lead to performance limitations. The variability and imbalance in data across different domains can degrade the generalization capability of prediction models. This study aims to introduce a methodology to enhance the performance of RUL prediction models by enriching the source domain through data augmentation and utilizing deep domain adaptation to create a model more suited to the target domain. Additionally, by applying methods tailored to the characteristics of sensors to extract features, we aim to improve prediction performance and reduce variability. This methodology enhances the practical applicability in industrial settings and is expected to significantly improve the efficiency and safety of equipment operations.

4 - Multiclass Classificaiton of Alzheimer's Disease Prodromal Stages Using Sequential Embeddings and Regularized Multikernel Support Vector Machine

Oyekanmi Olatunde, Amazon, Seattle, WA, United States, Kehinde Oyetunde, Jihun Han, Mohammad Khasawneh, Hyunsoo Yoon

The detection of patients in the cognitive normal (CN), mild cognitive impairment (MCI), and Alzheimer's disease (AD) stages of neurodegeneration is crucial for early treatment interventions. However, the heterogeneity of MCI data samples poses a challenge for one-shot CN vs. MCI vs. AD multiclass classification, as some samples are closer to AD while others are closer to CN in the feature space. Previous attempts to address this challenge produced inadequately accurate results, leading most frameworks to break the assessment into binary classification tasks such as AD vs. CN, AD vs. MCI, and CN vs. MCI. Other methods proposed sequential binary classifications such as CN vs. others, and then dividing others into AD vs. MCI. While those approaches may have yielded encouraging results, the sequential binary classification method makes interpretation and comparison with other frameworks challenging and subjective. Those frameworks exhibited varying accuracy scores for different binary tasks, making it unclear how to compare the model performance with those of other direct multiclass methods. Therefore, we introduce a classification framework comprising unsupervised ensemble manifold regularized sparse low-rank approximation and regularized multikernel support vector machine (SVM). This framework first extracts a joint feature embedding from MRI and PET features, which were then combined with the Apoe4, Adas11, MPACC digits, and Intracranial volume features using a regularized multikernel SVM. The framework achieved a state-of-the-art (SOTA) result in a CN vs. MCI vs. AD multiclass classification and generalizes well to binary classification tasks, achieving SOTA results in all but the CN vs. MCI category.

5 - A Multi-Source Domain Generalization Method for Intelligent Fault Diagnosis Based on Domain Meta-Information

Hoyeon Lee, Yonsei University, Seoul, Korea, Republic of, Hyunsoo Yoon

Intelligent fault diagnosis plays a crucial role in ensuring the reliability and efficiency of complex machines in industrial fields. However, traditional fault diagnosis methods often fail to generalize well to new or unseen machines due to domain discrepancies among machines operating under different conditions. Domain adaptation aims to mitigate such discrepancies by adapting models trained on a source domain to perform effectively on a target domain. While effective, domain adaptation typically needs access to data from the target domain during training, which may not always be feasible or cost-effective. In contrast, domain generalization approaches focus on learning representations that are invariant to domain discrepancies, without requiring any data from the target domain. The proposed method extends the capabilities of domain generalization by leveraging the meta-information from multiple source domains. We evaluate the effectiveness of the proposed method on various benchmark fault diagnosis datasets. Experimental results demonstrate that our method outperforms other existing domain generalization methods, achieving superior fault diagnosis accuracy.

1 - Causal Decision Making and Causal Effect Estimation Are Not the Same…and Why It Matters

Foster Provost, New York University, New York, NY, United States, Carlos Fernández-Loría

Causal decision making (CDM) at scale has become routine. Increasingly CDM is based on machine learning. Businesses algorithmically target offers, incentives, and recommendations to affect consumer behavior. Recently, research related to CDM and causal effect estimation (CEE) using ML models has accelerated. However, CDM is not the same as CEE, and counterintuitively, accurate CEE is not necessary for accurate CDM. Our experience is that this is not well understood by practitioners or most researchers. Technically, the estimand of interest is different, and this has important implications both for modeling and for the use of statistical models for CDM. This paper highlights three implications. (1) We should consider carefully the objective function of the causal ML, and if possible, optimize for accurate treatment assignment rather than for accurate effect-size estimation. (2) Confounding affects CDM and CEE differently. For supporting CDM it may be just as good or even better to learn with confounded data. Finally, (3) causal modeling may not be necessary at all to support CDM because a proxy target for statistical modeling might do as well or better. This third observation helps to explain at least one common CDM practice that seems wrong at first blush---the widespread use of non-causal models for targeting interventions. The last two implications are particularly important in practice, as acquiring (unconfounded) data on both ``sides" of the counterfactual can be quite costly and often impracticable. To facilitate research in this area we point to recent related articles from multiple contributing fields.

2 - GIFAIR-FL: A Framework for Group and Individual Fairness in Federated Learning

Raed Al Kontar, University of Michigan, Ann Arbor, MI, United States, Xubo Yue, Maher Nouiehed

In this paper we propose GIFAIR-FL: a framework that imposes Group and Individual FAIRness to Federated Learning settings. By adding a regularization term, our algorithm penalizes the spread in the loss of client groups to drive the optimizer to fair solutions. Our framework GIFAIR-FL can accommodate both global and personalized settings. Theoretically, we show convergence in non-convex and strongly convex settings. Our convergence guarantees hold for both i.i.d. and non-i.i.d. data. To demonstrate the empirical performance of our algorithm, we apply our method to image classification and text prediction tasks. Compared to existing algorithms, our method shows improved fairness results while retaining superior or similar prediction accuracy.

3 - Achieving Reliable Causal Inference with Data-Mined Variables: A Random Forest Approach to the Measurement Error Problem

Mochen Yang, University of Minnesota, Minneapolis, MN, United States

Combining machine learning with econometric analysis is becoming increasingly prevalent in both research and practice. A common empirical strategy uses predictive modeling techniques to "mine" variables of interest from available data, then includes those variables into an econometric framework to estimate causal effects. However, because the predictions from machine learning models are inevitably imperfect, econometric analyses based on the predicted variables likely suffer from bias due to measurement error. We propose a novel approach to mitigate these biases, leveraging the random forest technique. We propose employing random forest not just for prediction, but also for generating instrumental variables for bias correction. The random forest algorithm performs best when comprised of a set of trees that are individually accurate in their predictions, yet which also make "different" mistakes, i.e., have weakly correlated prediction errors. A key observation is that these properties are closely related to the relevance and exclusion requirements of valid instrumental variables. We design a data-driven procedure to select tuples of individual trees from a random forest, in which one tree serves as the endogenous covariate and the others serve as its instruments. Simulation experiments demonstrate its efficacy in mitigating estimation biases, and its superior performance over alternative methods.

4 - Sparse Density Trees and Lists: An Interpretable Alternative to High-Dimensional Histograms

Lesia Semenova, Duke University, Durham, NC, United States, Siong Thye Goh, Cynthia Rudin

Histograms, as piecewise constant density estimation models, are easy to visualize, are accurate with enough data in each bin, and have a logical structure that most people find interpretable. However, all of these properties fail in more than two or three dimensions, particularly for binned binary or categorical data. We present sparse tree-based and list-based density estimation methods as higher dimensional analogies to variable bin width histograms for binary/categorical data. In each leaf of the tree (or list), the density is constant, similar to the flat density within the bin of a histogram. Our models can easily be visualized in more than two dimensions, are sparse, and have priors that help with generalization. Our generative modeling methods allow the user to specify the preferred number of leaves or branches within a Bayesian prior for the tree or the preferred number and length of rules within the prior for the rule list. The new approaches often yield a better balance between sparsity and accuracy of density estimates than other methods for this task. We present an application to crime analysis, where we estimate how unusual each type of modus operandi is for a house break-in.

Power System Operation and Planning Under Uncertainty

Invited Session

ENRE: Electricity

Chair: Angela Flores, Universidad de Chile, Santiago, Chile

Co-Chair: Rodrigo Moreno, University of Chile, Santiago, Chile

1 - Power system planning under multi-scale climate-induced uncertainty

Angela Flores, University of Chile, Santiago, Chile, Iván Pérez, Byron Castro

Power systems are facing increasing pressure from climate change. The rise in global temperatures, more variable precipitation patterns, and the increase in frequency and severity extreme of weather events pose substantial risks for power systems in multiple time-scales. In this study we introduce a comprehensive power system planning model that allows to anticipate both short and long-term uncertainties, leveraging multi-scale stochastic programming. Furthermore, we present a novel approach for constructing multi-scale scenario trees for representing climate-induced uncertainty, using historical weather data and future climate projections.

2 - Analyzing and modeling the behavior of data centers and digital currency miners in power systems

Ignacio Andrés Aravena Solís, Lawrence Livermore National Laboratory, Livermore, CA, United States, Subir Majumder, Le Xie

Over recent years, power grids have seen an increase in the deployment and interconnection of large data centers and digital currency mining facilities, with power consumption levels reaching 700MW. In this work, we study the empirical behavior of large data centers and mining facilities in Texas and how their consumption is affected by factors like currency conversion factors, electricity price, local temperature, system demand, and different pricing mechanisms (seasons with and without peak pricing). We employ data transformation techniques to account for the very skew distribution of consumption (and demand response), and we fit and validate a SARIMA model to the transformed data. We find that during short-term mining operations, surprisingly, miners' consumption is not correlated or explainable by changes in digital currency prices. Instead, the primary factors impacting consumption are temperature, energy prices, and demand response strategies implemented in the Electric Reliability Council of Texas (ERCOT). We use the fitted model to generate public, synthetic datasets, which can be used to account for the behavior of this type of consumer in other markets. Finally, we discuss potential explanations for the observed behaviors and postulate profit-maximizing models that capture these behaviors for short-term operation and planning studies.

3 - Unit Commitment Problem with Energy Storage Under Correlated Renewables Uncertainty

Rodrigo Moreno, University of Chile, Santiago, Chile, Felipe Cordera, Fernando Ordonez

The extensive integration of renewable generation in electricity systems is significantly increasing the variability and correlation in power availability and the need for energy storage capacity. This increased uncertainty and storage capacity should be considered in operational decisions such as the short-term unit commitment (UC) problem. In this work, we formulate a day-ahead UC problem with energy storage, considering multistage correlated uncertainty on renewables' power availability. We solve this multistage stochastic unit commitment (MSUC) problem with integer variables in the first stage using a new variant of SDDP that can explicitly deal with temporal correlations. Our computational results on the IEEE 118-bus system demonstrate the significance of considering multistage uncertainty and correlations, comparing our solution with other multistage solutions, two-stage solutions, and deterministic solutions typically used by industry. We also solve the MSUC problem for a representation of the Chilean power system, finding superior UC solutions for scenarios where adapting generation to the unfolding uncertainty is costly. Finally, we demonstrate that the MSUC approach can be used to define a more efficient deterministic UC solution, outperforming the current industry practice.

4 - Capacity Expansion Planning under Uncertainty subject to Expected Energy Not Served Constraints

Marilena Zambara, National Technical University of Athens, Athens, Greece, Daniel Avila, Anthony Papavasiliou

We present a method for solving a large-scale stochastic capacity expansion problem which explicitly considers reliability constraints, in particular constraints on expected energy not served. Our method tackles this problem by a Lagrange relaxation of the expected energy not served constraints. We solve the relaxed formulation in an iterative manner, using a subgradient-based method. Each iteration requires the solution of a stochastic capacity expansion problem, for which we implement a subgradient decomposition scheme in a high-performance computing infrastructure. We apply the proposed methodology on the Economic Viability Assessment model that is used by ENTSO-E in the annual European Resource Adequacy Assessment. The Economic Viability Assessment is extended to include reliability constraints. We are able to solve this generalization of the Economic Viability Assessment and obtain the least-cost capacity expansion plan for meeting specific reliability requirements per zone, fully accounting for uncertainty. Our approach also allows us to compute the shadow price of load shedding by zone (through the Lagrangian multipliers of the relaxed constraints) which can serve as an indication of the zone-specific VOLL or price cap that could in principle deliver the appropriate level of investments within an energy-only market.

Advancements in Learning and Control for Power Systems

Invited Session

ENRE: Energy-Climate

Chair: Apurv Shukla, Texas A&M, College Station, TX, United States

1 - Recent Advances in design of dispatch policies for power grid

Apurv Shukla, Texas A&M, College Station, TX, United States

Look-ahead dispatch is a widely deployed policy across system operators for economic dispatch. However, little analysis of the impact of inter-temporal ramping constraints, forecast errors, and window size on loss in terms of generation cost and price fluctuations have been studied in antecedent literature. In this paper, we provide counter-examples demonstrating system behavior contrary to established folklore practices. Building on these examples, we conduct a thorough performance analysis and develop performance guarantees for look-ahead dispatch policies in the presence of intermittent renewable generation, storage, network congestion, and load forecast errors. These insights are further used to provide several policy recommendations regarding the practical usage of such policies. All our results are corroborated on a suite of numerical experiments based on IEEE 24 and 118 bus-systems.

2 - Towards Closing the Electricity-Transportation-Human Loop via Control and Market

Junjie Qin, Purdue University, West Lafayette, IN, United States

Electric power systems and transportation systems become deeply interconnected due to transportation electrification. The couplings between these systems can be leveraged to optimize the performance of both systems. In this talk, we will go through two such examples. In the first example, we consider the design of workplace electric vehicle (EV) charging tariffs in a morning commute setting. We demonstrate that a time-varying charging tariff can play the role of a dynamic toll to improve the traffic or nudge the EV arrival times to optimize electricity system costs. In the second example, we introduce a business model where EVs are shared for joint provision of transportation and electricity services. We justify using shared EVs to provide a particular electricity service (i.e., demand charge reduction) by exploring the statistics of load data of large electricity users and analyze the optimal spatial pricing problem for joint service provision with a shared EV fleet. Impacts of the proposed operation is simulated using real transportation network company data and electric load data for the city of San Francisco.

3 - The Architecture of Green Energy Systems

Michael Ferris, University of Wisconsin, Madison, WI, United States, Andy Philpott

The world is undergoing a transition from using fossil-fuel energy that emits greenhouse gases (mainly carbon dioxide) to using energy that does not. This transition is a global response to calls to limit global warming that has been caused by the emission of greenhouse gases over the post-industrial era. The current scale and speed of this transition appears insufficient to keep global temperatures below agreed targets. There are many technical, economic, social and political reasons for this slowness that have been canvased in a number of recent reports.

Our purpose in this paper is to examine the contribution that mathematics and mathematical models can make to understanding and overcoming the barriers that are faced in the transition. In particular we will focus on what we call the architecture of energy systems, which consists not only of the physical infrastructure for generating and transporting energy, but also the market and contractual arrangements that give incentives for investing in this infrastructure and that allow for it to be operated in an efficient manner. This paper examines the contributions that mathematical modeling can make to help accelerate this transition. The models we catalog are confined to optimization and equilibrium models, but cover a range of physical scales and time scales. Our focus is on novel model formulations that can help overcome the challenges of the transition by unpicking the complexity inherent in many settings and quantifying the tradeoffs that must be made when developing energy policy.

4 - Optimal Forest Management for Interdependent Products: a Nested Stochastic Dynamic Bioeconomic Model

Tong Wu, Cornell University, Ithaca, NY, United States, C.-Y. Cynthia Lin Lawell, David Just, Jiancheng Zhao, Zhangjun Fei, Qiang Wei

Sustainable forest management is an important issue worldwide. Forests supply the world’s population with timber and non-timber forest products, including renewable products such as fruits, nuts, and maple syrup that can be harvested at more frequent intervals than the trees themselves. We develop a nested dynamic bioeconomic model and dynamic structural econometric model of the management of forests that generate interdependent products that differ in their growth cycles, rates of growth, lengths of growing periods, and potential harvest frequency. We apply our model to detailed daily panel data we have collected and constructed on bamboo shoot and bamboo stem harvesting decisions made by bamboo farmers, in order to assess the optimality of bamboo farmers’ forest management strategies and to understand the beliefs and perceptions that underlie and rationalize their management strategies. Our nested stochastic dynamic model nests an inner finite-horizon within-year dynamic programming problem that captures daily bamboo shoot growth within a season, inside an outer finite-horizon between-year dynamic programming problem that captures bamboo stem growth from year to year. Sources of uncertainty in our model include stochastic rain, stochastic prices, and stochastic survival. We plan to use our dynamic model to simulate, analyze, and design policies and institutions to improve sustainable forest management. Our research has important implications for the sustainable management of forests worldwide, particularly when the forests produce products that grow on trees, are renewable, and can be harvested at more frequent intervals than the trees themselves.

5 - Modeling Equilibrium EV Charging Behavior Considering Driver (Un)availability and Waiting Times

Hannah Davalos, UC Berkeley, Berkeley, CA, United States, Shmuel Oren, Candace Yano

Range anxiety and shortages of chargers in certain geographic areas are concerns for prospective EV purchasers and thus also for auto manufacturers. Using data from a U.S. car manufacturer, we examine actual charging patterns of EV drivers and develop a model that allows us to capture factors such as driver (un)availability, electricity time-of-use rates and disutility for waiting to obtain estimates of equilibrium EV charging behavior and waiting times. Sensitivity analysis using our model enables us to explore how the addition of more EV drivers and charging stations would affect the equilibrium day-of-week and time-of-day demands for charging and the load on the electrical grid.

Energy Systems Modeling and Optimization VI: Methods for Modern Power Systems

Invited Session

ENRE: Other Energy

Chair: Antoine Lesage-Landry, Polytechnique Montréal, Montreal, QC, H4A 3L3, Canada

1 - Frequency Dynamics-Aware Real-TIME Locational Marginal Pricing of Electricity

Christine Chen, University of British Columbia, Vancouver, BC, Canada, Bo Chen, Roohallah Khatami, Abdullah Al-Digs

We present a method to generalize the well-known concept of locational marginal prices (LMPs) to embed the impact of system frequency dynamics into real-time electricity markets. The proposed frequency dynamics-aware LMPs can help to mitigate costs associated with setting aside ever more reserve capacity to offset larger, faster, and more frequent transient excursions arising from greater renewable integration. We formulate a dynamics-aware economic dispatch (ED) by augmenting a traditional static ED with constraints pertinent to system frequency dynamics, including those from inertial response, primary frequency control, and the automatic generation control. Similar to their traditional counterparts, dynamics-aware LMPs are composed of Lagrange multipliers associated with the power balance and transmission line power flow constraints. Numerical simulations involving standard test systems validate our findings, confirm added revenue opportunities for generators contributing to frequency support, and demonstrate computational scalability.

2 - Optimal Electric Vehicle Charging with Dynamic Pricing, Customer Preferences and Power Peak Reduction

Miguel Anjos, University of Edinburgh, Edinburgh, United Kingdom, Luce Brotcorne, Gaël Guillot

We consider a provider of electric vehicle charging that operates a network of charging stations and uses time-varying pricing to maximize profit and reduce the impact on the electric grid. We propose a bilevel model with a single leader and multiple disjoint followers. The customers (followers) makes decisions independently from each other. The provider (leader) sets the prices for each station at each time slot, and ensures there is enough energy to charge. The charging choice of each customer is represented by a combination of a preference list of (station, time) pairs and a reserve price. The proposed model takes thus into accounts for the heterogeneity of customers with respect to price sensitivity and charging preferences. We define a single level reformulation based on the reformulation for the rank pricing problem. Computational results highlight the efficiency of the new reformulation and the impact of the model on the grid peak.

3 - Online Interior-Point Methods for TIME-Varying Equality-Constrained Optimization

Jean-Luc Lupien, UC Berkeley, Berkeley, CA, United States, Iman Shames, Antoine Lesage-Landry

An important challenge in the online convex optimization (OCO) setting is to incorporate generalized inequalities and time-varying constraints. The inclusion of constraints in OCO widens the applicability of such algorithms to dynamic but safety-critical settings such as the online optimal power flow (OPF) problem. In this work, we propose the first projection-free OCO algorithm admitting time-varying linear constraints and convex generalized inequalities: the online interior-point method for time-varying equality constraints (OIPM-TEC). We derive simultaneous sublinear dynamic regret and constraint violation bounds for OIPM-TEC under standard assumptions. For applications where a given tolerance around optima is accepted, we propose a new OCO performance metric - the epsilon-regret - and a more computationally efficient algorithm, the epsilon OIPM-TEC, that possesses sublinear bounds under this metric. Finally, we showcase the performance of these two algorithms on an online OPF problem and compare them to another OCO algorithm from the literature.

4 - The Influence of Short-Term Electricity Pricing Strategies on Long-Term Supply Flexibility

Han Shu, Cornell University, Ithaca, NY, United States, Jacob Mays

As the rapid integration of renewable energy sources such as wind, solar, and storage, electricity markets demand to adopt pricing strategies to ensure long-term flexibility and grid reliability. This study investigates how short-term electricity pricing strategies influence long-term investments in flexible generators and energy storage. We develops a sequential decision problem faced by system operators, to access price formation in wholesale electricity markets given variability, uncertainty, non-convexity, and intertemporal operating constraints. Numerical study shows that different pricing strategies can result in markedly different price outcomes and revenues streams. Moreover, these pricing mechanisms shape the energy mix and grid reliability over time by either promoting or hindering the deployment of flexible generation resources. Our findings highlight the critical need for policymakers to integrate considerations of long-term flexibility into the design of short-term pricing policies, particular in the context of decarbonized electricity markets.

Chair: Shuotao Diao, Northwestern University, Evanston, IL, 60208, United States

1 - Multi-stage Stochastic Programming for Integrated Network Optimization in Hurricane Relief Logistics and Evacuation Planning

Sudhan Bhattarai, Clemson University, Clemson, SC, United States, Yongjia Song

This study addresses the integrated hurricane relief logistics and evacuation planning (IHRLEP) problem, combining hurricane evacuation and relief item pre-positioning operations, which are usually managed separately. We introduce a fully adaptive multi-stage stochastic programming (MSSP) model and develop solution approaches based on two-stage stochastic programming (2SSP). By leveraging historical forecast errors using an auto-regressive model of order one, we generate hurricane scenarios and approximate the hurricane process as a Markov chain, with each state defined by the hurricane's location and intensity. Our comprehensive numerical experiments, inspired by Hurricane Florence and Hurricane Ian case studies, demonstrate the superior out-of-sample performance of the MSSP model's fully adaptive policies compared to the static policies of the 2SSP model. Additionally, an extensive sensitivity analysis provides valuable insights into the conditions under which fully adaptive policies outperform static ones, highlighting key problem parameters.

2 - Convergence and Complexity Analysis of a Stochastic Frank - Wolfe Algorithm with Away Steps

Natthawut Boonsiriphatthanajaroen, Cornell University, Ithaca, NY, United States, Shane Henderson

We study the convergence properties of the Frank Wolfe algorithm, also known as the conditional gradient method, with away steps for linearly constrained stochastic optimization. The algorithm makes use of unbiased gradient estimates. The convergence analysis of the algorithm relies on an assumption that the estimated gradient is sufficiently accurate with high enough probability, which can be ensured in our context by using a sufficient number of replications. Under these and other conditions, we show that the algorithm converges to a neighborhood of a globally optimal solution where the rate of convergence, sample size, and number of iterations until convergence also depend on the geometry of the feasible set.

3 - Piecewise Linear Decision Rules are Asymptotically All You Need

Yue Lin, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Daniel Zhuoyu Long, Viet Anh Nguyen, Jin Qi

Two-stage risk-averse distributionally robust optimization (DRO) problems are ubiquitous across many engineering and business applications. In these problems, the decision-maker commits to a capacitated first-stage decision, anticipating that second-stage recourse decisions can be executed after observing the realization of the uncertain parameters. Despite their promising resilience, two-stage DRO problems are often intractable because the recourse decisions are infinite-dimensional. To address this issue, a practical yet powerful solution approach is to approximate the recourse decisions using parametric decision rules. This paper focuses on the approximation using piecewise linear decision rules (PLDRs), which deliver better quality than linear decision rules but are more computationally demanding. Besides distributional uncertainty, we also capture the decision maker's attitude towards risk. We propose a heuristic method to find the first-stage decision and the second-stage PLDR by solving a deterministic, finite-dimensional optimization problem. Moreover, our simple heuristic solution is asymptotically optimal as the magnitudes of the problem parameters, including the uncertain parameters and the first-stage capacity, inflate to infinity at an appropriate rate. This asymptotic optimality highlights the surprising power of PLDRs from a new perspective. We validate our theoretical findings through numerical simulations in assemble-to-order problems. In the data-driven setting, our finely tuned heuristic solution can achieve small optimality gaps and surpass the sample-average approximation method in the out-of-sample performance.

4 - Deterministic and Stochastic Frank-Wolfe Recursion on Probability Spaces

Raghu Pasupathy, Purdue University, West Lafayette, IN, United States

Motivated by applications in emergency response and experimental design, we consider smooth stochastic optimization problems over probability measures supported on compact subsets of the Euclidean space. With the \emph{influence function} as the variational object, we construct a deterministic Frank-Wolfe (dFW) recursion for probability spaces, made especially possible by a lemma that identifies a ``closed-form'' solution to the infinite-dimensional Frank-Wolfe sub-problem. Each iterate in dFW is expressed as a convex combination of the incumbent iterate and a Dirac measure concentrating on the minimum of the influence function at the incumbent iterate. To address common application contexts that have access only to Monte Carlo observations of the objective and influence function, we construct a stochastic Frank-Wolfe (sFW) variation that generates a random sequence of probability measures constructed using minima of increasingly accurate estimates of the influence function. We demonstrate that sFW's optimality gap sequence exhibits $O(k^{-1})$ iteration complexity almost surely and in expectation for smooth convex objectives, and $O(k^{-1/2})$ (in Frank-Wolfe gap) for smooth non-convex objectives. Furthermore, we show that an easy-to-implement fixed-step, fixed-sample version of (sFW) exhibits exponential convergence to

ε-optimality. We end with a central limit theorem on the observed objective values at the sequence of generated random measures. To further intuition, we include several illustrative examples with exact influence function calculations.

5 - A Reliability Theory of Compromise Decisions for Large-Scale Stochastic Programs

Shuotao Diao, Northwestern University, Evanston, IL, United States, Suvrajeet Sen

Stochastic programming models can lead to very large-scale optimization problems for which it may be impossible to enumerate all possible scenarios. In such cases, one adopts a sampling-based solution methodology in which case the reliability of the resulting decisions may be suspect. For such instances, it is advisable to adopt methodologies that promote variance reduction. One such approach goes under a framework known as "compromise decision", which requires multiple replications of the solution procedure. We study the reliability of stochastic programming solutions resulting from the "compromise decision" process. This process is characterized by minimizing the aggregation of objective function approximations across replications, presumably conducted in parallel. We refer to the post-parallel-processing problem as the problem of "compromise decision". We quantify the reliability of compromise decisions by estimating the expectation and variance of the "pessimistic distance" of sampled instances from the set of true optimal solution set. Such pessimistic distance is defined as an estimate of the largest possible distance of the solution of the sampled instance from the "true" optimal solution set. The Rademacher average of instances is used to bound the sample complexity of the compromise decision.

1 - Optimizing On-site Green Hydrogen Consumption of Heavy-duty Hydrogen Fuel Cell Electric Vehicles

Mohammad Reza Ghorbanali Zadegan, University of Central Florida, Orlando, FL, United States, Zhaomiao Guo

Transitioning to zero-emission heavy-duty freight vehicles, such as fuel cell electric vehicles (FCEVs), considerably contributes to mitigating the environmental footprint of the freight sector in transportation emissions. Our study develops a mixed-integer programming (MIP) model that optimizes the routing/scheduling, refueling, and hydrogen production operations of FCEVs, leveraging on-site green hydrogen sources. The model integrates solar-powered hydrogen production to utilize renewable resources for FCEVs refueling, and reduce reliance on non-renewable energy sources. Our findings demonstrate that this approach deals with different logistical challenges by strategically determining the locations and sizes of hydrogen refueling stations (HRSs) based on geographic and spatiotemporal conditions. Our model was initially tested using well-established Solomon benchmark instances to evaluate its robustness and efficiency. Consequently, we implemented the model in a real-world case study of freight distribution across Florida, further demonstrating its applicability. Extensive sensitivity analyses were conducted on various parameters to ensure that our model performs reliably under a variety of operational and environmental conditions. Keywords: Fuel Cell Electric Vehicles (FCEVs), Freight Transportation, Renewable Hydrogen Production, Hydrogen Refueling Stations (HRSs)

2 - Improving Resilience and Trust in AI Driven Cyber Physical Systems

Apurva Narayan, University of Western Ontario , London, ON, Canada

In today's interconnected digital era, Cyber-Physical Systems (CPS) have emerged as the backbone of critical infrastructures, encompassing a wide range of applications from smart grids to autonomous vehicles. With the advent of Artificial Intelligence (AI) technologies, these systems have witnessed unprecedented advancements, leading to improved efficiency, adaptability, and automation. However, the integration of AI introduces new challenges related to system resilience and trustworthiness, as these systems become susceptible to a new breed of threats and vulnerabilities. In this talk, he will present some of the work he's doing in his group to ensure the reliability of ML systems in the presence of adversarial attacks, primarily patch attacks in computer vision. The focus of our work has been to introduce novel strategies for practical attacks on AI driven computer vision systems and subsequently developing defences against such vulnerabilities by characterizing properties of patches. In the second part of his talk, he will showcase some recent work in the domain of digital twins where he and his group have developed novel strategies to develop robust AI systems in data scarce situations using transfer learning and active transfer learning.

3 - Integrated Modeling of Shared Mobility Systems

Hua Cai, Purdue University, West Lafayette, IN, United States, Hao Luo

Shared mobility, including bike-sharing, shared e-scooter, and ride-hailing, could improve transportation sustainability when substituting private car use and integrating with public transit. However, if shared mobility competes with other green modes, it cannot guarantee sustainability benefits. The competing and synergistic relationships between conventional modes and shared mobility are complex and not well-studied to date. We built a city-scale agent-based model that is supported by real-world mode choice survey and trip data to better study how different design and pricing of different mobility systems will lead to different competing and synergistic relationship among the shared mobility and conventional transportation systems. Using Indianapolis as the case study city, our results show that the current deployment of shared mobility systems (mainly in downtown area) does not help improve urban sustainability because the shared mobility is primarily competing with green travel modes such as walking and bus. To reduce transportation emissions, the shared micro-mobility vehicles need to be optimally deployed and rebalanced to areas that can supplement public transit network to enable multi-modal trips as an alternative to driving.

4 - Exploring the Implications of Alternative Approaches to Flood Frequency Analysis on Urban Costal Flood Attribution

Julianne Quinn, University of Virginia, Charlottesville, VA, United States, Daniel Lassiter, Daniel Wright

Characterizing flood risks in urban coastal systems is complex due to the compound, non-independent drivers of flooding (rainfall and storm surge), and nonlinear propagation of excess water through the storm sewer network. Yet understanding these risks and their drivers is critical to informing flood mitigation designs. In this study, we explore how estimates of flood volumes at different return periods and their associated drivers depend on the method used for Flood Frequency Analysis (FFA). Using the City of Norfolk, VA as a case study, we compare three FFA methods: a conventional design storm (DS) approach and two compound event (CE) approaches that use either stochastic storm transposition (SST) or stochastic storm rescaling (SSR). The DS approach simulates stylistic 24-hour precipitation time series independent of storm surge levels and assumes flood volume probabilities have the same return period as the precipitation event. The CE approaches estimate flood volume probabilities empirically from a time series of simulated storms, whose rainfall and storm surge characteristics are correlated through a copula fit to the historical record. In SST, rainfall time series are produced by stochastically transposing historical radar rainfall events in space over a meteorologically homogenous transposition domain, while in SSR, they are generated by rescaling historical storms at the same location. For each method, we decompose the flood volumes at different locations and return periods into that which can be attributed to rainfall, storm surge, and their interaction. Future work will explore the implications of these differences on optimal flood mitigation designs.

Making the most of this AI Moment: A Fireside Chat with Charles Isbell and Michael Littman

Plenary/Keynote Session

Plenary

Chair: Polly Mitchell-Guthrie, Kinaxis, Scottsdale, AZ, United States

1 - Making the most of this AI Moment: A Fireside Chat with Charles Isbell and Michael Littman

Cynthia Rudin, Duke University, Durham, NC, United States, Charles Isbell, Michael Littman

Interest in AI, which was already high, has reached a fever pitch since the release of ChatGPT two years ago. Fascination and fear abound, so how do we engage the public for the health of society to ensure AI is a force for good and not for harm? How do we broaden access to computing to shape its future? How can comedy and humor help? What roles should leading scientists take to best impact these issues? These are just a few of the questions to be discussed during this fireside chat, which longtime INFORMS member Cynthia Rudin will lead with two fellow computer scientists, who are excited to share their combined 60+ years of experience in AI and machine learning.

Monday, October 21, 10:45 AM - 12:00 PM

Summit - 320

Information Sharing in Service Operations

Invited Session

Service Science

Chair: Dongwook Shin, HKUST Business School, Clear Water Bay, Hong Kong

Co-Chair: Jeunghyun Kim, Korea University, Seoul, Korea, Republic of

1 - Recommender Systems Under Privacy Protection

Shouqiang Wang, University of Texas at Dallas, RICHARDSON, TX, United States, Can Kucukgul, Ozalp Ozer

Consumers make inferences about a product’s relevance or even get access to it through recommendations. Namely, recommendations often play both informative and allocative roles. However, the pervasive use of personal data by modern algorithmic recommender systems has sparked public outcry for tighter privacy regulations. Personal preferences over different product offerings are a basic constituent of consumer privacy. We study how a profit-driven online platform designs its recommender policies in response to different privacy protection regimes that grant users varying degrees of control over their personal data. We demonstrate the effective equivalence between the opt-out protection and the unprotected privacy. As a key finding, consumers’ autonomy over their privacy (to the extent that they could misrepresent their personal data) may compel platforms to distort their recommender policies and lead to unintended consequences. When the recommendation only plays an informative role, such level of privacy protection deters the platform from any personalized recommendation; if the recommendation can, in addition, act allocatively to control consumers’ access to products, algorithmic discrimination may arise, whereby the disadvantaged minority in the society are restricted or deprived of access to potential valuable opportunities. Ultimately, these distortions could inadvertently hurt both platforms and consumers, relative to less stringent privacy protection regimes. Counter-intuitively, enacting the recommendation’s allocative role (by restricting users’ access to certain products) in addition to its informative role can in fact benefit both the platform as well as the users, especially when users are given the autonomy over their privacy.

2 - Information Sharing to Optimize the Waiting-TIME Experience

Jeunghyun Kim, Korea University, Seoul, Korea, Republic of, Laurens Debo, Robert Shumsky

We develop a model to optimize the provision of queue-position information to waiting customers. A customer’s emotional response, and satisfaction with the wait, may be driven by loss aversion in expected waiting time and/or by disutility due to wait-time uncertainty (we call this latter effect ‘uncertainty awareness’). We consider a class of announcement strategies characterized by frequency of updates between two announcements one upon arrival and the other upon entering service. We control the frequency by the number of queue-position advancements needed to hear the next announcement and optimize it. We find that when customers are purely loss-averse, a strategy that never provides intermediate updates (arrival-only) is optimal while with purely uncertainty-aware customers, a strategy that updates customers with every single step (full information) is optimal. For customers affected by both loss aversion and uncertainty, there is an interior solution and the degree of customer satisfaction improvement (relative to the arrival-only and full information) becomes more substantial as the system becomes more loaded.

3 - The Effects of Queue-Related Information on Abandonment in The Emergency Department

Vahid Sarhangian, University of Toronto, Toronto, ON, Canada, Yaniv Ravid, Philipp Afèche, Rouba Ibrahim

Patients who leave without being seen pose a significant operational challenge to many emergency departments. We study how patients' probability of abandoning changes as they observe different events in the waiting room, by constructing a dynamic hazard model to describe patients' wait using time-dependent covariates. We find that during specific time intervals of their waiting period, observing others enter and leave the waiting area significantly affects patients' risk of abandoning before being seen by a doctor. Moreover, our results indicate that the effect changes at different congestion levels. For example, observing others arrive into the waiting room increases a patient's risk of abandoning when congestion is low, but when there are sufficiently many others waiting for service, observing others arrive reduces one's risk of abandoning. Our results can help emergency departments identify patients that are at high risk of abandoning based on the events that they have observed during their wait.

4 - Should a Platform Compete with a Third-Party Seller?

Zihao Zhang, University of Science and Technology of China, Hefei, China, People's Republic of, Ming Fan, Dongyuan Zhan

Platforms, such as Amazon, have been criticized to manipulate product information by Bayesian persuasion when competing with third-party sellers. We develop a model to analyze the phenomenon. We find that while Bayesian persuasion may improve social welfare, it causes unfair competition and always hurts third-party sellers and customers. We propose a method to reduce the strength of information manipulation and improve the fairness.

Summit - 321

Junior Faculty Network Session Across Societies

Flash Session

Quality, Statistics and Reliability

Chair: Hongyue Sun, University of Georgia, Athens, GA, United States

Co-Chair: Elynn Chen, New York University, New York, NY, 10012, United States

Co-Chair: Mansah Preko, Ghana Institute of Management and Public Administration (GIMPA), Accra, N/A, Ghana

1 - Introduction

Hongyue Sun, University of Georgia, Athens, GA, United States

. This is a network/interaction session for junior faculties, and the list of people will just briefly introduce themselves in around 2 minutes.

2 - AI/ML enabled data/knowledge fusion for quality and productivity improvements of complex engineering system

Shancong Mou is an incoming assitant Professor in the School of Industrial & Systems Engineering (ISyE) at University of Minnesota Twin Cities. He got his Ph.D. degree from ISyE, Gatech, advised by Dr. Jianjun Shi. Shancong's research interest focuses on AI/ML enabled data/knowledge fusion for quality and productivity improvements of complex engineering systems, with methodological development in robust learning, meta-learning and physics informed learning, which interfaces high-dimensional statistics, optimization research, machine learning, and computational science. His work has generated multiple papers published in top journals, recognized by various best paper awards from INFORMS QSR, IISE DAIS, and IISE QCRE divisions, and several scholarships/fellowships from ASA, IISE, ISA, and Georgia Tech. He is also the recipient of the ISyE Outstanding Graduate Student Instructor of the Year award in 2022. Shancong serves as a board member for the IISE QCRE division. He also organizes seminars, sessions, workshops, and data challenges at INFORMS, IISE, CVPR, and ECCV conferences.

3 - Balancing Optimality and Diversity: Enhancing Human Decision-Making through Generative Curation

Shixiang Woody Zhu, Carnegie Mellon University, Pittsburgh, PA, United States

"Woody Zhu is an Assistant Professor in Heinz College of Information Systems and Public Policy, Carnegie Mellon University. He obtained his Ph.D. in Machine Learning at H. Milton Stewart School of Industrial and Systems Engineering, Georgia Institute of Technology. His research lies in the broad area of machine learning, statistics, and operations research. He is particularly interested in spatio-temporal modeling and decision making under uncertainty. Much of his work aims to develop new methodologies that address high-impact problems in various applications, including power system, renewable energy, urban planning, transportation, and healthcare. "

4 - Tensor-view Topological Graph Neural Network

Elynn Chen, New York University, New York, NY, United States

"I currently serve as an Assistant Professor in the Department of Technology, Operations, and Statistics (TOPS) at NYU Stern School of Business. Prior to this role, I was a postdoctoral fellow at the University of California, Berkeley's Department of Computer Sciences under the mentorship of Prof. Michael I. Jordan. I also held a postdoctoral position at Princeton University's ORFE, collaborating with Prof. Jianqing Fan. I received my Ph.D. degree in Statistics from Rutgers University, where I was guided by Prof. Rong Chen. My research interests are centered around developing cutting-edge methodologies for data-driven decision-making and the analysis of complex datasets, particularly in the fields of business, economics, and finance. Currently, my work is focused on advancing the areas of Tensor Learning, Reinforcement Learning, and Fusion Learning. For more information about my research and publications, please visit my website at https://elynncc.github.io/."

5 - Ethics in Action: Operationalizing Fairness in Algorithmic Decision-Making

Hadis Anahideh, University of Illinois Chicago, Chicago, IL, United States

Dr. Hadis Anahideh is as an Assistant Professor of Industrial Engineering at the University of Illinois Chicago. She earned her M.Sc. and Ph.D. in Industrial Engineering and holds a B.S. in Applied Mathematics. Her research is centered on black-box optimization, active learning, machine learning, and algorithmic fairness, with a focus on developing innovative methodologies for engineering operations, design, and social systems. Dr. Anahideh is the director of the Optimal Learning and Exploration Laboratory (OPLEX) at UIC, where she leads a dynamic team of students and collaborators on projects that push the boundaries of her research interests.

6 - Advanced Machine Learning for Complex Physical Systems

Yinan Wang, Rensselaer Polytechnic Institute, Troy, NY, United States

Dr. Yinan Wang is an Assistant Professor in the Department of Industrial and Systems Engineering at Rensselaer Polytechnic Institute. He received the B.S. degree in Electrical Engineering and Automation from Xi’an Jiaotong University, the M.S. in Electrical Engineering from Columbia University, and the Ph.D. in Industrial and Systems Engineering from Virginia Tech. His research interests include data analytics and machine learning techniques in quality control of advanced manufacturing systems. He is the recipient of FTC Early Career Award, 10 Best Paper/Poster/Featured Article Awards, and two Best Ph.D. Dissertation Awards. He is selected as the Mary and Joseph Natrella Scholar from the American Statistical Association (ASA), Scialog Fellow from the Research Corporation for Science Advancement (RCSA), and the Panel Fellow in the NSF CMMI Game Changer Academy. He was co-organizer for the Symposium and Workshop in Manufacturing Science and Engineering Conference (MSEC) 2023 and SIAM International Conference on Data Mining (SDM) 2023 and 2024. He serves as an active Board Director in the IISE Data Analytics and Information Systems (DAIS) division and program director in the Automatic Controls and Robotics Division (ACARD) of the International Society of Automation (ISA).

7 - Structured Data Analysis with Weak Supervision in Healthcare Applications

Xin Zan, University of Iowa, Coralville, IA, United States

Xin Zan is joining the University of Iowa as an assistant professor in the Department of Industrial and Systems Engineering in Fall 2024. Xin received her BS degree in industrial engineering from Shanghai Jiao Tong University, China, in 2019, the master’s degree in statistics and Ph.D. degree in industrial and systems engineering from the University of Florida in 2022 and 2024, respectively. Her research interests are focused on advanced data analytics for complex system modeling, monitoring, and diagnosis to improve system performance with applications mainly in healthcare. Xin’s research works have had a broad impact and been recognized by several distinguished awards from INFORMS, IISE, and COVID Information Commons (CIC), etc. She is a member of INFORMS and IISE.

8 - Toward Explainable Time Series Data Mining via Motif

Yifeng Gao, University of Texas Rio Grande Valley, Brownsville , TX, United States

Researchers work on time series data driven health applications

9 - Privacy-aware Time Series Data Sharing

Li Zhang, University of Texas Rio Grande Valley, Brownsville, TX, United States

Li Zhang is an assistant professor in the Department of Computer Science at the University of Texas Rio Grande Valley (UTRGV). She received his Ph.D. degree at George Mason University in 2023. She has worked on time series data mining for five years and published in premier data mining conferences in data mining research fields such as ICDM and SDM. She is currently interested in developing robustness and interpretable time series models for anomaly detection, forecasting, evolving pattern discovery methods in manufacture, health care and renewable energy related applications.

10 - Process Monitoring and Control of Advanced Manufacturing based on Physics-Assisted Machine Learning

I am an Assistant Professor in the Department of Industrial Engineering at Pusan National University in Korea. I received a Ph.D. in Industrial and Systems Engineering at Virginia Polytechnic Institute and State University (May 2023). My research area is developing data-driven methods, including artificial intelligence, machine learning, and statistical learning, to achieve quality assurance in advanced manufacturing processes and solve various problems in healthcare systems and material analysis.

11 - Process Monitoring and Control of Advanced Manufacturing based on Physics-Assisted Machine Learning

Jihoon Chung, Virginia Tech, Blacksburg, VA, United States

I am an Assistant Professor in the Department of Industrial Engineering at Pusan National University in Korea. I received a Ph.D. in Industrial and Systems Engineering at Virginia Polytechnic Institute and State University (May 2023). My research area is developing data-driven methods, including artificial intelligence, machine learning, and statistical learning, to achieve quality assurance in advanced manufacturing processes and solve various problems in healthcare systems and material analysis.

12 - The Sooner, the Better? Optimal Vaccination Policy with Limited Vaccine Supply

Miao Bai, University of Connecticut, Storrs, CT, United States

Miao Bai is an assistant professor in the Department of Operations and Information Management at the University of Connecticut, Storrs, CT and a research collaborator at Mayo Clinic, Rochester, MN. His primary research interest is to analyze and address complex problems in the domains of public health, healthcare operations management, and medicine.

13 - Recent advances on multi-task learning and fine-tuning: An algorithmic perspective

Hongyang Zhang, Northeastern University, Boston, MA, United States

Recent advances on multi-task learning and fine-tuning: An algorithmic perspective

14 - "Empowering Frontline Health Workers to Tackle Stock-outs in LMICs: Evaluating Training Programs in Indonesia"

Amir Karimi, The University of Texas at San Antonio, San Antonio, TX, United States

"Professor Amir Karimi's research is positioned at the intersection of Global Health, Healthcare Supply Chains, and Socially Responsible Supply Chains. In particular, his research endeavors are focused on improving access to essential health commodities (e.g., contraceptives, antimalarials, HIV medication) in Low- and Middle-income Countries (LMICs). For individuals who are deprived access to such essential health commodities , the consequences can be dire. For example, without reliable access to contraceptives, women may suffer unintended pregnancies, imposing economic and psychological burden, and adverse health outcomes including injuries, infections, and even deaths. HIV patients unable to obtain antiretrovirals may face delays in treatment initiation and interruptions during the treatment process, subsequently increasing the risk of viral resistance, treatment failure, and mortality. Focusing on this context, Amir's research aims to: (i) Empirically evaluate and uncover the factors that impact health commodity access in LMICs by leveraging field data and using a combination of rigorous econometric and predictive modeling techniques; (ii) Generate actionable insights that public health organizations, governments, and donors can use to improve health commodity access in LMICs. Amir has a Ph.D. in Supply Chain and Operations from the University of Minnesota, a master's degree in Production and Operations Management from University of Tehran, and a bachelor's degree in Industrial Management from Shiraz University."

15 - New Wine in Old Bottle: Statistical Learning in Operations Management

Zhengyuan Zhou, Stern School of Business, New York University, New York, NY, United States

Zhengyuan Zhou is currently an assistant professor in New York University Stern School of Business, Department of Technology, Operations and Statistics. Before joining NYU Stern, Professor Zhou spent the year 2019-2020 as a Goldstine research fellow at IBM research. He received his BA in Mathematics and BS in Electrical Engineering and Computer Sciences, both from UC Berkeley, and subsequently a PhD in Electrical Engineering from Stanford University in 2019.

16 - Generative AI in Action: Applications in Consumer Insights, Mental Health, and More

Yuan Zhang, University of Memphis, Memphis, TN, United States

Dr. Yuan Zhang is an assistant professor in Management Information Systems in the Fogelman College of Business and Economics at the University of Memphis. Mainly using applied econometrics, experiments, and causal inference machine learning, her research investigates user experience, user behaviors, and IT artifacts design focusing on usability and affordance primarily in the contexts of social media and video games. Her research has been published in major information systems and interdisciplinary journals including JAIS and I&M and presented at major conferences including CIST, INFORMS, WISE, HICSS, WITS, ACR.

17 - Robustness in Data-Driven Decision-Making

Mohammed Amine Bennouna, Massachusetts Institute of Technology, Cambridge, MA, United States

Amine Bennouna is an incoming Assistant professor at Kellogg School of Management at Northwestern University. He completed his PhD at MIT's Operations Research Center. His research interests lie at the intersection of machine learning, optimization and statistics, with a focus on developing novel machine learning and data-driven decision-making algorithms with desirable properties such as robustness and interpretability. Prior to joining MIT, he received a Bachelor and Master of Science in Applied Mathematics from Ecole Polytechnique.

18 - Active Learning Techniques for Uncertainty Quantification

Ozge Surer, Miami University, Oxford, OH, United States

Özge Sürer is an Assistant Professor of Business Analytics at Miami University. Before joining Miami University, she was a postdoctoral research fellow at the Northwestern Argonne Institute of Science and Engineering, where she specialized in developing novel techniques utilizing Bayesian uncertainty quantification and computational statistics. Dr. Sürer earned her Ph.D. in Industrial Engineering and Management Sciences from Northwestern University in December 2020, with her dissertation centered on creating interpretable predictive models for large data sets.

19 - On algorithms and complexity to address high-dimensional nonconvex optimization

Yue Xie, University of Hong Kong, Pokfulam, Hong Kong

Dr. Yue Xie is a Research Assistant Professor in Musketeers Foundation Institute of Data Science (HKU-IDS) and Department of Mathematics at the University of Hong Kong. He was a postdoc at UW Madison working in the nonconvex optimization group led by Professor Stephen J. Wright. He received his PhD degree in Pennsylvania State University and Bachelor degree from Tsinghua University. Dr. Yue Xie has been focusing on algorithm design and analysis to address large-scale nonconvex and stochastic optimization problems with all types of applications including machine learning and data science. He has published/served as the referee of top-tier journals including Mathematical Programming, SIAM Journal on Optimization, and IEEE Transactions on Automatic Control, etc. More details about him can be found at: https://yue-xie.github.io.

20 - Data-Driven Methods for Healthcare Operations

Yanhan (Savannah) Tang, SMU Cox School of Business, Dallas, TX, United States

Savannah Tang is an Assistant Professor at SMU Cox School of Business. She earned her Ph.D. in Operations Management from the Tepper School of Business at Carnegie Mellon University and also holds a Master's degree in Machine Learning from CMU's School of Computer Science. Savannah's research focuses on data-driven decision-making in critical real-world applications, including organ allocation, child welfare, and personalization.

21 - AI in Healthcare - Are African Healthcare Policies Ready?

Mansah Preko, Ghana Institute of Management and Public Administration , Accra, Ghana

Dr. Mansah Preko is an information systems researcher, an industry IT professional, and an adjunct lecturer at the Ghana Institute of Management and Public Administration (GIMPA). She holds a Ph.D. in Information Systems (IS) with specialization in digital health from the University of Ghana, a Master of Science in Management Information Systems from Coventry University, and a Bachelor of Science in Information and Communication Technology from GIMPA. Her studies have covered a wide range of topics in the areas of digital transformation, business intelligence, eHealth, and information systems in general. Over the years, Dr. Preko has addressed some of the pertinent issues in the field of IS and developing economies through data-driven research. These include her works that focused on the role of technology in promoting doctor entrepreneurship, the role of technology in mitigating brain drain in the health sector, the challenges and mitigating strategies in digitalizing healthcare, the unintended negative consequences of digitalization in the health sector, stakeholder conflicts in healthcare digitalization, the role of business intelligence in the banking industry, the use of drones in transforming the healthcare industry, among others. Her interest is also found in 'neoliberalism and gender' in higher education, as well as women in STEM research. Dr. Preko serves as an editorial reviewer and advisory board member for several IS and engineering journals and conferences across the globe.

She is a certified Project Management Professional (PMP) and a member of various professional associations. Dr. Preko can be reached at mansah.preko@gmail.com

22 - Score2Text: a Large Language Model for Interpretable Credit Scoring

Huan Yu, University of Southampton, Southampton, United Kingdom

Dr Huan Yu is a Lecturer in Business Analytics within Southampton Business School at the University of Southampton. Huan is also a member in CORMSIS (Centre for Operational Research, Management Science and Information System) at the University of Southampton. Huan joined the Southampton Business School as a Lecturer in September 2019. Before Huan joined the University of Southampton, she completed her PhD in Management Science and Engineering from the School of Management at the University of Science and Technology of China in May 2019. During her PhD, she was also a Visiting Researcher at IESEG School of Management in 2014-2016 and National University of Singapore in 2018.

23 - From Full-Time to Flexi: Examining the Outcomes of Workforce Changes in Primary Healthcare Delivery

Harshita Kajaria-Montag, Indiana University, Bloomington, IN, United States

From Full-Time to Flexi: Examining the Outcomes of Workforce Changes in Primary Healthcare Delivery

24 - An Efficient Algorithm for Large-Scale Stochastic Optimization with Constraints

Baoyu Zhou, Arizona State University, Tempe, AZ, United States

Baoyu Zhou is an Assistant Professor in the School of Computing and Augmented Intelligence at Arizona State University (ASU). Before joining ASU, he was a postdoctoral researcher at the University of Michigan and the University of Chicago. He received his Ph.D. in Industrial and Systems Engineering from Lehigh University. He won the Elizabeth V. Stout Dissertation Award at Lehigh University in 2022. His research focuses on developing, analyzing, and implementing efficient algorithms for solving large-scale optimization problems that are potentially nonlinear, stochastic, and constrained.

25 - Structural properties of integer programming with bounded subdeterminants

Luze Xu, University of California, Davis, Davis, CA, United States

"Luze Xu currently holds the position of Krener Assistant Professor in the Department of Mathematics at UC Davis, mentored by Professor Matthias Köppe and Professor Jesús De Loera. He received his Ph.D. in Industrial and Operations Engineering at the University of Michigan in April 2022, under the guidance of Professor Jon Lee. He is an optimizer specializing in mixed integer programming. His research interests include integer programming, mixed integer programming, global optimization, and theories that bridge continuous and discrete optimization. His current research focuses on structural integer programming with bounded subdeterminants, mixed integer semidefinite optimization, and mixed integer quadratic optimization."

Summit - 322

Data Analytics and Machine Learning for Advanced Manufacturing processes

Invited Session

Quality, Statistics and Reliability

Chair: Zimo Wang, SUNY Binghamton, Binghamton, NY, United States

Co-Chair: Chen Kan, The University of Texas at Arlington, Arlington, TX, United States

1 - Debiasing Machine Learning with Partial Information for Design and Manufacturing

Yanwen Xu, University of Texas at Dallas, Richardson, TX, United States

Uncertainty quantification stands as a foundational element in both design and manufacturing processes. However, accurately quantify uncertainty within complex engineering systems presents a formidable hurdle due to the involvement of numerous parameters, thereby imposing substantial computational demands for failure testing. To mitigate the computational costs associated with uncertainty quantification, researchers have turned to machine learning models as substitutes for expensive physical models. We are particularly interested in the Gaussian process (GP) model, which has garnered increasing attention in manufacturing applications. Constructing GP-based machine learning models typically necessitates fully observed information or sample points. However, many engineering scenarios involve missing values in collected datasets, stemming from factors such as unobserved input features, unreliable sensors, and data collection errors. The availability of only limited fully observed data results in increased variance and diminished model accuracy. ***Integrating partially observed datasets could potentially expand the dataset size, but naively imputing the missing data may introduce bias.*** To address the challenge posed by partially observed information, ***this paper introduces a hierarchical framework designed to alleviate bias in machine learning***. The framework aims to leverage all available information comprehensively, rather than solely relying on the fully observed portion. We provide theoretical guarantees (asymptotic normality) for our approach, which can be used for inference and construct confidence intervals. This is pivotal for design and manufacturing since it furnishes a spectrum of plausible parameter values, providing valuable insights into the precision and uncertainty of the estimate.

2 - A Shapley explanation-based active learning machine for inferencing high dimensional acoustic informatics: an application for in-situ nanomachining monitoring

Xinchen Wang, Binghamton University, Vestal, NY, United States, Zimo Wang

Understanding streaming sensor signals is critical for in-process monitoring and quality inspection for various industry applications. The streaming sensor signals are induced with real-time information of the underlying processes, allowing immediate anomaly detection and diagnosis for potential quality issues. Critical issues arise as the monitored process scale decreases to micro- and even nano-level. Due to the unavoidable acquisition step, the obtained information is overwhelmingly submerged in high-level noises, which may adversely impact the accuracy and effectiveness of extracting information from monitored sensor signals. In addition, without understanding the sources and frequency responses of the environmental noises under high precision level, it is impractical to directly screen out the interferences using conventional techniques (e.g., band filtering and denoising autoencoder). This paper proposes an active learning strategy for the streaming signal data with the shapely embedded space projection from high dimension Fourier domain to low dimension spectral domain to allow the recognition of weak signals in high noise level environments. The proposed approach is tested by experimental music timbre recognition problems followed by real-time surface morphology characterizations under nanomachining processes. The results indicate that the proposed approach can effectively capture the underlying spectral patterns of acoustics signals. Further investigations into the sensor-based monitoring scheme for the nanomachining process suggest that the presented approach achieves an accuracy of around 92% for predicting the cutting depth and 82% for cutting width in real-time. The presented framework opens up an avenue to allow real-time characterizations and quality inspection for surface characteristics under the nanoscale.

3 - Incremental Profiling of 3D Point Clouds for In-Situ Quality Assurance of Additive Manufacturing

Chen Kan, The University of Texas at Arlington, Arlington, TX, United States, Zehao Ye

In this work, we introduce an innovative framework for point cloud-based quality control of additive manufacturing (AM). Point clouds have shown great potential in AM process monitoring and anomaly detection. However, given the high-volume, high-dimensionality, and unstructured nature of point clouds, it is critically challenging to efficiently process them and extract defect-pertinent information, especially in a real-time manner. To address this challenge, this work develops an efficient point cloud representation learning approach that updates the low-dimensional geometric profile of the point cloud in an incremental way. This is particularly suited for layer-wise monitoring and detection of geometric defects in AM builds. The developed framework is evaluated and validated in simulation and real-world studies, which demonstrate its effectiveness.

4 - Mixed Effects Model via Distribution-in-distribution-out Regression

Mengfan Fu, University at Buffalo, Buffalo, NY, United States, Yujing Huang, Xiaoyu Chen, Xinwei Deng

Mixed effects model has been the key technique to jointly consider fixed effects and random effects in the analysis of an experiment. It requires one to first create a design of experiment by generating design matrices for both fixed effects and random effects. Motivated by the imperfect controllers in many manufacturing and healthcare systems, rather than considering deterministic design matrices, we propose to create such design matrices as probability distributions. These distributional design matrices allow one to consider the randomness of the controllers that realize the design, leading to distributional response. To analyze the deterministic relationship between distributional design matrices and the distributional responses, we propose to employ a distribution-in-distribution-out (DIDO) regression model by analyzing such relationship on 2-Wasserstein space. We will also demonstrate that the existing mixed effects model is a special case of such DIDO regression model when reducing to Euclidean space. Simulation studies and a case study were created to validate the proposed methodology.

Summit - 323

Modeling Complex and High-dimensional Data for Healthcare Engineering

Invited Session

Quality, Statistics and Reliability

Chair: Manni Zhang, Purdue University, West Lafayette, IN, United States

Co-Chair: Ana Estrada Gomez, Purdue University, West Lafayette, IN, United States

1 - missRASS-CPD: Variable Selection for Multimodal Data from Multiple Groups with Missing Values

Manni Zhang, Purdue University, West Lafayette, IN, United States, Ana Estrada Gomez

Nowadays, multi-modal data collected from complex systems is ubiquitous. In such systems, each modality provides myopic information about the system. Therefore, fusing the data from all the modalities is critical to understanding the system as a whole. For example, to diagnose Inflammatory Bowel Diseases, ulcerative colitis (UC) and Crohn's disease (CD), different omics data are needed. Transcriptomic data provides information about gene expressions, proteomic data about protein levels, while metabolite data provides information about microorganisms' concentrations. Using only one type of omics data results in limited diagnosis accuracy and poor treatment plans. Furthermore, to improve diagnosis and treatment, differences and similarities across groups (UC, CD, and healthy individuals) need to be incorporated into the analysis. In this work, we propose a framework that fuses multi-modal data while exploiting the similarities and differences across groups for accurate diagnosis. The framework finds the joint latent variables for each group and the individual latent variables for each modality, and identifies the key features in each modality. Furthermore, the framework is capable of imputing missing data and removing outliers. Our method decomposes the data into a low-rank component, that captures the true signal, and a sparse component, that captures the outliers. Then, using CP decomposition on the low-rank component with a sparse group Lasso penalty, we simultaneously learn the joint and individual latent variables. The performance of the proposed framework is illustrated through simulated and real data examples. In particular, we use the proposed framework to identify key biomarkers for UC and CD patients.

2 - Multi-Modal Graph Neural Networks for Predictive Modeling of Multiple Chronic Conditions

Adel Alaeddini, The University of Texas at San Antonio (UTSA), San Antonio, TX, United States, Julian Carvajal Rico, Joseph Mccormick, Susan Fisher-Hoch

We developed a specialized Cross-Modality Graph Neural Network (GNN) to learn the stochastic relationship between patient's pre-existing conditions and future chronic conditions based on their metabolic information. The model was validated using a large longitudinal cohort study.

3 - Functional Connectome Fingerprinting through Semi-symmetric Tucker2 Tensor Decomposition

Vitor Farias Costa de Carvalho, Purdue University, West Lafayette, IN, United States, Mintao Liu, Ana María Estrada Gómez, Joaquín Goñi

The human functional connectome (FC) represents the functional couplings between brain regions derived from blood oxygen level-dependent (BOLD) signals. Studying the FC enables obtaining insights about individual traits from subjects. In this study, we aim to maximize FC identifiability by performing semi-symmetric Tucker decomposition in data from the Human Connectome Project (HCP). Identifiability is the general paradigm of correctly pairing FCs that belong to the same subject within a dataset where there is test and retest for all subjects. Here we measure fingerprinting via a measurement denominated matching rate. Studying identifiability through FCs enables verifying their consistency over time and understanding how subjects differ from each other at an individual level. Here we used test-retest fMRI data from 426 unrelated subjects from the Young Adult HCP dataset. For each subject, test-retest data includes resting state and seven tasks (Gambling, Emotion, Language, Motor, Relational, Working Memory, and Social). To analyze the high-complexity data, we structured it into a tensor and used tensor decomposition to project the data into a lower dimensional space. By doing so, the first two components capture information related to the brain's functional couplings, whereas the third component captures subject-specific information. We repeated these analyses for three brain parcellations. Results show that subjects can be correctly matched with 71-100% accuracy across resting state and all evaluated tasks. Higher granularity led to higher matching rates for all fMRI conditions. We also extended this approach to assess fingerprinting when using resting state data as test and task data as retest.

DEI Special Issue of Production and Operations Management: Selected Papers

Invited Session

Diversity, Equity, and Inclusion

Chair: Michael Johnson, University of Massachusetts Boston, Boston, MA, 02125, United States

1 - No Country for Young Refugees: Barriers and Opportunities for Inclusive Refugee Education Practices

Sebnem Manolya Demir, Marshall School of Business, University of Southern California, Los Angeles, CA, United States, Feyza Guliz Sahinyazan, Bahar Y. Kara, Elfe Buluc

The recent refugee crises in Ukraine and Syria have created millions of refugees, 40% of whom are children. The education systems of countries hosting refugees struggle to integrate such large populations. In addition, language barriers and stigma hamper inclusive and equitable education opportunities for refugee children. “Lost generations” distanced from education may have a long-term dependency on social security systems and monetary aid. This study considers the following research question: How can a host country improve the inclusion of refugee children in the education system without overburdening its infrastructure? First, we document the availability and accessibility challenges and opportunities that refugee children face during the Syrian refugee crisis. We then develop an inclusive planning strategy aligned with existing capacity and resources and formulate two adaptations of the maximum covering problem (MCP): cooperative capacitated MCP with heterogeneity constraints (CCMCP-HC) to improve the current schooling access in Türkiye and Modular CCMCP-HC to guide early planning in the case of a future crisis. Our computational analyses illustrate that the proposed approach yields higher schooling rates and capacity utilization than existing approaches. Our results emphasize the importance of having a planning strategy in the initial phases of a crisis that considers future integration possibilities.

2 - Toward a More Diverse and Equitable Food Distribution System: Amplifying Diversity, Equity, and Inclusion in Food Bank Operations

Mikaya Hamilton, North Carolina A&T State University, Greensboro, NC, United States, Benjamin Morrow Jr., Lauren Davis, Shona Morgan, Julie Ivy, Steven Jiang, Min Chi, Kyle Hilliard

This article provides an evidence-based discussion of an ongoing effort within the operations of hunger relief organizations to address diversity, equity, and inclusion (DEI) by sourcing and distributing more culturally relevant food. Through nearly 100 interviews with food bank personnel in diverse roles (from partner agency relations to executives) representing various regions of the United States, we explore the challenges faced by organizations' different functional units. These interviews indicate a shift to more inclusive language, more personalized metrics, and more inclusive operations. We critically analyze the related literature and identify opportunities for infusing DEI practices in studying hunger relief supply chains.

3 - Diversity in Frontline Employee Perceptions: Policies and Procedures, Training, and Leadership as Drivers of Service Equality

Ken Kelley, University of Notre Dame, Notre Dame, IN, United States, Eve Rosenzweig, Elliot Bendoly

Excellent service assumes equivalency in its application, yet reality is far more complex. In hotel settings, providing excellent service to diverse guests is nuanced when frontline employees themselves are diverse. While operational tactics are used to promote excellent service, it is unclear whether training, policies and procedures, and leadership designed to advance excellence have the same impact on employees who, by virtue of their own background, are more attuned to guests' needs. We show that operational tactics impact frontline employees' perceptions of service equality, with racial/ethnic minority employees perceiving different levels. Employing a sample of 25,698 employee-year observations across 32 luxury hotels in the US over 3 years, we find that training and codified policies and procedures improve perceptions of guest service equality. However, racial/ethnic minority employees are less impacted than their White counterparts by leadership stances that seem to promote equality more broadly. After controlling for year and other employee- and hotel-level variables, operational tactics (a) improve perceptions of service equality and (b) reduce the disparity between White and racial/ethnic-minority service-quality assessments. Our findings demonstrate that managers can elevate perceptions of customer service equality with training and policies and procedures, thus making operations management a key driver of equality.

Infrastructure Planning to Address Climate Change

Flash Session

Chair: Alireza Azadnia, George Mason University, 4400 University Drive, Fairfax, VA, 22030, United States

1 - Assessing and Reducing the Environmental Impacts of Global Maritime Freight Flows in Changing Climate Conditions

Alireza Azadnia, George Mason University, Fairfax, VA, United States, Elise Miller-Hooks

This talk presents an optimization-based approach to estimating greenhouse gas (GHG) emissions and other air pollutants emitted by cargo ships in the maritime system. Based on the relationships and criteria presented in the Fourth IMO GHG Study 2020 for vessel emissions by fuel and engine type, meteorological conditions, vessel speed, and vessel draught, the model builds on a previously developed mixed-integer linear programming formulation, Benders branch-and-cut solution methodology and global maritime network representation to estimate emissions produced by global vessel traffic under changing climate conditions. The model is extended to incorporate optimal speed and routing decisions that can aid in meeting global climate targets.

2 - Research on the mechanism of regional innovation ecosystems, including 31 provinces and cities

Chengzhao Li, Huazhong University of Science and Technology, Wuhan, China, People's Republic of

The fundamental component in comprehensively executing the national innovation-driven development strategy is regional innovation capability. It is crucial to identify the factors that influence this capability and to investigate the mechanism that links regional innovation capabilities to expedite regional innovation capability enhancement. Establishing innovation ecosystems (IEs) in different provinces and regions poses a significant challenge for enterprises seeking to thrive in the aftermath of the pandemic. This study focuses on the IEs of 31 provinces and cities, examining the impact of the regional ecosystem configuration on regional innovation performance across various dimensions through fuzzy-set qualitative comparative analysis (fsQCA).

Two high-innovation configurations are identified, namely, creative acquisition and knowledge co-creation, as well as two non-high-innovation configurations, namely, environmental alienation and technology block. The findings highlight the developmental trajectory of regional innovation ecosystems (RIEs) and underscore the significance of implementing supportive financing and talent development policies within a region.

This study employs configuration analysis to examine various antecedent conditions that can enhance innovation performance in enterprises. It focuses on the post-epidemic conditions in China and establishes a comprehensive research framework centered on RIEs.

3 - Designing and Optimization of Sustainable Supply Chain for Converting Agricultural Waste to Bioenergy

Maryam Roudneshin, University College Dublin, Dublin, Ireland, Amanda Sosa

The growing concerns about global warming and the need for energy security have underscored the importance of exploring alternative energy sources to fossil fuels. The use of agricultural waste for bioenergy production has attracted significant attention for its ability to reduce environmental impacts while creating sustainable energy sources. However, achieving profitability and attractiveness to stakeholders and investors requires optimal supply chain network design, including the selection of appropriate locations for plants. Thus, this study sets out to develop a supply chain network design that prioritizes sustainability (economic, environmental, and social considerations). Initially, a two-pronged approach was employed to identify potential biorefinery locations, leveraging both Geographic Information System (GIS) and

MCDM to balance environmental and economic factors. Subsequently, an innovative mathematical model was presented to determine the optimal bioenergy supply chain configuration in Ireland.

4 - Strategic Performance Indicators for Building Resilient Supply Chains

Afrooz Moatari-Kazerouni, Widener University, Chester, PA, United States, Yvonne Lederer Antonucci

This study undertakes an extensive examination of operational-level Key Performance Indicators (KPIs), which are crucial for enhancing the resilience of supply chains. As a pivotal element in supply chain management, resilience refers to the ability of an organization to quickly recover from disruptions while maintaining high standards of service quality and ensuring customer satisfaction. This research draws upon a broad spectrum of established theories and existing literature to delineate eight core capabilities that embody supply chain resilience: Anticipation, Sustainability, Visibility, Flexibility, Agility, Adaptability, Strategic Alignment, and Collaboration. Through a comprehensive literature review, the study identifies specific KPIs associated with each resilience capability, offering organizations practical metrics for assessing their supply chain performance. The selection of KPIs is geared towards enabling companies to effectively anticipate disruptions, adapt to changes, and recover from setbacks while fostering sustainability and strategic collaboration. To validate these findings, expert opinions were collected via a structured survey, which confirmed the relevance and applicability of the identified KPIs. This research contributes to the field by providing a detailed, actionable framework that practitioners and scholars can utilize to measure and enhance supply chain resilience. The outcomes aim to equip businesses with the tools needed to sustain competitive advantage and thrive in dynamic market environments.

OR in Defense Planning

Invited Session

Military and Security

Chair: Isabella Sanders, Dept. of Systems Engineering, United States Military Academy, Newburgh, United States

1 - Microgrid capacity planning

Daniel Reich, Naval Postgraduate School, Monterey, CA, United States

We present a heuristic search method for distrubuted energy resource sizing, released in Microgrid Planner, an open-source software platform. Our method is constructed to identify a wide range of microgrid design options that satisfy a given set of power load requirements, allowing a decision maker to weigh trade-offs between potential designs and select preferred solutions. We introduce a global binary search algorithm to build a diverse set of microgrid design options and refine them using a local linear search method.

2 - The Maximal Covering Location Disruption Problem

Brian Lunday, Air Force Institute of Technology, WPAFB, OH, United States

This research sets forth and examines a new sequential, competitive location problem. The *maximal covering location disruption problem* is a zero-sum Stackelberg game comprised of two stages. A leader denies access to at most q out of n possible facility locations in the first stage and, in the second stage, a follower solves a maximal covering location problem while emplacing at most p facilities. Identifying this problem as both relevant and unaddressed in the current literature, this research examines properties of the bilevel programming formulation to inform heuristic development, subsequently evaluating the efficacy and efficiency of two variants each of an iterative, bounding heuristic (IBH) and a reformulation-based construction heuristic (RCH) over a two sets collectively consisting of 2160 test instances representing a breadth of relative parametric values. Although we illustrate that each heuristic may not identify an optimal solution, computational testing demonstrates the superlative and generally excellent performance of the RCH variants. For the 12.4% of instances for which the RCH does not readily verify the optimality of its solution, lower-bounding procedures characterize solution quality. Both of the RCH variants attain solutions with an average 4.08% relative optimality gap, and they scaled well over different parametric value combinations, solving instances in an average of 98.0 and 123.6 seconds, respectively.

3 - Impact Assessment and Course of Action Generation with Reinforcement Learning

Matthew Powers, MITRE, McLean, VA, United States

These MITRE models leverage reinforcement learning to yield high-quality COAs and COA utility scores. The contested logistics model produces strategies in operational environments requiring maneuver from strategic locations. The SOCEUR-sponsored SOF Impact Model assesses non-kinetic battlefield impact. These models propose RL and human-machine interface to overcome human cognitive limitations.

4 - Quantifying Capability Gaps via Information Relaxation and Deep Reinforcement Learning in Infinite-Horizon Markov Decision Processes: A Military Air Battle Management Application

Joseph Liles, Air Force Institute of Technology, WPAFB, OH, United States, Matthew Robbins, Brian Lunday

In this paper, we investigate the application of an information relaxation technique for approximating upper bounds on solution quality to a complex stochastic and dynamic assignment problem in military air battle management. Information relaxation refers to relaxing the non-anticipativity constraints in a sequential decision-making problem that require a decision-maker to act only on currently available information. We implement a temporal event horizon that provides a decision-maker with adjustable access to the outcome of future stochastic uncertainties in the problem environment. Whereas previous work has investigated information relaxation with regard to problems that can be solved more easily under a deterministic relaxation, we demonstrate a methodology for applying the approach to a continuous-time problem in continuous space that requires a solution approximation technique even in deterministic conditions. We formulate the problem as a discounted, infinite-horizon Markov decision process and solve it by employing a deep neural network-based approximate policy iteration algorithm in concert with several designed computational experiments. We demonstrate how a multidimensional sensitivity analysis of the event horizon and other problem features helps quantify potential improvements to decision policy effectiveness resulting from either a change to tactics or a modification to capabilities. Applied to real-world capability gap assessments, the quantification objectively augments traditionally subjective analysis to guide decision-making and establish more effective requirements for acquisition programs.

Invited Session

Auctions and Market Design

Chair: Alireza Fallah, UC Berkeley, Berkeley, CA, United States

Co-Chair: Michael Jordan, UC Berkeley, Berkeley, CA, United States

1 - The Limits of Price Discrimination Under Privacy Constraints

Alireza Fallah, UC Berkeley, Berkeley, CA, United States, Michael Jordan, Ali Makhdoumi, Azarakhsh Malekian

We study a producer's problem of selling a product to a continuum of privacy-conscious consumers, where the producer can implement third-degree price discrimination, offering different prices to different market segments. We consider a privacy mechanism that provides a degree of protection by probabilistically masking each market segment. We establish that the resultant set of all consumer-producer utilities forms a convex polygon, characterized explicitly as a linear mapping of a certain high-dimensional convex polytope into $\mathbb{R}^2$. This characterization enables us to investigate the impact of the privacy mechanism on both producer and consumer utilities. In particular, we establish that the privacy constraint always hurts the producer by reducing both the maximum and minimum utility achievable. From the consumer's perspective, although the privacy mechanism ensures an increase in the minimum utility compared to the non-private scenario, interestingly, it may reduce the maximum utility. Finally, we demonstrate that increasing the privacy level does not necessarily intensify these effects. For instance, the maximum utility for the producer or the minimum utility for the consumer may exhibit nonmonotonic behavior in response to an increase of the privacy level.

2 - Leveraging Inspections and Penalties in Mechanism Design

Xuanjie Li, Duke University, Durham, NC, United States, Ali Makhdoumi, Alexandre Belloni

We consider a mechanism design problem where a seller allocates multiple items to multiunit-demand buyers. The seller can inspect the buyers to learn their types and use this information to reward truthful buyers through payments. We characterize the (approximately) optimal mechanism in this setting. We first characterize the solution to the single-buyer problem that constitutes selling a single item to a single buyer subject to an upper bound on the allocation probability. The optimal allocation strategy of the single-buyer problem is described as a continuous and monotonically increasing function of the types and can be attained by solving an ordinary differential equation. With the solution to the single-buyer problem, and by using connections to the magician problem, we design a mechanism that achieves $(1-\sqrt{\alpha})$ of the optimal revenue of the general problem, where each buyer requires at most α fraction of all units of one item. Our mechanism can be extended to the case where the underlying value distribution is erroneous but has a small total variation distance from the true distribution.

3 - Debiasing Switchback Price Experiments with Forward-Looking Demand

Yifan Wu, Northwestern University, Evanston, IL, United States, Ramesh Johari, Orrie Page, Vasilis Syrgkanis, Gabriel Weintraub

We consider a retail seller who is running pricing experiments over time, for a single product, for a sufficiently long-horizon. At each period, the seller chooses a price p from a set of predefined prices, with some probability distribution over these prices. The goal is to estimate the demand and the gradient of the demand around a particular price point, with the goal of incrementally adjusting price to improve revenue after the experiment. Crucially, buyers are forward looking with a discounted utility and will choose to not purchase now, if they expect to face a lower price in the near future, due to experimentation. We show that with a simple three-price level experiment, the seller can debias the demand and gradient estimates and recover the true demand and gradient, that removes the bias due to strategic price-anticipatory behavior.

4 - Reduced Rank Multi-Objective Policy Learning and Optimization

Ezinne Nwankwo, University of California, Berkeley, Berkeley, CA, United States, Michael Jordan, Angela Zhou

Evaluating the causal impacts of possible interventions is crucial for informing decision-making, especially towards improving access to opportunity. However, if causal effects are heterogeneous and predictable from covariates, personalized treatment decisions can improve individual outcomes and contribute to both efficiency and equity. In practice, however, causal researchers do not have a single outcome in mind a priori and often collect multiple outcomes of interest that are noisy estimates of the true target of interest. For example, in government-assisted social benefit programs, policymakers collect many outcomes to understand the multidimensional nature of poverty. The ultimate goal is to learn an optimal treatment policy that in some sense maximizes multiple outcomes simultaneously. To address such issues, we present a data-driven dimensionality-reduction methodology for multiple outcomes in the context of optimal policy learning with multiple objectives. We learn a low-dimensional representation of the true outcome from the observed outcomes using reduced rank regression. We develop a suite of estimates that use the model to denoise observed outcomes, including commonly-used index weightings. These methods improve estimation error in policy evaluation and optimization, including on a case study of real-world cash transfer and social intervention data. Reducing the variance of noisy social outcomes can improve the performance of algorithmic allocations.

5 - Techniques for Trajectory-Constrained Optimization

Jad Salem, US Naval Academy, Annapolis, MD, United States, Swati Gupta, Vijay Kamble

Exploratory sampling in online learning can result in undesirable outcomes. For example, fluctuating decisions can reduce consumer trust in the decision-making system, decisions that worsen over time (from the perspective of the user) can lead to user abandonment, and decisions which increase disparities in outcomes across groups or individuals can be viewed as unfair. Incorporating trajectory constraints can address these issues, although algorithm design and analysis is non-trivial, even for simple settings. In this talk, lay the groundwork for monotonic stochastic convex optimization and discuss challenges in more general settings.

Co-Chair: Mohamed Mostagir, University of Michigan, Ann Arbor, MI, United States

1 - Traffic Network Games with Risk-averse Players

Emerson Melo, Indiana University Bloomington, Bloomington, IN, United States

Congestion in traffic networks is pervasive, with costs soaring from 15 billion dollars in 1982 to 190 billion in 2021. Heavy and uncertain traffic conditions exacerbate commuting experiences for millions across the US. The Wardrop Equilibrium (WE), a foundational concept for analyzing traffic network games, assumes risk-neutral players, neglecting congestion cost variability. To address this, we propose a model incorporating the stochastic nature of congestion costs, focusing on risk-averse users. We model risk-averse behavior using tail risk measures, capturing the influence of rare, heavy traffic events. Our contributions include establishing conditions for risk-averse WE in various networks, quantifying inefficiencies in risk-averse WE, and extending our model to study spatial oligopoly price competition in networked markets affected by congestion. Our analysis highlights the network topology's role, congestion cost functions, and the characteristics of stochastic congestion shocks, providing insights into optimizing traffic flow in uncertain environments. Finally, we discuss how our framework is suitable for implementing data-driven techniques to recover the parameters describing the cost functions and users' degree of risk aversion.

2 - Algorithmic Demand Allocation to Heterogeneous Sellers in Inventory Competition

Shengyu Cao, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Ming Hu

In the digital commerce era, platforms such as Amazon and PDD employ sophisticated algorithms of demand allocation to optimize operational efficiency and market dynamics. In this paper, we explore the dynamics between platform rules and seller behavior within online marketplaces, particularly focusing on how inventory-level allocation strategies shape market competition and platform intermediation practices. Through a detailed analysis of two sellers offering identical products on a monopolistic platform, we investigate the effects of different allocation rules on seller order decisions, platform payoff, and overall market equilibrium. Contrary to expectations, findings reveal that inventory-agnostic priority rules can mirror monopolistic decision-making scenarios, suggesting that these allocation methods do not necessarily influence the platform's optimal payoff or affect the equilibrium total order quantity. Moreover, the introduction of randomness in demand allocation intensifies competition and influences replenishment strategies, potentially increasing the platform's payoff and altering market dynamics significantly. The introduction of inventory-aware allocation rules offers a novel approach to demand allocation, promoting competitive restocking strategies. Our study further extends to a multiple-seller framework, analyzing how various allocation rules impact seller behavior and platform economics in a more complex market setting. This comprehensive analysis sheds light on the strategic design of allocation mechanisms, highlighting their significant implications for seller competition and platform intermediation in the digital commerce landscape.

3 - Peer Filtering: Democratic Misinformation Control in Social Networks

Calvin Roth, University of Minnesota, Minneapolis, MN, United States, Ankur Mani, Krishnamurthy Iyer

Online social networking platforms suffer from the problem of misinformation spread that has serious societal implications in areas such as politics and public health, among others. Social networking platforms spend a lot of effort on curtailing misinformation and the techniques are often top down involving content moderation. Research on misinformation in social networks has overlooked the ability of the network as a whole to moderate the content in a more democratic way. We study the power of peers in filtering out false information (peer filtering) in social networks and how the platform can assist in peer filtering without direct content moderation or judging individuals. We present a tractable model of content spread in a social network of Bayesian users who derive utility from sharing a content depending upon its veracity and alignment with their opinions. Based on their posterior beliefs, the users choose whether or not to further share the content. We study the resulting equilibrium in the network and the different types of equilibria that emerge. We show that, under all types of equilibria, true content spreads more in the network than false content, but true content cannot go viral without false content also going viral. Using this model, we describe how key metrics of the network vary with the parameters of the model. These metrics include how much false content is successfully filtered out and how much true content remains as well as the volume and engagement in the network.

Invited Session

Telecommunications and Network Analytics

Chair: Jin-Zhu Yu, UT Arlington, Arlington, TX, United States

1 - Enhancing the Resilience of Large-Scale Infrastructure Networks Using GNN-Enhanced Deep Reinforcement Learning

Jin-Zhu Yu, UT Arlington, Arlington, TX, United States

Infrastructure systems are vital for socio-economic prosperity and public safety. Optimizing the restoration sequence of damaged components in capacitated infrastructure networks after disruptions is crucial. However, this task is an NP-hard problem that cannot be solved efficiently, particularly for large-scale networks. This study introduces a GNN-enhanced deep reinforcement learning (GNN-DRL) framework to strengthen the resilience of large-scale infrastructure networks. The GNN model effectively learns network embeddings, while the DRL model optimizes repair decisions and network flow. Extensive numerical experiments on various real-world and synthetic large-scale networks under multiple hazard scenarios are conducted to validate the GNN-DRL model. When compared to heuristic approaches like greedy algorithms and genetic algorithms, the GNN-DRL model outperforms them in solution quality, resulting in higher system resilience.

2 - Generating Graph Flows via Diffusion-Based Generative Model

Yu Wang, University of Oregon, Eugene, OR, United States, Jinzhu Yu

Real-world infrastructure systems, such as power grids, water supply networks, telecommunication systems, and transportation routes, are inherently structured as complex graphs. These networks are composed of nodes that represent crucial control points, such as stations or operators, and edges that depict the flow of resources or data. Accurate modeling of these infrastructure graphs is essential for a range of applications, including enhancing infrastructure design, optimizing flow management, and contributing to social science research. A primary challenge in this field is capturing the distinct graph topology and the intricate dynamics dictated by domain-specific physical laws. In response to this challenge, we introduce "Diff-Infra," a cutting-edge diffusion-based generative model designed to create realistic infrastructure graphs. The model operates in two phases: In the forward phase, Diff-Infra systematically introduces noise to degrade the graph's structure, while in the reverse phase, a graph neural network is trained to remove this noise, effectively learning to reconstruct and denoise the infrastructure graphs. Additionally, physical constraints are rigorously integrated to ensure the model adheres to realistic dynamics. Our experimental findings confirm that Diff-Infra adeptly replicates both the local and global characteristics of infrastructure graphs. It accurately models essential features such as flow conservation, cyclic trends, and congestion at critical junctions, demonstrating its potential to significantly improve infrastructure planning and operations.

3 - Hazard, Infrastructure, and Community Resilience Network Models

Kenneth Harrison, National Institute of Standards and Technology (NIST), Gaithersburg, MD, United States, Tasnim Faiz, William Hughes, Zeinab Farahmandfar

Natural disasters, like floods, tornadoes, earthquakes, and wildfires, damage a community's critical infrastructure and buildings and disrupt its daily functions. Communities must prioritize resource allocation to take mitigation actions to reduce the impact of disasters while constrained by budgetary and other restrictions. For effective community resilience planning, a modeling framework incorporating structural engineering and the physical and social sciences is necessary to quantify the impact of uncertain hazards on the built environment and translate these impacts into societal outcomes. This work presents a novel decision-making framework that leverages existing probabilistic relationships throughout for simulating hazards, modeling the response of engineered structures, assessing impacts on building functionality, and ultimately, estimating whether societally meaningful objectives will be met, such as surviving the hazard event and remaining in one's home. The optimization model underlying the framework utilizes the network structures of the interdependent infrastructure and social systems to aid the decision-making process for critical infrastructure and buildings, considering varied scenarios and restrictions. Case studies of different communities facing various hazards are presented to show the adaptability of the model and decision framework.

4 - Machine Learning for Disrupting Max Flow Networks

N. Orkun Baycik, University of Denver, Denver, CO, United States

This study presents machine learning based approaches (MLBA) to solve the maximum flow network interdiction problem (MFNIP). The mathematical formulation of this NP-complete problem is an Integer Program (IP) and large size instances can be computationally expensive to solve. As an alternative, this study applies tree-based learning methods (the decision tree and random forest regression techniques) to various sizes of networks to analyze the solution times as well as the optimality gaps compared to the IP formulation of MFNIP. The proposed methods rely on predicting disruptions that individual arc interdictions can cause on the network. Without solving an optimization model, the decision-maker can choose a set of arcs with high predicted disruptions to cause the maximum damage. They can also produce insights into the most vulnerable components of a network using this approach. The results indicate that MLBA are able to find solutions within seconds and increasing the network size does not affect these solution times. The quality of the solutions are acceptable for the majority of the instances especially for small to medium interdiction budget levels. For large-size instances, the results indicate that MLBA are efficient and effective, whereas solving an IP model can require long solution times and consume a significant amount of computer memory.

5 - Enhancing Decision-making and Representation of Complex Infrastructure Systems Using Advanced Graph Neural Networks

Xudong Fan, SUNY at Buffalo, Buffalo, NY, United States, Jürgen Hackl

Aging urban infrastructure systems pose risks to urban daily functions, resulting in economic losses and public health concerns when failures occur. To enhance the sustainability and resilience of urban infrastructure systems, public utilities are actively seeking optimal strategies for infrastructure management. However, making optimal decisions for a resilient infrastructure system is difficult due to the dynamic behaviors. In this study, we first introduced the Deep Reinforcement Learning (DRL) and Graph Convolutional Networks (GCN) for the resilience-oriented decision-making in urban infrastructure systems. We will then introduce our studies about developing efficient graph learning algorithm for accurate network representation of complex infrastructure systems, namely regional spatial graph convolutional network (RSGCN). The performance of developed RSGCN model is evaluated by modeling three spatially embedded network datasets, including a synthetically made network dataset and two real-world infrastructure network datasets.

6 - Strategic Cyber Defense: Game-Theoretic Penetration Testing, Risk Assessment, and Resilience in 5G-Enabled Networks

Quanyan Zhu, New York University, New York, NY, United States

Penetration testing assesses an organization's IT infrastructure's security posture and its resilience against cyber threats. It helps strategically design cyber defense to counter vulnerabilities and bolster security. This strategic defense can be modeled using game-theoretic and learning-based methods. This approach facilitates the development of agent-based technologies for automating strategic penetration testing and proactive defenses. This talk aims to address challenges in modeling, analyzing, and computing dynamic game models in modern industrial control systems integrated with 5G networks and cloud services. We propose new game-theoretic solution concepts to capture the networks' dynamic and multiscale attributes. The talk will discuss new learning-based and computationally scalable algorithms to advance penetration testing technologies. Integrating control, learning, and game-theoretic methodologies provides a quantitative approach to assess risks, enhance resilience, and guide policy-making, including standards and cyber insurance.

1 - Price Subsidies with OR Without Physical Procurement: Impact on Quality, Profits, and Welfare

Omkar D. Palsule Desai, Indian Institute of Management Indore, Indore, India, Aysajan Eziz, Srinagesh Gavirneni

Newly introduced price subsidy programs without physical procurement have resulted in an increased (vis-\`{a}-vis the subsidy programs with physical procurement) preponderance of deliberate quality degradation for certain crops by Indian farmers. The physical procurement of crops from farmers provides an alternate sales channel for farmers, enabling the government to subdue the competition between farmers in the open market. The farmers' deliberate quality degradation may moderate the benefits of the altered competitive structure. The viability of such programs has been questioned, and policymakers are looking for guidance. Using a multi-stage incomplete information-based (Bayesian) game-theoretic model, we comprehensively characterize the farmers' strategic production and selling decisions. We demonstrate that the government's price support with multiple sales channels created by physically procuring the crop improves the producer surplus when the farmers' landholdings are highly disparate and the quality-based competition is lower. A higher minimum support price (MSP), a higher landholding for a farmer producing a high-quality crop, and a lower high-quality crop price premium in the open market improve the consumer surplus, the social surplus, and the average quality of the crops supplied by farmers when the government does not procure the crop physically v/s when it does. To eliminate farmers' deliberate crop quality degradation, when MSP is moderate, if not lower, the government should (should not) procure the crop physically if the high-quality crop price premium in the open market is higher (lower). We provide guidance to the government exercising caution in selecting MSP and the farmer subsidy program.

2 - Stochastic Dominance in Cultivar Selection: Addressing Climate Change Uncertainties for Resilient Agriculture

Shayan Tohidi, Iowa State University, Ames, IA, United States, Sigurdur Olafsson

Food supplies are at risk due to climate change, which can affect their accessibility and quality. Extreme and unpredictable weather events recognize climate change while their patterns also change, implying more uncertainty that leads to higher risk. This calls for better methods for cultivar selection that can both consider risk due to current variability of environments, and the increased risk due to changes in environments caused by climate change. We refer to probabilistic ranking as ordering cultivars based on their probability to perform better across a set of environments versus their mean performance. Such probabilistic rankings address both mean performance (e.g., mean yield) and uncertainties due to environments and potentially also environmental changes. Motivated by the need for better methods to select crop cultivars that are resilient to change in environments caused by climate change, we have proposed a novel probabilistic ranking method based on stochastic dominance, a partial ranking between two random variables. By exploring all cultivar pairs, this method can order cultivars by their yield distribution in a computationally efficient manner. For each, we identify the superior one for a risk-averse decision-maker. It also helps us obtain a sensitivity analysis for each pair of cultivars, so we know beforehand that changing the distributions will determine how the result will be varied. Thus, by estimating current and future climate accurately, we can find the best cultivars for now and the appropriate potential adjustments for the future, leading to a more thoughtful decision in response to climate change.

3 - Early Harvest Behavior in Fruit Supply Chains

Hengyu Liu, Beijing University of Posts and Telecommunications, Beijing, China, People's Republic of

In developing countries, fruit farmers are price takers and the market price is determined by the aggregate supply. To reduce price (or inventory) pressure, many farmers harvest their fruit early, when it is not yet fully ripe. Also, farmers face two types of uncertainties: (*i*) yield and (*ii*) unripe quality uncertainty in the early harvest season. Usually, the farmers' early harvest behavior (EHB) will lead to the effect of negative word of mouth (WOM), decreasing the subsequent demand for ripe fruit. By accounting for the competition among farmers, yield and unripe quality uncertainties, and WOM, we develop a game-theoretical model to examine the fruit supply chain and market dynamics that engender EHB as well as to analyze its implications to different stakeholders. We fully characterize the farmers' equilibrium planting decisions and EHB. We demonstrate that the EHB can be eliminated only when the realized yield is moderate and is of relatively low quality. Contrary to the prevailing intuition that EHB hurts consumers because they are enticed to consume unripe (i.e., low-quality) fruit, we show that this behavior can increase their welfare under certain conditions due to the higher supply. Furthermore, we caution that the famers' EHB can make themselves worse off if they face a moderate degree of yield uncertainty. In general, if there are a small number of famers competing in the market while facing a high degree of yield uncertainty, EHB can make the farmers and consumers achieve a win-win situation in the market.

1 - Dynamic Programming for Efficient Semiparametric Estimation: Control of Universal Least Favorable Flows

KAIWEN HOU, Columbia Business School, New York, NY, United States

To aid reliable and efficient causal estimation, previous literature has proposed constructing normalizing flows in a statistical manifold, with tangent vectors aligned with the efficient influence function of the estimand. This paper formulates the same problem from the dynamic programming perspective. Starting from an initial suboptimal estimator of the probability measure (which may be highly biased), the next optimal perturbation step is determined by locally aligning with the efficient influence function evaluated at that point.

By adopting a dynamic programming approach, we extend this perturbation to a global scale, enabling the identification of an integral curve on the statistical manifold that passes through the initial estimator. This integral curve essentially defines a universal least favorable flow, corresponding to the tightest Cramér-Rao lower bound for the estimation problem. Dynamic programming techniques allow us to control this flow effectively, ensuring each step minimizes estimation variance and enhances efficiency.

Furthermore, theoretical guarantees are provided, demonstrating the robustness and optimality of our approach. Specifically, we establish a local perturbation error bound, ensuring that each step's deviation from the true efficient influence function is controlled. Additionally, a global approximation error bound is derived, indicating the cumulative error over the entire estimation process. We also establish the consistency and asymptotic normality of the estimators obtained through our method, showing that they achieve the semiparametric efficiency bound. Preliminary simulation studies related to the estimation of the population mean confirm the effectiveness of our approach, consistently yielding lower mean-squared errors compared to traditional methods such as targeted learning.

2 - Near-Optimal Cost Function Approximation for Multi-Period Technician Routing and Scheduling

Kaiwen Li, Beijing Foreign Studies University, Beijing, China, People's Republic of, Xi Chen

We study the problem of designing near-optimal formulation of cost function approximation (CFA) for multi-period technician routing and scheduling problem in an online learning setting. Prior works using CFA design the parameterized model based on domain knowledge and tune parameters in an offline setting without providing error analysis. However, when the impact of uncertainty is easy to recognize, we propose an approach to find a near-optimal formulation of CFA a prior. More precisely, we first build Kullback-Leibler ambiguity set of future cost incurred by certain action, then we use the relationship between regularization and robust optimization to construct an equivalent regularization term, which leads to the modified cost function in CFA. Next, the performance gap between our proposed approach and optimal policy is given by error analysis of state aggregation. Numerical experiment demonstrates that the proposed approach (without tuning parameters) performs close to optimal in various settings of urban delivery.

3 - Optimal Co-production for Data-Intensive Goods

Bozhuang Lei, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Gang Li, Yimin Yu

Many firms owning reams of production or consumer usage data lack advanced AI capabilities and thus seek partnerships with AI-powered platforms to co-produce data-intensive products such as automotive vehicles. Using a game-theoretical model, we characterize the optimal data-algorithm co-production scheme between the firm and platform, deriving the optimal data size and algorithm construction level respectively contributed by the firm and platform. We also specify the output requirement and transfer payment under the co-production. In the single-period setting, our analysis shows that the firm is willing to build the partnership when the data leakage cost is low. In the two-period setup with data collection, we find that the firm strategically lowers its first-period price to gather more consumer data and can adopt either fully sharing or withholding strategy for data sharing in the second period. The firm prefers cooperation only when the data leakage cost is low and the data collection efficiency is high. We also show that the firm benefits more from data-hungry or data-efficient algorithms than those with a relatively balanced data and algorithm importance. Overall, this study investigates the market implications of co-production for AI-powered products and highlights the roles of data-algorithm interaction features in driving the firm profitability.

4 - Effects of cost information asymmetry on business model choice of online platforms

Bingru Wang, Xi'an Jiaotong University, Xi'an Shaanxi, China, People's Republic of, Jun Lin

We utilize a game-theoretic model to examines how the strategic interaction between a manufacturer and an online platform determines the channel structure and how private cost information affects the platform strategy decision. First, we study the platform model selection strategies under symmetry cost information. We find that in most cases, the resale model remains the optimal choice for platforms, unless the agency model features higher platform fees and lower manufacturer costs. And there always exists a certain range where both platform and manufacturer prefer either the reselling or agency model, achieving a win-win situation. Second, we utilize signaling game analysis to examine the impact of cost information asymmetry on platform strategic decisions and supply chains. We find that type-L manufacturers, in order to distinguish themselves from other types, tend to actively distort prices downward, deviating from the optimal price. This results in a decrease in profits and efficiency for supply chain members under the agency model, while consumer surplus increases. Unlike symmetric cost information, there exists only a range where both parties prefer the reselling model under cost information asymmetry. Finally, we discuss the platform strategy shifts under cost information asymmetry and find that with the increase in commission rate of agency model (or proportion of type-L manufacturers), the range of platform preference for reselling model expands.

5 - Innovation and pricing competition with absorptive capacity

Xiuli He, UNC Charlotte, Charlotte, NC, United States, Huimin Zhan, Xianjin Du, Hong Fu

We develop a game theoretical model of sequential entrance in which an entrant with absorptive capacity tries to enter a market where the innovator exists. The innovator decides on innovation and pricing strategies to prevent or allow the market entry of the absorptive entrant. We show that the entrant's absorptive capacity negatively affects the innovator's pricing strategy, which may even sell at a lower price than that of the entrant. However, the innovation efforts may increase to establish higher barriers to invasion. The innovator may have to allow the market entry if the entrant has a stronger absorptive capacity or the competition between products is lower. Interestingly, the entrant has a second-mover advantage under certain conditions. Our findings reveal the effect of absorptive capacity and competition in operational decisions and provide practical recommendations for decision-making by competing manufacturers.

6 - Contracts for Procurement under Spot Price Fluctuations

Ozgun Caliskan Demirag, Penn State Erie, The Behrend College, Erie, PA, United States, Yong-Hong Kuo, Jie Wang

Employing a three-stage game-theoretic model, we delineate the equilibrium strategies of suppliers and manufacturers engaged in procurement option contracts amid price volatility and breach contingencies. We find that contract effectiveness diminishes with demand and spot price variability but rises with the supplier's spot market search costs. Notably, flexibility in renegotiation outperforms models presuming no breaches. Our findings offer crucial insights for businesses reliant on product trading. Despite breach risks, well-designed option contracts tailored to address price fluctuations can enhance supply chain profitability. Notably, renegotiation schemes yield maximal benefits.

Tensor Factor Models in Finance and Business

Invited Session

Finance

Chair: Elynn Chen, New York University, New York, NY, 10012, United States

1 - 3D-Pca: Factor Models with Restrictions

Martin Lettau, UC Berkeley, Berkeley, CA, United States

This paper proposes latent factor models for multidimensional panels called 3D-PCA. Factor weights are constructed from a small set of dimension-specific building blocks, which give rise to proportionality restrictions of factor weights. While the set of feasible factors is restricted, factors with long/short structures often found in pricing factors are admissible. I estimate the model using a 3-dimensional data set of double-sorted portfolios of 11 characteristics. Factors estimated by 3D-PCA have higher Sharpe ratios and smaller cross-sectional pricing errors than models with PCA or Fama-French factors. Since factor weights are subject to restrictions, the number of free parameters is small. Consequently, the model produces robust results in short time series and performs well in recursive out-of-sample estimations.

2 - Shrinking the Term Structure

Markus Pelger, Stanford University, Stanford, CA, United States, Damir Filipovic, Ye Ye

We propose a new framework to explain the factor structure in the full cross section of Treasury bond returns. Our method unifies non-parametric curve estimation with cross-sectional factor modeling. We identify smoothness as a fundamental principle of the term structure of returns. Our approach implies investable factors, which correspond to the optimal spanning basis functions in decreasing order of smoothness. Our factors explain the slope and curvature shapes frequently encountered in PCA. In a comprehensive empirical study, we show that the first four factors explain the time-series variation and risk premia of the term structure of excess returns. Cash flows are covariances as the exposure of bonds to factors is fully explained by cash flow information. We identify a state-dependent complexity premium. The fourth factor, which captures complex shapes of the term structure premium, substantially reduces pricing errors and pays off during recessions.

3 - Stochastic Low-Rank Tensor Bandits for Multi-Dimensional Online Decision Making

Emma Jingfei Zhang, Emory University, Atlanta, GA, United States

Multi-dimensional online decision making plays a crucial role in many real applications such as online recommendation and digital marketing. In these problems, a decision at each time is a combination of choices from different types of entities. To solve it, we introduce stochastic low-rank tensor bandits, a class of bandits whose mean rewards can be represented as a low-rank tensor. We consider two settings, tensor bandits without context and tensor bandits with context. In the first setting, the platform aims to find the optimal decision with the highest expected reward, a.k.a, the largest entry of true reward tensor. In the second setting, some modes of the tensor are contexts and the rest modes are decisions, and the goal is to find the optimal decision given the contextual information. We propose two learning algorithms tensor elimination and tensor epoch-greedy for tensor bandits without context, and derive finite-time regret bounds for them. Comparing with existing competitive methods, tensor elimination has the best overall regret bound and tensor epoch-greedy has a sharper dependency on dimensions of the reward tensor. Furthermore, we develop a practically effective Bayesian algorithm called tensor ensemble sampling for tensor bandits with context. Extensive simulations and real analysis in online advertising data back up our theoretical findings and show that our algorithms outperform various state-of-the-art approaches that ignore the tensor low-rank structure.

4 - Distributional Matrix Completion via Nearest Neighbors in the Wasserstein Space

Jacob Feitelberg, Columbia University, New York, NY, United States

We introduce the problem of distributional matrix completion: Given a sparsely observed matrix of empirical distributions, we seek to impute the true distributions associated with both observed and unobserved matrix entries. This is a generalization of traditional matrix completion where the observations per matrix entry are scalar valued. To do so, we utilize tools from optimal transport to generalize the nearest neighbors method to the distributional setting. Under a suitable latent factor model on probability distributions, we establish that our method recovers the distributions in the Wasserstein norm. We demonstrate through simulations that our method is able to (i) provide better distributional estimates for an entry compared to using observed samples for that entry alone, (ii) yield accurate estimates of distributional quantities such as standard deviation and value-at-risk, and (iii) inherently support heteroscedastic noise. We also prove novel asymptotic results for Wasserstein barycenters over one-dimensional distributions.

1 - Query Efficient Weighted Stochastic Matching

Mohammad Saneian, Northeastern University, Brookline, MA, United States, Mahsa Derakhshan

In this talk, we discuss the *weighted stochastic matching* problem. Let $G=(V, E)$ be a given edge-weighted graph and let its realization $\mathcal{G}$ be a random subgraph of G that includes each edge $e\in E$ independently with a known probability p_e. The goal in this problem is to pick a sparse subgraph Q of G without prior knowledge of G's realization, such that the maximum weight matching among the realized edges of Q (i.e., the subgraph $Q \cap \mathcal{G}$) in expectation approximates the maximum weight matching of the entire realization $\mathcal{G}$.

In this work, we present a 0.68 approximation algorithm with $O(1/p)$ queries per vertex, which is asymptotically tight. This is even an improvement over the best-known approximation ratio of $2/3$ for unweighted graphs within the $\text{poly}(1/p)$ regime due to Assadi and Bernstein [SOSA'19]. The $2/3$ approximation ratio is proven tight in the presence of a few correlated edges in $\mathcal{G}$, indicating that surpassing the $2/3$ barrier should rely on the independent realization of edges. Our analysis involves reducing the problem to designing a randomized matching algorithm on a given stochastic graph with some *variance-bounding* properties.

2 - Fundamental Limits for Broken Sample Problems

Jiaming Xu, Duke University, Durham, NC, United States

In this talk, I will explore a classic statistical challenge: the broken sample problem. Imagine a random sample of vectors is drawn from a joint distribution. Before observing them, each vector in the sample is broken into two subvectors and the original pairing information is lost. The central question we address is whether it is possible to recover this lost pairing information just by observing these two sets of subvectors. The broken sample problem has a rich history in statistics, dating back to the 1960s, with initial applications in matching records for surveys and censuses. Recently, this problem has gained renewed interest due to its relevance in fields such as data de-anonymization, robotics, multi-target tracking, signal processing, and data integration. It encapsulates a range of related problems found in the literature, including record linkage, database alignment, geometric matching, and shuffled regression. Despite extensive research over the past decade, determining the precise statistical thresholds for detection and estimation has remained a challenge. In this presentation, I will discuss our latest progress in determining these thresholds and important open problems on this topic.

3 - Online Matching in Geometric Random Graphs

Flore Sentenac, HEC Paris, Jouy en Josas, France, Vianney Perchet, Nathan Noiry, Laurent Ménard, Matthieu Lerasle

In online advertisement, ad campaigns are sequentially displayed to users. Both users and campaigns have inherent features, and the former is eligible to the latter if they are ``similar enough''. We model these interactions as a bipartite geometric random graph: the features of the 2N vertices (N users and N campaigns) are drawn independently in a metric space and an edge is present between a campaign and a user node if the distance between their features is smaller than c/N, where c>0 is the parameter of the model. Our contributions are two-fold. In the one-dimensional case, with uniform distribution over the segment [0,1], we derive the size of the optimal offline matching in these bipartite random geometric graphs, and we build an algorithm achieving it (as a benchmark), and analyze precisely its performance. We then turn to the online setting where one side of the graph is known at the beginning while the other part is revealed sequentially. We study the number of matches of the online algorithm closest, which matches any incoming point to its closest available neighbor. We show that its performances can be compared to its fluid limit, completely described as the solution of an explicit PDE. From the latter, we can compute the competitive ratio of closest.

4 - Online Matching for Edge Arrivals with Vanishing Probabilities

1 - Potential-Based Greedy Matching for Dynamic Delivery Pooling

Matias Romero, Columbia University, New York, NY, United States, Hongyao Ma, Will Ma

We study a dynamic non-bipartite online matching problem motivated by applications in mobility platforms. Food delivery platforms, in particular, implement real-time order pooling strategies to optimize operational efficiency and sustainability. These decisions involve a trade-off between immediate reward and potentially better future pooling opportunities. Existing heuristics often stem from general online matching algorithms but vary in effectiveness across applications. This paper introduces a new potential-based greedy (PB) algorithm, which balances instant reward with the potential loss incurred by matching non-ideal job pairs, without relying on forecasts or partial information about future arrivals.

We analyze the theoretical performance of PB in a dynamic non-bipartite matching model under different reward structures. Our findings demonstrate that PB significantly improves upon the naive greedy approach in terms of worst-case performance, particularly for reward functions that capture the distance saved by pooling deliveries. Empirical validation through simulations and order-level data from a food delivery platform shows that PB outperforms commonly used heuristics. These results highlight PB's robustness and practical effectiveness, offering a promising solution for real-time decision-making in diverse dynamic matching scenarios.

2 - Dynamic Matching with Post-Allocation Service and Its Application to Refugee Resettlement

Soonbong Lee, Yale University, New Haven, CT, United States, Kirk Bansak, Vahideh Manshadi, Rad Niazadeh, Elisabeth Paulson

Motivated by our collaboration with a major refugee resettlement agency in the U.S., we study a dynamic matching problem where each new arrival (a refugee case) must be matched immediately and irrevocably to one of the static resources (a location with a fixed annual quota). In addition to consuming the static resource, each case requires post-allocation services from a server, such as a translator. Given the uncertainty in service time, a server may not be available at a given time, thus referred to as a dynamic resource. Upon matching, the case waits to avail service in a first-come-first-serve manner. Bursty matching may result in undesirable congestion of the servers. Consequently, the planner (the agency) faces a dynamic matching problem with an objective combining the matching reward (pair-specific employment outcomes) with the cost for congestion for dynamic resources and over-allocation for the static ones. Motivated by the observed fluctuations in the refugee pools across the years, we aim to design algorithms with no distributional knowledge. We develop learning-based algorithms that are asymptotically optimal in certain regimes, easy to interpret, and computationally fast. Our design is based on learning the dual variables of the underlying optimization problem; however, the main challenge is the time-varying nature of the dual variables associated with dynamic resources. Our theoretical development integrates techniques from Lyapunov analysis, adversarial online learning, and stochastic optimization. When tested on our partner agency's data, our method outperforms existing ones making it a viable candidate for replacing the current practice upon experimentation.

3 - Constrained Contracts in Sequential Duopolies

Woo-Jin Kim, University of Southern California, Los Angeles, CA, United States, Afshin Nikzad, Guofu Tan

We study a model of duopolistic competition in which two sellers sequentially offer sales contracts with one unit of the divisible good to a buyer with private information. The first-mover can choose an arbitrary contract (i.e., a potentially uncountable set of price-quantity pairs) whereas the contract-constrained follower can only make a take-it or leave-it offer (i.e., selling one unit of the good for a fixed price). We characterize the equilibrium of the game and find that (i) the optimal mechanism for the first-mover also involves a take-it or leave-it offer but with a smaller quantity and a lower price than the second-mover, and (ii) the follower earns higher revenue than that of the first-mover, despite the constrained contract space it can choose from. Moreover, (iii) we show that the presence of the second seller reduces the first (incumbent) seller's profit and increases the buyer's surplus as well as the total surplus.

4 - Algorithmic Solutions for Choice-Based Matching Markets

Alfredo Torrico, Cornell University, New York, NY, United States

Choice-based matching platforms have recently proliferated thanks to their application in outsourcing, dating, accommodation and carpooling. These markets are generally characterized by: (i) two opposite sides who are looking to match and (ii) their decentralized nature in which users can freely choose someone (or not) from the displayed alternatives. Platforms, then, serve as a mediator that facilitates the matching process between both sides by controlling what users see and how they interact. One of the main challenges that these platforms face is choice congestion: If the display of alternatives is not carefully designed, then the most popular users may get more requests than they can actually serve. Two-sided assortment optimization has recently gained significant attention as an algorithmic tool to reduce congestion. An ideal algorithm balances between offering enough relevant alternatives to keep users engage and controlling the display of popular options to minimize congestion. In this talk, I will present recent advances in two-sided assortment optimization such as how different platform designs impact the market's outcome and the algorithmic challenges that each design poses.

1 - Avoiding Unrealistic Behavior in ScanPro-like Demand Models

Arian Aflaki, University of Pittsburgh, Pittsburgh, PA, United States, Deniz Eskandani, Su-Ming Wu

Empirical multiproduct demand models such as ScanPro can exhibit undesirable properties due to their log-linear nature. For example, increasing the price of all products can increase total demand. We propose an approach combining choice and empirical models to avoid these undesirable properties while maintaining ease of estimation.

2 - Dynamic Assortment in Make-To-Order Systems

Yuan Guo, George Washington University, DC, DC, United States, Chen-An Lin

This paper studies a dynamic assortment problem under a make-to-order system. The firm determines an assortment to each incoming customer, where customers arrive following a Poisson process and decide whether to purchase or balk upon seeing the assortment and the system congestion level. Products vary in production time, cost, and selling price. The make-to-order system operates as a first-come-first-served single-server queue. If a customer chooses to buy, they join the queue until production is complete while their order is added to the system congestion level as the updated system state. The firm aims to maximize long-run average profit rates by selecting assortments for different congestion levels. We show that, under linear product profit in production time, the optimal assortment policy aligns with revenue-ordered sets. We find that, typically the optimal assortment increases with congestion levels, but the full structure suggests it can first expand and then contract, indicating a delicate balance between congestion and profit maximization.

3 - Rational Choice Models: The Temporal Tree Representation

QI FENG, Purdue University, WEST LAFAYETTE, IN, United States, J Shanthikumar, MENGYING XUE

Choice models, specifying the consumer's choice probability of an option over a given choice set, are widely studied and applied in many fields. We propose a temporal tree representation of choice that covers all rational choice models. Compared with the existing structural choice models, the tree representation exhibits two major advantages that overcome the major challenges of model identification. First, all rational choice models have a tree representation, and a subclass of tree representation (with set-dependent branching) has a one-to-one correspondence to the rational choice models. This bridges the gap in the existing characterizations of structural models, which are unidentifiable, impose uninterpretable conditions, or do not cover the entire space of rational choice models. Second, the tree representation allows for the flexibility of systematically specifying the choice model structure based on available knowledge and data. In particular, the number of parameters needed to specify a tree representation can be primarily determined by the sufficient knowledge level, which corresponds to a specific layer of the tree branching. The sufficient knowledge level can be empirically determined based on the amount of available data, which in turn determines the number of parameters needed for model estimation. Therefore, the tree representation allows for a natural way of data integration, avoiding misspecification due to restrictive assumptions and overfitting for general models.

4 - Discrete Choice via Sequential Search

Aydin Alptekinoglu, The Pennsylvania State University, University Park, PA, United States

We study the information collection or search phase and its impact on final choices in a retail shopping context. To this end, we embed an analytically tractable discrete choice model in a classical model of sequential search with perfect recall. Although significant progress has been made in the theory literature in analyzing consumers' discrete choice behavior using random utility models, discrete choice through a sequential search process has not received enough attention due to analytical intractability issues. We build on the seminal *Pandora's Problem* introduced by Weitzman (1979) as a model of sequential search with perfect recall, and on the *Exponomial Choice* model (Alptekinoglu and Semple 2016) as a model of discrete choice (with each choice specified by a deterministic or observable utility component, minus a random utility component following an exponential distribution). We derive the search path and final choice probabilities in closed form, develop all the analytical tools to optimize prices for a given assortment of products, and show that the optimal assortment must contain some number of highest-value products at optimal prices. These results enable joint optimization of assortment and prices efficiently in retail shopping scenarios that can be well represented by sequential search. The structure of the solution accommodates a distinct group of products that are priced just so they remain on the search path with higher probability. We also conduct a simulation study to compare our model with the state-of-the-art in empirical modeling of sequential search.

1 - Online Learning for Pricing in On-Demand Vehicle Sharing Networks

Huanan Zhang, University of Colorado Boulder, Boulder, CO, United States, Saif Benjaafar, Xiangyu Gao, Xiaobing Shen

We consider the pricing problem in on-demand vehicle sharing networks with online demand learning. When there is no prior information available on the demand functions, the main challenge in designing an online learning algorithm is how to explore the demand functions while maintaining a balanced network. We address this challenge with an online learning algorithm adapted from the ellipsoid method. In our algorithm, the search subroutine is based on the idea of bisection and the Upper Confidence Bound, which can locate the price associated with a desired demand level for each type of trip, as characterized by the trip origin and destination, and estimate the gradient information at the price point. By carefully selecting the center of the ellipsoid for each iteration, we can ensure that the expected revenue improves and maintain a balanced network in each iteration. We prove that the regret of our learning algorithm is bounded by \tilde O(sqrt{T}) given a fixed workload parameter Delta. The numerical performance of the algorithm is illustrated using synthetic data. We also discuss extensions to the online learning algorithm in which the workload parameter Delta is unknown.

2 - Assortment Optimization for Office Meal Delivery Platforms

Saman Lagzi, UNC Kenan-Flagler Business School, Chapel Hill, NC, United States, Ningyuan Chen, Pin Gao, Sheng Liu, Chenhao Wang

We study the problem that an office meal delivery platform faces every day. Such platforms connect client office workers to restaurants by offering a menu of compatible restaurants to all the workers in an office. The platform's revenue is a fixed percentage of the value of the restaurant orders. The platform incurs the delivery cost. Each restaurant allocates a fixed capacity to the platform. We model the problem as a join assortment optimization. We prove the problem is APX-Hard while its special cases with only one restaurant or one client are NP-hard.

Using a Linear Programming relaxation of the original model, and by leveraging the rather soft nature of the capacity constraints in practice, we devise an asymptotically optimal randomized rounding algorithm that may breach any capacity constraint only by a negligible probability, as the number of clients and the restaurant capacities grow.

In collaboration with Canada's largest office meal delivery platform, we test the performance of our algorithm in a controlled switchback experiment in the city of Vancouver. We compare the performance of our methodology with that of the platform, before and after the experimental period. Our results suggests that our methodology improves platform's profit by over 9%, and it improves platform's revenue by nearly 7%.

3 - Benefit of Opaque Selling for Inventory Management

Mingyang Fu, National University of Singapore, Singapore, Singapore, Xiaobo Li

Opaque selling is a sales strategy where the seller does not disclose some specific details of a product or service until after a purchase is made. This approach can effectively generate sales and reduce surplus inventory. In this paper, we consider the case of balancing holding and backlog cost. We begin by examining the inventory costs under different opaque selling schemes and allocation policies. Our findings reveal that the benefits of opaque selling in inventory management is attributed from both allocation flexibility and the demand pooling effect. We show that even a modest degree of flexibility in general opaque selling can result in nearly constant relative inventory cost savings as market size expands. In terms of the profit, we show that when customers' utilities of products adhere to Salop's circle model or are independently and identically distributed, the mixed opaque selling with allocation flexibility consistently yields higher profits by optimizing the balance between the inventory costs saving and the potential revenue loss.

4 - Distributionally Robust Newsvendor on a Metric

Ayoub Foussoul, Columbia University, New York, NY, United States, Vineet Goyal

An e-commerce seller operates multiple warehouses and faces sequentially arriving demand from different locations on a metric. The demand is uncertain with only the first and second moments available. The goal of the seller is to exploit the benefits of risk pooling over demand uncertainty between the warehouses and jointly decide on an initial inventory allocation and demand fulfilment policy that minimize the total expected inventory and fulfillment costs under the worst-case demand distribution. This is a fundamental generalization of the classical distributionally robust newsvendor problem of Scarf (1958). We design a near-optimal policy for the problem with theoretical guarantees on its performance. Our policy generalizes the solution of Scarf (1958), maintaining its simplicity and interpretability: it identifies a hierarchical set of clusters, assigns a “virtual” underage cost to each cluster, then makes sure that each cluster holds at least the inventory suggested by Scarf’s solution if the cluster behaved as a single point with “virtual” underage cost and original overage cost. As demand arrives sequentially, our policy fulfills orders from nearby clusters, minimizing transshipment costs, while balancing inventory consumption across the clusters to avoid depleting any single one. In addition to its theoretical performance, numerical experiments show that our policy performs well in practice.

Advances in Market Algorithms and Design

Invited Session

Revenue Management and Pricing

Chair: Anil Omer Saritac, Singapore Management University, Singapore, NW16BJ, Singapore

1 - Multi-Homing Across Platforms: Friend or Foe

Tolga Dizdarer, Carroll School of Management, Boston College, Boston, MA, United States, Gerard Cachon, Gerry Tsoukalas

The gig economy offers flexible work opportunities where contractors enjoy the freedom to control when and how they do their work. In this project, we look at one particular form of freedom: ability to work on multiple platforms, a practice termed multi-homing. We study whether it is in the best interest of the platforms to allow multi-homing and what users have to gain from it, if any. The answer depends on the characteristics of the market. With multi-homing, a platform has less incentive to invest in supply capacity. It also has less incentive to build scale, dampening the excessive competition between platforms. In markets where the latter effect is prominent, platforms have their cake and eat it too. By allowing multi-homing, platforms extract more revenue from the market and also give their workers more freedom, a key move that strengthens platforms' case against regulators that its workers are free from platform's control. Authors: Gerard Cachon, Tolga Dizdarer, Gerrry Tsoukalas

2 - Attribute-Based Pricing: A Novel Formulation and Convergent Algorithms

Mengzhenyu Zhang, University College London, London, United Kingdom, Christopher Ryan

Attribute-based pricing—giving a price to potential product attributes individually and allowing customers to choose the attributes that form the final product—has been shown to improve customer satisfaction in the hospitality industry. In this paper, we consider the problem of finding optimal attribute prices to maximize the expected revenue from selling to a customer who chooses one product from a set of products that differ by only a few attributes. Because of complicated substitution effects among the final products that share common attributes, expected revenue is not concave in attribute prices. Nonetheless, we provide an algorithm to solve the attribute pricing problem and show that it converges to a stationary point that provides a high-quality solution to the problem. Through numerical experiments, we show our algorithm is, on average, ten times faster than gradient-based methods, both in terms of runtime and number of iterations. We also extend our algorithm to a setting where attribute prices are constrained through linear inequalities and prove convergence to a stationary point. We implement our algorithm on a real hotel data set and demonstrate its revenue benefits.

3 - Traffic Management in Live Stream Commerce

Feifan Zhang, Duke University, Durham, NC, United States, Wenchang Zhang, Liu Ming

We study optimizing real-time traffic acquisition for maximizing conversion and profit in live streaming commerce. We introduce a control model emphasizing the strategic use of cash incentives by streamers to attract viewers and enhance revenue. Leveraging TikTok data, we analyze optimal traffic management strategies across different scenarios and delve into platform algorithm design to identify thresholds for optimal recommendations, aligning with platform objectives. Two central research questions guide our analysis: optimizing temporal traffic management from the streamer's perspective and enhancing platform algorithm design. Our first analysis centers on the optimal traffic management strategy for live streamers. Depending on the initial traffic level of the live stream, we identify three distinct scenarios. In the first scenario, we encounter streamers with nascent or marginal popularity, operating in smaller live rooms. These streamers engage in a strategy best described as "survive in the cracks" due to insufficient initial audience. Their focus is to maintain their current viewer base, given the slim prospects of winning the algorithmic promotion. The second scenario involves streamers positioned just below the threshold for receiving algorithmic promotion. These streamers employ more aggressive strategies to reach the threshold at an early stage of the livestream. In the third scenario, we observe streamers with substantial initial viewership who already benefit from algorithmic promotion and thus focus on sustaining their audience base. Interestingly, we find that the cash incentive is highest in the second scenario when the streamer is about to reach the algorithmic recommendation.

4 - Slide or Feed: Content Recommendation with Creators' Incentives

Shu Zhang, the Chinese University of Hong Kong, Hong Kong, China, People's Republic of, Hongfan(Kevin) Chen, Renyu Zhang, Zhou Zhou

In online video platforms, optimizing recommendation systems is paramount for maximizing profit and incentivizing content creators.

Our work delves into the comparative efficacy of two modes of recommendation systems: the single-column (slide) and double-column (feed) formats. We aim to identify the circumstances under which each mode outperform the other in profit maximization and creator incentivization.

We build up a gaming model to describe the dynamics between recommendation modes and their impact on platform economics, where the two modes leads to differences in recommendation accuracy as well as user consumption cost. We illustrate how the performance of recommendation system is affected by both the modes and the total demand on the platform. The equilibrium results show that the strength of the recommendation algorithm plays an important role in this comparison.

Insights from our research contribute to a deeper understanding of how modes of recommendation system influence user content consumption patterns, creator engagement and the financial sustainability of online video platforms.

Equilibrium in Complicated Games and Applications II

Invited Session

Decision Analysis Society

Co-Chair: Jeff Shamma, University of Illinois Urbana-Champaign, Champaign, IL, United States

1 - A review of terminologies and approaches regarding interdependencies in Project Portfolio Selection

Gustavo Vieira, Instituto Tecnologico de Aeronautica, São José dos Campos - SP, Brazil, Hévilla Oliveira, Jonatas Almeida, Carmen Belderrain

Project Portfolio Selection (PPS) is a relevant activity in organizations to define the best possible set of projects to pursue their strategic objectives. Although many authors recognize the importance of interdependencies between projects in PPS and program implementation, most approaches consider projects independently. In addition, there are different understandings of the meaning and the implications of interdependencies in the literature. Therefore, we present a literature review focused on project interdependencies within project portfolios. The main goals for this review were: (i) map the different definitions of the relationships between projects and their implications for PPS; (ii) summarize the several methods that address project interdependency in PPS; (iii) identify possible gaps for methodological improvement focused on optimizing project portfolios and enhancing program implementation by considering project interdependencies. Our search identified 72 papers from Scopus and Web of Science databases that were adherent to the parameters of a pre-defined protocol tailored to match the previously-mentioned goals. Hence, we depict an unprecedented contribution to PPS research by proposing a novel definition for relationships between projects that organizes and clarifies the meanings of the pre-existing definitions for interdependencies, interactions, and synergy and fulfills the existing gaps in those current definitions. We also present an overview about how future developments can improve

PPS by considering these interdependencies. Thus, this work summarizes the recent advances and future paths for dealing with PPS and improving PPS maturity within organizations by considering interdependencies between projects.

2 - AI based algorithm to compute Nash equilibrium in Bayesian games with continuous state and actions

Lichun Li, FAMU-FSU College of Engineering, Tallahassee, FL, United States, Andres Eduardo Ho Lee

Bayesian Games are characterized by players possessing private information, such as the cost per unit for each player. This study specifically addresses scenarios where both private information and player actions are drawn from a continuous set. Previous research has examined the existence and uniqueness of a Bayesian Nash Equilibrium (BNE) in such games. We introduce an efficient computation method for this equilibrium using neural networks and game-oriented energy functions.

To compute the BNE, we begin by constructing a strategy model, represented as a neural network, for each player. Then, an energy function is developed to quantify the extent to which each player seeks deviation from the actions computed by their respective strategy models. By minimizing the energy function to zero, the strategy models converge towards the BNE of the game. This indicates that no player has an incentive to deviate from the actions determined by their neural network, given that other players rely on their respective strategy models for computing their actions.

The concept is validated by experimentation in symmetrical and asymmetrical multi-player rent-seeking games. Our proposed method computes a similar strategy that aligns closely with existing approaches found in the literature. Additionally, this method can seamlessly scale to accommodate scenarios involving more than two players because complexity increases with respect to the number of training samples instead of the number of players, requiring adjustments in the number of training samples as the player count increases.

3 - A Game-Theoretic Approach for Distributed Data Placement with Non-metric Access Costs

Rasoul Etesami, University of Illinois Urbana-Champaign, Champaign, IL, United States

Motivated by applications in web caches and content delivery in peer-to-peer networks, we consider the non-metric data placement problem and develop distributed algorithms for computing or approximating its optimal solutions. In this problem, the goal is to store copies of the data points among a set of cache-capacitated servers to minimize overall data storage and clients' access costs. We first show that the non-metric data placement problem is inapproximable up to a logarithmic factor. We then provide a game-theoretic decomposition of the objective function and show that a natural type of Glauber dynamics in which servers update their cache contents with probability proportional to the utility they receive from caching those data will converge to an optimal global solution for a sufficiently large noise parameter. In particular, we establish the polynomial mixing time of the Glauber dynamics for a certain range of noise parameters. Such a game-theoretic decomposition not only provides a good performance guarantee in terms of content delivery but also allows the system to operate in a fully distributed manner, hence reducing its computational load and improving its robustness to failures. Moreover, we provide another auction-based distributed algorithm, which allows us to approximate the optimal solution with a performance guarantee that depends on the ratio of the revenue vs. social welfare obtained from the underlying auction.

4 - Decentralized Strategies for Network Jamming Games

Brandon Van Over, Colorado State University, Fort Collins, CO, United States, Ali Pezeshki, Edwin Chong

We consider a two-player game over a multihop wireless network, involving multiple flows of packets. Each flow has its own source and destination, and each packet in a flow has a hard deadline. Player 1 wishes to determine a power control and routing policy to maximize the expected value of the average number of packets delivered prior to their deadlines, subject to a set of average power constraints. This performance metric is called timely throughput. Player 2 is a jammer that wishes to minimize the timely throughput by controlling the probability of failure for packet transmission across links in the network through injecting interference in the links, subject to its own set of average power constraints. We show that each player can employ a decentralized stationary randomized policy to play optimally against any fixed history-dependent randomized policy of their opponent. We investigate the convergence of such decentralized strategies to the Nash equilibrium of the game. Our work extends the results of Singh and Kumar (2018) on decentralized network control to network jamming games.

Equilibrium in Complicated Games and Applications

Invited Session

Decision Analysis Society

Chair: Lichun Li, FAMU-FSU College of Engineering, Tallahassee, FL, United States

Co-Chair: Jeff Shamma, University of Illinois Urbana-Champaign, Champaign, IL, United States

1 - Multi-Agent Learning vs Equilibrium in Games

Jeff Shamma, University of Illinois Urbana-Champaign, Champaign, IL, United States, Sarah Toonsi

The framework of multi-agent learning in games explores the dynamics of how individual agent strategies evolve in response to the evolving strategies of other agents. Of particular interest is whether agent strategies converge to well-known solution concepts, such as Nash Equilibrium (NE) or its variants, under natural assumptions on the learning strategies. This talk begins with a brief introduction of the learning in games framework and an overview of both positive and negative results that describe when specific learning algorithms do or do not converge to NE, respectively. The talk concludes with a presentation of recent results that illustrate how a system theoretic approach to learning in games can leverage feedback control concepts (e.g., decentralized stabilization, strong stabilization, and robustness) to lead to new perspectives on what is or is not achievable in learning in games.

2 - Learning-Based Incentive Design for Cyberphysical Systems

Roy Dong, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Jung-Hoon Cho, Siqi Du, M. Umar B. Niazi, Cathy Wu

Incentive design for cyberphysical systems has the potential for significant societal impact. For example, in ground transportation, if we were able to incentivize eco-driving behaviors amongst drivers, we could reduce vehicle emissions between 10-45%. However, in these cyberphysical systems, the underlying physical dynamics can significantly complicate the incentive design problem: if one agent chooses a particular action, we not only have to consider how that action instantaneously affects other agents, but how that action (and resulting responses) propagate throughout the dynamics of the system. If we were able to explicitly account for this coupling in the form of a utility function, then classical incentive design optimization methods could be applied… but such a utility function is often not available in practice when the dynamics and coupling are complicated. In our work, we explore how we can abstract out the incentive design problem into a choice of 'driving policy' for each driver, rather than an explicit action. This lends itself to more amenable methods of simulation to determine the coupling between agents and their optimal responses when we can only access the dynamics through simulation or real-world deployment. We explore the efficacy of this method in the context of transportation networks, and demonstrate how these algorithms can automatically uncover the 'influential' agents who may most effectively be incentivized to steer the overall system. (For example, on a one-lane road, incentivizing the front car to slow down will implicitly force the cars behind it to slow down.)

3 - Learning Nash in Constrained Markov Games with a Near-Potential

Ceyhun Eksin, Texas A&M University, College Station, TX, United States, Soham Das

We develop a best-response algorithm for solving constrained Markov games assuming limited violations for the potential game property. The limited violations of the potential game property mean that changes in value function due to unilateral policy alterations can be measured by the potential function up to an error α. We show the existence of stationary ϵ-approximate constrained Nash policy whenever the set of feasible stationary policies is non-empty. Our setting has agents accessing an efficient probably approximately correct solver for a constrained Markov decision process which they use for generating best-response policies against the other agents' former policies. For an accuracy threshold $\epsilon>4\alpha$, the best-response dynamics generate provable convergence to ϵ-Nash policy in finite time with probability at least $1-\delta$ at the expense of polynomial bounds on sample complexity that scales with the reciprocal of ϵ and δ.

4 - Collaborative Coalitions in Multi-Agent Systems

Jason Marden, University of California, Santa Barbara, Santa Barbara, CA, United States, Bryce Ferguson

The emergence of new communication technologies allows us to expand our understanding of distributed control and consider collaborative decision-making paradigms. With collaborative algorithms, certain local decision-making entities (or agents) are enabled to communicate and collaborate their actions with one another to attain better system behavior. By limiting the amount of communication, these algorithms exist somewhere between centralized and fully distributed approaches. In this talk, we explore this collaborative paradigm and identify potential opportunities associated with collaborative decision-making in distributed resource allocation problems. In particular, we will provide a characterization for how the level and structure of collaboration impacts the efficiency of the emergent collective behavior. Note that having such a characterization is essential for identifying whether or not the communication cost necessary to facilitate the desired collaborations is worth the gains in system welfare.

5 - Enhancing Social Welfare Leveraging Pure Nash Equilibrium in Integer Programming Games for Aquatic Invasive Species Prevention

Hyunwoo Lee, Virginia Tech, Blacksburg, VA, United States, Robert Hildebrand, Esra Toy

This study introduces a framework designed to enhance social welfare within non-cooperative integer programming games. With advancements in the IPG literature, attaining the best Pure Nash Equilibrium in terms of social welfare has become feasible. Recognizing the best PNE as both a fair and optimal equilibrium, we propose two integer programming models that leverage this equilibrium for post-game refinement: a refined social welfare model and a refined coalitional model. Both models ensure each player's utility at the socially optimum PNE is preserved while aiming to enhance the overall social welfare. The first model maintains the original non-cooperative game settings, preserving individual player strategies. The second model pools strategies within coalitions, promoting collaborative benefits. We apply this framework to edge-weighted budgeted maximum coverage games for Aquatic Invasive Species prevention, aligning player objectives with both state-level and county-level goals. Computational experiments demonstrate significant improvements in social welfare achieved through our proposed methods.

Building MCDM/A Models: Practical and Methodological Issues

Invited Session

Multi Criteria Decision Making

Chair: Eduarda Frej, Universidade Federal de Pernambuco, Recife, Brazil

Co-Chair: Danielle C. Morais, Universidade Federal de Pernambuco - UFPE, Recife - PE, Brazil

1 - Supporting Resource Allocation to Combat Drought Through a Multicriteria Sorting Model

Danielle C. Morais, Universidade Federal de Pernambuco - UFPE, Recife - PE, Brazil, Gabriel Castro

This study addresses the global impact of drought on water resources and aims to support resource allocation to combat its adverse effects. It proposes a multicriteria sorting model to assist the government in evaluating municipalities in a river basin in Brazil. The model categorizes the municipalities into high, moderate, and low-priority tiers for effective drought mitigation efforts. The findings demonstrate the model's capacity to support strategic public policies, enabling informed resource allocation and the development of targeted actions to address the specific needs of cities most impacted by drought, thereby mitigating the overall adverse effects of this natural disaster.

2 - Analytical Exploration of the Theoretical Foundation of Fitradeoff Method

Jonatas Almeida, Universidade Federal de Pernambuco , Caruaru, Brazil, Eduarda Frej, Lucia Roselli, Adiel Almeida

The ability to make effective decisions is fundamental to personal, professional, and organizational success, as it determines the course of actions to be followed, influencing the results obtained through the use of efforts and resources. Decision-making becomes particularly challenging when the decision maker has multiple objectives, requiring judgments to express how much they are willing to sacrifice on one objective to enhance another. The FITradeoff method, belonging to the set of Multi-Attribute Value Theory (MAVT) methods, is based on the tradeoff procedure and aims to analyze how the subspace of weights, limited by partial information, defines values and preference relationships between alternatives to construct a recommendation. Methodological improvements to FITradeoff have been published in various journals and conferences, including expansions to address different problematics, improved usability and cognitive performance through neuroscience studies, and the incorporation of holistic evaluation in the elicitation process combined with the decomposition procedure. This study seeks to analyze how the combined elicitation procedure is used to explore the weight subspace, how it can help identify inconsistencies in the decision maker's statements, and how certain heuristics can be employed to expedite the reduction of the viable weight subspace, aiding in the more efficient construction of a recommendation.

3 - A Multicriteria Decision Model for Carrying Company Selection in the Clothing Sector in Brazil

Layra Almeida, Universidade Federal de Pernambuco, Caruaru, Brazil, Jonatas Almeida, Eduarda Frej

The clothing industry is an important sector of Brazilian economy. Clothing companies are distributed in several regions of the country. These companies interact through products and services. Brazil is a country with continental dimensions, and carrying is an essential service for integrating the supplier chain. In this context, a multicriteria decision model was developed for a carrying company selection in the Brazilian clothing sector. A framework for building multicriteria decision models was applied. The framework has a successive refinement process, which allows for enriching the decision model by returning to any previous step to incorporate more information. Definition of basic elements of the problem and methodology are conducted through the application of the framework. A well-structured multicriteria decision model presents advantages as a proper representation of a real problem, and provides a robust and reliable recommendation for the addressed decision problem.

4 - Choice of Method for Multicriteria Decision Using a Framework for Structuring and Building Models

Adiel De Almeida, Universidade Federal de Pernambuco, Recife, Brazil, Lucia Roselli, Eduarda Frej, Danielle C. Morais

The Choice of method for multicriteria is discussed in this presentation. This choice can be done in several ways. This is one of the main issues in the decision process, which uses a Framework for structuring the decision problem and then building a multicriteria decision model. The preference modeling is the main focus on the choice of MCDM/A methods, in which the main steps is the analyzes of compensatory and non-compensatory preferences. An information and decision support system has been developed to assist the Analysist and the Decision Maker in this process.

5 - A Structured Protocol for Sensitivity Analysis in the Fitradeoff Method

Eduarda Frej, Universidade Federal de Pernambuco, Recife, Brazil, Pedro Henrique De Souza, Wagner Gouveia, Adiel de Almeida

This work presents a structured protocol to perform Sensitivity Analysis in the FITradeoff method, in order to verify the robustness of the solutions obtained. Sensitivity Analysis is a crucial step in Multicriteria Decision Making/Aiding models, in order to provide to the DM a view on how robust or sensitive are the solutions obtained by the applied method, considering variations on inputs' values. However, performing a sensitivity analysis can be challenging in partial information methods, as is the case of the FITradeoff method, since partial rankings of the alternatives that may be obtained. The proposed protocol has basically two steps. First, af a robustness analysis of the original solution is perfomed based on a Monte Carlo simulation process, and then the application of the Kendall Correlation Statistical Test is made, to verify the statistical significance of the correlations between the rankings obtained in the simulation analysis compared to the original ranking. The proposed protocol was embedded into the FITradeoff Decision Support System, enabling DMs to have a better understanding of possible variations on the solution obtained and further practical implications.

Advancements in Robotics and AI Applications

Contributed Session

Chair: Ranit Senapati, IIT KHARAGPUR, 721302

1 - Exploring the Interplay between Brand Identity and AI-Based Service Robots

Dongtan Li, Auburn University, Auburn, AL, United States, Pei Xu

With the rapid advancement of artificial intelligence technology, generative AI has dramatically attracted abundant attentions in both academia and industry. AI-based service robot, as one of the most creative and commercial applications, has made great contributions to increase service efficiency and reduce labor cost, especially in the hospitality industry. Recent research indicated a positive correlation between AI service robots and customer satisfaction ratings in hospitality (Borghi et al., 2023); whereas studies on brand identity in terms of brand personality are still limited. As a consequence of COVID 19 pandemic, consumers are increasingly aware of the risk of infectious diseases from interpersonal interactions and the implementation of service robot has been significantly boosted in the hospitality industry. However, certain utilizations of service robot can also precipitate the transformation of brand identity, which may either strengthen or damage the brand image. In order to investigate the interplay between brand identity and service robots, this study suggests brand personality as the main measurement of brand identity, which describes a brand from five dimensions including sincerity, excitement, competence, sophistication, and ruggedness (Aaker 1997). This study further examines how the implementation of service robots impact brand personality in the short- and long-term, and how such impact is moderated by brand position. Findings of our study can help hospitality brands better recognize the possible alteration of their brand identity while deploying AI service robot.

2 - Analyzing restaurant customers' and owners' preferences for serving robots using choice experiment and latent class analysis

Changeun Park, Kyung Hee University, Yongin, Korea, Republic of, Jungwoo Shin

Serving robots are growing by innovating customer experiences, providing positive benefits to both restaurant customers and owners by improving productivity, resolving labor shortages, and providing new experiences and services. However, along with digital literacy, there are also negative perceptions about robots, such as the discomfort of robots resembling human and human replacement. The purpose of this study was to identify serving robot types and restaurants operation types that restaurants customers and owners prefer using Choice Experiments (CE) and Latent Class Analysis (LCA). The study found that customers were divided into two groups: technology change adopters, who would accept supporting both voice and app calls with serving robots, and technology change avoiders, who would not accept serving robots and would prefer only voice calls, while owners were divided into two groups: those who valued interactivity, such as the call method and those who valued the anthropomorphism of the robot more than the call method. The analysis of the acceptance scenarios by attribute for each group showed that both groups preferred a combination of serving robots and human labor, with customers preferring non-humanoid serving robots and owners preferring fixed type or humanoid serving robots. Customers were least likely to accept humanoid serving robots, suggesting the possibility of an uncanny valley effect, and restaurants owners should consider it when introducing serving robots.

3 - Minimizing energy consumption by controlling the base positions of a robotic arm based on a statistical approach

Seung Hyeon Eom, Kyung-Hee University, Yongin-si, Korea, Republic of, Hyun Woo Jeon

The usage of industrial robots, especially robotic arms, is in an increasing trend. Reducing the energy consumption of industrial robotic arms is one of the most important energy-related issues in the industrial sector. Although the base position of robotic arms is crucial for managing and saving energy consumption, this research problem has not been studied comprehensively. Moreover, rather than more scientific research or data, the intuition or experience of engineers is used as the basis to determine the base position. Therefore, this study aims to optimize the base position of robotic arms by minimizing energy consumption for tasks. For the optimization formulation, we use robotic arm power models estimated from a statistical method, in which we consider three simple input variables: starting point, ending point, and payload. We also show the convexity of the objective function (energy consumption for a given task). From analysis, we present that the best base position of robotic arms for each task can be determined by minimizing energy consumption.

4 - A critical review on applications of Surrogate Modeling, Machine Learning and Deep learning techniques in New Product Development

Ranit Senapati, Indian Institute of Technology Kharagpur, Kharagpur, India, Biswajit Mahanty

The application of advanced computational techniques such as surrogate modeling, machine learning, and artificial intelligence has enhanced decision making and innovation in the domain of new product development. Designers can easily construct surrogate models from simulations or experiments, enabling them to evaluate design alternatives, optimize product performance, and explore the design space efficiently. Additionally, these surrogate models serve as invaluable tools for sensitivity analysis and uncertainty quantification, aiding in risk management and robust design. Machine learning techniques enable designers to perform predictive modelling, pattern recognition, and anomaly detection, facilitating data-driven decision making at every product development lifecycle stage. Through techniques such as natural language processing, computer vision, and deep learning, AI systems can analyze unstructured data, extract actionable insights, and generate innovative ideas, revolutionizing ideation and concept generation processes. In conclusion, the synergistic integration of surrogate modeling, machine learning, and artificial intelligence heralds a new era of agility, innovation, and competitiveness in product development. By harnessing the predictive power of these technologies, organizations can expedite time-to-market, mitigate risks, and deliver customer-centric products that resonate with evolving market demands. However, addressing challenges related to data quality, algorithmic biases, and organizational readiness is imperative to realize the full potential of these computational techniques.

Hexaly/Artelys

Invited Session

Technology Showcase

1 - Hexaly, a New Kind of Global Optimization Solver

Fred Gardi, Hexaly, Brooklyn, NY, United States

Hexaly is a new kind of global optimization solver. Its modeling interface is nonlinear and set-oriented. It also supports user-coded functions, thus enabling black-box optimization and, more particularly, simulation optimization. In a sense, Hexaly APIs unify modeling concepts from mixed-linear programming, nonlinear programming, and constraint programming. Under the hood, Hexaly combines various exact and heuristic optimization methods: spatial branch-and-bound, simplex methods, interior-point methods, augmented Lagrangian methods, automatic Dantzig-Wolfe reformulation, column and row generation, propagation methods, local search, direct search, population-based methods, and surrogate modeling techniques for black-box optimization.

Regarding performance benchmarks, Hexaly distinguishes itself against the leading solvers in the market, like Gurobi, IBM Cplex, and Google OR Tools, by delivering fast and scalable solutions to problems in the space of Supply Chain and Workforce Management like Routing, Scheduling, Packing, Clustering, Matching, Assignment, and Location problems. For example, on notoriously hard problems like the Pickup and Delivery Problem with Time Windows or Flexible Job Shop Scheduling with Setup Times, Hexaly delivers solutions with a gap to the best solutions known in the literature smaller than 1% in a few minutes of running times on a basic computer.

In addition to the Optimizer, we provide an innovative development platform called Hexaly Studio to model and solve rich Vehicle Routing and Job Shop Scheduling problems in a no-code fashion. The user can define its problem and data, run the Optimizer, visualize the solutions and key metrics through dashboards, and deploy the resulting app in the cloud – without coding.

2 - Model and solve nonlinear optimization problems with Artelys Knitro

Richard Waltz, Artelys, Los Angeles, CA, United States

The challenges faced by operational research (OR) practitioners, whether in operational scenarios or during techno-economic analyses, are typically intricate and inherently nonlinear. A skilled modeler's task is to simplify this complexity and identify the core issue whose resolution untangles the rest.

A common strategy is to linearize the problem to leverage the wealth of theoretical and practical tools provided by linear programming, such as duality, sensitivity analysis, and efficient algorithms. While this approach can be effective, one can often obtain significantly better solutions by directly solving a nonlinear model that more closely resembles the actual problem.

Artelys Knitro is the leading solver focused on large-scale, nonlinear (potentially non-convex), optimization problems. Knitro offers both interior-point and active-set algorithms for continuous models, as well as tools for handling problems with integer variables and other discrete structures. This tutorial will introduce the key features of Knitro, and demonstrate how to use Knitro to model and solve optimization problems in various environments.

This tutorial will showcase several instances of nonlinear problems, typically addressed through linear relaxation, yet warranting a direct approach. It will delve into the methodologies and tools employed to tackle these challenges. This tutorial aims at an audience familiar with the basics of mathematical optimization, focusing on practical examples.

Technology, Innovation Management and Entrepreneurship

Chair: Janne Kettunen, The George Washington University, Vienna, VA, United States

1 - Innovation Management on Online Platforms

Sidika Tunc Candogan, University College London, London, United Kingdom

In my thesis, I study operational decisions on online platforms that facilitate crowd-based innovation and new product development, and I provide insights into how the economic value generated on these platforms can be enhanced. In the first two chapters, I focus on crowdsourcing platforms (e.g., InnoCentive and Topcoder) that create value by regularly organizing innovation contests to find solutions to their clients' innovation-related problems from the crowd. In the third chapter, I focus on crowdfunding platforms (e.g., Kickstarter and Indiegogo), where entrepreneurs launch campaigns to crowdsource funding to bring their innovative ideas to life. In this talk, I will briefly talk about what motivated me to work on the project in each chapter, research questions, key tradeoffs, and managerial insights.

2 - Emerging Technologies in Healthcare Operations

Jiatao Ding, Nanyang Technological University, Singapore, Singapore

This dissertation investigates the operational implications of emerging technologies in healthcare through three essays. The first essay examines strategic collaborations between biopharmaceutical firms and technology providers in acquiring analytics capabilities. Using event study methodologies, we find that such collaborations yield significant positive abnormal returns, especially when aimed at enhancing prelaunch R&D or involving multiple therapeutic areas. We also explore how firm characteristics influence the impact of these collaborations on shareholder value. The second essay focuses on malaria-endemic countries, analyzing optimal intervention strategies with subsidy program and traceability technology adoption for combating counterfeit antimalarial drugs. Using a game-theoretic model, we demonstrate that traditional purchase subsidies may not be effective in the presence of uncertified distribution channels. Instead, we advocate for tailored approaches, supported by numerical analysis, to design effective policies and technologies for improving access to life-saving medicines. The third essay assesses the operational implications of virtual triage chatbot adoption in acute care settings, addressing the challenges of patient self-triage inaccuracy. Using a queueing game model, we explore the trade-offs between informativeness and volume in virtual triage recommendations, highlighting the need for custom solutions and effective regulation to enhance acute care delivery. Overall, these essays contribute actionable insights for policymakers, practitioners, and researchers, emphasizing the importance of strategic collaborations, tailored interventions, and customized technology adoption in advancing healthcare operations and enhancing patient outcomes.

3 - Managing the nanostore supply chain: Base-of-the-pyramid retail in emerging markets

Rafael Escamilla, Arizona State University, Tempe, AZ, United States

The presentation will delve into the intricacies of nanostore supply chains in emerging markets, focusing on the financial, material, and information flows within them. First, I will discuss how suppliers benefit operationally from allowing short-term payment delays, despite inherent risks. The discussion will then shift to the challenges of digitization for nanostore shopkeepers, who fear that adopting digital technologies could expose tax evasion. Then, I will discuss the competition between nanostores and convenience stores, highlighting the benefits of value-added digital services. Finally, I will discuss the strategic decision suppliers face in determining their visit frequency, which directly impacts shopkeeper behavior.

4 - Information Sharing and Operational Transparency on On-Demand Service Platforms

Swanand Kulkarni, Tuck School of Business, Dartmouth College, Hanover, NH, United States

The three chapters in this dissertation examine the operational practices of on-demand service platforms, pertaining to information sharing and operational transparency on the supply-side. On-demand service platforms such as ridesharing, food delivery, grocery delivery, and courier delivery platforms critically depend on the services of workers, who are independent contractors. Given that these workers have discretion over their labor supply decisions, the platform's information provision to workers plays a key role in influencing workers' decisions and in eventually meeting the customer demand. In this dissertation, I employ game-theoretic modeling and conduct incentivized experiments with human subjects to evaluate the implications of a platform's practices around information sharing and operational transparency with workers, for workers' decisions and for the platform's operational outcomes. In Chapter 1, using game-theoretic modeling and lab experiments, we investigate how an on-demand service platform's mechanism to share demand–supply mismatch information spatially affects drivers' relocation decisions and the platform's matching efficiency. Chapters 2 and 3 experimentally examine how a platform's compensation practices, considered jointly with the level of transparency that workers have into the pay determination process, influence worker participation with the platform. In Chapter 2, we examine the impact of the intuitiveness and transparency of a platform's compensation model on worker participation. In Chapter 3, motivated by platforms' experiments around managing the commission that they charge workers, we study the impact of consistency in (across service instances) and transparency of the platform's commission on worker participation.

5 - Three Essays on New Product Development: Creating Value from Internal and External Innovation

Hossein Nikpayam, Frankfurt School of Finance & Management, Frankfurt, Germany

Innovation drives business success, particularly through new product development (NPD). This dissertation explores the intricate balance between resource allocation, communication strategies, and incentives in managing NPD initiatives. It investigates how firms can optimize the allocation of scarce resources, highlighting the importance of balancing flexibility with dedicated resources to enhance project selection without excessive information acquisition costs. Additionally, it examines the role of strategic communication and financial incentives in guiding resource allocation, emphasizing how these factors influence decision-making in environments with varying levels of internal and external project information. Finally, the research delves into the dynamics of innovation contests, identifying conditions under which truthful and fully informative performance feedback is most effective. These insights collectively offer practical strategies for firms to effectively navigate the complexities of innovation management.

Waste and the Circular Economy

Invited Session

MSOM: Sustainable Operations

Chair: Adem Orsdemir, University of California Riverside, Riverside, CA, United States

Co-Chair: Anna Saez de Tejada Cuenca, IESE Business School, Barcelona, Spain

1 - Competitive mass customization and environmental sustainability in fashion

Adem Orsdemir, University of California Riverside, Riverside, CA, United States, Aydin Alptekinoglu

We explore adoption of mass customization (MC) -- in place of mass production (MP) -- in a profit-driven competitive environment as a solution to the serious problem of overproduction (and all the environmental waste that it generates) endemic in the fashion industry. Building on a demand model sensitive to product variety, price and a lead time for mass-customized products, we analyze a duopoly competition game that includes production technology selection between MP and MC. We then take the equilibrium of this game as a characterization of the profit-driven market outcome, and analyze its environmental impact. This analysis teaches us when adoption of MC leads to lower environmental impact and why. We uncover, for example, when MC adoption by one firm (with the other sticking with MP) leads to higher profits for both firms and lower total environmental impact -- a so called win-win-win. Also, generally speaking, low-to-medium marginal cost of production is more conducive for MC adoption to lead to greener outcomes. This is good news in that lower marginal costs typically imply lower prices and higher sales volumes in practice, pointing to the part of the fashion industry that has larger absolute environmental impact.

2 - Lowering the environmental impact of fashion retail assortments: Balancing profit maximization and impact minimization

Jean-Sebastien Matte, McGill University, Montreal, QC, Canada, Mehmet Gumus, Robert Rooderkerk

There is a general consensus that the fashion industry needs to reduce its environmental impact. However, there is confusion and misunderstanding between retailers, consumers, and policymakers as to how the different dimensions of environmental impact in fashion are understood and valued. In addition, there are currently no regulation in place to curb the industry's highly impactful production.

We propose an integrated framework that combines an incentive-aligned choice-based conjoint (IA-CBC) experiment, a Hierarchical Bayes Multinomial Logit (HB-MNL) model, and joint product-line and pricing optimization model to measure preferences and willingness-to-pay (WTP) for three environmental attributes---Recycled Content, Durability, and Circularity Design---and the trade-off between profits and environmental constraints (regulations). Our experimental design also includes a between-subjects manipulation to study the impact of priming consumers as a reconciling mechanism between consumers, retailers and policymakers.

We find that environmental attributes are important, but that Price remains the main driver of choice. Our results also define a clear hierarchy of importance between environmental attributes and their levels, and highlight confusion towards Durability. We find that constraints on Recycled Content have the most impact on business performances, and that it is almost always optimal for the retailer to offer a Circularity Design level.

Finally, we find that priming consumer significantly shifts attribute importance, increases WTP, and consequently considerably eases the profit-environmental impact trade-off.

For managers, our methodology and results provide a strategic decision support tool to optimally adapt assortments to consumer demand and regulations. For policymakers, we provide valuable empirical evidence to develop fair regulations.

3 - Customer-to-Customer Returns Logistics: Can it Mitigate the Negative Impact of Online Returns?

(Ayse) Sena Eruguz, Vrije Universiteit Amsterdam, AMSTERDAM, Netherlands, Oktay Karabag, Eline Tetteroo, Carl van Heijst, Wilco van den Heuvel, Rommert Dekker

Customer returns are a major problem for online retailers due to their economic and environmental impact. In this talk, we introduce a new concept for handling online returns: customer-to-customer (C2C) returns logistics. The idea behind the C2C concept is to deliver returned items directly to the next customer, bypassing the retailer's warehouse. To incentivize customers to purchase C2C return items, retailers can promote return items on their webshop with a discount. We build the mathematical models behind the C2C concept to determine how much discount to offer to ensure enough customers are induced to purchase C2C return items and to maximize the retailer's expected total profit. Our first model is a customer-based formulation of the problem and provides an easy-to-implement constant-discount-level policy. Our second model formulates the real-world problem as a Markov decision process (MDP). Since our MDP suffers from the curse of dimensionality, we resort to simulation optimization and reinforcement learning methods to obtain reasonably good solutions. We apply our methods to data collected from a Dutch fashion retailer. Our results indicate that significant benefits can be achieved with the C2C returns program in terms of both expected profit and return rate. Even in cases where the cost-effectiveness of the C2C returns program is not pronounced, the proportion of customer-to-warehouse returns to total demand becomes lower. Therefore, the system can be defined as more environmentally friendly. The C2C concept can help retailers financially address the problem of online returns and meet the growing need for reducing their environmental impact.

4 - Timing of remanufactured product introductions over evolving product generations in steady state

Ana Muriel, University of Massachusetts, Amherst, MA, United States, Yue Jin

We analyze alternative remanufacturing strategies for a firm that introduces new product generations at regular intervals. The literature has mainly focused on steady state models where the new product competes with a certain remanufactured version of the product each interval. We propose a new steady state model that breaks the generation interval into two periods. The new product is introduced at the beginning of period 1 and competes with the remanufactured version of the old generation. At some point, remanufacturing the new generation product will become feasible and the company can choose to transition to period 2, offering remanufactured products of the new generation which is more appealing to the customer. We quantify the benefits associated with the two-period strategy, analyze the timing decision for offering the new version of the remanufactured product, characterize structural properties of the solutions, and study their sensitivity to various model parameters.

5 - Achieving Resilience Amidst Crises in U.S. Dairies: The Importance of Sustainability Investments and Women in Farming

Veronica Villena, Arizona State University, Tempe, AZ, United States, Elizabeth Ransom, David Abler

The COVID-19 pandemic created major supply chain disruptions, forcing managers to focus their attention on short-term survival. Using the dairy sector, we show that investing in long-term sustainability practices builds resilience. This study suggests that now is the time to reinforce sustainability investments in order for dairy farms to better navigate future disruptions. Building upon the research stream on sustainability and resilience in agriculture operations, we conducted two empirical consecutive studies. The first, a qualitative study, reveals (a) the types of sustainability interventions made by dairy farms, (b) the unknown challenges that dairy farms faced during COVID, and (c) the reasons why farms long investing in sustainability practices exhibited higher resilience. It also shows some unique differences between women and men operators. The second, a quantitative study, tested the propositions emerging from the first study in a large-scale survey involving 588 Pennsylvania dairy farms. Both studies show that farms that have long invested in environmental, labor, and animal welfare practices are more likely to continue their operations and implement an emergency plan that allows them to run safe operations. Interestingly, they reveal that, compared to environmental and animal welfare practices, dairy farms' human resource practices are very nascent and precarious, which is worrisome given this sector's severe labor shortage and high turnover rate. Furthermore, the results show that women operators benefit more from sustainability investments than men operators, even when the odds are against for them.

Advances in network optimization under uncertainties: Theories and applications

Invited Session

OPT: Integer and Discrete Optimization

Chair: Thanakrit Piyachayawat, Texas Tech university, Lubbock, TX, United States

1 - Network Enhancement via Robust Interdiction Methods

Thanakrit Piyachayawat, Texas Tech university, Lubbock, TX, United States

In the classic network interdiction games, the leader (the first decision-maker) traditionally acts as an attacker, aiming to disrupt their opponent's solutions such as paths, connected components, or spanning trees. In this work, we propose a novel reinterpretation of the leader's role as a network user, focusing on enhancing network structures while mitigating uncertainties originating from multiple sources. Using new reformulation methods, we address this class of problems effectively. We demonstrate that, across a range of feasible decisions dictated by optimistic and pessimistic perspectives, optimal robust solutions can be obtained through single-level mixed linear programming formulations, which are tractable via proposed cut-generation approaches. Moreover, using facet analysis techniques, we show that our reformulated models simplify this network enhancement problem while preserving its optimal characteristics. These findings open up new avenues for studying and addressing more complex network problems.

2 - A Robust Bi-Level Network Interdiction with Applications in Human Trafficking Disruption

Daniel Lopes da Silva, Clemson University, Clemson, SC, United States, Thomas Sharkey, Yongjia Song

We investigate a robust bi-level network interdiction problem motivated by applications in human trafficking. In this problem, the follower, who operates the network, solves a minimum cost flow problem. The leader, who interdicts the network, minimizes the number of arcs from a special set with flow on them in the minimum cost flow solution obtained by the follower. The problem includes data uncertainty as the leader does not know the cost vector but only that it belongs to a polyhedral set. The follower has complete knowledge about its own parameters and therefore makes decisions in a ``wait-and-see'' fashion.

3 - Optimizing Microgrid Investment to Improve Resilience Using Stochastic Optimization

Ramsey Rossmann, University of Wisconsin — Madison, Madison, WI, United States, James R. Luedtke, Line Roald

Distribution networks in the power grid are rapidly changing with increases in distributed energy resources, posing challenges to serving load as well as opportunities for increasing reliability. Installing switches and power sources within a distribution feeder can increase operational flexibility of the feeder and allow for more load to be served during outages. In extreme circumstances, widespread outages can shut down feeders for days even when resources within the feeder could supply power to serve some load. A key challenge in many outages is that when a line has a fault (e.g., a tree falls on it), the fault will spread until it can be isolated, causing more parts of the feeder to be de-energized. To decrease the impact of outages, utilities may consider installing switches to isolate faults and change the feeder's topology as well as generators, batteries, and solar arrays to provide power for the feeder when the substation is unavailable. Given uncertainties in outages, load, and solar availability as well as the non-convexities of binary decisions and power flow constraints, optimizing such feeder investments is challenging. We propose a simplified model for making optimal investment decisions in a feeder under uncertainty by approximating feeder operations with a network flow formulation. We use various approximation and decomposition approaches to find solutions to the resulting two-stage stochastic integer program. Preliminary results suggest these models are good approximations of the original model and perform well across a variety of instances.

4 - Relay-Hub Network Design for Consolidation Planning Under Demand Variability

Onkar Kulkarni, Georgia Institute of Technology, Atlanta, GA, United States, Mathieu Dahan, Benoit Montreuil

In this work, we study a two-stage stochastic program to design relay-based transportation network. In the first stage, we position the relay-hubs and size them, and design a minimum-cost consolidation plan to transport commodities upon realization of commodity demand uncertainty in the second stage. Due to commodity consolidation considerations, second stage consists of general integer decision variables which makes the problem challenging to solve. We devise a decomposition-based branch-and-cut algorithm with nested Benders decomposition and integer L-shaped method to solve the problem-at-hand exactly. To test and validate our methodology, we design large-scale resilient relay networks to be used for finished vehicle deliveries for a US-based car manufacturer that partnered with our research team. Finally, we provide managerial insights regarding inducing flexibility in the relay network to hedge against commodity demand variability.

Quantum Computing and Optimization (Part 2)

Invited Session

OPT: Linear and Conic Optimization

Chair: Mohammadhossein Mohammadisiahroudi, Lehigh University, Bethlehem, PA, 18015, United States

Co-Chair: Zeguan Wu, Lehigh University, Bethlehem

1 - Solving Stochastic Binary Optimization Problems with Quantum Approximate Optimization Algorithm

Anthony Wilkie, University of Tennessee-Knoxville, Knoxville, TN, United States

There are many problems in stochastic programming that are currently intractable using today's classical computers. These problems usually involve a large number of binary variables with a recourse function that may be non-convex and discontinuous. Quantum computing is a new technology that has the potential to solve these problems. Specifically, the Quantum Approximate Optimization Algorithm (QAOA) is a quantum algorithm that has been shown to approximate solutions to combinatorial optimization problems. As a result, this project will explore the use of QAOA to solve stochastic binary programs. We propose a method to solve the deterministic equivalent of the stochastic program using QAOA. We will show how to encode our problem in a quantum circuit and how QAOA is able to approximate the solution. This proof of concept will be tested on small problems to demonstrate the potential of QAOA to solve stochastic binary programs. Then we explore potential methods to create more efficient quantum circuits and improve the performance of QAOA.

2 - Quantum Relaxation for Combinatorial Optimization Problems

Zichang He, JPMorgan Chase, New York, NY, United States, Rudy Raymond, Ruslan Shaydulin, Marco Pistoia

Quantum optimization holds promise for providing advantages in solving combinatorial optimization problems. One key component involves the exact encoding of a classical cost function into a quantum Hamiltonian, which is widely utilized in quantum algorithms. However, an alternative approach involves relaxed encoding, inspired by quantum random access codes. This quantum relaxation enables the handling of problems that are 2-3 times larger while utilizing the same number of qubits. Despite this, quantum algorithms for solving the relaxed Hamiltonian have received less attention. In this talk, we will discuss recent advancements in quantum algorithms and their implementation for addressing relaxed optimization problems.

3 - Constrained local Hamiltonians: quantum generalizations of Vertex Cover

Sankara Sai Chaithanya Rayudu, University of New Mexico, Albuquerque, NM, United States, Ojas Parekh, Kevin Thompson

Given the diversity of combinatorial optimization problems and their impact on the development of new algorithms, it is natural to ask if we can find quantum generalizations of some of the constrained combinatorial problems, which, in turn, can inspire new quantum algorithms. In this work, we propose a quantum generalization of the vertex cover problem, which we call 'Transverse Vertex Cover' (TVC). We prove that TVC is in the complexity class StoqMA-hard and develop an approximation algorithm for it based on a quantum generalization of the classical local ratio method. Additionally, we demonstrate our quantum local ratio method on a traditional unconstrained quantum local Hamiltonian version of the Vertex Cover, which is equivalent to the well-studied anti-ferromagnetic transverse field Ising model in physics.

4 - Iterative Refinement for Quantum Computing Algorithms

Mohammadhossein Mohammadisiahroudi, Lehigh University, Bethlehem, PA, United States, Tamás Terlaky, Brandon Augustino, Giacomo Nannicini, Zeguan Wu, Muqing Zheng, Pouya Sampourmahani

Quantum linear system algorithms (QLSAs) offer potential complexity advantages over classical methods for solving linear systems, with respect to dimension. Yet, extracting classical solutions requires a quantum tomography algorithm (QTA), which increases both error and time complexity. Recent advancements have integrated QLSA with QTA to develop quantum interior point methods (QIPMs) for solving different types of linear conic optimization problems. Although these innovations promise polynomial speed-ups relative to dimension, their efficiency is limited by polynomial dependencies on precision and the condition number, hindering their utility for finding a precise solution. Our work utilizes iterative refinement methods (IRMs) to achieve precise solutions by iteratively employing quantum oracles of limited precision. We demonstrate how IRMs can exponentially accelerate QLSA combined with QTA and QIPMs concerning precision. Furthermore, IRMs mitigate the impact of the condition number on the computational complexity of QIPMs. Another challenge for QLSAs is that their gate complexity is far larger than what is implementable on current noisy intermediate-scale quantum computers. We also explore the potential of IRMs in facilitating the early implementation of QLSAs, enhancing the practicality and precision of quantum computing methods in solving systems of linear equations and consequently, solving linear optimization problems.

5 - Lagrangian Reformulation for Nonconvex Optimization: Tailoring Problems to Specialized Solvers

Rodolfo Alexander Quintero Ospina, Lehigh University, Bethlehem, PA, United States, Juan Vera, Luis Zuluaga

Advancements in computing technologies, such as quantum and Ising devices, have led to a surge of interest in studying different ways to reformulate nonconvex optimization problems, especially those involving binary variables. In this talk, I will present results that show the equivalence between a class of equality-constrained nonconvex optimization problems and their Lagrangian relaxation, bridging classical optimization theory with emerging quantum computational approaches and filling a gap in classical optimization literature. Moreover, we explore the implications of these findings for solving Integer Programs and Mixed Integer Problems using quantum optimization algorithms.

Chair: Lijun Ding, University of California San Diego, La Jolla, CA, 77843, United States

Co-Chair: Liwei Jiang, Georgia Institute of Technology, Atlanta, GA, United States

1 - *Non-Asymptotic Global Convergence Analysis of Bfgs*

Aryan Mokhtari, University of Texas at Austin, Austin, TX, United States

In this talk, we discuss the non-asymptotic global convergence rates of the Broyden-Fletcher-Goldfarb-Shanno (BFGS) method for two scenarios: when it is implemented with an exact line search and when it is implemented with an inexact line search that utilizes the Armijo-Wolfe conditions. For both cases, we establish global convergence rates that hold for any initial point and any initial Hessian approximation. To the best of our knowledge, these are the first results that are able to characterize the overall iteration complexity of the BFGS quasi-Newton method.

2 - Clip-Ocular: Seeing Through the Lense of Visual Language Models

Mahdi Soltanolkotabi, University of Southern California, Los Angeles, CA, United States, Zalan Fabian, Berk Tinaz

Multimodal generative AI models have achieved unparalleled success as conversational agents capable of interpreting both image and text inputs. However, recent research has cast serious doubt on the visual understanding and reasoning capabilities of such vision-language models (VLMs). Popular multimodal models often fail at surprisingly simple visual tasks where humans achieve near-perfect performance. Research shows that VLMs struggle even with basic spatial relations such as deciding what is left or right in an image, with performance close to random guessing on some benchmarks. In this work, we take a deep dive into investigating the fundamental causes of such shortcomings from a vision perspective. In particular, we study the most common image encoders leveraged by VLMs and propose a technique to "see through the eyes" of the model, which we call CLIP-Ocular. This allows us to gain new insights into VLM shortcomings in a principled manner. We then utilize these new insights to redesign the VLM training pipeline to enhance their spatial reasoning capabilities.

3 - Maximum Entropy Solution of Linear Systems

Michael Friedlander, University of British Columbia, Vancouver, BC, Canada

A Newton-type method is described for obtaining a maximum-entropy solution over the probability simplex to an underdetermined linear system. The method accomodates direct and indirect linear algebra operations, including preconditioning. Numerical experiments on synthetic and real data confirm the accuracy and scalability of the approach.

Joint work with Nicholas Barnfield and Tim Hoheisel.

4 - Sum-of-Minimum Optimization

Wotao Yin, DAMO Academy, Alibaba US, Bellevue, WA, United States, Lisang Ding, Ziang Chen, Xinshang Wang

Machine learning (ML) typically trains a single model by minimize the average training loss across all data points. This approach is sub-optimal when dealing with heterogeneous data or when the data come from multiple sources. We propose a novel "sum-of-minimum" optimization model by considering an ensemble of k models and optimizing them jointly. The key idea is to find the optimal assignment of each data point to the model that performs best on it, while simultaneously training these models. This approach is mathematically formulated as:

minimize $\text{sum}_{i=1,..,n} \min\{\text{loss}(x_1, \text{data}_i), ..., \text{loss}(x_k, \text{data}_i)\}$

where $x_1,...,x_k$ are decision variables that represent the parameters of the k models. By minimizing the sum of minimum losses, each of the k model is incentivized to specialize in a subset of the data points where it achieves the lowest loss.

Although this optimization problem is both non-smooth and non-convex, we present an algorithm that approximately solves the problem with guarantees. Under favorable assumptions, we provide tight performance and convergence bounds for our algorithm.

We demonstrate the effectiveness of our approach through experiments on various tasks, including generalized principal component analysis, multi-neural network training, and mixed linear regression. We believe that the "sum-of-minimum" model can significantly improve ML performance when dealing with diverse and complex datasets.

1 - Reinforcement Learning for Infinite-Horizon Average-Reward MDPs with Multinomial Logistic Function Approximation

JAEHYUN PARK, KAIST, Daejeon, Korea, Republic of

We study model-based reinforcement learning with non-linear function approximation where the transition function of the underlying Markov decision process (MDP) is given by a multinomial logistic (MNL) model. In this paper, we develop two algorithms for the infinite-horizon average reward setting. Our first algorithm **UCRL2-MNL** applies to the class of communicating MDPs and achieves an **O(dD√ T)** regret, where **d** is the dimension of feature mapping, **D** is the diameter of the underlying MDP, and **T** is the horizon. The second algorithm **OVIFH-MNL** is computationally more efficient and applies to the more general class of weakly communicating MDPs, for which we show a regret guarantee of **O(d 2/5 sp(v*)T 4/5)** where **sp(v*)** is the span of the associated optimal bias function. We also prove a lower bound of **Ω(d √ DT)** for learning communicating MDPs with MNL transitions of diameter at most **D**. Furthermore, we show a regret lower bound of **Ω(dH3/2√K)** for learning **H**-horizon episodic MDPs with MNL function approximation where **K** is the number of episodes, which improves upon the best-known lower bound for the finite-horizon setting.

2 - Parameter-Free Algorithms for Performative Regret Minimization under Decision-Dependent Distributions

4 - Stochastic-Constrained Stochastic Optimization with Markovian Data

Yeongjong Kim, POSTECH, Pohang, Korea, Republic of, Dabeen Lee

This paper considers stochastic-constrained stochastic optimization where the stochastic constraint is to satisfy that the expectation of a random function is below a certain threshold. In particular, we study the setting where data samples are drawn from a Markov chain and thus are not independent and identically distributed. We generalize the drift-plus-penalty framework, a primal-dual stochastic gradient method developed for the i.i.d. case, to the Markov chain sampling setting. We propose two variants of drift-plus-penalty; one is for the case when the mixing time of the underlying Markov chain is known while the other is for the case of unknown mixing time. In fact, our algorithms apply to a more general setting of constrained online convex optimization where the sequence of constraint functions follows a Markov chain. Both algorithms are adaptive in that the first works without knowledge of the time horizon while the second uses AdaGrad-style algorithm parameters, which is of independent interest. We demonstrate the effectiveness of our proposed methods through numerical experiments on classification with fairness constraints.

Data-Driven Methods for Robust and Distributionally Robust Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Irina Wang, Princeton University, Princeton, NJ, United States

Co-Chair: Bartolomeo Stellato, Princeton University, Princeton, NJ, United States

1 - Beyond Absolute Continuity: a New Class of Dynamic Risk Measures

Jincheng Yang, The University of Chicago, Chicago, IL, United States, Rui Gao, Luhao Zhang

The modern theory of risk measures copes with uncertainty by considering multiple probability measures. While it is often assumed that a reference probability measure exists, under which all relevant probability measures are absolutely continuous, there are examples where this assumption does not hold, such as certain distributional robust functionals. In this talk, we introduce a novel class of dynamic risk measures that do not rely on this assumption. We will discuss its convexity, coherence, and time consistency properties.

2 - A Decision Rule Approach for Two-Stage Data-Driven Distributionally Robust Optimization Problems with Random Recourse

Xiangyi Fan, ExxonMobil, Spring, TX, United States, Grani Adiwena Hanasusanto

This research investigates two-stage stochastic optimization problems with random recourse, where the adaptive decisions are multiplied by the uncertain parameters in both the objective function and the constraints. To mitigate the computational intractability of infinite-dimensional optimization, we propose a scalable approximation scheme via piecewise linear and piecewise quadratic decision rules. Based on the decision rule structure, we develop a data-driven distributionally robust framework with two layers of robustness to address distributional uncertainty. Additionally, we establish out-of-sample performance guarantees for our proposed scheme. The resulting optimization problem can be reformulated as an exact copositive program, which allows for tractable approximations using semidefinite programming. Furthermore, we design a decomposition algorithm that enables parallel solution of smaller-size semidefinite programs, leading to reduced runtime. Through numerical examples, we empirically demonstrate that our method produces significantly better solutions with reasonable computational effort than the traditional sample-average approximation scheme, especially when the data is limited.

3 - Learning Decision-Focused Uncertainty Sets in Contextual Dynamic Optimization

Irina Wang, Princeton University, Princeton, NJ, United States, Bartolomeo Stellato

We propose a data-driven technique to automatically learn the uncertainty sets in robust optimization. Specifically, the uncertainty sets learned are based on contextual information and for a parametric family of adaptive robust optimization problems; using machine learning, we learn a mapping from context parameters to context-specific uncertainty sets. We formulate the problem using stochastic bi-level optimization, where in the outer level we minimize the expected loss of the data-driven decisions across the parametric family, subject to guaranteeing constraint satisfaction. In the lower level, we solve the parametric robust optimization problems for the data-driven decisions. Our approach is very flexible and can learn a wide variety of uncertainty sets while preserving tractability. We solve the constrained learning problem using a stochastic augmented Lagrangian method, and show convergence, under mild conditions, to a feasible solution. Numerical experiments show that our method outperforms traditional and non-contextual approaches in robust optimization in terms of out-of-sample performance and constraint satisfaction guarantees.

4 - Neur2RO: Neural Two-Stage Robust Optimization

Justin Dumouchelle, University of Toronto, Toronto, ON, Canada, Esther Julien, Jannis Kurtz, Elias B. Khalil

Robust optimization provides a mathematical framework for modeling and solving decision-making problems under worst-case uncertainty. This work addresses two-stage robust optimization (2RO) problems (also called adjustable robust optimization), wherein first-stage and second-stage decisions are made before and after uncertainty is realized, respectively. This results in a nested min-max-min optimization problem which is extremely challenging computationally, especially when the decisions are discrete. We propose Neur2RO, an efficient machine learning-driven instantiation of column-and-constraint generation (CCG), a classical iterative algorithm for 2RO. Specifically, we learn to estimate the value function of the second-stage problem via a novel neural network architecture that is easy to optimize over by design. Embedding our neural network into CCG yields high-quality solutions quickly as evidenced by experiments on two 2RO benchmarks, knapsack and capital budgeting. For knapsack, Neur2RO finds solutions that are within roughly 2% of the best-known values in a few seconds compared to the three hours of the state-of-the-art exact branch-and-price algorithm; for larger and more complex instances, Neur2RO finds even better solutions. For capital budgeting, Neur2RO outperforms three variants of the k-adaptability algorithm, particularly on the largest instances, with a 10 to 100-fold reduction in solution time. In addition, extensions to single-stage robust optimization will be presented.

5 - Enhancing Scalability for Two-Stage Distributionally Robust Optimization over 1-Wasserstein Balls

Geunyeong Byeon, Arizona State University, Tempe, AZ, United States

We present a decomposition algorithm along with several algorithmic enhancements designed to address two-stage distributionally robust optimization problems over 1-Wasserstein balls. Through a numerical analysis on a facility location problem with demand uncertainty, we highlight the potential benefits of employing a particular distance metric for enhanced out-of-sample performance, while also examining its computational trade-offs. Furthermore, we explore alternative approaches aimed at enhancing the scalability of our proposed algorithm.

Co-Chair: Jiawei Zhang, MIT, Cambridge, MA, United States

1 - Hardware-Efficient Deep Learning Algorithms: Foundation and Practice

Jiawei Zhao, Meta FAIR, Pasadena, CA, United States

In recent years, neural networks have demonstrated impressive performance across various disciplines, including conversational AI and scientific discovery. Training has become increasingly challenging due to the growing size of parameters and computational demands. On the other hand, the optimization algorithms (e.g., SGD and Adam), which are fundamental to deep learning, have remained largely unchanged. Although powerful, these classical algorithms may be inadequate for addressing the recent challenges in large-scale training, where hardware limitations are a primary bottleneck. In this talk, I will discuss my work on developing hardware-efficient learning algorithms that jointly consider the optimization and hardware constraints. Specifically, I will introduce my recent work GaLore, for memory-efficient training of large language models. GaLore projects gradients into low-rank subspaces to reduce memory requirements for optimizer states and gradients during training. It reduces total training memory by 63.3% while preserving modeling performance, as demonstrated in training LLaMA models from scratch on the C4 dataset. GaLore makes it feasible to pre-train the LLaMA 7B model on consumer GPUs with 24GB of memory (e.g., NVIDIA RTX 4090) without the need for model parallelism, checkpointing, or offloading strategies. In closing, I will discuss the challenges and opportunities for further enhancing the efficiency of training large language models.

2 - Analyzing the deep learning optimization in the easy way

Yingyu Liang, The University of Hong Kong, Hong Kong, China, People's Republic of

Deep learning is a key factor in the recent breakthroughs in artificial intelligence. Despite the empirical success, the theoretical understanding remains largely elusive, especially because of the challenges in analyzing the optimization involved. This talk will discuss why optimization is key for understanding deep learning, review the NTK analysis approach and its limitations, and present our recent effort to go beyond that.

3 - Landscape evolution of neural networks through the lens of neuron splitting

Tian Ding, Shenzhen Institute of Big Data, Shenzhen, China, People's Republic of

In the field of artificial intelligence, the size of neural networks has rapidly increased, resulting in deeper and wider models. While it is believed that increasing the width of a neural network enhances its training efficiency, the underlying mechanisms remain not fully understood. In this presentation, we investigate the evolution of the optimization landscape as network width increases. Specifically, we establish relationships between stationary points in shallow and wide networks through an operator known as "neuron splitting." Our analysis yields three theoretical insights as neural networks become wider. First, stationary points at the same loss levels become interconnected. Second, local minima transform into plateaus that predominantly include saddle points but may also contain local minima. Third, when the network width exceeds a certain threshold, there exists a non-increasing path from any stationary point to a global minimum. These findings provide a new understanding of the behavior and potential of wide neural networks, contributing to the ongoing development of more effective AI models.

4 - Diffusion Model for Data-Driven Black-Box Optimization

Zihao Li, Princeton University, Princeton, NJ, United States

Generative AI has redefined artificial intelligence, enabling the creation of innovative content and customized solutions that drive business practices into a new era of efficiency and creativity. In this paper, we focus on diffusion models, a powerful generative AI technology, and investigate their potential for black-box optimization over complex structured variables. Consider the practical scenario where one wants to optimize some structured design in a high-dimensional space, based on massive unlabeled data (representing design variables) and a small labeled dataset. We study two practical types of labels: 1) noisy measurements of a real-valued reward function and 2) human preference based on pairwise comparisons. The goal is to generate new designs that are near-optimal and preserve the designed latent structures. Our proposed method reformulates the design optimization problem into a conditional sampling problem, which allows us to leverage the power of diffusion models for modeling complex distributions. In particular, we propose a reward-directed conditional diffusion model, to be trained on the mixed data, for sampling a near-optimal solution conditioned on high predicted rewards. Theoretically, we establish sub-optimality error bounds for the generated designs. The sub-optimality gap nearly matches the optimal guarantee in off-policy bandits, demonstrating the efficiency of reward-directed diffusion models for black-box optimization. Moreover, when the data admits a low-dimensional latent subspace structure, our model efficiently generates high-fidelity designs that closely respect the latent structure. We provide empirical experiments validating our model in decision-making and content-creation tasks.

5 - Tuning-Free Stochastic Optimization

Ahmed Khaled, Princeton University, Princeton, NJ, United States, Chi Jin

Hyperparameter tuning is too costly to use in today's large-scale machine learning problems. This creates a need for algorithms that can tune themselves on-the-fly. We formalize the notion of "tuning-free" algorithms that can match the performance of optimally-tuned optimization algorithms up to polylogarithmic factors given only loose hints on the relevant problem parameters. We consider in particular algorithms that can match optimally-tuned Stochastic Gradient Descent (SGD). When the domain of optimization is bounded, we show tuning-free matching of SGD is possible and achieved by several existing algorithms. We prove that for the task of minimizing a convex and smooth or Lipschitz function over an unbounded domain, tuning-free optimization is impossible. We discuss conditions under which tuning-free optimization is possible even over unbounded domains. In particular, we show that the recently proposed DoG and DoWG algorithms are tuning-free when the noise distribution is sufficiently well-behaved. For the task of finding a stationary point of a smooth and potentially nonconvex function, we give a variant of SGD that matches the best-known high-probability convergence rate for tuned SGD at only an additional polylogarithmic cost. However, we also give an impossibility result that shows no algorithm can hope to match the optimal expected convergence rate for tuned SGD with high probability.

1 - Daily Opportunity Charging Scheduling for Electric Buses: Exact and Heuristic Methods

Dan McCabe, University of Washington, Seattle, WA, United States, Xuegang Ban, Balazs Kulcsar

Transit agencies across the world are transitioning to fully electric bus fleets. For many of these agencies, current battery range is not sufficient to cover all daily driving needs, so high-power opportunity charging will be an essential tool to extend effective range. However, introducing this extra activity into the service day can negatively impact passenger service if it is not planned carefully. Because opportunity chargers are expensive and scarce, uncoordinated charging can lead to extensive queuing at charging stations, creating delays for passenger trips later in the day. To avoid these issues, transit system operators should plan charging schedules in advance each day that minimize passenger delays while ensuring all buses stay sufficiently charged.

This work generates opportunity charging schedules with a novel model that directly tracks queuing at chargers in order to set and propagate departure delays. We solve the complex MILP model with two tailored algorithms (one exact, one heuristic) based on decomposition. Computational tests on both a simple notional transit network and the real-world bus system of King County, Washington demonstrate our methods' effectiveness. The heuristic algorithm in particular, which runs in polynomial time, is shown to generate near-optimal solutions quickly and scales well enough to apply to large bus networks.

2 - Operational Policy Design and Evaluation for Connected Pudo Facilities

Xinyu Liu, Georgia Tech ISyE, Atlanta, GA, United States

Pickup and drop-off (PUDO) facilities have long been essential in facilitating passenger transportation and goods delivery. Emerging mobility services, such as on-demand hailed rides and time-sensitive deliveries, create a need for frequent pickups and drop-offs of passengers and small shipments close to the end consumers. The pickups and drop-offs of passengers and goods are frequently observed at limited designated spaces on the curb. The scarcity of such spaces in dense urban areas, as opposed to the increasing demand, leads to safety and efficiency concerns arising from double-parking behaviors and unnecessary vehicle detours. Thus, carefully designed and operated PUDO facilities are much needed to fulfill this emerging demand. In this talk, I will introduce mathematical and computational models to optimize the long-term performance metrics under uncertainty. Unlike traditional quantitative methods, our stochastic models capture realistic vehicle conflicts and dependencies, thus unveiling new insights into facility operations. Our work also proposes and evaluates practical, interpretable, and implementable approximate operational policies with demonstrated near-optimality, envisioning a future with enhanced connectivity and computational power.

3 - Optimizing Autonomous Transfer Hub Networks: Quantifying the Potential Impact of Self-Driving Trucks

Kevin Dalmeijer, Georgia Institute of Technology, Atlanta, GA, United States, Chungjae Lee, Pascal Van Hentenryck, Peibo Zhang

Autonomous trucks are expected to fundamentally transform the freight transportation industry. In particular, Autonomous Transfer Hub Networks (ATHNs), which combine autonomous trucks on middle miles with human-driven trucks on the first and last miles, are seen as the most likely deployment pathway for this technology. This paper presents a framework to optimize ATHN operations and evaluate the benefits of autonomous trucking. By exploiting the problem structure, this paper introduces a flow-based optimization model for this purpose that can be solved by blackbox solvers in a matter of hours. The resulting framework is easy to apply and enables the data-driven analysis of large-scale systems. The power of this approach is demonstrated on a system that spans all of the United States over a four-week horizon. The case study quantifies the potential impact of autonomous trucking and shows that ATHNs can have significant benefits over traditional transportation networks.

4 - Noise-Aware and Equitable Urban Air Traffic Management: An Optimization Approach

Zhenyu Gao, The Hong Kong University of Science and Technology, Hong Kong SAR, Hong Kong, Yue Yu, Qinshuang Wei, Ufuk Topcu, John-Paul Clarke

Urban air mobility (UAM), a transformative concept for the transport of passengers and cargo, faces several integration challenges in complex urban environments. Community acceptance of aircraft noise is among the most noticeable of these challenges when launching or scaling up a UAM system. Properly managing community noise is fundamental to establishing a UAM system that is environmentally and socially sustainable. In this work, we develop a holistic and equitable approach to manage UAM air traffic and its community noise impact in urban environments. The proposed approach is a hybrid approach that considers a mix of different noise mitigation strategies, including limiting the number of operations, cruising at higher altitudes, and ambient noise masking. We tackle the problem through the lens of network system control and formulate a multi-objective optimization model for managing traffic flow in a multi-layer UAM network while concurrently pursuing demand fulfillment, noise control, and energy saving. Further, we use a social welfare function in the optimization model as the basis for the efficiency-fairness trade-off in both demand fulfillment and noise control. We apply the proposed approach to a comprehensive case study in the city of Austin and perform design trade-offs through both visual and quantitative analyses.

Simulation and Learning for Smart Transportation Systems

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Li Jin, 800 Dongchuan Lu, 200240

Co-Chair: Shenhao Wang, University of Florida, Gainesville, FL, United States

1 - Combining AI and Network Science for Transportation Network Planning

Zhan Zhao, University of Hong Kong, Hong Kong, China, People's Republic of

The advancement in machine learning and artificial intelligence (AI) technologies, coupled with the increasing prevalence of mobility big data, has profoundly transformed the ways we analyze, and understand, our transport systems. While current AI applications in transportation mostly focus on short-term demand forecasting and operations, long-term demand forecasting and transportation planning tasks have received less attention. As transportation systems are often organized in networks, it is necessary to account for the intricate spatial interactions along the network space in transportation planning. In this talk, I will discuss how AI can be combined with network science to enhance long-term travel demand forecasting to support transportation network planning decisions. Specifically, I will introduce a series of case studies, including the planning of bike sharing systems, metro systems, and street networks.

2 - Modeling Urban Traffic Data with Matrix and Tensor Factorization Approaches

Xinyu Chen, Massachusetts Institute of Technology, Cambridge, MA, United States

In urban systems, large amounts of human movement data, such as urban mobility and traffic flow, are readily available for implementing downstream tasks and supporting decision-making. Since these data are characterized by spatiotemporal dimensions and demonstrate data patterns of the systems, it is important to reformulate urban system problems with machine learning. In this talk, we introduce two scentific problems: 1) imputing missing values from partially observed traffic data, and 2) discovering spatial and temporal patterns from time-varying urban systems. Since these spatiotemporal data always (empirically) reveal low-rank properties and spatiotemporal correlations, we start from a sequence of low-rank matrix and tensor methods such as matrix/tensor factorization. To reinforce the model for building temporal correlations and dynamics, we integrate time series convolution and autoregression into the framework. In the modeling process, we intend to highlight the importance of temporal modeling in the low-rank matrix and tensor methods.

3 - Machine Learning for Large-Scale Combinatorial Optimization

Sirui Li, Cambridge, MIT, MA, United States

Combinatorial Optimization (CO) is widely used in transportation, with applications in Vehicle Routing, Scheduling to Logistics and Production Planning. However, solving CO problems can be time consuming. For instance, it takes over one hour to solve a Vehicle Routing problem with 2000 locations. In this talk, I will present several of my PhD projects on using machine learning to speed up combinatorial optimization. These include: (1) Learning to Delegate for Large-scale Vehicle Routing. This is a novel learning-augmented local search framework designed to solve large-scale VRPs. The method iteratively improves the solution by identifying appropriate subproblems and delegating their improvement to a black box subsolver. Our method accelerates state-of-the-art VRP solvers by 10x to 100x while achieving competitive solution qualities for VRPs with sizes ranging from 500 to 3000. (2) Learning to Configure Separators in Branch-and-Cut. Here, we focus on general-purpose Mixed Integer Linear Programming (MILP) solvers. We identify that MILP solvers can be drastically accelerated by appropriately selecting separators to activate. As the combinatorial separator selection space imposes challenges for machine learning, we learn to separate by proposing a novel data-driven strategy to restrict the selection space and a learning-guided algorithm on the restricted space. Our method predicts instance-aware separator configurations which can dynamically adapt during the solve, effectively accelerating the open source MILP solver SCIP by improving the relative solve time up to 72% and 37% on synthetic and real-world MILP benchmarks.

4 - Towards Financial Viability for Electric Mobility: Explore Profitability Models for Electric Vehicle Owners

Anqi Han, Hong Kong University of Science and Techonology(Guangzhou), Guangzhou, China, People's Republic of

Efforts to mitigate climate change enable Electric Vehicle (EV) as a sustainable alternative of transportation to conventional ones. Meanwhile, Vehicle-to-Grid (V2G) technology provides EV stakeholders with an energy trading market, where EVs can provide services directly to the grid. Sets of business models have been under discussion to create economic values for V2G integration. To bridge the gap between theoretical V2G concepts and practical applications, this paper chose to study Vehicle-to-Building (V2B) configurations, extending to private and public charging scenarios. We emphasize exploring EV owner's profitability under arbitrage trading conditions, where EVs are charged either at home or at public charging stations, and subsequently provide energy to workplace. First, a synthetic dataset of EV travel profiles is generated using the Monte Carlo simulation approach, incorporating stochastic elements to reflect real-world variability. Then actions to charge, discharge, or to take no actions are determined by EV's State of Charge (SoC) and its daily trip constrains. Next, a mixed integer Linear Programming approach is applied to model the profitability of EV owners, considering the total costs embedded in each charge/discharge cycle and cumulative returns gained from V2G participation. Specifically, the novel contribution of this paper lies in attaching financial attributes to EVs. The core idea is to design a progressive time-based V2G incentive pricing that reflects the value of a vehicle's availability time to discharge. Our findings indicate that incorporating financial attributes into EVs not only underscores the economic viability for individual EV owners but also facilitates the practical integration of V2G technologies.

5 - Optimizing Food Delivery Services: Reinforcement Learning for Enhanced Efficiency and Equity

Yi Fan, Tongji University, Shanghai, China, People's Republic of

Food delivery services have become very popular in recent years. As delivery demand increases exponentially, optimizing the efficiency and safety of these services has become increasingly crucial. In this work, we utilize a combination of operations research and artificial intelligence within a gridded rider delivery environment to analyze and predict rider delivery route selection and order preferences. By integrating these factors into the objective function of our reinforcement learning model, we assess the reasonableness of the current dispatch data used by Meituan. Ultimately, by explicitly accounting for rider behavior and transportation equity, the platform can develop and optimize dispatch assignments that lower costs for the system as a whole – a rare win-win outcome.

Summit - 430

Machine Learning Application in Aviation

Invited Session

Aviation Applications

Chair: Xiyitao Zhu, University of Illinois Urbana-Champaign, Champaign, IL, 61822, United States

1 - Learning for Aircraft Trajectory Optimization in the Airspace

Xiyitao Zhu, University of Illinois Urbana-Champaign, Champaign, IL, United States, Jing Gao, Lavanya Marla, Ankur Mani

In the US National Aviation System (NAS), aircraft rely on weather information for routing decisions. We propose that using en-route aircraft as sensors to collect updated weather information at the right place and right time maintains high-quality weather information that benefits the NAS. Motivated by the spatial and temporal correlations in weather, we propose a novel modeling framework for routing decisions on (airspace) networks with non-stationary Gaussian bandits, temporal information diffusion, and in particular, with combinatorial path structures. Our framework is also applicable to intra-city aircraft and unmanned aircraft such as UAVs and drones.

2 - ML models for hotspots' identification

Guglielmo Lulli, University of Milano Bicocca, Milano, Italy, Sameer Alam, Davide Falanga, Giacomo Lancia, Bizhao Pang

In this talk, I will present some of the outcomes of the Italy-Singapore AI4ATM research project, co-funded by MIUR and A*STAR, focusing on the application of machine learning models for the analysis of air traffic trajectories and hotspots' identification and prediction. Additionally, I will discuss strategies for resolving these hotspots.

3 - Benefits of Slot Substitutions for Airlines during Ground Delay Programs

Jing Xu, University of California, Berkeley, Berkeley, CA, United States

Slot substitution is one part of Collaborate Decision Making (CDM). This policy provides airlines some flexibility during Ground Delay Programs (GDPs). This paper simulates how airlines perform slot substitutions and estimates benefits of slot substitutions for American Airlines during GDPs. We assume an optimization model to minimize delay cost for airline slot substitution. By synthetic data and substitution simulation, we calibrate the model by finding parameter values that produce a close match between modeled and observed distributions of slot substitution frequencies for American Airlines, Delta Airlines, and United Airlines. We can infer that the three major airlines may willing to sacrifice a maximum of 7.34 hours of delay for each flight to avoid step-costs caused by misconnection issues. These three airlines saves about $49.4 million dollars from being able to perform slot substitutions in 991 GDPs in 2019. The savings from slot substitution are sensitive to GDP airports.

4 - Feature-based Pricing for Airline Ancillary Products

Xiao JIN, NUS Institute of Operations Research and Analytics, National University of Singapore, Singapore, Singapore, Changchun Liu, Chung Piaw Teo

This study addresses the challenge of feature-based pricing with limited price experiments. As the airline industry strives for customized pricing through refined feature-based customer segmentation, calibrating the underlying models becomes more challenging. With limited seats per flight, the maximum transactional data acquired remains constrained. Traditional calibration methods, such as Maximum Likelihood Estimation (MLE), often fail to provide stable feature-based pricing under these conditions. Our approach addresses this stability issue by calibrating a feature-based Marginal Exponential Model (MEM) through minimizing market share discrepancy. This method stabilizes with less data, enabling a reliable pricing for each segment. Applied to luggage pricing for Flyscoot, a low-cost carrier, our feature-based pricing strategy assesses how each feature influences customer choices, leading to more profitable pricing decisions. These findings suggest that when data is limited, calibration that minimizes share discrepancy is not only feasible but also superior in terms of solvability and stability. This approach offers a refined solution for airlines aiming to enhance ancillary pricing strategies in a competitive market. Additionally, this method can extend to other industries where feature-based pricing and customer segmentation are essential but constrained by limited price experiments.

Railway Technology Innovations and Modeling

Invited Session

Railway Applications

Chair: Carl Van Dyke, TransNetOpt, 6 Snowbird Ct, West Windsor, NJ, 08550, United States

1 - Changing Tank Car Markets and Demand Drivers

Daniel Windle, TrinityRail, Dallas, TX, United States

Compared to the shale boom of the mid-2010s, the market drivers for tank car demand are more varied and will require coordination between shippers, car owners, and railroads to make sure the market is served. This presentation will review some of the drivers for tank car demand and what analytical solutions may be needed to start to account for these changes.

2 - OR-related fleet modeling approaches at TTX Co.

Muhannad Ramahi, TTX Company, Chicago, IL, United States

Automobile manufacturers (shippers) provide railroad companies with annual forecasts of their monthly shipping volumes from various origins to different destinations. The railroad companies (carriers) jointly operate pools of railcars to transport automobiles. Each pool comprises equipment of a particular type and serves one or more shippers. RELOAD, a fleet management group within TTX (an independent company), manages the repositioning of empty railcars of each type for the carriers. The problem is to determine the smallest fleet size that will provide adequate service

3 - Using AI for cleaning of waybills and other data

Daril Vilhena, CEDAR, Seattle, WA, United States

Railroads have significant issues with inconsistent and bad data, as well as applying various overrides to shipping instructions. Traditionally these issues have been addressed by using static rules tables and replacement (alias) tables to "fix" or "override" the offending data fields. AI offers the opportunity to automate this correction process, reducing or eliminating the cumbersome rules tables, improving accuracy, maintainability of their systems and reducing labor requirements.

4 - Parallel Systems' Autonomous Rail Vehicles: Development and Applications

Marty Schlenker, Parallel Systems, Mechanicsburg, PA, United States

Marty Schlenker, Head of Strategy for Parallel Systems, will provide an update on the development of Parallel Systems' autonomous, battery-electric rail vehicles, including Parallel's viewpoints on their ability to attract freight from truck to rail in specific applications and their interoperation with conventional trains on rail networks.

Responsible Research in Behavioral Operations

Invited Session

Behavioral Operations Management

Chair: Karen Donohue, University of Minnesota, Minneapolis, MN, United States

Co-Chair: Yeonjoo Lee, University of Minnesota, Minneapolis, MN, United States

1 - Nudging Green-but-Slow Shipping in Online Retail

Yeonjoo Lee, University of Minnesota, Minneapolis, MN, United States, Karen Donohue

Faster e-commerce fulfillment often comes at an environmental cost by using more energy-intensive transportation modes or more frequent, less consolidated, last mile delivery. While faced with these externalities, retailers still feel pressure to provide fast delivery to stay competitive. But, what if consumers could be nudged to choose a green but slow shipping option? In practice, a variety of information strategies are used to nudge such decisions, but it remains unclear which strategy fits a given logistical context and why. We examine these questions in two logistical contexts: no-rush shipping and consolidated shipping. Drawing from practice and behavioral research, we identify a comprehensive set of information strategies for both contexts and develop a theory to inform effective strategies based on their ability to overcome psychological barriers.

2 - Selection, Payment, and Information Assessment in Social Audits: A Behavioral Experiment

Gabriel Alfonso Pensamiento Calderon, University of Pittsburgh, Pittsburgh, PA, United States, Leon Valdes

Companies often rely on third-party social audits to assess suppliers' social responsibility (SR) practices. However, empirical evidence suggests these audits can often be too lenient and poor practices go unreported, particularly if the auditor feels beholden to the supplier. We design and conduct an incentivized lab experiment to study how a supplier choosing and/or paying the auditor affects audit reports. We explore whether and how these levers affect auditors' assessment of noisy signals about the supplier's practices, and investigate the role of two behavioral phenomena: motivated reasoning and reciprocity. We find that auditors who are paid and chosen by the supplier are more lenient, with the effect more pronounced when the information observed suggests poor SR practices. We do not find evidence of auditors being more likely to believe the supplier has good practices when chosen by it. Conversely, reciprocity towards the supplier plays an important role behind our results. Finally, auditors who are merely paid by the supplier are not more lenient, which offers good news for practitioners. Our results can help guide companies' auditing and procurement policies. First, they show that removing a supplier's ability to choose its own auditor is critical to increase detection of poor SR practices, particularly when the risk of them is high. Second, removing the suppliers' ability to choose their auditor—while still paying them—might be enough to reduce leniency. Finally, our findings shed light on some of the behavioral drivers behind auditors decisions, which can guide interventions to mitigate audit leniency.

3 - Using Behavioral Nudges to Reduce Food Wastage in Ghana: Evidence from a Field Experiment

Mahyar Eftekhar, Arizona State University, Tempe, AZ, United States, Xinming Liu, Yanchong Zheng, Richard Boso

Research indicates that food waste is a global issue affecting countries across various income levels, with about 931 million tonnes—or 17% of consumer-available food—being discarded in 2019. Meanwhile, nearly 3 billion people worldwide cannot afford a nutritious diet. This study showcases a straightforward, practical method aimed at reducing food waste by focusing on the food preparation processes in restaurants, which contribute to approximately 26% of the total waste.

4 - Matching Volunteers with Clients in a Non-Profit Organization

Ravi Subramanian, Georgia Tech, Atlanta, GA, United States, Shikha Safaya, Basak Kalkanci

Non-profit organizations (NPOs) are often challenged with volunteer participation and retention in the absence of monetary incentives. Based on rich survey data collected in collaboration with our NPO partner, we observed that volunteers and clients have heterogenous preferences: some prefer the base service only, while others prefer the differentiated service that includes interpersonal interactions besides the basic meal delivery service. We build upon this insight to study volunteer management policies by comparing two task assignment policies: a pooled policy that groups volunteers together irrespective of their task preferences; and a preference-based policy that incorporates volunteer preferences for task assignment. Our study explores the tradeoff between incorporating volunteer preferences in task assignments versus pooling volunteers to alleviate mismatch between supply and demand. We endogenize volunteers' participation decisions based on their utility from volunteering as well as their outside commitments. We analytically derive the conditions under which a particular policy may be preferred by all the stakeholders (the non-profit, volunteers, and clients). Our results shed light on managerial levers that NPOs can deploy to improve client welfare and volunteer utility. Thus, our model insights highlight alternatives to simply pooling volunteers into a single bucket, and offer prescriptive insights for NPOs to advance their service missions and enhance volunteer engagement.

Advancements in Optimal Control of Queues: Innovations and Applications

Invited Session

Applied Probability Society

Chair: Hayriye Ayhan, ISyE Georgia Tech, Atlanta, GA, United States

Co-Chair: Xinchang Wang, Washington State University, Pullman, WA, United States

1 - A Randomized Routing Control for A Non-Stationary Finite Horizon Multi-Class and Multi-Server Queueing System

Amy Cochran, University of Wisconsin Madison, Madison, WI, United States, Gabriel Zayas-Caban

We consider a non-stationary finite-horizon problem with multiple job classes and finite-capacity service facilities, where any number of jobs may be assigned at any time, there are facility-dependent constraints on the number of class groups allowed in each facility, and service rates are facility-dependent. A heuristic for routing jobs in this system is proposed and shown to be asymptotically optimal.

2 - Discrete-Review Control of Queueing Networks

Mir Mikdad Talpur, University of Toronto, Toronto, ON, Canada, Vahid Sarhangian

Optimal control of stochastic queueing networks which are used in modeling and analysis of service systems (e.g., hospitals, contact centers, and ride/bike sharing systems) has been the subject of extensive research. The literature is predominantly concerned with continuous-time control, whereby the controller can interact with the system at any point in time. In many service settings, however, the system manager can only interact with the system at discrete and possibly long time-intervals. That is, although relevant information is becoming available, the controller cannot exercise control before the beginning of the next review time. Our main objective is to develop fundamental insights on the impact of imposing the discrete-review limitation on the performance of dynamic control policies. A key question we will answer is the effect on the value function of the optimal control problem as the length of the review period is varied, for a general formulation of queueing control problems. We work with a generic continuous-time control problem where we restrict operational control to the start of fixed time-intervals. Due to the intractability of the transition probabilities under discrete-time control in an exact Markov Decision Processes (MDP) approach that makes the analysis intractable, we instead work with the associated fluid control problems that are justified through Functional Strong Law of Large Numbers (FSLLN) for appropriately scaled sequence of the underlying processes. We then investigate partial derivatives of the value function with respect to the period lengths.

3 - Estimating Ship Arrival Rates and Charterer Taste Coefficients with Unobservable Balking

weikun xu, Washington State University, Pullman, WA, United States, Xinchang Wang

This work investigates the joint estimation of the ship arrival rate, service rate, and charterer taste coefficients for a port terminal using ship data. The service process at the terminal, including ship berthing and cargo loading/unloading, is modeled as an M/M/1 queue. Incoming ships decide whether to use the terminal or balk based on a multinomial logit (MNL) model that maps the taste coefficients of ship charterers to choice probabilities. The problem is challenging since the data are censored as balking ships are not observed. We formulate the estimation problem as a maximum likelihood estimation model. We characterize the conditions for model parameters to be identified or uniquely determined. Algorithms are developed to solve the problem and their performances are evaluated against benchmark algorithms.

4 - Optimal Pricing with Impatient Customers

Jieqi Di, ISyE Georgia Tech, Atlanta, GA, United States, Sigrun Andradottir, Hayriye Ayhan

We investigate the optimal pricing strategy in a service-providing framework, where customers can become impatient and leave the system prior to completing service. In this setting, a price is quoted to an incoming customer based on the current number of customers in the system. When the quoted price is lower than the price the incoming customer is willing to pay (which follows a fixed probability distribution), then the customer joins the system and a reward equal to the quoted price is earned. A fixed cost is incurred upon abandonment and a holding cost is incurred for customers waiting to be served. Our goal is to determine the optimal pricing policy that maximizes the long-run average revenue. Our analysis shows that under reasonable assumptions, the optimal quoted price increases as the number of customers in the system grows. Using this insight, we propose a monotone policy iteration algorithm that efficiently computes the optimal pricing policy. Moreover, we introduce a heuristic that charges a fixed price until the number of customers in the system reaches a certain threshold. By selecting the optimal threshold that maximizes the long-run average gain, the heuristic achieves near optimality. We provide an efficient algorithm to find that optimal threshold.

The Power of Optimization in Sequential Decision Making

Invited Session

Applied Probability Society

Chair: Adam Block, MIT, Cambridge, MA, United States

Co-Chair: Abhishek Shetty, University of California, Berkeley, Berkeley, CA, United States

Co-Chair: Sasha Rakhlin, MIT, Cambridge, MA, United States

1 - Empirical Risk Minimization Beyond Independent Data

Adam Block, MIT, Cambridge, MA, United States, Sasha Rakhlin, Abhishek Shetty

In order to circumvent statistical and computational hardness results in sequential decision-making, recent work has considered smoothed online learning, where the distribution of data at each time is assumed to have bounded likeliehood ratio with respect to a base measure when conditioned on the history. While previous works have demonstrated the benefits of smoothness, they have either assumed that the base measure is known to the learner or have presented computationally inefficient algorithms applying only in special cases. This work investigates the more general setting where the base measure is \emph{unknown} to the learner, focusing in particular on the performance of Empirical Risk Minimization (ERM) with square loss when the data are well-specified and smooth. We show that in this setting, ERM is able to achieve sublinear error whenever a class is learnable with iid data; in particular, ERM achieves error scaling as
with the statistical complexity of learning the function class with iid data. In so doing, we prove a novel norm comparison bound for smoothed data that comprises the first sharp norm comparison for dependent data applying to arbitrary, nonlinear function classes. We complement these results with a lower bound indicating that our analysis of ERM is essentially tight, establishing a separation in the performance of ERM between smoothed and iid data.

2 - Is Behavior Cloning All You Need? Understanding Horizon in Imitation Learning

Dylan Foster, Microsoft Research, New York, NY, United States, Adam Block, Dipendra Misra

Imitation learning (IL) aims to mimic the behavior of an expert in a sequential decision making task by learning from demonstrations, and has been widely applied to robotics, autonomous driving, and autoregressive language generation. The simplest approach to IL, behavior cloning (BC), is thought to incur sample complexity with unfavorable quadratic dependence on the problem horizon, motivating a variety of different online algorithms that attain improved linear horizon dependence under stronger assumptions on the data and the learner's access to the expert.

In this talk, we revisit the apparent gap between offline and online IL from a learning-theoretic perspective, with a focus on general policy classes up to and including deep neural networks. Through a new analysis of behavior cloning with the logarithmic loss, we will show that it is possible to achieve *horizon-independent* sample complexity in offline IL whenever (i) the range of the cumulative payoffs is controlled, and (ii) an appropriate notion of supervised learning complexity for the policy class is controlled. When specialized to stationary policies, this implies that the gap between offline and online IL is not fundamental. We will then discuss implications of this result and investigate the extent to which it bears out empirically.

3 - Online Estimation via Offline Estimation: An Information-Theoretic Framework

Jian Qian, MIT, Cambridge, MA, United States, Dylan Foster, Yanjun Han, Alexander Rakhlin

The classical theory of statistical estimation aims to estimate a parameter of interest under data generated from a fixed design ("offline estimation"), while the contemporary theory of online learning provides algorithms for estimation under adaptively chosen covariates ("online estimation"). Motivated by connections between estimation and interactive decision making, we ask: is it possible to convert offline estimation algorithms into online estimation algorithms in a black-box fashion? We investigate this question from an information-theoretic perspective by introducing a new framework, Oracle-Efficient Online Estimation (OEOE), where the learner can only interact with the data stream indirectly through a sequence of offline estimators produced by a black-box algorithm operating on the stream. Our main results settle the statistical and computational complexity of online estimation in this framework. Statistical complexity. We show that information-theoretically, there exist algorithms that achieve near-optimal online estimation error via black-box offline estimation oracles, and give a nearly-tight characterization for minimax rates in the OEOE framework. Computational complexity. We show that the guarantees above cannot be achieved in a computationally efficient fashion in general, but give a refined characterization for the special case of conditional density estimation: computationally efficient online estimation via black-box offline estimation is possible whenever it is possible via unrestricted algorithms. Finally, we apply our results to give offline oracle-efficient algorithms for interactive decision making.

4 - Oracle-Efficient Differentially Private Learning with Public Data

Zhiwei Steven Wu, CMU, Pittsburgh, PA, United States

Due to statistical lower bounds on the learnability of many function classes under privacy constraints, there has been recent interest in leveraging public data to improve the performance of private learning algorithms. In this model, algorithms must always guarantee differential privacy for the private samples while also ensuring learning guarantees when the private data distribution is sufficiently close to that of the public data. Previous work has demonstrated that when sufficient public, unlabelled data is available, private learning can be made statistically tractable, but the resulting algorithms have all been computationally inefficient. In this work, we present the first computationally efficient, algorithms to provably leverage public data to learn privately whenever a function class is learnable non-privately, where our notion of computational efficiency is with respect to the number of calls to an optimization oracle for the function class. In addition to this general result, we provide specialized algorithms with improved sample complexities in special cases when the function class is convex or when the task is binary classification.

Joint work with Adam Block, Mark Bun, Rathin Desai, and Abhishek Shetty.

Stochastic Systems

Invited Session

Applied Probability Society

Chair: Mark Squillante, IBM Research, Mathematical Sciences, Thomas J. Watson Research Center, Yorktown Heights, NY, 10958, United States

1 - An Efficient High-dimensional Gradient Estimator for Stochastic Differential Equations

Jose Blanchet, Stanford University, Stanford, CA., CA, United States, Shengbo Wang, Peter Glynn

Overparameterized stochastic differential equation (SDE) models have achieved remarkable success in various complex environments, such as PDE-constrained optimization, stochastic control and reinforcement learning, financial engineering, and neural SDEs. These models often feature system evolution coefficients that are parameterized by a high-dimensional vector in the n-dimensional Euclidian space, aiming to optimize expectations of the SDE, such as a value function, through stochastic gradient ascent. Designing efficient gradient estimators for which the computational complexity scales well with n is of significant interest. We introduce a novel unbiased stochastic gradient estimator—the generator gradient estimator—for which the computation time is relatively insensitive to the size n of the parameter space. We discuss unbiasedness and finite variance of the estimator, but also perform numerical experiments that test our estimator in large linear-quadratic control problems parameterized by high-dimensional neural networks. The results show a significant improvement in efficiency compared to the widely used path-wise differentiation method: Our estimator achieves near-constant computation times, increasingly outperforms its counterpart as n increases, and does so without compromising estimation variance.

2 - Long-Time Behavior of Interacting Diffusions on Sparse Graphs

Kevin Hu, Brown University, Providence, RI, United States

We study the long-time behavior of a Conditional McKean-Vlasov (CMVE) equation arising in the study of interacting diffusions on regular trees. We construct a Lyapunov function on the space of probability measures for the weak solution of the CMVE and prove exponential convergence to equilibrium.

3 - Prediction-Enhanced Monte Carlo: A Machine Learning View on Control Variate

Henry Lam, Columbia University, New York, NY, United States, Agostino Capponi, Haoxian Chen, Fengpei Li, Jiahe Lin, Yuriy Nevmyvaka

Despite being an essential tool across engineering and finance, Monte Carlo simulation can be computationally intensive, especially in large-scale, path-dependent problems that hinder straightforward parallelization. A natural attempt is to replace simulation with machine learning or surrogate prediction, but at the expense of a more opaque understanding of the incurred errors. In this talk, we present a Prediction-Enhanced Monte Carlo (PEMC) framework where we leverage machine learning prediction as control variates, thus maintaining unbiased evaluations compared to the direct use of these predictors. On the other hand, unlike existing control variate approaches that rely on mean knowledge and aim for per-sample variance reduction, PEMC takes an expanded perspective on overall-cost-based variance reduction that removes the need of mean knowledge. We demonstrate how PEMC can outperform well-established control variates in traditional problems, and apply in cases where no good control variates are known. We illustrate our effectiveness in two production-grade exotic option-pricing problems, namely swaption with the Heath-Jarrow-Morton model and variance swap with a stochastic local volatility model.

4 - On Efficient Solutions of Structured Markov Processes in Quantum Computational Environments

Mark Squillante, IBM Research, Mathematical Sciences, Yorktown Heights, NY, United States

We study the fundamental problem of efficiently computing the stationary distribution of general classes of structured Markov processes. In strong contrast with previous work, we consider this problem within the context of quantum computational environments from a mathematical perspective and devise the first quantum algorithms for computing the stationary distribution of structured Markov processes. We derive a mathematical analysis of the computational properties of our quantum algorithms together with related theoretical results, establishing that our quantum algorithms provide the potential for significant computational improvements over that of the best-known classical algorithms in various settings of both theoretical and practical importance. Although motivated by structured Markov processes, our quantum algorithms have the potential for being exploited to address a much larger class of numerical computation problems.

Simulation (tentative title)

Invited Session

Simulation Society

Chair: Wei Xie, Northeastern University, Boston, MA, United States

1 - Algorithms for Efficient Design of Simultaneous Controlled Experiments in the Presence of Subject Covariates

William Fisher, Clemson University, Clemson, SC, United States, Qiong Zhang

Algorithms for Efficient Design of Simultaneous Controlled Experiments in the Presence of Subject Covariates William Fisher and Qiong Zhang School of Mathematical and Statistical Sciences, Clemson University Abstract: Controlled experiments are a form of experiment that allows one to analyze a proposed treatment by comparing responses between a treatment group and control group. Researchers or organizations may run multiple, separate controlled experiments simultaneously due to time, budget, or other considerations. In this setting, subjects often participate in more than one experiment, and thus responses across experiments coming from the same subject are not independent. In addition, outside of the treatment, certain subject covariates may be explanatory factors in the subject's response to each experiment. In this talk, we consider the optimal experimental design problem of allocating subjects to treatment or control when subjects must participate in multiple controlled experiments simultaneously and subject covariate information is available. The goal of the allocation is to provide precise estimates of treatment effects for each experiment. Deriving the precision matrix of the treatment effects in this setting and using D-optimality as our allocation criterion, we propose algorithms which provide solutions to the D-optimality problem. These algorithms decompose the D-optimality problem into a sequence of subproblems, where each subproblem can be solved either through integer programming or a semi-definite programming based randomized algorithm that originates from the MAXCUT problem. We showcase the performance of our allocation algorithms and demonstrate other properties of the algorithms through a suite of simulation studies.

2 - Variance Reduction Based Experience Replay for Policy Optimization

Wei Xie, Northeastern University, Boston, MA, United States, Hua Zheng, Mingbin Feng

For reinforcement learning on complex stochastic systems, it is desirable to effectively leverage the information from historical samples collected in previous iterations to accelerate policy optimization. Classical experience replay treats all observations uniformly, neglecting their relative importance. To address this limitation, we introduce a novel Variance Reduction Experience Replay (VRER) framework, enabling the selective reuse of relevant samples to improve policy gradient estimation. VRER, as an adaptable method that can seamlessly integrate with different policy optimization algorithms, forms the foundation of our sample efficient off-policy learning algorithm known as Policy Gradient with VRER (PG-VRER). Furthermore, the lack of a rigorous understanding of the experience replay approach in the literature motivates us to introduce a novel theoretical framework that accounts for sample dependencies induced by Markovian noise and behavior policy interdependencies. This framework is then employed to analyze the finite-time convergence of the proposed PG-VRER algorithm, revealing a crucial bias-variance trade-off in policy gradient estimation: the reuse of older experience tends to introduce a larger bias while simultaneously reducing gradient estimation variance. Extensive experiments have shown that VRER offers a notable and consistent acceleration in learning optimal policies and enhances the performance of state-of-the-art (SOTA) policy optimization approaches.

3 - Efficient Nested Simulation for Risk Measurement: a Decoupling Approach

Nifei Lin, Fudan University, Shanghai, China, People's Republic of, Yingda Song, Jeff Hong

Estimating risk measures in real-time is essential for effective risk management but poses significant challenges, particularly when managing complex portfolios influenced by numerous risk factors. Traditional methods, relying on simplified models with analytical solutions, compromise accuracy for speed. Recent advances in nested simulations have enabled more realistic modeling, yet these methods are not sufficiently efficient for real-time application. We introduce a novel framework that decouples nested simulation into an offline learning phase for accurate loss surface fitting and an online application phase for rapid risk factor simulation. This approach significantly enhances computational efficiency and offers the flexibility to adapt various smoothing techniques for surface fitting. We demonstrate the framework's effectiveness by applying it to estimation of the systemic risk measure, CoVaR, a task that poses significant challenges under conventional nested simulation setups. Our results show that our method achieves superior convergence rates, presenting a significant advancement in real-time risk management.

4 - Langevin Diffusion-Based Linear Noise Approximation for Bioprocessing Mechanistic Model Bayesian Inference

Wandi Xu, Northeastern University, Boston, MA, United States, Wei Xie

Driven by the critical challenges in the bioprocess mechanistic and hybrid model inference, we propose a novel Bayesian inference approach called Langevin diffusion-base linear noise approximation (LD-LNA) to efficiently generate posterior samples. It is inspired by a combination of two mechanisms, i.e., Langevin diffusion from Metropolis-adjusted Langevin algorithm (MALA) and linear noise approximation (LNA). The Langevin diffusion leverages the gradient information from the target posterior to improve the mixing rate of the classic random walk-based MCMC sampling approach, while the LNA helps to bypass the difficult task of step size selection in the original MALA. We show that the convergence of the proposed LD-LNA to the desired posterior distribution under certain conditions. Further, we provide a quantitative bound to assess its finite-sample performance. Numerical experiments inspired by the real-world problems in the biomanufacturing processes demonstrate the effectiveness of the proposed algorithm, showing its potential to guide the most “informative” data collection to reduce model uncertainty and support optimal robust decision making.

5 - Development of subsampling methods for Multi-Fidelity optimization with constraints

Shun Tanaka, Osaka University, Suita, Japan, Hiroshi Morita

Multi-fidelity optimization is a method that integrates computational models of various complexities. It is suitable for situations where high-accuracy computations are costly, but time and costs can be reduced with low-accuracy models. For example, during the optimization of hyperparameters in deep learning, strategies for pruning and resource allocation can be considered by utilizing intermediate epoch evaluation values. By deciding the proportion of the total to be sampled and constructing a low-fidelity model, it is possible to accelerate the process over time. In this case, there is a trade-off between time and the optimal solution, so care must be taken. We have devised a method to reduce optimization time by generating different fidelity models through subsampling and incorporating the relationship between models into sequential model-based optimization.

Innovative Interventions for Advancing Public Health

Invited Session

Health Applications Society

Chair: Amir Karimi, The University of Texas at San Antonio, San Antonio, TX, United States

1 - When Should Fractional-Dose Vaccines be Used?

Naireet Ghosh, London Business School, London, United Kingdom, Francis de Véricourt, Jérémie Gallien

Vaccination campaigns often face challenges such as limited stockpiles, delivery delays, and constrained administration capacity. In such contexts, fractional-dose vaccines have been described in the medical literature as a possible strategy because their efficacy reduction is typically less substantial than dose reduction, allowing for greater population coverage. We seek to determine the optimal use and potential benefits of a fractionated vaccine dose with lower and more uncertain efficacy, given the specific operational constraints faced in a vaccination campaign. We employ a Susceptible-Infected-Recovered (SIR) epidemic model integrating vaccination with full- and fractional-doses over time. We embed it within a deterministic optimal control model aimed at identifying vaccination policies that minimize total infections during an epidemic, taking into account restrictions on vaccine stockpile, delivery rate, and administration. Using a statistical approach from clinical literature for estimating the uncertainty around fractional-dose efficacy, we conduct two case-studies reflecting real-world scenarios. Our theoretical analysis provides an intuitive characterization of the optimal vaccination policy which, depending on the epidemic and operational parameters, may utilize a combination of full- and fractional-dose vaccines, either simultaneously or sequentially. We also examine simpler policies that employ a single vaccine dosage throughout the epidemic. Our findings suggest that, while single-dosage policies can be almost as effective as the optimal policy in averting infections, they are not as robust to the uncertainty affecting fractional-dose efficacies. We conclude that fractional-dose vaccines, used either alone or in conjunction with full-dose vaccines, present an opportunity to significantly reduce infections during an epidemic in resource-constrained settings.

2 - Strengthen Blood Transfusion System in Africa: Motivating Donations with Utility-Based Blood Drive Planning and Strategic Advertising

Yiqi Tian, University of Pittsburgh, Pittsburgh, PA, United States, Bo Zeng, Jayant Rajgopal, Bopaya Bidanda, Pratap Kumar, Juan Puyana

Blood transfusion is a critical medical intervention that saves millions of lives annually. However, in many low- and middle-income countries, the blood supply often faces significant shortages with many deaths that actually are preventable. To address this critical issue, our presentation introduces a novel two-stage, multi-period optimization model designed to enhance the blood supply system through utility-based blood drive planning and strategic advertising. The model focuses on increasing the willingness to donate blood by incorporating various uncertainties associated with human behavior. It uniquely integrates decision-dependent uncertainty and ambiguity sets, allowing decision-makers to consider how their strategies may influence donor’s behavior over time. We will detail the model’s features, demonstrate its practical applications, and discuss its potential to improve blood availability and save lives in resource-limited settings.

3 - Modeling People's Decisions on Npi Compliance and Vaccination Willingness

Geonsik Yu, Purdue University, West Lafayette, IN, United States, Michael Garee, Mario Ventresca, Yuehwern Yih

Protecting public health from infectious diseases often requires a collective effort from community members. Individual decisions regarding vaccination, hand-washing, social distancing, and mask-wearing can collectively have an external effect or synergy in disease mitigation. The challenge is that the information individuals use for their decision-making may be limited due to their choice of information sources. Additionally, their reasonable decisions, based on situations such as resource availability, can inadvertently lead to outcomes unfavorable to the entire system. Recognizing the crucial role of each individual's choices is paramount to ensuring the overall effectiveness of public health measures.

To understand how people make decisions in response to a spreading disease, we developed decision-making scenarios from an individual’s perspective based on insurance theory and sequential decision trees. We then designed the corresponding agent-based simulation framework to model the consequences of individual decisions and examine the effects of various opinion interventions for disease mitigation. Our focus is on people's decisions in the context of a pandemic, where they can choose either to wear a mask or not and either to get vaccinated or not, aiming to minimize potential losses due to infectious diseases. We calibrated the agent-based simulation model to the empirical data of the COVID-19 pandemic to generate realistic testbeds for our study. Additional datasets were also incorporated to capture some characteristics of the actual population. Our tentative results highlight the importance of understanding the characteristics of the audience population when choosing channels for opinion intervention for disease mitigation.

4 - The Role of Market Interventions to Increase Access of Health Commodity in Lmic: A Case of The Ipaqt

Parshuram Hotkar, Indian School of Business, Hyderabad, India, Sarang Deo

Low and medium income countries (LMICs) face challenges to provide access to health commodities. This paper explores the use of market interventions that coordinate pricing in a supply chain to improve access to diagnostic tests for tuberculosis (TB) in the LMICs. Specifically, we analyze the role of the Initiative for Promoting Affordable and Quality TB Tests (IPAQT) in India, which aimed to lower the cost of the Xpert MTB/Rif assay through negotiations with manufacturers and coordination with private labs. Using a game-theoretic model, we assess the feasibility and sustainability of market-transforming interventions and their impact on test consumption. We identify the conditions under which such interventions successfully coordinate the transformation from a high-price, low-volume market to a low-price, high-volume market. Additionally, we demonstrate that internal price control mechanisms like IPAQT lead to higher consumption compared to external mechanisms such as price regulations, particularly in the presence of heterogeneity in private labs. This research contributes to our understanding of the economics of market-transforming interventions, their generalizability, and provides guidelines for policy makers and donors for intervention designs aimed at enhancing access to health commodities in the LMICs.

1 - Optimization of Active Surveillance for Prostate Cancer Under Model Ambiguity

Brian Denton, University of Michigan, Ann Arbor, MI, United States, Weiyu Li

Variation across longitudinal medical studies can lead to multiple stochastic models of disease progression. To address this ambiguity, we propose a new multi-model partially observable Markov decision process (MPOMDP) framework. Here, model ambiguity is defined as the case where there are multiple credible optimization models with the same structure but different model parameters. The proposed MPOMDP model aims to learn the distribution of the true model from system outputs over time and to find the single optimal policy that maximizes the expected sum of all future rewards in all possible models. We discuss properties of the proposed MPOMDP model which motivate solution methods for MPOMDPs. We develop an exact solution method and two approximation methods that are shown to converge asymptotically and compare their performance in computational experiments. Finally, we use a case study of active surveillance for prostate cancer to demonstrate how the MPOMDP model can be applied to a real-world problem to improve medical decision-making by creating policies robust to model ambiguity.

2 - From Kidney Allocation to Administrative Costs: My Health Care OR Journey

Stefanos Zenios, Stanford University, Stanford, CA, United States

In this talk I will share the lessons I have learned over 30 years of Health Care OR. I will focus on 4 specific projects: a) Managing the equity-efficiency trade-off in health care; b) Using incentives to improve healthcare delivery; c) Understanding product development in medical devices; d) Reducing administrative costs. There will be some equations and some philosophical reflections.

3 - AI for Social Good - Leveraging Digital Therapeutics and Advanced Analytics for Health Literacy

Rema Padman, Carnegie Mellon University, Pittsburgh, PA, United States

Health literacy is a widely recognized challenge worldwide, with many adults lacking the requisite skills to engage successfully in the management of their health and healthcare. Affecting both individual and societal health outcomes, limited health literacy particularly exacerbates the increasing physical and psychological burden for patients with multiple health conditions as well as pediatric, elderly and disadvantaged populations. Recent developments in digital therapeutic solutions offer an opportunity to apply systems thinking combined with analytic methods to synthesize the myriad components of a multi-pronged approach to improving societal health literacy at scale. This talk will highlight some of these developments with a focus on digital platforms and algorithmic artifacts in the healthcare delivery setting, recognizing the challenges of misinformation, disinformation, inclusivity and representativeness in identifying and disseminating authoritative and accurate content for educating and empowering patients and the public.

1 - Prediction of Left Ventricular Ejection Fraction from a 12-Lead Electrocardiogram

Catherine Ning, MIT, Cambridge, MA, United States, Dimitris Bertsimas, Yu Ma

Within the Holistic AI in Medicine (HAIM) framework, we propose a promising opportunity to develop a more efficient and cost-effective approach to estimate left ventricular ejection fraction (LVEF) using 12-lead electrocardiogram (EKG) data. LVEF is one of the essential parameters for assessing cardiac function as it represents the percentage of blood ejected from the heart's left ventricle during each contraction (the normal range is 55-65%). A reduced LVEF may serve as an crucial diagnostic and prognostic marker for heart failure severity and risk of sudden death. Traditionally, EF estimation relies on time-consuming and expensive imaging techniques, such as echocardiography or MRI. In our project, we aim to extract accurate EF predictions from routine, readily available EKGs only, which could significantly enhance early detection, risk stratification, and treatment monitoring for patients both with and without known history of heart failure.

In close collaboration with the cardiologist team at Hartford Healthcare (HHC), we carry out a retrospective study on outpatients from the HHC data systems who have both a 12-lead EKG and an echocardiogram record, the latter serving as the ground-truth LVEF measurement. Our preliminary 4-class classification results based on 12 leads attain a per-class AUC averaging to 0.883 using XGBoost models. We are excited to extend this work to a multi-modal, multi-task unified prediction framework targeting other heart-related problems such as hypertrophic cardiomyopathy, aortic stenosis, and atrial fibrillation from EKGs alone.

2 - From Data to Action: HAIM Modeling for Medication-Related Readmissions

Yubing Cui, Operations Research Center, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas, Lisa Everest

Prior to discharging an inpatient, it is optimal for pharmacists to review each patient's medications to mitigate the risk of medication-related complications. However, limited pharmacist resources often render this impractical. In collaboration with Hartford HealthCare and leveraging the HAIM framework, we are developing a multimodal machine learning model designed to identify patients at high risk for medication-related adverse events or readmissions. This approach allows for the strategic allocation of pharmacist resources to those patients who are most in need.

3 - Automating care reviews for denial management with multimodal AI

Karl Zhu, Massachusetts Institute of Technology, Cambridge, MA, United States, Yubing Cui, Dimitris Bertsimas

We are partnering with Hartford HealthCare, Connecticut's largest healthcare system, to develop an automated care review system with multimodal AI. This initiative aims to mitigate errors in level-of-care decisions and reduce insurance denials, which impose significant financial challenges within the healthcare sector. Traditional care review methods, reliant on manual data extraction from electronic health records, are inefficient and prone to inaccuracies, frequently resulting in unjustified denials.

Our multimodal approach combines structured tabular data — including patient demographics, vitals, lab results, and medications — with embeddings derived from unstructured textual data, such as provider notes. Preliminary tests on classifying patient status for those admitted through the emergency department demonstrate that our multimodal approach outperforms unimodal ensemble methods in terms of AUC.

4 - Multimodal Approach to Predicting Psychosis Relapse

Emily Hahn, Massachusetts Institute of Technology, Cambridge, MA, United States, Jiayi Gu

Predicting prognostic outcomes (length of stay, readmission,etc.) represents a crucial challenge in psychiatric healthcare. For example, relapse in psychosis is often preceded by detectable symptom changes nearly two months in advance. However, current screening tools have limited predictive capability. Aiming to enhance patient outcomes and reduce economic burdens on health systems, this study utilizes the Holistic Artificial Intelligence in Medicine (HAIM) framework to develop advanced machine learning algorithms using multimodal EMR data for predicting prognostic outcomes such as re-admission . This retrospective study includes 6800 adult patients admitted to the Behavioral Health Network within Hartford Healthcare from 2018 to 2023, Our models integrate advanced machine learning algorithms to process structured and unstructured EMR data, including clinical notes through Natural Language Processing (NLP) and brain imaging when available. By creating predictive models using the HAIM framework, the study aims to demonstrate the potential of such tools in improving prognoses and long-term outcomes for patients, ultimately supporting more proactive and personalized healthcare strategies.

Managing Product Returns

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Huseyn Abdulla, University of Tennessee, Knoxville, TN, United States

Co-Chair: Nail Tahirov, University of Zurich, Zurich, Switzerland

1 - Salesperson Incentives and Consumer Returns

Seulchan Lee, Michigan Technological University, Houghton, MI, United States, Huseyn Abdulla

As a widely-adopted practice, retailers deduct from the paychecks of salespeople entire sales commission earned on sales of products that are eventually returned to stores, for any reasons. This practice, coupled with lenient no-questions-asked, full-refund policies, results in significant paycheck uncertainty for salespeople and threatens their economic welfare. We examine the monetary refund policies and commission chargeback decisions of a retailer in response to consumer product returns. Our results challenge the widely adopted practice of "full refund for customers, full commission chargeback from salespeople."

2 - Pricing and Returns in the Era of Big Tech: Implications of Information Asymmetry Reversal

Kiarash M. Hassani, Queen's University, Canada, Kingston, ON, Canada, Murray Lei, Anton Ovchinnikov

We present a model to optimize the sales and return policy of a monopolistic seller under three information scenarios and examine the resultant profit and consumer surplus. The consumer's ex-ante information is her type and the firm's ex-ante information about a consumer may be the distribution of consumer types (uninformed firm, standard information asymmetry), the consumer type (equally-informed firm), or the actual validation (better/fully-informed firm, reversal of information asymmetry). In the base model we assume consumers incur no hassle costs for returns, and relax this in an extension.

The results of the base model show that when returns are not allowed, the firm collects twice as much profit when it has equal information compared with the standard information asymmetry but being fully informed brings no additional value. When returns are allowed, full information is always better than equal information, and equal information is always better than no information for the firm. Likewise, when the firm is fully informed, it is always profitable to allow returns. The value of information is decreasing in salvage value, and when the salvage value equals the production cost, additional information does not improve the profit. When returns are not free for consumers, we end up with various pricing policies based on the magnitude of return hassle costs and other variables. These policies and their effects on the firm and consumers differ depending on the firm's information level.

3 - Does Less Result in More? the Role of Information and Rewards in Take-Back Programs for Clothing

Anna Saez de Tejada Cuenca, IESE Business School, Barcelona, Spain, Erin Mckie, Vishal Agrawal

Fashion retailers are increasingly implementing take-back programs to reduce textile waste and prevent clothes from being landfilled. Through a series of experiments involving over 3,500 participants, we examine the effect of different types of information and reward levels on consumers' propensity to return their used clothes to take-back programs.

4 - The Impact of *Buy Now, Pay Later* on Customer Sales and Returns in Online Retail

Christoph Baldauf, Stockholm School of Economics, Stockholm, Sweden

Product returns remain a major issue for online retailers. The emergence of new, flexible, payment methods that allow customers to buy products without having to pay at the point of purchase may incentivize them to return products at an even higher rate. Such forms of payment are commonly referred to as “Buy Now, Pay Later” (BNPL). In this paper, we examine the role of customers’ payment method choice in retail transactions by focusing on the impact of BNPL on sales and returns in online retail. We analyze a unique dataset from a global fashion retailer containing over 30 million transactions from two European markets. Our findings suggest that, compared with other payment methods, BNPL increases sales, but also leads to a substantial increase in returns. We dive into factors that may moderate the negative effect of BNPL on returns and conduct back-of-the-envelope analyses to quantify its economic impact.

Empirical Platform Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Yifan Feng, National University of Singapore, Singapore, Singapore

1 - Impact of Estimated TIME of Arrival on the Supply and Demand for Food Delivery Platforms

Qianyi Tao, Tsinghua University, Beijing, China, People's Republic of, Tirui Cao, Lei Zhao, Hai Wang

In food delivery services, the *estimated time of arrival* (ETA) is a crucial decision that may significantly impact the demand and supply. Serving as a service commitment to customers and a delivery requirement for couriers, ETA interconnects customers (the demand side) and couriers (the supply side). Therefore, the design of the ETA strategy may simultaneously influence the satisfaction and retention of both customers and couriers. This research aims to study the causal effect of ETA on customer satisfaction, customer retention, and courier retention. To address potential endogeneity issues, we use the Heckman two-stage method to control the potential sample self-selection bias in the customer satisfaction model. Additionally, we meticulously identify appropriate explained variables, select explanatory variables, and introduce proxy variables into our econometric models. Based on the real data from a major food delivery platform in China, we discover that, as ETA increases from the current status quo in Beijing, the customer dissatisfaction rate will first decrease to a minimum point and then increase, the customer retention will decrease, and the courier retention will increase. Robustness checks across various cities and time slots validate our empirical results. Furthermore, a large-scale randomized field experiment conducted on the demand side of our collaborator's platform also validates the credibility of our models. Interestingly, the experimental results show that an increase in ETA corresponds to a subsequent increase in the *actual time of arrival* (ATA). Our study sheds valuable managerial insights into designing ETA strategies for food delivery platforms.

2 - Optimal Stockist Selection and Contract Design: Evidence from a Supply Chain in India

Yu Long, the Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Jussi Keppo, Wei Jiang, Omkar D. Palsule-Desai

We study incentives and contract design when a manufacturer can select, contract, and learn about its stockists. We model this relationship using a two-period principal-agent framework in which the manufacturer is the principal and the stockists are agents. Using a multi-armed bandit model, we examine how competition among stockists for future contracts and their career concerns on the level of future compensation influence the optimal contract. We show that competition incentivizes stockists to exert more effort, whereas career concerns have opposite incentives, particularly when the manufacturer has dominant bargaining power. By calibrating our model to unique contract and sales data from an Indian potato chips manufacturer, our counterfactual analysis shows that the competition raises (career concerns decrease) the stockists' effort by more than 192% (77%) and the manufacturer's value by over 6% (about 3%).

3 - Unlocking Nanostores' Operational Potential via a Buy Now Pay Later Program

Guan-Yuan Wang, Tilburg University, Tilburg, Netherlands, Jan Fransoo, Han Oh

We study how Buy Now Pay Later (BNPL) trade credit can foster business performance for Base-of-Pyramid retail shopkeepers, leveraging granular data from East Africa. By employing difference-in-difference estimators and quantile regression models, we show that BNPL credit can improve BOP retailers' business growth. By estimating different estimands, we suggest inclusive BNPL policies would greatly benefit small-scale retail stores.

4 - Understanding Labor Supply in Gig Economy: Evidence from a Logistics Platform

Sixing Hu, National University of Singapore, Singapore, Singapore, Yifan Feng, Jussi Keppo

We provide a detailed empirical examination of labor supply behavior in an e-commerce logistics platform, contributing to the nuanced interplay between daily compensation and labor supply. Using a unique dataset, which contains information about predetermined compensation for ``scheduled'' jobs and compensation offered to non-participating agents, we avoid many common sources for endogeneity. We employ a collection of econometrics tools to empirically characterize the daily extensive (i.e., whether the agent participates) and intensive (i.e., how long the agent works) margins, respectively. We also investigate the ``intraday'' dynamic margins, meaning how compensation changes of times of the day affect the labor supply in the remaining of the day.

Our findings regarding the intensive margins confirm the qualitative insights of Camerer et al. Specifically, we find that the intensive margin is negative. Our intraday analysis finds that the negative elasticity mainly comes from near the end of the day, supporting the interpretation that agents set ``income targets.'' However, the intensive margin is only part of the story since the agents in the gig economy do not typically work full-time. We find that the extensive margin is positive. That is, higher compensation leads to more agents to participate on a given day. The positive elasticity mainly comes from the beginning of the day, suggesting that agents first decide on whether to work and then how long to work. After combining intensive and extensive margins, we find that the total labor supply correlates positively with compensation, thus reverting the qualitative takeaway of Camerer et al..

5 - Bargaining in Parallel: the Impact of Multiple Concurrent Bargaining on Final Selling Prices

Wen Zhang, Baylor University, Waco, TX, United States, Guihua Wang

Many studies suggest that competition among buyers typically benefits sellers. However, this may not always hold true in online marketplace bargaining when multiple buyers simultaneously compete for the same item. In this paper, we examine the impact of multiple concurrent negotiations on the selling prices of items. Utilizing a novel dataset, we find that an increased number of concurrent bargaining instances can actually decrease an item's selling price. Furthermore, we employ tree-based machine learning algorithms to explore the heterogeneous effects of competition among buyers on bargaining outcomes. This analysis provides practical insights for online marketplace sellers.

Empirical Research in Supply-Chain Networks

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Kashish Arora, Indian School of Business, Hyderabad, India

1 - Supply Chain Cash Flow Chess: Seasonality in Trade Credit Late Payment

Zhi Li, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Jing Wu, Ling Cen

Using a sample of US public firms and a unique dataset of trade credit payments, we document several key findings regarding this late payment seasonality. We observe spikes in trade credit late payments at the fiscal year-end. We also find such late payment in trade credit is associated with an increase in customers' cost of goods sold, suppliers' sales, and both of their cash ratios at fiscal year-end. However, the focal firms do not increase their accounts payable, suggesting that they are only delaying payments for existing trade credit instead of receiving more credit. These results suggest delayed payments are related to changes in working capital around fiscal year-end. We find firms with higher short-term debt are more likely to delay payments, suggesting trade credit functions as a substitute for bank financing. Late payment seasonality is also more pronounced for firms facing tighter financial constraints. However, we find no evidence that late payment could hurt either suppliers' or customers' profits. Our findings shed new light on why and how trade credit late payment seasonality arises and its implications for firms' financial flexibility and liquidity management.

2 - Vertical Integration and Market Power in Supply Networks

Kashish Arora, Indian School of Business, Hyderabad, India, Amandeep Singh, Mamta Sahare

Vertical integration, a strategic approach where firms control multiple stages of production and distribution, offers potential operational efficiencies. While the operations management literature emphasizes its benefits for supply chain coordination, and reduced transaction costs, certain antitrust studies concern how vertical mergers may enable dominant firms to limit competition by creating entry barriers and causing market foreclosure. There is some evidence of the potential supply chain benefits of vertical integration across a few industries. However, empirical evidence on its anti-competitive effects remains scarce. This paper contributes to closing this gap by examining vertical integration's impact on firms' market power, as measured by their price-marginal cost markups. Our research investigates pre- and post-integration markups to determine whether firms gain anti-competitive market power after integration. Since firms' marginal costs are not usually observed in data, we estimate markups using production function estimations, following recent advances in empirical industrial organization. We compile a novel dataset on vertical integration cases using the FactSet Revere and the SDC platinum databases. Specifically, we identify 213 vertical mergers between firms with existing buyer-supplier relationships from 2003 to 2022. We employ a staggered difference-in-difference approach in conjunction with instrumental variables that cause an exogenous variation in firms' decisions to integrate vertically. Our analysis reveals that vertical integration increases acquiring firms' markups by 13\% and their rivals' markups by 12\%. Interestingly, we find that the increase in firms' market power post-integration does not come from improved operational efficiencies but from higher than competitive prices.

3 - Examining the Evidence of Value Smile Curve

Nikolay Osadchiy, Emory University, Atlanta, GA, United States

In this article, we examine the existence of Value Chain Smile, a concept first introduced by Stan Shih, then CEO of Acer group, at the firm level for all U.S. companies and over time. We study whether the most upstream or downstream firms capture more value compared to the intermediate firms. We further investigate the value addition at the industry level and over time. In the last, we study whether the firms that move upstream or downstream can extract more value following the evidence of the smile curve.

4 - A framework for synthetic graph generation with user-specified metrics

Nolan Feeny, University of Michigan, Ann Arbor, MI, United States, Seth Guikema

Supply chain managers have historically prioritized manufacturing efficiency at the cost of greater scale supply chain network (SCN) resiliency. Although researchers have recently put more emphasis into understanding SCN network resiliency, lack of substantial data remains a common obstacle due to competition and security reasons. This presentation proposes a framework to generate synthetic networks exhibiting network metric targets within an error range that users can define and adjust. We combine existing graph generation algorithms with a genetic optimization algorithm focused on specific network-defining metrics to score each graph. Metrics such as average nodal degree, average shortest path length, and clustering coefficient are indicative of network resilience and are thus included in our scoring function. The resulting output of the genetic algorithm is a final network that meets the user's desired specifications. The framework demonstrates an ability to successfully generate networks with metrics resemblant of real-world networks with user-defined metric targets and precision. This is an alternative method to provide sufficient and realistic synthetic data for network resilience analysis and machine learning applications, especially in industries where data is difficult to obtain.

Co-Chair: Xiaomeng GUO, Hong Kong Polytechnic University, Kowloon, Hong Kong

1 - How Sustainable are Sustainability-Linked Loans?

Jonathan Hsu, The University of Hong Kong, Hong Kong, Hong Kong, Wenqiang Xiao, Guoming Lai

Sustainability-linked loans (SLLs) have grown to rival green loans as one of the principal instruments of green financing. SLLs eschew the use-of-funds model used by green loans in favor of a performance-based model wherein the repayment terms are linked to the sustainability performance of the firm. However, it is unclear whether and how SLLs may be more effective than green loans at incentivizing ESG improvements by the borrower. We develop a model of corporate financing wherein a borrower with a green project can improve pecuniary and non-pecuniary outcomes as well as reduce their default risk by investing effort into improving their ESG performance. We show that a green loan results in ESG underinvestment due to both the inability to align lender and borrower preferences over non-pecuniary outcomes and the endogeneity of borrower default. An SLL eliminates these agency frictions by tying the loan repayment terms to the borrower's *ex-post* ESG performance, thus restoring the first-best allocation of sustainability effort. This result holds even when the ESG performance of the borrower can only be measured imprecisely by the lender. However, noisier measurements "mask" the true ESG performance of the borrower, forcing the lender to issue more performance-sensitive SLLs in equilibrium. Finally, through an analysis of an information asymmetric setting, we show that an SLL can function as an inexpensive screening device. In particular, by committing to more ambitious sustainability targets, borrowers can credibly reveal private information about the effectiveness of their ESG performance at mitigating default risk.

2 - Price Competition in the Presence of Social Comparison and Demand Uncertainty

Yun Zhou, McMaster University, Hamilton, ON, Canada, Zhoupeng Zhang, Ming Hu, Tony Cui

Does social comparison intensify the competition among sellers in volatile markets? In this paper, we study price competition in markets with volatile sizes and, more importantly, with sellers that socially compare their profits with each other ex post for any realization of market sizes. While the classic social comparison theory, as well as conventional wisdom, has long suggested that the comparison behavior such as behind aversion (upward comparison) and ahead seeking (downward comparison) will intensify competition, we reveal how social comparisons can totally have opposite-directional impacts once interacting with the market variability. In particular, we show that a stronger behind aversion behavior will still intensify the price competition, yet somewhat surprisingly, the impact of ahead seeking is variability-dependent: there is a threshold on the market size variability such that the competition between sellers will, in fact, be softened if markets are more volatile than such a threshold, and vice versa. Interestingly, the aforementioned predictions go in the other direction when sellers are selling complementary products: we will have the impacts of behind aversion variability-dependent while the ahead seeking is always pro-competitive. Our insights are robust under a general demand structure and demand shock specifications, asymmetry in sellers and markets, and sellers' misperceptions in market variabilities. Our work sheds light on other interactions of strategic complements or substitutes in the presence of social comparisons, e.g., quantity competition and advertising competition.

3 - Impact of Direct Selling on Food Waste

Xinxiu Wang, University of Miami, Miami, FL, United States, Xin Geng, Nan Yang

The yield of agricultural produce is random and affected by many uncontrollable factors, which stimulates farmers' overproduction, ultimately leading to a large amount of food waste. Direct marketing is thought to be an effective strategy for reducing food waste by disposing of excess produce through direct sales channels. However, the benefits that direct selling brings to farmers may incentive them to produce more, thereby becoming a potential cause of increased waste. Motivated by such trade-offs, we establish a game-theoretic model to study the impact of direct selling on food waste.

4 - Product Bundling in the Presence of Vertical Differentiation

Amit Eynan, University of Richmond, Richmond, VA, United States, Xingxing Chen

We study a seller of two product types which can be sold as individual components or at a discount as a bundle in order to leverage customers' product preference variation as reflected through their willingness to pay. Because customers are also heterogenous in their affinity towards quality, we consider offering each product type in two quality versions, high and low. This results in multiple potential bundling offerings across the two product types. As each customer self-selects a utility maximizing option, we investigate which components or bundles the seller should offer based on the market characteristics and highlight the impact of combining these two discrimination techniques on product quality, price, and profit.

Causal Inference for Dynamic Operations

Invited Session

MSOM: Service Operations

Chair: Stefan Wager, Stanford GSB, Stanford, CA, United States

1 - Switchback Experiments under Geometric Mixing

Yuchen Hu, Stanford University, Stanford, CA, United States, Stefan Wager

The switchback is an experimental design that measures treatment effects by repeatedly turning an intervention on and off. While the switchback is a robust way to overcome cross-unit spillovers, it is vulnerable to bias from temporal carryovers. In this paper, we consider properties of switchback experiments in Markovian systems that mix at a geometric rate. We find that, in this setting, standard switchback designs suffer considerably from carryover bias: Their estimation error decays slowly in terms of the experiment horizon, whereas in the absence of carryovers a faster rate would have been possible. We also show, however, that judicious use of burn-in periods considerably improves the situation, and enables errors that decay almost as fast as a parametric rate. Our formal results are mirrored in an empirical evaluation.

2 - Posterior Sampling by Autoregressive Generation

Daniel Russo, Columbia University, New York, NY, United States

We provide a bridge between generative sequence modeling and sequential decision making problems that require quantifying uncertainty and judiciously exploring to resolve it. We demonstrate ideas through a meta bandit modeling the recurring problem of learning about newly released content on a recommender system. Our solution first pre-trains an autoregressive model to predict a sequence of repeated feedback/outcomes (e.g., responses to news articles shown to different users over time). At decision-time, we autoregressively sample an imagined sequence of outcomes for each action, and choose the action with the largest average imagined reward. Far from a heuristic, our approach is an implementation of Thompson sampling (with a learned prior), a prominent active exploration algorithm. We prove our pretraining loss directly controls online decision-making performance. Then, we demonstrates our insights empirically on a news recommendation task; this demonstration includes end-to-end fine-tuning of a language model and synthesizing it with data on user interactions.

3 - Balancing Risk and Reward: A Batched-Bandit Strategy for Automated Phased Release

Iavor Bojinov, Harvard Business School, Somerville, MA, United States, Yufan Li, Jialiang Mao

Phased releases are a common strategy in the technology industry for gradually releasing new products or updates through a sequence of A/B tests in which the number of treated units gradually grows until full deployment or deprecation. Performing phased releases in a principled way requires selecting the proportion of units assigned to the new release in a way that balances the risk of an adverse effect with the need to iterate and learn from the experiment rapidly. In this paper, we formalize this problem and propose an algorithm that automatically determines the release percentage at each stage in the schedule, balancing the need to control risk while maximizing ramp-up speed. Our framework models the challenge as a constrained batched bandit problem that ensures that our pre-specified experimental budget is not depleted with high probability. Our proposed algorithm leverages an adaptive Bayesian approach in which the maximal number of units assigned to the treatment is determined by the posterior distribution, ensuring that the probability of depleting the remaining budget is low. Notably, our approach analytically solves the ramp sizes by inverting probability bounds, eliminating the need for challenging rare-event Monte Carlo simulation. It only requires computing means and variances of outcome subsets, making it highly efficient and parallelizable.

1 - Enhancing Effectiveness and Responsiveness of Humanitarian Food Aid Delivery &Mdash;&Mdash; Data-Driven Optimization Framework

(Lluvia)Weijia Jing, Northeastern University, Boston, MA, United States, Ozlem Ergun

Each year, the Bureau for Humanitarian Assistance (BHA) under the U.S. Agency for International Development (USAID) plays a vital role in the global distribution of food aid. However, meeting the increasing demand with finite resources remains a persistent challenge(ref). In this paper, we examine the USAID global food aid supply chain, focusing on its multi-echelon, multi-commodity, and multi-modal nature. We adopt a multi-stage stochastic programming model to optimize warehouse locations and safety stock levels. This model integrates pre-disaster pre-positioning with post-disaster inventory replenishment, effectively catering to both deterministic (ongoing) and stochastic (sudden-onset) demands. Leveraging advance deep learning models, our approach enhances demand pattern analysis and realistic scenario planning. We aim to optimize BHA/FFP's food aid procurement, prepositioning, and distribution strategies, thereby enhancing the resiliency and responsiveness of USAID's global food aid operations.

2 - A Location-Allocation Model for Meal Kit Distribution in Post-Disaster Environments

Diana Ramirez-Rios, University at Buffalo, Buffalo, NY, United States, Angelo Soto-Vergel, Trilce Encarnacion, Johanna Amaya

This presentation focuses on the food bank network design in post-disaster environments that minimizes the social costs of human suffering. The social costs include the costs of the delivery operation and the external costs on the population's suffering caused by the delays in the relief in the form of deprivation costs. We propose a location-allocation model that selects the optimal location and allocation of PODs (i.e., food pantries) for the distribution of food after an emergency occurs, as well as the relief distribution strategy. Given a set of food bank locations, a set of PODs considered for the distribution of food supplied by the food bank, and a set of population regions (e.g., ZIP codes), the model searches for the optimal PODs that can be activated to serve the people in need, their allocation to the population centers, and the amount and frequency of truck deliveries to the POD during the critical period of the emergency. We study the case of the Houston Food Bank and its response after Hurricane Harvey with the actual network of PODs and its capacities. The deprivation cost function used was empirically estimated for meal kit distribution and is a polynomial function with respect to time that people have to drive and wait for the delivery.

3 - D-optimal orienteering for post-earthquake reconnaissance planning

Ilya Ryzhov, University of Maryland, College Park, MD, United States, Jiaqi Wang, Weijun Xie, Nikola Markovic, Gaby Ou

Immediately following a major earthquake, reconnaissance surveys seek to assess structural damage throughout the region with the help of a limited number of on-ground inspections. The goal is to collect informative and representative data that will guide subsequent relief efforts. We formulate a new type of vehicle routing problem, in which vehicles are tasked with data collection, and the objective function measures data quality using a nonlinear, nonseparable experimental design criterion. We create novel exact methods for this problem, and demonstrate their practical potential in a realistic case study using a state-of-the-art earthquake simulator.

4 - The Price of Funding Inflexibility in Humanitarian Operations

Ece Gulserliler, Tilburg University, Tilburg, Netherlands, Atalay Atasu, Dan Iancu, Luk Van Wassenhove

Humanitarian organizations (HO) respond to many emergencies with limited financial resources. For an effective and timely response, they need to prepare for potential emergencies, and allocate resources efficiently between programs. However, current funding practices often impede this. HOs receive a significant portion of funds in the aftermath of a crisis, preventing preparedness efforts. Moreover, these funds are often earmarked to a specific response, preventing organizations from preparing for and responding to other (usually smaller, under-the-radar) crises. This paper introduces a framework to quantify the price (i.e. value loss to beneficiaries) of such donor-imposed constraints in humanitarian operations. To that aim, we use a two-stage stochastic model where in the first stage, a humanitarian organization makes preparedness investments for multiple potential emergencies with unknown demand, subject to a budget and constraints on the use of the budget. In the second stage, the demands are realized and the HO utilizes the preparedness investments to respond. We quantify and compare the prices due to earmarking and preparedness constraints, and discuss how they depend on the demand and cost parameters. Our results have important implications for both humanitarian organizations and donors for understanding the consequences of funding inflexibility in various contexts.

5 - The Whiplash Effect: Congestion Dissipation in a Disrupted Circulatory System

Chaoyu Zhang, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Ming Hu

In this paper, we build a fluid model in transient states to investigate how disruptions at one port can affect the disrupted port and its counterpart in a circulatory container shipping system. Port disruption leads to two types of congestion: the inbound backlogs, which occur when ships are unable to enter the port, and the outbound backlogs, which arise when goods are unable to be loaded onto ships. We characterize the recovery time of the system of two ports in closed form and the dynamics of inbound and outbound backlogs during the recovery process. We identify a whiplash effect in the outbound backlog process at both ports in which ports take turns being whipsawed by outbound backlogs that may go up and down. This counterintuitive phenomenon is due to the uneven spatial distribution of ships on the routes caused by the disruption. Furthermore, using the base two-port model as a building block, we obtain more general results in characterizing the recovery process of those bipartite port networks. We also extend the fluid model to a diffusion model to capture the second-order effect of the real-life system. Finally, we use our model prediction as a feature and apply machine learning techniques to predict the time that vessels spend in the Shanghai port after a typhoon disruption and show that using our model predictor, alongside all relevant vessel and voyage attributes as raw features, significantly reduces prediction errors by 10% to 30% on average compared to not using it.

1 - Emergency Department Wait TIME Forecasts: Outdoing Complex Machine Learning with Parametric Models

Donald Lee, Emory University, Atlanta, GA, United States, Ragip Gurlek, Francis de Vericourt

Patient time-to-treatment is a key metric for benchmarking the operational performances of emergency departments (ED). In the past decade, increasingly sophisticated machine learning methodologies have been developed to better forecast wait times for individual patients. In this work, we explore how using information specific to the ED setting leads to simpler models that outperform more complex machine learning approaches.

2 - Primary Care Panel Optimization

Dilara Sonmez, The University of Chicago Booth School of Business, Chicago, IL, United States, Daniel Adelman, George Weyer

We target primary care providers' success in value based care through altering primary care visit patterns. We formulate the problem of finding physicians' optimal patient panels and prescribing patients with a primary care dosage as a mixed-integer nonlinear optimization problem. We take into account the operational constraints and primary care visit pattern dynamics. We capture the effect of visit patterns on the financials and incorporate those dynamics into the optimization model. We propose a heuristic method to be used for the large instances of the problem.

3 - Failures of Health Equity: An Examination of Bias in Clinical Trials

Ling Li, Indiana University, Bloomington, IN, United States, Kurt Bretthauer, Xiaoshan Peng

Failures of health equity are closely intertwined with biases in healthcare treatment. We study how underrepresentation bias in clinical trials affects health outcomes and equity. We propose behavioral models to analyze physicians’ treatment decisions. In our model, as supported in the literature, physicians’ treatment decisions are influenced by two distinct cognitive systems: the intuitive and the rational. We model the intuitive system as a Markov decision process where decisions are influenced by the treatment outcome of the previous patient using a "win-stay/lose-shift" heuristic. This illustrates a propensity among physicians to modify their treatment choices following negative outcomes. By modeling the rational system as a multi-armed bandit problem, physicians select treatments based on their subjective probabilities of treatment efficacy, subsequently updating these evaluations based on treatment outcomes. Moreover, physicians can alternate between the two cognitive systems. To model this behavior, we construct a hybrid cognitive model employing an ε_n-greedy strategy, which increasingly favors rational decision-making as patient outcome data accumulates. Our findings indicate that, when no bias is present, both intuitive and rational systems maintain a nonzero probability of choosing the less effective treatment. When underrepresentation bias in the clinical trials is introduced, we show that the incomplete learning (i.e., the choice of the less effective treatment) resulting from the Gittins index policy in the rational system might be exacerbated. However, our key takeaway shows that the hybrid cognitive model overcomes this bias such that the physician eventually chooses the more effective treatment.

4 - Primary Care Visit Regularity: How and when Does It Matter?

Yingchao Lan, University of Nebraska-Lincoln, Lincoln, NE, United States, Vishal Ahuja, Aravind Chandrasekaran

Patients with chronic conditions visit their primary care providers (PCPs) repeatedly. For such patients, regular visits are an important part of care management process. Variations in visit regularity can be detrimental to patients as it could result in untimely or inappropriate care, potentially leading to adverse outcomes. Our research studies this in the context of diabetes. We study how regularity affects health outcomes and the conditions under which such effects are strengthened.

1 - Privacy-Preserving Resource Allocation: near Optimal Algorithms and Policy Implications

Chen Du, Nanyang Technological University, Singapore, Singapore, Geoffrey Chua

When multiple agents compete for limited resources, how should the resources be optimally allocated to maximize total utility while preserving agents' privacy, such as utility functions, consumption functions, and special needs? This question sums up today's challenges in balancing the provision of two essential public goods, i.e. healthcare and personal privacy. To address such offline resource allocation problems with privacy concerns, we propose an algorithm called "Noisy Dual Mirror Descent" that privatizes dual variables for privacy and exploits primal-dual schemes for allocation decisions. We show that the algorithm is near optimal and is able to provide a formal privacy guarantee in terms of joint differential privacy. Numerical studies justify our findings and further shed light on policy implications.

2 - A Marginal Distributions Constrained Optimization Approach of Estimating True Prevalence of Pediatric Mental Health Conditions in Washington State

Shan Liu, University of Washington, Seattle, WA, United States, Yinsheng Wang, Kathryn Brandeau

Pediatric mental health disorders such as depression, anxiety, and behavior disorder significantly impact the well-being of children and youth. In Washington state (WA), data has shown that more than one third of people live in areas lacking mental health providers. Accurately mapping the geographic distribution of true demand in WA is crucial for designing an optimal continuum of care network for pediatric mental health services. This study began by estimating the true prevalence of several youth mental health conditions utilizing multiple data sources such as the National Survey of Children's Health (NSCH), WA Healthy Youth Survey (HYS) and American Community Survey (ACS). We developed multivariate regression models using the NSCH data informed by demographic factors, including age, race, sex, insurance status, poverty status, family size, caregiver employment status, etc. To estimate the prevalence of each mental health condition on the census tract level in WA, we constructed a marginal distributions constrained optimization model. The model recovers detailed demographic groups proportions by harmonizing regression results from the NSCH data to estimates in other dataset such as the HYS data, under the constraints of marginal distributions found in the ACS. This approach facilitates the integration of national and local datasets to improve small area estimation and supports the strategic placement of new facilities and programs in downstream research. Overall, this study demonstrates effective data fusion to enhance prediction quality and service planning.

3 - Rl OR Url: Managing Outpatient (Tele)Visits with Strategic Behavior

Nan Liu, Boston College, Chestnut Hill, MA, United States, Shan Wang, Noa Zychlinski

As outpatient care increasingly incorporates telemedicine, providers face the challenge of integrating virtual (URL, or internet) services with traditional in-person (RL, or real-life) services. Whereas telemedicine offers convenience, reducing waiting and travel costs for patients, it may require follow-up in-person visits, which could offset initial benefits. This study examines how providers can optimally balance virtual and in-person service delivery, and explores interventions that can enhance virtual service effectiveness and reduce the need for follow-up in-person visits.

4 - Optimizing Nurse Staffing: Balancing Resource Pooling and Surge Capacity in Health Networks

Zhuoyang Liu, Stanford University, Stanford, CA, United States, Yue Hu, Yueyang Zhong

We explore the joint impact of two hedging methods against demand uncertainty—resource pooling and surge capacity—on nurse staffing in a multi-unit health network. Pooled nurses are pre-staffed and allocated swiftly, while surge nurses are real-time staffed at a higher cost. We assess them based on staffing costs and demand corrections.

1 - The BAR-approach for Continuous-time Stochastic Systems

Jim Dai, Cornell University & CUHK-Shenzhen, Ithaca, NY, United States

I will give a tutorial on the basic adjoint relationship (BAR)-approach for steady-state analysis of continuous-time stochastic systems. In such a system, the distributions of stochastic primitives (e.g, service times) are assumed to be general, not necessarily exponential or phase-type. I will illustrate that the BAR-approach is an effective tool to prove (1) the state space collapse in a join-shortest-queue system, (2) asymptotic steady-state independence for queueing networks in multi-scale heavy traffic.

Amazon Supply Chain Optimization

Invited Session

The Practice Section of INFORMS

Chair: Garrett van Ryzin, Amazon, New York, NY, United States

1 - Dynamic Package Route Computation at Scale

Luciana Buriol, Amazon, Bellevue, WA, United States, Yuri Shevchenko, Olivier Durand de Gevigney, Nithin Lingala, Thomas Helleboid

The journey of a customer package through the Amazon outbound network starts at an inventory location and can go through other Amazon buildings (Sortation Centers, Delivery Stations) and ground, air, rail, and sea legs. Package routing must be compliant with customs and other transportation restrictions. Finally, part of the Amazon demand is delivered by 3P carriers. To delight our customers the routes need to be fast and cheap. In this talk we will describe the first stage of this journey: determining the package routes. For that we developed an algorithm engineering framework that enables fast and dynamic route computation at scale.

2 - Consensus Planning for Capacity Planning: A Market-based Approach to Coordination at Amazon

Garrett van Ryzin, Amazon, Brooklyn, NY, United States

Managing Amazon's fulfillment network is extraordinarily complex due to its vast scale and scope and optimizing overall supply chain performance requires a high degree of coordination across multiple organizations and systems. To address this problem, we developed a distributed, market-based approach to coordination called Consensus Planning Protocol (CPP). In this talk, we describe CPP and how it is being used at Amazon to build an automated planning system (APS) for supply chain capacity planning. APS coordinates complex capacity decisions that were previously made separately and uses scenario-based optimization to jointly hedge capacity decisions against supply and demand risk. The modular, agent-based design enables us to build APS quickly, and easily scale and expand the system in the future.

3 - Consensus Planning with Primal, Dual, and Proximal Agents

Alvaro Maggiar, Amazon.com, New York, NY, United States

The Consensus Planning Protocol (CPP) is a coordination mechanism to align different distributed agents (systems) that share common resources and who act in order to optimize a joint goal. The framework has been adopted within and outside of SCOT to coordinate complex systems. Nonetheless, the interfaces with the agents can be of different types, primal, dual, and proximal, and most of the work thus far has restricted agents to have the same interface, or be either primal or dual. We present in this work a general CPP algorithm that allows for any mix of agents. We prove convergence results for the algorithm, namely a sublinear $O(1/k)$ convergence rate under mild assumptions, and two-step linear convergence under stronger assumptions. We additionally discuss enhancements such as acceleration and provide illustrating results.

4 - A primal recovery method for improving convergence speed of distributed algorithms

Tetiana Parshakova, Amazon, New Haven, CT, United States

We address the problem of minimizing a function that is a sum of agent functions subject to affine constraints that couple them. We assume the agent functions can only be accessed via a conjugate subgradient oracle, meaning agents return their optimal actions given prices. We introduce a new primal recovery method that uses a convex combination of epsilon-optimal solutions to reduce the optimality condition residuals. In the nonconvex case, the produced new primal variable approximately solves a nonconvex problem. Through various examples we show that our method typically converges to a reasonable approximate solution in a modest number of iterations.

Combining Large Language Models and OR/MS to Make Smarter Decisions

Invited Session

TutORial

Chair: Harish Krishnan, University of British Columbia, Vancouver, BC, Canada

1 - Combining Large Language Models and OR/MS to Make Smarter Decisions

Segev Wasserkrug, IBM Research, Haifa, Israel, Leonard Boussioux, Wei Sun

Operations Research/Management Science (OR/MS) capabilities can provide tremendous value in helping enterprises and individuals make smarter decisions. However, the creation and deployment of OR/MS-based decision-making solutions require significant time and expertise, making their widespread application challenging. LLMs, exemplified by models such as ChatGPT, Gemini, and Claude, are deep neural network models encompassing billions/trillions of parameters. These models are pre-trained with a vast scope of general knowledge and quickly adaptable to many downstream tasks. Beyond core capabilities LLMs exhibit emerging capabilities, such as learning new tasks from a few natural language examples. Generative AI technologies like LLMs, have transformative potential for many fields. In this work, we explore the potential of LLMs and their capabilities to significantly improve the creation of OR/MS based decision-making solutions. We show this potential through three concrete and detailed examples: using LLMs to significantly reduce time required to create decision-making applications while improving their quality; using LLMs to extract structured information from unstructured text without the need to create new natural language processing models, for demand forecasting; and using LLMs to drive natural language-based interfaces enabling a business user to easily and flexibly interact with analytical models used for decision making. As LLMs are a new technology that introduces new risks, this work also provides guidelines for their productive, ethical and responsible use and describes ongoing developments relevant to the OR/MS profession. We hope this work will serve as a starting point both for the application of LLMs to the OR/MS use cases we described.

Navigating the New Frontier: The Intersection of Artificial Intelligence and the Future of Work

Invited Session

Information Systems

Chair: J. Frank Li, UBC Sauder School of Business, Vancouver, BC, Canada

1 - Knowing More is Better? Examining the Influence of Customer Knowledge Transfer on Customer Service Outcomes

Zixi Lei, University of Texas at Austin, Austin, TX, United States, Wen Wen, Cheng Zhang, Andrew Whinston

This study explores the impacts of customer knowledge transfer among workers on service outcomes in service-oriented industries. Our empirical analysis reveals that customer knowledge transfer among workers significantly improves service outcomes, measured by customer spending. By categorizing customer knowledge into personality, family, service preferences, service descriptions, and recommendations, we also analyze how different types of customer knowledge influence service outcomes. We find that while knowledge about personality traits and service recommendations significantly boost customer spending, the use of sensitive customer knowledge such as their family can negatively impact spending, especially among privacy-sensitive customers. Our findings highlight the dual nature of customer knowledge transfer: it can enhance service outcomes when managed carefully but may backfire if perceived as intrusive. This research contributes to the literature by bridging the gap between customer data use and intra-organizational knowledge transfer. It also provides practical implications for effectively leveraging customer knowledge in organizational settings.

2 - "Generate" the Future of Work through AI: Empirical Evidence from Online Labor Markets

Xi Nan, University of Washington, Seattle, WA, United States, Jin Liu, Xingchen Xu, Yongjun Li, Yong Tan

Large Language Model (LLM) based generative AI, such as ChatGPT, is considered the first generation of Artificial General Intelligence (AGI), exhibiting zero-shot learning abilities for a wide variety of downstream tasks. Due to its general-purpose and emergent nature, its impact on labor dynamics becomes complex and difficult to anticipate. Leveraging an extensive dataset from a prominent online labor market, we uncover a substantial post-ChatGPT decline in labor supply, demand, and transactions for submarkets pertaining to text-related and programming-related job categories, in comparison to those not directly exposed to ChatGPT's core functionalities. Meanwhile, these affected submarkets exhibit a discernible increase in the complexity of the remaining jobs and a heightened level of competition among freelancers. Intriguingly, we find that the decrease in programming-related labor supply is relatively smaller, which is attributed to the increasing participation of freelancers who previously engaged in text-only jobs. Although the overall job diversity freelancers bid for per period tends to be more limited, those who successfully navigate skill transitions from text to programming demonstrate greater resilience to ChatGPT's overall market contraction impact. As AI becomes increasingly versatile and potent, our paper offers crucial insights into AI's influence on labor markets, the gig economy, and pertinent regulations, underscoring the necessity for proactive interventions to address the challenges and opportunities presented by this transformative technology.

3 - Unpacking the AI Blackbox: The Impact of AI Strategies on Firm Performance with a Dual Lens on Product and Process Orientation

Jaecheol Park, University of British Columbia, Vancouver, BC, Canada, myunghwan lee, J. Frank Li, Gene Moo Lee

Artificial intelligence (AI) technologies have become increasingly pervasive and hold great potential for large-scale economic impact. Aligned with this trend, recent studies explore the adoption and use of AI technologies on firm performance. However, they predominantly focus on AI as an input (e.g., labor/job posting), neglecting to consider the strategies to leverage their AI inputs in business operations. Thus, it is crucial to understand "how" and "where" to use AI to achieve business value. In this paper, we examine how firms' strategic AI orientation affects firm performance with a dual lens on product and process orientation. We measure AI strategic orientation by employing LLM to assess it from business descriptions in Form 10-K filings between 2015 and 2022. Our findings show that 13% of firms have AI orientation, 7% have AI product orientation, and 3% have AI process orientation. Additionally, we will provide some preliminary results on the impact of AI orientation on firm performance.

4 - The Impacts of Generative AI on Software Development

Sardar Fatooreh Bonabi, University of California, Irvine (UCI), Irvine, CA, United States, Sarah Bana, Vijay Gurbaxani, Tingting Nian

Large Language Models (LLMs) like ChatGPT, have significantly influenced various occupational fields. This study investigates their impact on the software development sector, focusing on productivity and knowledge dissemination. Leveraging a natural experiment resulting from a temporary ChatGPT ban in Italy, our study utilizes a Difference-in-Differences approach to assess the impact of ChatGPT on software development. We compare activity data from GitHub users in Italy with users in France and Portugal to isolate the effects of ChatGPT on productivity and knowledge dissemination within the sector. Our analysis covers a 16-week period, including pre-ban, during-ban, and post-ban phases, involving 95,164 users.

Our findings reveal that access to LLMs enhances software development productivity outcomes by an average of 5.4%. This may be because LLMs enable developers to complete their tasks more rapidly and effectively. More intriguingly, the lifting of the ban led to a 7.8% increase in knowledge dissemination activities, such as reviewing pull requests and opening issues, highlighting how the saved time through LLM usage is redirected towards collaborative and knowledge-sharing efforts. These results suggest that employing LLMs not only boosts productivity but also enhances collaborative learning and knowledge exchange within the software development community.

This paper contributes to understanding the broader implications of AI in the workplace, emphasizing how AI tools can transform not just individual productivity but also collective industry dynamics. Our study underscores the potential of generative AI to advance industry standards, efficiency, and innovation, suggesting a future where AI tools are integral to the software development ecosystem.

Modern Statistics in Social Media Analysis

Invited Session

Social Media Analytics

Chair: Alexander Gilgur, Amazon Kuiper, Sunnyvale, CA, United States

1 - Inferring Unusual Metrics from Social Media

Alexander Gilgur, Amazon Kuiper and Stevens Institute of Technology, Sunnyvale, CA, United States

Social media is a trove of information, open for mining without violating people's privacy. With some creativity, statistics-based machine learning tools can be applied off the shelf and / or created new to infer unhappiness, resilience, and even understand the importance of explanatory variables. In this presentation, the author shares some of these ideas that were developed over the course of 6 years of research.

2 - Causal inference through privacy compliant experimentation that makes social advertising more relevant

Carlos Avello, Amazon, Seattle, WA, United States

Conventional Machine Learned marketing operations run on troves of observational data (impressions, clicks, conversions). Observational data is marred by confounders (treatment and effect being correlated beyond causality) which leads to unreliable indicators of incremental effects of the marketing treatment that we run our ML marketing operations for. Therefore, in order to optimize to true incremental effect, ground truth causality information needs to be integrated into our systems. We will describe how to leverage highest science standard of causality via Randomized Control Trials in Social advertising while complying with latest privacy guarantees (DMA). Then we will describe ML marketing operation systems that incorporate RCT data as feedback loop and how it improves relevance and hence greater incremental return to marketing spend

3 - Enhancing low-resource LLMs classification with PEFT and synthetic data

Parth Patwa, Amazon, Santa Clara, CA, United States

Large Language Models (LLMs) operating in 0-shot or few-shot settings achieve competitive results in Text Classification tasks. In-Context Learning (ICL) typically achieves better accuracy than the 0-shot setting, but it pays in terms of efficiency, due to the longer input prompt. In this talk, we describe a proposed a strategy to make LLMs as efficient as 0-shot text classifiers, while getting comparable or better accuracy than ICL. Our solution targets the low resource setting, i.e., when only 4 examples per class are available. Using a single LLM and few-shot real data we perform a sequence of generation, filtering and Parameter-Efficient Fine-Tuning steps to create a robust and efficient classifier. Experimental results show that our approach leads to competitive results on multiple text classification datasets.

4 - Engagement Prediction in Short Video Sharing Platforms —The Case of a Health Campaign on TikTok

Amirmohammad Paksaz, University of Iowa, Iowa City, IA, United States, Kang Zhao, Bingbing Zhang

In recent years, short video sharing platforms, such as TikTok, have emerged as powerful platforms for raising public's awareness about health-related issues through launching health awareness campaigns such as #BreastCancerAwareness. While initial research has begun to explore the features of health-related campaign videos on such platforms, limited research has conducted large-scale examinations beyond a couple of hundred videos. At the same time, understanding the characteristics of health campaign videos systematically and predicting users' engagement with such videos, particularly those related to #BreastCancerAwareness, is crucial due to their demonstrated positive impact on community building and social support. It is also important for video creators to know if their videos will be engaging and, if not, how they can better design their videos. To address this gap, we collected a large dataset of health campaign videos related to #breastcancerawareness during breast cancer awareness month (October 1st, 2023-October 31st, 2023) from TikTok, the most popular short video sharing platform. By examining characteristics of these videos (e.g., length, resolution, and content) and their publishers (e.g., behavior history and account descriptions), we will build multi-modal machine learning models that predict how users engage with these videos. Such a prediction will be the foundation of more in-depth analyses on how to run a more effective health campaign on short video sharing platforms.

Power of LLMs in the Analytics Classroom: The Good, the Bad, and the Inevitable II

Invited Session

INFORMS Committee on Teaching and Learning

Chair: Sourav Chatterjee, University of North Texas, 1155 Union Circle, #311160, Denton, TX, 76203, United States

1 - Analytics in the Age of Generative AI

Sourav Chatterjee, University of North Texas, Denton, TX, United States

In this study, we explore the adoption, use, and impact of Generative AI within the business analytics field. Specifically, we investigate how LLMs are transforming the data analytics workflow. Instead of focusing on manual tasks like data cleaning, model building, and coding, business analytics professionals now need to spend more time assessing and managing analyses performed by the LLM models. To understand the impact of this transition, we interviewed industry leaders across various sectors. Our findings highlight an increased emphasis on problem-solving, critical thinking, and domain knowledge. Additionally, the shift toward LLM-driven analytics pushes for a more interactive and personalized learning environment for students pursuing an analytics degree.

2 - Closing the Gap: Leveraging GenAI for Inclusive Data Learning

Gabriela Gongora-Svartzman, Carnegie Mellon University, Pittsburgh, PA, United States

This session explores the integration of GenAI tools in the classroom to enhance student comprehension and proficiency in exploratory data analysis and visualization. Through hands-on exercises and group activities, students understand the impact of GenAI, enhance their data literacy, boost their confidence in coding and become more engaged in the learning process. We address concerns regarding over-reliance on GenAI tools by advocating for a balanced approach that emphasizes critical thinking and understanding of coding principles, ultimately preparing students for a life-long journey of tech learning.

3 - Using Gen AI in an Undergraduate Business Analytics Course: An Informal Case Study

Manoj Chari, University of North Carolina at Chapel Hill , Chapel Hill, NC, United States

We will discuss some experiences of incorporating Gen AI into a Python based undergraduate Business Analytics course as an assistive tool to enhance student learning of basic python programming for analytics. The goal was to allow and, in fact, encourage students to use Gen AI for feedback and guidance for programming homework and practice work, thus augmenting personal individual guidance available during the class and office hours. We will also discuss the supporting material that was created, the guidelines the students were expected to follow on the use of Gen AI, the adaptation of the course assessment in this context, and anecdotal evidence of students' actual use of Gen AI and students' perceptions of its learning benefits.

4 - Generative AI & LLMsfor Analytics: Fairness-informed Pedagogy

Deepak Khazanchi, University of Nebraska Omaha, Omaha, NE, United States

In AI & LLM applications, unfairness is triggered due to bias in the data, curation process, erroneous assumptions, and implicit bias rendered within the ML development process. As ML applications come into broader use in teaching analytics, it is important the students and instructors understand the attributes necessary for developing fair AI & LLM applications. We have proposed and *prima facie* validated a multidimensional notion of ***perception of fairness*** that should be ideally integrated as a means to assure the use of AI & LLMs in the analytics teaching enterprise.

AI in SCM

Invited Session

Artificial Intelligence

Chair: Huihui Chi, NEOMA business school, paris, France

Co-Chair: Michael Lash, University of Kansas, Lawrence, KS, United States

1 - Post-Disaster Emergency Supply Chain Optimization: Multi-Period and Multi-Variety Supplies Allocation and Distribution Amid Uncertain Demand

Shimin Gao, Central University of Finance and Economics, Beijing, China, People's Republic of, Hui Li, Xi Wang, Jian Wang

Disasters like earthquake, flood and snowstorm not only threaten lives of human beings, but also make a huge impact on social and economic development. After the disaster, the damage to communication and road capacity could cause an explosive growth in demand for emergency supplies, and the demands for different types of emergency supplies may vary with the period. Due to the bad communication between disaster area and outside, the pattern of demands generation also shows a strong randomness. How to optimize the routing problem in emergency supply chain, find an effective and robust strategy among stochastic requests, became the popular concern in the research filed of SCM.

We address this challenge by presenting a novel anticipatory routing, acceptance and postponement policy for the Multi-period Dynamic Vehicle Routing Problem with Stochastic Requests (MDVRPSR). We first show an example that demonstrates the features of MDVRPSR well. Then, we apply a Markov Decision Process to establish the mathematical model of this problem. Considering the problem's features, our model is designed to response stochastic requests at multi-period dynamic procedure, in which gives a detailed perspective of the decision state, reward setting, transition procedure and objective function. After that, to acquire the effective policy, we use deep reinforcement learning method like Deep Q-Network to solve this dynamic problem. Computational experiments are conducted to find possible optimal policies in this problem. Finally, we give a full review of our work, evaluate the effectiveness and applicability of our policy.

2 - Does Selling More Expiring Food Reduce Waste? a Perspective of Retail Inventory Allocation

Huihui Chi, EM Lyon, Écully, France

Emerging sustainable logistics systems for perishable products (such as food and pharmaceutical products) have been proposed in the recent past with the aim of reducing food waste and improving food quality. Trying to answer the practitioners' question of "does selling more expiring milk reduce milk waste?" from the inventory allocation perspective, in this research, we develop a two-stage model with shelf-space-dependent demand, where the retail shelf space is limited for placing two perishable products with long (high quality) and short (low quality) remaining shelf life. We identify the optimal allocation preferences between the capacitated shelf space and uncapacitated warehouse with stochastic demand. We calculate the bounds on the optimal solution that are integrated in the heuristic method. In conclusion, we discuss the managerial implications of food waste reduction from the perspective of inventory allocation strategy.

3 - Post-hoc Interpretability using Counterfactually-guided Multi-agent Contextual Bandits

Michael Lash, University of Kansas, Lawrence, KS, United States

Machine learning (ML) explainability (MLX) allows decision-makers to assess whether an ML model is making predictions "for the right reasons" and is thus crucial to the AI-powered decision-making pipeline. Obtaining faithful, quality explanations is therefore equally crucial. To such an end, this work proposes a multi-agent counterfactually guided contextual bandit approach to the MLX problem. The method is designed to synthesize explanation-producing policies using an off-policy counterfactually-guided search scheme. Our experiments show that the explanations obtained using our proposed method are superior to those obtained from competing methods.

4 - Toward Trustworthy AI: Mitigating Misleading Explanation's Risk in Machine Learning Predictions

Amir Asrzad, University of Massachusetts Lowell, Lowell, MA, United States

Machine learning, especially deep learning, excels at tackling complex prediction tasks with impressive accuracy. However, the lack of transparency in these "black-box" models raises concerns. Explainable AI (XAI) techniques aim to bridge this gap by providing human-interpretable explanations for model decisions. Yet, XAI explanations can sometimes be insufficient or misleading, leading to user distrust and hindering the adoption of AI technology. Despite its significance, the XAI literature lacks robust strategies to mitigate the risk of misleading explanations. This study addresses this gap by introducing a novel approach for generating risk-sensitive counterfactual explanations. Our method balances two key challenges: Overly weak explanations: We create robust counterfactuals to avoid explanations lacking reliable insights. Uninformative explanations: We introduce alert counterfactuals to prevent misleadingly late suggestions. The effectiveness of our proposed method is rigorously evaluated on real-world datasets to demonstrate its empirical value.

2024 INFORMS Prize

Invited Session

INFORMS Prize 2024

Co-Chair: Yulia Vorotyntseva, University of St. Thomas, Minneapolis, MN, United States

1 - 2024 INFORMS Prize Winner JD.com

Hau Lee, Stanford University, Stanford, CA, United States

JD.com, also known as Jingdong,marked its entry into the e-commerce sector in 2004 and is a leading supply chain-based technology and service provider. The company's expansive portfolio spans across sectors including retail,technology, logistics, health, and more,underscoring its diverse and multifaceted operations. In 2023, JD.com ranked 52nd on the Fortune Global 500 list.The company serves nearly 600 million active users, supported by an extensive infrastructure, ensuring unparalleled service and efficiency in its operations.JD. com has long been committed to applying operations research and management science to solve practical problems and has been selected as a finalist for the Franz Edelman Award twice,in 2021 and 2023. JD. com has been named the 2024 INFORMS Prize recipient its outstanding utilization of operations research and data science methodologies,driving innovation and excellence across its supply chain and e-commerce operations.

Analytics in Healthcare Decision Making

Invited Session

Analytics Society

Chair: Charles Nicholson, The University of Oklahoma, Norman, OK, United States

1 - Scalable and Trustworthy Deep Neural Networks for Imbalanced Data

Rachel Bennett, University of Oklahoma, Oklahoma City, OK, United States, Talayeh Razzaghi

Advancements in data availability have significantly placed neural networks at the forefront of successful learning algorithms, particularly for healthcare applications. However, training with large datasets requires extensive resources, and presents notable challenges, such as managing class imbalance and ensuring fairness. To address these challenges, we introduce a novel Multilevel Deep Neural Network (MLDNN) approach, which is designed to scale effectively with large datasets and provide a robust solution to class imbalance. We will demonstrate that MLDNN offers more accurate and robust classification results compared to traditional models using both healthcare-specific and benchmark datasets.

2 - A Systematic Review of Stochastic Optimization Techniques in Healthcare Decision Making: Methods, Applications, and Future Directions

Mansura Roly, The University of Oklahoma, Norman, OK, United States, Charles Nicholson

Stochastic optimization techniques have emerged as powerful tools for decision support in healthcare systems, offering robust methodologies to address the uncertainties inherent in medical decision-making processes. This presentation synthesizes recent advancements in the application of stochastic optimization models within the healthcare domain, focusing particularly on their utilization in decision-making scenarios such as resource allocation, treatment planning, and operational management. Through a comprehensive survey of the literature, this presentation explores the various stochastic optimization methodologies employed, including stochastic programming, Markov decision processes, and simulation optimization, among others. By providing a systematic overview of the existing research landscape, this work aims to inform healthcare practitioners, policymakers, and researchers about the potential benefits and limitations of stochastic optimization approaches.

3 - Optimal Grid Placement for Treatment Planning of Grid Therapy

M. Soheil Hemmati, University of Oklahoma, Norman, OK, United States, Grant M. Benson, Raghavendiran Boopathy

As a special form of radiation therapy, grid therapy is often used to treat bulky tumors, possibly with irregular shapes. At current, treatment planning is essentially performed based on institutional guidelines for target contouring, which requires placing uniform-size grids within a certain distance from each other, while ensuring the grids are sufficiently spared from the surrounding organs-at-risk (OARs). Further, the process is performed manually with no account for optimality in placing the grids with respect to objectives such as maximum coverage, maximum tumor control, or minimum normal tissue complication probability. We propose a family of mixed-integer programs to formulate the optimal grid placement problem in grid therapy. We solve instances of our proposed models for a set of cancer patients treated with grid therapy at the University of Oklahoma's Health Science Center and compare the outcomes of our models with the existing clinical procedures for treatment planning of grid therapy.

4 - Revisiting the Gateway Hypothesis by Considering the Effect of Age-of-First use on Subsequent Illicit Drug use

Matthew Beattie, University of Oklahoma, Norman, OK, United States

The Gateway Hypothesis claims that drug use evolves in stages. It begins with either tobacco or alcohol use, progresses to use of the other, then to marijuana, then to other more dangerous and illicit substances. Drug use in one stage is required for, but not a determinant of, use in subsequent stages. This study builds upon this established and validated work by showing the relationship between age of first use (AFU) of quasi-licit drugs and the likelihood of use of illicit drugs. Two explainable machine learning techniques, decision tree (DT) and logistic regression (LR), are applied to NSDUH 2016-2019 and 2022 data to model the relationship between determinant features (AFU of tobacco, alcohol, and marijuana) and any lifetime use of other illicit drugs. Both models are accurate, with AUROC values of 0.84 and 0.85 respectively. The DT model accurately predicts 84% of illicit drug users and 74% of non-users. The LR model predicts 79% of users and 77% of non-users. Both models find that marijuana AFU is a far more important predictive feature than alcohol AFU or tobacco AFU, and highlight risks of early marijuana use. These findings point to the need to set policies that improve limitations on access of marijuana to underage users.

5 - Effeciency Vs Education: the University of New Mexico&Rsquo;S Journey to Increased Efficiency in the Context of Emergency Medical Resident Education

Matt Frederick, University of New Mexico, Albuquerque, NM, United States

In 2023 UNM's emergency Department's overcrowding was exacerbated by the state mandated closing of “hall beds.” These beds (literally, in a hallway in the emergency department) allowed a higher number of patients to be out of the waiting room and in a more monitored environment but were technically unlicensed. The outcome of increased waiting room patients into such a stressed system inevitably leads to statistically poorer outcomes, and in a tangible sense often leads to people actually dying in the waiting room, only feet from some of the world’s most advanced resuscitation technology.

A vertical care (VC) area was created which allowed a more rapid evaluation and treatment of patients that would previously have been evaluated only in the waiting room. This unburdened the waiting room staff allowing them to be more efficient in their tasks leading to an overall decrease length of stay and better patient care.

However, the changes necessary for the VC implementation led to dramatic challenges within the educational ecosystem. Resident physicians are a key work force for our facility, and there is an inherent tension between educating future doctors and efficiently treating patients.

Our presentation will present this journey. We will cover the data-based decisions and then explore the human and educational factors that ultimately caused a deviation from our initial design. We will also present the outcome of our intervention, which has in a very real sense saved lives and ultimately improved the educational experience for our learners.

Digital Strategy

Invited Session

eBusiness

Chair: Haoyuan Liu, Nanyang Technological University, Singapore, N/A, Singapore

1 - Does Political Leaders&Rsquo; Technical Background Affect Firms&Rsquo; Digital Transformation?

Xinjun Yang, Nanyang Technological University, Singapore, Singapore, Haoyuan Liu, John Qi Dong

Digital transformation as firms’ changes of business models with digital technologies have been reshaping the competitive landscape across industries, yet scholarly understanding of its antecedents remains limited. This study addresses this gap from a resource dependence perspective by investigating the impact of technocrats with technical background in provincial governments on firms’ decisions toward digital transformation. Leveraging on the exogenous assignment of provincial government leaders in China, we find that a higher proportion of technocrats in provincial government leaders correlates with increased willingness of firms in the province to pursue digital transformation. This effect is notably more pronounced among private firms compared to state-owned enterprises and foreign firms, possibly due to resource limitations and thus a higher dependence on external institutional relations with governments.

---

2 - The Strategic Secretary Problem

Yufei Zhu, National University of Singapore, Singapore, Singapore, Joel Goh

In the classical secretary problem, secretaries have no decision agency and are simply assumed to arrive in a random order. In this paper we consider a novel variation of the classic problem. Motivated by modern online labor platforms where job-seekers have much more information at their disposal, we assume that secretaries are strategic agents and can choose their arrival time based on a privately revealed quality score. We consider a game between the hiring firm and N strategic secretaries and analyze the structure of the equilibria of this game. This paper tackles the questions: Do strategic secretaries gain more utility than non-strategic ones? Does the firm's ability to select the best secretary improve or deteriorate when secretaries are strategic?

3 - Echoes of Authenticity: Reclaiming Human Sentiment in the LLM Era

Yi Ding, University of Warwick, Conventry, United Kingdom, Yifei Wang, Ashkan Eshghi, Ram Gopal

This paper scrutinizes the unintended consequences of employing large language models (LLMs) like ChatGPT for editing user-generated content, particularly focusing on alterations in sentiment. Through a detailed analysis of a climate change tweet dataset, we uncover that LLM-rephrased tweets tend to display a more neutral sentiment than their original counterparts. By replicating an established study on public opinions regarding climate change, we illustrate how such sentiment alterations can potentially skew the results of research relying on user-generated content. To counteract the biases introduced by LLMs, our research outlines two effective strategies. First, we employ predictive models capable of retroactively identifying the true human sentiment underlying the original communications, utilizing the altered sentiment expressed in LLM-rephrased tweets as a basis. While useful, this approach faces limitations when the origin of the text—whether directly crafted by a human or modified by an LLM—remains uncertain. To address such scenarios where the text's provenance is ambiguous, we develop a second approach based on the fine-tuning of LLMs. This fine-tuning process not only helps in aligning the sentiment of LLM-generated texts more closely with human sentiment but also offers a robust solution to the challenges posed by the indeterminate origins of digital content. This research highlights the impact of LLMs on the linguistic characteristics and sentiment of user-generated content, and more importantly, offers practical solutions to mitigate these biases, thereby ensuring the continued reliability of sentiment analysis in research and policy.

4 - When Should an Online Retailer Reach Out to Consumers after Their Purchase?

Youngsoo Kim, Texas Tech University, Lubbock, TX, United States

This study attempts to answer when a full-line online retailer selling products from diverse categories (i.e., Amazon.com) should reach out to consumers after their purchase. We collected the data showing 361,263 transactions of 10,103 consumers from an online retailer selling diverse products. Our empirical analyses show that consumers buy at the *Amazon.com-style* online retailer highly irregularly due to increased shopping time flexibility. We find that online retailers need to reach out to consumers with marketing activities immediately after their purchase, because the likelihood of another purchase at the retailer continuously drops as inter-purchase time increases (monotonic decreasing hazard rate). We also confirm two other price promotion effects, in addition to the stockpiling effect of price promotion (i.e., cheaper prices induce more purchase). First, consumers who benefit from price promotions tend to adjust the next purchasing timing for another price promotion; consumers become more price-sensitive after experiencing a price promotion. Second, after consumers benefit from a price promotion, they are likely to purchase sooner at the retailer again than the consumers who purchased without a price promotion. This behavior is rationalized on habitual decision of an online retailer (a good impression after benefiting from a price promotion) or the increased loyalty to the online retailer. Our results provide useful bases for differentiation of marketing campaign timing according to purchase situation (e.g., elapsed time since the last purchase) as well as time-variant individual profile.

ENRE: Optimization and Learning for Sustainable Grids

Invited Session

ENRE: Electricity

Chair: Tongxin Li, The Chinese University of Hong Kong, Shenzhen, Shenzhen, N/A

1 - Reliable Machine Learning-Augmented Algorithms for Energy Systems and Sustainability

Nicolas Christianson, California Institute of Technology, Pasadena, CA, United States

Modern AI and ML algorithms hold immense promise for improving performance in decision-making under uncertainty, where traditional algorithms designed for the worst case may be overly conservative; this can potentially be transformative for energy and sustainability applications, where rapid improvements are crucial to facilitate the energy transition and reduce carbon emissions. However, AI and ML lack worst-case guarantees, hindering their deployment to real-world problems where safety and reliability are crucial. In this talk, I will discuss recent work on developing machine learning-augmented algorithms with provable performance guarantees and their application across the domains of energy systems and sustainable computing. In particular, I will focus on the questions of algorithmic upper and lower bounds for integrating ML and classic, worst-case approaches, how to optimally leverage uncertainty in decision-making, and designing risk-averse algorithms in these settings.

2 - Towards Environmentally Equitable AI via Geographical Load Balancing

pengfei Li, University of California, Riverside, Riverside, CA, United States

Fueled by the soaring popularity of large language and foundation models, the accelerated growth of artificial intelligence (AI) models' enormous environmental footprint has come under increased scrutiny. While many approaches have been proposed to make AI more energy-efficient and environmentally friendly, environmental inequity -- the fact that AI's environmental footprint can be disproportionately higher in certain regions than in others -- has emerged, raising social-ecological justice concerns. This paper takes a first step toward addressing AI's environmental inequity by balancing its regional negative environmental impact. Concretely, we focus on the carbon and water footprints of AI model inference and propose equity-aware geographical load balancing (GLB) to explicitly address AI's environmental impacts on the most disadvantaged regions. We run trace-based simulations by considering a set of 10 geographically-distributed data centers that serve inference requests for a large language AI model. The results demonstrate that existing GLB approaches may amplify environmental inequity while our proposed equity-aware GLB can significantly reduce the regional disparity in terms of carbon and water footprints.

3 - Hierarchical Forecasting in the Energy Domain: A State Estimation Approach

Matthew Motoki, University of Washington, Seattle, WA, United States, Jiayi Li, Baosen Zhang

In the energy sector, data often exhibits a natural hierarchical structure; for example, energy consumption data can be organized from device-level to household-level, to substation-level, and so on. Another natural hierarchy occurs when splitting sources of renewable generation into categories such as solar, wind, and hydro. Accurate and coherent forecasts across all levels in the hierarchy is critical for operational efficiency and strategic planning. In this paper, we present a novel hierarchical forecasting approach that generalizes traditional forecast reconciliation methods by formulating the task of creating coherent forecasts as a state estimation problem. Our method not only improves the accuracy at both the user and system levels but also addresses scalability challenges often encountered with existing techniques. We derive the optimal forecasts for the case where the users' noise is correlated and their target variable is a linear function of their input and show through simulation that our approach outperforms conventional methods. Furthermore, our method works with various objective functions and can be used to minimize the error in peak prediction, which historically has been a challenging problem. Finally, we provide empirical results involving nonlinear forecast models, such as neural networks and gradient-boosted decision trees, and introduce a scalable, distributed algorithm whose effectiveness is validated with real-world data.

Data Mining on Electronic Health Records: Extracting Key Features and Patterns Using Machine/Deep Learning

Invited Session

Data Mining

Chair: Zhuqi Miao, SUNY-New Paltz, New Paltz, NY, United States

1 - A Novel Hyperparameter Search Approach for Accuracy and Simplicity in Disease Prediction Risk Scoring

Yajun Lu, Jacksonville State University, Jacksonville, AL, United States, Thanh Duong, Zhuqi Miao, Thanh Thieu, Jivan Lamichhane, Abdulaziz Ahmed, Dursun Delen

This study introduces a novel approach to crafting risk scores for disease prediction models based on logistic regression. The objective is to find the optimal number of regression units per risk point, striking a balance between simplicity and accuracy for effective patient risk stratification. The proposed technique employs an adapted line search method and integrates the DeLong test to ensure accuracy comparable to existing approaches. Evaluation is conducted through case studies predicting diabetic retinopathy (DR) and hip fracture readmissions (HFR), involving large patient cohorts. Results show that our risk scores achieve comparable accuracies to existing methods. Notably, our scores exhibit a compact scale, contrasting with the broader ranges of existing methods. The discussion underscores the simplicity and accuracy of our approach, presenting it as a competitive alternative for disease risk prediction. In conclusion, this study offers a generalizable framework for developing precise risk scores with compact scales, addressing the need for effective risk stratification tools in healthcare.

2 - Empowering Disease Prediction: Data Extraction and Transformation from Cerner AWS Ehr Database

Hieu Nghiem, Oklahoma State University, Stillwater, OK, United States

In the era of data-driven healthcare which focuses on better outcomes, predictive analytics emerges as a transformative tool, offering the potential for accurate prediction of diseases. This leads to improvements in patient outcomes, as well as optimization of resource allocation for proper treatment strategies.

However, the efficacy of predictive models depends on the quality, breadth and diversity of the underlying data. Generally, in a data pipeline to prepare input for machine learning / predicitve modeling, ETL (Extract, Transform, Load) process plays a crucial role. ETL serves as the fundamental gateway, enabling the preparation and transformation of raw data into a format suitable for analysis and modeling. By ensuring data quality, consistency, and accessibility, a proper and efficient ETL process sets the foundation for building accurate, reliable, and effective ML models that can generate valuable insights and drive informed decision-making in various domains, especially in healthcare analytics.

This presentation focus on the data extraction and transformation process from raw data in Cerner EHR databases that are hosted on AWS Cloud (Amazon Web Services). The data is established and distributed through Apache Spark, a widely used unified analytics engine for large-scale data processing in the industry. By performing a comprehensive exploration of data wrangling workflows and methodologies through Python, SQL and PySpark API, we elucidate strategies for effective and accurate data orchestration process in which siloed data is extracted from multiple tables, combined, organized and tailored to match the unique demands of EHR data analysis and disease prediction.

3 - Extracting Patient History from Clinical Text: a Comparative Study of Transformer-Based Clinical Language Models

Zhugo Miao, SUNY New Paltz, The State University of New York, New York, NY, United States

History of Present Illness (HPI) and Past, Family and Social History (PFSH) are two crucial sections of a clinical note, providing valuable information that assists physicians in diagnosing and developing treatment plans. Moreover, they enable effective communication and continuity of care among healthcare professionals involved in the patient's care. However, extracting and analyzing patient history data documented in free-text clinical notes constitute a consistent burden to healthcare professionals. To address this challenge, this study developed a transformer-based named entity recognition model, which can identify detailed HPI and PFSH elements from clinical notes. We evaluated the model's performance and conducted error analysis to identify factors impacting the model's accuracy.

AI and Analytics for Good

Invited Session

Data Mining

Chair: Joseph Cazier, Arizona State University, Tempe, AZ, United States

1 - Ai for Good! for Sure?

Ryan LaBrie, Seattle Pacific University, Seattle, WA, United States

There has been a recent trend in artificial intelligence (AI) literature focused on AI advancements for “good”. Good for who? Good for the environment, good for humanity, good for the companies (and their shareholders) that create the technology, or perhaps good for all (or at least many of) those groups. This session seeks to examine and discuss some of the pinch points in which AI might not live up to the hype of being “good for all” and investigate what mechanisms can we use to prevent bias, ensure some level of transparency, or at least reproducibility, and ensure responsible AI usage? Are AI audits a viable solution or are there other frameworks or techniques we can draw upon to ensure an AI justice for all and advancement of human flourishing… for all!

2 - Primum Non Nocere: Guiding Principles for Model Development

Hina Arora, Arizona State University, Tempe, AZ, United States

AI models hold tremendous potential for societal benefit. However, without careful design and implementation, they can also lead to substantial harm. This presentation will use case studies from multiple sectors to extract key design principles for developing models that first do no harm.

3 - Succeeding in AI and Analytics

Joseph Cazier, Arizona State University, Tempe, AZ, United States

Reports on research into best practices for leading societal transformation with AI and Analytics.

4 - New INFORMS Resources to Foster Ethical and Successful AI and Analytics

Terry Rawls, Vulcan Academics, Durham, NC, United States

This presentation details updates to the INFORMS Course Leading in Analytics, including the inclusion of the INFORMS Ethics Course and updates for advances in AI.

1 - Enhancing AI-Assisted Medical Decision-Making: The Vital Role of Uncertainty Quantification

Shengfan Zhang, University of Arkansas, Fayetteville, AR, United States, Maryam Kheirandish

The use of Deep Neural Network (DNN) models in risk-based decision-making has garnered significant attention across fields such as medicine, finance, manufacturing, and quality control. To mitigate risks, it is crucial to assess prediction confidence or uncertainty alongside the algorithm's overall performance. Transitioning from deterministic and probabilistic DNNs to Bayesian deep learning models allows for quantifying prediction uncertainty through second-order prediction distributions. The Shannon entropy and mutual information help quantify and decompose this uncertainty into epistemic and aleatoric components, essential for uncertainty reduction strategies. However, entropy-based measures can be inconsistent, and mutual information may limit the consideration of multiple sources of epistemic uncertainty. Additionally, assuming errors following normal distributions, despite its simplicity, is inadequate for discrete errors. We propose a framework to quantify prediction uncertainty for DNN binary classification models using the variation-ratio measure. This approach supports risk-based decision-making when discrete errors in predictors are present. Our model addresses two sources of epistemic uncertainty: model parameters and errors in predictors with a known finite discrete distribution. This measure helps detect significant contributions of predictor errors to total uncertainty. Applied to a case study predicting tuberculosis treatment outcomes and 10 simulated datasets, our framework identifies risk-sensitive cases prone to prediction alterations due to predictor errors. Even when assuming epistemic uncertainty arises solely from model parameters, our framework demonstrates superior uncertainty awareness compared to the Monte Carlo dropout method.

2 - Medication Reconciliation with Artificial Intelligence and Operations Research Methods

Xinyu Yao, Carnegie Mellon University, Pittsburgh, PA, United States, Amogh Rao, Holly Wiberg, Rema Padman

Medication reconciliation is a vital intervention in healthcare management during care transitions, which aims at identifying the most accurate and complete list of the patient's medications by comparing the physician's admission, transfer, and discharge orders and addressing potential discrepancies. Ensuring alignment of the drug name, dosage, frequency, and route between the patient's existing medication regimen and the newly prescribed medication, medication reconciliation is promising to play a crucial role in enhancing patient safety and minimizing potential medication errors and adverse drug events (ADE) throughout their healthcare journey. Despite ongoing efforts to implement medication reconciliation, challenges persist in realizing its full effectiveness in practice. In this research, we develop an automated medication reconciliation process based on a combination of artificial intelligence (AI) and operations research (OR) algorithms. Our research objective is to significantly enhance the performance of medication reconciliation, thereby contributing to improved patient outcomes and reduced risks associated with medication-related issues.

3 - Abdominal Aortic Aneurysm Rupture Risk Classification Aided by Random Forest Using Biomechanical, Morphological, And Clinical Surrogates

Juan Restrepo, The University of Texas at San Antonio, San Antonio, TX, United States, Satish C. Muluk, Mark Eskandari, Ender Finol

Abdominal Aortic Aneurysms (AAA) ruptures lead to more than 15,000 deaths every year in the US. If a rupture occurs in the interior areas, up to 90% of patients suddenly die within 48 hours if left untreated or improperly treated. Predicting rupture risk is critical for timely surgical intervention and improved patient safety. The current standard of care is determined by a one-size-fits-all, maximum diameter approach. This study introduces an advanced classification framework using Random Forest (RF) to better predict AAA rupture risk, accounting for biomechanical, morphological, and geometric surrogates to translate clinical assessment towards patient-specific approaches. Our findings highlight the potential of integrating patient-specific surrogates into machine learning frameworks to enhance AAA rupture risk assessment. This approach could significantly aid clinicians in making more informed decisions regarding the necessity and timing of interventions, ultimately leading to personalized patient care and better clinical outcomes.

Flexibility Analysis for Renewable Dominated Power Systems

Invited Session

ENRE: Electricity

Chair: Jun Wang, The Univeristy of Hong Kong, Pokfulam Road, Hong Kong, Hong Kong, N/A, Hong Kong

Co-Chair: Yue Chen, The Chinese University of Hong Kong, Shatin, NT, Hong Kong, N/A

Co-Chair: Yunhe Hou, The University of Hong Kong, Hong Kong, Hong Kong

1 - Robust generator maintenance for resilient power systems

yang yang, NUS, Singapore, Singapore

Normal operation of a power system requires that alternating current frequency be maintained at a nomq frequency requires adequate inertia and frequency regulation reserve in the power system, which are primarily provided by online generators. In daily operations, generators that are due for preventive maintenance must be taken offline, and thus an improper maintenance schedule could jeopardize frequency security, as exemplified by the recent Texas power blackout. However, this natural nexus between frequency security and preventive maintenance has been overlooked largely in the literature. We fill the gap by developing a generator maintenance scheduling model over an annual planning horizon that incorporates frequency security constraints with hourly fidelity to meet industrial standards. These constraints essentially amount to scheduling adequate inertia and frequency regulation reserve by considering the uncertain power deficiency and inertia that result from intermittent renewable energy. We hedge the uncertainties by employing a robust optimization approach in which historical data are used to construct ambiguity sets. This inevitably results in an ultra-large-scale robust model because of the hourly fidelity. We show that it can be reformulated as a large-scale mixed-integer linear program. An algorithm based on the progressive hedging idea is then proposed to decompose the model into subproblems that can be solved in parallel. To speed the large-scale optimization, we develop a duality-free cutting-plane method for the subproblems and a novel lower bound for the model to collectively enhance computational efficiency. Compared with the standard progressive hedging algorithm and an L-shaped algorithm with strengthened Benders cuts, our algorithm can be 15 times faster and avoids the out-of-memory problems that arise with these benchmarks.

2 - Adaptive Flexibility Planning for Renewable-Power Charging Stations Under Decision-Dependent EV Diffusion Uncertainty

Yujia Li, Lawrence Berkeley National Laboratory, Berkeley, CA, United States, Feng Qiu, Yixuan Chen, Yunhe Hou

When deploying fast charging stations (FCSs) to support long-distance trips of electric vehicles (EVs), there exist indirect network effects: while the gradual diffusion of EVs directly influences the timing and capacities of FCS allocation, the decisions for FCS allocations, in turn, impact the drivers' willingness to adopt EVs. This interplay, if neglected, can result in uncovered EVs and security issues and even hinder the effective diffusion of EVs. In this paper, we explicitly incorporate this interdependence by quantifying EV adoption rates as decision-dependent uncertainties (DDUs) using decision-dependent ambiguity sets (DDASs). Then, a two-stage decision-dependent distributionally robust FCS planning (DR-FCSP) model is developed for adaptively deploying FCSs with on-site sources and expanding the coupled distribution network. A multi-period capacitated arc cover-path cover (MCACPC) model is incorporated to capture the EVs' recharging patterns to ensure the feasibility of FCS locations and capacities. To resolve the nonlinearity and nonconvexity, the DR-FCSP model is equivalently reformulated into a single-level mixed-integer linear programming by exploiting its strong duality and applying the McCormick envelope. Finally, case studies highlight the superior out-of-sample performances of our model in terms of security and cost-efficiency. Furthermore, the byproduct of accelerated EV adoption through an implicit positive feedback loop is highlighted.

3 - Flexiramp in Real-time Balancing: Product Introduction, Bidding Strategy Analysis, and Procurement Mechanism Optimization

Ziqing Zhu, Hong Kong Polytechnic University, Kowloon, Hong Kong

Flexiramp products are widely adopted in the United States electricity markets, such as CAISO and MISO, to address load uncertainty during real-time operations by incentivizing generators to reserve flexible ramping capacity within specific time intervals. However, the procurement and pricing mechanisms of this product remain open research questions, lacking simulation-based insights into generator bidding behaviors and social welfare under different mechanisms. This talk will first introduce existing pricing and procurement mechanisms for flexiramp products, followed by an exploration of utilizing multi-agent reinforcement learning methods to simulate bidding games in electricity markets with flexiramp products. Finally, we will analyze simulation results to derive optimization strategies for pricing mechanisms.

4 - Advanced Optimization for transportation electrification

Lusha Wang, University of Alabama, Tuscaloosa, AL, United States

Transportation Electrification will significantly reduce carbon emissions and reliance on fossil fuel. The world has seen an accelerating transition to electric vehicles (EVs) driven by environmental concerns, government promotions and battery technology advancements. On one hand, this transition brings in great positive environmental impacts; on the other hand, it introduces enormous challenges to existing power systems which were designed and constructed without considering massive EV integration. It is thus imperative to rethink the planning and operations of power grids and pave the way for EV everywhere. This talk will introduce challenges and opportunities associated with transportation electrification, especially in power distribution systems. In terms of operation, new optimization and economic models will be discussed to unleash EV flexibilities and enable various vehicles-to-grid (V2G) services such as voltage control, power regulation and outage restoration; in terms of planning, we will introduce new models for charging station placement considering both electricity and transportation system constraints and their interactions. These proposed methods can help stakeholders including governments, utilities, third-party operators and consumers, to mitigate EV impacts on power systems, leverage EVs to improve grid operations and renewable energy integration, as well as make optimal infrastructure investments to support a sustainable and equitable EV transition.

Futuristic Planning in Energy Generation and Markets

Invited Session

ENRE: Environment and Sustainability

Chair: Alexandra Newman, Colorado School of Mines, Golden, CO, 80401, United States

1 - Enhancing An Industrial-Scale Linear Program to Plan Capacity for a Power Generation System

Kathleen Tomon, Colorado School of Mines, Golden, CO, United States, John Ayaburi, Edikan Udofia, Alexandra Newman

The Regional Energy Deployment System (ReEDS) is a capacity planning model to examine the long-term effects of technology changes, market evolution, and policy decisions. ReEDS minimizes total capital and operational cost while adhering to capacities, demands, policies and technology interaction constraints. Because of added model complexities, solution times have grown. Previous work on improving the formulation led to a 35% reduction in model run time. We seek to further decrease solve times by enhancing formulation efficiency and employing advanced solution techniques.

This work is sponsored by GAMs.

2 - Optimizing Design and Dispatch of a Microgrid with Heterogeneous Heating Loads

Alexander Zolan, National Renewable Energy Laboratory, Golden, CO, United States, William Becker, An Pham

The adoption of distributed energy resources to serve all or part of a building's electrical load is growing in response to the declining cost of onsite renewables and energy storage. In addition to this, electrification of the built environment motivates the inclusion of thermal loads when considering technology selection to meet a building's combined energy needs, especially when considering decarbonization goals. We introduce REOpt, an open-source web tool that obtains cost-minimizing distributed energy resource designs subject to meeting electrical, heating, and cooling loads with or without a utility connection for residential and commercial customers. We present an extension to include multiple heating loads of different quality and demonstrate the impact of this extension on design selection. We then present case studies showing the impact of technology availability, costs, and emissions reduction goals on technology selection.

3 - Evaluating the State of Optimization Techniques in Environmental Sustainability Metrics for Mine Planning

Raymond Kudzawu-D'pherdd, Colorado School of Mines, Golden, CO, United States, Kwame Awuah-Offei, Esteban Koberg de La Cruz, Marcos Goycoolea, Alexandra Newman

Environmental metrics, critical for evaluating mining impacts in the 21st Century, are inconsistently applied in the mine planning processes. This mine-specific arbitrariness often leads to overlooked environmental considerations at the mine planning stages. Community opposition, driven by environmental concerns and a general distrust towards mining regulatory authorities and mining companies, has been amply documented from across the globe. In response, the concept of "sustainable mining" has emerged, aiming to harmonize community interests and mitigate opposition by focusing on environmental sustainability in mining operations. Despite the growing acknowledgment of the benefits of sustainable mining, there is a noticeable lack of literature on the effectiveness of current environmental metrics in fostering sustainable outcomes. We seek to address this gap by reviewing the status quo to identify, assess and proffer effective environmental metrics for sustainable mining. Our objective is to provide mining companies with recommendations for integrating environmental sustainability metrics into strategic planning, thereby improving operational efficiency, reputation, and stakeholder relationships. Surreptitiously, we are discovering how these metrics can be included at different stages of the mine planning process for entire mining value chain optimization.

4 - Trade-Offs from Vertical Integration Between Natural-Gas and Electricity Markets

Ramteen Sioshansi, Carnegie Mellon University, Pittsburgh, PA, United States

Electricity systems are becoming more dependent upon natural gas as an electricity-generation fuel. As such, electricity and natural-gas markets are becoming more interconnected. Some electricity and natural-gas markets are vertically integrating, through the merger of electricity and natural-gas suppliers. The market-efficiency impacts of this vertical integration is unclear. To study this question, we develop a Nash-Cournot model of the two interconnected markets. The model is converted into a linear complementarity problem, which allows deriving Nash equilibria readily. The model is applied to a stylized example with a range of parameter values. We find that integration is social-welfare enhancing--which implies that mitigating double marginalization outweighs the exercise of market power. In most cases, the effects of merger can give rise to a prisoner's-dilemma-type outcome, whereby firms have strong incentives to merge but merger is detrimental to producers.

5 - Sectoral Decomposition Methods for Multi-Sector Energy Capacity Expansion Models

Frederico Parolin, Massachusetts Institute of Technology, Boston, MA, United States, Ruaridh Macdonald, Yu Weng

Decarbonizing our energy systems will be significantly less expensive if investments and operations are coordinated across sectors, such as electricity, hydrogen, liquid fuels, etc. This coordination is especially important as technology and policy decisions in one sector will have knock-on effects elsewhere. This has created a need for multi-sector energy capacity expansion models which can co-optimize investments and operations across several sectors, long timeseries and multiple regions. However, adding additional sectors greatly increases the number of variables and constraints in the model, limiting optimizations to a few regions or short representative periods. This risks biasing the results. Decomposition methods offer a means of overcoming this problem, breaking up the original large optimization into an iterative process between several smaller problems. Bender's decomposition has successfully been applied to decompose models in time and in this work we have extended that method to also decompose models across sectors. In this presentation we describe the method and demonstrate the performance and accuracy compared to alternative approaches for a large model of the US lower-48 states. We show the reduction in runtime and memory usage versus model scale and how the additional model detail changes the investment results in the solution.

6 - Better Representative Period Selection in Capacity Expansion Optimizations Using Cheap Approximate Solutions

Nirmal Bhatt, Massachusetts Institute of Technology, Boston, MA, United States, Ruaridh Macdonald

Recent research has shown that capacity expansion optimizations give more robust solutions when they consider several years or decades of correlated weather and demand data. Similarly, stochastic optimization approaches allow extreme weather and events to be considered but also require optimizations to cover years of data. This need for long timeseries limits the feasible spatial resolution of models, meaning they do not capture important regional disparities, transmission congestion, and similar issues. One means of overcoming this challenge is to optimize energy systems over a subset of the timeseries, selecting representative periods which encompass the range of weather and demand patterns and lead to the same investment decisions and operational costs. This is a common method and can be combined with decomposition methods to parallelize the optimization and allow it to be distributed across a high-performance computer. So far, representative periods have been selected based on the model inputs but in this work we demonstrate that this can be improved by also incorporating approximate solutions to the investment and operations optimization. We show that our selection method allows for fewer or shorter representative periods to be used, reducing the total runtime even after calculating the approximate solutions and allowing for greater spatial resolution in the model, while also giving more accurate results.

Power System Planning and Operation IV: Stochastic Energy Infrastructure Planning at Scale

Invited Session

ENRE: Other Energy

Chair: Rahman Khorramfar, MIT, Cambridge, United States

1 - Adversarial Generation of Uncertainty Realizations for Adaptive Robust Optimization

Aron Brenner, MIT, Cambridge, MA, United States, Rahman Khorramfar, Jennifer Sun, Saurabh Amin

Adaptive robust optimization is a powerful approach for planning under uncertainty that aims to balance costs of "here-and-now" first-stage decisions with those of "wait-and-see" recourse decisions made after uncertainty is realized. Chance-constrained variants of these problems aim to optimize first-stage decisions with consideration of a priori probabilistic guarantees on resulting second-stage costs and feasibility. In general, these models cannot be optimized exactly and must be solved using safe approximations, which can be extremely conservative in data-driven settings where the true distribution of uncertainty is unknown. In this work, we develop a column-and-constraint generation algorithm for a class of adaptive robust optimization problems that generates adversarial uncertainty realizations using a variational autoencoder (VAE). We provide uncertainty sets with corresponding probabilistic guarantees and perform worst-case analysis using a projected gradient approach over the VAE latent space that differentiates the optimal second-stage objective value with respect to uncertain parameters. Finally, we apply our approach to an adaptive robust capacity expansion model for a zonal representation of the New England power system and compare our results to existing methods for adaptive robust optimization.

2 - Impact of Improved Power Flow Representation on Stochastic Nodal Capacity Expansion Planning

Tomas Valencia Zuluaga, University of California at Berkeley, Berkeley, CA, United States, Amelia Musselman, Jean-Paul Watson, Shmuel Oren

More frequent and intense weather events have highlighted the importance of planning for a resilient power grid, underscored by increasingly weather-responsive electricity demand and generation. The challenge of handling these inherently uncertain risks can be addressed with stochastic nodal capacity expansion planning models that incorporate climate projection data. However, that comes at a high computational cost driven by the need for a finer geographic resolution. The use of power transfer distribution factors (PTDF) in the representation of power flow constraints can help in reducing the size of the resulting problem. It can also make it more suitable for scenario decomposition methods like the progressive hedging algorithm, but necessitates special consideration, since the topology of the system changes as part of the optimization process. In this talk, we extend an existing PTDF formulation for transmission expansion planning to our stochastic, joint generation, transmission and storage expansion planning model. We consider different linear model formulations with varying representation accuracy of nodal power flow constraints and analyze their impact on the resulting optimal cost and investment plan returned by the model, using a realistic 500-bus system as test case and a year of representative days.

3 - Stochastic Capacity Expansion Planning Considering Interconnection Queue Uncertainty

Elizabeth Glista, Lawrence Livermore National Laboratory (LLNL), Livermore, CA, United States

Planning for the future of the power grid is of growing importance due to a variety of concerns: increasing demand for electric power, a shift toward weather-dependent sources of power generation, and increasing uncertainty due to climate risks. In this setting of high variability and uncertainty, multi-stage stochastic capacity expansion planning (CEP) can be used to inform long-term transmission, generation, and storage investment in a power system. However, its usefulness in practice is limited by the fact that most proposed expansion projects will never reach commercial operation. The overwhelming majority of proposed generation and storage projects are withdrawn at some point during or after the interconnection queue process. In this talk, we develop a probabilistic framework for quantifying the likelihood that a queued project will reach operational status, and we offer two distinct stochastic CEP variations that make use of these interconnection queue probabilities to inform investment decisions in the CEP model. By considering historical levels of queue clearing and construction, our models provide a more realistic description of possible future capacity expansion than existing CEP models. We compare results from the different nodal CEP model formulations on a large-scale synthetic-but-realistic California test case with over 8,000 buses and a year of representative future days. Our work demonstrates how the existing interconnection process limits CEP, providing further motivation for interconnection policy reforms.

4 - Integrated energy system planning under short-term and long-term uncertainty: Modelling and algorithms

Hongyu Zhang, Norwegian University of Science and Technology, Trondheim, Norway, Ignacio E. Grossmann, Brage Rugstad Knudsen, Ken McKinnon, Rodrigo Garcia Nava, Asgeir Tomasgard

We propose the REORIENT (REnewable resOuRce Investment for the ENergy Transition) model for energy system planning with the following novelties: (1) integrating capacity expansion, retrofit and abandonment planning, and (2) using multi-horizon stochastic mixed-integer linear programming with short-term and long-term uncertainty. We apply the model to the European energy system considering: (a) investment in new hydrogen infrastructures, (b) capacity expansion of the European power system, (c) retrofitting oil and gas infrastructures in the North Sea region for hydrogen production and distribution, and abandoning existing infrastructures, and (d) long-term and short-term uncertainty. We propose enhanced Benders decomposition methods to solve the model efficiently. We propose: (1) stabilising Adaptive Benders with the level set method and adaptively selecting the subproblems to solve per iteration for more accurate information, (2) a centred point stabilisation approach when the level method problem is hard to solve, and (3) dynamic level set management to improve the robustness of the algorithm by adjusting the level set per iteration.

The results show that: (1) compared with a traditional investment planning model, the REORIENT model yields 24% lower investment cost in the North Sea region, and (2) for a 1.00% convergence tolerance, the enhanced Benders is up to 6.8 times faster than the reference algorithm for MILP instances, and is up to 113.7 times faster than standard Benders and 2.14 times faster than unstabilised Adaptive Benders for LP instances. Finally, the dynamic level set management makes the algorithms more robust and is very helpful for solving large problems.

Data-Driven Optimization for Reliable Machine Learning (I)

Invited Session

Computing Society

Chair: Vasileios Digalakis, HEC Paris, Jouy-en-Josas, France

Co-Chair: Michael Lingzhi Li, Harvard Business School, Boston, MA, 02163, United States

1 - Distributionally Robust Optimization in Credible Learning with Healthcare Applications

Ioannis (Yannis) Paschalidis, Boston University, Boston, MA, United States, Yang Hu, Ruidi Chen

We consider the supervised learning of predictive models where predictor variables are organized into a group recommended by domain experts and several other groups of variables, where each other group contains variables encoding some specific type of information about the sample (e.g., indicator variables of some categorical predictor). We are interested in models that are dense in the expert group and group-sparse in the remaining groups, possibly allowing for the same variable appearing in multiple groups. We provide a distributional robust optimization formulation of this problem and a solution methodology. We demonstrate the effectiveness of our approach in several healthcare applications.

2 - Smart Predict-Then-Optimize for Two-Stage Linear Programs with Side Information

Alexander Estes, University of Maryland-College Park, College Park, MD, United States, Jean-Philippe Richard

We study two-stage linear programs with uncertainty in the right-hand side in which the uncertain parameters of the problem are correlated with a variable called the side information, which is observed before an action is made. We propose an approach in which a linear regression model is used to provide a point prediction for the uncertain parameters of the problem. We use an approach called *smart predict-then-optimize*. Rather than minimizing a typical loss function for regression, such as squared error, we approximately minimize the objective value of the resulting solutions to the optimization problem. We conduct computational tests that compare our method with other approaches for optimization problems with side information. The results indicate that our method can provide better objective values in situations where the true model is reasonably close to a linear model. Although the procedure we propose requires a longer time for fitting than existing methods, it requires less time to produce a decision for each given observation of the side information.

3 - An Extended Validity Domain for Constraint Learning

Yilin Zhu, University of Iowa, Iowa City, IA, United States, Samuel Burer

Many real-life optimization problems involve constraints that do not have explicit formulae, and learned constraints from available data will be used as an approximation. Therefore, we consider embedding a (predictive) machine learning model within a (prescriptive) optimization problem. In this setting, called constraint learning, we study the validity domain, a subset of the feasible set that constrains the optimization problem on a region where machine learning predictions are more reliable. In this talk, we propose a new validity domain which uses the convex hull idea in an extended space. We investigate its properties and compare it empirically with existing techniques on a set of test problems for which the ground truth of the optimization problems are known. Numerical results show that the extended convex hull method outperforms the existing methods in terms of function value errors. We also consider our approach within a pricing case study using real-world data.

4 - On a Rounding Mechanism for Orthogonality Constrained Optimization Problems

Ryan Cory-Wright, Imperial College London, London, United Kingdom, Jean Pauphilet

We propose a new rounding mechanism for orthogonality constrained problems, and study the quality of its solutions in both theory and practice. Orthogonality constraints arise in product recommendation applications like matrix completion, and data science applications line sparse principal component analysis with multiple components among others.

Joint work with Jean Pauphilet.

This is work in progress, stay tuned for a more detailed abstract nearer the conference.

Decision Diagrams for Optimization

Invited Session

Computing Society

Chair: Anthony Karahalios, Carnegie Mellon University, Pittsburgh, PA, United States

1 - Cutting Planes in Column Elimination

Anthony Karahalios, Carnegie Mellon University, Pittsburgh, PA, United States, Willem Jan van Hoeve

Column elimination is an exact method for solving discrete optimization problems. The method solved an open instance of the vehicle routing problem with time windows with 1,000 locations. To do this, column elimination solves a Lagrangian reformulation using a subgradient descent method. We study the incorporation of cutting planes in column elimination. We develop methodologies for adding both robust cuts and non-robust cuts from the column generation literature. For non-robust cuts, we implement weakened versions of the cuts and compare their strength to the weakened versions used in column generation. We compare different implementations and show experimental results on the capacities vehicle routing problem.

2 - Solving the Weapon Target Assignment Problem with Decision Diagrams

Ryan O'Neil, Nextmv, TBD, PA, United States

The Weapon Target Assignment Problem can be challenging to solve and to model. We examine this problem from the perspective of Decision Diagrams and Domain-Independent Dynamic Programming. We show this approach reduces modeling complexity and can yield good results.

3 - CODD: A Decision Diagram-based Solver for Combinatorial Optimization

Willem-Jan van Hoeve, Carnegie Mellon University, Pittsburgh, PA, United States, Laurent Michel

This presentation introduces CODD, a system for solving combinatorial optimization problems using decision diagram technology. Problems are represented as state-based dynamic programming models using the CODD language specification. The model specification is used to automatically compile relaxed and restricted decision diagrams that are embedded inside a branch-and-bound search process. We introduce abstractions that allow us to generically implement the solver components while maintaining overall execution efficiency. We demonstrate the functionality of CODD on a variety of combinatorial optimization problems and compare its performance to other state-based solvers as well as integer programming and constraint programming solvers. CODD provides competitive results and can outperform the other solvers, sometimes by orders of magnitude.

E-commerce Supply Chain Operations

Invited Session

Service Science

Chair: Ting Wang, University of Science and Technology of China, Hefei, N/A

1 - From Storefronts to Screens: An Exploration of Ship-From-Store, Customer Behavior, and Sku-Level Impacts

Hsiao-Hui Lee, National Chengchi University, Taipei, Taiwan, Wenzheng Mao, Zhanyu Dong, xiaoli Liu

In the ongoing evolution from brick-and-mortar (B&M) stores to multichannel operations, the “Ship-from-Store” (SFS) strategy stands out as a pivotal approach for achieving seamless omnichannel integration. Through SFS, B&M stores harness their in-store inventory to swiftly cater to the online demands of proximate customers. However, despite its potential to broaden customer reach, inappropriate implementation of SFS may yield detrimental effects for retailers, such as diminished cross-selling opportunities. Leveraging empirical data from a pharmacy retailing chain, this paper embarks on an investigation into the effects of SFS on customer behavior, inventory management, and resultant profitability. The paper's data-driven insights particularly underscore the significance of SKU-level analysis in comprehending the multifaceted implications of SFS on retail operations. With empirical observations as a foundation, we construct a stylized model and find the conditions under which a B&M retailer can benefit from SFS-namely, when in-store visit costs outweigh online waiting costs, thereby promoting a demand pooling effect and enhancing in-store fill rates. The study further reveals that reduced online waiting costs through SFS can induce market expansion or channel cannibalization, with the former proving the most profitable trajectory. In scenarios of partial channel cannibalization, profits can be augmented by astutely selecting high-margin, high cross-selling, and well-stocked items for online listing. Finally, our empirical analyses substantiate the paper's theoretical postulations and results, providing a cohesive narrative on the dynamics of SFS in modern retail.

2 - How Retail System Complexity Drives Inventory Record Inaccuracy: Empirical Evidence from Cross-Border E-Commerce

Ting Wang, University of Science and Technology of China, Hefei, China, People's Republic of, Kejia Hu, Stanley Lim, Yun Fong Lim, Yugang Yu

Problem definition: Accuracy of inventory recording stands as a fundamental pillar for maintaining and enhancing operational efficiency within retail systems. However, the advent of e-commerce presents an escalated challenge to this accuracy by exposing e-retailers to complex retail systems. Despite previous focus on internal complexity in offline retailing, understanding of how external complexity influences inventory record inaccuracy (IRI) remains scarce. This paper broadens the scope from traditional retail settings to e-commerce, offering an empirical exploration of the diverse dimensions of retail system complexity and their impact on IRI.

Methodology/Results: Utilizing a proprietary panel dataset from a cross-border e-retailer, inclusive of inventory, sales, and product attribute data, we delineate retail system complexity into various dimensions (internal versus external, static versus dynamic, and product versus component). We employ random-effects models to probe the relative significance of these dimensions in predicting IRI and use an instrumental variable approach to explore their causal effects on IRI. Our results underscore the overlooked role of external complexity as a more potent predictor of IRI in e-commerce, both independently and through its amplification of internal complexity's effects on IRI.

Managerial implications: Our findings lead to actionable insights into how e-retailers can strategically manage their retail system complexity to mitigate IRI and enhance profits. While system complexity can erode profit through IRI, it can also augment profit by attracting greater demand. Our counterfactual analysis yields specific guidelines for e-retailers to leverage the dual nature of retail system complexity for profit maximization.

3 - Supply Chain Instant Retail Introduction Strategy Considering Consumer Time Value

Sichao Yang, Tianjin University, Tianjin, China, People's Republic of, Baofeng Huo, Lin Miao

Online retailers and brick-and-mortar stores have collaboratively developed an "order online, fulfill in-store" instant retail service, leveraging online traffic and physical store capabilities to meet consumers' immediate needs, thereby creating a novel retail model. This study examines the introduction strategies of instant retail channels based on online channels of e-retailers and offline channels of physical retailers. It incorporates the quantified time value of consumers into channel selection, analyzing how time value, delivery timeliness, and commissions impact the competitive and cooperative relationships and game-theoretic equilibrium between channels. The findings indicate that the introduction of instant channels significantly affects the pricing competitiveness of both online and physical retail channels. When consumers' sensitivity to time value is low, the instant channel exhibits a clear competitive advantage, leading to a decline in market shares for both online and offline channels. Conversely, when consumers' time value sensitivity is high, the competitiveness of the instant channel diminishes, thereby enhancing the market shares of online and offline channels. Additionally, as consumers' sensitivity to time increases, the pricing and profits of instant and offline channels improve, though this change may adversely affect the market demand for the instant channel. Meanwhile, the additional costs of offline channels and consumers' perceptual differences in channel value significantly influence operational strategies. Overall, by implementing a reasonable instant channel strategy, it is possible to optimize channel efficiency and enhance the profitability of the entire supply chain without undermining the interests of offline channels, thereby achieving a Pareto improvement in the supply chain system.

4 - Exploring the Impact of Data Sharing and Direct Sales Channels on Corporate Decision-Making: A Perspective on Data Value

chunshen wang, Tianjin University, Tianjin, China, People's Republic of, Sichao Yang, Lin Miao, Baofeng Huo

With the rapid evolution of the digital economy, data resources have significantly become a key asset for companies to gain competitive advantage. In various links of the supply chain, the sharing of data has produced important new influences on product sales and service decisions. To deeply explore the interaction between enterprises' data sharing decisions and channel selection strategies, we constructed a game theory model involving a single manufacturer and a single retailer. The research findings indicate that in traditional retail channels, the decision of the manufacturer and retailer to share data is primarily influenced by both the cost of data sharing and the value of the data itself. In scenarios without direct sales channels, lower sharing costs prompt both parties to lean towards sharing data, while higher costs lead to a choice to retain data. After introducing direct sales channels, the decision-making process becomes more complex, especially in the context of higher sharing costs, leading to divergent strategic choices between manufacturers and retailers. Moreover, this study also finds that, whether under data sharing or retention strategies, manufacturers consider introducing direct sales channels only when the data has high mining value, whereas retailers tend to prefer maintaining traditional single channels. This research provides profound management insights into data sharing and direct sales channel strategies, emphasizing the importance of the unit value of data in decision-making, and the significant impact of data sharing strategies on enterprise profitability in a data-driven business environment.

Recent Advances in Design and Analysis of Computer Experiments

Invited Session

Quality, Statistics and Reliability

Chair: Cheoljoon Jeong, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Upala Junaida Islam, Arizona State University, Tempe, AZ, United States

1 - Selective Parameter Calibration via Sliced Sequential Design

Cheoljoon Jeong, University of Michigan, Ann Arbor, MI, United States

Parameter calibration seeks to estimate unobservable parameters in a computer model by aligning field observations with computer model outputs. In the building sector, a physics-based building energy computer model is developed to analyze the building energy use, given various weather conditions and operational scenarios. To obtain accurate simulations, it is necessary to calibrate building-related parameters required for pre-configuration. Recently, Bayesian optimization has received attention in the literature, but it suffers when the number of parameters is large since it tends to overly search the parameter space near the boundaries where predictive uncertainty is high. It becomes even more problematic when model misspecification occurs in these boundary regions, yielding unreasonable outcomes. To address this challenge, this study suggests a new calibration approach that slices the parameter space stochastically based on the importance measure and that designs the next query point in the respective subspaces sequentially. The numerical studies and building energy simulation case study demonstrate that the proposed approach achieves a significant improvement in both calibration accuracy and efficiency, compared to other alternatives. Furthermore, our approach allows to explain the parameter importance, so that it examines which parameters receive greater emphasis throughout the calibration process.

2 - Complete Active Learning for Emulation and Optimization

Difan Song, ISyE Georgia Tech, Atlanta, GA, United States, Roshan Joseph

Gaussian process (GP) models are widely used in active learning for emulation and optimization of black-box functions. The existing GP-based active learning procedures start with an initial design and then add points using some acquisition functions. If the initial design is too small, the response surface may be under explored and the algorithm may terminate prematurely at a local optima. On the other hand, if the initial design is too large, then we may waste valuable resources and may miss the interesting regions of the response surface. This article proposes a new active learning procedure that completely avoids the initial design. This is achieved by using a new correlation function and a new GP model, which automatically embeds a projection-based space-filling criterion into the acquisition functions. Through theory and simulations, we show that the proposed procedure, which we call COMPlete ACTive (COMPACT) learning, outperforms the existing active learning procedures.

3 - Consistent Exploration-Exploitation Trade-Off in Active Learning Regression with Dirichlet Process Prior

Ashif Iquebal, Arizona State University, Tempe, AZ, United States, Upala Junaida Islam

The trade-off between exploration and exploitation in active learning for regression problems remains significantly understudied. This paper addresses this challenge by generalizing a Bayesian hierarchical model to estimate the trade-off parameter η dynamically. We model η using a mixture distribution with a Dirichlet process prior, effectively capturing uncertainty within and between querying stages. Our work is the first to provide theoretical guarantees on the convergence and consistency of the exploration-exploitation trade-off, as well as bounds on the sample complexity of the active learning framework. We validate our approach through simulated and real-world case studies, demonstrating an average 14% reduction in generalization error compared to traditional active learning methods.

4 - Bayesian Optimization for Knowledge Discovery in Electromagnetics

Pouya Ahadi, Georgia Institute of Technology, ATLANTA, GA, United States, Kamran Paynabar, Reza Marzban, Ali Adibi

Electromagnetic (EM) nanostructures, such as metamaterials and metasurfaces, play a crucial role in advancing the compactness and functionality of modern devices by controlling light-matter interactions at subwavelength scales. Understanding and optimizing these interactions is key to fully utilizing their potential, yet traditional design methods are often hindered by extensive computational demands and limitations in accurately capturing the complex dynamics involved. The primary goal is to enhance device performance through novel designs that effectively control electromagnetic wave propagation, which is crucial for developing next-generation technologies.
Artificial intelligence (AI)-based methods have been used to enhance design optimization, providing powerful tools for predicting and optimizing the behavior of nanostructures. Despite their advantages, these techniques often face challenges with non-unique design scenarios and can be complex to implement and understand. In this study, we use the Gaussian Process (GP) regression technique to build a relationship between the design of a nanostructure and its wave propagation, as measured by its reflection spectrum. Considering the time-consuming nature of experimental measurements of wave propagation for a specific design, we face the challenge of limited data availability. We apply Bayesian Optimization (BO) to explore near-optimal design patterns, aiming to provide practical improvements in the field of electromagnetic nanostructures. Our experimental results validate the effectiveness of our proposed BO framework in achieving improved design solutions.

5 - Accelerating Material Discovery through Balanced Exploration-Exploitation of the Design Space

Ahmed Shoyeb Raihan, West Virginia University, Morgantown, WV, United States, Imtiaz Ahmed

The quest for discovering new materials with optimal properties is a critical endeavor in advancing technological and environmental progress. Our research addresses the critical challenge of balancing exploration and exploitation within the domain of accelerated material discovery, employing sequential learning techniques. The exploration-exploitation dilemma is a major challenge in material discovery and development, where exploration refers to the search across a broad range of potential material configurations, often leading to novel discoveries, and exploitation involves focusing on refining known materials to optimize their properties. Efficiently managing this trade-off is crucial as excessive exploration can deplete resources without guaranteeing results, whereas excessive exploitation might overlook potentially superior materials. Our approach is designed to navigate the extensive material design space efficiently, aiming to quickly hone in on materials with the desired properties while minimizing experimental resources. We propose a strategic framework that improves upon traditional methods by better managing the exploration-exploitation balance, thereby significantly reducing the time and cost associated with experimental trials. This study is expected to offer insights into more effective strategies for material discovery, enhancing the speed and efficiency of identifying materials with desired properties across various domains.

High-dimensional Data Analysis: Modeling, Monitoring and Control

Invited Session

Quality, Statistics and Reliability

Chair: Mohammad Bisheh, Georgia Institute of Technology, Atlanta, GA, United States

1 - Robust multivariate functional tensor decomposition

Mohammad Bisheh, Georgia Institute of Technology, Atlanta, GA, United States

In the landscape of Industry 4.0, a vast array of data is captured during manufacturing processes, frequently contaminated with outliers that can severely weaken the performance of process monitoring procedures, particularly in complex and high-dimensional environments. Addressing this, we propose a robust functional tensor decomposition algorithm to enhance monitoring processes by tackling time decentralization and anomaly contamination effectively. Signal data, whether from manufacturing sensors or health monitoring devices, commonly encounters the dual challenges of decentralized time recording and universal anomalies across time and feature domains. These complications can significantly undermine the efficacy of traditional control charting systems. Our novel algorithm strategically decomposes the observed functional tensor into two distinct components: the true low rank functional tensor and an anomalous tensor. This decomposition is achieved by leveraging the continuity characteristic in functional signals and exploiting the sparsity of anomalies, thus ensuring a more accurate anomaly detection and isolation. To validate our approach, we employ a simulation framework that demonstrates the algorithm's enhanced capability to identify and separate anomalies within sparse tensors. This capability marks a significant improvement over conventional methods that typically neglect the functional nature of data or struggle with cell-wise or component-wise anomalies. The results not only emphasize a theoretical advancement in functional data analysis but also highlight practical implications for industries reliant on precise and reliable data monitoring systems.

2 - Optimizing Machine-to-Machine Reproducibility with Deep Auto-Encoding Multi-Task Gaussian Processes

Logan Heck, The University of Texas at San Antonio (UTSA), San Antonio, TX, United States, Adel Alaeddini, Krystel Castillo

Manufacturing industries continually seek innovative approaches to enhance product quality in a cost-effective manner. Machine learning algorithms are proficient in recognizing complex features and patterns in large swaths of data. This study introduces a deep auto-encoding multi-task Gaussian process to improve manufacturing reproducibility for parts produced using a Form 3+ SLA 3D printer. Building on prior research that captured input parameters and dimensional deviations for the selected SLA printer, this study leverages the proposed Gaussian process to predict the resulting deviations on parts based on specific input parameters. This utilization of a machine learning algorithm for optimization purposes will allow for a less time-consuming method in determining what input parameters significantly influence the overall quality of parts produced via additive manufacturing. While limited by a small number of available data points, this study showed promising results in the algorithm's ability to better predict the true deviations of the printed parts over time.

3 - Sparse Linear Discriminant Analysis with Knowledge Transfer

Xinwei Deng, Department of Statistics, Virginia Tech, Blacksburg, VA, United States, Xiaoning Kang, Xiaoyu Chen

High-dimensional data with limited sample size commonly arise in the scientific and engineering applications. The data scarcity brings much difficulty for training models and conducting inference. The transfer learning is known to be a useful technique when different but possibly related data (auxiliary data) are available in addition to the original target data in the study for modeling and estimation. In this work, we propose a transfer learning method for sparse linear discriminant analysis under the high-dimensional data setting. The key idea of the proposed method is to effectively identify the informative auxiliary data and transfer the useful information from such selected auxiliary data to greatly enhance the modeling of the target data. Theoretical properties of the proposed method are investigated coupled with developing an efficient computational algorithm for model estimation. The performance of the proposed method is evaluated by both simulation and real case study.

4 - Predictive modeling of surface topography using power signal in wire electrical discharge machining

Bochi Liu, Rutgers, The State University of New Jersey, Piscataway, NJ, United States, Yuebin Guo, Weihong "Grace" Guo, Wenyuan Wang

Wire electrical discharge machining (WEDM) is a non-contact manufacturing process that uses a travelling wire electrode to cut hard workpieces with complex geometries. Surface topography significantly impacts the performance of machined workpieces, affecting qualities such as fatigue life, abrasive wear, and corrosion resistance. Measuring the surface topography of machined workpieces usually needs to be done after the machining process is complete, and some measurements may cause irreversible damage to workpieces. Therefore, online reconstruction of surface topography in WEDM is necessary to improve surface quality and production efficiency. Furthermore, as WEDM gets smarter and more complex, it involves a large number of control parameters, such as peak current, voltage, pulse on time, pulse off time, and electrode feed rate, etc. Current physics-based methods require complex mathematical modeling of the WEDM process, which is often challenging to implement. Machine Learning (ML) methods can estimate the complicated relationship between control parameters and surface topography based on data, which reflects their advantages compared with physics-based methods. Additionally, since WEDM relies on electrical discharges to remove material, it is promising to simplify the high-dimensional control parameters using WEDM's discharge power. This study proposes a predictive modeling of surface topography based on power signal in WEDM. Time-frequency analysis and empirical mode decomposition are used to extract features from the power signal and measured surface topography. Multiple ML models are employed to find the complex nonlinear relationship between these features. Spatial interpolation analysis is applied to reconstruct the predicted surface topography.

Diversity, Equity, and Inclusion Research in Operations Management

Invited Session

Diversity, Equity, and Inclusion

Chair: Lu Kong, University of South Florida, Tampa, FL, United States

1 - Bias Beyond the Screen: An Inequity Wake-up Call in Online Teaching's Evaluations

Lu Kong, University of South Florida, Tampa, FL, United States, Kejia Hu, Lanfei Shi, Timothy Vogus

Our study investigates the impact of the transition to online education on student evaluations of teaching (SETs), with a particular focus on disparities related to the gender and race of instructors. Utilizing data from RateMyProfessor.com, which includes 598,252 ratings from instructors at the top 150 U.S. colleges, we employ a Difference-in-Differences-in-Differences (DDD) model design combined with Propensity Score Weighting to analyze these effects. This approach helps us quantify changes in SETs following the shift from offline to online teaching environments, particularly during the first six months after U.S. universities adopted online formats due to COVID-19.

Our findings reveal a pronounced decline in evaluations for non-white male instructors, who experienced a 27.03% drop in ratings—a significantly steeper decrease than their counterparts. Further analysis using text mining techniques on student comments suggests that this disparity is partly driven by reviews containing language sensitive to diversity and inclusion, as well as comments emphasizing the hedonic aspects of education.

The study highlights the underlying mechanisms contributing to biases in SETs and suggests that these disparities are exacerbated in online learning contexts. To address these issues, we propose several strategies for educational institutions. These include the adoption of multiple assessment methodologies to evaluate teaching effectiveness, the redesign of teaching evaluation questionnaires to eliminate inherent biases, and initiatives to raise awareness about potential biases among students and faculty.

Our research provides valuable insights into the challenges of fair evaluation in online education and offers practical recommendations for enhancing equity in academic assessments.

2 - Racial Disparities in Health Technology and Its Impacts on Quality of Care: the Case of Biased Readings from Spo2 Sensors

Gaurav Jetley, Colorado State University, Fort Collins, CO, United States, He Zhang

Recent explorations in healthcare processes have revealed a significant bias in clinical measurements affecting care delivery, particularly within Intensive Care Units (ICU). Notably, pulse oximetry has been identified as systematically overestimating oxygenation levels in Black patients compared to White patients. This study investigates how such biases in SpO2 measurements influence subsequent clinical and operational decisions, thereby impacting patient outcomes and resource utilization in ICUs. Utilizing a comprehensive dataset of approximately 73,000 ICU stays, patients were divided into those monitored with only SpO2 and those with both SpO2 and SaO2 measurements. We use a serial mediation model which focuses on the impact on early readmissions due to early discharges taking place because of lower supplemental oxygen delivery likelihood due to inflated SpO2 measurements for Black patients. Our causal identification strategy using instrumental variables shows that Black patients in the SpO2-only group were less likely to receive supplemental oxygen, which leads to shorter LOS and higher 30-day readmission rates. This relationship was mediated by the omission of supplemental oxygen and a shortened LOS, suggesting a risk of premature discharge. Conversely, the availability of both SpO2 and SaO2 measurements neutralized racial disparities in oxygen delivery and early discharge. The findings underscore the need for refined healthcare protocols and information systems to identify and protect high-risk patients, ensuring equitable healthcare delivery across all demographic groups. These operational insights are crucial for improving quality of care and reducing readmissions in racially diverse populations.

3 - Can Workplace DEIB enhance manufacturing environmental performance? Evidence from Employment Non-Discrimination Acts

Suvrat Dhanorkar, Pennsylvania State University, University Park, PA, United States, Max Ji, Suresh Muthulingam, Kevin Linderman

In this study, we explore how enhanced workplace Diversity, Equity, Inclusion, and Belonging (DEIB) affects toxic releases in manufacturing operations. To investigate this idea, we utilize the staggered adoption of Employment Non-Discrimination Acts (ENDA), which prohibit discrimination based on gender identity or sexual orientation. We adopt a robust staggered difference-in-differences (SDiD) approach, which allows for heterogeneous effects and a conditional parallel trend assumption, and find that enhanced workplace DEIB, facilitated by ENDA enactments, leads to better environmental performance.

4 - Racial and Gender Biases in Customer Satisfaction Surveys: Evidence from a Restaurant Chain

Yong-Pin Zhou, University of Washington, Seattle, Seattle, WA, United States, Masoud Kamalahmadi, Qiuping Yu

Racial and gender inequalities are ubiquitous in the workplace. Whereas previous studies have primarily focused on employer discrimination, we study the role of customers, using 1,444,044 transactions and 257,656 customer satisfaction surveys from a full-service casual-dining restaurant chain in the US. We find that customer ratings of servers are biased against racial minority, and, interestingly, also against females despite their majority in this occupation. We further find evidences that suggest that statistical discrimination is the primary driver for racial biases, while status-based discrimination is likely the main driver for gender biases. These findings are robust in a number of additional tests. Given these underlying mechanisms, we propose tailored strategies to mitigate the biases.

Summit - 325

Pricing and Selling Strategies

Contributed Session

Chair: Mitsuki Nakano, Waseda University, Tokyo, N/A, Japan

1 - Foot-in-the-door auctions: Surcharges in online procurement

Timo Heinrich, Hamburg University of Technology, Hamburg, Germany, Ernan Haruvy, Matthew Walker

Anecdotal evidence suggests that buyers in online procurement are at the risk of hold-ups despite reputation mechanisms and possible litigation. In a first step, we analyze data from a popular platform that offers buyer-determined procurement auctions for services. Based on a structural econometric model, we provide evidence that some bidders ask for very low prices that can be rationalized through unexpected surcharges. We assume that negative costs are recovered through unobserved surcharges and estimate a lower bound for their effect on buyer surplus. We find that for medium-cost and high-cost projects, the effect is negligible. However, for low-cost projects, surcharges amount to at least a quarter of the final price, which reduces expected buyer surplus. In a second step, we conduct a pre-registered online experiment to evaluate which aspects of the decision environment drive surcharging. Many factors can affect surcharging in the field, including widely studied aspects such as the cost overruns, expected cost of litigation or reputational concerns. We develop a stylized procurement game and disentangle the role of three additional factors: fairness norms, social norms, and competition.

2 - Interactions between the platform's entrant and manufacturer's channel decisions under the dual-market system

Ruiying Yuan, Tianjin University, Tianjin, China, People's Republic of, Zhaofang Mao, Zuojun Max Shen

The full lifecycle concept has prompted sellers to provide ancillary services based on traditional product sales, leading to a dual-market system consisting of a base market and an add-on market. In this study, we consider a manufacturer selling base products through an online retail platform and then selling add-on products directly to consumers who have purchased base products. We investigate how the manufacturer's distribution channel strategy in the base market interacts with the platform's entrant strategy in the add-on market. We identify the manufacturer's wholesale price effect (sales-control effect) in the base market caused by the platform's entrant of the add-on market under the reselling (agency) channel. Additionally, when facing negative influences, the dual-market system endows the manufacturer with the focus-shift effect. If the manufacturer adopts the agency (reselling) channel in the base market, the platform prefers (not) to enter the add-on market to compete with the manufacturer; if the manufacturer adopts the dual-channel, the platform prefers to enter only if both the commission rate and channel competition are high. Furthermore, the manufacturer prefers the dual-channel when both the commission rate and channel competition are low. Interestingly, due to the interactions between the two firms, the manufacturer will adopt the agency channel instead when the commission rate is extremely high. Finally, we examine conditions under which the platform has incentives to allow the manufacturer to change from a single-channel to a dual-channel in the base market.

3 - Dynamic Pricing Algorithm with Demand Learning Under Minimax Regret

Jingcheng Lei, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, ruijing wu, Shaoxuan Liu

We consider a monopoly firm that sets prices for a new product dynamically under incomplete information. At the beginning of the selling season, the firm only knows the support of customers' valuation, but has no information about the distribution of their valuation. In order to model this situation, we design a robust dynamic pricing scheme whose objective is to minimize the worst-case regret. By observing customers' purchase actions, the firm learns customers' valuation continuously and updates their pricing decisions dynamically. We consider two distinct kinds of customers: homogeneous customers and heterogeneous customers. For homogeneous customers, we design an optimal pricing policy with respect to the minimax total period regret rule for each possible scenario. We show that the minimax regret is identical in any price paths and prove that the T-period minimax regret is bounded by O(log T). For heterogeneous customers, given information on historical prices, we propose an forward algorithm of calculating optimal price under minimax regret. Furthermore, numerical experiments show that the algorithm can accurately learn the optimal price and performs better compared to the traditional methods.

4 - Pricing Non-Standard Vegetables Considering Customer Evaluation

Mitsuki Nakano, Waseda University, Tokyo, Japan, Kotomichi Matsuno, Takahiro Ohno, Yoshikuni Edagawa, Takaaki Kawanaka, Shinya Takata

In Japan, approximately 1.7 million tons of harvested vegetables are not shipped, accounting for about 13.7% of the total. Additionally, some vegetables are discarded before being counted in the harvest. Including these discarded vegetables, it is reported that approximately 30% of the vegetables produced are wasted. These vegetables that do not meet shipping standards are called "non-standard vegetables." Non-standard vegetables are produced by farmers that do not meet the standards set by agricultural cooperatives due to damage, size, shape, etc., and cannot be sold on the market.

Currently, an increasing number of farmers are selling through D2C channels such as e-commerce sites to reduce the loss of non-standard vegetables. However, interviews with e-commerce businesses that sell substandard vegetables revealed that demand is unstable. This may be

due to incorrect pricing.

The purpose of this research is to propose a method for calculating the price that consumers feel is appropriate for non-standard vegetables when compared with standard vegetables. A prediction model is constructed using the appearance characteristics (blemishes, size, shape, color) and consumer attributes of non-standard vegetables as explanatory variables, and the expected purchase price as the objective variable. Based on the vegetable standards set by agricultural cooperatives, the appearance characteristics of non-standard vegetables are divided into two to three levels. An experimental design method is used to conduct an online survey asking consumers what a fair price is. The results of this research are expected to lead to methods that increase consumers' willingness to purchase non-standard vegetables at reasonable prices.

1 - A Study on the Successful Opportunity of Regional Revitalization in Old Public Dormitories: A Dynamic Perspective from Actor-Network Theory

wenjung Chang, National Chung Hsing University, Taichung, Taiwan, Chang-Yen Lee, Mingchang Chih, Yu-Jyun Ma

In recent years, with the rapid development of urbanization, countries around the world are facing the problem of unbalanced urban and rural development, with the decrease and aging of rural populations becoming increasingly prominent. Therefore, areas outside of cities need to actively seek pathways for revitalization, cultural preservation, and sustainable development in the future. Governments worldwide are paying more attention to balanced urban and rural development, with local innovation becoming a popular keyword for regional revitalization.

The article adopts an Actor-Network Theory (ANT) perspective to explore the dynamic evolution of the life cycle of the " regional revitalization" industry across four stages: issue formation, organizational networks, productivity, and redevelopment, as well as decline and dissipation. Through this exploration, it aims to observe the dynamic developmental trends of network governance among organizations.

Through an open-convergent exploratory research approach, the study aims to identify the issues in network governance at each stage within an integrated framework, along with the key influencing factors on implementation. Additionally, employing independent sample t-tests and Cohen’s d to test effect sizes, the study conducts independent sample heterogeneity difference analysis between the PR and BM groups, revealing significant cognitive differences regarding the success opportunities for the revitalization of Zhongxing New Village street blocks at the "Organizational network stage". The findings contribute to broadening the theoretical perspective on inter-organizational network governance relationships, while also proposing research conclusions and practical strategy recommendations for the development of organizational networks in revitalizing old military dependents’ village street blocks.

2 - Assessment and Industry Benchmarking of Supply Chain Resilience to Understanding Resiliency Capabilities in Specific Industries in Singapore

Ning Liu, Advanced Remanufacturing & Technology Centre (ARTC), Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, Allan N Zhang, Louiz Lee, Shanshan Yang

Within the dynamic landscape of Singapore, the imperative of Supply Chain Resilience (SCR) amidst global COVID-19 pandemics, natural disasters, and geopolitical tensions, is critical for businesses. This paper presents a combination of qualitative and quantitative methodologies for resilience assessment and benchmarking in specific industries. SCR, the capacity to withstand disruptions while consistently delivering goods and services efficiently, is investigated through seven crucial capabilities, including agility, anticipation, collaboration, diversification, flexibility, redundancy, and visibility. To measure SCR, a resilience score (R+) ranging from 1 to 5 is proposed for benchmarking.

This paper presents some key findings as follows. Firstly, it offers insights into the companies’ SCR status at enterprise level, identifying gaps and providing a roadmap for bolstering SCR. Secondly, we investigate the industry landscape of Singapore, highlighting differentials and gaps in SCR capabilities across sectors. Notable resilience variations across industries and significant differences between the top and bottom tiers are also explored. Thirdly, by illuminating industry-specific resilience dynamics, we contribute to the scholarly understanding of SCR in the Singaporean context by benchmarking against peer performance. Finally, this paper provides a systematic approach for assessing SCR including identifying gaps, prioritizing necessary capabilities, and creating actionable plans for practitioners and policymakers. Tailored approach designed to address the unique challenges encountered by each sector are recommended to foster the adoption of robust SCR practices throughout Singapore's supply chains.
This research is supported by the Agency for Science, Technology and Research (A*STAR) under its A*STAR – MiRXES Agile Diagnostics Manufacturing Joint Lab (Grant No.: I2301E0017)

3 - A unified modeling framework of mixed traffic based on macro-micro behavioral connection

Jia Li, Washington State University, Pullman, WA, United States, Di Chen

Traffic systems are shared by heterogeneous driving agents (e.g. human drivers and autonomous vehicles, passenger cars and trucks), therefore modeling mixed traffic plays a pivotal role in understanding, managing, and operating such systems. Various mixed traffic models have been proposed in recent years, but their context and rationales vary considerably from each other. There lacks a unified framework to connect and coherently explain them, and this limited understanding hinders the interpretability and generalization of these models. In this presentation, we propose a unified analytical modeling framework to fill this gap and show how the framework helps to better understand

mixed traffic behaviors. The core idea of this framework is establishing the connection between macroscopic flux functions of mixed traffic with microscopic agent interactions, encapsulated by their speed functions and cooperativeness. We show that interactions of agents will fully determine a mapping between microscopic perceived density and macroscopic density of the system. This property allows a unified derivation of macroscopic flux functions of mixed traffic, which reduces to computing microscopic perceived densities and estimating speeds of different classes of agents. Using this framework, we will discuss the connections of a few popular models of mixed traffic and uncover microscopic behaviors of driving agents implied by these models and highlight the role of driving agent interactions in achieving collective cooperation in mixed traffic systems.

4 - Commuters' periodic mode usage pattern in the credit-based mobility system with trip uncertainty

HONGXING DING, The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Xinwei Li, Hai Yang

Uncertainty has received great attention in traffic demand management, which is commonly considered from an aggregate viewpoint. Few studies investigate tip uncertainty that arises from individual future uncertain trip needs. This study examines heterogeneous commuters’ day-to-day strategic mode usage behavior during a credit Charge-cum-Reward (CCR) scheme period, considering individual trip uncertainty. We consider whether commuters are confronted with an irregular and urgent trip as a random variable which is known only to the individual at the start of each day. Based on such trip type information, each commuter decides the mode usage behavior for both current day and future mode usage pattern to minimize individual periodic travel cost. We model commuters’ day-to-day mode choices as a two-stage mixed-integer linear programming problem. The model provides a closed-form solution for each commuter’s daily best strategy based on the current trip type and credit balance. The day-to-day variances in both individual mode usage behavior and system-wide flow pattern across a CCR scheme period are further examined. We also explore the system properties and stability conditions. Our findings show that the system-wide auto flow exhibits two trends across the period, with relatively high flow at the beginning stage and relatively low flow at the second stage. The trend change point is related to the CCR scheme. We reveal the impact of the period length on commuters’ daily decisions and provide insights into how individual commuters make optimal day-to-day dynamic mode choices under the CCR scheme with trip uncertainty.

5 - Optimal Allocation of Critical Equipment in Collocation Data Centers

Neda Zarayeneh, Hitachi America, Santa Clara, CA, United States, Malarvizhi Sankaranarayanasamy, Pegah Mavaie , Omanshu Thapliyal, Prasun Singh, Ravigopal Vennelakanti

In the digital era, colocation data centers support businesses of varying sizes but need help with the supply backlog of critical equipment, delaying the fulfillment of customer demands. To address this issue, this paper presents a comprehensive approach encompassing all stakeholders within the data center's supply chain, including demand, supply, procurement, and operational processes. We emphasize the importance of forecasting demands well in advance to enable timely procurement of essential equipment. We integrate internal and external demand signals to develop precise, long-term, multi-horizon forecasting models.

Our study introduces a novel multi-variable time series forecasting framework designed to predict the power capacity needs of colocation data center customers. This framework uses a modified transformer-based model, PatchTST, customized for power capacity predictions. We evaluate its performance against RNN-based models like SegRNN and LSTM and transformer-based models like FEDformer and Informer, demonstrating its effectiveness in long-term demand forecasting.

Current industry practice of predicting demand based on the past two to three quarters often leads to inflated or inaccurate forecasts influenced by sales personnel, a phenomenon known as sandbagging. Our method incorporates external factors like macroeconomic indicators to enhance forecasting precision. After establishing demand, we align predicted capacities with required equipment and manage procurement. We then optimize resource allocation to meet customer demands, minimize wait times, and enhance the order-to-cash cycle. A dynamic system tracks remaining customer capacity and prioritizes resources effectively. The problem is mathematically formulated to reduce delivery times and increase revenue, constrained by facility capacity, demand sufficiency, resource availability, and non-negativity.

1 - Improved Bayes Risk Can Yield Reduced Social Welfare Under Competition

Meena Jagadeesan, UC Berkeley, Berkeley, CA, United States, Michael Jordan, Jacob Steinhardt, Nika Haghtalab

As the scale of machine learning models increases, trends such as scaling laws anticipate consistent downstream improvements in predictive accuracy. However, these trends take the perspective of a single model-provider in isolation, while in reality providers often compete with each other for users. In this work, we demonstrate that competition can fundamentally alter the behavior of these scaling trends, even causing overall predictive accuracy across users to be non-monotonic or decreasing with scale. We define a model of competition for classification tasks, and use data representations as a lens for studying the impact of increases in scale. We find many settings where improving data representation quality (as measured by Bayes risk) decreases the overall predictive accuracy across users (i.e., social welfare) for a marketplace of competing model-providers. Our examples range from closed-form formulas in simple settings to simulations with pretrained representations on CIFAR-10. At a conceptual level, our work suggests that favorable scaling trends for individual model-providers need not translate to downstream improvements in social welfare in marketplaces with multiple model providers.

2 - Social Learning with Bounded Rationality: Negative Reviews Persist Under Newest First

Atanas Dinev, Massachusetts Institute of Technology, Cambridge, MA, United States, Jackie Baek, Thodoris Lykouris

We study a model of social learning from reviews where customers are computationally limited and make purchases based on reading only the first few reviews displayed by the platform. Under this bounded rationality, we establish that the review ordering policy can have a significant impact. In particular, the popular Newest First ordering induces a negative review to persist as the most recent review longer than a positive review. This phenomenon, which we term the "Cost of Newest First", can make the long-term revenue unboundedly lower than a counterpart where reviews are exogenously drawn for each customer.

We show that the impact of the "Cost of Newest First" can be mitigated under dynamic pricing, which allows prices to depend on the set of displayed reviews. Under the optimal dynamic pricing policy, the revenue loss is at most a factor of 2. On the way, we identify a structural property for this optimal dynamic pricing: prices should ensure that the probability of a purchase is the same, regardless of the state of reviews. We also extend this to a model where customers put more weight on more recent reviews (and discount older reviews based on their time of posting). We show that Newest First is still not the optimal ordering policy if customers discount slowly.

Lastly, we corroborate our theoretical findings using real-world review datasets. In line with our theoretical results, we find that the average rating of the first page of reviews is statistically significantly smaller than the overall average rating.

3 - Measuring User Strategization on Recommender Systems

Andrew Ilyas, Stanford Statistics, Palo Alto, CA, United States, Sarah Cen, Jennifer Allen, Hannah Li, Aleksander Madry

Modern recommendation algorithms are data-driven: they generate personalized recommendations by observing users' past behaviors. A common assumption in recommendation is that how a user interacts with a piece of content (e.g., whether they choose to "like" it) is a reflection of the content, but not of the algorithm that generated it. Although this assumption is convenient, it fails to capture user strategization: that users may attempt to shape their future recommendations by adapting their behavior to the recommendation algorithm. In this work, we test for user strategization using a lab experiment and survey. We adopt a model of strategization in which strategic users select their engagement behavior based not only on the content, but also on how their behavior affects downstream recommendations.

Using a custom music player, we study how users respond to different information about their recommendation algorithm as well as to different incentives about how their actions affect downstream outcomes. We find strong evidence of strategization across outcome metrics, including participants' dwell time and use of "likes." For example, users who are told their behavior will be aggregated behave very differently from users who are told their behavior will be used to generate recommendations. In our post-experiment survey, nearly half of participants self-report strategizing "in the wild," with some stating that they ignore content they actually like to avoid over-recommendation of that content in the future. Together, our findings suggest that user strategization is common and that platforms cannot ignore the effect of their algorithms on user behavior.

4 - Balancing Producer Fairness and Efficiency via Prior-Weighted Rating System Design

Thomas Ma, MIT Sloan School of Management, Cambridge, MA, United States, Michael Bernstein, Ramesh Johari, Nikhil Garg

Online marketplaces use rating systems to promote the discovery of high-quality products. However, these systems also lead to high variance in producers' economic outcomes: a new producer who sells high-quality items, may unluckily receive a low rating early, severely impacting their future popularity. We investigate the design of rating systems that balance the goals of identifying high-quality products (``efficiency'') and minimizing the variance in outcomes of producers of similar quality (individual ``producer fairness'').

We show that there is a trade-off between these two goals: systems that promote efficiency are necessarily less individually fair to producers. We introduce prior-weighted rating systems as an approach to managing this trade-off. Informally, the system we propose sets a system-wide prior for the quality of an incoming product; subsequently, the system updates that prior to a posterior for product quality based on user-generated ratings over time. We show theoretically that in markets where products accrue reviews at an equal rate, a stronger prior makes the

marketplace discount early ratings data (increasing individual fairness), but slows the platform in learning about true item quality (hampering efficiency). We further analyze this trade-off in a responsive market where customers make decisions based on historical ratings. Through calibrated simulations using 19 different real-world datasets, we show that the choice of prior strength mediates the same trade-off in this setting. We demonstrate that by tuning the prior as a design choice in a prior-weighted rating system, platforms can be intentional about the balance between efficiency and producer fairness.

Learning Augmented Mechanism Design

Invited Session

Auctions and Market Design

Chair: Vasilis Gkatzelis, Drexel University, Philadelphia, 19104

Co-Chair: Xizhi Tan

1 - Strategic Facility Location with Predictions

Vasilis Gkatzelis, Drexel University, Philadelphia, PA, United States, Priyank Agrawal, Eric Balkanski, Tingting Ou, Xizhi Tan

We introduce an alternative model for the design and analysis of strategyproof mechanisms that is motivated by the recent surge of work in “learning-augmented algorithms”. Aiming to complement the traditional approach in computer science, which analyzes the performance of algorithms based on worst-case instances, this line of work has focused on the design and analysis of algorithms that are enhanced with machine-learned predictions regarding the optimal solution. The algorithms can use the predictions as a guide to inform their decisions, and the goal is to achieve much stronger performance guarantees when these predictions are accurate (consistency), while also maintaining near-optimal worst-case guarantees, even if these predictions are very inaccurate (robustness).

We initiate the design and analysis of strategyproof mechanisms that are augmented with predictions regarding the private information of the participating agents. To exhibit the important benefits of this approach, we revisit the canonical problem of facility location with strategic agents in the two-dimensional Euclidean space. We study both the egalitarian and utilitarian social cost functions, and we propose new strategyproof mechanisms that leverage predictions to guarantee an optimal trade-off between consistency and robustness guarantees. This provides the designer with a menu of mechanism options to choose from, depending on her confidence regarding the prediction accuracy. Furthermore, we also prove parameterized approximation results as a function of the prediction error, showing that our mechanisms perform well even when the predictions are not fully accurate.

2 - MAC Advice for Facility Location Mechanism Design

Zohar Barak, Tel Aviv University, Tel Aviv, Israel, Anupam Gupta, Inbal Talgam-Cohen

Algorithms with predictions have attracted much attention in the last years. We study the k-facility location mechanism design problem with predictions,
where the n agents are strategic and might misreport their location.
Unlike previous models, where predictions are for the k optimal facility locations, we receive n predictions for the locations of each of the agents.
However, these predictions are only "mostly" and "approximately" correct (or MAC for short) --- i.e., some fraction of the predicted locations are allowed to be arbitrarily incorrect,
and the remainder of the predictions are allowed to be correct up to an epsilon-error.
We make no assumption on the independence of the errors. Can such predictions allow us to beat the current best bounds for strategyproof facility location?

We show that the geometric median of a set of points is naturally robust under corruptions, which leads to an algorithm
for single-facility location with MAC predictions. We extend the robustness result to a "balanced" variant of the k facilities case.
Without balancedness, we show that robustness completely breaks down, even for k=2 on a line.
For this "unbalanced" setting, we devise a truthful random mechanism that outperforms the best known result of Lu et al.~[2010], which does not use predictions.
En route, we introduce the problem of "second" facility location (when the first facility's location is already fixed).
Our robustness findings of the 1-median, and more generally k-medians, may be of independent interest as quantitative versions of classic breakdown-point results in robust statistics and robust clustering.

3 - Learning-Augmented Metric Distortion via (p,q)-Veto Core

Xizhi Tan, Drexel University, Philadelphia, PA, United States, Ben Berger, Michal Feldman, Vasilis Gkatzelis

In the metric distortion problem, there is a set of candidates and a set of voters, all residing in the same metric space. The objective is to choose a candidate with the minimum social cost, defined as the total distance of the chosen candidate from all voters. The challenge is that the algorithm receives only ordinal input from each voter, in the form of a ranked list of candidates in non-decreasing order of their distances from the voter, whereas the objective function is cardinal. The distortion of an algorithm is its worst-case approximation factor with respect to the optimal social cost. A series of papers culminated in a 3-distortion algorithm, which is tight with respect to all deterministic algorithms. Aiming to overcome the limitations of worst-case analysis, we revisit the metric distortion problem through the learning-augmented framework, where the algorithm is provided with some (machine-learned) prediction regarding the optimal candidate. The quality of this prediction is unknown, and the goal is to evaluate the performance of the algorithm under a perfectly accurate prediction (known as consistency), while simultaneously providing worst-case guarantees even for arbitrarily inaccurate predictions (known as robustness). This talk we will fully characterize the robustness-consistency Pareto frontier for the metric distortion problem. We will also discuss some new tight bounds for metric distortion without predictions that helped in proving the tight guarantees, which is of individual interest.

4 - Strategyproof Scheduling with Predictions

Eric Balkanski, Columbia University, New York, NY, United States, Vasilis Gkatzelis, Xizhi Tan

In their seminal paper that initiated the field of algorithmic mechanism design, Nisan and Ronen studied the problem of designing strategyproof mechanisms for scheduling jobs on unrelated machines aiming to minimize the makespan. They provided a strategyproof mechanism that achieves an n-approximation and made the bold conjecture that this is the best approximation achievable by any deterministic strategyproof scheduling mechanism. After more than two decades and several efforts, Christodoulou et al. have recently validated the conjecture. This strong negative result, however, heavily depends on the fact that the performance of these mechanisms is evaluated using worst-case analysis. To overcome such overly pessimistic, and often uninformative, worst-case bounds, a surge of recent work has focused on the ``learning-augmented framework", whose goal is to leverage machine-learned predictions to obtain improved approximations when these predictions are accurate (consistency), while also achieving near-optimal worst-case approximations even when the predictions are arbitrarily wrong (robustness).

In this work, we study the classic strategic scheduling problem of Nisan and Ronen using the learning-augmented framework and give a deterministic polynomial-time strategyproof mechanism that is 6-consistent and 2n-robust. We thus achieve the ``best of both worlds": an O(1) consistency and an O(n) robustness that asymptotically matches the best approximation possible. We then extend this result to provide more general worst-case approximation guarantees as a function of the prediction error. Finally, we complement our positive results by showing that any 1-consistent deterministic strategyproof mechanism has unbounded robustness.

1 - Collaborative Efforts with Users: A Novel Cloud Service Business Model

Aijun Lu, College of Management and Economics, Tianjin University, Tianjin, China, People's Republic of, Fuzan Chen, Harris Wu, Minqiang Li, Haiyang Feng

It was once believed that Cloud Service Providers (CSPs) primarily held responsibility for service availability, yet user efforts are equally essential. Some leading CSPs like Amazon have shifted towards a collaborative approach by implementing the Customer Enablement (CE) system. It comprises resources, tools, and expertise programs to enhance users' cloud capabilities, which suggests a transformative business model promoting joint efforts in the cloud industry.

Inspired by such observations, this paper explores several questions: (1) How should a CSP optimally allocate investments between availability and the CE system? (2) What are users' optimal availability efforts and CE-based efforts? (3) How does the unit downtime loss, affect the efforts interactions between the two parties? (4) Are the service quality improvements effective in increasing the CSP's profitability? Employing game-theoretic models, we derive the CSP's optimal pricing, availability efforts, and CE function level, as well as users' optimal efforts. We further analyze the equilibrium results to answer the above questions and investigate some management insights.

This study reveals several interesting findings. First, with increasing unit downtime loss, the CSP prefers enhancing the CE system over increasing its availability efforts, which leads to an effective improvement in service quality due to strengthened CSP-user collaboration. Second, the CSP's profits first decrease and then increase as downtime loss grows, illustrating that higher quality from intensified efforts does not always translate into higher returns. This paper has strong management implications for the cloud industry, and the findings provide valuable insights for the CSPs.

2 - Enhancing Success in IT Procurement within State Agencies

Mackey Cardinell, Western Washington University, Bellingham, WA, United States, Stella Hua

In this study, we investigate how state agencies' commitment to Lean practices and IT vendors' agile development approaches enhance the success of IT procurement. We examine IT projects within the California Department of Motor Vehicles (DMV) and other state agencies. We look into the impact of agile development practices such as minimum viable products (MVPs) and proof of concepts (POCs) on vendor selection, evaluation, and progress monitoring. Our findings contribute to the procurement literature and provide insights for state agencies pursuing IT modernization.

3 - Appointment Management from Theory to Application: 'Qararment' An Innovative Decision Support System

Majed Hadid, Division of Engineering Management and Decision Sciences, College of Science and Engineering, Hamad Bin Khalifa University, Qatar Foundation, Doha, Qatar, Adel Elomri

Background: Appointment management in the service industry confronts challenges due to subprocesses' stochastic nature and interdependence. The gap between theoretical models and practical application is wide, particularly for end-users without operations research background. This situation is compounded by the prevalence of commercial software that prioritizes digitization over optimization, leaving a void for optimization-based solutions.

Aim: Our research develops Qararment, a machine learning and simulation-based optimization software for appointment planning and scheduling, adaptable to various process configurations and management policies, addressing multiple objectives.

Methodology: We developed a self-configuring, data-driven simulation model of the service process, synergistically combined with genetic algorithms to constitute the core engine of the software. This combination allows for a dynamic and flexible adaptation to different service settings, making the software highly versatile.

Results: Implemented in a major chemotherapy center, Qararment showcased significant adaptability, improving patient waiting times, staff overtime, and computational efficiency by 37%, 17%, and 48%, respectively. The user-friendly interface facilitated model configuration and optimal scheduling, receiving positive feedback for ease of use and effectiveness.

Conclusions: This research highlights the challenges and opportunities of implementing operations research and optimization-oriented solutions in real-world environments, considering the perspectives of end-users. It opens new avenues for exploring the practical application of service operations management theories, particularly in environments that have not been fully investigated, emphasizing the need for solutions that are both sophisticated in capability and simple in user experience.

4 - Point Cloud Registration With Quantile Assignment

Ecenur Oğuz, Northwestern University, Evanston, IL, United States, Yalim Dogan, Ugur Gudukbay, Oya Karasan, Mustafa Pinar

Point cloud registration is a fundamental problem in computer vision. The problem encompasses critical tasks such as feature estimation, correspondence matching, and transformation estimation. The point cloud registration problem can be cast as a Quantile Assignment problem. We refined the Quantile Assignment algorithm by integrating prevalent feature descriptors and transformation estimation methods to enhance the correspondence between the source and target point clouds. We evaluated the performances of these descriptors and methods with our approach through controlled experiments on a dataset we constructed using well-known 3D models. This systematic investigation led us to identify the most suitable methods for complementing our approach. Subsequently, we devised a new end-to-end, coarse-to-fine pairwise point cloud registration framework. Finally, we tested our framework on indoor and outdoor benchmark datasets and compared our results with state-of-the-art point cloud registration methods.

Optimizing Networked Environments and Demand Matching

Flash Session

1 - Enhancing Communication Network Traffic Engineering through Machine Learning

Sharon Arroyo, Boeing Company, Seattle, WA, United States, Yingxi li, Raju Mattikalli, Ali Teshnizi, Madeleine Udell, Mikel Woo

Tactical communication networks currently struggle to maintain throughput and service levels to changing network conditions and traffic. Software defined networking (SDN) offers a solution by allowing for greater control and optimization of network capacity, resulting in improved performance in terms of throughput, delay and loss. One key aspect of SDN is traffic engineering (TE).

TE in tactical SDN involves computing routes for point-to-multi-point service requests within a known communications network. This network is defined by point-to-point links, each with its own bandwidth and delay characteristics. Service requests are characterized by priority, bandwidth consumption, and maximum allowed delay.

Traditional mathematical programming methods, like mixed integer optimization solvers, have limitations in solving real-world traffic engineering (TE) problems. These methods face difficulties in handling the complex requirements and scalability demands of TE, particularly under real-time constraints. To address these challenges, we have turned to reinforcement learning and supervised learning algorithms. Our approach has yielded high-quality solutions significantly faster than traditional TE methods. In our presentation, we will showcase the results and provide valuable insights into effectively tackling hard constraints in combinatorial optimization problems.

Our goal is to bridge the gap between traditional mathematical programming and machine learning approaches. By harnessing the strengths of both fields, we can effectively tackle the intricacies of TE problems and meet the real-time demands of communication networks

2 - A Resource Allocation Game Between Attackers and Defenders in a Multi-Entrance, Multi-Layered, and Multi-Target System

Ting Zan, University at Buffalo, Buffalo, NY, United States, Jun Zhuang

Many security systems, including airports, schools, and public transit, feature multiple entrances and interconnected layers to ensure efficacy and safety. The optimal allocation of defensive resources across these layers to minimize overall system risk, especially against a strategic attacker, has been underexplored in the literature. This research addresses this gap by examining a sequential game-theoretical resource allocation model and demonstrating its results through a case study.

3 - Junction Hub Location Problem

CHANCHAL KUMAR SALODE, Indian Institute of Technology Delhi, New Delhi, India, Prasanna Ramamoorthy

In this study, we introduce the junction hub location problem, focusing on locating a set of interconnected hub lines, where hubs are connected by means of a line, while assigning non-hub nodes to hubs in a single allocation scheme. These hub lines intersect at a common hub referred to as junctions. This problem finds applications in various domains such as public transportation, telecommunications, and rapid transit systems, where the cost of designing networks is high compared to routing costs, making full interconnection of hubs impractical. The objective is to minimize transportation costs between all pairs of origin and destination nodes. To address this problem, we propose a Mixed Integer Linear Programming (MILP) model. Additionally, to solve this problem on large scale, we propose Benders branch and cut algorithm.

Computational results obtained on two sets of benchmark instances confirm the efficiency of the proposed algorithm, which is considerably faster and able to solve larger instances than a general purpose solver.

4 - Using combinatorial auctions to allocate parcel logistic services in Hyperconnected City Logistics

Simon Kwon, Georgia Institute of Technology, Atlanta, GA, United States, Walid Klibi, Mathieu Dahan, Benoit Montreuil

Aligned with Physical Internet-enabled hyperconnected city logistics initiatives, this study explores a setting in which an urban logistics orchestrator aims to design a multi-party service network. In this network, logistic activities, such as hub processing and transportation, are assigned to specific service providers through term contracts via a single-round combinatorial auction. The orchestrator's role is to cater to citywide origin-destination demand flows, ensuring delivery time guarantees and service reliability while maximizing profit. The path of these flows is segmented into logistic activities, including transport and hub processing. Each logistic activity is associated with a reliable service level agreement (e.g., 30 minutes for transport in Local cell 1 at 99.9%) to fulfill origin-destination time guarantees, and service providers participating in the auction (bidders) must adhere to their claimed service level agreements.

Due to the decision lag caused by the auction mechanism's tactical nature, bidders may not uphold their claimed service level agreements after auction, leading to uncertainty in origin-destination services and potential profit erosion. Additionally, considering the historical service performance of bidders, different risk levels for the orchestrator result in varying reliability in bidders. Therefore, the orchestrator must incorporate these uncertainties when determining winners to achieve desired reliability in origin-destination services.

We present a chance-constrained stochastic mixed-integer programming optimization model for this problem, utilizing chance constraints to ensure origin-destination deliveries at desired reliability levels while maximizing expected profit. Our numerical results demonstrate the impact of the chance-constrained programming approach on delivery guarantees, contrasting with the traditional deterministic approach for origin-destination flows.

5 - Traffic control as a process: A novel outlook on task execution and operational performance

Léon Sobrie, Virginia Tech, Falls Church, VA, United States, Jasmijn De Clercq, Bart Roets, Konstantinos Triantis

This paper proposes a novel outlook toward traffic control by centralizing the operator and the tasks they execute. The operator's actions are modeled as a process, consistent with a functional representation of a system, in which we unravel sequences of different task types. The analysis delves into multitasking and the time lag between events as two explanatory characteristics for the operational performance of traffic control. The method is operationalized and validated at Infrabel, Belgium's national railway infrastructure company. The setup is generalized for other traffic control settings and more general settings where task execution can be modeled as a process. Also, linkages between traffic control as a process and different modeling paradigms (such as machine learning, DEA and systems thinking) are discussed.

6 - Braess Paradoxes in Coupled Power and Transportation Systems

Minghao Mou, Purdue University, West Lafayette, IN, United States, Junjie Qin

Transportation electrification introduces strong coupling between the power and transportation systems. In this paper, we generalize the classical notion of Braess Paradox to coupled power and transportation systems, and examine how the cross-system coupling induces new types of Braess Paradoxes. To this end, we model the power and transportation networks as graphs, coupled with charging points connecting to nodes in both graphs. The power system operation is characterized by the economic dispatch optimization, while the transportation system user equilibrium models travelers' route and charging choices. By analyzing simple coupled systems, we demonstrate that capacity expansion in either transportation or power system can deteriorate the performance of both systems, and uncover the fundamental causes for such new Braess Paradoxes, leading to managerial insights for infrastructure planners. For general networks, we develop efficient algorithms for computing the equilibrium of and identifying Braess Paradoxes for the coupled system.

7 - Smarter Traffic Management: Leveraging Deep Learning for Enhanced Flow Predictions

Zhe Fu, UC Berkeley, Berkeley, CA, United States

Effective traffic management is essential for fostering smarter, sustainable cities. In this study, we revolutionize traffic flow predictions by applying deep learning to the Lighthill-Whitham-Richards (LWR) traffic model, a foundational macroscopic framework governed by hyperbolic partial differential equations (PDEs). Traditional numerical methods for solving these PDEs lack the flexibility and computational efficiency required for real-time urban traffic management, often resulting in suboptimal decision-making.

Our innovative approach employs deep learning neural networks as advanced numerical approximators, integrating traditional numerical principles with the governing conservation laws of traffic flow. This methodology significantly enhances predictive accuracy and computational efficiency in traffic simulations, leading to more informed and agile traffic management decisions. The benefits of our approach include:
1) Enhanced prediction accuracy for traffic flow, leading to more reliable estimates of travel times and expected time of arrival (ETA), crucial for route planning and congestion management.
2) Reduced computational complexity, facilitating quicker adjustments in traffic control systems to accommodate real-time conditions.
3) Improved adaptability across diverse traffic models and flux functions, increasing the resilience of traffic systems against varying urban dynamics.

By advancing deep learning applications in traffic flow modeling, our research supports smarter, data-driven decisions for better world outcomes, optimizing urban mobility and reducing environmental impacts through enhanced traffic management strategies.

Advanced Analytics in Health and Well-being

Contributed Session

Chair: Mohammad Rahimi, Virginia Tech, Blacksburg, VA, United States

1 - Enhancing Depression Detection in Social Media Texts Using Generative Adversarial Networks

Kaung-Yu Chao, Department of Information Management, National Chi Nan University, Nantou, Taiwan, Puli, Taiwan, Jing-Rung Yu

In contemporary society, the prevalence of depression is rising, leading to many negative outcomes. Research indicates that mental health status can be inferred from users' texts, images, and interaction patterns on social media. Early identification of mental health issues through social media text analysis is crucial for timely intervention and treatment. However, obtaining large labeled depression datasets is challenging due to the intensive labor required. Therefore, we use datasets from Kaggle and employ Generative Adversarial Networks (GANs) to augment the data for our training and testing datasets. To enhance the robustness of the BERT model in detecting depression in texts, we utilize various loss functions, such as cross-entropy. We evaluate whether using GANs or adjusting the loss function helps maintain or improve the model's accuracy and robustness. This approach aims to strengthen sentiment analysis models based on the BERT model by using GANs and modifying the loss function. We compare the performance of various BERT models with and without using GANs and adjusting the loss function.

2 - Enhancing Sleep Apnea Diagnosis with Machine Learning: A Study on Wearable Biometrics and Smartphone Application Data

HyungJu Kim, Korea University, Seoul, Korea, Republic of, Taesu Cheong, Chul-Hyun Cho

Sleep apnea is a condition in which breathing stops temporarily during sleep. It causes irregular breathing patterns and reduced oxygen levels, which can lead to poor quality of rest and can cause fatigue and difficulty concentrating during the day. There are many causes of sleep apnea, including obesity, age, smoking, and alcohol. Sleep apnea can be diagnosed through polysomnography to determine the presence and severity of apnea. Treatment can also be provided through questionnaires and patient information. However, in mild cases, it is difficult for patients to recognize the disease, and questionnaires can be difficult to diagnose and treat due to the subjective nature of the patient. There is a need for an objective and quantitative method to complement this. We aimed to classify sleep apnea severity with a machine learning model using biometric data from wearable devices and self-reported data through a smartphone application. Due to the small number of patients, we applied oversampling technique, and the classification model used tree-based models such as ngboost and XGB, and performed parameter tuning. The results showed significant classification performance (AUC 0.70 ~ 0.80). We believe that this methodology can complement the existing diagnostic process.

3 - A New Genomics-based Psychographic Segmentation Strategy

Camelia Taheri Protzel, University of North Carolina - Charlotte, Charlotte, NC, United States

Advances in behavioral genetics provide a paradigm shift in the development of a genomics-based psychographic segmentation strategy. Genetics can explain most of the systematic variation between individuals, the continuity of behavioral and personality traits, as well as 50% of the variance in human traits. Leveraging that all human behaviors and psychological traits are influenced in some way by the individual's genetic constitution, a theoretical framework is presented for the definition of a new genomics-based psychographic segmentation. Genomics-based psychographic segmentation takes into account the genetic predisposition measured by polygenic scores (PGS), a combination of thousands of single-nucleotide polymorphisms (SNPs) associated with a specific trait that can estimate heritability and predict phenotypes. The study empirically shows the applicability of this new genomics-based psychographic segmentation through K-mean clustering analyses of the alcohol consumption market using 7 different PGS related to personality and cognitive traits. The study increases the predictive power of consumer behavior and marketing segmentation leveraging molecular genetics and 150 years of behavioral genetics replicable findings. It presents for the first-time fundamental principles from behavioral genetics to lay the ground for genomics marketing and the transformation of segmentation strategies. It proposes the segmentation of markets through the genetic propensity of consumers. It not only highlights embryonic research in genomics marketing but also shows the practical application of genomics segmentation through the usage of molecular genetics to create clusters and understand consumption patterns of each subset.

4 - Optimizing Postpartum Depression Screening Systems in the Neonatal Intensive Care Unit and Pediatric Emergency Department: A Simulation-based Analysis of the Workflow

Fatima Sadjadpour, Virginia Tech, Falls Church, VA, United States, Niyousha Hosseinichimeh, Lenore Jarvis, Sofia Perazzo, Lamia Soghier

Perinatal mood and anxiety disorders (PMAD) are a large group of disorders that encompass postpartum depression, anxiety, acute stress disorder, perinatal psychosis, obsessive-compulsive disorder, and post-traumatic stress disorder. Postpartum depression, occurring within the first year after childbirth, affects 13-15% of mothers globally, posing a significant obstetric complication and a prominent factor in maternal suicide. The impact of postpartum depression extends beyond mothers to affect all caregivers, and the long-term consequences result in higher rates of anxiety, depression, and behavioral issues among infants. Particularly vulnerable are caregivers of infants in neonatal intensive care units (NICU), where postpartum depression prevalence is markedly higher around 39-45%, leading to recurrent visits to the pediatric emergency department (PED). Despite its pervasive impact, clinical recognition, and treatment of postpartum depression in these settings remain challenging. At Children's National Hospital in 2021, internal benchmarking data shows that only 64% (n=577) of eligible NICU parents and 34% (n=1270) of eligible PED parents are screened even with an established PMAD team of social workers and screeners. To address these complexities, a system dynamics group model building (GMB) approach is employed to analyze the current screening system and develop a simulation model aimed at enhancing screening and referral processes in NICU and PED settings. Findings from GMB sessions included interventions, such as 24/7 access and staffing, standardizing screening as part of routine care, and improving public relations. By integrating these solutions into the system dynamics model, we aim to test their potential impact within the broader system.

5 - Which is more beneficial, superficial or deep integration? Exploring the impact of work-family integration on employees' creative process engagement

Wei Liu, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Ning Wang, Mi Zhou, Meng Qin

With the dual influence of digital human resources and the post-epidemic period, remote work has emerged as a prevailing trend. It is inevitable that work-family integration will occur. Existing literature suggests that work-family integration can take multiple forms. Hence, we classified work-family integration as superficial integration and deep integration according to content dimensions. Recognizing the importance of not only the outcomes but also the process of innovation, we proposed a model to examine how different forms of work-family integration affect creative process engagement. We hypothesized that work-related rumination (affective rumination and problem-solving pondering) would mediate these relationships, with the partner's communal motivation acting as a moderating factor. In study 1, using a within-person daily diary study lasting ten days (data was collected from 21 dual-earner couples), we validated our proposed model. In study 2, we also used a between-person design from 228 employees to determine whether our model held. As predicted, superficial or deep integration affects creative process engagement positively. What's more, problem-solving pondering mediates deep integration to creative process engagement, while affective rumination does not mediate superficial integration to creative process engagement. Additionally, partner's communal motivation would buffer the indirect effect of deep integration on creative process engagement through problem-solving pondering, while partner's communal motivation would not buffer the indirect effect of superficial integration on creative process engagement through affective rumination. Overall, this study advances separating work-family integration into superficial and deep types, demonstrating that creative process engagement follows a dual path through these two types.

6 - What Do You Mean You&Rsquo;Re Sorry?! You&Rsquo;Re Just a Machine! Empathy in Conversational AI: the Case of Large Language Models in Mental Health

Mohammad Rahimi, Virginia Tech, Blacksburg, VA, United States, Idris Adjerid, Paul Lowry, Warren Bickel

The mental health crisis has been rapidly growing over the last few decades and further exacerbated by the COVID-19 pandemic, turning it into a deadly global challenge that leads to the loss of twelve billion working days each year, accounts for more than 14% of all deaths, and will cost the world's economy $16 trillion by 2030. Half of the world's population will experience a mental health disorder during their lifetime. A major problem is the lack of qualified personnel to address this crisis. We explore whether AI agents, with their latest advancements, can be a viable solution. Emotional support is a key factor in this domain as it encourages clients' information self-disclosure, which is usually the first step when seeking help in this context. Recent studies indicate that modern AI agents can emulate human empathy with high precision. Such advancements hold promise, especially in fields like mental health where empathy and comprehension are paramount. Past studies have either focused solely on emulating human-like empathy or treated empathy as a simple and aggregated concept. Our study is the first to address these two important gaps in the literature, offering a granular examination of AI expressing components of human empathy (e.g., cognitive, and affective) and evaluating the efficacy of complimenting human-like empathy with unique AI data capabilities–a new phenomenon we coin as *collective artificial empathy*. We will conduct a 3x2 randomized between-subjects experiment with three levels of empathy (low, medium, high) and two different types of empathy (human-like and machine-like empathy).

2 - A Study Of The Reliability Of Crypto Data Provision

Gustavo Schwenkler, Santa Clara University, Santa Clara, CA, United States, Aakash Shah, Darren Yang

We analyze the supply of cryptocurrency data from leading providers and uncover significant quality issues. We document the impact of these issues on the empirical analysis of cryptocurrency markets, emphasizing the risks of relying on single sources. We propose a methodology to aggregate data across providers that ensures consistency and demonstrate its benefits in an asset pricing study. We recommend the adoption of a unified identification system for cryptocurrencies, akin to traditional financial markets, to enhance data reliability. We also flag a need for potential regulatory oversight to ensure consumer protection in the market for crypto data.

3 - Long-History PCA in a Dynamic Factor Model with Weaker Loadings

Baeho Kim, Korea University Business School, Seoul, Korea, Republic of, Robert Anderson, Dean Ryu

Estimated covariance and precision matrices of asset returns significantly influence the set of portfolios compliant with risk budgets and their potential losses. Statistical risk modeling approaches often assume temporal stability for consistency with a static factor structure, typically estimated within $T_M \sim 250$ days of data history, resulting in finite-sample estimation error when the dimension of the population exceeds the number of observations. Our study introduces Long-History PCA (LH-PCA), utilizing extended data histories (e.g., $T_L \sim 1500$ trading days) to forecast the daily risk profile based on dynamic factor structures with heterogeneous factor strengths. The use of a longer data history mitigates excess dispersion bias in the estimated factor loadings, particularly in the presence of weaker factors. Augmented by Responsive

Covariance Adjustment (RCA) employing a short half-life (T_S) of 40 days, our approach substantially mitigates second-order risk biases compared to traditional approaches using medium horizons (T_M) of 250 days, in both simulations and empirical studies.

4 - Do AI-Algorithmic Traders Lead to Market Instability? A Multi-Agent Reinforcement Learning Approach

Yang Fan, Stanford University, Stanford, CA, United States, Markus Pelger, Xintong Yu

We show that AI-powered algorithmic trading can lead to inefficient and instable market. We investigate the impact of algorithmic traders on market equilibrium using a multi-agent deep reinforcement learning framework. We develop a conceptual simulation framework to study the market equilibrium among informed speculators with asymmetric information under different market conditions. Our findings reveal that more informed algorithmic traders engage in manipulative behavior, leading to local market price bubbles and deviations from the fundamental price. The informed AI-traders exploit and actively distort the learning process of less informed AI-traders. These results are robust across different number of agents and buying power scenarios. Unlike existing studies on algorithmic collusion, our research highlights the novel finding of the emergence of local price bubbles. Given the rapid growth in AI-powered algorithmic trading, our results identify a new form of systematic risk.

1 - On the Optimality of Bisection Search in Noisy Environments

Sanghwa Kim, KAIST, Daejeon, Korea, Republic of, Dohyun Ahn, Seungki Min

In adaptive testing, the tester sequentially determines the difficulty of the next query in order to identify the ability level of the testee as efficiently as possible. We study a stochastic version of the bisection search algorithm, a simple heuristic that selects the next difficulty level at which a positive outcome and a negative outcome become equally likely with respect to the currently estimated parameter. Adopting bandit and experimental design approaches, we analyze the optimality of this algorithm under three criteria: (i) sample complexity in the fixed confidence setting, (ii) error rate in the fixed budget setting, and (iii) Fisher information. For each criteria, we provide a theoretical limit that no algorithm can achieve, and provide sufficient conditions under which this algorithm achieves the limit asymptotically (up to some constant factor).

2 - Mixed-Effects Contextual Bandits

Kyungbok Lee, Seoul National University, Seoul, Korea, Republic of, Myunghee Cho Paik, Min-hwan Oh, Gi-Soo Kim

We study a novel variant of a contextual bandit problem with multi-dimensional reward feedback formulated as a mixed-effects model, where the correlations between multiple feedback are induced by sharing stochastic coefficients called random effects. We propose a novel algorithm, Mixed-Effects Contextual UCB (ME-CUCB), achieving tildeO(d sqrt(mT)) regret bound after T rounds where d is the dimension of contexts and m is the dimension of outcomes, with either known or unknown covariance structure. This is a tighter regret bound than that of the naive canonical linear bandit algorithm ignoring the correlations among rewards. We prove a lower bound of Omega(d sqrt(mT)) matching the upper bound up to logarithmic factors. To our knowledge, this is the first work providing a regret analysis for mixed-effects models and algorithms involving weighted least-squares estimators. Our theoretical analysis faces a significant technical challenge in that the error terms do not constitute martingales since the weights depend on the rewards. We overcome this challenge by using covering numbers, of theoretical interest in its own right. We provide numerical experiments demonstrating the advantage of our proposed algorithm, supporting the theoretical claims.

3 - Simple Data-Driven Solutions and Uncertainty Quantification for Multistage Stochastic Optimization

Yunhao Yan, Columbia University, New York, NY, United States, Henry Lam

Multistage stochastic optimization problems appear commonly in various disciplines in operations management and system control. While computational methods have been studied, they are mostly restricted to two-stage problems due to the exponentially increasing complexity arising from multistage scenarios. We argue that for some interesting applications, these problems exhibit stagewise independence and, with the use of suitable classes of policies, they are amenable to simple data-driven solutions and uncertainty quantification methodologies based on natural multisample generalizations of the well-known sample average approximation (SAA) and single replication procedure. We justify the statistical consistency and coverage guarantees of our approaches, and demonstrate how they reduce variances compared to the naive use of SAA. Our results require developing several functional limit theorems of the so-called multisample U-processes that closely connect to multistage stochastic optimization, which allow us to work with closed-loop control policies beyond Euclidean parametrization classes.

4 - Collaborative Intelligence in Sequential Experiments: A Human-in-the-Loop Framework for Drug Discovery

Jinghai He, University of California, Berkeley, Berkeley, CA, United States, Cheng Hua, Yingfei Wang, Zeyu Zheng

Drug discovery is a complex process that involves sequentially screening and examining a vast array of molecules to identify those with the target properties. This process, also referred to as sequential experimentation, faces challenges due to the vast search space, the rarity of target molecules, and constraints imposed by limited data and experimental budgets. To address these challenges, we introduce a human-in-the-loop framework for sequential experiments in drug discovery. This collaborative approach combines human expert knowledge with deep learning algorithms, enhancing the discovery of target molecules within a specified experimental budget. The proposed algorithm processes experimental data to recommend both promising molecules and those that could improve its performance to human experts. Human experts retain the final decision-making authority based on these recommendations and their domain expertise, including the ability to override algorithmic recommendations. We applied our method to drug discovery tasks using real-world data and found that it consistently outperforms all baseline methods, including those which rely solely on human or algorithmic input. This demonstrates the complementarity between human experts and the algorithm. Our results provide key insights into the levels of humans' domain knowledge, the importance of meta-knowledge, and effective work delegation strategies. Our findings suggest that such a framework can significantly accelerate the development of new vaccines and drugs by leveraging the best of both human and artificial intelligence.

1 - Just a Few Bits: Improving Human Decision-Making with Minimal Algorithmic Intervention

Stefanos Poulidis, INSEAD, Fontainebleau, France, Haosen Ge, Hamsa Bastani, Osbert Bastani

Interpretable algorithmic advice has been shown to enhance human decision-making and performance. However, current forms of algorithmic advice predominantly provide action signals, which prescribe specific courses of action. These action signals can be challenging to estimate, brittle, and susceptible to unobserved confounders. In this work, we introduce attention signals as an alternative. Attention signals are simple binary indicators that do not recommend specific actions. We develop a novel algorithm to determine the optimal timing for offering action and attention algorithmic signals within the context of chess, which can be readily extended to general Markov Decision Processes (MDPs). Then, we conduct a comprehensive behavioral experiment including 36 titled chess masters (e.g., Grandmasters), to study the effects of attention signals on human decision-making and performance. Our findings indicate that attention signals lead to a more efficient distribution of human search effort, more profitable actions, and substantial performance gains. We synthesize our findings to uncover the key mechanism driving the performance gains induced by attention signals, providing insights for the effective deployment of algorithmic advice.

2 - Incentive-Aware Synthetic Control: Accurate Counterfactual Estimation via Incentivized Exploration

Keegan Harris, Carnegie Mellon University, School of Computer Science, Pittsburgh, PA, United States, Daniel Ngo, Anish Agarwal, Vasilis Syrgkanis, Steven Wu

We consider the setting of synthetic control methods (SCMs), a canonical approach used to estimate the treatment effect on the treated in a panel data setting. We shed light on a frequently overlooked but ubiquitous assumption made in SCMs of "overlap": a treated unit can be written as some combination---typically, convex or linear combination---of the units that remain under control. We show that if units select their own interventions, and there is sufficiently large heterogeneity between units that prefer different interventions, overlap will not hold. We address this issue by proposing a framework which incentivizes units with different preferences to take interventions they would not normally consider. Specifically, leveraging tools from information design and online learning, we propose a SCM that incentivizes exploration in panel data settings by providing incentive-compatible intervention recommendations to units. We establish this estimator obtains valid counterfactual estimates without the need for an a priori overlap assumption. We extend our results to the setting of synthetic interventions, where the goal is to produce counterfactual outcomes under all interventions, not just control. Finally, we provide two hypothesis tests for determining whether unit overlap holds for a given panel dataset.

3 - Incentivized Exploration via Filtered Posterior Sampling

Yonatan Gur, Stanford University, Netflix, Stanford, CA, United States, Anand Kalvit, Aleksandrs Slivkins

We study the issue of incentivized exploration (IE) in social learning problems where the principal (recommendation algorithm) can leverage information asymmetry to incentivize sequentially-arriving agents to take exploratory actions. This work expands upon extant literature on IE in bandits, and generalizes theory along several practically-relevant dimensions.

4 - Secondary Migration-Aware Placement For Refugees

Salomon Wollenstein-Betech, Stanford University, Stanford, CA, United States, Kostas Bimpikis, Yonathan Gur, Jens Hainmueller

About 17% of refugee migrants worldwide do not stay in their initial destination for more than a year and they seek for a new location -- known as *secondary migration (or onward movements)*-- to achieve self-sufficiency. Current matching methods to allocate refugees to destinations only consider the first destination and do not incorporate explicitly the long-term effect of future migration in their resettlement decisions which restricts the overall success of the match. In this work, we incorporate the notion of secondary migration by formulating and solving an augmented matching problem that takes into account the *long-term* probability of employment and destination capacities. We leverage historical US resettlement data between 2004-2017 to understand the secondary migration patterns and we develop a simulated environment to compare the long-term benefits of using a secondary-migration aware policy against a myopic one. Our results show that our long-term resettlement decisions could reduce in half the number of refugees that experience secondary migration while keeping overall employability at current levels. Moreover, we show that a modest 10% reduction in employability could reduce migration by 40%.

Sustainable and Responsible Revenue Management

Invited Session

Revenue Management and Pricing

Chair: Xiao Lei, University of Hong Kong, Hong Kong, N/A, Hong Kong

1 - Dynamic Pricing with Fairness Constraints

Sentao Miao, University of Colorado Boulder, Boulder, CO, United States, Maxime Cohen, Yining Wang

Following the increasing popularity of personalized pricing, there is a growing concern from customers and policy makers regarding fairness considerations. This paper studies the problem of dynamic pricing with unknown demand under two types of fairness constraints: price fairness and demand fairness. For price fairness, the retailer is required to (i) set similar prices for different customer groups (called group fairness) and (ii) ensure that the prices over time for each customer group is relatively stable (called time fairness). We propose an algorithm based on an infrequently-changed upper-confidence-bound (UCB) method, which is proved to yield a near-optimal regret performance. We then leverage this method to address the extension of non-stationary demand, which is particularly relevant for time fairness to prevent price gouging practices. For demand fairness, the retailer is required to satisfy that the resulting demand from different customer groups is relatively similar (e.g., the retailer offers a lower price to students to increase their demand to a similar level as non-students). In this case, we design an algorithm adapted from a primal-dual learning framework and prove that our algorithm also achieves a near-optimal regret performance.

2 - Temporal Fairness in Learning and Earning: Price Protection Guarantee and Phase Transitions

Ruihao Zhu, Cornell University, Ithaca, NY, United States, Qing Feng, Stefanus Jasin

Motivated by the prevalence of "price protection guarantee", which helps to promote temporal fairness in dynamic pricing, we study the impact of such policy on the design of online learning algorithm for data-driven dynamic pricing with initially unknown customer demand. Under the price protection guarantee, a customer who purchased a product in the past can receive a refund from the seller during the so-called price protection period (typically defined as a certain time window after the purchase date) in case the seller decides to lower the price. We consider a setting where a firm sells a product over a horizon of T time steps. For this setting, we characterize how the value of M, the length of price protection period, can affect the optimal regret of the learning process. We show that the optimal regret is $\tilde{\Theta}(\sqrt{T}+\min\{M,\,T^{2/3}\})$. Our results reveal the surprising phase transitions of the optimal regret with respect to M. Specifically, when M is not too large, the optimal regret has no major difference when compared to that of the classic setting with no price protection guarantee. We also show that there exists an upper limit on how much the optimal regret can deteriorate when M grows large.

3 - Heuristic but Effective Pricing with Data Expiry

Jialin Li, Rotman School of Management, Toronto, ON, Canada

Small business owners who cannot afford a data scientist team may resort to data analytics platforms. In compliance with emerging privacy regulations, platform service providers remove data from the database after retaining it for a specified period of time. In this dynamic process, existing demand learning or pricing methods can easily fail in this situation because the platform user can never enjoy a large sample size. In this work, we demonstrate a simple estimator that leads to effective learning and pricing for a firm user who has been setting heuristic prices in history.

4 - Pricing and Control for Digital Addictive Services

Jiacheng Chang, University of Hong Kong, Hong Kong, Hong Kong, Xiao Lei, Feng Tian

Digital addictive services, such as video games and video sharing platforms, have become prevalent in daily life, raising concerns about digital addiction. Unlike traditional addictive goods, these services allow for personalized dynamic pricing and manipulation of experience randomness. In this paper, we investigate optimal pricing strategies for digital service providers and effective regulatory measures to curb addiction levels from a policymaker's perspective. Employing an infinite-horizon dynamic program that accounts for users' habit-formation behavior, we compare dynamic and fixed pricing across various scenarios. Our findings reveal that dynamic pricing results in higher profits and reduced addiction, benefiting both the firm and users. Similarly, one-time promotions for new users initially foster addiction but ultimately lead to decreased levels in the long run. Furthermore, we analyze addiction control policies such as consumption tax, price lower bounds, and consumption limits. By assessing the profit-addiction efficiency frontier of these regulatory approaches, our study demonstrates that the choice of pricing scheme (fixed or dynamic) and experience randomness significantly influence the optimal regulatory strategy. This research provides valuable insights for tackling digital addiction while preserving profitability.

Summit - 338

Bundling and Opaque Selling Strategies

Invited Session

Revenue Management and Pricing

Chair: Xiaobo Li, National University of Singapore, Singapore, Singapore

1 - Less is More: a General Framework of Opaque Selling

Jie Liu, School of Data Science, The Chinese University of Hong Kong, Shenzhen, Shen Zhen, China, People's Republic of, Hailun Zhang, Zhenghua Long

Selling opaque products has become popular on e-commerce platforms where the hidden attribute is often color or style, thanks to its obvious advantage in risk pooling the demand. The objective of this study is to quantify the value of the flexibility that underlies opaque selling and investigates the opaque design problem. We first consider a setting in which an online retailer sells a product with N items that only differ in a certain secondary attribute, and in addition, offers opaque options where the customer selects a subset of all products from which the seller allocates one to the customer. We find that the cost savings from using just 2-opaque products is on the same order as the fully flexible case where the opaque product contains all N products, extending the results in Elmachtoub et al. (2019). We next investigate the opaque design problem where the objective is to maximize the expected profit through opaque product design and pricing, and identify conditions under which partial design beats full design. Extensive numerical experiments are conducted to support our main results and insights.

2 - Optimizing Size-Based Bundle Promotions

Ruijiu Mao, National University of Singapore, Singapore, Singapore, Xiaobo Li, Chung Piaw Teo

Current size-based bundle promotions often overlook the diverse needs of customers and variations among products. Recognizing these limitations, we conducted a comprehensive exploration of size-based bundling promotions. We examined key elements such as determining promotion numbers, selecting product pools, setting bundle prices, and estimating customer utility for different products. We studied a choice model for size-based bundle promotions and proposed an efficient polynomial-time assortment planning method under reasonable assumptions. We also compared our results with the heuristics applied by e-tailing companies.

3 - Separation in Distributionally Robust Monopolist Problem

Qiu Hao, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of, zhen wang, Simai He

We consider a monopoly pricing problem, where a seller has multiple items to sell to a single buyer, only knowing the distribution of the buyer’s value profile. The seller’s goal is to maximize her expected revenue. In general, this is a difficult problem to solve, even if the distribution is well specified. In this paper, we solve a subclass of this problem when the distribution is assumed to belong to the class of distributions defined by given marginal partial information. Under this model, we show that the optimal strategy for the seller is a randomized posted price mechanism under which the items are sold separately, and the result continues to hold even when the buyer has a budget feasibility constraint. Consequently, under some specific ambiguity sets which include moment-based and Wasserstein ambiguity sets, we provide analytical solutions for these single-item problems. Based on the additive separation property, we show the general additive separation problem is a special case of resource allocation problems that can be solved by known polynomial-time algorithms.

4 - Joint Assortment and Inventory Optimization for the Front-End Warehouse

Kexin Wu, National University of Singapore, Singapore, Singapore, Xiaobo Li, Xue-Ming Yuan

This paper considers the single-period inventory and warehouse assortment planning problem for a two-warehouse system containing a front-end warehouse and a back-end warehouse. In the first stage, before the customers come, the company makes the inventory and assortment decisions for the front-end warehouse. After the customers have placed the orders, the company determines which orders should be fulfilled by the front-end warehouse and which by the back-end warehouse, not considering order splitting as it is cost-prohibitive. Orders assigned to the back-end warehouse incur higher fulfillment costs compared to those fulfilled by the front-end warehouse, primarily due to increased distances and extended waiting times. We formulate the problem as a two-stage stochastic programming model with a total capacity constraint. The primary objective is to minimize the overall product storing fixed cost and fulfillment cost. Optimal fulfillment policies for order structures including pure bundles, series cover bundles, and star cover bundles are proposed. For general order structures, we propose an approximation for the inventory problem and introduce the corresponding approximation algorithm. A tight 1/Z performance bound for the approximation is proved, where the Z indicates the largest number of order types that include a certain product. For two special cases of star cover bundle and sparse demand, we also show tighter performance bounds.

Summit - 339

Optimization for Portfolio Selection

Contributed Session

Chair: Johannes Norheim, University of Strathclyde, Glasgow, 02139

1 - Prescriptive Bi-level Approach for Portfolio Risk-return Management

Junyao Yang, Governors State University, University Park, IL, United States, Aleksandr Vinel

Bi-level optimization, a class of hierarchical mathematical programming, has gained significant attention in decision-making. In this study, we consider the following broker-investor portfolio problem. An investor is interested in contracting with a broker. Naturally, the broker can select model parameters to adjust his risk preferences and performance-based incentive structure. The investor can be reasonably assured that the broker will maximize the portfolio return. What may be missing is a more concerted effort to minimize risk, due to the mismatch objective between the parties. Therefore, we consider this challenge and provide some modeling and computational insights. We intend to divide the decision space using prediction to introduce a novel view of risk. Specifically, we use machine learning to predict market movement and split the decision space apart into two sub-spaces, bullish and bearish. We assume that the investor will focus only on the bullish set, which formulates an upper-level risk minimization problem. The broker at the lower level is guided by the investor in seeking return, with the constraint of risk ensuring that the lower level risk remains within acceptable bounds. Most importantly, the upper level will have a different decision space from the lower level. The main contributions of this work are as follows: 1) we incorporate a hierarchical bi-level approach with two-level decision-making on portfolio optimization problems 2) we develop a new bi-level optimization formulation that considers modern ML technology in making decisions while performing risk hedging and seeking returns.

2 - Optimizing portfolio performance through Linearized Adaptive Boosting combination

Minsu Chung, Yonsei University, Seoul, Korea, Republic of, Seongmoon Kim

This study introduces a portfolio combination algorithm, named the Linearized Adaptive Boosting combination (LABc), which employs the modified Adaptive Boosting method to combine multiple portfolio models and obtain the optimal portfolio. LABc adjusts its corresponding combination weight according to the Euclidean distance of investment weight for each individual portfolio model, relative to the optimal investment weight determined by the Tangency portfolio. This approach is logical, as a larger Euclidean distance indicates that the individual portfolio model is further from the Tangency portfolio thus less optimal. Through iterative adjustments, LABc dynamically modifies the combination weight by considering both the error term and the importance value, which will be detailed in this paper.

To evaluate the performance of LABc, we conducted an investment experiment using 10 different datasets. The results demonstrate that LABc achieve significantly high Sharpe ratio, Sortino ratio, and a high Calmar ratio across every datasets, compared to 8 different benchmark portfolios. Additionally, LABc maintains a reasonably low turnover ratio, which is crucial for ensuring that the actual profit is not eroded by excessive trading costs. Through extensive experimentation, our study demonstrates that LABc consistently outperforms its benchmark portfolios.

3 - News Sentiment-Based Adjustment to the Markowitz Portfolio Model

Joomi Park, Yonsei University, Seoul, Korea, Republic of, Minsu Chung, Hongseon Kim, Seongmoon Kim

This paper suggests a portfolio selection model that adjusts the Markowitz portfolio selection model based on sentiment analysis results. This model is designed to adjust the weights of investments according to the results of sentiment analysis, making a flexible response to market conditions possible. News headline data were collected from eight major South Korean economic daily newspapers, and sentiment indices were derived using KR-FinBERT. To evaluate the performance of the model, we conducted empirical experiments using historical monthly return data from the South Korean market.

4 - Formulas for Calculating Out-of-Sample Performance of Constrained Portfolios

Luis Chavez-Bedoya, ESAN Graduate School of Business, Lima, Peru

Within the framework of Kan and Zhou (2007), this paper investigates the out-of-sample performance of optimal mean-variance (MV) portfolios under a set of linear weight constraints. These optimal portfolios combine the risk-free asset, the constrained minimum-variance portfolio, and a hedge portfolio with zero exposure to the constraints and maximum performance. Our analysis yields insights that contribute to the development and evaluation of strategies aimed at enhancing out-of-sample performance. Furthermore, our findings offer theoretical results and formulas pertaining to expectations of functions of quadratic forms and random matrices. These results prove valuable for examining out-of-sample returns and performance of constrained MV portfolios.

5 - Portfolio Selection Models with Shrinkage Factors Derived from a Nonlinear Shrinkage Method Reflecting Macroeconomic Variables

Jihye Yang, Yonsei University, Seoul, Korea, Republic of, Seongmoon Kim

We propose portfolio selection models with weight constraints reflecting four important macroeconomic variables: Baltic Dry Index, Interest rate, Money supply, and Inflation rate. We design two types of macro augmented portfolio models (MAPs); MAPs with a linear shrinking factor (MAPsL), MAPs with a nonlinear shrinking factor (MAPsN). Furthermore, we incorporate four nonlinear shrinking factors (NSFs) altogether into the construction of MAP with the combination level derived from a tracking signal (MAPcN). We assess the performance of the MAPs compared to those of benchmarks in 12 different stock markets and find that the MAPs outperformed the benchmarks, with the MAPsN outperforming the MAPsL and the MAPcN outperforming the MAPsN in terms of the Sharpe ratio, Sortino ratio, and Rachev ratio. Furthermore, we evaluate the performance of MAPs against each other. In terms of individual measure as well as collective ones, each of MAPsN outperforms the corresponding constituent of MAPsL. The effectiveness of the nonlinear shrinkage method measured by the ratio of the Sharpe ratio (*RS*) is differentiated by stock market's characteristics. The *RS* for BDI, IR, MS, and INF is closely related to the trade dependence, the openness of financial market, the stability of money supply, and the market concentration, respectively.

6 - Robust Optimization for Technology R&D Portfolios

Johannes Norheim, Massachusetts Institute of Technology, Cambridge, MA, United States, Afreen Siddiqi, Olivier L. de Weck

One of the key challenges in technology roadmapping is the strategic decision-making regarding which technologies to invest in over time. Unlike financial investments, the returns on technology investments are closely tied to the technology's added value in revenue-generating products. However, the lack of extensive historical data on technology complicates accurate performance forecasting, introducing risk with the investment in specific technologies. We introduce a robust optimization methodology for decision-making in technology R&D portfolios to address data sparsity and uncertainty. We demonstrate the effectiveness of our approach with a technology R&D portfolio case study from the aerospace industry. Our results underscore the potential of robust optimization in managing the uncertainties and complexities associated with technology investment decisions, offering a promising avenue for future research and application.

Advances in Information Design and Platform Design

Invited Session

Decision Analysis Society

Chair: Qian Zhang, California State Polytechnic University Pomona, Pittsburgh, PA, United States

1 - Rating Systems under Customer Disconfirmation Bias: Convergence and Granularity

Qian Zhang, University of Pittsburgh, Pittsburgh, PA, United States, Arian Aflaki

Customers and platforms increasingly rely on online ratings to gauge the quality of the products and services. Additionally, customers reflect on their own experiences by rating the product. Empirical work has established the presence of reference effects when customers post reviews. In other words, customers' prior beliefs about the product's quality affect their judgment, which is influenced by the previous reviews. In this work, we study the convergence of the ratings to the product's intrinsic quality in the presence of reference effects. In contrast to the case when customers' judgments are absolute, we show that the sequence of ratings affects this convergence with reference effects. Specifically, a rational agent can infer the intrinsic quality from the entire rating history. However, platforms often post only statistics of these ratings, such as their average. In this case, we show that convergence to intrinsic quality is not guaranteed in the presence of reference effects. This creates information asymmetry between the platform and customers.

2 - Inventory Disclosure with Product Returns

Ceren Gultekin, CUNY, Graduate Center, Baruch College, New York, NY, United States, Tolga Aydinliyim

Consumers may strategically defer their purchases in anticipation of future discounts at the risk of a stock-out. Retailers can mitigate the adverse profit implications of consumers' strategic waiting by optimally deciding whether to disclose the inventory availability or mask it by displaying "in stock" messages. We study the optimal inventory disclosure strategy when consumer valuations are uncertain which might trigger returns. We use a price- and refund-setting newsvendor framework with availability-dependent demand. Returned and unsold units from the primary selling period are salvaged during clearance. Under masked inventory, boundedly rational consumers form beliefs about the clearance period availability and make buy now or wait decisions accordingly. We show that contrasting the optimality of consistent disclosure of low availability with known customer valuations and no product returns, selective disclosure can be optimal when uncertain consumer valuations trigger product returns. We characterize the economic conditions that favor the optimality of selective disclosure. Furthermore we prove that selective disclosure is more likely to sustain at equilibrium for high margin products when it complements the retailer's optimal refund decision.

3 - Why Would a Principal Sponsor a Persuasive Agent with Conflicts of Interest

luying wang, Tianjin University, Champaign, China, People's Republic of

In this paper, we examine conflicts of interest that arise in sponsorship scenarios where a principal (he) sponsors a persuasive agent (she) to boost his sales among her followers, particularly when the agent owns a product.
We propose a Bayesian persuasion model allowing the agent to design the structure of the match information between the players' products and followers (i.e., changing the persuader's style or mode of communication).
We find that given payment by the principal, the persuasive agent with product ownership may have a higher Level of Persuasiveness (LP), i.e., the greater extent of the sponsor-orientated manipulation on the information structure, than the one without.
Interestingly, the principal may be more motivated to sponsor an agent with a product than without.
This is particularly the case when there is a strong Direct Persuasive Conflict (DPC) between their respective demands, and an Indirect Persuasive Conflict (IPC) affecting the principal's sales revenue and the agent's information utility.
This result is robust even when the manipulation of the persuasive agent could be self-orientated.
Finally, we find that the sponsorship between the principal and the agent might hurt followers' welfare and social welfare.

4 - Optimal dynamic contracting for teams

Ping Cao, University of Science and Technology of China, Hefei, China, People's Republic of, Peng Sun, Feng Tian, Yangge Xiao

We consider a continuous-time setting of a principal contracting with a team of agents to undertake a project. The success rate of the project depends on the agents' hidden effort level. Assuming that the principal and the agents are all risk-neutral and do not discount the future, we consider three scenarios: cooperation in which the agents work together, noncooperation with team performance in which the agents work separately and the principal can only observe the joint outcome, and noncooperation with individual performance in which the principal can observe each agent's outcome. We derive the optimal contracts for these scenarios, and find that a randomized firing may be required in the latter two scenarios. By comparing the principal's optimal utilities under these scenarios, we obtain some implications for optimal contract design.

5 - The Water Far away Can Put Out the Fire Nearby: Enhancing Healthcare Accessibility through Platform Design

Li Xiang, Peking University, Beijing, China, People's Republic of, Li Ling, Lu Yiping

Telemedicine and telehealth show potential for reducing barriers to access and enhancing quality of healthcare. However, the impact of online healthcare platforms on patients' choices of providers and the resulting spatial distribution of healthcare utilization remains poorly understood. This study assesses the impact of demand shocks—particularly in regions with inadequate healthcare resources—on the flow of online medical consultations using a unique dataset from Baidu Health, a leading online healthcare platform in China. We analyze Baidu search queries to explore demand shocks linked to outbreaks of respiratory illnesses nationwide. Our findings indicate that the platform's design, especially its matching algorithm, significantly contributes to reducing disparities in healthcare resource allocation across regions, as well as between urban and rural areas, and among socioeconomic groups. Furthermore, we utilize an equilibrium model of patient search to quantitatively assess the welfare gains attributed to these matching algorithms, which are found to be 12.0% greater in the presence of demand shocks. These results have important policy implications for enhancing healthcare access in China and potentially other countries.

1 - Identifying Cognitive Decliners using Neuroimaging Data

Samaneh Rezaeimanesh, Oklahoma State University, Stillwater, OK, United States, Mohammad Fili, Parvin Mohammadiarvejeh, Guiping Hu, Auriel Willette

As people age, cognitive decline often becomes a natural aspect of the aging process. However, cognitive trajectories vary among individuals. Identifying Cognitive Decliners is crucial for understanding the factors that protect against or prevent cognitive decline, thereby contributing to successful aging. This study involved 711 participants aged 65 and above from the UK Biobank. Participants were categorized as "Cognitive Decliners" or "Others" based on cognition scores from three tests: Fluid Intelligence (FI), Pairs Matching Memory (PMM), and Reaction Time (RT). We assessed the effectiveness of various Magnetic Resonance Imaging (MRI) modalities, including resting-state functional MRI (rsfMRI), diffusion MRI (dMRI), and structural MRI (sMRI), in identifying Cognitive Decliners.

2 - An Exploratory Analysis on the Effects of Introduction of Electronic Health Record Systems Act on Patients Outcome

Masoud Salehi, Iowa State University, Ames, IA, United States

The adoption of Electronic Health Record (EHR) systems represents a pivotal transition in modern healthcare delivery, promising streamlined data management and improved patient care. However, the implications of the legislative mandates surrounding EHR implementation, such as the Electronic Health Record Systems Act (EHRSA), remain underexplored in terms of their direct impact on patient outcomes. This study embarks on an exploratory journey to elucidate the multifaceted effects of EHRSA implementation on patient health metrics and healthcare quality.

3 - Enhancing Patient Care Through Telemedicine: Linking Primary Care with Specialists

Mohammad Delasay, Stony Brook University, Stony Brook, NY, United States, SALIGRAMA AGNIHOTHRI, Arvind Sainathan

We investigate how using telemedicine and e-consultation platforms to link primary care doctors with specialists can enhance patient care and coordination. We also examine how referral choices and resource allocation are affected by different payment methods.

Co-Chair: Andre Cire, University of Toronto, Toronto, ON, Canada

1 - The Impact of Race-Blind and Test-Optional Admissions on Racial Diversity and Merit

Allen Sirolly, Columbia Business School, New York, NY, United States, Yash Kanoria, Hongyao Ma

How significant was the role of racial preferences in U.S. college admissions before the Supreme Court’s 2023 decision to ban affirmative action? How much might test-optional admission policies impact racial diversity and academic merit? In this work, we estimate a simple model of college admissions decisions from 2012–2021, leveraging a novel dataset of applicant profiles and admissions outcomes across the full spectrum of college selectivity. We find that, broadly, the impact of race and testing policies on diversity and merit of admits decreases by college selectivity. For America’s less selective colleges that collectively enroll over three quarters of students, fully eliminating racial preferences (expressed either directly or via unobserved correlates) has little impact on the proportion of underrepresented minorities (URM), and on the average SAT score of admitted students. In contrast, for the 34 most selective colleges accounting for 3 percent of total enrollment, our estimates suggest that admissions going "race blind", absent any compensating changes in admissions criteria, could result in a 40–50% decrease in URM admission and a 9–14 point increase in the average SAT score of admits. Similarly, we estimate that universal test-optional admissions may increase URM admissions by 10–15% and decrease the average SAT score by 15–23 points at elite colleges, but may not materially affect the less selective institutions.

2 - A Rolling Recruitment Process Under Applicant Stochastic Departures

Qing Li, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Chenyin Gong

We study rolling recruitment processes in which applicants arrive stochastically over time and are available for a random amount of time. In each period, the recruiter either stops or waits. If they stop, they determine how many offers to make and whom to make offers to, and the applicants who do not receive an offer will leave. The focus of our study is on the effects of applicant qualifications, measured by scores, on the recruiter's optimal policy.

For each applicant's score, there are two thresholds. If the score exceeds the higher threshold, the recruiter stops and makes an offer to the applicant and possibly to others. If the score falls below the lower threshold, the recruiter also stops but makes no offer to the applicant. If the score is in between the two thresholds, the recruiter waits. What is the impact on an applicant's likelihood of receiving an offer if their competitors become more qualified? When the score of another applicant increases, the recruiter may change from making an offer to an applicant to waiting or to instead making an offer to the other applicant whose score has increased. In other words, an applicant may be disadvantaged if they face stronger competitors. However, an applicant may also benefit from having stronger competitors. When the score of another applicant increases, the recruiter may change from not making an offer to an applicant to making an offer to both applicants. We also numerically evaluate the benefit of endogenously determining the stopping rule.

3 - Who Gets to Ride? Comparing Transportation Eligibility Policies for Saanich Public Schools

Olivia Phillips, H. Milton Stewart School of Industrial and Systems Engineering at Georgia Tech, Atlanta, GA, United States, Arthur Delarue, Sebastien Martin

In public school transportation, eligibility policies determine which students get to ride the bus and which do not. Determining the operational cost of individual eligibility policies is an intractable problem and school districts must often make decisions with incomplete information. We collaborate with the Saanich School District in British Columbia, Canada, to develop methodologies to evaluate the costs and benefits of various eligibility policies. Our work involves both analyzing the costs and benefits of the current policy as well as designing optimization models that maximize utility while keeping costs below a given threshold.

4 - Beyond the Scores: Incorporating Chance in Sequential Admission Processes

Andre Cire, University of Toronto - Rotman School of Management, Toronto, ON, Canada, Shreyas Sekar

We investigate a sequential decision making problem where a University sends offers to students to achieve a given admission’s target, but only learns the true outcomes of student’s after a number of periods have elapsed. The resulting model is a challenging dynamic combinatorial system due to the uncertain action response and delayed rewards. We propose offline and online policies under a new smoothed penalty function associated with the desired student target, which allow us to derive interpretable ordering and threshold strategies that are suitable to large-scale hiring processes. Our interpretable policies come close to achieving the optimal outcome, and considerably improve on the performance of status-quo greedy policies that are utilized in many organizations. In particular, our work establishes that incorporating candidates' acceptance probabilities into the admissions process can result in significant improvements over existing policies that only prioritize candidates with high scores. We assess the quality of our policies on a large-scale University dataset.

1 - A network analysis of external shocks on the dynamics and resilience of the global staple food trade

Huimin Wang, Tianjin University, Tianjin, China, People's Republic of, Guijun Liu

International food trade plays a crucial role in enhancing global food security by connecting regions with diverse agricultural capabilities and resource endowments. This study employs ecological network analysis to investigate the historical dynamics of global staple food trade network resilience from 1986 to 2020. Additionally, structural decomposition and econometric analysis are used to explore the drivers of resilience from both internal and external perspectives. The findings reveal significant heterogeneity in the resilience dynamics of global staple food trade when faced with external shocks, such as COVID-19 and geopolitical tensions. Staple foods such as wheat, rice, and potatoes have demonstrated increased resilience in response to disruptions caused by the pandemic, whereas maize and wheat have been more adversely affected by geopolitical tensions, showing a more pronounced inhibitory effect on their resilience. Potatoes emerge as the most resilient staple, while soybeans exhibit the lowest resilience. Interestingly, the inclusion of a greater variety of staple foods in the aggregated staple food basket does not necessarily give rise to higher resilience. For instance, integrating potatoes, which are characterized by high network efficiency, into the aggregated staple food basket increases resilience, while integrating soybeans with low network efficiency reduces resilience. Furthermore, the diversity of trade flows and trade partners play an important role in enhancing resilience. This comprehensive analysis provides valuable insights for policymakers and stakeholders aiming to bolster the resilience of the global food trade network.

2 - An "Initial-Engineering-Enduse" Quasi-Market Pricing Mechanism under Cascading Risk for Cross-Regional Water Rights Trading

Gang Liu, Tianjin University, Tianjin, China, People's Republic of, Xuxia Li

Water rights trading, operating under a market economy, is recognized as an effective approach to enhance water use efficiency and address water scarcity. It remains a crucial challenge to design a water rights pricing mechanism that incorporates the spatial heterogeneity of water resources. This study aims to address this issue by proposing an “Initial-Engineering-Enduse” quasi-market pricing mechanism based on an empirical study of cross-regional water rights trading in Pingxiang, Jiangxi, China. The proposed mechanism consists of three stages, accounting for associated risks for each stage. Three pricing models, namely stochastic differential game, incomplete contract theory, and the Nash-bargaining model, are calibrated for the three stages based on our study. The interplay among the three equilibrium water prices in each stage is examined to understand cascade effects. It is worth noting that the local government of Pingxiang has adopted and implemented this pricing mechanism. Empirical results demonstrate the following key findings: (1) The quasi-market pricing mechanism effectively reveals the determination of enduse water prices. (2) The government's initial investment can mitigate trading risks and enhance the stability of water rights trading. (3) Neglecting the value of ecosystem services results in an undervaluation of both initial water rights prices and enduse water prices. Furthermore, the government should consider making initial investments in water conservancy projects to minimize risks. Overall, this study provides a practical and promising approach to pricing cross-regional water rights trading in both water-rich and water scarce areas.

3 - Hierarchical determinants of farmer’s water conservation decisions with bounded rationality

Yi Xiao, Tianjin University, Tianjin, China, People's Republic of, Xinran Guo

Despite significant advancements in water conservation technologies, their underutilization by farmers poses a challenge in achieving deeper conservation. Farmers’ interests and decision-making processes are crucial for the successful and effective implementation of water-saving policies considering their essential roles in agricultural production, irrigation, and making water-saving decisions. This research focuses on the micro-perspective of individual farmers, aiming to understand the influence path of various determinants on farmers' water-saving decisions and simulate the impact of incentive policies based on these influence pathways. Using PRISMA statement and meta-analyses, key factors influencing farmers' water conservation decisions are identified from diverse sources including journal articles and government reports. The hierarchical structure of these factors is outlined using the fuzzy interpretive structural model. Then a water conservation decision framework is constructed to characterize the decision-making mechanism of farmers with bounded rationality, which consisting of a decision model for individual farmers, and a dynamic evolutionary game model among multiple farmers. The interactions between the societal and hydrological systems are simulated based on the above models, so that the influence of various water-saving policies on the overall adoption rate of water-saving measures and ecological effects can be investigated. Key sensitive determinants are identified and the pathways of their impact on water-saving behavior could be understood. Recommendations for intervention pathways through new and existing policies and guiding strategies can be proposed. The findings provide valuable insights for enhancing water conservation efforts within agricultural practices, and supporting sustainable water management in critical regions.

4 - Research on the coordination mechanism of platform ecosystem value co-destruction conflict from the perspective of stakeholders

Yu Han, School of Business, Changzhou University, Changzhou, China, People's Republic of

Based on the theory of graph model for conflict resolution, this project (1) investigates and judges deviation. Consider the value preferences of stakeholders, determine the ideal goal of multi-benefit win-win platform value co-creation development, and analyze the deviation between the platform operating status and the ideal situation; (2) designs coordination mechanism. According to the deviation, a multi-objective conflict coordination integer programming model of platform system is constructed. The objective function of the model is determined according to the minimization of the deviation between the preference that can achieve the ideal situation and the current preference. It tries to solve the value conflict problem under the joint action of human stakeholders and non-human stakeholders.

The research results are intended to provide theoretical reference and decision-making suggestions for platform enterprise efficiency, consumer improvement, government and other functional departments to enhance management effectiveness and stabilize platform market operation order.

Advanced Analytics: Insights and Innovations

Contributed Session

Chair: Ezgi Eren, PROS, Inc., Houston, TX, United States

1 - Bite by Byte: An open-source automatic bite detection system from mealtime videos in children

Yashaswini Rajendra Bhat, Pennsylvania State University, State College, PA, United States, Timothy Brick, Kathleen Keller, Alaina Pearce

Our innovative, open-source bite detection system advances eating behavior research by utilizing deep neural networks. This system can overcome the challenges associated with traditional manual annotations of bite, which are error-prone, time-consuming, and expensive, thus limiting their practicality for large-scale studies. Unlike available automatic sensor-based tools such as acoustic and oral strain sensors, alter naturalistic eating behaviors and have low accuracy, our system can be utilized in preserving natural eating behaviors.

We employ adapted Faster R-CNN for face detection (80% accuracy) and utilize AlexNet and LSTM models for bite classification. Our dataset consists in-lab recorded meal videos of children (n=345 meal videos), split into a 70:15:15 split for training, validation, and testing.

This approach enhances bite detection in small-scale labs, facilitating quicker annotations for eating behavior studies. It advances the field by providing a scalable, user-friendly tool for health outcome analysis and personalized, adaptive interventions based on live eating behavior.

2 - Which machine learning models resemble human perception? An empirical analysis through the uncanny valley

Woojae Kim, Yonsei university, Seoul, Korea, Republic of, Kyuho Maeng, Youngsang Cho

Many researchers are currently working on improving the accuracy of image classification. However, in the perspective of human robot interaction, especially in uncanny valley, whether artificial intelligence (AI) can measure the similarity of robot's similarity like human is important because similarity recognized by human is used as criterion of uncanniness. Therefore, we conducted the experiment to investigate which feature extraction models have human's perspective. To reflect our hypothesis that the distance of robot image from the hyperplane of SVM will increase as the robot image is not similar to human, we used SVM based on distance-based similarity concept. For data, we used the human image data from Flickr-Faces-HQ Dataset (FFHQ) and robot image data from A-bot database and Mathur and Reichling's study. For feature extraction models, we used CNN, CNN-PCA and derived the distance by the SVM with extracted features. Then, we compared the robot images' similarities that previously responded by people in the survey with the distance from the hyperplane of the SVM. Through the experiment, it is expected that effective technology development will be possible to determine whether the robot appearance in the development stage will be located in an uncanny valley.

3 - A weighting local search for extended binary integer programs

Shunji Umetani, Recruit Co., Ltd., Tokyo, Japan

We present a weighting local search algorithm for a class of binary integer programs including a wide variety of assignment problems. The quality of locally optimal solutions typically improves using a well designed neighborhood search specified for the problem to be solved. However, we have few alternatives other than k-filp neighborhood search due to few useful features for improving the efficiency of algorithms from the general form of binary integer programs. To overcome this, we consider an extended formulation of the binary integer programs that introduces additional data for deriving a specially designed neighborhood search for a class of specific combinatorial structures. We introduce data of bipartite graph in addition to the binary integer programs that derives shift and swap neighborhood search used in a wide variety of assignment problems. The extended formulation enables us to solve a wide variety of assignment problems with both high performance and versatility; e.g., we can easily introduce additional side constraints into the generalized assignment problem with high performance and it makes great advantages to tackle real industrial applications.
We report our computational results of the proposed model and algorithm for a number of test instances.

4 - Data Engineering and Machine Learning Made Easy with KNIME Analytics Platform

Dursun Delen, Oklahoma State University, Tulsa, OK, United States

In the rapidly evolving field of data science, the ability to simplify complex tasks is paramount. In this presentation, you will learn about the KNIME Analytics Platform, a free, open source, no-code tool that makes advanced data engineering and machine learning accessible to everyone. By eliminating the need for extensive coding knowledge, KNIME empowers a broader audience (i.e., citizen data scientists) to engage with intricate processes such as data wrangling, data blending, and machine learning.

5 - Adaptive Data-Driven Revenue Management and Integration with Pricing

Ezgi Eren, PROS, Inc., Houston, TX, United States, Jiabing Li

Traditional revenue management relies on long and stable historical data and predictable demand patterns, which are not possible to meet for certain industries with high demand volatility or relatively shorter history of revenue management practice. Even for passenger airlines where revenue management is the most established, susceptibility to external shocks is a well-known challenge, which often necessitates user monitoring and intervention. We present a robust data-driven approach to revenue management which eliminates the need for demand forecasting and mathematical optimization techniques. We develop a methodology to generate bid prices using only historical booking data without the need for historical controls. Our approach is an ex-post greedy heuristic to estimate proxies for bid prices as a function of remaining capacity and time to departure solely based on historical booking data. We utilize a neural network algorithm to project bid price estimations into the future. An extensive simulation study shows that our methodology is robust to demand shocks as the revenue stays within 1% of the theoretical optimum for a wide range of deviation of expected demand from true demand parameters. We also present results from simulations where we highlight the strategy used for integrating revenue management into pricing is critical for optimal revenue performance.

Gams/D-Wave

Invited Session

Technology Showcase

1 - Optimization pipeline design: from data curation to algebraic modeling with GAMSPy

Adam Christensen, GAMS Development Corp, Fairfax, VA, United States, Atharv Bhosekar

Algebraic modeling languages (AMLs) have been a cornerstone in the fields of optimization and economics. These tools are popular because they are able to effortlessly link the worlds of algebra and computer science — that is, the syntax of the AML closely approximates that of handwritten algebra but its execution is automated and scalable. AMLs, by design, are not general purpose programming languages; as a result, it can be difficult to gather, clean and prepare data for a modeling environment. Recent years have seen sophisticated data science tools enter the mainstream. Languages such as Python and R can leverage Numpy/Pandas and Shiny/Tidyverse/Dplyr to efficiently work with large data in deployable environments. Modern infrastructure tools such as Docker and Kubernetes make it possible to isolate workflows and scale compute resources via cloud platforms. All of these compute resources mean that data assets are arriving at optimization model instances from an ever-diversifying number of start points. In this workshop, we present a Python package called GAMSPy that leverages modern data science tools with the flexible nature of Python to construct a powerful Python-AML. This presentation will cover a number of real-world inspired examples that illustrate how to bring data into an environment and effectively clean it for use in an optimization model.

2 - Quantum Optimization: Applying Quantum Computing to Business Optimization Challenges

Murray Thom, D-Wave, Vancouver, BC, Canada

A recent Hyperion Research survey reveals that businesses expect up to 20x return on investment from quantum optimization investments, and over 21% plan production-level use of quantum computing over the next 12-18 months–a 50% increase over the past two years.

Attend this session to learn about quantum optimization, and how these new resources are being used for challenging combinatorial optimization problems such as:
• Optimized workforce scheduling for improved employee experience
• Enhanced production scheduling to improve customer satisfaction
• More efficient and more sustainable logistics routing.

This content is most relevant to Associate (Early Career), Professional (Mid-Career), and Executive (Senior Level).

Summit - 346

Advanced Algorithms and Stochastic Modeling in Complex Systems

Contributed Session

Chair: Elif Rana Yoner, Bilkent University, Ankara, 06800, Turkey

1 - Enhanced Quantification of Renewable Carbon in Co-Processed Fuels Using Interpretable Segmentation Modeling

Alimzhan Kussainov, University of South Florida, Tampa, FL, United States, Liang Cao, Kaixun Hua

To address the challenge of accurately quantifying renewable carbon content in co-processed fuels, we propose a method that employs an optimal decision tree model. Traditional approaches apply feature selection uniformly across the entire dataset, failing to adapt to different operational conditions. Our method enhances accuracy by partitioning the dataset into subsets guided by the decision tree model. Each subset then independently develops a robust Bayesian linear regression model, utilizing features identified along the specific decision path. This tailored approach has proven effective in real-world oil refining datasets, providing a precise tool for assessing renewable fuel content.

2 - Using Characteristic Functions of Binary LÉVy Processes for Degradation-Based Reliability Analysis

Yu Shi, Tarleton State University, Stephenville , TX, United States, Qianmei Feng

Engineering systems frequently undergo complicated degradation processes compounded by random shocks, introducing risks to their operational reliability. The analysis of inter-dependence among multiple degradation processes remains a challenging in the field of reliability engineering. One effective approach to model the inter-dependency and the stochastic jumps among degradation processes is by using multi-dimensional Lévy processes. However, a significant hurdle arises in determining the closed mathematical form of the reliability function under Lévy measures and distributions. This research addresses this challenge by investigating the Lévy measure and the characteristic function of multiple dependent degradation processes. The dependence across all dimensions is described by a Lévy copula and the associated multi-dimensional Lévy measure. For a two-dimensional case, we derive the reliability function and probability density function from the characteristic function and the inverse Fourier transform. Numerical examples are provided to illustrate the applications of proposed models for reliability and lifetime analysis of multi-dimensional degradation processes in engineering systems.

3 - Carousel greedy algorithms for the minimum stretch spanning tree problem

Bruce Golden, University of Maryland-College Park, College Park, MD, United States, Jiaqi Wang, Carmine Cerrone

The minimum stretch spanning tree problem aims to find a spanning tree that minimizes the maximum ratio of the distance in the spanning tree to that in the original graph between each possible pair of vertices. Existing heuristic algorithms for this problem are slow and often result in large optimality gaps. To tackle this challenge, we introduce a straightforward and promising carousel greedy algorithm. By investigating the properties of the problem, we further enhance the algorithm's performance. The enhanced algorithm significantly outperforms the best-known algorithms in the literature in terms of both solution quality and running time.

4 - A Decomposable Branch-and-Price Formulation for Optimal Classification Trees

Elif Rana Yoner, Bilkent University, Ankara, Turkey, Ozlem Karsu, Taghi Khaniyev

Construction of Optimal Classification Trees (OCTs) via modeling them as mixed-integer programs which can be solved to optimality, is possible, yet computationally quite cumbersome, especially as the size of the dataset and the maximum depth worked with grows. Our research presents an approach to solving these involved programs to optimality using a novel Branch-and-Price algorithm. We model the classification tree using a "pattern-based" formulation, deciding which feature each leaf must be split upon at each level's decision node. Our preliminary results showcase promising runtimes, displaying the power of decomposition in the realm of binary OCTs.

5 - Epidemic spreading in group-structured populations

Filippo Radicchi, Indiana University, Bloomington, IN, United States

Individuals involved in common group activities/settings – e.g., college students that are enrolled in the same class and/or live in the same dorm – are exposed to recurrent contacts of physical proximity. These contacts are known to mediate the spread of an infectious disease, however, it is not obvious how the properties of the spreading process are determined by the structure of and the interrelation among the group settings that are at the root of those recurrent interactions. Here, we show that reshaping the organization of groups within a population can be used as an effective strategy to decrease the severity of an epidemic. Specifically, we show that when group structures are sufficiently correlated – e.g., the likelihood for two students living in the same dorm to attend the same class is sufficiently high – outbreaks are longer but milder than for uncorrelated group structures. Also, we show that the effectiveness of interventions for disease containment increases as the correlation among group structures increases. We demonstrate the practical relevance of our findings by taking advantage of data about housing and attendance of students at the Indiana University campus in Bloomington. By appropriately optimizing the assignment of students to dorms based on their enrollment, we are able to observe a two- to five-fold reduction in the severity of simulated epidemic processes.

6 - Controlling Tail Risk in Online Ski-Rental

Thomas Lavastida, University of Texas at Dallas, Richardson, TX, United States, Michael Dinitz, Sungjin Im, Benjamin Moseley, Sergei Vassilvitskii

The classical ski-rental problem admits a textbook 2-competitive deterministic algorithm, and a simple randomized algorithm that is $e/(e\text{-}1)$-competitive in expectation. The randomized algorithm, while optimal in expectation, has a large variance in its performance: it has more than a 37% chance of competitive ratio exceeding 2, and the change of the competitive ratio exceeding n is $\Theta(1/n)$!

We ask what happens to the optimal solution if we insist that the *tail risk,* i.e., the chance of the competitive ratio exceeding a specific value, is bounded by some constant δ. We find that this additional modification significantly changes the structure of the optimal solution. The probability of purchasing skis on a given day becomes non-monotone, discontinuous, and arbitrarily large (for sufficiently small tail risk δ and large purchase cost *n*).

1 - Exploit or Explore? An Empirical Study of Resource Allocation in Research Labs

Ran Zhuo, University of Michigan, Ann Arbor, MI, United States

Balancing exploitation and exploration in resource allocation under incomplete information is a classic problem in operations management theory. Yet little research has empirically studied how and how well decision-makers make the exploitation-exploration tradeoff in a complex real-world situation. This paper empirically studies how a group of large publicly funded research labs traded off the exploitation of safe projects to maximize short-term productivity versus the exploration of high-variance projects to acquire information and improve long-term productivity. Using granular data on the allocation of almost one million input bundles to more than 300,000 research projects from 2000 to 2015, we model the resource allocation process as a multi-armed bandit and estimate a dynamic structural model to reveal how these labs balanced exploitation and exploration. We find the labs' decision model strongly resembles a simple Upper Confidence Bound (UCB) index. Estimates of the model's free parameters suggest that the labs explored extensively. Counterfactual simulations show that exploration substantially increased the labs' productivity—had they not explored, their output quantity would have decreased by 51%, and their citations would have decreased by 57%. Further simulations demonstrate that the labs' decision model outperformed popular alternative allocation models, including the Gittins Index, Thompson Sampling, and Explore-Then-Commit. Addition- ally, processes that promoted information utilization during allocation contributed to better outcomes. Had the labs not collected and performed data analytics on the information revealed during exploration, they would have saved 3% of funding but lowered output quantity by 7% and citations by 9%.

2 - Using Artificial Intelligence for Reducing Food Waste in Commercial Kitchens

Yu Nu, Cornell University, New York City, NY, United States, Elena Belavina, Karen Girotra

In this study, we estimate the reduction in food waste from the deployment of a system that digitally records instances of food items discarded in a commercial kitchen. We also shed light on the mechanisms that drive this impact. In a quasi-experimental setting, where the system was deployed in ~900 kitchens in a staggered manner, we estimate the impact using synthetic difference-in-differences method. We find that three months after adoption, kitchens generate 29% lower food waste, on average, than they would have in absence of the system— without any corresponding reductions in sales. Utilizing a long-short-term- memory fully-convolutional-networks classifier, we document that these reductions are accompanied by a 23% decrease in demand chasing, a known bias in human inventory management. Upgrading to a system that uses computer vision for waste classification leads to a further 30% reduction in food waste generated by the kitchen, a year after the upgrade. This further reduction is due to accurate recording of infrequent but very high-impact instances of food wasted that are often not entered in the the manual classification system. We also observe substantial effect heterogeneity. Smaller kitchens and those with buffet service (vs. table service) experience almost double the reduction in food waste from the adoption of the system and also from the computer vision upgrade. Low and high-demand-variability sites have higher reductions from adoption than those with medium-demand-variability (42% vs 25%). The impacts of the upgrade are not detectably different with different demand variability.

3 - Optimal Prototyping on Experimentation Platforms

Sanjiv Erat, University of California-San Diego, La Jolla, CA, United States, Sreekumar Bhaskaran

Testing and prototyping comprise an integral part of almost any new product development process. Recent emergence of experimentation platforms who specialize in offering evaluation/assessment ofprototypes to outside parties have opened up the possibilities for firms in reconfiguring their product development processes. Firms can, by outsourcing the evaluation stage of their dev-test cycles, obtain cost efficiencies and scale. At the same time, lack of visibility into the actual evaluation process andthe possible ambiguity in the product development firm's requirements may lead to potentially noisy evaluations, raising concerns regarding the fidelity and accuracy of results. The current article formulates a model of "outsourced-evaluations" and examines howthe noisy low-fidelity evaluations alter the firm's optimal prototyping. Our results demonstrate imperfect evaluation fidelity changes the client's optimal experimentation, with starkest difference being that it can make optimal for the client to select and launch a prototype that did not yield the best evaluation. In addition, our analysis reveals the client should optimally request most precise measurements when their exante uncertainty is moderate. Finally, examining the optimal measurement technology choices ofthe platform, we find that when the client's exante uncertainty increases from moderate to high values, the platform should offer lower fidelity evaluations, butat a higher fee. We develop managerial insights for the optimal choice of fidelity and the optimal length of the evaluation cycle should be planned depending on the platform's evaluation fees and the client's exante uncertainty. The resulting framework can offer guidance to product and software development firms who leverage external experimentation platforms.

4 - Managing Multihoming Workers in the Gig Economy

Park Sinchaisri, University of California Berkeley, Berkeley, CA, United States, Gad Allon, Maxime Cohen, Kenneth Moon

Gig economy platforms compete to source labor from common pools of workers, who multihome by dynami- cally allocating their services in real-time across multiple platforms. The question of how such workers choose between competing platforms has grown in salience. However, the unavailability of comprehensive data has limited our understanding of workers' dynamic multihoming decisions and their impact on the labor supply and operations of platforms. We address this gap by integrating a major ride-hailing platform's proprietary data regarding individual drivers' detailed trips with public data on the drivers' outside options. Using empirical methods that overcome the remaining data limitations using simulation and machine learning, we structurally estimate the perceived costs that motivate drivers' forward-looking decisions and behavior. Our analysis reveals that workers are short-sighted and value sequences of consistent rewards (e.g., jobs and pay) over highly variable ones. Based on these findings, we explore the impact of compensation and incentives on the platform's labor supply and operations. Our counterfactual analyses indicate that consis- tent pay dominates variable pay in retaining multihoming workers. For gig platforms seeking to maintain a stable platform workforce, they can further control their labor supply by rewarding uninterrupted work or delaying quits. For policymakers, our research gives insights regarding the design of gig economy incentive schemes and regulations, including specifically New York City's 2018 Driver Income Rules, and their impact on multihoming behavior.

1 - Combating Textual Toxicity in MOBA Games

Sunan Qian, University of Notre Dame, South Bend, IN, United States, Xinxue (Shawn) Qu, Corey Angst, Nicholas Berente

Multiplayer Online Battle Arena (MOBA) games such as League of Legends (LoL) and Defense of the Ancients (DotA) attract millions of users globally. Online games provide rich environments for social interaction, where players can collaborate, compete, and establish relationships. However, the emergence of toxic behavior among players has become a significant concern in online gaming, especially for MOBAs that are more competitive. Generally, two aspects of toxic behavior can manifest in the gaming environment – abusive communications (e.g., harassment, verbal abuse, and flaming) and disruptive gameplay (e.g., griefing, spamming, and cheating), all of which fall under the broad notion of toxicity. Such toxic behavior can degrade the gaming experience, impact players retention, and even harm engagement in the gaming community. Understanding and mitigating toxic behavior is crucial for maintaining a positive gaming environment. In this study, we mainly focus on the textual toxicity in chat messages in MOBA games using a rich dataset collected from Dota 2. First, we aim to understand factors that may drive textual toxicity in MOBA games. Second, we plan to investigate both short-term and long-term impacts on players' gaming behavior and community engagement. Lastly, we intend to explore potential interventions that platforms can adopt to mitigate toxic behavior and promote positive playing.

2 - Growing Up Digital: Decoding Age and Gender Influences on Digital Maturity with Explainable AI

Aqib Siddiqui, IE Business School, Madrid, Spain, Konstantina Valogianni, Nancy Pouloudi

In today's digital landscape, fostering healthy Information and Communication Technology (ICT) usage among youth has emerged as a pressing necessity. Digital maturity, a multidimensional construct encompassing a range of competencies, enables young individuals to navigate the digital realm effectively and responsibly. This study investigates the interplay among age, gender, and various dimensions of digital maturity, while also exploring the potential influence of socio-economic status on these competencies. Utilizing a comprehensive survey instrument, we employ Explainable Artificial Intelligence (XAI) technique, SHapley Additive exPlanations (SHAP), to quantify the impact of each digital maturity dimension on overall scores. Our analysis unveils distinct age and gender patterns in dimension salience. For instance, younger children (11-14) prioritize Respect Towards Others, Risk Awareness, and Digital Literacy, while older adolescents (15-18) value Individual Growth, Digital Citizenship, and Support Seeking Behavior. Gender stereotypes also influence dimension importance; Digital Literacy and Individual Growth are consistent across genders, but Regulation of Aggressive Impulses and Support Seeking Behavior vary. We emphasize the need to investigate the socio-cultural contexts shaping digital maturity, aiming to further explore socio-economic status's role. These findings carry implications for educational policies, technology design, and social interventions, advocating for tailored strategies that acknowledge diverse developmental trajectories and socio-economic influences. This study contributes to Information Systems research by offering empirical evidence of dynamic digital competencies, advocating for a holistic approach to technology use. Ultimately, our research advocates for an inclusive digital environment ensuring all youth, regardless of demographics, can thrive in the digital age.

Recent Advances in Mixed-Integer Nonlinear Programming

Invited Session

OPT: Integer and Discrete Optimization

Chair: Zedong Peng, Massachusetts Institute of Technology, Cambridge, MA

1 - Recent Developments in the Gurobi Global Minlp Solver

Gregory Glockner, Gurobi Optimization, Bellevue, WA, United States, Edward Rothberg

This talk will focus advances in the Gurobi Global MINLP Solver, both regarding solver performance and model creation. Modeling improvements primarily involve the addition of direct support for modeling nonconvex multivariate nonlinear functions. Performance improvements include better numerical stability, additional presolve reductions, and faster times to the first feasible solution on a significant number of models.

2 - Exploiting Structure in Hybrid Control Problem by Linking Consecutive Periods

Jisun Lee, UC Berkeley, Berkeley, CA, United States, Andres Gomez, Alper Atamturk

We study a mixed-integer quadratic programming formulation of an n-period hybrid control problem with a convex quadratic cost function and a linear system. For the one-dimensional case, we propose a dynamic programming algorithm that solves this problem as a shortest path problem on a directed acyclic graph in polynomial time. Subsequently, we derive an equivalent SOCP formulation in an extended space using path constraints. We discuss how to generalize these results to multi-dimensional cases with potentially side constraints. Finally, we present computational results testing the proposed formulations.

3 - A Spectral Outer Approximation Algorithm for Binary Semidefinite Problems

Daniel de Roux, Carnegie Mellon University, Pittsburgh, PA, United States, David Bernal

This work introduces a spectral second-order outer approximation algorithm to solve to optimality integer semidefinite programs that are exact formulations of binary quadratically constrained quadratic problems. Our approach is inspired by polyhedral and second-order representable regions that outer approximate the feasible set of a semidefinite program relying on a spectral decomposition of a matrix that simultaneously diagonalizes the objective matrix and an aggregation of the constraint matrices. We give substancial evidence that our approach solves larger instances of binary semidefinite problems than the available software alternatives.

4 - Hybrid Quantum Branch-and-Bound Method for Quadratic Unconstrained Binary Optimization

David Bernal Neira, Purdue University, USRA/NASA, West Lafayette, IN, United States, Zedong Peng, Pedro Maciel Xavier

This work presents an enhancement of branch-and-bound (B&B) methods for Quadratic Unconstrained Binary Optimization (QUBO) problems using quantum and classical heuristics as a source of primal solutions. The enhancements in performance if commercial B&B codes when incorporating these heuristics is quantified in reduction of explored notes and wall clock time. Careful consideration is taken when deciding when the heuristics are to be applied, in particular incorporating the limitations of these heuristics into the call-back procedure.

Experiments carried with the commercial B&B solver Gurobi enhanced with classical heuristics such as those implemented in the MQLib and quantum methods such as the D-Wave quantum annealer provide the avenue of accelerating the performance of Gurobi noticeably when aiming to solve QUBO problems to optimality. The implementation is done through the QUBO.jl software package, efficiently integrating Ising/QUBO solvers with mathematical programming solvers available through JuMP.

5 - Automating Idealness Proofs for Binary Programs with Application to Rectangle Packing

Jamie Fravel, Virginia Tech, Blacksburg, VA, United States, Robert Hildebrand

We develop an optimization framework for identifying ideal Mixed Binary Linear Programs (MBLP) which is linear when using known input data and nonconvex quadratic over parametric input data. These techniques are applied to various formulations for rectangle packing, conjectured to be pairwise-ideal. Additionally, we address a variation of the rectangle packing problem which incorporates clearances along selected edges of the packed objects. We present both existing and novel MBLP formulations for the underlying disjunctive program and investigate the poor performance of Gurobi's default branch-and-cut methodology. We operate under a strip-packing objective that aims to minimize the overall height of the packed objects.

Summit - 421

Optimization Software Session I

Invited Session

OPT: Computational Optimization and Software

Chair: Hans Mittelmann, Arizona State University, Tempe, AZ, United States

1 - Recent Advances in the Cardinal Optimizer

Gerald Gamrath, COPT GmbH, Berlin, Germany

In this talk, we present the recent developments in the Cardinal Optimizer (COPT). We discuss some key techniques that contributed to the performance improvements of our MIP solver and present performance numbers of the latest COPT release for all problem classes.

2 - Advancements in Mindopt: Enhancements in Mixed Integer and Nonlinear Solver

Kuo-Ling Huang, Alibaba, Bellevue, WA, United States

We will present the latest enhancements made to MindOpt, with a specific emphasis on our advancements in Mixed Integer Programming (MIP) and nonlinear solvers. We will discuss the innovative techniques and algorithmic strategies that have been integrated to improve both performance and reliability.

3 - Recent Developments in Optverse Optimization Solver

Zirui Zhou, Huawei Technologies Canada, Burnaby, BC, Canada

In this talk, we present latest development of Optverse optimization solver and some of its successful applications. We will also discuss some new techniques in mixed-integer linear programming and infeasibility detection that improve the performance of Optverse optimization solver.

4 - Recent Developments in the Gurobi Optimizer

Edward Rothberg, Gurobi Optimization, LLC, Beaverton, WA, United States, Ed Klotz, Gregory Glockner, Xavier Nodet

This talk will discuss new features and enhancements in Gurobi 12, including performance improvements. While considering all problem types that Gurobi solves, the talk will focus on the advances in the Gurobi Global MINLP Solver, including its direct support for modeling nonconvex multivariate nonlinear functions.

5 - LeOPT: A Smart Optimizer

wenli ouyang, Lenovo, Beijing, China, People's Republic of

LeOPT is a smart optimizer developed by Lenovo Research AI Lab, currently excels in solving general linear programming and mixed integer linear programming problems. Its modular design and development encompasses various components such as the simplex method, interior point method, branch and bound, cut separation, conflict analysis, and primal heuristics. Crucially, this modular, cross-language implementation enables seamless integration with machine learning models. With the progress in combinatorial optimization driven by artificial intelligence, LeOPT empowers smarter and faster problem-solving.

Summit - 422

Recent Advances in Statistical Learning and Optimization

Invited Session

OPT: Machine Learning

Chair: Moise Blanchard, MIT, Cambridge, MA, United States

1 - Online Convex Optimization with Prediction Through Accelerated Gradient Descent

Junhui Zhang, MIT, Cambridge, MA, United States, Patrick Jaillet

We study online convex optimization with predictions -- at each time step t, predictions about the next k steps are available -- and coupled costs over time step -- the cost function at time step t depends on the decisions made between time $t-a$ and $t+b$ for some nonnegative integers a,b.

We provide a general recipe to run synchronous update in an asynchronous fashion that respects the sequential revelation of information. Combined with existing convergence results for convex optimization using inexact first-order oracle, we show that acceleration is possible in this framework, where the dynamic regret can be reduced by a factor of $(1-O(\sqrt{\kappa}))^{\frac{k}{a+b}}$ through accelerated gradient descent, at a cost of an additive error term that depends on the prediction accuracy. This generalizes and improves the $(1-\kappa/4)^k$ factor obtained by Li and Li (2020) for $a+b = 1$. Our algorithm also has smaller dependency on longer-term prediction error.

2 - Extracting Trustworthy Rule Ensembles for Interpretable ML

Brian Liu, MIT, Cambridge, MA, United States, Rahul Mazumder

We present an optimization framework to extract sparse representative subsets of decision rules from tree ensembles, that are easy for a practitioner to examine. These frameworks have new functionalities such as penalties to encourage fusion and stability in the selected rules. Optimization problems in our framework are challenging to solve due to problem scale and the non-convexity of our regularization penalties. As such, we develop specialized optimization solvers to tackle problems in our framework, that can solve problems beyond the capabilities of off-the-shelf optimization software. We show in our experiments that rule ensembles extracted using our framework can outperform existing algorithms for constructing sparse rule sets in terms of both predictive performance and interpretability.

3 - Benign overfitting and adaptive nonparametric regression

Julien Chhor, Toulouse School of Economics, Toulouse, France

Benign overfitting is a counter-intuitive phenomenon recently discovered in the context of deep learning. It has been experimentally observed that in certain cases, deep neural networks can perfectly overfit noisy training data, while still achieving excellent generalization performance for predicting new data points. This goes against the conventional statistical viewpoint which posits that there should be a necessary tradeoff between bias and variance. This paper aims to understand benign overfitting in the simplified setting of nonparametric regression. We propose using local polynomials to construct an estimator of the regression function with the following two properties. First, this estimator is minimax-optimal over Hölder classes. Second, it is a continuous function that interpolates the set of observations with high probability. The key element of the construction is the use of singular kernels. Moreover, we demonstrate that adaptation to unknown smoothness is compatible with benign overfitting: indeed, we propose another interpolating estimator that achieves minimax optimality adaptively to the unknown Hölder smoothness. Our results highlight that in the nonparametric regression model, interpolation can be fundamentally decoupled from the bias-variance tradeoff.

4 - On the Robustness of Spectral Algorithms for Semirandom Stochastic Block Models

Naren Manoj, Toyota Technological Institute of Chicago, Chicago, IL, United States

In a graph bisection problem, we are given a graph G with two equally-sized unlabeled communities, and the goal is to recover the vertices in these communities. A popular heuristic, known as spectral clustering, is to output an estimated community assignment based on the eigenvector corresponding to the second-smallest eigenvalue of the Laplacian of G. Spectral algorithms can be shown to provably recover the cluster structure for graphs generated from probabilistic models, such as the Stochastic Block Model (SBM). However, spectral clustering is known to be non-robust to model mis-specification. Techniques based on semidefinite programming have been shown to be more robust, but they incur significant computational overheads. We study the robustness of spectral algorithms against semirandom adversaries. Informally, a semirandom adversary is allowed to "helpfully" change the specification of the model so that's consistent with the ground-truth solution. Our semirandom adversaries in particular are allowed to add edges inside clusters or increase the probability that an edge appears inside a cluster. Semirandom adversaries are useful tool to determine the extent which an algorithm has overfit statistical assumptions on the input. On the positive side, we identify a wide range of semirandom adversaries under which spectral bisection using the unnormalized Laplacian is strongly consistent, i.e., it exactly recovers the planted partitioning. On the negative side, we show that in many of these settings, normalized spectral bisection outputs a partitioning that makes a classification mistake on a constant fraction of the vertices. FWe demonstrate numerical experiments that complement our theoretical findings.

1 - Range Value-at-Risk under Distributional Ambiguity: Tight Bounds with Support Information

Zhi Chen, The Chinese University of Hong Kong, Shatin, Hong Kong, Zhenyu Hu, Guangwu Liu, Ruiqin Wang

Estimating risk measures, such as value-at-risk (VaR) and conditional value-at-risk (CVaR), plays an important role when making decisions with limited information. In this paper, we examine the problem of bounding a more general class of risk measures called, range value-at-risk (RVaR), over mean-variance and Wasserstein ambiguity sets. While existing results all assume unbounded support, we characterize tight upper and lower bounds when there is support information. Our numerical results further demonstrate the significant value of support information.

2 - Chance-Constrained Maximum Clique Problem

Shunyu Yao, University of Arizona, Tucson, AZ, United States, Neng Fan, Pavlo Krokhmal

Finding sufficient conditions for the existence of a subgraph H within a larger graph G has a rish story in graph theory and discrete mathematics. Random graphs, as a powerful tool to prove the existence of graphs, have been widely used to gain insight on graph behavior and have been applied more broadly to solve combinatorial problems. One of the problems is to determine how large the probability p needs to be in an Erdős–Rényi graph G(n,p) to ensure the presence of a specific fixed-size subgraph with high probability. In this presentation, we explore the identification of maximum cliques in random graphs and address this problem using some methods from chance-constrained combinatorial programming.

3 - Adaptive Sampling-based Nonconvex and Nonsmooth approaches for Stochastic Programs with Implicitly Decision-dependent Uncertainty

Boyang Shen, Tsinghua University, Beijing, China, People's Republic of, Junyi Liu

We consider a class of stochastic programming problems where the implicitly decision-dependent random variable follows a nonparametric regression model with heteroskedastic error. By the compositional structure, the stochastic optimization problem is weakly convex under suitable conditions. However, the Clarke subdifferential and surrogate functions are not readily obtainable due to the latent decision dependency. To deal with such a computational difficulty, we develop an adaptive sampling-based algorithm that integrates the simulation scheme and statistical estimates to construct sampling-based surrogate functions in a way that the simulation process is guided by the algorithmic procedure. We establish the nonasymptotic convergence analysis in terms of (ϵ, δ)-nearly stationarity in expectation under variable proximal parameters and batch sizes that leads to superior convergence rate and more stable performance in both theory and practice. Furthermore, we show that the proposed adaptive simulation scheme embedded in the sampling-based algorithm leads to better error control of sampling-based surrogate functions and thus further enhance the stability of the sampling-based algorithm. We provide numerical results which illustrate the benefits of variable parameter setting and adaptive simulation schemes in terms of algorithmic stability and efficiency.

4 - Chance Constrained Optimization with Gaussian Mixture Models

Sanjay Mehrotra, Northwestern University, Evanston, IL, United States, Shibshankar Dey, Anirudh Subramanyam, Yi Tianyang, Adrian Maldonado

We develop mixed-integer quadratically constrained program (MIQCP) and second-order cone program (SOCP) formulations for chance-constrained optimization problems with Gaussian mixture models. By leveraging the convex-concave characteristics of the standard normal cumulative distribution function (CDF), we provide both piecewise-linear inner and outer approximations of the original problem. Optimal objectives from these approximations are shown to lie within an epsilon difference of the true value with an adequate number of linear pieces. Additionally, for the conservative SOCP formulation, a bound for relative optimality gap is provided. To expedite computation, we outline a heuristic that selects a significantly lower number of linear pieces than our derived worst-case complexity, without sacrificing desired approximation accuracy. Through extensive numerical experiments analyzing the trade-off between solution time and approximation quality, we find that our formulations offer a significant computational advantage over classical Sample Average Approximation (SAA) methods across various scenarios, including different problem classes and sizes, mixture components, chance constraint reliability levels, and reference distributions.

Co-Chair: Raghu Bollapragada, The University of Texas at Austin, Austin, TX, United States

1 - A Smoothed Augmented Lagrangian Framework for Convex Optimization with Nonsmooth Stochastic Constraints

Peixuan Zhang, Penn State University, University Park, PA, United States, Uday Shanbhag

Motivated by the need to develop simulation optimization methods for more general problem classes, we consider a convex stochastic optimization problem where both the objective and constraints are convex but possibly complicated by uncertainty and nonsmoothness. We present a smoothed sampling-enabled augmented Lagrangian framework that relies on inexact solutions to the AL subproblem, obtainable via a stochastic approximation framework. Under a constant penalty parameter, it is shown that the dual suboptimality diminishes at a rate of $\mathcal{O}(1/K)$ while primal infeasibility and suboptimality both diminish at a rate of $\mathcal{O}(1/\sqrt{K})$. Lastly, we show the flexibility of the framework in accommodating compositional convex constraints and weakly convex objectives.

2 - Modified Line Search Sequential Quadratic Methods for Equality-Constrained Optimization with Unified Global and Local Convergence Guarantees

Raghu Bollapragada, The University of Texas at Austin, Austin, TX, United States

We propose a method that has foundations in the line search sequential quadratic programming paradigm for solving general nonlinear equality constrained optimization problems. The method employs a carefully designed modified line search strategy that utilizes second-order information of both the objective and constraint functions, as required, to mitigate the Maratos effect. Contrary to classical line search sequential quadratic programming methods, our proposed method is endowed with global convergence and local superlinear convergence guarantees. Moreover, we extend the method and analysis to the setting in which the constraint functions are deterministic but the objective function is stochastic or can be represented as a finite-sum. We also design and implement a practical inexact matrix-free variant of the method. Finally, numerical results illustrate the efficiency and efficacy of the method.

3 - Optimization with Highly Adversarial Gradient and Function Value Corruptions: A Unified Framework for High-Probability Iteration Complexity Analysis

Miaolan Xie, Cornell University, Ithaca, NY, United States, Katya Scheinberg

We consider an unconstrained continuous optimization problem in the setting where the gradients can be arbitrarily corrupted in every iteration with a probability greater than $\frac 1 2$. Additionally, the function value estimates may be noisy or adversely corrupted throughout the algorithm's duration. We provide a high probability iteration complexity analysis framework for such an adversarial setting. This analysis offers a unified approach to adaptive stochastic optimization, accommodating noisy or corrupted function value estimates and encompassing both line search and trust region methods.

1 -
Toward a Grand Unified Theory of Accelerations in Optimization and Machine Learning

Ernest Ryu, Seoul National University, Department of Mathematical Sciences, Los Angeles, CA, United States

Momentum-based acceleration of first-order optimization methods, first introduced by Nesterov, has been foundational to the theory and practice of large-scale optimization and machine learning. However, finding a fundamental understanding of such acceleration remains a long-standing open problem. In the past few years, several new acceleration mechanisms, distinct from Nesterov’s, have been discovered, and the similarities and dissimilarities among these new acceleration phenomena hint at a promising avenue of attack for the open problem. In this talk, we discuss the envisioned goal of developing a mathematical theory unifying the collection of acceleration mechanisms and the challenges that are to be overcome.

2 - Nonlinear Conjugate Gradient Methods: Worst-case Convergence Rates via Computer-assisted Analyses

Shuvomoy Das Gupta, MIT Operations Research Center, Cambridge, MA, United States, Robert Freund, Andy Sun, Adrien Taylor

We propose a computer-assisted approach to the analysis of the worst-case convergence of nonlinear conjugate gradient methods (NCGMs). Those methods are known for their generally good empirical performances for large-scale optimization, while having relatively incomplete analyses. Using our computer-assisted approach, we establish novel complexity bounds for the Polak-Ribière-Polyak (PRP) and the Fletcher-Reeves (FR) NCGMs for smooth strongly convex minimization. In particular, we construct mathematical proofs that establish the first non-asymptotic convergence bound for FR (which is historically the first developed NCGM), and a much improved non-asymptotic convergence bound for PRP. Additionally, we provide simple adversarial examples on which these methods do not perform better than gradient descent with exact line search, leaving very little room for improvements on the same class of problems.

3 - Novel first-order methods via performance estimation programming

Kevin Shu, Georgia Institute of Technology, Atlanta, GA, United States, Alex L. Wang, Benjamin Grimmer

We will discuss recent work on designing new first order methods via the performance estimation problem. This methodology uses semidefinite programming to analyze the effect of multiple steps of the algorithm in unison, rather than examining each step separately. Our main contribution is showing that it is possible to achieve asymptotic convergence rates of $O(1/T^{1.27})$ for smooth convex functions by just varying the step sizes of gradient descent. If time allows, we may also discuss additional results.

Joint work with Ben Grimmer and Alex Wang.

4 - The Exact Worst-case Convergence Rate of the Alternating Direction Method of Multipliers (ADMM)

Hadi Abbaszadehpeivasti, Tilburg University, Tilburg, Netherlands, Moslem Zamani, Etienne de Klerk

Recently, semidefinite programming performance estimation has been employed as a strong tool for the worst-case performance analysis of first-order methods. In this talk, I derive new non-ergodic convergence rates for the alternating direction method of multipliers (ADMM) by using performance estimation. I also study the linear and R-linear convergence of ADMM in terms of dual objective. I establish that ADMM enjoys a global linear convergence rate if and only if the dual objective satisfies the Polyak–Łojasiewicz (PŁ) inequality in the presence of strong convexity. In addition, I give an explicit formula for the linear convergence rate factor. Moreover, I study the R-linear convergence of ADMM under two scenarios.

2 - Charging Station Location and Sizing for Electric Vehicles Under Congestion

Omer Kinay, Amazon, Toronto, ON, Canada, Fatma Gzara, Sibel Alumur

This paper studies the problem of determining the strategic location of charging stations and their capacity levels under stochastic electric vehicle flows and charging times taking into account the route choice response of users. The problem is modeled using bilevel optimization, where the network planner (leader) minimizes the total infrastructure cost of locating and sizing charging stations while ensuring a probabilistic service requirement on the waiting time to charge. Electric vehicle users (followers) minimize route length and may be cooperative or noncooperative. Their choice of route in turn determines the charging demand and waiting times at the charging stations and hence, the need to account for their decisions by the network planner. The bilevel problem reduces to a single-level mixed-integer model using the optimality conditions of the follower's problem when the charging stations operate as M/M/c queues and the followers are cooperative. To solve the bilevel model, a decomposition-based solution methodology is developed that uses a new logic-based Benders algorithm for the location-only problem. Computational experiments are performed on benchmark and real-life highway networks, including a new eastern U.S. network. The impact of route choice response, service requirements, and deviation tolerance on the location and sizing decisions are analyzed. The analysis demonstrates that stringent service requirements increase the capacity levels at open charging stations rather than their number and that solutions allowing higher deviations are less costly. Moreover, the difference between solutions under cooperative and uncooperative route choices is more significant when the deviation tolerance is lower.

5 - Multimodal Vaccine Distribution Network Design with Drones

Shakiba Enayati, University of Missouri - Saint Louis, St Louis, MO, United States, Haitao Li, James Campbell, Deng Pan

Childhood vaccines are essential for public health, yet in remote regions, poor infrastructure and cold chain challenges hinder vaccine availability. This study explores the potential of drones (UAVs) for efficient vaccine delivery by addressing the problem of multimodal vaccine distribution. We develop two mathematical optimization models to strategically determine the locations of distribution centers, drone bases, and relay stations, while respecting cold chain time constraints and drone range limitations. The first model offers a compact formulation that aggregates vaccine travel time but can be overly conservative in adhering to cold chain requirements. The second model uses a layered network framework to track vaccine flow for each origin-destination pair, allowing control over the number of transshipments and drone stops, which improves practical feasibility. Both models are applied to the vaccine distribution network in Vanuatu, using two types of drones as a case study. The results demonstrate significant cost savings with optimal drone usage, highlighting distinct roles for large and small drones

Machine Learning/Reinforcement Learning for Vehicle Routing Problems

Invited Session

TSL: Freight Transportation

Chair: Xinwei Chen, Bucknell University, Lewisburg, PA, 74104, United States

1 - The Iterative Chainlet Partitioning Algorithm for the TSP with Drone and Neural Acceleration

Jae Hyeok Lee, KAIST, Daejeon, Korea, Republic of, Minjun Kim, Jinkyoo Park, Changhyun Kwon

This study introduces a novel algorithm, Iterative Chainlet Partitioning (ICP), to solve the Travelling Salesman Problem with Drones (TSP-D). ICP divides TSP-D routes into smaller segments, called chainlets, and applies a precise subroutine, namely TSP-ep-all, to each chainlet. The methodology selects chainlets with the highest incremental improvement for optimization, enabling rapid convergence to high-quality solutions, even for large-scale problems. To further enhance our approach, we integrate a Graph Neural Network (GNN) to predict incremental improvements, significantly reducing the computational burden. Comparative evaluations show that ICP outperforms existing algorithms on most benchmark instances in terms of both solution quality and computational time.

2 - What can we learn from reinforcement learning? Explainable reinforcement learning for on-demand delivery

Xinwei Chen, The University of Tulsa, Tulsa, OK, United States, Xiexin Liu

In recent years, an increasing amount of research has been focused on applying reinforcement learning (RL) to address challenges in on-demand delivery. While various methods have shown improvements over traditional approaches, little attention has been paid to why. This lack of insight into the decision-making process hinders the practical implementation of RL policies, raising concerns about their robustness, etc. In this talk, we introduce a novel framework for learning from RL. We first train the policy for an on-demand delivery problem using an existing deep RL approach. Then, we use supervised learning to learn how different states and actions are mapped. Finally, using the insights we learn from the RL policy, we design policies that are easy to implement and explain to stakeholders. Computational results demonstrate that our proposed policy shows better performance in robustness compared to the conventional RL policy.

3 - Revenue management of customer delivery time offers in on-demand delivery systems

Mathias Klapp, Pontificia Universidad Católica de Chile, Santiago, Chile, Diego Mendieta, Felipe Lagos

We study operational revenue management decisions for on-demand delivery systems by formulating and solving the Personal Shopper Problem with Delivery Time Offers. In this crowdsourced grocery delivery service model, each arriving customer request is offered a delivery time window upon completion of shopping and before payment occurs. Once the offer is made, each customer accepts or rejects it based on their personal preferences. If the customer accepts the offer, the request enters the system and must be served. If the customer rejects the offer, the request is lost, and the platform loses revenue. We design decision policies via an ad-hoc value function approximation that minimizes expected lost revenue and customer dissatisfaction.

4 - Neural Genetic Operators for the Traveling Salesman Problem

Hyeonah Kim, KAIST, Daejeon, Korea, Republic of, Jae Hyeok Lee, Jinkyoo Park, Changhyun Kwon

Genetic algorithms are widely recognized as effective meta-heuristics for tackling diverse combinatorial optimization, including the traveling salesman problem. However, the performance of genetic algorithms heavily relies on the careful design for genetic operations, i.e., crossover, mutation, and selection, leading to the requirements of deep comprehension and problem-specific knowledge. Consequently, genetic algorithms face challenges in directly applying to newly emerging problems that have been insufficiently studied. To mitigate the lack of task expandability, we propose an algorithm design framework for genetic algorithms utilizing the recent progress in deep learning. This allows a general design process of genetic operators for various routing problems.

5 - Serving E-Commerce and E-Grocery Deliveries Together with Learning-Based Vehicle Dispatching

Gürhan Kok, Koc University, Istanbul, Turkey, Oguz Sohret, Barış Yıldız

We examine a collaboration process between a grocery and an e-commerce company, who agree to deliver online orders using a single vehicle. Grocery orders including same-day-delivery are delivered within time windows, whereas e-commerce orders can be delivered anytime within a day.

We present a machine-learning based approach to support the routing optimization model and compare it with reference models.

Emerging Technologies (AVs, EVs, robots, lockers, etc.)

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Tho Le, Purdue University, West Lafayette, IN, United States

1 - A Two-Stage Stochastic Optimization Model for Sidewalk Robot Food Delivery Systems

Tho Le, Purdue University, West Lafayette, IN, United States

The rapidly expanding online food delivery (OFD) market poses significant challenges to last-mile delivery operations. Sidewalk delivery robots (SDRs) offer a promising alternative to relying on on-demand workers, as these box-sized robots can quickly deliver food or groceries within a short range via sidewalks. This paper proposes a two-stage stochastic optimization model for a multi-depot SDR system. The first stage determines the optimal fleet size for each depot and the allocation of battery-swapping facilities at some of the depots. The second stage solves the routing problem with a late arrival penalty. A novel solution algorithm is developed, utilizing continuous approximation (CA) in the first stage to quickly obtain a reduced solution space, and a heuristic algorithm in the second stage to provide high-quality solutions efficiently. The CA model considers factors such as time constraints, battery swapping, and order compliance. The second-stage results guide the adjustment of the CA model used in the first stage. Finally, the sample average approximation (SAA) method is applied to choose the solution corresponding to the lowest average second-stage objective value. A numerical example demonstrates the effectiveness of the proposed approach in reducing computational time while maintaining accuracy. Future work includes evaluating the proposed approach against benchmarks and solving large-scale instances.

2 - Deploying Autonomous Mobile Parcel Locker in Last-mile Parcel Delivery

Yubin Liu, Singapore-MIT Alliance for Research and Technology Center, Singapore, Singapore, Dingtong Yang, Hamsa Balakrishnan, Hai Wang

The vigorous growth of e-commerce transactions has intensified the need for rapid and adaptable last-mile delivery services. Conventional delivery methods involving human-operated vehicles may not adequately meet increasing demands due to escalating labor costs and a scarcity of trained personnel. In response, Mobile Parcel Lockers (MPLs), supported by advancements in autonomous driving technology, have been increasingly implemented by logistics providers as a viable solution to these challenges. Compared to static parcel lockers, MPLs capitalize on their mobility advantage to reduce the walking distance required for customers to retrieve/deliver their packages, thereby enhancing customer convenience. This research investigates a scenario where MPLs dynamically relocate their positions according to customers' spatial distribution to optimize parcel pick-up and delivery processes, considering factors such as customer walking distances and preferred service time windows. The study introduces a mixed integer programming model to optimize the operations of MPLs, aiming to reduce operational costs. Specifically, the research seeks to determine i) the optimal locations for MPL stopovers to maximize the customers being served at each stopover, ii) the optimal duration of service at each MPL stopover, and iii) the most efficient routing for MPL fleets among various stopovers. By examining the impact of customer walking distances on the stopover positioning, the service duration of each stopover, and operational costs, this study assists operators in more effectively allocating MPL services. This strategic deployment allows operators to meet customer needs more cost-effectively, thereby enhancing service reach and efficiency.

3 - Vehicle Routing Problems in the Age of Semi-Autonomous Driving

Hins Hu, Cornell University, Ithaca, NY, United States, Samitha Samaranayake

We are in the midst of a semi-autonomous era in urban transportation in which varying forms of vehicle autonomy are gradually being introduced. This phase of partial autonomy is anticipated by some to span a few decades due to various challenges, including budgetary constraints to upgrade the infrastructure and technological obstacles in the deployment of fully autonomous vehicles (AV) at scale. In this study, we introduce the vehicle routing problem in a semi-autonomous environment (VRP-SA) where the road network is not fully AV-enabled in the sense that a portion of it either not suitable for AVs or requires additional resources in real-time (e.g., remote control) for them to pass through. Moreover, such resources are scarce and usually subject to a budget constraint. An exact mixed-integer linear program (MILP) is formulated to minimize the total routing cost of service in this environment. We propose a two-phase algorithm based on a family of feasibility recovering sub-problems to solve the VRP-SA efficiently. Our algorithm is implemented and tested on a new set of instances that are tailored for the VRP-SA by adding stratified grid road networks to the benchmark instances. The result demonstrates a reduction of up to 37.5% in vehicle routing costs if the fleet actively exploits the AV-enabled roads in the environment. Additional analysis reveals that cost reduction is higher with more budget and longer operational hours.

4 - Collaborative Electric Vehicle Routing for Energy Consumption Minimization

Fangting Zhou, Chalmers University of Technology, Gothenburg, Sweden, Ivan Sanchez-Diaz, Balazs Kulcsar

Electric vehicles for urban delivery have emerged as a promising solution to mitigate the environmental impact. This paper proposes a collaborative electric vehicle routing problem (CoEVRP) for urban logistics, in which the exchange of goods at meet points is strategically planned en route. The objective of the proposed CoEVRP is to minimize energy consumption. Time and space synchronization constraints are considered for better collaboration between vehicles. An energy estimation model is introduced to estimate energy consumption in the routes by considering the variation of ambient temperature. The proposed problem is modeled as a mixed-integer linear programming problem. This paper develops a matheuristic method that combines adaptive large neighborhood search with linear programming for real-world implementations. The study is demonstrated using the real case of two grocery stores in the city of Gothenburg and large-scale experiments. The findings show that on top of reducing travel distance and costs, horizontal collaboration between transportation companies is environmentally sustainable, with around 20% less energy consumption. This paper also suggests that the collaboration between vehicles is more significant during the winter season when the battery performance is more subjected to low temperatures.

Summit - 430

Competition in the Aviation Industry

Invited Session

Aviation Applications

Chair: Gianmarco Andreana, University of Bergamo, Bergamo, Italy

1 - Demand Estimates and Valuing Slots

Gianmarco Andreana, University of Bergamo, Bergamo, Italy

This paper estimates air transport demand for business and leisure segments in the European, North American, and transatlantic markets, with two primary objectives. First, we estimate a set of general logit demand parameters for fares, frequencies, distances, and directness, which can be used in applied (game) theoretical models. Second, we examine the differences in demand parameters across the various segments and markets and investigate the implications of a slot reduction at two major hubs, one in Europe (London) and one in North America (Atlanta). We explore how these effects propagate through the network. Our game-theoretic model of airline competition with slot constraints at these major hubs reveals non-trivial outcomes, including an increase in airline market power, a reduction in consumer surplus, and a decrease in environmental damage. These findings highlight the sophisticated impacts of slot regulation on the aviation industry and demonstrate the importance of considering the effects of slot reductions at multiple major hubs across different regions.

2 - Two-stage Drone Delivery Network Design with Uncertain Demand

Wenjia ZENG, Hong Kong University of Science & Technology, Hong Kong, China, People's Republic of, Ruiwei Jiang, Hai Yang, Hai Wang

Drones are expected to play an important role in the logistics and transportation sectors, with numerous nations and corporations already initiating pilot programs for the rapid delivery of goods, including fast food and groceries, using drones. There is a burgeoning interest in the potential for broader application of this drone delivery service. In light of this, this paper studies a drone delivery network design problem with uncertain demand, particularly focusing on the urban low-altitude context. Our goal is to achieve a cost-effective solution that minimizes both the investment costs on network infrastructure and the subsequent operational costs. A critical aspect of our paper is the consideration of both the soft and hard time windows for customers and the capacity of drone parking and recharging facilities. The lack of extensive historical data on demand patterns, coupled with inherent variability in consumer behavior and market dynamics, also poses challenges for our problem. To tackle this challenge, we propose a two-stage distributionally robust optimization approach, which utilizes a distribution separation procedure and split cuts within Benders decomposition algorithm. The validity and robustness of our proposed method are demonstrated through extensive experiments.

3 - Impact of Traffic-Following on Order of Autonomous Airspace Operations

Anahita Jain, The University of Texas at Austin, Austin, TX, United States

In air traffic management, fostering safe, expeditious, and orderly traffic are key objectives. Air traffic controllers ensure safe separation distances between vehicles and often expedite traffic to enhance system throughput. In maintaining the orderliness of traffic, controllers ensure aircraft compliance with established route structures, and they apply equitable first-come, first-serve service. They dynamically organize traffic into patterns to effectively navigate complexity and workload challenges, especially in airspaces with high traffic densities. Order is often traded for expediency and safety, for example, deviating from route structures to gain time or resolve traffic conflicts.

In this work, we investigate the dynamic emergence of traffic order in a distributed multi-agent system, aiming to minimize inefficiencies stemming from unnecessary structural impositions. We introduce a methodology for developing a dynamically updating traffic pattern map of the airspace by leveraging information about the consistency and frequency of flow directions used by current and preceding traffic. Informed by this map, an agent can discern the degree to which it is advantageous to follow traffic by trading off utilities such as time and order. We show that for the traffic levels studied, for low degrees of traffic-following behavior, there is minimal penalty in terms of aircraft travel times while improving the overall orderliness of the airspace. On the other hand, heightened traffic-following behavior may result in increased aircraft travel times, while marginally reducing the overall entropy
of the airspace. Ultimately, this work can be used to optimally and dynamically adjust an agent's traffic-following behavior based on these trade-offs.

4 - Exploring the Role of Drones and UAVs in Logistics and Supply Chain Management: A Novel Text-Based Literature Review

Bahareh Kargar, New Jersey Institute of Technolog, Newark, NJ, United States

Drones and Unmanned Aerial Vehicles (UAVs) have become pivotal in Logistics and Supply Chain (LSC) management. Our study uncovers a significant disparity highlighted through an examination of recent review papers, indicating a deficiency in UAV applications across entire supply chains. We utilize a novel text-mining method, incorporating qualitative assessments and temporal trend analysis on 5,364 papers. By employing the Latent Dirichlet Allocation (LDA) model, we identify ten distinct research topics, suggesting four promising avenues for future exploration, including sustainability, scalability, pandemic response, and integration with multimodal transportation, providing insights for advancing drone-based logistics systems.

Summit - 431

RAS Round Table on Railway Service Reliability - Part 1

Invited Session

Railway Applications

Chair: Michael Gorman, University of Dayton, 300 college park, Dayton, OH, 45419, United States

Co-Chair: Erick Wikum, Wikalytics LLC, 4906 Whispering Creek Ct, Maineville, OH, 45039, United States

1 - Setting the table: Rail Reliability

Michael Gorman, University of Dayton, Dayton, OH, United States

I kickoff the session with an overview of rail reliability and discuss its causes and overview the cures.

2 - Service Design and Rail Reliability

Carl Van Dyke, TransNetOpt, West Windsor, NJ, United States

Reliability and service quality have long been issues in the rail industry. While originally associated primarily with the carload element of the railroad's lines of business, they also appear within the context of both unit train and intermodal operations. The presenter will review the history of the reliability issue, some of the underlying causes, and the possible ways that these issues could be addressed.

3 - Reliability from a Yard Perspective

Edwin Kraft, TEMS, Inc., Frederick, MD, United States

For many years, yards have been a stubborn source of rail shipment delays and missed connections, leading to service failures and poor equipment utilization. However, it can be difficult in yards to physically access arriving cars that need to make specific connections without also processing many other cars that might not be needed or wanted. Variability in train arrival times and traffic volume fluctuations challenge yard managers, while congestion, switch crew capabilities and restrictive track layouts limit management flexibility and options. We will discuss possible operational and infrastructure approaches for making yards more productive, predictable, and controllable given the practical constraints of day-to-day operations.

4 - Business Imperative to Address Service & Reliability

Sanford Sexhus, Oliver Wyman, Dallas, TX, United States

If railroads simply maintain the status quo with respect to service and reliability they are likely to continue to lose market share in the N.A. transport market. If railroads were to meaningfully move the needle with respect to service, then their ability to maintain or increase market share improves, with large, long term, financial rewards. The nature and scale of this opportunity will be presented.

5 - Incorporating reliability into railway operations planning: select real-life applications.

Stefano Rieppi, Norfolk Southern Railway, Roswell, GA, United States

In this presentation, select case studies regarding the incorporation of the reliability concept into railway operations planning will be presented. The area of focus will be rolling stock distribution planning, where variation in reliability can impact timing of availability of rolling stock, as well as progress of said rolling stock towards planned points of loading. The presentation will cover potential failure modes we seek to manage, as well as systems-based processes in place to manage reliability challenges in the context of optimized distribution operations.

6 - Service Reliability and Amtrak

Jeremiah Dirnberger, Amtrak, Jacksonville, FL, United States

Amtrak has three Service Lines: Northeast Corridor, State Supported and Long Distance. I will discuss the various interactions with the freight railroads for each of the Service Lines. These interactions determine the different performance targets for each Service Line and the overall perspective that Amtrak has on Service Reliability.

Summit - 432

Sustainability and Donations in Behavioral Operations

Invited Session

Behavioral Operations Management

Chair: Leon Valdes, University of Pittsburgh, Pittsburgh, PA, United States

Co-Chair: Gabriel Alfonso Pensamiento Calderon, University of Pittsburgh, Pittsburgh, PA, 15213, United States

1 - Building Alliances for Corporate Social Responsibility

Han Zhang, Michigan State University, East Lansing, MI, United States, Ruth Beer, Kyle Cattani

Problem definition: When multiple companies share the same social responsibility problem, forming an industry alliance can help the companies pool resources, spread the cost, and have greater influence. Companies, however, have the incentive to free ride on the effort of others. What mechanism can avert free riding and let companies form a successful alliance?

Methodology/results: Motivated by an industry case, we model alliance formation as a two-stage public goods game among companies with different brand values and degrees of prosociality. One company can invite another to form an initial alliance before other companies decide to join. We find that the invitation mechanism is the key to success. We identify two mechanisms that affect the type of alliance formed: status seeking and prosocial behavior. We test the theory in an incentivized laboratory experiment. The experiment confirms the essential role of invitation. The experiment also shows that the initiator predominantly invites a high-brand-value company—evidence of status seeking. Once an initial alliance is formed, the prosocial tendency drives further contribution of other high-brand-value companies but not that of low-brand-value companies.

Managerial implications: Establishing an early alliance is the key to addressing a shared social responsibility problem. Companies should leverage status seeking and prosocial tendencies to engage other companies. While there may be clear advantages to inviting companies with highly valued brands, our results show that when the prosocial tendency is strong and status seeking weak, an initiating company may benefit by proactively inviting lesser-known brands early on.

2 - Generic Drug Transparency - Testing a Regulatory Policy Proposal

Sebastian Villa, University of New Mexico, Albuquerque, NM, United States, Gloria Urrea, George Ball, John Gray

The generic drug industry is opaque. Consumers have little ability to determine the quality or manufacturing location of their drugs. We ran two experimental studies to test public's and pharmacists' reaction to increasing generic drug transparency. Our results lead to actionable policy recommendations that can help strengthen the drug supply chain.

3 - On the Impact of Food Packaging On the U.S. Households' Food Waste

Chao Wu, Wayne state university, Rochester Hills, MI, United States, Monireh Mahmoudi, Stanley Lim

In this study, we explore the impact of packaging on U.S. households' food waste. First, we conduct an 8-week diary study with Qualtrics Panelists to examine the impact of various packaging features on household food waste. Then, we confirm the findings by running a follow-up experiment with student population and further explore the potential mechanisms. Implications for operations and policy are discussed.

4 - Reference-dependent effects in volunteering: Expected vs. experienced effort

Leon Valdes, University of Pittsburgh, Pittsburgh, PA, United States, Mahyar Eftekhar, Gabriel Pensamiento

Humanitarian and nonprofit organizations often rely on volunteer labor to accomplish different tasks. We design an incentivized laboratory experiment to study how someone's volunteering experience being above or below effort-expectations affects their decision to volunteer again. In doing so, we study the role of reference-dependent preferences in a not-for-profit setting, which is not well understood in the literature. We also aim to shed light on which responses may be unique to (or more pronounced in) a volunteering setting by comparing our results against a similar task in a for-profit context.

Online Learning in Operations

Invited Session

Applied Probability Society

Chair: Sean Sinclair, Northwestern University, Evanston, IL, United States

1 - Multi-Task Contextual Dynamic Pricing

Jingwei Ji, University of Southern California, Los Angeles, CA, United States, Renyuan Xu, Adel Javanmard

We study the dynamic pricing problem faced by a firm which sells a large number of products.
A product is fully characterized by feature, a d dimensional vector.
The customer will buy the product if our price is better than the competitors', and otherwise not.
We assume a structured pricing model of the competitor, whose parameters are unknown a priori.
The parameters for pricing different products may or may not be similar to each other.
We characterize the overall similarity by $\deltamax$.
The firm's objective is to minimize the expected regret, namely, the expected revenue loss against a clairvoyant policy which has the knowledge of the parameters used by the competitor for different products.
We propose a multi-task learning dynamic pricing strategy which leverages the potential similar structure shared by different products.
More specifically, we show that the regret of our policy is better than both a policy which treats each product individually, and a policy which treats all products as the same.
Moreover, the regret is bounded by $\tilde{O} \paren{ \deltamax \sqrt{TM} d } $, where M is the number of products.

2 - Experimental Design in Supply Chains

Yunhong Wang, National University of Singapore, Singapore, Singapore, Jinglong Zhao, Hanzhang Qin

In this paper, we develop a framework for analyzing biases when implementing experiments in a supply chain system. Operations, such as replacing a fast-moving product with a slow-moving product, could have a long-term effect on the demand. The biases occur due to the spillover effect of the supply chain system, as customers who have not fulfilled their needs at the current FC may turn to other FC so there is interference among customers. We build up a stochastic model for this system and use the mean-field limit method to capture system dynamics which depend on local stock-out events and customer behavior. We also specify the source of interference and discuss the trade-off between different types of interference. Finally, we propose some experimental designs and associated estimators and show that our methods can help to reduce biases compared to the classical demand side "customer randomization(CR)" experimental design.

3 - Reinforcement Learning in Mdps with Exogenous Inputs

Sean Sinclair, Northwestern University, Evanston, IL, United States

Many operations management problems require sequential decision-making under uncertainty, where the only uncertainties affecting the outcomes are exogenous variables outside the control of the decision-maker. We introduce a modeling framework known as Markov Decision Processes with Exogenous Inputs (Exo-MDPs), which explicitly incorporates these uncontrollable inputs into the system dynamics. We outline two algorithmic strategies tailored for these models. The first strategy, Hindsight Learning (HL), achieves data efficiency by leveraging a key insight: having samples of the exogenous variables allows past decisions to be revisited in hindsight to infer counterfactual consequences, thereby accelerating policy improvements. The second strategy addresses settings where the exogenous inputs are censored, designing algorithms that exploit low-rank structure to infer the underlying exogenous randomness for data-efficient learning. We compare our algorithms against classic baselines in applications such as cloud computing, airline revenue management, and inventory problems with lost sales and positive lead times.

4 - A Minibatch-Sgd-Based Learning Meta-Policy for Inventory Systems with Myopic Optimal Policy

Shilin Yuan, Tsinghua University, Beijing, China, People's Republic of, Jiameng Lyu, Jinxing Xie, Yuan Zhou

Stochastic gradient descent (SGD) has proven effective in solving many inventory control problems with demand learning. However, it often faces the pitfall of an infeasible target inventory level that is lower than the current inventory level. Several recent works (e.g., (Huh and Rusmevichientong 2009, Shi et al. 2016)) are successful to resolve this issue in various inventory systems. However, their techniques are rather sophisticated and difficult to be applied to more complicated scenarios such as multi-product and multi-constraint inventory systems.

In this paper, we address the infeasible-target-inventory-level issue from a new technical perspective -- we propose a novel minibatch-SGD-based meta-policy. Our meta-policy is flexible enough to be applied to a general inventory systems framework covering a wide range of inventory management problems with myopic clairvoyant optimal policy. By devising the optimal mini-batch scheme, our meta-policy achieves O(T^(1/2)) regret for the general convex case and O(\log T) regret for the strongly convex case. To demonstrate the power and flexibility of our meta-policy, we apply it to three important inventory control problems: multi-product and multi-constraint systems, multi-echelon serial systems, and one-warehouse and multi-store systems by carefully designing application-specific subroutines. We also conduct extensive numerical experiments to demonstrate that our meta-policy enjoys competitive regret performance, high computational efficiency, and low variances among a wide range of applications.

Advances in Adaptive Experimentation

Invited Session

Applied Probability Society

Chair: Lin Fan, Northwestern University, Kellogg School of Management, Evanston, IL, United States

1 - Asymptotically Optimal Adaptive A/B Tests for Average Treatment Effect

Vikas Deep, Northwestern University, Evanston, IL, United States, Achal Bassamboo, Sandeep Juneja

Typically in A/B testing, an experiment designer sequentially assigns treatment A or B to arriving individuals to identify the better treatment (known as the best treatment identification (BTI) problem), that is, the one with better mean performance. We focus on a related, equally important, but more informative problem of estimating the difference between the two means, defined as the average treatment effect (ATE). For computational efficiency, we restrict accuracy to a confidence interval (CI) of width at most ε, where the probability of CI not containing ATE is restricted to at most δ. The objective is to estimate a CI of ATE with the minimum expected sample size. We first establish a lower bound on the expected sample size of the A/B test needed for any adaptive policy, which constructs a CI of ATE with desired properties as the

solution to a max-min problem for small δ. The min-max problem provides the asymptotic fraction of the assignment of treatments A and B for any asymptotically optimal policy.
Using the insights provided by the max-min problem, we construct an adaptive policy that is asymptotically optimal, i.e., matches the lower bound on the expected sample size for small ε and δ. Finally, we present a comparative analysis between our ATE problem and the BTI problem revealing marked differences in the asymptotically optimal fraction of assignment of treatments in ATE and BTI problems.

2 - Optimizing Adaptive Experiments: A Unified Approach to Regret Minimization and Best-Arm Identification

Chao Qin, Stanford University, Stanford, CA, United States, Daniel Russo

Practitioners conducting adaptive experiments often encounter two competing priorities: maximizing total welfare (or `reward') through effective treatment assignment and swiftly concluding experiments to implement population-wide treatments. Current literature addresses these priorities separately, with regret minimization studies focusing on the former and best-arm identification research on the latter. This paper bridges this divide by proposing a unified model that simultaneously accounts for within-experiment performance and post-experiment outcomes. We provide a sharp theory of optimal performance in large populations that not only unifies canonical results in the literature but also uncovers novel insights. Our theory reveals that familiar algorithms, such as the recently proposed top-two Thompson sampling algorithm, can optimize a broad class of objectives if a single scalar parameter is appropriately adjusted. In addition, we demonstrate that substantial reductions in experiment duration can often be achieved with minimal impact on both within-experiment and post-experiment regret.

3 - Brownian Bandits

Dawei Li, University of Chicago, Chicago, IL, United States, Baris Ata, Michael Harrison

We consider a Gaussian bandit formulation in continuous time and solve the corresponding Bellman equation using deep learning. Leveraging this solution, we propose policies for the discrete-time analogs of our formulation and provide comparisons with benchmark policies.

4 - Robustness Benefits of Structured Bandits

Lin Fan, Northwestern University, Evanston, IL, United States, Peter Glynn

We study the tail of the regret distribution of algorithms optimized for asymptotic expected regret in structured bandit settings. In classical bandit settings, the rewards collected for an arm do not provide information about the quality of the other arms. In the absence of such information-sharing, optimized algorithms quite often make catastrophic statistical errors in estimating the quality of the arms, thereby resulting in very heavy regret distribution tails and fragility to model mis-specification, as exposed in Fan and Glynn (2021). By contrast, in structured bandit settings with information-sharing among arms, we show that optimized algorithms can be significantly more robust.

Robust MDPs and Reinforcement Learning

Invited Session

Applied Probability Society

Chair: Yashaswini Murthy, University of Illinois Urbana-Champaign, Urbana, IL, 61820, United States

1 - On the Convergence of Modified Policy Iteration in Exponential Cost Risk Sensitive MDPs

Yashaswini Murthy, University of Illinois Urbana-Champaign, Urbana, IL, United States

Modified Policy Iteration (MPI) is a dynamic programming algorithm that combines elements of policy iteration and value iteration. The convergence of MPI has been well studied in the context of discounted and average-cost MDPs. In this work, we consider the exponential cost risk-sensitive MDP formulation, which is known to provide robustness to model parameters. Although policy iteration and value iteration have been well studied in the context of risk sensitive MDPs, MPI is unexplored. We provide the first proof that MPI also converges for the risk-sensitive problem in the case of finite state and action spaces. Since the exponential cost formulation deals with the multiplicative Bellman equation, our main contribution is a convergence proof which is quite different from the proof of existing results for discounted and risk-neutral average-cost problems as well as risk sensitive value and policy iteration approaches. We conclude our analysis with simulation results, assessing MPI's performance relative to alternative dynamic programming methods like value iteration and policy iteration across diverse problem parameters. Our findings highlight risk-sensitive MPI's enhanced computational efficiency compared to both value and policy iteration techniques.

2 - Achieving the minimax optimal sample complexity of offline reinforcement learning: a DRO-based approach

Shaofeng Zou, Arizona State University, Tempe, AZ, United States, Yue Wang, Jinjun Xiong

Offline reinforcement learning aims to learn from pre-collected datasets without active exploration. This problem faces significant challenges, including limited data availability and distributional shifts. Existing approaches adopt a pessimistic stance towards uncertainty by penalizing rewards of under-explored state-action pairs to estimate value functions conservatively. In this paper, we show that the distributionally robust optimization (DRO) based approach can also address these challenges and is \textcolor{blue}{asymptotically minimax optimal}. Specifically, we directly model the uncertainty in the transition kernel and construct an uncertainty set of statistically plausible transition kernels. We then show that the policy that optimizes the worst-case performance over this uncertainty set has a near-optimal performance in the underlying problem. We first design a metric-based Hoeffding-style uncertainty set such that with high probability the true transition kernel is in this set. We prove that to achieve a sub-optimality gap of ϵ, the sample complexity is $\mathcal{O}(S^2C^{\pi^*}\epsilon^{-2}(1-\gamma)^{-4})$, where γ is the discount factor, S is the number of states, and C^{π^*} is the single-policy clipped concentrability coefficient which quantifies the distribution shift. To achieve the optimal sample complexity, we further propose a less conservative Bernstein-style uncertainty set, which, however, does not necessarily include the true transition kernel. We show that an improved sample complexity of $\mathcal{O}(SC^{\pi^*}\epsilon^{-2}(1-\gamma)^{-3})$ can be obtained, which asymptotically matches with the minimax lower bound for offline reinforcement learning, and thus is asymptotically minimax optimal.

3 - Policy Evaluation for Variance in Average Reward Reinforcement Learning

Shubhada Agrawal, Georgia Institute of Technology, Atlanta, GA, United States

We consider an average reward reinforcement learning (RL) problem and work with asymptotic variance as a risk measure to model safety-critical applications. We design a temporal-difference (TD) type algorithm tailored for policy evaluation in this context. Our algorithm is based on linear stochastic approximation of an equivalent formulation of the asymptotic variance in terms of the solution of the Poisson equation. We consider both the tabular and linear function approximation settings, and establish $\tilde {O}(1/k)$ finite time convergence rate, where k is the number of steps of the algorithm. Our work paves the way for developing actor-critic style algorithms for variance-constrained RL. To the best of our knowledge, our result provides the first sequential estimator for asymptotic variance of a Markov chain with provable finite sample guarantees, which is of independent interest.

4 - First-order Policy Optimization for Robust Policy Evaluation

Guanghui Lan, Georgia Institute of Technology, Atlanta, GA, United States, Yan Li

We adopt a policy optimization viewpoint towards policy evaluation for robust Markov decision process with s-rectangular ambiguity sets. The developed method, named first-order policy evaluation (FRPE), provides the first unified framework for robust policy evaluation in both deterministic (offline) and stochastic (online) settings, with either tabular representation or generic function approximation. In particular, we establish linear convergence in the deterministic setting, and O(1/\epsilon^2) sample complexity in the stochastic setting. FRPE also extends naturally to evaluating the robust state-action value function with (s,a)-rectangular ambiguity sets. We discuss the application of the developed results for stochastic policy optimization of large-scale robust MDPs.

5 - Prelimit Coupling and Steady-State Convergence of Constant-stepsize Nonsmooth Contractive SA

Yixuan Zhang, University of Wisconsin-Madison, Madison, WI, United States, Lucy Huo, Yudong Chen, Qiaomin Xie

Motivated by Q-learning, we study nonsmooth contractive stochastic approximation (SA) with constant stepsize. We focus on two important classes of dynamics: 1) nonsmooth contractive SA with additive noise, and 2) synchronous and asynchronous Q-learning, which features both additive and multiplicative noise. For both dynamics, we establish weak convergence of the iterates to a stationary limit distribution in Wasserstein distance. Furthermore, we propose a prelimit coupling technique for establishing steady-state convergence and characterize the limit of the stationary distribution as the stepsize goes to zero. Using this result, we derive that the asymptotic bias of nonsmooth SA is proportional to the square root of the stepsize, which stands in sharp contrast to smooth SA. This bias characterization allows for the use of Richardson-Romberg extrapolation for bias reduction in nonsmooth SA.

Large-Scale Simulation Optimization

Invited Session

Simulation Society

Chair: Jinbo Zhao, Texas A&M Univeristy, College Station, TX, United States

Co-Chair: David Eckman, Texas A&M University, College Station, TX, United States

1 - Using Functional Properties to Screen Solutions for Multi-Objective Simulation Optimization

Jinbo Zhao, Texas A&M Univeristy, College Station, TX, United States, David Eckman

We propose a class of screening procedures designed for multi-objective simulation-optimization problems. The procedures screen out solutions that are deemed Pareto-dominated by leveraging known or assumed properties of the functions describing solution performance, such as convexity and Lipschitz continuity, while simulating only a small subset of all solutions. Whether to screen out a given solution is determined by solving a non-convex mixed-integer program, the size of which scales with the number of simulated solutions and the number of objectives. The screening decisions are accompanied by several statistical guarantees, including uniform confidence and consistency. We discuss how modeling choices for the underlying optimization problem impact both the statistical effectiveness and the computational efficiency of the procedures and demonstrate the resulting performance via numerical experiments. Extensions to problems with stochastic constraints will also be discussed.

2 - Dice and Slice Simulation Optimization for High-Dimensional Problems

Harun Avci, Northwestern University, Evanston, IL, United States

Stochastic optimization problems associated with real-life applications sometimes can be simplified enough to get managerial insights, or structured enough to solve via mathematical optimization, but frequently simulation optimization (SO) is needed. We describe such a problem arising from our collaboration with General Motors on “future mobility.” Unfortunately, large-scale problems with high-dimensional discrete solution spaces are computationally impossible to solve with current SO technology. To make solving such problems computationally feasible, we propose the Dice and Slice Simulation Optimization (DASSO) methodology and algorithm. This method decomposes a Bayesian prior distribution on the objective function into an additive form, reducing the problem dimensionality to facilitate efficient posterior updates, and identifies the most-promising solutions efficiently. Our results reveal that it can find good solutions rapidly on large-scale problems with more than a trillion feasible solutions, far beyond the reach of any other discrete SO algorithm.

3 - Sample-Efficient Clustering and Conquer Procedures for Parallel Large-Scale Ranking and Selection

ZISHI ZHANG, Peking University, Beijing, China, People's Republic of, Yijie Peng

We propose novel "clustering and conquer" procedures for the parallel large-scale ranking and selection (R&S) problem, which leverage correlation information for clustering to break the bottleneck of sample efficiency. In parallel computing environments, correlation-based clustering can achieve an O(p) sample complexity reduction rate, which is the optimal reduction rate theoretically attainable. Our proposed framework can achieve improvements without the necessity of highly accurate correlation estimation and precise clustering. Additionally, we propose a parallel few-shot clustering algorithm tailored for large-scale problems. In large-scale AI applications such as neural architecture search, our method demonstrates excellent numerical performance.

4 - Evaluating Solvers for Linearly Constrained Simulation Optimization

Litong Liu, Georgia Institute of Technology, Atlanta, GA, United States

Linearly constrained simulation optimization problems are those that include deterministic linear constraints in addition to an objective function that can only be evaluated through simulation. We provide several solvers for linearly constrained simulation optimization that all rely on gradient estimates of the objective function. We compare these solvers on random instances of 4 test problems from SimOpt.

Optimizing Hospital and Public Health Operations

Invited Session

Health Applications Society

Chair: Vikram Tiwari, Vanderbilt University Medical Center, Nashville, TN, United States

1 - Data-Driven Approach to the Surgical Block Auto-Release Decision

Sandeep Rath, University of North Carolina at Chapel Hill - Kenan Flagler, Chapel Hill, NC, United States, Moe Lim

Surgical block allocation involves reserving block time in operating rooms (OR) for surgeon scheduling. This gives the surgeons independence to manage their own schedules predictably and ensures fair distribution of OR capacity across departments. However, unused block time can result in idle time in the OR, leading to lower OR utilization. In order to improve utilization and total case volume, unused blocks are auto-released for open access several days before surgery. Deciding how far in advance to auto-release block time is a trade-off between predictable surgeon scheduling and OR utilization. Although block allocation optimization is a well-studied topic, the decision on how far in advance to automatically release unfilled block time has received less attention in the literature. To address this gap, we developed a data-driven approach for surgical block auto-release using historical data of surgical case bookings timestamps from a large academic medical center. Our model improves OR utilization without compromising predictable surgeon scheduling.

2 - Machine Learning from Social Determinants of Health in Predicting Diabetes Outcomes

Seung-Yup Lee, University of Alabama at Birmingham, Birmingham, AL, United States, Musawir Haseeb, Mohammad Saleem, Leslie Hayes, Alison Garretson, Heather Bradley, Erin DeLaney, Andrew Land, Andrea Cherrington, Carrie Howell, Allyson Hall, Jane Banaszak-Holl

Despite the increasing recognition of social determinants of health (SDoH) as key factors in diabetes patient health trajectories, their integration into predictive models for tailored interventions remains limited.

In this study, we aim to employ large-scale SDoH data to predict outcomes for diabetes patients. Our retrospective prediction modeling study utilizes Latent Dirichlet Allocation for natural language processing (NLP) topic modeling and the Least Absolute Shrinkage and Selection Operator (LASSO) for feature selection. These methods analyze a comprehensive set of over 100 distinct SDoH items, derived from both categorical and free-text social histories, to develop predictive models for 30-day emergency department (ED) revisits among diabetic patients.

To demonstrate the value of integrating SDoH into prediction modeling, we adopted a progressive model development approach by developing three classification models with increasing sizes of predictors and complexity. Model 1 includes demographic information and geographical SDoH such as the area deprivation index and social vulnerability indices. Model 2 adds 43 categorical SDoH items to Model 1. Model 3 incorporates an additional 59 individual-level SDoH items from free-text data.

We identified 11,775 ED patient-visits to the University of Alabama at Birmingham Healthcare System due to diabetic concerns in 2018. We observed significant improvements across the models: sensitivity of classification increased from 0.098 in Model 1 to 0.332 in Model 3; precision improved from 0.410 to 0.507; and the area under the curve from 0.609 to 0.705. Our results demonstrate the significant predictive capability of SDoH data in forecasting ED revisits among diabetes patients.

3 - Locations of Drone Ambulance Stations to Improve Response TIME of Cardiac Arrest Patients: Ambulance Dynamics in the Euclidean Plane

EUNBI KIM, Korea University, Seoul, Korea, Republic of, Joonyup Eun, Taesu Cheong

This study aims to identify the optimal locations of manned drone ambulance stations to reduce response time for cardiac arrest patients. When responding to a cardiac arrest incident, it is advisable to dispatch either a ground ambulance or a manned drone ambulance, depending on the time of each option taken to reach the patient. The ambulance that can reach the patient in earlier is selected by calculating the relative travel time in the Euclidean plane, considering the locations of the cardiac arrest patient and each ambulance. Furthermore, the MILP model is employed to rapidly identify optimal locations for drone ambulance stations out of 25 fire stations in Seoul, with a focus on 13,039 cases of cardiac arrests in 2022.

4 - Impact of Shift Structure on Fatigue among Emergency Department Service Workers

Chia-Chun Yang, University of Cincinnati, Cincinnati, OH, United States, Craig Froehle, Elizabeth Leenellett

It is well-established that worker fatigue can have deleterious consequences for work quality. However, less is known about how shift structure – an operational policy decision – influences worker fatigue. We collected primary data through a month-long fatigue-monitoring program we developed and implemented in an emergency department at a large, midwestern, academic hospital. Using a combination of nonparametric and econometrics models, we found that both the duration of a shift and its timing (i.e., when the shift starts) have important and differential impacts on workers' perceived physical and mental fatigue. In addition, we observed that time spent on either extra-clinical professional responsibilities or personal chores reduces the efficacy of a clinician's recovery time in terms of fatigue reduction. In contrast, we find that time spent with family and loved ones can significantly improve the effectiveness of fatigue recovery periods between work shifts. We conclude that scheduling policies that mitigate the physical and mental fatigue induced by shift work and allow for enhanced fatigue recovery between shifts should be preferred by organizations concerned with both employee well-being and consistently high service quality.

Co-Chair: Reza Skandari, Imperial College London, London, United Kingdom

1 - Sequential Updating Machine Learning Models for Diagnostic Testing

Kevin Smith, Industrial and Operations Engineering, University of Michigan, Ann Arbor, MI, United States, Erkin Otles, Siqian Shen, Brian Denton

Machine learning (ML) models are often used to recommend whether or not a patient should receive a diagnostic test. However, ML models are subject to *concept drift* whereby model performance degrades over time. One way to address concept drift is to update the ML model using recent data. However, in such cases the available data is subject to verification bias because results are only available for patients who received the diagnostic test. In this presentation, we discuss approaches for trading off the competing goals of model updating to improve referral decisions and avoiding unnecessary diagnostic testing for patients with a low risk of disease. We illustrate the approaches using a case study in the context of prostate cancer diagnosis.

2 - Unsupervised Learning Approaches to Detect Patterns in the Co-Occurrence of Diseases: Evidence from Medical Expenditure Panel Survey (Meps)

Ali Jafari, University of Massachusetts, Amherst, Amherst, MA, United States, Hari Balasubramanian

Understanding the relationships between diseases is one of the crucial aspects in healthcare and clinical practice. While certain associations between diseases, such as diabetes and hypertension (high blood pressure), are well established, others remain less obvious, and may remain undetected. In this study we use the Medical Expenditure Panel Survey (MEPS 2016 - 2019) to study associations between diseases. The MEPS provides comprehensive patient information, including specific medical conditions indicated by their corresponding International Classification of Diseases, Tenth Revision (ICD-10) codes. We structured a dataset from the MEPS records, facilitating access to individual disease profiles. Subsequently, we applied the Apriori algorithm to identify various disease combinations and association rules. Moreover, we implemented a novel unsupervised learning algorithm to perform clustering, offering deeper insights into the interrelations among diverse disease categories. Using these methodologies, we aim to enhance our understanding of disease relationships, potentially contributing to more effective healthcare strategies and interventions.

3 - Interpretable Mortality Simulation and Decision-Making Agent for Heart Transplantation

Yingtao Luo, Carnegie Mellon University, Pittsburgh, PA, United States, Rema Padman, Reza Skandari, Arman Kilic

Decisions regarding acceptance of a donor's heart for a patient on the transplant waitlist is currently based on evaluation by a committee of doctors who review many factors but are still quite ad-hoc. Given the volume and range of data collected by the United Network for Organ Sharing (UNOS) on waitlisted patients, donors, clinicians and organs, there is increasing interest among all stakeholders, particularly clinicians, in leveraging model-based approaches that learn from the vast amount of historical data on organ acceptance/rejection to optimize the heart transplantation outcomes and assist human decision making. In response to this need, we benchmark and propose machine learning models to provide accurate and interpretable predictions regarding transplant mortality at both the individual and population levels. We train our model with more than 30,000 patient records and 350 variables. This robust training has enabled the best model to achieve a C-statistic of 0.9, significantly better than previous benchmarks which only attained a C-statistic between 0.62 and 0.75 with 20 to 30 variables. This level of accuracy provides a reliable foundation upon which clinicians can base their decisions with a greater degree of confidence. We have also identified the key features that drive the predictions and verified the clinical significance of these results through close collaboration with the domain experts.

4 - Optimizing Colorectal Cancer Surveillance Policies Considering Uncertainty in Colonoscopy Outcomes

Mahboubeh Madadi, San Jose State University, San Jose, CA, United States, Jaleh Soltanpour, Amin Asadi

Colorectal and rectum cancer (CRC) is a significant cause of morbidity and mortality
worldwide. This work aims at optimizing colorectal cancer surveillance policies. Specifically, we propose a model to maximize a patient's quality adjusted life years (QALYs) through personalizing CRC surveillance strategy informed by patient's colonoscopy history. We propose a partially observable Markov decision process (POMDP) to model CRC dynamics. The proposed model incorporates the uncertainty in size and number of detected polyps in a colonoscopy test. We use data of over 47,000 colonoscopy reports (over 21,000 patients from 5 VA medical centers) to estimate the proposed POMDP parameters. Incorporating the detailed pre-cancerous states (i.e., size and number of detected polyps) results in a POMDP model with a large state space. We use different approaches such as approximate point-based value iteration and Reinforcement learning to find personalized optimal surveillance policies.

5 - A Machine Learning Model for Mortality Prediction of Paralytic Ileus Patients Admitted to ICU

Houshang Darabi, University of Illinois-Chicago, Chicago, IL, United States, Martha Razo

Paralytic Ileus (PI) patients in the Intensive Care Unit (ICU) are at a significant risk of death. Prediction of at-risk patients for mortality after 24 hours of admission of ICU PI patients is important to increase the life expectancy of PI patients. We propose a model called DLMP (Deep Learning Model for Mortality Prediction) that can predict the mortality event of the PI patients after 24 hours of admission to ICU. DLMP is a powerful deep learning model consisting of six total unique clinical lab items and two demographics as inputs to a Neural Network (NN) of only two neuron layers. Using the Medical Information Mart for Intensive Care IV (MIMIC-IV) dataset of 1,017 ICU PI patients, the DLMP results in the best prediction performance with an AUC score of 0.889. DLMP framework significantly improves the prediction of mortality for PI patients compared to process mining and other machine learning models. The proposed DLMP has the potential to allow clinicians to create targeted interventions that reduce mortality for PI patients in an ICU setting.

Analytics for Pharmaceutical Shortages

Invited Session

Health Applications Society

Chair: Daniel Kosmas, Northeastern University, Boston, MA, United States

Co-Chair: Noah Chicoine, Northeastern University, Boston, MA, United States

1 - When Should the FDA Inspect Pharmaceutical Manufacturing Facilities to Better Mitigate Drug Shortages?

Daniel Kosmas, Northeastern University, Boston, MA, United States, Ozlem Ergun

Drug shortages have been a persistent problem in American healthcare for decades, and the resulting lack of access to necessary drugs has been disastrous to patient health. A majority of these shortages were caused by quality issues related to problems in the manufacturing process. More frequent inspections can help reduce quality concerns, but deciding when to inspect is a complex problem; strict regulation enforcement can force low-profit facilities to close due to excessive maintenance costs, while lax enforcement allows for regulation violations to persist, both of which can cause drug shortages. We propose a novel POMDP model to assist inspectors in determining how long to wait between subsequent inspections that balancing the trade-off of recurring inspection costs, the benefits of allowing a facility to stay in operation, and the risks of allowing for disruptive events. We theoretically show that this problem can be reduced to only needing to consider whether or not to inspect immediately, which is independent of the time horizon. Our computational study highlights the importance of allocating more resources to high-risk facilities that produce drugs that highly impact public health. We additionally find that optimal inspection time is more sensitive to changes in the penalty from an unexpected disruptive event occurring the longer it has been since the last inspection.

2 - A Deep Reinforcement Learning Aided Inventory Control Approach for Managing Drug Shortages: Impact of Information Sharing and Adaptive Reward Shaping

Zohreh Raziei, Dematic, Plano, TX, United States, Ozlem Ergun

Pharmaceutical supply chains have long faced challenges in maintaining resilience, leading to drug shortages and inefficient inventory management. To address this issue, our study proposes a novel approach to inventory control that utilizes a multiagent deep reinforcement learning decision support system. This system models agents' behaviors and investigates the effects of partial and full information sharing during supply chain disruptions. We implement a reward-shaping strategy that helps increase stability during the training process and obtain more accurate policies under long and severe disruption scenarios. We proposed an automated weight adaptation strategy for the shaped reward, enabling the system to learn effective policies for maintaining supply chain resilience and mitigating the impact of disruptions on drug shortages.

3 - Assessing the Feasibility of an Intra-hospital Information Sharing System to Improve Drug Shortage Management

Noah Chicoine, Northeastern University, Boston, MA, United States, Jacqueline Griffin

During some drug shortages, hospital pharmacies receive little to no information regarding the cause and pervasiveness of the shortage. With such information, pharmacists could draw important inferences, such as future availability of the product and its alternatives, to guide their sourcing and ordering decisions. In this study, we develop a game-theoretic model of a supply chain system that aims to enhance hospitals' views of broader drug shortage market dynamics. In the model, hospitals anonymously share inventory and order information with each other during a drug shortage and make sourcing decisions based on that information. We test the feasibility of such an information sharing system and explore potential consequences, such as hoarding or external market consequences. The information-sharing system presented in this work could be incorporated into current inventory management software to help build resiliency in pharmaceutical supply chains. Hospitals, with the ability to make more informed inventory management and sourcing decisions, may be able to achieve more optimal care for their patients during drug shortages.

4 - Equitable Drug Distribution Under Panic Buying

Emily Tucker, Clemson University, Clemson, SC, United States, Marta Wosinska, Dan Li

When there is a signal that a drug shortage is imminent, health providers may rapidly begin to panic buy medications. As a response, wholesalers may impose order limits based on historical demand to spread available supply across providers. Yet, these approaches may not be sufficient to ensure that slower-responding health providers, e.g, less sophisticated systems, independent hospitals, or rural facilities, also receive medically-necessary drugs during shortages. In this project, we (i) study panic buying behaviors of health providers, including the characteristics of providers that receive drugs, and (ii) evaluate potential order limit policies to improve equity in drug distribution under different panic buying settings. Data is provided by a large drug wholesaler.

Frontiers in Inventory Control: Asymptotic Analysis and Demand Learning

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Jinzhi Bu, The Hong Kong Polytechnic University, Hong Kong, N/A

1 - Asymptotic Optimality of Projected Inventory Level Policies in Lost Sales Inventory Systems

Joachim Arts, University of Luxembourg, Luxembourg City, Luxembourg, Poulad Moradi, Melvin Drent

We study the canonical periodic review lost-sales inventory system with positive leadtime and i.i.d. demand. We demonstrate that the relative value function, under the constant order policy and the long-run cost rate criterion, satisfies the Wiener-Hopf equation. We employ ladder processes associated with a random walk featuring independent and identically distributed (i.i.d.) increments, to obtain an explicit solution for the relative value function. Our analysis reveals that as lead time and penalty costs increase significantly, the value function tends to converge towards a quadratic form, irrespective of the demand distribution function, given that it possesses finite first and second moments. Furthermore, we show that under this regime, the projected inventory level policy outperforms the constant order policy.

2 - Asymptotic Optimality of Open-Loop Policies in Lost-Sales Inventory Models with Stochastic Lead TIMES

Xingyu Bai, University of Illinois at Urbana-Champaign, Urbana, IL, United States

In this paper, we consider the lost-sales inventory model in which the lead time is not only large but also random. Under the assumption that the placed orders cannot cross in time, we establish the asymptotic optimality of constant-order policies as the lead time increases for the model with divisible products. For the model with indivisible products, we propose a bracket policy, which alternates deterministically between two consecutive integer order quantities. By employing the concept of multimodularity, we prove that the bracket policy is asymptotically optimal. Our theoretical results can be extended to the models with order crossover, random supply functions, Markov-modulated demands and cyclic demands. Finally, we provide a comprehensive numerical study to demonstrate the good performance of the proposed open-loop policies, and derive further managerial insights.

3 - Managing Perishable Inventory Systems with Positive Lead TIMES: Inventory Position vs. Projected Inventory Level

Huanyu Yin, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Jinzhi Bu, Xiting Gong

We consider periodic-review perishable inventory systems with a fixed product lifetime and positive replenishment lead times. Demands are satisfied by on-hand inventories of different ages following a general issuance policy. Unsatisfied demand is either backlogged or lost. The objective is to minimize the long-run average holding, penalty, and outdating costs. The optimal replenishment policy for these systems is notoriously complex and intractable due to the curse of dimensionality. Previous studies have shown that the class of base-stock policies, which maintains a constant inventory position in each period, performs poorly when the unit penalty cost is large. In this paper, we propose a more appealing class of projected inventory level (PIL) policies that maintains a constant expected on-hand inventory level at the time of each order arrival. For both backlogging and lost-sales systems under a general issuance policy, we prove that the best PIL policy is asymptotically optimal with large unit penalty costs under a large class of demand distributions. For the backlogging system, we further prove that its optimality gap decays to zero exponentially fast in the product lifetime and in the demand population size under a large class of issuance policies. Our numerical results show that the best PIL policy performs close to optimal and much better than the best base-stock policy.

4 - Bayesian Inventory Management with High-Dimensional Data

Weizhou Zhang, National University of Singapore, Singapore, Singapore, Hanzhang Qin, Jussi Keppo

We study Bayesian inventory control problems where the parameters of the demand distribution are known to belong to the exponential family a priori, but the parameters need to be learned from demand samples. We consider a finite-horizon perishable inventory control problem setting with unobserved lost sales, thus the sales data are censored by the inventory level. Besides estimating the demand parameter from the posterior belief, we derive the maximum likelihood estimation (MLE) approach to estimate the demand parameter using the right-censored sales data. Indeed, we show that the posterior mean can be recovered from the MLE expression when we have a sufficiently large number of data samples. Meanwhile, we develop a data-driven scheme to predict the stock-out probability (i.e., the predicted service level) at each retailer given any base-stock inventory control policy -- we show the probability can be uniquely identified from the data. Moreover, we extend the model, algorithm, and analysis to a joint price and inventory Bayesian model which is an extension of the existing single-parameter Bayesian inventory model. We conducted the numerical experiment against synthetic data for single and two-dimensional Weibull distribution data. An approximate inference scheme is applied when the dimensionality of the latent variable space is high and no closed-form analytical solution exists.

5 - Partial Backorder Inventory System: Asymptotic Optimality and Demand Learning

Zhaoxuan Wei, Institute of Operations Research and Analytics, NUS, Singapore, Singapore, Andrew Lim, Hanqin Zhang

We develop a stochastic inventory system which accounts for the limited patience of backlogged customers. While limited patience is a feature that is closer to the nature of unmet demand, our model also unifies the classic backlogging and lost-sales inventory systems which are special cases of the one we propose. We establish the uniform (asymptotic) optimality of the base-stock policy when both demand and patience distributions are known. When the backlogged demands become unobservable, we introduce a novel policy family that operates without backlogged demands information, and prove that it can approach the cost efficiency of the optimal policy in the system when the demand and patience distributions are known. Finally, we consider an online inventory control problem in which backlogged demand is unobservable and demand and patience distributions are also not known, and develop a UCB-type algorithm that yields a near-optimal policy.

The regret bounds given by the algorithm are provably tight within the planning horizon, and are comparable to the state-of-the-art results in the literature, even in the face of partial and biased observations and weaker system ergodicity.

Social Impact of Operations Management

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Jun Li, Ross School of Business, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Zhihan Wang, Ross School of Business, University of Michigan, Ann Arbor, MI, United States

1 - Maternal Health Interventions with Combinatorial Restless Bandits

Lily Xu, University of Oxford, Oxford, United Kingdom, Bryan Wilder, Elias Khalil, Milind Tambe

Restless bandits are a useful model for many real-world problems, whose deployments include for maternal healthcare interventions in India. However, existing approaches have been restricted to simplified action settings that allow for tractable solutions. Unfortunately, public health interventions often have complex combinatorial constraints — such as path constraints or scheduling constraints — that cannot be addressed by existing solvers.

Here, we consider CoRMAB, a broader class of problems with combinatorial actions that cannot be decoupled across the arms of the restless bandit, requiring direct solving over the joint action space. Leveraging recent advances in embedding trained machine learning models into optimization problems, we propose SEQUOIA, an algorithm for training a reinforcement learning agent to find a good policy that considers long-term reward by embedding a Q-network directly into a mixed-integer program to select one of exponentially many combinatorial actions in each timestep. SEQUOIA builds on the widely used deep Q-network framework but also benefits from a set of enhancements that accelerate training by exploiting the structure of CoRMAB. We empirically validate this approach on novel restless bandit problems with combinatorial constraints, including from maternal healthcare in India.

2 - Disruptions, Resilience and the Performance Gender Gap in Small Firms

Amrita Kundu, McDonough School of Business, Georgetown University, Washington, DC, United States, Kamalini Ramdas, Stephen J. Anderson

Why a large gender gap in firm performance persists – especially for small firms in developing countries – is not well understood. In this paper, we study the operating environment of such firms to assess to what extent firm-specific disruptions contribute to the performance gender gap. Further, we examine to what extent building resilience can help women-led firms improve performance. In a sample of 646 small firms in Kampala, Uganda, we find evidence of a sizeable gender gap in the downside losses from firm-specific disruptions, which reduce managerial capacity and resource availability. On average, business disruptions decrease short-term sales and sales growth of small women-led firms by an additional 11.6% (p=0.013) and 15.2 percentage points (p=0.084), respectively, relative to those of men-led firms. In the longer term, disruptions alone explain 8% of the profit gender gap. Building resilience helps women-led firms buffer against the negative impact of disruptions. In the absence of resilience, women-led firms that face managerial disruptions see a decline in sales of 13.4% (p = 0.069) and those that face operational disruptions lose 48% in sales (p = 0.001) in a six-month period. In contrast, women-led firms with high resilience fully overcome these disruption-related losses. In our sample, women-led firms are 9% less likely than men-led firms to have high relational resilience (p = 0.000) and 5% less likely to have high resource resilience (p = 0.002). Our results indicate that substantial gains could accrue from instituting resilience training for women-owners of small firms.

3 - Impact of in-Class Smartphone Bans on Student Outcomes

Andreas Bjerre-Nielsen, Univeristy of Copenhagen, Copenhagen, Denmark

We evaluate a novel large-scale RCT on in-class smartphone bans. We investigate its impact on students' academic outcomes in terms of grades obtained as well as class attendance and student wellbeing.

4 - Optimization Meets Participation: Iterative Zone Generation for School Assignment

Irene Lo, Stanford University, Stanford, CA, United States

In U.S. public schools, geographic boundaries significantly influence student-school assignments. However, such boundaries often replicate residential segregation patterns in schools. To address this, the San Francisco Unified School District (SFUSD) adopted guidelines for multi-school zones, balancing neighborhood assignment and citywide choice to mitigate segregation. Optimizing these zones is computationally and socially complex due to their direct and indirect impacts on policy goals. We propose an iterative framework that promotes stakeholder participation in optimizing multi-school zones. Our approach alternates between a consumer search process using interactive tools for constraint identification and selection, and computational methods generating solutions satisfying those constraints. We develop novel computational approaches for the multi-school zone problem using both optimization and sampling-based methods. Comparing our approaches to benchmarks from the literature, we find that our multilevel optimization approach consistently produces better zone-level statistics for larger zones, while our recursive optimization-based approach excels in generating numerous small zones. Our framework supported SFUSD's development of a zone-based policy and is being used to facilitate stakeholder participation in determining the final zones.

5 - Closer Childcare Better Career: An Empirical Study of Childcare Availability and US Knowledge Workers

Damian Beil, University of Michigan, Ann Arbor, MI, United States, Zhihan Wang, Jun Li

The scarcity of quality childcare services has long obstructed the career progression of working parents in the US. Leveraging large-scale national job profile data from 1997 to 2019, we investigate how the career development of employees in a variety of industries is influenced by the availability and location of childcare services nearby their working sites.

MC50

Summit - 442

Empirical Healthcare Operations

Invited Session

MSOM: Healthcare

Chair: David Rea, Lehigh University College of Business, Bethlehem, PA, United States

1 - A Framework to Study Health Inequities: A Case Study of Breast Cancer Survival

Margret Bjarnadottir, University of Maryland, College Park, MD, United States, Ritu Agarwal, Wedad Elmaghraby, Shana Ntiri, Lindy Rosal, Nawar Shara

We present a health inequity framework that can summarize health inequities and guide action toward eliminating them, by highlighting drivers of inequity and their relative importance. We present a novel approach to linking unadjusted inequity to adjusted inequity highlighting both key quantifiable drivers and the degree to which the inequity is a results of structural and systemic racism, or other or unmeasurable or omitted factors. We offer the framework as a decision support tool for health systems to study their own outcomes and drive a deeper understanding of health inequity outcomes.

2 - Designed for Variability: An Empirical Study of a Dedicated Observation Unit

Temidayo Adepoju, Rutgers Business School, Newark, NJ, United States, Anita Carson, Cherisse Carlo, Chris Manasseh

Safety-net hospitals with focused units have to provide care for patients who do not fit the focused unit's parameters. We study how a dedicated observation unit transforms into a "variability-absorbing" unit to treat patients with comorbidities and more complex conditions. Studies on observation units have largely been based on the unit treating patients with no comorbidities. Higher-rate of reimbursement for patients who stay more than two midnights on inpatient units have triggered hospital managers to find capacity and resources to care for the patients who stay less than two midnights yet with comorbidities and complex conditions. Transforming the DOU into a "variability-absorbing unit" to admit these patients keeps the inpatient unit "focused" on patients who stay more than two midnights. Managerial intervention, such as external collaborative coordination (ECC) improves performance of the DOU. To study this empirically, we use data from Delta Hospital to quantify the effect of the DOU transformation. We find a decrease in ED boarding time and total per visit average reimbursement for the two midnights or more patients admitted into the inpatient unit. Next, we find that the DOU transforming into a "variability-absorbing unit" worsened length of stay (LOS) compared to its prior performance. However, through the implementation of ECC, we demonstrate that the DOU has the potential to perform efficiently with LOS eventually decreasing. We conclude that the DOU can serve as a strategy for hospital managers seeking to provide a path forward for creating focused units in hospitals.

3 - Learning from Quality Signal to Improve Fairness and Accuracy: Evidence from the Hospital Readmissions Reduction Program

Mohamad Soltani, University of Alberta, Edmonton, AB, Canada, Bob Batt, Hessam Bavafa

Policymakers often employ quality indicators to evaluate the performance of an organization and to provide incentives for quality improvements. A potential concern, however, is that a specific quality indicator may be unfair to agents facing different circumstances. We explore the effects of the Hospital Readmissions Reduction Program on 30-day readmissions in over 2,000 US hospitals. While the policy does not differentiate between readmission reductions within the 30-day time window, our findings show that the extent of improvement depends on the timing of readmission. We attribute this variation to the time-dependent costs associated with reducing readmissions. This finding, combined with the inconsistent readmission distributions across hospitals, shows that HRRP is unfair to safety-net hospitals that treat low-income patients with limited access to care.

4 - Time Vs Testing: Physician Information Gathering Under Variable Conditions

David Rea, Lehigh University, Bethlehem, PA, United States, David Anderson, Margret Bjarnadottir

Using a comprehensive data set from a large emergency department, we provide empirical evidence that physician's gather information in different ways depending how much time they have. Their behavior at the beginning and end of shift depends on the initial and terminal workload conditions. This has implications for patient care and hospital flow.

5 - Responsible Clinician-AI-Collaboration Framework to Build Trustworthiness AI in Health Systems.

Elham Nasarian, Virginia Tech, Blacksburg, VA, United States, Kwok-Leung Tsui

This systematic review investigates the use of interpretable machine learning (IML) and explainable artificial intelligence (XAI) in healthcare, focusing on clinical decision support systems (CDSS). AI technologies like medical sensors, health trackers, telemedicine, mobile health (mHealth), large language models (LLMs), and digital care twins (DCTs) significantly influence clinical decision-making. However, the complexity of medical decisions requires that AI-generated results be interpretable and explainable to clinicians, as a lack of interpretability can lead to mistrust and reluctance to use AI.

The study aims to examine the processes, methods, applications, and challenges of IML and XAI in digital health interventions (DHIs). It categorizes the IML process into pre-processing, interpretable modeling, and post-processing phases to foster a comprehensive understanding of robust interpretability in CDSS. The goal is to enhance communication between AI systems and clinicians.

Using the PRISMA guideline and the PICO method, the authors searched databases like PubMed, Scopus, and Web of Science. After screening and quality assessment, 74 publications were selected for analysis, including reviews and experimental studies.

The paper highlights the need for an interpretability framework in CDSS across three levels and explores XAI applications within each tier. It discusses tools for evaluating XAI in health systems and presents a roadmap for implementing XAI in clinical settings. The conclusion emphasizes the importance of XAI models and acknowledges their limitations, suggesting future research directions to bridge existing gaps.

Supply Chain Finance and Risk Management

Invited Session

MSOM: iForm

Chair: Gangshu Cai, Santa Clara University, Santa Clara, CA, United States

Co-Chair: Tingyi Yu, Shanghai Jiao Tong University, Shanghai, N/A

1 - Managerial Incentives, Partial Ownership, and Channel Decentralization

Bangdong Zhi, University of Bristol, Bristol, United Kingdom, Jiong Sun

This study proposes a simple mechanism in which passive ownership in the downstream firm of a vertical relationship fosters economic incentives for downward decentralization. This mechanism works by motivating intrafirm managerial efforts aimed at enhancing productivity. The enhanced productivity results in higher profits for the firm when it sells its product indirectly compared to selling it directly. Interestingly, this scenario happens when the managerial effort cost falls within an intermediate range—not too low, yet not too high. Furthermore, this mechanism remains effective in incentivizing downward decentralization even in the presence of competition, albeit by strategically demotivating managerial efforts as a means to soften competition. Finally, we demonstrate the effectiveness of this mechanism in motivating upward decentralization provided that the firm retains channel power.

2 - A Decision Support System for Social Media Online Harassment Using Blockchain

Edwin (Yuchen) Wang, University of Massachusetts Boston, Boston, MA, United States, Nesreen El-Rayes, Adeela Gulzari

Online harassment has become an increasingly severe issue, particularly impacting minority communities. According to the Anti-Defamation League (2022), 35% of Americans have experienced harassment that specifically targets their ethnic, religious, or sexual identities. While blockchain technology (BCT) has been extensively applied in commercial settings, this paper focuses on its potential to enhance information management for decision making to combat online harassment. Existing literature on BCT proposes frameworks with comprehensive design features; however, these often exhibit overlapping functionalities. The proposed BCT framework allows users to maintain anonymity yet undergoes a singular verification process to ensure accountable behavior without compromising privacy. Furthermore, the framework utilizes smart contracts to automatically enforce community standards. Users consent to these regulations upon registration, with breaches triggering automatic penalties. This is facilitated by consensus mechanisms that allow the community to confirm harassment reports. Additionally, the framework introduces a blockchain-based reputation system, wherein positive interactions boost user reputation, whereas verified harassment incidents result in penalties. From a decision analysis perspective, this paper integrates a systematic evaluation of strategic choices within the blockchain model, optimizing the balance between anonymity and accountability.

Information Provision and Platforms

Invited Session

MSOM: Service Operations

Chair: Wenchang Zhang, Indiana University, Bloomington, IN, United States

1 - Optimal Information Provision and Competition among On-Demand Service Platforms

Wenchang Zhang, Indiana University, Bloomington, IN, United States

This research examines the transformative impact of on-demand service platforms on service delivery and consumption, emphasizing the strategic role of information policy design in managing platform dynamics, service provider decision-making, and consumer behavior. Through a model analyzing interactions across an infinite discrete-time horizon, the study investigates how platforms use information provision and commission policies to influence the market, particularly focusing on service quality. Analyses in both monopoly and competitive scenarios demonstrate that optimal information policies can simplify platform strategies and enhance competitive positioning by aligning service offerings with consumer expectations. In monopolistic markets, platforms can optimize their strategies using convex quadratic programming, while in competitive markets, platforms engage in a Stackelberg game to effectively manage information, thus optimizing provider participation and maximizing revenue. The findings highlight information policy as a crucial lever for platforms to navigate market complexities and secure a competitive advantage.

2 - Information Design of a Delegated Search

Yangge Xiao, Institute of Operations Research and Analytics , National University of Singapore, Singapore, Singapore, Zhenyu Hu, Shouqiang Wang

A principal delegates a sequential search with finite search opportunities to an agent, who bears the search cost and can terminate the search. The termination payoff is split between them according to a pre-specified proportion. Novel in our setting, only the principal can evaluate the search outcomes and design a policy to decide whether to continue the search and, if so, what information to provide to the agent after each search. Formulating the principal's problem by dynamic information design, we obtain a complete analytical characterization of her optimal information policy featuring a sequence of deterministic acceptance standards. The agent is recommended and voluntarily willing to continue the search if and only if the current termination payoff fails to meet the corresponding standard. For non-recallable search, the acceptance standards are descending and informative, underscoring the importance of timely feedback to the agent for non-recallable searches such as talent recruiting or housing hunting. In contrast, for recallable search, the optimal thresholds can become completely uninformative before a cutoff opportunity, where the agent searches in the dark. After the cutoff opportunity, the principal sets a sequence of descending acceptance standards by equating the agent's marginal cost and return from one additional search. For innovation-driven searches like pharmaceutical R&D, where search outcomes accumulate, our results suggest that search incentives are best motivated by an idealistic vision followed by realistic compromises. Overall, our findings show how costless information can be used as an incentive device in the absence of costly pecuniary instruments.

3 - Platform Endorsement and Customer Search: Evidence from Airbnb

Fanyin Zheng, Imperial College London, London, United Kingdom, Omar Besbes, Yuri Fonseca, Zhenyu Lai, Ralph Mastromonaco

We study the impact of platform endorsement on customer's search and purchase decisions on large two-sided service platforms. We model customer's behavior using a sequential search model and estimate the model using data from a large hospitality platform.

4 - Diverse Assortments in Online Recommendations

Mahsa Hosseini, University of Windsor, Windsor, ON, Canada, Opher Baron, Shreyas Sekar, Azarakhsh Malekian

This paper explores the business benefits of incorporating diverse content into recommendation systems, particularly in online marketplaces and platforms that rely on ranking algorithms. While such systems enhance short-term user engagement by promoting popular content, they inadvertently risk sacrificing diversity in recommendations, potentially jeopardizing the long-term health of the marketplace. This paper studies the interplay between consumer engagement and the phenomenon of "satiation" - a concept that examines how past consumption patterns influence consumers' future valuation of goods or services. Our research finds conditions under which a more diverse recommendation policy is optimal. Our findings show that optimal policy favors diversity during earlier periods. However, as time progresses, the optimal policy gravitates towards consistently offering products with the highest perceived value. This implies that a more diverse recommendation set is more desirable over extended time frames. Furthermore, we prove a satiation threshold policy, offering insights into determining optimal recommendations based on varying satiation levels at different periods. By incorporating diversity into our satiation model, we show that our optimal recommendation strategy not only promotes diversity and equity for consumers but also improves platform profitability.

Advances in Sustainable Supply Chains: Theory and Practice

Invited Session

MSOM: Supply Chain

Chair: Li Chen, Cornell University, Ithaca, NY, United States

Co-Chair: Shiqing Yao, Monash University, Melbourne, Australia

1 - Converting Counterfeiters in Emerging Markets to Authorized Suppliers

Burak Kazaz, Syracuse University, Syracuse, NY, United States, Liling LU, Xin Fang, Yini Gao

In recent years, “super fakes,” counterfeits of high quality, have become popular. Super fake manufacturers’ capability to produce high-quality products inspires a new anti-counterfeiting measure: converting counterfeiters to authorized suppliers. To study the effectiveness of this anti-counterfeiting measure, our paper employs a game-theoretic model to examine the interactions between a brand-name firm with its home supplier and a counterfeiter who produces high-quality counterfeits but can be potentially converted to an authorized overseas supplier. Our results show that a counterfeiter can be converted to an authorized overseas supplier by dual sourcing or single sourcing, if the difference in production costs between two suppliers or the penalty from law enforcement is high. Otherwise, the brand-name firm may have no incentive to convert the counterfeiter due to limited cost savings and due to the high wholesale price needed. However, the overseas supplier may still decide to enter the market to sell the counterfeit if the penalty from law enforcement is low. With a smaller difference in the perception of quality from the brand-name and counterfeit, we demonstrate that it is easier for the brand-name firm to deter the overseas supplier's counterfeiting by single sourcing from overseas supplier than by dual sourcing. We also examine the impact of this anti-counterfeiting measure on consumer and social surplus, and find that converting a counterfeiter to an authorized supplier may hurt consumer surplus and does not always improve social surplus.

2 - Consumer Status Signaling, Wealth Inequality and Non-deceptive Counterfeits

Shiqing Yao, Monash University, Melbourne, Australia, Li Chen, Zhen Lian

The rising of ecommerce has made it easy for consumers to search and purchase cheap non-deceptive counterfeits to send a “deceptive” status signal, posing a new challenge to the luxury (status product) industry. Motivated by these industry dynamics, we consider a market entry deterrence game between an incumbent status product firm and a non-deceptive counterfeiter who attempts to enter the market. Our analysis yields three main insights. First, without counterfeits, the firm is strictly better off from the heightened motive of consumer status signaling; however, such benefit would be neutralized by the potential counterfeiter entry. Second, the presence of counterfeits lowers the firm’s profit, but may induce the firm to raise its price. Third, the presence of counterfeits has mixed effects on social welfare; only when the wealth inequality among consumers is moderate, will social welfare increase. The findings from our analysis offer some initial guidelines to managers of luxury brands and e-commerce platforms in addressing the nondeceptive counterfeit problem.

3 - Impacts and Implications of Transformative Adaptation in Food Systems in Response to Severe Droughts

Bingyan Dai, Cornell University, Ithaca, NY, United States, Miguel Gomez, Harry Kaiser

Drought is one of the most significant drivers of food production shocks. It can impact various aspects of food systems, from crop yields, food distribution and market access to consumption. Transformative adaptation provides potential solutions by fundamentally altering agricultural systems in response to actual or expected climate shocks. However, there is limited understanding of how such transformation impacts economic and environmental performances of food systems, particularly in fresh vegetable supply chains. This research examines the impact of transformative adaptation on food systems in response to increased drought risks, focusing on fresh vegetables in the United States. Specifically, we utilize a production-transportation optimization model to examine the fresh broccoli supply chain in the eastern U.S. market, a centralized supply system vulnerable to drought-induced disruptions in California. We find that while increasing drought severity could substantially decrease broccoli shipments from its major supplier, California, the reallocation of production from California to the East Coast in response would modestly decrease total supply-chain costs (by 1.4% in the worst-case scenario) in the eastern market. Our results also identify optimal production locations, production volumes and product flows during two drought scenarios. The method and findings contribute insights applicable to other vulnerable fresh vegetable supply chains, and inform policymakers and food industry stakeholders on effective adaptation strategies for building resilient food systems amidst drought risks.

4 - Ultra-Fresh Fashion: Creating Demand with Freshness and Agility

Hau Lee, Stanford University, Stanford, CA, United States, Li Chen, Shiqing Yao

Using agile supply chains, fast fashion companies have been viewed as best-practice examples in industries. Prior research has focused on how agility can equip such companies with strong “sense and respond” capabilities to identify and fulfill unpredictable customer demands. There is another powerful dimension of agility—the ability to create new products frequently—that has enabled recent market success of companies such as Shein. We seek to model this dimension of agility as an operational strategy for demand creation. Our model enables us to explore the impacts through the lens of profit to the firm, consumer surplus, and environmental performances.

Operational Insights into Innovation, Economics, and Digitalization

Invited Session

MSOM:Technology, Innovation, and Entrepreneurship

Chair: Xiaojin Liu, Virginia Commonwealth University, Richmond, VA, United States

Co-Chair: Pankaj Kumar, Virginia Tech, Blacksburg, VA, United States

1 - Operations Safety Innovations and Applications: the Entrepreneurial Journey of Immune Material Imu+

Chris K. Y. Lo, The Hong Kong Polytechnic University, PolyU Business School (PBS), Hong Kong, Hong Kong, Chi Wai Kan

The ongoing challenges of infectious diseases, highlighted during the COVID-19 pandemic, emphasize the crucial need for innovative safety solutions. This presentation outlines the entrepreneur journey of Immune Material Limited (IMU+). This venture was co-founded by Prof. Chris K. Y. Lo, who conducted years of research in operational safety risks, health and safety violations, safety management systems, and supply chain risks into the creation of advanced antimicrobial material technologies. The technology can potentially control health hazards in health care and service operations. Utilizing a risk-based innovation framework, Prof. Lo pioneered these technologies to address critical public health safety needs across various high-contact environments in Hong Kong and China, creating values from identifying and mitigating operational risks.

IMU+'s antimicrobial materials have been adopted in over 300 Hong Kong facilities, including public hospitals, hotels, schools, and shopping malls. It can dramatically reduce pathogen transmission and enhance operational safety with less manpower. This technology has successfully secured substantial private and public funding and market adoption, demonstrating its effectiveness and broad applicability in healthcare, schools, and other public infrastructures. This case study showcases how the strategic application of a risk-based innovation framework can improve operations safety and efficiency and set new operations standards for public health and safety.

2 - Mandatory Environmental Disclosure and Environmental Performance

Jie Lian, The University of Oklahoma, Norman, OK, United States, Yan Dong, Keith Skowronski, Sining Song

Regulators frequently use mandatory environmental disclosure regulations to encourage corporate environmental improvements. This research explores the broader implications of such mandates, examining how they may lead firms to reallocate resources and make technological trade-off decisions across different environmental domains. Our findings illuminate the multidimensional impacts of these regulations, offering insights into their effectiveness and potential unintended consequences.

3 - Routines, Disruptions and Organizational Adaptation

Rob Glew, McGill University (Desautels), Montréal, QC, Canada, Jeremy Hutchison-Krupat

It is well-established that routines and norms help to drive organizational efficiency. It is also well-established that organizations need to adapt. The need to adapt becomes even more salient when a disruption has occurred. However, disruptions do not necessarily require organizational norms and routines to change; organizations that abandon valuable routines unnecessarily will underperform. In this paper we build a model to study how organizations adapt to disruptions and characterize an organization’s propensity to adapt under different conditions and the likelihood that an organization adapts unecessarily.

4 - How Do Managerial and Operational Governance Impact Firm Innovation?

Tianxiu Zhang, University of Science and Technology of China, Hefei, China, People's Republic of, Zhijian Cui, Xiaojin Liu

Corporate governance can be divided into two distinct types: managerial governance and operational governance. Scholars of managerial governance focus on addressing agency problems and aim to regulate the decision-making process of senior managers and control the allocation of a firm's resources. Conversely, scholars of operational governance concentrate on how firms use process management techniques (such as TQM, Six Sigma, and other quality controls) to regulate operational routines and strategy implementation, thereby improving operational efficiency and innovation. The effectiveness of governance relies on the integration and coordination of these different levels. In this study, we empirically investigate whether and how these two types of governance affect firms' innovation performance, considering both exploitative and exploratory innovation. To do this, we develop proxies for corporate governance and operational governance using a panel sample of Chinese listed companies from 2007 to 2020, leveraging governance indices and China Quality Award acceptances and awards. Our analysis incorporates the xgboost machine learning model as a part of our empirical strategy. The results suggest that both managerial and operational governance are positively associated with exploitative innovation; however, operational governance has a detrimental effect on exploratory innovation. Our findings also highlight the significant substitution and/or complementary effects between managerial and operational governance when it comes to different types of innovation.

5 - An Empirical Study of Organic Product Spillover in Assortment

Zhihao Zhang, University of Missouri - Kansas City, Kansas City, MO, United States, Yan Dong, Sriram Venkataraman, Jayanth Jayaram

We study how introducing and increasing organic products affect conventional product assortment and revenue at retail stores. We address this research question by using proprietary scanner data with respect to organic and conventional yogurt sales spanning four years.

Chair: Shima Azizi, INFICON, Westbury, NY, United States

1 - Optimizing Foster Care Visitation Scheduling

Shima Azizi, INFICON, Westbury, NY, United States, Andrew Trapp, Erhun Kundakcioglu, Caroline Johnston

Child welfare agencies charged with ensuring foster children regularly visit biological parents can be challenged due to fixed workforce levels and fluctuating caseloads. We introduce the Foster Care Visitation Scheduling Problem to assign, schedule, and route workers to foster children. We develop a two-phased network-based optimization approach that 1) preprocesses and pre-computes a time-space network structure, and 2) solves a novel large-scale integer optimization problem over this network. We incorporate our approach into an interface, assists foster care organizations to better operationalize their resources, and improves the consistency of visits and so quality of life for foster children. We discuss computational experiments on a variety of instances inspired by real data from New York State that reveal encouraging computational performance.

2 - Disaster Relief Inventory Simulation: Managing Resources in Humanitarian Camps

Erhun Kundakcioglu, Ozyegin University, Istanbul, Turkey, Cem Yarkin Yildiz

Disasters often displace populations into temporary settlements, creating complex challenges in post-disaster inventory management. While existing research primarily focuses on isolated aspects, such as funding variability, there remains a significant gap in adopting a holistic approach. This lack of comprehensive understanding limits the validation and applicability of proposed policies to real-world scenarios.

To address these limitations, this study introduces an extensive, event-based, open-source simulation framework tailored for the unique aspects of humanitarian inventory management. The simulation framework models the problem from the perspective of a central decision-maker, responsible for decisions on replenishment and transshipment, aiming to satisfy the demands of multi-camps for multi-items. It integrates a full spectrum of dynamics—including the perishability of items, demand, migration, funding with earmarked and in-kind options, and supply disruptions—without reliance on Markovian assumptions.

All events are generated based on stochastic properties with any distribution and parameters. The framework's engine manages event dependencies, ensuring that any state change triggers necessary events to regenerate to satisfy non-Markovian properties. Users can configure their settings and implement their policies with ease, and detailed performance indicators for simulations are provided. This enables realistic simulations of complex humanitarian scenarios and facilitates thorough policy evaluations.

The framework not only advances theoretical research but also equips practitioners with a robust tool for simulating diverse scenarios, thereby enhancing practical decision-making in disaster response.

3 - Optimizing Surplus Medicine Donations: Corporate Social Responsibility and Supply Chain Coordination

Telesilla Kotsi, The Ohio State University, Columbus, OH, United States, Soh Hyun Chu, James Hill

Pharmaceutical firms are essential in improving health through medicine donation programs that help people in the U.S. and around the world. This study looks at donations of prescription drugs for chronic conditions in the U.S., where the high cost of medications can be challenging for many. Brand-name prescription drugs cost an average of $334 per month, compared to $58 for generics, making affordability a problem for many, especially seniors and the uninsured. We examine the "push" supply chain model used for surplus medicine donations, focusing on pharmaceutical firms since they determine the quantities of donated drugs that flow through the rest of the supply chain. Our extensive discussions with many firms revealed that effective collaboration between Corporate Social Responsibility and Supply Chain teams is crucial for managing these donations and ensuring that medicines with limited shelf lives (6-18 months) reach those in need. We use a game-theoretical model and lab experiments to understand how supply chain managers make decisions and identify incentives that align their choices with the firm's social sustainability goals. This method explains how personal traits influence donation decisions and offers insights into improving supply chain strategies for both economic and social sustainability. The study emphasizes the importance of coordinated efforts to address the medication needs of vulnerable populations and ensure access to medicines for the most vulnerable.

4 - Optimization Models for 15 Minute Cities

Farima Salamian, University of Iowa, Iowa City, IA, United States, Ann Campbell

The 15 Minute City(15MC) framework aims to enhance urban livability by ensuring access to daily needs for residents, such as schools, parks, grocery stores, and medical offices, within a fifteen-minute walk. The 15MC concept promotes sustainability and improves quality of life. Our study advances the implementation of the 15MC concept by modeling the selection of proposed locations for various key amenities for city planners. Our research employs mixed integer linear programming to optimize the location of new amenities, considering different objective functions that reflect maximizing accessibility. We test our models using data from Iowa City, including walking distances and the locations of current amenities. Our results provide insights regarding the implications of different objective functions and suggest several directions for future research.

Empirical Research in Healthcare Analytics

Invited Session

Health Applications Society

Chair: Jong Myeong Lim, Miami Herbert Business School, Coral Gables, FL, United States

1 - The Unintended Costs of Congestion Mitigation Through Financial Barriers: Empirical Evidence from Online Health Communities

Jie Chen, Arizona State University, Tempe, AZ, United States, Kan Xu, Tongxin Zhou

While information technology fosters greater and equal accesses to consumers by creating a decentralized market, it also raises challenges due to market congestion where high screening costs suppliers have to pay to enhance matching quality. This paper examines the use of financial barriers to address market congestion in Online Health Communities (OHCs), a setting where congestion issues have especially significant implications for societal welfare and health equity. By leveraging a natural experiment within the POZ community, we provide causal evidence of both the intended and unintended effects of financial barriers implementation on user participation. Our findings show that while financial barriers reduced inquiries by approximately 17.5 percentage points in the treated forum, they also led to significant unintended consequences. Specifically, there was a 15.8 percentage point decrease in the likelihood of users asking any questions in the treated forum, accompanied by a 5.8 percentage point drop in demand and a 6.1 percentage point decrease in posting likelihood in untreated forums. Further analysis reveals that these negative spillovers are consistent across users with varying tenures and usage frequencies. Additionally, results for users' behavioral responses after the policy announcement show that users form questions with more effort and negative emotions. Our study contributes to the congestion mitigation literature by highlighting crucial negative spillovers associated with financial barriers in OHCs. Contrary to existing research suggesting that minimal costs can improve matching quality, our findings underscore the complexities and potential drawbacks of implementing financial barriers, challenging the notion that they universally enhance platform efficiency.

2 - How Vertical Integration Effect the Efficiency of the Hospitals in the U.S

Jingyun Su, Miami Herbert Business School, Coral Gables, FL, United States, Jong Myeong Lim

This study investigates the effects of vertical integration on the efficiency of hospitals within the United States. Using Data Envelopment Analysis (DEA), we compute efficiency scores for a diverse set of hospitals to determine their operational effectiveness relative to the best-performing entities. Further, we employ regression analysis to explore the relationship between vertical integration and efficiency scores, controlling for various hospital characteristics such as size, and location. Preliminary findings suggest that vertical integration may contribute to enhanced operational efficiency, potentially driven by improved resource allocation and streamlined management practices. This analysis not only sheds light on the operational dynamics of vertically integrated hospitals but also informs policy discussions on healthcare management and organizational structure. The implications of these findings for healthcare policy and management are significant, suggesting pathways for enhancing hospital performance through structural adjustments.

3 - How Recreational Cannabis Legalization Impacts Hospital Operations

Max Yakovlev, Kellogg School of Management, Northwestern University, Chicago, IL, United States, Maria Ibanez

Cannabis is the most common federally illegal drug in the US. The federal stance contrasts with the growing trend of recreational cannabis legalization (RCL) across states. A vital implementation question is how legalization affects hospitals. We propose that as cannabis spreads throughout society, its effects permeate healthcare systems, particularly inpatient wards. Based on medical research, patients using or exposed to cannabis will suffer from challenging symptoms, including aggravated chronic conditions, psychosis, agitation, and intractable vomiting. These peculiar symptoms will increase workload complexity, restrict the staff time and hospital capital resources available to other patients, and cause disturbance. To unpack these effects, we study how RCL influences hospital operations across three dimensions: throughput times (length of stay), experiential quality of care, and medical providers' behaviors. Using a difference-in-differences approach, we find that hospitals speed up care, with legalization shortening inpatient lengths of stay by 2.6%. We attribute this phenomenon to cannabis generating workload for hospital staff that reduces the resources (including staff time) available to other patients. Second, we find adverse effects on experiential quality of care: Patient satisfaction with hospital noise levels at night, hospital staff helpfulness, and information received about home recovery significantly decreases by 5-10%, resulting in potential financial damages for hospitals. Third, disciplinary actions against doctors, physician assistants, and nurses increase by 34%. Supplementary analyses investigate admissions, cannabis-associated procedures (lung ventilation), hospital's colocation with recreational cannabis stores, and familiarity with cannabis patients.

4 - Telehealth in Acute Care: Pay Parity and Patient Access

Ozden Cakici, American University, Washington, DC, United States, Alex Mills

Several US states have recently adopted telehealth pay-parity policies. Such policies require that payers reimburse healthcare providers for telehealth services at the same rate as office visits. But health policy researchers have stated that telehealth may not be as effective as an office visit for acute care. Specifically, telehealth is associated with increased probability of a subsequent office visit (a "duplicate visit"). We examine whether
telehealth pay-parity policies are effective at improving access to acute care, and under what conditions. Using a three-stage game theoretic model, we study the impact of telehealth pay parity. Patients arrive and choose between telehealth and office visits according to an equilibrium queueing network. We find structural results for the equilibria under both homogeneous and heterogeneous illness types, and we fully characterize the equilibria in closed-form for homogeneous patients. When the duplicate visit rate is moderate, pay parity leads providers to allocate too much capacity to telehealth, resulting in lower overall patient access than could be otherwise achieved. We characterize a reimbursement level that avoids this misalignment and maximizes patient access, which is less than parity. On the other hand, copayments cannot align the system. In the fee-for-service environment that is common in the US for acute care, duplicate visits resulting from telehealth lead to an incentive alignment problem because they generate extra work and provider revenue, without any corresponding increase in patient access. Legislating pay parity for telehealth can lead to providers committing more capacity to telehealth, which may not always be good.

1 - Bridging Learning and Decision Making

Dylan Foster, Microsoft Research, New York, NY, United States

This tutorial will give an overview of the theoretical foundations of interactive decision making (high-dimensional/contextual bandits, reinforcement learning, and beyond), a promising paradigm for developing AI systems capable of intelligently exploring unknown environments and making decisions in a data-driven fashion. The tutorial will focus on connections and parallels between supervised learning/estimation and decision making, and will build on recent research which provides (i) sample complexity measures for interactive decision making that are necessary and sufficient for sample-efficient learning, and (ii) unified algorithm design principles that achieve optimal sample complexity. Using this unified approach as a foundation, the main aim of the tutorial will be to give a bird's-eye view of the statistical landscape of reinforcement learning and decision (e.g., understanding what modeling assumptions lead to sample-efficient algorithms). Topics covered will range from basic challenges and solutions (exploration in tabular reinforcement learning, contextual bandits) to the current frontier of understanding. We will also highlight practical algorithms.

Under the Roof Process Design and Optimization

Invited Session

The Practice Section of INFORMS

Chair: Herm Li, Amazon, Sammamish, United States

Co-Chair: Herm Li, Amazon, Sammamish, United States

1 - Amazon Logistics Labor Planning Platform and Its Eco System

Herm Li, Amazon, Bellevue, WA, United States, John Jiang

Amazon Logistics (AMZL) manages a network of delivery stations (DS) that are essential for its last-mile delivery services. Each station functions as a crucial hub, receiving packages from fulfillment centers, sorting them, and dispatching them to their final destinations. The efficiency of these operations relies significantly on the effective planning and utilization of associates working at the delivery stations. This presentation covers the design and implementation of a labor planning platform that optimizes various labor factors, including hiring, release, labor share, voluntary time off, and voluntary extra time, ensuring demand is met while minimizing labor costs. Over the years, modular extensions of the basic labor planning model have been developed, creating an ecosystem that addresses multiple aspects of labor planning. This includes the Mandatory Extra Time (MET) Estimator, Hourly Internal Transfer System (HITS), and Associate Schedule Generator (ASG). This presentation will also introduce these modules and demonstrate how the labor planning eco system coordinates AMZL's labor planning and influences operations.

2 - Experimental Design and Analysis in Supply Chain Operations

Brayan Ortiz, Amazon.com, Bothell, WA, United States, Andrew Bruce

Technology innovations are driving changes to fulfillment networks and supply chain operations. Sensors combined with sophisticated computer vision and machine learning algorithms offer the promise of increased automation and quality control. The technology, however, comes with significant cost and real-world performance often doesn't match offline controlled studies. Before making a significant investment, companies will conduct pilot studies to assess the benefit of the innovation in actual operations.

In contrast to traditional industrial experimentation (see "Statistics for Experimenters", Box, Hunter, and Hunter, 1978), field studies in supply chains share more in common with clinical trials in medical research. Pilot studies at Amazon typically involve multiple phases, with the initial phases focusing on safety and reliability and the subsequent studies designed to determine efficacy. Since pilots are conducted in operational settings, confounding factors can impact the outcomes. In particular, a main source of variation is often due to differences between individuals performance. It is important to design the study with sufficient statistical power to ensure reasonable confidence in the outcomes.

Amazon is developing a framework to conduct pilot studies addressing the challenges with experimentation in the field. This framework provides technical subject matter experts and product managers a guideline to design a statistically robust pilot study, from definition of the hypotheses to final analysis and outcome determination. Drawing from actual pilot studies at Amazon, we review key concepts in this framework, such as randomization and sample size determination, along with common pitfalls that experimenters often face in the field.

3 - A General Framework for Scheduling Under-the-Roof Processes in Amazon

Nikos Lappas, Amazon, Seattle, WA, United States

At Amazon, we harness the latest technological advancements and experiment with newly discovered capabilities, often resulting in diverse facility configurations, equipment types, and designs. Nevertheless, each facility must operate at maximum potential, which requires optimal resource scheduling to meet customer demand, on-time.

In this talk we will discuss how we leveraged the generality of the Resource-Task-Network (RTN) representation to adapt seamlessly to various facility floorplans & configurations, the importance of time representation and how the existence of a State definition unlocks multiple avenues for optimizing the schedule. We will also demonstrate how we applied concepts from Model Predictive Control (MPC) to develop a near-real-time adaptive scheduling approach, empowering facility managers to navigate the challenges and uncertainties of daily operations.

4 - From Science to Product: a Case Study on Labor Planning Platform of Amazon Logistics

Zhengqian jiang, Amazon, Santa Clara, CA, United States, Herm Li

Transforming science into a practical product is a complex journey. This talk will focus on how we implemented scientific models into products now utilized daily by Amazon's most critical logistics networks, aiding users in making crucial labor planning decisions. We will discuss three key aspects: selection of the optimal solution approach, ensuring the accuracy and reliability of data through cleansing and validation, and building user-friendly interface with effective data visualization. Through these aspects, we aim to address several challenges, including: the rapidly changing nature of labor planning operations, earning user trust, and demystifying the optimization model for users.

Interventions for Patients with Complex Medical and Social Needs

Invited Session

TutORial

Chair: Muge Capan, University of Massachusetts Amherst, Amherst, MA, United States

1 - Interventions for Patients with Complex Medical and Social Needs

Hari Balasubramanian, University of Massachusetts, Amherst, Amherst, MA, United States, Sindhoora Prakash, Ali Jafari, Arjun Mohan, Chaitra Gopalappa

Patients with multiple chronic conditions and social needs represent a small percentage of the population but have a disproportionate impact on healthcare costs and utilization. Organizations around the United States have created programs – often referred to as complex care interventions – to improve the health and well-being of such patients and reduce avoidable hospital and emergency department use. In this tutorial, we focus on two emerging themes in the field: (1) identifying clinically meaningful subgroups in complex care populations through unsupervised learning methods; and (2) describing the key operational features of interventions with an emphasis on staffing needs and the impact on patient outcomes. The material presented in this tutorial draws on the research of the Healthcare Operations Research Lab at the University of Massachusetts, Amherst, and its collaborating partners. To illustrate these themes and contextualize the details of complex care delivery, we use a range of patient-level examples, visualizations, descriptive summaries, case studies, and results from the clinical literature.

Social Media Insights and Innovations: Unveiling New Trends and Perspectives

Invited Session

Information Systems

Chair: Hongyi Zhu, The University of Texas at San Antonio, San Antonio, TX, United States

1 - Assessing Public Sentiment on AI-Generated Art Across the United States Using Deep Learning

Lan Sang, University of Colorado Boulder, Boulder, CO, United States, David Dobolyi, Kai Larsen

Art is crucial in conveying the rich tapestry of human feelings and societal values. However, the recent development of high-quality AI-generated art has created controversy in terms of how this new form of art should be perceived and valued. Understanding the public's attitudes towards AI-generated art can help AI companies improve products and guide the government's policy regarding the generative AI industry. This study uses social media data (i.e., Twitter/X) to analyze sentiment toward AI-generated artwork across the United States. Analyses of these data show a generally negative attitude towards AI art in most states. The findings also indicate that AI and art market maturity and urbanization rate positively impact public sentiment on AI-generated art, whereas median household income is negatively correlated with attitudes toward AI-generated artwork. Collectively, these findings highlight the importance of building mature AI and art markets.

2 - SKNews: A Design Framework for Skill-oriented Education Program Rankings

Yueqing Li, University of Arizona, Tucson, AZ, United States, Yong Ge, Shuojia Guo

Education program rankings are pivotal in shaping the reputation of higher education institutions and guiding academic choices for students and parents. While the labor market is currently experiencing significant transformations, students try to seek programs that enhance their competitiveness in the job market, expecting training that not only improves their skill sets but also aligns with employer demands. However, traditional rankings often fall short in providing the detailed insights necessary to meet these specialized needs. To bridge this gap, we introduce a deep learning framework that delivers personalized, reasonable, and demand-driven rankings of education programs. Our framework comprises three core modules: (1) Skill Extractor, which employs the Wide and Deep model to distill skill-related keywords from an extensive corpus; (2) CookieLM, a hybrid model that enhances a pre-trained language model with factual knowledge and domain-specific expertise to generate skill representations; and (3) ERIQ, a query-based ranking method that provides customized educational program rankings according to individual user requirements. The empirical analyses demonstrate our framework's superior effectiveness over existing techniques and offer insightful, user-specific evaluations across different scenarios.

3 - Evaluating Social Media Surveillance Risks: A Multimodal Large Language Model Approach to Linking Sensitive and Identifiable User Accounts

Fangyu Lin, The University of Texas at San Antonio, San Antonio, TX, United States

Social media surveillance poses a significant societal issue, with many users unaware of the risks associated with linking social media accounts that share sensitive information to identifiable ones. In this study, aiming to evaluate the likelihood of connecting accounts across social media platforms and increase user awareness of potential surveillance risks, we design a novel Cross-platform Social Media Surveillance Risk Assessment Framework. Central to this framework is X-FuseER, a multimodal Large Language Model (LLM)-based User Identity Linkage (UIL) model with two novel features: (1) Intermodal Attention that identifies and emphasizes modality-specific features critical for cross-modality relevance and (2) Hybrid Cross-modal Contrastive Loss that optimizes the similarity of embeddings within and across modalities for matched and unmatched record pairs. We systematically evaluated X-FuseER against benchmark ER and multimodal models on LinkSocial and self-developed UIL datasets. X-FuseER consistently outperformed benchmark models by statistically significant margins. To demonstrate the proposed framework's practical utility, we executed a case study to evaluate an anonymized Reddit user's social media surveillance risk. The findings reveal that the user's anonymized Reddit account, where she shares her explicit photos, can be linked to an identifiable Instagram profile. The proposed framework has important implications for various stakeholders, such as protest participants. In addition, we discuss several design principles of X-FuseER that can help guide future design science-based fraud detection, social media analysis, forensics and criminal investigations research.

4 - A Comparative Analysis of Pure and Shoppable Ads on Social Media Platforms

Jiayu Fan, Temple University, Philadelphia, PA, United States

Social media platforms are increasingly adopting monetization strategies that integrate e-commerce functionalities. Platforms like TikTok and Instagram have pioneered the use of shoppable ads, which can generate both ad revenue and commission revenue. For social media platforms, it is unclear whether shoppable ads are more profitable than pure ads. Furthermore, the ad pricing strategy and ad amounts can be different for pure ads and shoppable ads, which may be affected by the commission rate. However, there is no existing study that can answer these questions. Hence, our study fills this gap by providing a framework to compare the profit, ad price, and ad amount for pure ads and shoppable ads. Our findings suggest that shoppable ads may generate higher profit than pure ads even if users dislike shoppable ads more than pure ads and the product value sold through shoppable ads is relatively low. In addition, if users dislike pure ads more than shoppable ads: 1) the platform may still price pure ads at a lower rate compared to shoppable ads when the market size of pure ads is larger than that of shoppable ads; 2) the platform may put more pure ads than shoppable ads, interestingly, this may happen when users' aversion to pure ads is greater than a given threshold meanwhile product value is relatively high. This understanding provides actionable insights for platforms looking to optimize their advertising revenue and commission revenue.

Social Media Analytics

Chair: Sridhar Nerur, University of Texas-Arlington, Arlington , TX, United States

Co-Chair: Sagar Mahesh Badve, The University Of Texas At Arlington, Bedford, TX

1 - Is More Always Better? A Deep Dive into Twitch Streamer Success

Roopa Ramesh Desai, The University of Texas at Arlington, Arlington, TX, United States, Kay-Yut Chen, Jennifer Zhang

Video games have had a profound impact on entertainment and leisure activities since their inception in the 1950s. Technological advancements and the availability of various devices and platforms have increased video games' popularity across all age groups. Social media platforms like Twitch.tv, YouTube, and Facebook have led to the rise of video game live streaming as a profession, especially among young people. With the growth of the video game industry, live streaming has become a profitable profession for many streamers who focus on maximizing their revenue through various means. A video game streamer's effort level significantly impacts their revenue, partnership/sponsorship opportunities and audience growth. Thus, this paper investigates the relationship between streaming effort, streamer quality, and additional factors in the context of Twitch streaming, employing game theory as a theoretical background to further support the findings. We begin by examining how streamer effort, measured by hours streamed, is influenced by perceived streamer quality. A market share model is developed to explore the influence of streamer quality fluctuations on streaming hours and subsequent market reach. Using total subscribers as an initial proxy for quality, we uncover an unexpected concave relationship, suggesting that beyond a certain threshold, increased quality may lead to diminishing returns in the streaming effort. To further explore the components of streamer quality, we introduce additional variables such as age, involvement in esports, and gender. Our analysis explores various aspects that could potentially define streamer quality, shedding light on the complex dynamics of streamer success on Twitch.

2 - Illuminating the Shadows: Leveraging OSINT and AI for Enhanced Analysis of Dark Web Activities

sreehas Gopinathan, University of Texas Arlington, Arlington, TX, United States, Sridhar Nerur

The dark web, a secluded fraction of the internet often associated with anonymity and illicit activities, presents significant challenges for cybersecurity professionals and law enforcement agencies. The traditional approaches to monitoring and analyzing these hidden services are often hampered by the inherent complexities of the dark web's architecture and the vast amount of unstructured data it contains. This presentation proposes a novel framework that harnesses the power of Open Source Intelligence (OSINT) and Artificial Intelligence (AI) to enhance the visibility and understanding of dark web ecosystems.

Our approach utilizes advanced AI techniques, including machine learning algorithms and natural language processing, to systematically collect and analyze data from the dark web. By integrating OSINT tools, our method not only identifies and aggregates data from publicly accessible dark web sources but also intelligently analyzes content to uncover patterns, trends, and actionable intelligence. This framework is designed to provide a comprehensive analysis of dark web marketplaces, forums, and other platforms, facilitating the detection of illegal activities, such as drug trafficking, weapon sales, and cyber threats.

3 - AI-Assisted Distributed Cognition in Data Science

Kaiyue Liu, University of Texas at Arlington, Arlington, TX, United States, Jayarajan Samuel, Sridhar Nerur

With the proliferation of generative AI, the debate about whether AI functions merely as a tool or as a collaborative partner continues. Although AI's capabilities recently improved significantly to solve increasingly complex problems, empirical examination of how AI collaboration impact task performance remains limited. Our study applies Distributed Cognition Theory (DCT) to examine the interaction between an artificial cognition system (ChatGPT) and an external structural cognition system (mind maps) on task performance, cognitive load, job satisfaction, and self-efficacy. Utilizing an experimental design, this research aims to peek into the mechanisms through which AI affects task performance. We anticipate demonstrating that AI usage improves performance and decreases cognitive load, with these effects significantly moderated by external cognition systems. This study aims to fill a literature gap in the empirical examination of AI's impact on productivity and cognitive dynamics. The findings are expected to challenge AI's role as merely auxiliary tools, proposing that effective AI integration enhances both individual and collaborative cognitive functions. This may provide valuable insights for practitioners on optimizing AI use and pave the way for future research into the cognitive dynamics of human-AI collaboration, potentially reshaping how AI is implemented in professional settings.

4 - Impact of Generative AI on the Value of Peer Produced Content - Evidence from Wikipedia

Srikar Velichety, University of Memphis, Memphis, TN, United States

Generative AI (GenAI) technologies such as ChatGPT, Gemini, Alpha Code, CoPilot, Diffusion, Dall-E, etc., have made headlines since late 2022 due to their ability to easily generate content, from text to multimedia, in various domains. These technologies are improving the productivity of workers in multiple industries, especially those that are based in the knowledge economy. Moreover, they are consistently reducing factual-content errors and making information easily accessible through multiple information formats including audio, images, and text. Large language models are at the core of this GenAI revolution. They are trained using publicly available information from platforms such as Wikipedia, Stack Overflow, GitHub, etc. Although GenAI tools have made information search more efficient, recent research shows they are undermining and degrading engagement with online question and answer (Q&A)-based knowledge communities like Stack Overflow and Reddit. We extend this stream of research by examining the impact of GenAI on the market value and quality of peer-produced content using the world's largest open-source knowledge repository i.e., Wikipedia, which is different from Q&A-based communities mentioned above. We follow an approach like Burtch et al. (2023) and extend empirical analyses focusing on ChatGPT's release on November 30, 2022. We collect monthly Wikipedia page views and content (text) data for six months before and after the release date as the treatment group. We then collect data for same months a year before as the control group. The difference-in-difference (DID) analyses demonstrate significant decrease in Wikipedia page views (market value) after the release of ChatGPT.

Emerging Problems in Platform Operations

Invited Session

Artificial Intelligence

Chair: Ruohan Zhan, The Hong Kong University of Science and Technology, Clear Water Bay, N/A, Hong Kong

Co-Chair: Zhengyuan Zhou, Stern School of Business, New York University, New York, NY, United States

1 - Assessing External Validity of A/B Tests Under Effect Ordering

Ariel Boyarsky, Columbia University, New York, NY, United States, Hongseok Namkoong, Naoki Egami

Assessing the external validity of experimental results is a pervasive challenge in the experimental design literature, threatening the generalizability of internally-valid findings. External validity issues, well-documented in the A/B testing and distribution shift literature, are prevalent in clinical trials, online platforms, and social science experiments. While specifying a target population is a common strategy to address these concerns, practitioners often lack access to the complete target distribution. To bridge this gap, we propose an optimization-based framework enabling practitioners to define target distributions at the site-level. To address common collinearity issues inherent in site-level experiments, we utilize the effect ordering principle, in which direct effects outweigh interaction terms, to obtain partially identified sets for the treatment effect on the target population. Our methodology employs a hierarchical semiparametric model, where potential outcomes are influenced by direct and indirect nuisance parameters estimated from individual-level covariates using machine learning techniques. We introduce an augmented debiased estimator and cross-fitting algorithm, and demonstrate that it achieves central limit behavior. Moreover, our optimization procedure facilitates flexible implementation of variations of the effect-ordering principle, tailored to specific domains. To illustrate the effectiveness of our approach, we apply it to the micro-credit expansion experimental dataset from Meager (2019) and survey experiment data from \Naumann (2018).

2 - Llm and Experimentation

Zikun Ye, University of Washington, Seattle, WA, United States, Hema Yoganarasimhan, Yufeng Zheng

We integrate LLM-based prediction models with bandit algorithms to enhance news headline selection. Our methodology encompasses several strategies, including in-context learning, GPT embedding-based classification, and LLM fine-tuning. These approaches achieve over 80% accuracy in headline selection. By pairing the prediction model with the 2UCB algorithm, we facilitate effective online decision-makingsignificantly boosts revenue.

3 - Adaptive Instrument Design for Indirect Experiments

Vasilis Syrgkanis, Stanford University, Stanford, CA, United States, Yash Chandak, Shiv Shankar, Emma Brunskill

Indirect experiments provide a valuable framework for estimating treatment effects in situations where conducting randomized control trials (RCTs) is impractical or unethical. Unlike RCTs, indirect experiments estimate treatment effects by leveraging (conditional) instrumental variables, enabling estimation through encouragement and recommendation rather than strict treatment assignment. However, the sample efficiency of such estimators depends not only on the inherent variability in outcomes but also on the varying compliance levels of users with the instrumental variables and the choice of estimator being used, especially when dealing with numerous instrumental variables. While adaptive experiment design has a rich literature for direct experiments, in this paper we take the initial steps towards enhancing sample efficiency for indirect experiments by adaptively designing a data collection policy over instrumental variables. Our main contribution is a practical computational procedure that utilizes influence functions to search for an optimal data collection policy, minimizing the mean-squared error of the desired (non-linear) estimator. Through experiments conducted in various domains inspired by real-world applications, we showcase how our method can significantly improve the sample efficiency of indirect experiments.

4 - A Simple Formulation to Causal Clustering

Jinglong Zhao, Boston University, Boston, MA, United States

We consider a network interference problem, in which an experimenter conducts experiments over a single connected network. We consider the setting where the network is known and the exposure mapping, which describes how one unit's treatment assignment impacts another's potential outcomes, is well-specified. In this setting, causal clustering refers to conducting clustered experiments to achieve accurate estimation and inference. This paper proposes a simple robust optimization approach to causal clustering, which also synthesizes several existing results in the literature.

AI, Operations, and Platforms

Invited Session

Information Systems

Chair: Manmohan Aseri, Robert H. Smith School of Business at University of Maryland, Pittsburgh, PA, United States

1 - Platform Intermediation and Firm Investments

Vaarun Vijairaghavan, University of Calgary, Calgary, AB, Canada, Barrie Nault

We study how firm investments can be coordinated in a setting where firms offering two kinds of complementary technology operate on a platform that intermediates the relationship between firms. We model this coordination problem by abstracting from the case of Demand Response (DR) on the Smart Grid, where the platform enables interoperability between two distinct but complementary types of DR products, firms invest to develop DR products, customers purchase DR products from firms, and a policymaker favors greater customer adoption of DR. In our setting, demand generated by a firm depends on own investments and prices which they choose, as well as cross-side investments and prices by other firms. The platform sets fees and transfers between firms. Among other results, we find that the platform and the policymaker goals are aligned as far as the transfers are concerned: the platform's choice of transfer coordinates firm prices and investments, and maximizes aggregate platform demand.

2 - Shipping Consolidation Using AI for Different Delivery Deadlines and Modes

VARUN GUPTA, University of North Georgia, Dahlonega, GA, United States

Shipping costs are a major cost to a company and many logistics service providers (e.g.; 3PL providers) promise significant savings on shipping costs to their customers. We explore how 3PL providers can utilize historical shipping data from their customers to implement shipping consolidation in real-time using advanced AI methodologies.

3 - Social Learning and Content Quality Under Polarization

Bharadwaj Kadiyala, University of Utah, Salt Lake City, UT, United States, Dongwook Shin

We study how polarization influences content consumption and production on digital platforms that monetize consumer engagement. Specifically, we consider a content that advocates a particular position on a divisive issue. Consumers with polarized preferences towards the content's position are sequentially exposed to the content. Initially, consumers are uncertain about the content quality, but they have the opportunity to learn about it using aggregate consumption metrics and other informative signals. We find that under polarization, social learning based on consumption metrics can mislead consumers to perceive low-quality content as higher quality, even in the long run. We explore the implications of this result on content design and platform operations.

4 - Ai-Generated Content: Recommend OR Not?

Di Yuan, University of Illinois Urbana-Champaign, Champaign, IL, United States, Luying Wang

With the increased usage of generative AI tools in digital content production, platforms adopt different approaches toward distributing AI-generated content. For example, Google demotes web pages written with generative AI in its search results, while Facebook and Instagram plan to assign a label to images and posts identified as AI-modified. Such divergent attitudes toward AI-assisted content reveal an intriguing question about optimal platform design with the rising trend in generative AI usage. We devise an analytical model to explore the economic implications of various platform policies on AI-assisted content detection and distribution.

Our model considers a monopoly platform with heterogeneous creators, where the creators' decision to use AI has implications for both horizontal and vertical competition. The platform, in turn, strategically decides whether to detect the creators' usage of AI and, subsequently, whether to recommend or hide it. By examining the strategic interactions between the platform and creators, we offer insights into the complex dynamics at play in the realm of AI-assisted content production and distribution.

Revolutionizing Healthcare: Advanced AI and Data Analytics for Decision Support

Invited Session

Analytics Society

Chair: Bahareh Kargar, New Jersey Institute of Technolog, Newark, NJ, United States

1 - A Mixed Integer Linear Programming Approach for Nurse Scheduling Problem with Diverse Read-World Factors

Hansol Kim, Department of Industrial Management Engineering, Pohang University of Science and Technology (POSTECH), Pohang, Gyeongbuk, Korea, Republic of, Eun-guk Cho, Byung-In Kim, Jinsuk Lee, Donghyung Kang

The nurse scheduling problem (NSP) holds significance in healthcare management. Currently, nurse rosters are predominantly manually created in hospitals, presenting significant challenges and consuming considerable time. In most Korean hospitals, head nurses manually draft rosters for each ward, undergoing multiple revisions before finalization, a process taking a minimum of 6 hours per ward. These rosters must satisfy the requests of nurses and adhere to scheduling rules. Automating this process offers the potential to generate higher-quality schedules within a more efficient timeframe. In this study, we propose a mixed integer linear programming approach designed to efficiently generate monthly schedules for 20 to 50 nurses, aligning with scheduling rules and meeting nurses' preferences. Our approach has been successfully deployed across 20 wards at Pohang SM Christianity Hospital, validated for its effectiveness, and is actively utilized in scheduling operations.

2 - A Deep Learning Approach to Predict Patient Length of Stay in a Burn Unit

Bryan Norman, Texas Tech University, Lubbock, TX, United States, Rafael Cacao

The length of stay (LOS) for patients in a burn ward is a crucial aspect impacting healthcare delivery, patient care quality, clinical management, and resource allocation. Despite its significance, LOS estimation methods have predominantly relied on a regression model dating back to 1987, with subsequent updates in studies from 2011. In this traditional regression model, Total Body Surface Area (TBSA) affected by burns has been regarded as the primary determinant of LOS. Patients with larger TBSA commonly experience prolonged LOS periods alongside heightened mortality rates. However, LOS can exhibit significant variations, even among patients with similar TBSA percentages. Additionally, burn patients frequently present with a spectrum of complex concurrent injuries, encompassing fractures, soft tissue trauma, traumatic brain injuries, infections, acute kidney injury, ventilator-associated pneumonia, and various comorbidities. These factors further complicate LOS prediction. In this study, we introduce a deep learning model that utilizes admission data to forecast a patient's LOS. Preliminary results demonstrate a notable improvement in prediction accuracy, with an R-squared value of 0.82, surpassing that of current state-of-the-art prediction models.

3 - Implementation of a Machine Learning Tool into the Electronic Health Record to Predict Delirium: An example illustrating MLOps in Medicine

Shant Ayanian, Mayo Clinic, Rochester, MN, United States, Sandeep Pagali

Background

Multicomponent delirium prevention tools have been successful in reducing episodes of delirium in hospitalized patients. Previously published models have proven effective in a prospective study. We describe the implementation of delirium prediction tool into clinical practice.

Purpose

Having a tool functioning seamlessly within the EHR and reporting back to providers and nurses in real time would be beneficial for patients as targeted interventions would reduce their risk for delirium.

Description

The delirium prediction tool is a set of two elastic net logistic regression models designed for medical and surgical patients, respectively.The implementation was challenging as two different models had to run separately on medical and surgical patients and be reported back. The two models were uploaded into an EHR native cloud service where they will receive live data feeds and provide a probability of delirium on a scale of 0-1 every 12 hours. Physicians see these probabilities on their patient lists and nurses within the nursing documentation flowsheets. The probabilities are also color coded to indicate low, intermediate, or high probability. Providers use that information to consult a geriatrics service for recommendations and managing medications. An ongoing pilot project focused on nursing workflows and its results will be presented in this poster as well.

Conclusions

This poster will highlight the feasibility of implementing an AI (Artificial Intelligence) model within the EHR and integrating it within existing workflows to benefit patients and providers.

4 - From Algorithms to eLearning: The Rollercoaster Ride of Digital Integration and Sustainment in Healthcare

Lindsey Philpot, Mayo Clinic, Rochester, MN, United States

Advanced analytics, predictive algorithms and other digital tools hold potential to transform healthcare delivery. Implementation and sustainment of these tools in clinical practice settings can be challenging. From an implementation and healthcare delivery science perspective, three case examples will be discussed considering successes and failures of integrating digital tools into practice: an algorithm for identifying patients with palliative care needs, a tool to help recommend imaging and procedural services for patients with advanced needs, and a suite of eLearning solutions for patients experiencing chronic pain.

5 - Equitable resource allocation with a health care application: is equity in the eye of the modeler?

Emanuele Blasioli, McMaster University, Hamilton, ON, Canada

This study examines equitable resource allocation by introducing four equity constraints categorized into general and domain-specific criteria. An equitable resource allocation strategy seeks to distribute a finite amount of resources with the goal of optimizing an objective function while complying with one or more equity principles. This can be accomplished by customizing the allocation process based on the criteria created to meet the unique requirements of the stakeholders. The need to ensure equity, in terms of serving populations or regions according to established equity standards, and to be efficient in terms of maximizing resource utilization for peak performance often poses a challenge. This challenge is analyzed both mathematically, as a trade-off, and in the context of policy-making. We represent equity through inequality-based indices, due to their compatibility with the knapsack model for addressing resource allocation issues. This work provides guidance on how equity interacts with effectiveness in an optimization framework. We illustrate our proposed methodology on a COVID-19 vaccine allocation case study and provide related managerial insights.

Yu Kan's Session

Invited Session

eBusiness

Chair: Yu Kan, University of Washington- Michael G. Foster School of Business, Seattle, WA, United States

1 - Taste of Free Lunch: The Impact of Free Product Disclosure on Review Dynamics

Yimin Yin, University of Hong Kong, Hong Kong, Hong Kong, Yipu Deng, Xiao Lei

This study investigates the impact of free product disclosure on review platforms, where reviewers voluntarily reveal if they received the product for free. Specifically, we examine whether and how this disclosure policy influences subsequent review generation. Using a quasi-experimental design on Steam, we find that free label reviews increase both volume and efficiency of subsequent reviews. Notably, the increase in volume is more pronounced when free label reviews are of poorer quality, indicating a disconfirmation effect. Additionally, active reviewers, who tend to write effective reviews, contribute significantly to review efficiency under this effect. Our findings suggest that user-generated content (UGC) platforms could leverage free product disclosure as a cost-effective strategy to improve subsequent UGC. This study also complements prior research showing that disclosing the exchange of benefits may not rectify the bias from benefited reviewers; instead, given proper disclosure, the UGC community can organically address this bias through subsequent reviews.

2 - Fleeting or Lasting Success? Unlocking the Power of Livestream Selling

Yipu Deng, University of Hong Kong, Hong Kong, Hong Kong, Weilong Wang, Guoxin Li, Jinyang Zheng, Karthik Kannan

Livestream selling has emerged as a powerful marketing tool for product promotion, delivering substantial revenue growth for retailers. This study delves into the cost-effectiveness of livestream selling by examining its temporal impact on sales during post-adoption days without live streaming, and seeks to unravel the mechanisms underpinning its success. Collaborating with a large Asian streaming platform, we employ a quasi-natural experimental setting. Our findings reveal a significantly positive immediate impact on sales while no discernible lagged effects are observed. This short-lived impact indicates that real-time interactions play a crucial role in driving performance within frequent livestream selling contexts. By offering a comprehensive understanding of the temporal dynamics of livestream selling, our study not only enriches the existing literature but also provides valuable insights for industry practitioners.

3 - Optimizing Paywall Design in Freemium Along with Pay-Per-Use Premium Access

Junzhi Xue, University of Science and Technology of China, Hefei, China, People's Republic of, Lizheng Wang, Yongjun Li, Yong Tan

Paywall has emerged as a pivotal monetization strategy for digital content platforms. In this study, we investigate the paywall design in the context of freemium along with pay-per-use access to premium, in which, consumers can have access to some free samples of a product and then pay for the remaining premium content per use. Based on the case of online book reading, we build a structural econometric model of how readers decide to keep purchasing the next chapter or stop reading forever by depicting consumer's book quality perception and forward-looking behaviors. We utilize detailed consumer chapter-by-chapter payment data to estimate the model. Through policy simulations, we reveal the optimal strategy of deciding the number of free samples and chapter price and verify the effectiveness of the nonuniform pricing strategy in the pay-per-use stage. We also find the optimal strategy for balancing consumer engagement and platform revenue. This study contributes to the literature on paywall design, pay-per-use pricing and engagement-revenue trade-off, offering valuable managerial insights for pricing content products in digital content industries.

4 - Customer Satisfaction as a Moderator: Unpacking the Effects of Managerial Response on Future Review Engagement

Yuqing Hu, University of Washington, Seattle, WA, United States, Lin Jia, Tongxin Zhou, Yong Tan

Online managerial responses not only influence the customers who receive them, but also are kept online as a public reference, affecting future engagement of potential customers. Existing literature presents inconsistencies regarding the impact of responses and the optimal response strategy, leaving it unclear whether responding to positive, negative, or both types of reviews is more effective. We address this gap by proposing customer satisfaction as an important moderator, where we focus on the satisfaction of potential customers. Drawing on data from a leading travel platform in China, our findings confirm that customer satisfaction moderates the effectiveness of responses on future engagement. Responses to positive reviews are more effective when customer satisfaction is low, while responses to negative reviews are more effective when customer satisfaction is high. Our findings highlight that an effective response strategy should be contingent on the business's capability and underscore customer satisfaction as a critical strategic variable.

5 - The Effects of Subway Transit Expansion on Demand for Ridesharing Services

Juan Qin, USTC, Hefei, China, People's Republic of, Stephanie Lee, Yong Tan, Xusen Cheng

As city planners and policymakers formulate transportation policies and make urban planning decisions, it is imperative to understand the relationship between the subway transit system and ridesharing services, especially in current times when the demand for ridesharing services surged dramatically. In particular, when making social overhead capital (SOC) investments in urban transportation, such as investments in the expansion of subway lines, it is important to consider the nuanced interplay between ridesharing and public transit systems. In this paper, we examine how ridesharing services complement and work together with the subway transit system when new subway lines open. We exploit a natural experiment setting in which additional subway lines opened in Beijing, China, and utilize detailed ridesharing order information from a leading Transportation Network Company (TNC). By exploiting a natural experiment setting and employing the difference-in-differences framework, we find that ridesharing services complement the subway transit system. After the opening of new subway stations, the demand for ridesharing services traveling to and from subway stations significantly increases. Moreover, ridesharing services not only provide first-mile and last-mile connections to public transits for residents living close to subway stations, but also provide longer distance connections for residents living far away from subway stations. In addition, we find that the complementary relationship dominates for incumbent subway stations whereas the substitution relationship dominates for newly opened stations. We find that newly opened subway stations generate ripple (spillover) effects on existent subway stations by changing the underlying network topological features of the subway system.

Next-generation Energy Markets

Invited Session

ENRE: Electricity

Chair: Daniel Bienstock, Columbia University, New York, NY, United States

1 - Next-Generation of Electricity Markets

RICHARD O'NEILL, self-employed, Silver Spring, MD, United States

We look look at the expected evolution of electricity markets and offer suggestions of efficiency enhancements including pricing, demand bidding, transmission planning, and the principle of beneficiaries pay/cost allocation.

2 - Resource Adequacy Under Deep Decarbonization

Conleigh Byers, Harvard University, Cambridge, MA, United States

The rise of variable renewable energy and storage in energy systems has called into question whether current electricity market designs are sufficient for a decarbonized future. While energy-only markets with locational marginal prices can theoretically provide cost recovery for the socially optimal mix of resources in the long-run, many systems today have turned to some form of centrally administered resource adequacy mechanism. In a future with high shares of zero-marginal cost resources, the positive skewness of revenue is expected to increase, i.e., capital costs will be recovered from fewer scarcity hours. This poses challenges for risk management, especially with incomplete markets in risk, exacerbating concerns about the ability of short-run markets to achieve resource adequacy.

Discussion has turned to increased reliance on centralized procurement, e.g., via hybrid markets. An alternative market-based approach to managing risk is to require a subset of market participants to enter into mandatory forward energy contracts. An advantage of this approach is that it could provide sufficient hedging such that regulators are more comfortable with allowing the volatility of full-strength energy prices that provide optimal operational and investment signals. The challenge of the contract design is providing hedging while preserving marginal incentives.

We formulate a mixed complementarity problem for incomplete markets and solve via a non-algorithmic approach that allows for exploration of multiple equilibria. We use this model to explore worst-case equilibria for reliability, allowing for a comparison of the consumer welfare from a resource adequacy perspective under different contacting regimes and levels of demand elasticity.

3 - Revealing Decision Conservativeness Through Inverse Distributionally Robust Optimization

Zhirui Liang, Johns Hopkins Univeristy, Baltimore, MD, United States, Qi Li, Andrey Bernstein, Yury Dvorkin

This talk introduces Inverse Distributionally Robust Optimization (I-DRO) as a method to infer the conservativeness level of a decision-maker, represented by the size of a Wasserstein metric-based ambiguity set, from the optimal decisions made using Forward Distributionally Robust Optimization (F-DRO). By leveraging the Karush-Kuhn-Tucker (KKT) conditions of the convex F-DRO model, we formulate I-DRO as a bi-linear program. We demonstrate that I-DRO not only guarantees the existence and uniqueness of an optimal solution but also establishes the necessary and sufficient conditions for this optimal solution to accurately match the actual conservativeness level in F-DRO. Furthermore, we identify three extreme scenarios that may impact I-DRO effectiveness. Our case study applies F-DRO for power system scheduling under uncertainty and employs I-DRO to recover the conservativeness level of system operators. Numerical experiments based on an IEEE 5-bus system and a realistic NYISO 11-zone system demonstrate I-DRO performance in both normal and extreme scenarios.

4 - Équilibria with Virtual Bidders

Garud Iyengar, Columbia University, New York, NY, United States

In wholesale electricity markets, suppliers and load-serving entities (LSEs) enter into contracts to secure energy in the Day-Ahead (DA) market and later adjust for any discrepancy between contracted quantities and actual deliveries in the Real-Time (RT) market. This two settlement structure offers hedging benefits for both suppliers and LSEs but may lead to market inefficiencies. We develop a supply function equilibrium model to explore how virtual trading — a financial strategy that allows participants to speculate on price differences between the

DA and RT markets without physical transactions — can mitigate these inefficiencies. Our analysis reveals that without virtual trading, LSEs often bid below their actual demand in the DA market, leading to DA prices that are lower than the expected RT prices. We show that introducing virtual trading narrows this price disparity and, with an increasing number of virtual traders, potentially eliminates it. Nonetheless, this mechanism prompts LSEs to further reduce their bids in the DA market, deviating from their true demand forecasts. Our analysis indicates that the presence of renewable energy suppliers leads LSEs to submit higher bids in the DA market, compared to scenarios with traditional energy suppliers only. We provide empirical support to our main model implications using data from the California and New York Independent System Operators.

5 - Market Equilibria and Efficiency for Linked Green-Grey Power Pools

Siyuan Wang, Argonne National Laboratory, Argonne, IL, United States, Muireann Lynch, Ben Hobbs

Concerns over climate change have led to electricity markets with greatly increased levels of variable renewable energy integration. New electricity market pricing mechanisms are needed for future highly renewable penetrated grids, to address challenges from resources with high capital cost and zero short-run marginal cost. In this work, we model a new market pricing approach in the context of the green power pool (GPP), which takes the form of an exclusive market for renewable power, cleared alongside a conventional power market. Two-way trading between the two markets is allowed. The definition, calculation methods, and properties of capacity pricing for renewable participating in the GPP are systematically presented. Using equilibrium models, we show that under the proposed pricing the GPP achieves the same market efficiencies with conventional market design in deterministic and risk-neutral stochastic settings. When renewable investors are risk-averse, compared to the conventional market, the proposed pricing can lead to different equilibria under a GPP, with an increased incentive for renewable generation.

Modern High-Dimensional Inference - Theory, Methods and Applications

Invited Session

Data Mining

Chair: Trambak Banerjee, University of Kansas, Lawrence, KS, United States

1 - A Bootstrap Test for Equality of Covariance Matrices in High-Dimension

Nilanjan Chakraborty, Missouri University of Science and Technology, Saint Louis, MO, United States, Sayar Karmakar, Hira Koul

In this talk, we propose a test for testing the equality of two high-dimensional covariance matrices in the two-sample set up. This test is based on the maximum of the absolute differences between the entries of the multiplier bootstrap Jackknifed estimators of the two population covariance matrices. We proved a Gaussian approximation result for two-sample U statistics and used it to derive the asymptotic distributions of the sequence of the proposed test statistics under the null and some local alternative hypotheses. These results are obtained under some weak conditions on the moments of the random vectors and the tails of the marginal distributions. The correlation structures of the random vectors can be arbitrary, the two sample sizes need not be equal and the dimension is allowed to grow exponentially with the two sample sizes. The test is shown to be consistent against a class of shrinking nonparametric alternatives. A finite sample simulation study reveals some superiority of this test compared to some of the existing tests.

2 - Rank Based Tests for Heterogeneous Data

Ritwik Sadhu, Cornell university, Ithaca, NY, United States, Nilanjan Chakraborty, Trambak Banerjee

In many modern inference tasks, the data-generation process contains inherent sources distribution heterogeneity, often resulting in multi-modality of the composite dataset on which statistical procedures must be performed. Such data containing distributional heterogeneity allows testing for the presence of an entirely new component distributions in a subset of the data. For this testing problem, henceforth called the remodeling problem, we propose a new test statistic constructed using optimal transport (OT)-based multivariate ranks, which allows for asymptotically consistent testing with correct asymptotic level under the assumption of well separated component distributions in the null. To the best of our knowledge, this is the first statistic in the literature for this problem with the aforesaid guarantees.

3 - Statistical Inference for Subgraph Densities Under Induced Random Sampling from Network Data

Ayoushman Bhattacharya, Washington University in St. Louis, St. Louis, MO, United States, Nilanjan Chakraborty, Soumen Lahiri

In this talk, we develop a framework for obtaining statistical guarantees for subgraph densities of a general population network under without replacement sampling (SRSWOR). The examples of such subgraph densities include edge density, triangle density, two-star density and other popularly studied graph summary statistics. Under this sampling scheme, we obtained a Berry-Esseen bound to establish asymptotic normality of the Horwitz-Thompson (HT) estimator for the population subgraph densities. To facilitate inferential procedures, we provide a jackknife estimator of the unknown population variance and establish its consistency. Our method works under certain popular super population network models like sparse graphons, stochastic block models (SBM) and others. We also establish the joint asymptotic normality of two subgraph densities which is crucial in establishing asymptotic normality of the global clustering coefficient/global transitivity of the sampled graph. Our results find a useful application to the problem of testing the equality of two population graphs using the subgraph densities as the test statistic. Finally, we present a simulation study and a real data analysis which corroborates our theoretical findings.

4 - On a Fast and Consistent Test for Equality of Means for High-Dimensional Data

Sayan Das, Washington University in St. Louis, St. Louis, MO, United States, Debraj Das, Subhajit Dutta

In this talk, we propose a two-sample test for high-dimensional means using a logistic regression framework. The crux of our method relies on identifying significant feature variables via LASSO (using the logit link) that can capture the population mean. The proposed test is based on the regression coefficients of these selected features, effectively reducing dimensionality. Theoretically, we have shown that our proposed test is consistent against a wide range of alternatives. In the ultra-high-dimensional regime, our test leverages the sparse structures of the means, making it computationally more efficient compared to other methods in the existing literature. Additionally, we have extended our method to test for equality of means across multiple groups. Finite sample studies corroborate our theoretical findings and reveal the superiority of our tests compared to several existing tests.

Expanding AI Boundaries to Education, eCommerce, and Sustainable Urban Mobility

Invited Session

Data Mining

Chair: Dervis Ozay, The University of Texas at Arlington, Arlington, TX, 76155, United States

Co-Chair: Shouyi Wang, The University of Texas at Arlington, Arlington, TX, 76019, United States

1 - A Novel Deep Learning Approach for Dynamic Pricing Optimization and Smarter Business Decisions: a Case Study of eCommerce

Dervis OZay, The University of Texas at Arlington, Arlington , TX, United States, Shouyi Wang, Bharani Nammi

The complexity of pricing strategies has become increasingly significant in the rapidly evolving world of e-commerce for companies looking to achieve profitability and remain competitive. There is perpetual flux in the pricing landscape, marked by swift competitor reactions, variable market conditions, and the requirement to set prices for a wide variety of products. Given this BSS Data Challenge opportunity, we developed a novel multi-step DL framework to provide optimal solutions to the dynamic pricing problem. In particular, we consider both Pricing and Ads Spend are decision variables. We propose two deep learning (DL) models. The first DL model is developed to make probabilistic forecasting and generate expected value ranges for Unit Price, Ads Spend, and Competitors' Prices given historical market behaviors. The second DL model is developed to model the complex relationships from Unit Price, Ads Spend, and Competitors' Prices to Unit Ordered and resulting Profit. The Deep Learning Model 2 is then used to predict the expected profit given different values of Unit Price and Ads Spend within the predicted ranges by the Deep Learning Model 1. The optimal Unit Price and Ads Spend are determined by their values that maximize Deep Learning Model 2's expected profit. The proposed DL framework is flexible and can be used to set daily optimal price and ads spend, as well as other time resolutions, such as every N days or one week. The proposed DL approach provides a novel data-driven solution to guide price and ads spend decisions for e-commerce products.

2 - Taming the AI Dragon: Reimagining Governance Frameworks and Data Management for AI Alignment

Darshan Desai, Pedago, New Providence, NJ, United States, Ashish Desai

As Artificial intelligence (AI) systems advances, it is becoming crucial to develop innovative governance structures and approaches to align these systems with human values early on. This research explores AI alignment challenges, focusing on large language models (LLMs), which present unique difficulties due to their generative capabilities and potential for bias. These models can produce unpredictable outputs, raising ethical concerns and the risk of perpetuating biases. Through strategic analysis of technology roadmaps, we investigate how governance frameworks can be reimagined to support AI alignment. We propose a novel framework for adaptive AI governance, emphasizing continuous oversight, high data quality, innovative architectural approaches, and stakeholder engagement. Our findings highlight the critical role of data management and governance in ensuring AI systems' reliability and trustworthiness, particularly in mitigating biases and ensuring more intentional augmentation and automation in decision-making processes. This study contributes to aligning AI technologies with ethical standards and societal values.

3 - Multiple Risks in Extended Markov Ratio Decision Processes

Alexander Zadorojniy, IBM Research, Haifa, Israel, Orit Davidovich, Takayuki Osogami

An Extended Markov Ratio Decision Process (EMRDP) enables the integration of a risk term into its underlying Markov Decision Process (MDP). We propose extending EMRDP to accommodate multiple risks and present an algorithm for determining the optimal policy for this enhanced EMRDP. We analyze both the theoretical properties of the algorithm and its empirical application to a grid world problem. Furthermore, we illustrate the application of EMRDP to financial trading, demonstrating that we achieve a strongly polynomial algorithm for this particular problem.

Mining for Health: Data Mining for Personalized Care and Operational Efficiency

Invited Session

Data Mining

Chair: Sara Nourazari, California State University, Long Beach, Long Beach, CA, United States

1 - Comparing Retrieval Augmented Generation Models, Embeddings and LLM Performance Using Context-Aware Models for Clinical Pathways and Outcomes

Jakka Sairamesh, CapsicoHealth, Inc, PALO ALTO, CA, United States, Shloke Meresh, Laurent Hasson, Supraja Krovvidi, Siham Belgadi

RAGs (Retrieval Augmented Generation) have become instrumental in driving valuable, semantically-oriented, context-driven inputs to LLMs to reduce errors, hallucinations and unusual responses from LLMs . In this presentation, we will focus on healthcare oriented questions and responses using RAGs and compare multiple LLMs (including LLAMA2, LLAMA3, GPT4, Mistral and several other models) on their performance to predict future clinical pathways for a range of conditions such as cardiovascular, behavioral health and oncology-care. We found that depending on the healthcare focused contextual searches (including text and image data) and distance vector based models, RAGs can augment the LLM accuracy for specific scenarios in clinical decision-making. We found over 75% accuracy with LLAMA2 and LLAMA3 models when compared to 95% accuracy in using context-specific using the same data sets but augmented with semantic models. Our results have demonstrated that context-aware LLMs outperform publicly available LLMs with RAG driven inputs.

2 - Augmented LLMs Through Context-Aware Semantic Search and Automated detection of Hallucinations for Healthcare Decision-Tools

Supraja Krovvidi, CapsicoHealth, San Mateo, CA, United States, Shloke Meresh, Siham Belgadi, Sairamesh Jakka, Laurent Hasson

Abstract: As LLMs become more widely used, it's crucial to address potential risks and ensure high accuracy for decision-making, especially in healthcare. A major concern is 'hallucination', where LLM outputs diverge significantly from expected responses. Our study's main aim is to evaluate, detect and analyze continuously the degree of hallucinations in responses from custom-built LLMs on patient treatment pathways and clinical trials.

Hypothesis: Our hypothesis is that automating early-detection of deviations in LLM outputs can ensure continuous evaluation and reliability of LLMs during operational clinical use. We trained our custom-built LLM with trusted patient pathways and real-world clinical drug data

Methodology: Our approach involves leveraging Retrieval-Augmented Generation (RAG) architecture which enables the user to ask questions about a certain patient journey pathway or trends regarding a certain drug and potentially get a response considering both semantic similarity and context relevance. Our hallucination detection module is based on discrepancy detection between generated responses and retrieved data. This helps us in identifying significant deviations from the retrieved context, indicating potential hallucinations or inaccuracies. Techniques such as cosine similarity, semantic overlap metrics, or tree-based heuristics are employed for hallucination detection.

Evaluation: To enable trustworthiness for decision-making, several metrics are needed to ensure high accuracy and low hallucination rates. Metrics such as precision, recall, and F1 score are used to evaluate context-aware semantic search effectiveness and hallucination detection accuracy

3 - Could Provider and Patient Characteristics Influence the Outcomes of Provider Coaching in Emergency Care?

Sara Nourazari, California State University, Long Beach, Long Beach, CA, United States

This study examines the influence of patient and provider characteristics on emergency department (ED) quality scores and the effectiveness of professional coaching in improving these scores. We analyzed over one million ED visits, combining workflow data, patient feedback, and coaching records. Our results demonstrate that specific patient and provider demographics significantly impact the success of coaching interventions. This highlights the need for tailored coaching strategies to maximize effectiveness within the dynamic ED environment.

1 - An Online Chance Constrained Optimization Framework in Resilient Microgrids Using Analytical Stability Sensitivity

Jun Wang, The university of Hong Kong, Hong Kong, Hong Kong

Offline optimization has traditionally been favored in power systems due to dependable generation and load forecasts. However, as renewable energy sources (RESs) and demand response technologies become more prevalent, the relevance of offline optimization is diminishing. This shift has prompted a greater focus on online optimization techniques in the power systems. To manage RESs uncertainties and stability issues in isolated resilient microgrids, this paper introduces a novel online chance constrained optimization framework accounting stability constraint. Thanks to proposed analytical sensitivities and linear reformulations, compared to conventional Monto-Carlo simulations, the computational burden is much lower, which can be acceptable to online optimization. Firstly, we propose a bi-level optimization problem, in which the upper level aims to minimize the expected generation cost without violating the stability chance constraint and the lower level gives the stability index in terms of a semi-definite program (SDP). Secondly, we apply the Gaussian mixture model (GMM) to handle the RES uncertainties and introduce analytical sensitivity analysis to reformulate chance constraints into linear deterministic versions. By incorporating linearized constraints, the bi-level tractable model can be solved by the Benders decomposition-based approach. Simulation results on the IEEE 33-bus microgrid test system reveal that compared to benchmarking approaches, the proposed model can converge in 1 minute and 30 times faster with more accurate solutions.

2 - Distribution System Restoration with Temporal Flexibility from Building AC Systems under Endogenous and Exogenous Uncertainties

Ruolan Cui, University of Hong Kong, Hong Kong Island, Hong Kong, Shunbo Lei

3 - Planning Resilient Distribution Grids

Miguel Heleno, Lawrence Berkeley National Laboratory, San Francisco, CA, United States, Alexandre Moreira

Distribution grid reliability and resilience have become critical issues for utilities and regulators, particularly due to the increasing severity of extreme events. Utilities are now considering significant investments in distribution grid assets to mitigate the impact of major outages. Effective quantification of the economic and risk-mitigation benefits of these investments to regulators is essential for the approval process. Current industry practices for reliability and resilience planning largely overlook these risk considerations and fail to properly quantify them. This talk discusses innovative optimization-based methodologies for distribution grid planning that balance the risk of outages cased by high impact low probability (HILP) events with the ones related to routine failures. This methodologies are illustrated with examples of reliability/resilience investments in real networks.

4 - Modelling Load Redistribution Attacks in Integrated Electricity-Gas Systems

Rongpeng Liu, McGill University, Montreal, QC, Canada, Xiaozhe Wang, Bo Zeng, Rawad Zgheib

As the proportion of gas keeps rising in electricity generation, integrated electricity-gas systems (IEGSs) have been deployed massively, facilitating gas transmission to gas-fired power generators and therefore mitigating generation costs. However, these deployments intensify the reliance of IEGSs on cyber infrastructures, such as communication systems, which in turn renders IEGSs progressively susceptible to cyberattacks. In this presentation, we delve into the paradigm and stealthy conditions of load redistribution (LR) attacks on IEGSs and propose a bilevel mixed-integer model to identify the most severe LR attack from an economic perspective. Under a mild assumption, we prove that the proposed model does not exclude any possible upper-level attack, which differs from existing models that may yield suboptimal solutions. A modified reformulation and decomposition (R&D) algorithm is developed to solve this model in a master-subproblem framework. Particularly, we design a new subproblem to address potential infeasibility issues in the master problem. Accordingly, two types of cuts are added to the master problem for ensuring algorithm feasibility and solution optimality. Testing results validate the effectiveness of the proposed model and solution method.

5 - Resilience Enhancement in Power Distribution Systems: Chance-Constrained Model with Decision-Dependent Atoms

Zeyu Wang, The George Washington University, Washington, DC, United States, Miguel Lejeune, Payman Dehghanian, Jinshun Su

Mobile power sources (MPSs) offer considerable promise to facilitate the exchange of spatiotemporal flexibility in the power distribution system (PDS) and enhance its resilience to extreme emergencies. The service restoration process can be made more efficient by strategically prepositioning MPSs in advance of and allocating them during high-impact low-probability extremes. This paper introduces a new decision-dependent chance-constrained model, where the atoms of the probability distribution of a random variable are distorted by decisions. The model is designed to address the service restoration problem in PDSs and optimize the pre-disaster deployment of MPSs. The proposed service restoration scheme is formulated as a mixed-integer nonlinear joint chance-constrained model with nonconvex continuous relaxation. We develop an efficient method to reformulate the chance-constrained model with decision-dependent uncertainty as an equivalent mixed-integer linear problem. Case studies demonstrate the effectiveness of the proposed restoration scheme in boosting PDS resilience and the significance of incorporating endogenous uncertainties in the service restoration process.

1 - When Where Watt: Harnessing the Value of TIME and Location of Electricity Generation for Renewables

Vishrut Rana, The Wharton School, Philadelphia, PA, United States, Christian Kaps, Serguei Netessine

Investments in renewable energy have surged worldwide in recent years, with over $1.7 trillion spent globally on clean energy investments. This surge can be attributed to growing policy support, energy security concerns, and most importantly, cost competitiveness of renewable energy. While technological advancements have ensured that costs for wind turbines and solar panels have plummeted, these lower costs do not translate to an increase in profits for renewable energy generation. Renewable power plants generate lower revenue compared to their conventional counterparts like coal and gas because renewable electricity is often generated in locations and at times with low wholesale market prices of electricity. To counter this, we propose a new site selection metric for renewable power plants – Quality Adjusted Power Value (QAPV) – which captures monetary value of electricity by accounting for time and location of renewable generation. We use geospatial satellite data to validate this metric on wind power plants installed in Texas between 2007-2014, and find that annual revenues for these plants can increase up to 30% if they were sited using QAPV. We conclude our discussion by identifying mechanisms that lead to sub-optimal locations being chosen for renewable power plants. Our work contributes two insights – for renewable developers, our site selection metric can be used to identify most profitable investment sites, and for policymakers, our results on counterfactual revenue can enable discussions around policies that streamline efficient investments in renewable energy.

2 - Buyer Management of a Supplier&Rsquo;S Social Responsibility Risk: Prevention, Detection, and Remediation

Junhao Yu, Miami University, Oxford, OH, United States, Tim Kraft

We study how retailers can proactively manage their suppliers' responsibility risk. We focus on a retailer's risk management strategy and consider three tactics the retailer can deploy—prevention, detection, and remediation—and study how combining the three can help the retailer achieve optimal results.

3 - When Workers Watch: the Impact of Metering Engagement on Energy Efficiency

Donggyu Jeon, Indiana University - Kelley School of Business, Bloomington, IN, United States, Owen Wu, Christopher Chen, Amrou Awaysheh

This study examines the impact of worker engagement with metering systems on energy efficiency in manufacturing settings. Metering systems, which form a vital part of the operational infrastructure, provide comprehensive data on energy and electricity usage, consumption flows and patterns, and CO2 emissions. Employing a rigorous empirical approach, this paper aims to empirically demonstrate the relationship between the dynamics of user-system interactions and energy efficiency outcomes. Our empirical findings reveal a positive relationship between the intensity of worker interaction with these systems—measured in terms of interaction frequency and duration—and the overall energy efficiency at the manufacturing facilities. In addition, qualitative aspects of interaction—specifically, the manner in which workers interact with the system and utilize or access different types of data—influence energy efficiency to varying extents. We consistently observe that heightened worker involvement with metering system and data leads to more energy-efficient operations at the manufacturing sites. Notably, we also find that user interactions focused on operational or energy-related tasks lead to greater energy efficiency compared to generic, administrative interactions. Overall, our findings show that enhanced access to information and broader data coverage, coupled with increased scrutiny of metering data by workers, translate into more informed decisions and practices that promote energy efficiency.

4 - The Value of Strategic Management of Residential Energy Storage Using a TIME-Invariant Control Policy

Na Rea Cho, Wichita State University, Wichita, KS, United States, Youngsoo Kim, Karthik Murali, Mesut Yavuz

While the deployment of renewable energy sources as an alternative to fossil fuels has garnered global attention, the intermittent and unpredictable nature of renewables has spurred a growing interest in energy storage. However, effective management of energy storage is far from trivial for residential consumers owing to various compensation and pricing structures, as well as uncertainties in electricity demand and generation.

In this paper, we establish an effective time-invariant policy to manage home energy storage and to improve the economic returns from residential solar and grid-tied battery systems. Through a numerical experiment, we show that this simple yet effective control policy substantially increases the value of home energy storage while performing nearly as well as battery optimization under certainty, thus leaving little room for improvement from more complex, forecast-driven approaches. From a policy perspective, our results indicate that imposing restrictions on the purchase of electricity from the grid to charge the battery is counter-productive to the adoption of this technology and the health of the grid and environment. In addition, through case studies, we show that strategically managing home energy storage makes this technology significantly more attractive even in communities where it would add no value when managed passively. Furthermore, real-world implementation in a community setting validates the effectiveness and robustness of the battery management policy established in this paper, highlighting its resilience to changes in billing and compensation plans. Our findings provide valuable insights into the effective utilization of residential energy storage systems under evolving regulatory and market conditions.

Energy Systems Modeling and Optimization VII: Macroenergy Systems (MES)

Invited Session

ENRE: Other Energy

Chair: Raziye Aghapour, University of Texas at Arlington, ARLINGTON, TX, United States

1 - Market equilibria with agent-specific capital costs in energy system models – towards a consistent model formulation

Christoph Weber, University Duisburg-Essen, Essen, Germany

It is common practice to use linear optimization approaches with a single, uniform discount rate in energy system modelling. This is also consistent with the standard central planner interpretation of such models. At the same time, it is well known that outcomes of appropriately formulated optimization models may be interpreted as competitive market equilibria. Empirical evidence yet suggests that investors in energy markets face differentiated capital costs (e.g. Steffen 2020, Polzin et al. 2021) depending on technology, market and investor characteristics. There have been pragmatic approaches to incorporate such differentiated capital costs into energy system models (e.g. Loulou et al. 2016, Tash et al. 2019, Lonergan et al. 2023). Through a thorough analysis of KKT conditions, a theoretically consistent solution may yet be established with succinct and explainable economic features. We illustrate the approach with a stylized application to capacity expansion in Germany and discuss how the outcomes may be linked to standard results. Also the implications for energy and climate policy are highlighted.

2 - Exploring Transmission Solutions for Texas' Renewable Energy Surge

Raziye Aghapour, University of Texas at Arlington, Arlington, TX, United States

Texas, a significant energy producer, has experienced a notable surge in the integration of renewable energy lately, with expectations of continued growth, particularly in the renewable-rich region of West Texas. However, this region's distance from major demand centers in the eastern cities, coupled with the lagging expansion of Texas's transmission infrastructure, poses challenges to accommodating this growing renewable energy production. These obstacles could lead to increased congestion and constraints within the ERCOT system. In this study, we aim to address these challenges by analyzing potential transmission enhancements to alleviate export constraints from West Texas. Using the Regional Energy Deployment System (ReEDS), a macro energy system modeling tool, we will explore various scenarios. Firstly, we will evaluate the effectiveness of ERCOT's transmission planning in mitigating congestion, followed by a comparison with our own findings, highlighting the respective strengths and weaknesses of each approach.

3 - Effects of Storage Participation on Wholesale Electricity Markets

Zhenhua Zhang , UCSD, San Diego, CA, United States

The strategic behaviors of storage systems that participate in wholesale electricity markets can influence market prices, system costs, and profit distributions among generation types. We develop a bi-level model to examine how these impacts vary across participation requirements in the Western Electricity Coordinating Council region. The upper level includes a storage profit maximization model and the lower level represents the market operator's economic dispatch problem. We find that strategic behaviors can significantly increase storage profit but increase system cost only by a small margin under various renewable penetration levels relative to the case when storage is ISO-controlled. Market prices decrease during charging events but remain similar during discharging events, subject to electricity demand conditions and discharge offer prices. For storage that also participates in resource adequacy programs with minimum state-of-charge requirements, a low non-compliance penalty can help recover storage investments without significantly increasing system costs. Future designs on wholesale participation models and resource adequacy programs should consider how ISO requirements and storage strategic behaviors interact and evaluate the trade-offs between generator profitability and system costs.

4 - Solar adoption in MA across sectors

Zana Cranmer, Bentley University, Waltham, MA, United States

Solar energy is a key component of strategies to reach net zero emissions. Understanding the current drivers of adoption of solar energy, particularly photovoltaics, is a key element to developing policies to address inequities and gaps in access. This work looks across sectors, including residential and commercial solar projects. Beyond demographic factors like income and homeownership, do measures of environmental attitudes and solar-focused municipal programs increase or accelerate adoption? What are the implications for reaching state targets for renewable energy, emissions, and equity? The identified drivers will then be applied to future projections for energy use and adoption.

5 - Optimizing Suburban Mobility: Scheduling Shared Autonomous Electric Vehicle Fleet with Stochastic Renewable Energy and Grid Load Variability

Luce Brotcorne, INRIA, Lille, France

The rapid development of Shared Autonomous Electric Vehicle (SAEV) fleets offers significant opportunities for enhancing suburban mobility. This paper addresses the challenge of integrating AEV routing with charging infrastructure, focusing on the stochastic nature of day-ahead renewable energy availability and grid load variations. Our study leverages scenario-based stochastic optimization to model and manage uncertainties. We propose a framework that combines AEV charging scheduling and passenger travel demand fulfillment in suburban areas equipped with solar PV-integrated charging stations. The primary objective is to minimize total operational costs, including travel and charging expenses, while penalizing any unmet passenger requests to ensure that the majority of passenger travel demands are met within their specified time windows. The mixed-integer linear programming (MILP) model incorporates constraints such as vehicle battery capacities, time windows for passenger trips and charging station availability. Multiple scenarios are generated based on historical data, each representing potential solar PV output and grid load realizations for the upcoming day. The MILP is solved for each scenario and the solutions are used to formulate strategies that optimize the system under uncertainty. A case study of a suburban French low voltage (LV) grid and transportation system demonstrates the effectiveness of our approach in reducing costs and enhancing system reliability. Our model reduces peak grid demand and costs associated with charging the SAEV fleet by aligning vehicle charging times with periods of high solar PV output.

Data-Driven Optimization for Reliable Machine Learning (II)

Invited Session

Computing Society

Chair: Vasileios Digalakis, HEC Paris, Jouy-en-Josas, France

Co-Chair: Michael Lingzhi Li, Harvard Business School, Boston, MA, 02163, United States

1 - A Mathematical Optimization Model for Solving the Contextual Multiobjective Inverse Ideal Point Problem

Nuria Gómez-Vargas, Universidad de Sevilla, Sevilla, Spain, Rafael Blanquero, Emilio Carrizosa

We propose a Mathematical Optimization model tailored to address the challenging Contextual Multiobjective Inverse Ideal Point Problem (CMIIPP). The CMIIPP involves yielding the underlying objective functions of a multicriteria decision-making model based solely on a set of pairs of concurrently observed context and decisions, particularly focusing on the ideal point scenario in multiobjective optimization. By formulating the CMIIPP as an optimization problem, our approach offers a framework to uncover the implicit preferences governing the decision-making process that led to a given ideal point solution preserving its consistency. Furthermore, considerations are made for incorporating domain-specific knowledge to enhance applicability and exploring other requirements such as interpretability.

2 - Global Optimization: a Machine Learning Approach

George Margaritis, Massachusetts Institute of Technology (MIT), Cambridge, MA, United States, Dimitris Bertsimas

Many approaches for addressing Global Optimization problems typically rely on relaxations of nonlinear constraints over specific mathematical primitives. This is restricting in applications with constraints that are black-box, implicit or consist of more general primitives. Trying to address such limitations, Bertsimas and Ozturk (2023) proposed OCTHaGOn as a way of solving very general global optimization problems by approximating the nonlinear constraints using hyperplane-based Decision-Trees and then using those trees to construct a unified mixed integer optimization (MIO) approximation of the original problem. We provide extensions to this approach, by (i) approximating the original problem using other MIO-representable ML models besides Decision Trees, such as Gradient Boosted Trees, Multi Layer Perceptrons and Suport Vector Machines, (ii) proposing adaptive sampling procedures for more accurate machine learning-based constraint approximations, (iii) utilizing robust optimization to account for the uncertainty of the sample-dependent training of the ML models, and (iv) leveraging a family of relaxations to address the infeasibilities of the final MIO approximation. We then test the enhanced framework in 81 Global Optimization instances. We show improvements in solution feasibility and optimality in the majority of instances. We also compare against BARON, showing improved optimality gaps or solution times in 11 instances.

3 - The Art of Selection: Large-Scale Optimal Experimental Design

Baizhi Song, London Business School, London, United Kingdom, Jean Pauphilet

Despite the recent explosion in data availability, data collection in certain fields remains challenging and expensive. Consequently, it is crucial to collect a subset of data samples that retains as much information as possible from the full population. This issue aligns with a fundamental problem in statistics: optimal experimental design. Recent examples of this problem in environmental sciences and agriculture introduce new challenges: (i) the total size is in the order of 10,000, (ii) data collection (e.g., via drones) is subject to complex operational constraints.

In this paper, we propose a discrete optimization approach that addresses both challenges. Our approach first solves the relaxation via outer approximation. On synthetic datasets, our approach extends the solvable problem scale by an order of magnitude (from 3,000 to 30,000). The corresponding Mixed Integer Optimization (MIO) problem benefits from a warm start of the solution and valid cuts generated during the relaxation phase. Our approach can include various geospatial/route constraints. In the context of ocean cleaning applications, we further investigate the trade-off between information and plastic collection.

4 - An online assignment and routing problem for the logistics of organ transplants

Sean Lo, MIT Operations Research Center, Cambridge, MA, United States, Alexandre Jacquillat

TransMedics is a US-based healthcare startup which operate devices for organ transplants. These portable devices preserve the shelf-life of donated organs outside the donor's body, allowing for less time-dependent organ donor-recipient matchings and improved healthcare outcomes. We help Transmedics solve a complex logistics problem on a rolling horizon with a hybrid assignment / routing structure: we assign surgeons, technicians, and devices to organ donors, and route them to organ recipients via a fleet of planes. We propose an online algorithm which takes into account uncertainty in case arrivals, and demonstrate how it outperforms a greedy approach. We deploy our method in TransMedics' operations center and show that we significantly improve on the volume of transplants served in real life.

Advanced Optimization for Mixed Integer Programming

Invited Session

Computing Society

Chair: Mikhail Bragin, University of California, Riverside, Marina del Rey, CA, United States

1 - Enhancing Quantum Optimization Scalability: A Singular Transformation Approach to Unit Commitment

Peng Zhang, Stony Brook University, Stony Brook, NY, United States, Mikhail Bragin, Yifan Zhou

Resilience-constrained unit commitment (RCUC) is a quintessential strategy for meeting electricity demands and boosting grid resilience against extreme events. However, solving RCUC is a long standing challenge due to its mixed-integer, nonlinear, and non-convex nature. The recent successes in exploiting the potential of quantum advantages spread hope to the power industry for achieving a ‘quantum leap’ of grid analytics. Our experiments have proven the feasibility of building quantum UC algorithms such as quantum alternating direction method of multipliers and quantum surrogate Lagrangian relaxation. However, these quantum algorithms are difficult to scale, restricted by the limited number of qubits, low connectivity between qubits, and coherent and incoherent errors, etc. In this talk, we will describe a promising method for tackling practical RCUC problems by empowering the decomposition and coordination-supported framework with singular transformation. This singularity-based method will result in a highly expressive quantum circuit with manageable quantum operators. The new method is expected to achieve a complexity independent of the system dimension, which will pave the way for the utilization of limited quantum resources to potentially solve the large-scale mix integer optimization problems. We will demonstrate the quantum RCUC algorithm's accuracy, efficiency, and resilience on representative power systems with NISQ devices.

2 - Acceleration of Level Adjustment for the Polyak Stepsize: Applications to Mixed Integer Programming

Mikhail Bragin, University of California, Riverside, Riverside, CA, United States, Anbang Liu, Zuzhao Ye, Nanpeng Yu, Osten Anderson

The Polyak stepsize has been widely used for convex problems. However, the stepsize requires a generally unknown optimal value. To guarantee convergence, we develop a novel level adjustment approach to successively estimate the optimal value with provable convergence. This is achieved by developing a decision-based procedure through a novel easy-to-solve "Polyak Stepsize Violation Detector" (PSVD) linear constraint satisfaction problem. Once a violation is detected, a tighter level value is obtained. Furthermore, because subgradients may be computationally costly, we develop an approximate subgradient method. Through a series of empirical tests of convex functions with diverse characteristics, we illustrate the practical advantages of our approach as compared to existing methods. For Mixed-Integer Programming (MIP) problems, our integration of Lagrangian Relaxation with the Polyak stepsize demonstrates significant efficiency gains, optimizing Lagrangian dual problems in operations research, power systems, transportation, and manufacturing sectors leading to speedups of 2-3 orders of magnitude as compared to standard MIP methods.

3 - Accelerating Branch-and-Price via Template Pricing

Luke Marshall, Microsoft Research, Redmond, WA, United States, Prachi Shah, Santanu Dey

Column generation (CG) for discrete optimization (i.e., branch-and-price), is a powerful method for solving large-scale and highly complex problems. However, it also faces challenges with convergence when degeneracy occurs. Many methods have been explored in the literature to stabilize dual values, reduce degeneracy, or generate compatible columns, with varying success. As an alternative, we propose a new *template pricing* approach, which modifies the standard subproblem that generates new columns. It uses additional objectives and constraints to guide similarity between new columns and a dynamic set of templates.

Template pricing aims to achieve three goals: (i) generate columns that are not only profitable, but also diverse-yet-compatible with other columns; (ii) directly avoid problems with dual instability to speed up the convergence of the CG algorithm; and (iii) can be implemented easily and efficiently. We show that template pricing can be applied to various types of mixed-integer programming (MIP) problems, and present different ways to select suitable templates. Moreover, we also show that our approach is compatible with standard dual-value stabilization techniques for even greater impact.

We perform extensive computational experiments on a variety of benchmark instances from the literature and compare our approach with other methods. Our results show that template pricing can significantly accelerate the CG algorithm, with some instances solving 500x faster. To the best of our knowledge, this is the first work that proposes and evaluates template pricing as a general acceleration method for column generation in integer programming.

4 - Using Lagrangian decomposition to coordinate order release planning and production scheduling

Hubert Missbauer, University of Innsbruck, Innsbruck, Austria, Reha Uzsoy, Gregor Blossey

Optimization models that determine order releases for a multi-period planning horizon simultaneously perform production smoothing and cycle time control by controlling the level of work in process inventory in the manufacturing system. The crucial modelling challenge is that of anticipating the effects of a specified order release schedule on the time-dependent cycle time distribution.
Previous authors have sought to improve this anticipation by decomposing the order release problem into a production smoothing subproblem, usually represented as a linear program, that determines the order releases for given time-dependent lead times, and a cycle time estimation subproblem for given releases, usually addressed by discrete-event simulation. The subproblems are solved iteratively until convergence. However, this procedure can fail to converge, and it has been shown recently that it is a flawed application of mathematical decomposition.

We propose a Lagrangian decomposition approach that decomposes the order release problem into order release and production scheduling subproblems. Coordination is achieved through Lagrange multipliers that act as prices for capacities and penalize long lead times. We show that linear prices cannot coordinate the subproblems. We test a variant of augmented Lagrangian relaxation that ensures separability and the Alternating Direction Method of Multipliers (ADMM). Preliminary computational results show that both methods work in principle but show shortcomings in their convergence behavior. We discuss these open questions and outline alternative ways to apply Lagrangian techniques to coordinate the order release and the scheduling level. This also aims at contributing to the integration of mathematical programming and discrete-event simulation.

Monday PC

Flex C

Monday Poster Competition

Poster Session

Poster

Chair: Sripad Devalkar, Indian School of Business, Hyderabad, India

Co-Chair: Masha Shunko, University of Washington, Seattle, WA, United States

Co-Chair: Shengfan Zhang, University of Arkansas, Fayetteville, AR, United States

1 - Life After Warming: How Can We Make It Better Using Systems Engineering for Societal Good?

Buket Cilali, University of Oklahoma, Norman, OK, United States, Kash Barker, Andres Gonzalez, Ahti Salo

Forced displacement is a pressing global issue, requiring proactive international solutions for relocation and integration planning. Particularly in climate-driven cases, where slow-onset climate change impacts render regions uninhabitable for the upcoming decades, addressing this large-scale displacement in the long term requires a comprehensive approach. To this end, we propose a two-stage stochastic optimization model that analyzes diverse demand scenarios and societal impacts to determine where and when people should go in order to assist decision-makers in preparing for future movements effectively.

2 - Bringing Sustainability to Mining Regions with an Evolutionary Interactive Multi-Objective Optimization with Multiple Stakeholders

Gen LI, Technical University of Munich, School of Management, Center for Energy Markets, Munich, Germany, Svetlana Ikonnikova

The rising demand for critical materials, driven by global decarbonization, is intensifying mining operations in the Global South. This trend necessitates research on sustainable mining practices that balance economic viability with social responsibility and environmental sustainability. Despite companies' focus on mutual financial gains, stakeholders including local communities, regulators, and downstream players frequently voice concerns over the neglect of their conflicting interests. This research aims to develop a practical AI-based simulation framework for (1) assessing the impact and outcomes associated with mining and (2) finding a compromise solution determining the mining setup and operations, acceptable to the affected stakeholders.

Built on interactive multi-objective optimization (iMOO), our framework is enhanced by integrating evolutionary algorithms with models of multilateral bargaining and choice behavior. This integration takes into account the evolving preferences and relationships of stakeholders, aspects often overlooked by traditional iMOO. The hybrid model effectively manages conflicting priorities and interests, identifies equitable solutions, and ensures that the benefits of mining developments are distributed fairly and responsibly. Additionally, the framework incorporates multi-actor multi-criteria analysis and utilizes advanced interactive visualization techniques to help stakeholders understand and evaluate the trade-offs among objectives. This aids in prioritizing final solutions and building consensus on sustainable practices.

Furthermore, our scalable simulation of the decision-making process demonstrates how stakeholders can learn about and negotiate trade-offs, thereby reaching a consensus on sustainable mining practices. This project contributes significantly to the field of operations research by illustrating how sophisticated analytical tools can facilitate sustainable decision-making in complex, multi-stakeholder environments.

3 - Integrating Satellite Imagery to predict and verify Supply Chain Carbon Emissions

Alexander Rose, WHU, Vallendar, Germany, Stefan Spinler

Accurate supply chain carbon emissions data is needed for successful decarbonization. However, data lacks accuracy with limited access to supplier primary information and heterogeneous calculation standards. We apply machine learning algorithms to compare and integrate satellite emissions data with public disclosures to predict and verify suppliers' emissions with increased accuracy.

4 - Advanced Satellite Scheduling Strategy for Snow Water Equivalent (SWE) Monitoring

Hadis Banafsheh, Arizona State University, Tempe, AZ, United States, Paul Grogan

Accurate monitoring and forecasting of Snow Water Equivalent (SWE) are essential for effective water resource management. Space-based observational data are sourced from two Earth Observation Satellite (EOS) types: publicly-available satellites and fee-based taskable satellites, which have unpredictable and limited availability.

This research aims to enhance the scientific value of satellite observations by implementing reward-based optimization strategies that determine the optimal timing and selection from both satellite types in the western United States. Our methodology utilizes shapefiles to define specific regions of interest and employs the SNODAS data set, a modeling and data assimilation system developed by NOHRSC1, to establish a baseline for SWE. This methodology enables the optimization of observations by calculating satellite ground tracks over designated areas, improving the effectiveness of observations to infer the true environmental state under budget limitations.

We have developed an analytical evaluation platform to compare various satellite scheduling strategies. Our study includes three scenarios: using publicly-available satellites alone, combining publicly-available and taskable satellites with an unlimited budget, and employing both satellite types under limited budget conditions with static and dynamic scheduling. Our experiment applies these strategies to satellite observations for an entire snow season. By analyzing resource utilization and observation frequency across these scenarios, we aim to demonstrate measurable improvements in the effectiveness of satellite observation scheduling. This comprehensive approach both tests theoretical models and provides practical insights into their operational viability, advancing satellite resource management and environmental forecasting practices.

5 - An Application of Multi-Objective Optimization in Green Supply Chain Network Design

Labiba Noshin Asha, University of Arkansas, Fayetteville, AR, United States, Harun Pirim, Nita Yodo, Zaidur Rahman

Purpose: This study proposes a multi-objective model to balance costs and carbon emissions in green supply chain management, aiming to simultaneously minimize total costs and carbon emissions across the entire supply chain network.

Originality:

•The multi-objective model is proposed by integrating various harvesting styles for green supply chain network design.

•A heuristic solution method is introduced, enhancing the model's applicability for both small and large-scale problems.

Approach: The study examines a supply network between crop production zones and processing plants. Using the weighted sum method, the multi-objective model is simplified. The heuristic approach effectively evaluates potential solutions, providing a practical model to enhance decision-making in green supply chain management.

Findings: The optimal solution is determined for a small-scale problem and subsequently compared with the heuristic solution. The result indicates a close proximity between the optimal and heuristic solutions for small-scale problems. Moreover, the result also shows that in more complex problem scenarios where finding the optimal solution is challenging, this heuristic approach effectively offers a practical and viable solution.

6 - DSS for Climate Mitigation Using Indifference Probabilities to Measure Impact Utilities

Kunsinee Srivichaiin, Boston University, Boston, MA, United States, Yu Gao, Kaumudi Dande

This poster focuses on the development of a decision support system to mitigate climate change impacts on a university campus. The project was funded by the Boston University (BU) Institute for Global Sustainability. The system helps a facility manager choose the best alternative among 3-5 retrofitting options. The challenge of quantifying climate risk impact is overcome by applying indifference analysis, which accounts for disruptions to operational activities and associated ripple effects. The R-Shiny web application requires a user to input the probability of the climate event, a list of mitigation options with their implementation costs, and the likelihood that the mitigation option will prevent the climate event from impacting the facility. Color-coded matrices are used to display uncertainty for indifference analyses by presenting sets of pairwise comparisons in an iterative manner using a binary search. The pairwise differences in the expected values of risk mitigation options, calculated from the indifference probabilities, are converted into option rankings utilizing the AHP methodology. The application is illustrated using a robotics laboratory facility located in a high wind risk area of the BU campus. Four risk response options were compared, including installation of windows with different design pressure rating and accepting the risk of window failure.

7 - Adapting the Inventory Routing Problem to Improve Water Delivery Scheduling for Water Insecure Households

Emerald Dudzinski, Virginia Tech, Blacksburg, VA, United States, Kimberly Ellis

Access to clean drinking water can be a luxury in impoverished communities in the United States. Nationally, more than 2 million people lack access to safe drinking water and indoor plumbing, and this figure does not include homes with a working tap of unsafe drinking water. Therefore, a far larger number of Americans face water insecurity. A recent examination of US Census and Safe Drinking Water Act violation data reveals that rural low-income and minority communities are significantly more likely to be burdened with unavailable or unsafe in-home drinking water. This research explores an alternative to traditional water infrastructure: how to optimally deliver drinking water to households without access to reliable, clean water sources by adapting the inventory routing problem (IRP) and creating heuristic algorithms to schedule efficient water delivery. The IRP and heuristics inform three key decisions: when to serve a customer, how much to deliver, and which delivery routes to use.

8 - Combining Fuzzy P-graph and Multi-Criteria Decision Making Method in the Case of Cogeneration System

TZUI TSAI, TUNGHAI UNIVERSITY, Taichung City, Taiwan, YI-HSIANG CHEN, TING YU LIN, Kuo-Ping Lin

With the increase in population and economic expansion, greenhouse gas emissions have become one of the significant factors contributing to the worsening phenomenon of global warming. Global natural resource use has already surpassed the Earth's renewable capacity. Developing cogeneration systems may be a potential solution to address the issues of energy depletion and carbon emissions. The P-graph has been widely applied to optimizing the structure of cogeneration systems. This study develops a new fuzzy P-graph method under real-world uncertainties and uses multi-criteria decision-making methods to consider the critical factors influencing cogeneration. Among the many feasible solutions, the optimal system structure is identified. Through the verification of a real-world case, it is found that the study results can provide decision-makers with comprehensive, feasible outcomes, avoiding subjective decisions by individual decision-makers regarding the system architecture. The fuzzy P-graph can handle data uncertainties, making the results more realistic.

9 - Win-win or Lose-win? Economic-Climatic Synergies and Trade-offs in Cattle Farming

Mario Guajardo, NHH Norwegian School of Economics, Bergen, Norway, Rasmus Bang, Ola Flaten, Julio Goez, Bjørn-Gunnar Hansen, Hanne Møller, Stine Samsonstuen, Jon-Kristian Sommerseth

Governments and societies strive to balance food production with environmental goals. In this context, identifying farm-level economic and climatic win-win and lose-win scenarios is essential, not only for farmers but also for policymakers and the broader society. This study aims to examine economic performance and greenhouse gas (GHG) emission intensity in combined milk and beef production on dairy farms. We present a quantitative framework to economically optimize production at farm level under various operational constraints and to calculate the corresponding GHG emissions. We apply this framework in Norway. Our results demonstrate that the effectiveness of various measures to increase economic performance and to reduce GHG emissions strongly depends on operational conditions. Moreover, they show that measures that produce win-win outcomes in some situations may result in lose-win or win-lose outcomes in others.

10 - Optimizing Vaccine Stockpiles: A Stochastic Model for Combination and Monovalent Vaccines

Ming Zhu, Rochester Institute of Technology, Rochester, NY, United States, Sheetal Aher, Ruben Proano

Vaccine shortages are one of the primary healthcare problems around the globe. Despite multiple initiatives to reduce vaccine shortages, supply interruptions are unexpected and unavoidable. To mitigate the risk of such interruptions, vaccine stockpiles have traditionally been the tool of choice. Vaccines that offer protection against more than one disease in one injection are. However, vaccine inventory models determine stockpile levels for a single product, ignoring the available supply and inventory levels of other vaccines which could partially satisfy the product's demands. This study aims to determine optimal stockpile levels for combination vaccines, considering the existing inventory of other vaccines offering subsets of their antigen content. We propose a stochastic tractable safety stock model that considers the availability of a pool of monovalent and combination vaccines in the stockpile that together can offer the same set of antigens as a vaccine that could face shortages. We contrast the recommendations from the stochastic safety stock model with a simulation and establish that the model recommendations are feasible and can effectively reduce the safety stock level, which is unique.

11 - A Quantum Optimization Algorithm for Electric Vehicle Charging Station Placement for Intercity Trips

Tina Radvand, University of Illinois at Urbana- Champaign, Urbana, IL, United States, Alireza Talebpour

Electric Vehicles (EVs) are set to revolutionize transportation by offering sustainable solutions to environmental challenges and the global energy crisis. However, their widespread adoption is hindered by inadequate charging infrastructure, which limits driving range and user convenience. Identifying optimal charging station locations in large transportation networks with minimal stations presents a well-known NP-hard combinatorial optimization problem, as the search space grows exponentially with the number of potential charging station locations.This paper introduces a quantum search-based optimization algorithm designed to enhance the efficiency of solving this NP-hard problem for both corridors and transportation networks. By leveraging parallel computation, amplitude amplification, and quantum phase estimation as a subroutine, the optimal solution is found quadratically faster than classical exact methods like branch and bound. The detailed design and complexity of a resource-efficient quantum circuit are discussed. The proposed quantum-optimization technique can also be applied to trip planning for EV drivers, providing guidance on optimal charging locations.

1 - Comparing Reformulation and Cutting Plane Methods in Solving Distributionally Robust Problems

Yiqi Tian, University of Pittsburgh, Pittsburgh, PA, United States, Bo Zeng

This study extends the well-studied reformulation and cutting-plane methods in robust optimization (RO) to distributionally robust optimization (DRO) and chance-constrained problems (DRCCP). We test these approaches on moment inequalities and Wasserstein ambiguity sets, comparing their effectiveness and efficiency in handling these distributionally robust problems. By conducting extensive comparisons, our research aims to provide a comprehensive analysis of their practical applications in uncertain environments.

2 - A Deep Variational Bayesian Approach for Modeling and Condition Monitoring of Dynamic Systems

Nadia Tanzeem, University of Miami, South Miami, FL, United States, Ramin Moghaddass

This paper introduces a Deep State-Space modeling framework tailored for monitoring complex and dynamic systems operating under varying conditions. By integrating Recurrent Neural Networks (RNNs) with generative models in a variational autoencoder form, the proposed framework effectively approximates the complex behaviors inherent in systems with latent states. Emphasizing the enhancement of system reliability with restrictive assumptions on dynamic behavior, the model excels at discerning stochastic patterns observed in both dynamic measurement data and latent states within complex degrading systems. The proposed model can capture complex temporal dependencies through RNNs and deploy advanced probabilistic techniques like ancestor sampling for robust inference. Moreover, its versatility extends to accommodating both continuous and discrete latent states, thereby enriching the representation of underlying data dynamics. Primarily, the model finds utility in latent state estimation and Time of Event prediction, critical in predictive maintenance and reliability engineering contexts. We have tested this framework using both simulations and real-world data. Also, a case study utilizing a Wind Turbine dataset further substantiates the proposed framework's effectiveness in early fault detection, thereby showcasing its broad applicability across diverse industrial settings.

3 - Designing algorithms for autonomous mobile robotic systems in package sortation centers

Yujie Sun, Singpore Management University, Singapore, Singapore

We study an autonomous mobile robotic system in the context of packages sortation center with multiple storage pods and processing stations, operating within a finite multi-period horizon. The arriving packages are interconnected, each associated with a specific delivery route. At the start of each period, our task involves selecting the pods for stowing the arriving packages at each station. At the end of each period, certain routes are called for delivery according to the delivery plan, requiring the selection of pods for retrieving packages associated with these routes. Our objective is to minimize the total travel cost of the autonomous mobile robots. We formulate an integrated packages stowage and retrieval problem over multiple periods with both deterministic and uncertain arriving packages. To make the problem tractable, we propose two approaches. In the first approach, we adopt the idea of decomposition by categorizing storage areas into several storage classes, each containing multiple pods. We first choose storage classes to stow or retrieve the packages in each period, then we select pods from the chosen storage classes for stowing and retrieving packages. In the second approach, we adjust the decision-making process by initially stowing packages to pods or retrieving them from pods without specifying the processing station. Subsequently, we determine the stations responsible for handling the stowage and retrieval. Both approaches not only yield approximate optimal solutions but also significantly reduce computational costs.

4 - Comparing the performance of the collaborative market and segmented market of ride-sharing system: A dynamic maximal weighted matching algorithm

xin dong, Pennsylvania State University, State College, PA, United States, Tingxue Gu, Jose Ventura, Vikash Gayah

Ride-sharing platforms, such as Uber and Lyft, have transformed urban transportation by reducing total travel distances and lifting vehicle occupancy rate. However, the efficiency of these platforms is often limited by market segmentation, where driver-rider matches are confined to specific platforms, potentially underestimating optimal pairings. This study employs a dynamic maximal matching algorithm to compare the efficiency of a segmented (duopolistic) market structure with that of a collaborative market. We model riders and drivers as graph vertices, with addition and deletion of dynamic weighted edges representing travel distances. The graph (ride-sharing market) is partitioned into sub-graphs corresponding to each platform and employs the dynamic maximal weighted matching algorithm to find the maximal-matching assignment within each sub-graph. Our findings demonstrate that a collaborative market significantly enhances the match and share rates within the ride-sharing system by overcoming the barriers imposed by market segmentation. Additionally, we explore how the computational performance of the dynamic maximal weighted matching algorithm varies with changes in the number of nodes and edges. These results underline the potential benefits of cross-platform collaboration in the ride-sharing industry, encouraging entities to cooperate in a competitive environment to optimize the operational efficiency.

5 - Adaptive Experimental Design: Machine Learning Directed Optimization of Additive Manufacturing for Thermoelectric Materials and Devices

Ke Wang, University of Notre Dame, Notre Dame, IN, United States, Alexander Dowling

Solid-state thermoelectric (TE) generators (TEGs) are promising for powering distributed sensor networks, biomedical devices, wearable electronics, and beyond. However, the efficiency of TEGs is limited by TE materials and their manufacturing methods. The Edisonian search, widely adopted by experimentalists to improve TE materials performance, remains expensive, slow, and unsuitable to handle large search space, e.g., $O(10^6)$. In recent years, artificial intelligence and machine learning have offered new approaches to leverage data to overcome these challenges.

This poster will focus on the data-driven optimization framework, integrating first-principle, machine learning, and Bayesian optimization to reduce the order of magnitude of fewer experiments than the Edisonian search. The application of the proposed framework for the optimization of TE materials and corresponding manufacturing methods, including material composition, 3D printing, and sintering, will be highlighted.

6 - A GNN-accelerated Heuristic for Solving Boolean Quadratic Programs

Natalie Isenberg, Pacific Northwest National Laboratory, Richland, WA, United States, Weimin Huang, Jan Drgona, Bistra Dilkina, Draguna Vrabie

Boolean Quadratic Programs (BQPs) are widely applicable in various applied domains, such as facility location and wind farm layout planning. However, solving large-scale instances of BQPs using traditional exact methods often becomes computationally impractical due to combinatoric complexity and nonconvexity. To address this, we propose a machine learning-based adaptation of the Undercover heuristic tailored for BQPs. This approach leverages the insight that fixing a subset of variables, specifically the minimum vertex cover of the Hessian graph, can simplify the problem by linearizing it, thus making it more tractable. While identifying this cover set is computationally efficient with existing algorithms, our novel contribution lies in integrating a graph neural network (GNN) within the heuristic to predict high-quality solutions for the cover variables. During inference, the trained GNN model is used to assign values to the cover variables, which are then fixed, reducing the BQP to a simpler linear sub-problem that can be solved efficiently. This method is particularly motivated by the need to solve the optimal wind farm layout problem, which can be formulated as a large-scale cardinality constrained BQP.

7 - Transistor routing algorithm in analog circuit for memory semiconductor design automation

SunJin Han, POSTECH, Pohang, Korea, Republic of, Beomhi Lee, Hyungjun Park, Byung-In Kim, Dong Gu Choi, Joonrak Kim, Hyunkyu Kim, Youjung Lee

In semiconductor manufacturing companies, the analog circuit design has been performed manually, so it is a time-consuming and error-prone task. Recently, the research on the automation of the task has been conducted actively. This study focuses on the automation of a design task that wants to minimize process variations while adhering to Common Centroid constraints and considering the importance of various evaluation metrics simultaneously. We develop a method for the task in which a rule-based approach derives diverse transistor placement results and utilizes a genetic algorithm to produce various routing results corresponding to each placement. To increase computational efficiency, the genetic algorithm initially evaluates the lower bound of fitness efficiently through analytical function. Subsequently, it selects elite sets for employing commercial solvers to derive accurate routing results. The validity of the developed algorithm is verified through test cases formulated in collaboration with industry experts.

8 - Control Policies for Telehealth Connecting Patients to Doctors

Shuwen Lu, Cornell University, Ithaca, NY, United States, Jamol Pender, Mark Lewis

This paper considers a sequential decision-making scenario in minute clinics faced by nurse practitioners (NPs) who accompany each patient through their visits. After an initial diagnosis of the patients, NPs have a decision to make on whether to continue the treatment themselves or to seek a collaborative telemedicine service with a (dedicated) general physician (GP). A Markov Decision Process (MDP) clearing system model is constructed and we are interested in a control policy that minimizes the cost of returning to the normative state after a demand spike.

Structural properties of the optimal policy have been investigated under different combinations of system parameters. The heuristics that are easily implementable given the parameter inputs are designed as approximate policies based on the observation and the proofs. The proposed heuristic policies have demonstrated their performance by showing only around 0.1\% worse than the optimal on average and outperforming the baseline policies. Finally, the insights are provided to both the decision-makers and the system designers.

9 - The Individual’s Perception of AI and Its Effects on the Organization’s AI Initiatives

Catherine Petersen, Johnson & Wales University, Mont Vernon, NH, United States

Investment in Artificial Intelligence (AI) does not result in returns for business despite improving technology. This study investigated one potential reason for the failure of AI when implemented within an organization with the intent to drive success with this technology. AI is unique amongst technologies due to its ability to inspire emotions from potential users and these emotions can affect the individual’s willingness to adopt the technology.

Using an explanatory sequential research design, this study examined the relationship between how an individual perceives AI and their willingness to accept the technology in their role within an organization. It also considered the role of experience and an individual’s perception of AI.

The results found that including AI in the description of the initiative decreased support from 81.5% to 54.8%. There was also a significant relationship between an individual’s perception of AI and their support of an initiative that specifically names AI ($p < .05$). In interviews, nine out of ten respondents discussed job replacement and showed a tension between hopes and fears with regard to the technology. No statistically significant relationship was found between an individual’s experience with AI and their perception of AI but there was a relationship between experience and their expectations for effort and performance. Interviews showed that an individual’s perception of job replacement or challenges with the technology were not affected or increased with experience using AI. Based on these findings, managers can better determine if their organizations are ready to implement AI successfully.

10 - Multiple Objective, Shortest Path-Based Running Route Optimization

John Sooter, University of Arkansas, Fayetteville, AR, United States

Runners prefer routes of an exact distance with desirable characteristics such as elevation change, pedestrian-friendly roads, and a natural setting. Finding routes that match these characteristics is important for the safety and enjoyment of a distance running routine. By capturing these attributes using OpenStreetMap data, one-to-all shortest path-based optimization can be used to generate high-quality routes as an alternative to finding routes by hand or running the same routes repeatedly. Both single and multiple objective variants of Dijkstra’s algorithm are explored to generate out-and-back running routes. Selecting the candidate destination nodes based on a radial distance criterion, we can guarantee the lower bound of feasible solutions to be the shortest path distance, then trimming routes if necessary to the exact desired distance. This approach has been implemented to power a web-based, route recommendation software that allows for the identification of preferences, selection of a route from a set of alternatives, and export of the route in the .gpx format for use with smartwatches.

11 - On-demand service capacity planning: a bi-level approach

Seokwoo Kim, Pohang University of Science and Technology (POSTECH), Pohang-si, Korea, Republic of, Seung Min Baik, Dong Gu Choi

This study addresses the capacity planning problem in on-demand service systems. Unlike conventional service systems, capacity uncertainty arises in the on-demand service systems due to high autonomy in servers. Recent on-demand platform studies have investigated strategic behaviors of servers based on game-theoretic approach. Expanding upon both traditional planning model and game-theoretic behavior model, this study proposes an integrated service capacity planning model by incorporating interactions among servers, as well as between servers and operators. The proposed model is formulated into a bi-level program with a single-leader multiple-follower structure. A pessimistic approach is chosen to mitigate the multiple equilibrium points. We show that the proposed bi-level model can be formulated as a two-stage stochastic copositive program.

12 - Three essays on multiple orders per job (MOJ) scheduling problems in two-stage permutation flowshop

Rohan Korde, Arizona State University, Tempe, AZ, United States, John Fowler, Lars Moench

My dissertation research (organized as three essays) focuses on machine scheduling problems encountered in a 300-mm wafer fabrication (fab) facility where semiconductor chips are manufactured in reentrant process flows on hundreds of tools. Front opening unified pods (known as FOUPs or jobs) transport 300-mm silicon wafers between the different tools using an automated overhead hoist transportation system (OHT). The number of FOUPs are typically far fewer than the number of customer orders received. In some cases, customer orders can be combined into the same FOUPs depending on certain factors. The FOUPs are then scheduled to be processed on tools to minimize a given performance measure. These scheduling problems are known as "multiple orders per job" (MOJ) problems and are the focus of my dissertation research. The first essay covers single objective MOJ scheduling problems to minimize makespan, total completion time, and total weighted completion time for orders with equal and unequal release times in a two-stage permutation flowshop. The second essay covers single objective MOJ scheduling problems to minimize maximum lateness, number of tardy orders, weighted number of tardy orders, total tardiness, and total weighted tardiness for orders with equal and unequal release times in a two-stage permutation flowshop. The third essay covers multiobjective MOJ scheduling problems to minimize pairs of uncorrelated performance measures for orders with equal and unequal release times in a two-stage permutation flowshop. In these essays we design full-factorial experiments to check optimality (small-sized instances) and solution quality (large-sized instances).

13 - A Stability Principle for Learning under Non-Stationarity

Chengpiao Huang, Columbia University, New York, NY, United States, Kaizheng Wang

We develop a versatile framework for statistical learning in non-stationary environments. In each time period, our approach applies a stability principle to select a look-back window that maximizes the utilization of historical data while keeping the cumulative bias within an acceptable range relative to the stochastic error. Our theory showcases the adaptability of this approach to unknown non-stationarity. The regret bound is minimax optimal up to logarithmic factors when the population losses are strongly convex, or Lipschitz only. At the heart of our analysis lie two novel components: a measure of similarity between functions and a segmentation technique for dividing the non-stationary data sequence into quasi-stationary pieces.

14 - Modeling TiA in Teams: Leveraging Acoustic and Lexical Features in Dynamic Trust Estimation

Morgan Klaeser, University of Wisconsin-Madison, Madison, WI, United States, Vianney Renata, John Lee

Traditionally, trust in automation has been characterized as a function of an individual's cumulative experience. Recent research highlights the role of team environments in shaping dynamic trust. Teams foster feedback loops and cultivate affective environments that influence cognitive processes underlying trust in automation.

This study assesses the suitability of a Bayesian Hierarchical Potts model in capturing trust dynamics within teams, using acoustic and lexical features to describe the team environment. The Potts model, from statistical mechanics, represents systems with interacting components and can capture phase transitions and clustering behavior. Inspired by prior work on the NASA Hera Study, we estimate trust dynamics in team contexts.

We analyze six weeks of naturalistic audio data from teams using an automated conversational agent during mission practice, examining experimental and social conditions linked to trust outcomes. Acoustic and lexical features describe the team environment, influencing the phase an individual occupies within the model. Likert scale ratings correspond to distinct phases, representing varying trust levels.

Our findings use a novel methodology for long-term trust characterization, quantifying the role of affective environments in cognitive trust formation. We show how social-emotional environments significantly impact trust in automation. Ignoring such a social environment risks latent variable bias in trust dynamics.

By quantifying the relationship between trust and team environment, our study offers insights for designing feedback systems to enhance team performance and ensure mission success. These insights extend to other environments where trust in automation is crucial, promoting smarter decision-making and a safer integration of automation in society.

15 - ESG Data Imputation and Greenwashing

Giulia Crippa, Princeton University, Princeton, NJ, United States

In recent years, there has been a notable surge of Environmental, Social, and Governance (ESG) investing. This paper provides a simple and comprehensive tool to tackle the issue of missing ESG data. Firstly, it allows to shed light on the failure of ESG ratings due to data sparsity. Exploiting machine learning techniques, we find that the most significant metrics are promises, targets and incentives, rather than realized variables. Then, data incompleteness is addressed, which affects about 50% of the overall dataset. Via a new methodology, imputation accuracy is improved with respect to traditional median-driven techniques. Lastly, exploiting the newly imputed data, a quantitative dimension of greenwashing is introduced. We show that when rating agencies do not efficiently impute missing metrics, ESG scores carry a quantitative bias that should be accounted by market players.

16 - Looking into the future: Job insecurity and future work selves as a moderator

Vivien Lim, National University of SIngapore, Singapore, Singapore, Thompson Teo

Studies across various fields have established the importance of positive possible selves in influencing a wide range of individual behaviors, from reducing in-school misbehaviors to increasing the frequency of engaging in exercise (e.g.,Oyserman et al., 2006). Due to the changing employment landscape, there is a growing scholarly interest in the study of possible selves specific to the work domain (Strauss, Griffin, & Parker, 2012). Termed future work selves, these possible selves embody individuals' hopes and aspirations with respect to their future careers.

The current study examined the motivational value of the future work self in the context of a work-related stressor, specifically job insecurity. We examined the moderating effect of salient future work selves and job insecurity on work-related outcomes among mid-career individuals. Data from this study were collected from 182 police officers and their immediate supervisors. Findings largely supported the importance of salient future work selves in buffering individuals from the negative effects of adversities, through increasing their motivation and confidence to overcome challenging situations.

In investigating the utility of the future work selves as a psychological resource in the job insecurity context, this study has important practical implications for employees as it provides evidence of future work selves as a valuable resource which individuals can draw upon when their job security is threatened. As individuals are increasingly required to manage their own careers, the future work self is an exciting construct that can help employees regulate their behaviors through stressful times.

17 - Effects of Heterogenous Decisionmakers in Disrupted Supply Chains

Souri Sasanfar, Northeastern University, Boston, MA, United States

Title:

"Effects of Heterogenous Decisionmakers in Disrupted Supply Chains"

Disruptions to the supply chain present serious problems, especially in the pharmaceutical industry where reliable and effective delivery is essential. This study examines the effects of decision-maker heterogeneity on supply chain performance during different types of disruptions, with a particular emphasis on three important profiles: followers, hoarders, and reactors. To study the dynamic interactions between these decision-makers and two important information sharing formats, Automated System Information (ASI) and Automated Demand Information (ADI), we created an agent-based simulation model.

The simulation looks at how different decision-maker types react to supply chain interruptions and how their actions interact with ADI and ASI to impact performance. By lowering supply chain expenses, panic purchases, and phantom ordering, the study seeks to determine which information sharing practices could enhance performance and offer suggestions for the best kinds of ADI and ASI for pharmaceutical supply chains.

The goal of the research is to provide a comprehensive understanding of the actions and tactics used by various decision-makers, along with recommendations for improving collaboration and decreasing inefficiencies. By doing so, stability in this important industry will be ensured and pharmaceutical supply chains will become more robust and effective.

18 - Anomaly Detection in Connected and Autonomous Vehicle Trajectories Using LSTM Autoencoder and Gaussian Mixture Model

Boyu Wang, Beijing University of Civil Engineering and Architecture, Beijing, China, People's Republic of, Wan Li, Zulqarnain Khattak

Connected and Autonomous Vehicles (CAVs) technology has the potential to transform the transportation system. Although these new technologies have many advantages, the implementation raises significant concerns regarding safety, security, and privacy. Anomalies in sensor data caused by errors or cyberattacks can cause severe accidents. To address the issue, this study proposed an innovative anomaly detection algorithm, namely the LSTM Autoencoder with Gaussian Mixture Model (LAGMM). This model supports anomalous CAV trajectory detection in the real-time leveraging communication capabilities of CAV sensors. The LSTM Autoencoder is applied to generate low-rank representations and reconstruct errors for each input data point, while the Gaussian Mixture Model (GMM) is employed for its strength in density estimation. The proposed model was jointly optimized for the LSTM Autoencoder and GMM simultaneously. The study utilizes realistic CAV data from a platooning experiment conducted for Cooperative Automated Research Mobility Applications (CAR-MAs). The experiment findings indicate that the proposed LAGMM approach enhances detection accuracy by 3% and precision by 6.4% compared to the existing state-of-the-art methods, suggesting a significant improvement in the field.

19 - A unified uncertainty-informed approach for risk management of deep learning models in the open world

Long Xue, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Sai Ho Chung, Lechang Yang, Xiaolin Wang, Xiaoge Zhang

Equipping deep learning models with a principled uncertainty quantification (UQ) has emerged as a cornerstone for safe and reliable adoptions of deep learning models in the open world. To handle uncertainty arising from two prevailing sources - distribution shift and out-of-distribution (OOD) - in the open-world setting, this paper develops a unified uncertainty-informed approach to assess and manage the risk of deep learning models. To this end, we propose to leverage a principled UQ approach – Spectral-normalized Neural Gaussian Process (SNGP) – to quantify the epistemic uncertainty associated with the model's predictions. Different from other UQ methods in the literature, the SNGP features two unique properties: (1) normalizing the weights of each hidden layer with spectral normalization to preserve the relative distance among samples during feature transformations; (2) replacing the traditional output layer in the neural network with Gaussian process for distance-aware uncertainty estimation. Based on SNGP, we divide the uncertainty into three levels by setting appropriate uncertainty thresholds to help decision-makers make risk-informed decisions. A case study on diabetes prediction is used to demonstrate how the proposed method facilitates risk assessment and management of deep learning models in the open environment. Computational results reveal that the proposed method achieves a prediction performance comparable to Monte Carlo dropout and deep ensemble methods. More importantly, the proposed method produces much more consistent and principled uncertainty estimations under no distribution shift, distribution shift, and OOD than the other methods in the literature.

20 - Color-Coding the Hydrogen Renaissance through a Prism of Hydrogen Production Technologies: Technology selection scenario analysis through bottom-up model construction

ChaeHyeon Kim, Seoul National University, Seoul, Korea, Republic of, Yoonmo Koo

As the era of hydrogen arrives, an innovative approach is needed to systematically prepare and promote the hydrogen Renaissance. This paper highlights the importance of hydrogen production technology during this transition period and analyzes its complexity by classifying various existing hydrogen production technologies by color. In this study, a bottom-up technology selection simulator named "Prism" is developed to analyze the selection weight of each technology under various scenarios, encompassing major hydrogen production technologies such as gray, blue, green, and yellow.

The innovation of this paper is to derive spectral results based on input data for each scenario in color form through the "prism" simulator. This method allows visual identification of the most suitable proportion of hydrogen production technologies under given conditions and scenarios through the colors representing each hydrogen production technology. This provides intuitive and clear guidelines for policymakers and industry in establishing sustainable hydrogen production strategies.

As a result, this study presents an innovative method of color-expressing the optimal technology combination and strategies for sustainable hydrogen production by comprehensively comparing and analyzing various aspects of hydrogen production technology. This study is expected to effectively visualize the economic, environmental, and technical characteristics of each technology and make an important contribution to establishing a policy direction for the sustainable development of hydrogen production technology through the application of a color code system that encompasses existing major hydrogen production technologies.

21 - How the Domain-Adaptation Language Model Works in Government Domain Section

jiwon kim, Kyung Hee University, Seoul, Korea, Democratic People's Republic of, Sunghyun Yoo, Sangjun Lee, yurianna Kim, Jae Hong Park

According to an industry survey, 55 percent of people lost their opportunities to apply for the programs because they don't know how to apply and what to need. Specially, people need to search and manually check whether such programs are fitted with them. In addition, many users have a difficulty to find information about what types of beneficiaries in the policy documents. Recently, a language model is regarded as a great tool and has shown a great performance in various tasks including document summarization (e.g., question-answering, summarizing, and understanding passages) to help people understand easily. So, we argue that using language model can give important information and opportunity to people who don't know how to apply a program. We believe that the language model with domain adaptation will make people to search clear information easily. So, this study proposes the language model to deeply understand the policy documents so that out model can help people search them easily. To do so, this study use government policy documents and domain NER data to train tokenizer and language model. In particular, this study develops the Auto Encoder language model 110,589 public policy data set. Our results, shows that domain adaptation significantly improves model performance. So, we believe that this study can contribute to the related literature in which this study conducts the tasks in government policy domain. Also, we believe that many people can easily search and find government subsidy documents to get more benefits.

22 - Data Utilization for Operational Efficiency and Customer Satisfaction in Gas Appliance Repair Services

Yuichiro Tanaka, TOKYO GAS CO.,LTD, Tokyo, Japan

Tokyo Gas Group serves around 9 million customers in the metropolitan area with electricity, gas, and services. Following the liberalization of Japan's electricity and gas retail markets in 2016 and 2017, expanding services beyond energy retail has become increasingly important.

TGG handles approximately 300,000 repair jobs annually for gas equipment. The reliance on individual skills in repair operations caused variability in service levels, leading to issues such as revisits to customer homes due to missing repair parts. This inconsistency indicates room for improvement in both operational efficiency and customer satisfaction.

To address these challenges, TGG overhauled the entire repair service and implemented data-driven operational transformations. We will introduce three key initiatives:

1. **Predict Fault Parts Before Visits**
- By developing a model to predict repair parts before visits, we significantly improved prediction accuracy over the current model. This suggests a potential to exceed the KPI of One-Time Completion Rate by 8 to 26 percentage points.

2. **Optimize Store Inventory Management**
- Using machine learning and statistical methods, we optimized inventory management. This indicated the potential to improve the Repair Parts Availability Rate by 30 percentage points and reduce excess inventory.

3. **Monitor Customer Satisfaction**
- Customer satisfaction was enhanced by monitoring and analyzing post-repair surveys. This resulted in a 5-point improvement in overall service satisfaction within one year.

23 - Defining abnormal trends and identifying abnormal wafers using object detection methods

kuhyun lee, Sungkyunkwan University, suwon, Korea, Republic of, Dong-Hee Lee

In a semiconductor wafer fabrication process, it is critical to identify abnormal wafers and to analyze the causes to improve the process. Because a massive number of wafers are fabricated, a large number of wafers are often inspected at the same time. In this case study, we assume a quality control system which displays quality inspection results of several wafers in a single chart. The purpose of this study is to define abnormal trends observed from the charts and further identify abnormal wafers that contribute to the trends. For this purpose, we employed object detection methods such as YOLO. Once the abnormal wafers are identified, their process log data are analyzed by the quality inspection system, so-called commonality analysis, to identify faulty machines that may have resulted in the abnormal wafers. The case study proved that the proposed definition of the abnormal trend is valid and the abnormal wafers identification method works well.

24 - BBScore: A Brownian Bridge Based Metric for Assessing Text Coherence

Chen Jiang, University of Minnesota, Minneapolis, MN, United States, Zhecheng Sheng, Tianhao Zhang, Dongyeop Kang

Measuring the coherence of text is a vital aspect of evaluating the quality of written content. Recent advancements in neural coherence modeling have demonstrated their efficacy in capturing entity coreference and discourse relations, thereby enhancing coherence evaluation. However, many existing methods heavily depend on static embeddings or focus narrowly on nearby context, constraining their capacity to measure the overarching coherence of long texts.
In this paper, we posit that coherent texts inherently manifest a sequential and cohesive interplay among sentences, effectively conveying the central theme, purpose, or standpoint. To explore this abstract relationship, we introduce the "BBScore," a novel reference-free metric grounded in Brownian bridge theory for assessing text coherence. Our findings showcase that when synergized with a simple additional classification component, this metric attains a performance level comparable to state-of-the-art techniques on standard artificial discrimination tasks.
We also establish in downstream tasks that this metric effectively differentiates between human-written documents and text generated by large language models under a specific domain. Furthermore, we illustrate the efficacy of this approach in detecting written styles attributed to diverse large language models, underscoring its potential for generalizability. In summary, we present a novel Brownian bridge coherence metric capable of measuring both local and global text coherence, while circumventing the need for end-to-end model training. This flexibility allows for its application in various downstream tasks.

25 - RealTwin: An Automated Scenario Generation Tool for Traffic Simulation

Guanhao Xu, Oak Ridge National Laboratory, Oak Ridge, TN, United States, Abhilasha Saroj, Ross Wang, Yunli Shao

Traffic simulation has been a valuable approach for urban planners, traffic engineers, and researchers to study traffic. Particularly, microscopic traffic simulation, which simulates individual vehicles' movements within a transportation network, has demonstrated its importance in analyzing and managing transportation systems. However, it has always been a challenge to integrate data from various sources, generate traffic scenarios, and import it into traffic simulators to conduct microscopic simulations. This paper provides solutions to overcoming this challenge. Specifically, RealTwin, a comprehensive tool for automated scenario generation for microscopic traffic simulation is presented in this paper. By providing a streamlined scenario generation workflow, RealTwin effectively bridges gaps between traffic data from various sources and traffic simulators, making microscopic traffic simulation more accessible for researchers and engineers across various levels of expertise. By using RealTwin to generate a real-world traffic scenario in AIMSUN and SUMO, the ability of RealTwin to construct comparable simulations in different simulators that lead to consistent simulation results is demonstrated. Furthermore, we introduce and illustrate RealTwin's extended capability for technology (e.g. autonomous vehicle) scenario generation. This extended feature can contribute to more comprehensive microscopic simulations, facilitating the analysis of the potential impacts of various technological innovations on mobility, energy efficiency, and safety.

26 - Optimizing Active Distribution Grids with Weather- and Decision-Dependent Reliability

Gejia Zhang, Rutgers University, Piscataway, NJ, United States, Robert Mieth

The reliability of power systems is critically influenced by weather conditions, which directly affect the operational integrity of physical infrastructure and electricity consumption patterns. Emerging smart grid technology enables system operators to react to temperature fluctuations, but tools to quantify and internalize failure risk on a component-level in operative decisions are still lacking. In this work we develop a distribution system model to optimize the control set-points of distributed generation units, battery energy storage systems, and demand response resources, that explicitly considers weather- and decision-dependent system reliability. Through decision-dependent reliability, our model captures how operational decisions and ambient temperature impact the likelihood of component failures, allowing operators to directly balance cost efficiency and reliability. To address the non-linear and non-convex optimization challenges of the model, we develop an iterative optimization strategy using linearization techniques around initial reliability estimations derived from a baseline scenario. We demonstrate our model and methodology using numerical case studies on IEEE test systems.

27 - Integrated supplier performance risk tool

chaoye pan, Ford Global Data Insight & Analytics, Northville, MI, United States, Oleg Gusikhin

For automotive industries, many potential threats are associated with working with suppliers, like quality issues, delivery disturbance, financial instability, and more. By identifying and assessing these risks upfront, implementation of an internal & external supplier performance risk management process will ensure supplier performance is embedded in end-to-end supply chain development & fulfillment activities. ISPR brings together QDC + Concentration & Compliance metrics in a single view to develop risk profiles for champions to understand the key risk and performance indicators associated, predictive analytics based on available internal & external supplier information and centralized location to prioritize case management, tracking and follow-up.

28 - SANO: a Sterilization Resource Allocation Tool via Network Optimization

Yuming Yang, Johnson & Johnson, Raritan, NJ, United States, Hanzhang Liu

In MedTech industry, a substantial portion of products undergo sterilization using Ethylene Oxide (EO) which is subject to stringent environmental regulations. Managing sterilization site capacity, optimizing utilization, and allocating products in the hierarchical supply chain network becomes critical to Multinational Corporations, given their global presence, production scale, and operation complexity. However, the traditional method of manual planning to configure network flow is suboptimal and uneven, resulting in extremely high utilization at certain sites while others are vacant. It is not only impractical for the long term, but also challenging to implement among teams when various business segments share capacity, leading to low efficiency and a lack of holistic perspective.

To address these supply chain challenges, we propose SANO: a Sterilization Resource Allocation Tool via Network Optimization. Specifically, we design a customized network optimization model in Python that accounts for real-life operational constraints and objectives. Furthermore, we deploy the model in a cloud-based environment and develop a user-friendly web interface with interactive dashboards, enabling scenario exploration and analysis to users without optimization background. Evaluation of real-world scenarios demonstrates a significant reduction of 50% in planner workload and complete elimination of capacity shortage, alleviating network bottleneck. Providing global optimal results, this solution minimizes total network costs, EO usage, and wastage. It also supports informed business decisions and aids in establishing a competitive and proactive supply chain network.

29 - Courier scheduling in last-mile delivery considering show-up rate dynamics and job proficiency

Yuin Moon, Pohang University of Science and Technology (POSTECH), Pohang, Korea, Republic of, Seokwoo Kim, Dong Gu Choi

In this study, we consider a courier scheduling problem for last-mile food delivery systems, considering characteristics of couriers; 1) uncertainty in the actual participation of scheduled couriers, 2) differences in job proficiency between couriers, and 3) uncertainty in customer demand. We formulate a two-stage mixed-integer stochastic programming model for our problem. The first stage presents the schedule of couriers during the planning phase, and the second stage comprises the adjustment decision during the operational phase. We develop a solution approach based on the progressive hedging algorithm. Furthermore, the effectiveness of the proposed model is validated using simulated environments based on real-world data.

30 - Development of an Integrated Mode and Route Choice Model for Shared Mobility in Minnesota

Mobina Nankali, University of Minnesota, Minneapolis, MN, United States, Micheal Levin

Shared mobility changes traffic congestion, infrastructure use, accessibility, and emissions. Predicting these changes is necessary for urban planners and policymakers to improve traffic management systems and strategize incorporating shared mobility into the existing infrastructure. By integrating a logit choice model with a user equilibrium (UE) model, the study addresses the growing complexities introduced by shared transportation options such as transportation network companies, bike sharing, and car sharing. The proposed model considers the fleet size limit as a constraint for certain modes of transportation. A function is introduced as a penalty added to the objective function to address this constraint. This approach separates the problem into two optimization problems, with the first one being a user equilibrium that is solved by a Bush-based algorithm. Findings from the model demonstrate its capability to accurately forecast changes in travel behavior and traffic patterns, highlighting the potential reductions in vehicle travel and greenhouse gas emissions through the adoption of bike sharing and electric car sharing.

31 - A link transmission model of eco-approach autonomous vehicles in mixed platoons to predict the impacts on energy consumption in city networks

Maziar Zamanpour, University of Minnesota, Twin cities, MN, United States, Michael Levin

Automated vehicles (AVs) have become highly valued due to the numerous potential benefits in transportation systems. AVs have unveiled promising opportunities to enhance safety, mobility, and efficiency. Utilizing technology and connectivity, speed control strategies have led to major energy efficiency by avoiding abrupt deceleration-acceleration cycles which we refer to as eco-approach AVs. Although speed control presents well-established energy benefits for AVs in limited scenarios, applying eco-approach speed control for AVs also affects any following human-driven vehicles (HVs) that are forced to drive at similar speeds.

This study is the first attempt to predict the network-level energy benefits of eco-approach AVs, including fuel benefits to HVs. A modified link transmission model (LTM) obtains traffic flow for each link in the network influenced by eco-approach AVs. HVs are modeled as either passing slower-moving eco-approach AVs or following their speed (and achieving speed benefits). An approximated but computationally faster speed control strategy is presented to mimic the eco-approach control (which typically involves solving model predictive control). A parametric longitudinal load model that incorporates the principles of vehicle dynamics estimates energy consumption which is reported for various AV penetration rates and also HVs. Moreover, since connected intersections play a crucial role in transmitting information for eco-approach AVs, we study the route choice of AVs for a limited number of equipped intersections (due to budget constraints). In addition to AVs, route choice and mobility for HVs are also compared for a test network.

32 - How to Compete with AI-Generated Contents?

Seyed Esmaeili, University of Chicago, Chicago, IL, United States

Generative AI will have significant impact on content creation platforms. In this paper, we study the dynamic competition between an AI and a human contributor. Unlike the human, the AI's content only improves by having access to more samples, however the AI has the advantage of generating content at a low cost. Given this model we study how the human contributor can maximize his utility when competing against the AI for content generation over a collection of topics. Specifically, we consider a long horizon setting and show a novel polynomial time algorithm to maximize the human creator's utility. In addition, we consider a setting where the samples have to be ``fresh" for high quality AI generation which is the case in many topics such as news and weather. Interestingly, we show that the problem of maximizing the human creator's utility in this setting is NP-hard. For this setting, we introduce a simple polynomial time algorithm that cycles between myopically optimizing over a short time window and pausing and show that it essentially has an approximation ratio of 0.5.

33 - Co-purchaser Choice in Threshold Group-Buying: Empirical Study with Panel Survival Analysis and Logit Model

JOOHWAN KIM, Kyung Hee University, Seoul, Korea, Republic of, yongjoon kwon, JAEHONG PARK

A group-buying is a method of purchasing goods together with a discounted price at platforms. In the group-buying platform, users can choose two roles – initiator or co-purchaser. The initiator starts the group-buying deal to buy goods together in the platform while the co-purchaser participates in the deal which the initiator already created. Since the deal can only be completed when the co-purchaser joins the deal, the participation of co-purchasers is essential to complete a deal on group-buying platforms. So, the success of the deal depends on the co-purchasers' choice. However, previous studies focus on the motivation of why people join the group-buying deals regardless of their roles - initiator or co-purchaser. Specially, few studies have examined the role of co-purchasers even though the co-purchasers are more important to complete the deal. So, this study investigates what factors make co-purchasers to join the deal with panel survival models. Specially, we examine the impact of the left time of the deal on co-purchasers' choice, which lead to the success of group-buying deals. Using real-time log data sets from one of the largest group-buying platforms in South Korea, we empirically show that the left time of the deal has a negative impact on its success of group-buying deals. Although the left time of the group-buying deals do not provide any utilities to the co-purchaser, we find that co-purchasers often join the deals with less time left. We suggest that co-purchasers might be motivated to purchase earlier due to their sense of urgency.

34 - Quality-based scheduling in a multistage manufacturing process using Monte Carlo tree search method

Sugyeong Lee, Department of Semiconductor and Display Engineering, Sungkyunkwan University, Suwon-si, Korea, Republic of, Dong-Hee Lee

In multistage manufacturing processes, quality can vary significantly depending on the chosen path, due to the difficulty of ensuring uniform product quality from each piece of equipment. We introduce the use of Monte Carlo tree search (MCTS) method to consider quality in addition to productivity in the path selection process. Specifically, we propose a method to incorporate both short-term and long-term benefits as rewards in the MCTS model by utilizing main effects and interaction effects from traditional experimental designs, to produce paths that maximize yield. This approach is expected to allow optimal scheduling while ensuring quality even in large-scale multistage process environments where conventional methods may struggle to estimate quality outcomes.

35 - <div max-w-[90%]"="">Optimal Battery Utilization and Swapping Service Level through Balanced Battery Inventory and Replenishment for an Electric Vehicle Battery Swapping Station Network

Reza Alizadeh, Magna International, Boston, MA, United States

Establishing an ample charging infrastructure is pivotal for the successful deployment of electric vehicles (EVs), mitigating concerns associated with restricted range and extended charging durations. Battery exchange stations arise as a promising remedy to alleviate these waiting periods. These stations act as intermediaries between the power grid and consumers, presenting a rapid alternative to recharging batteries. Ensuring their efficacy and profitability necessitates a robust business and operational model. This endeavor introduces an optimization framework for the operational structure of battery swapping stations, emphasizing balanced battery inventory management. The framework offers features like flexible battery restocking from depots and equitable battery inventory distribution among charging stations. The battery float percentage and battery utilization rate are augmented, eliminating unmet demand and minimizing the overall shipment cost. The findings demonstrate the feasibility of the proposed model as a business case, as well as its efficacy in delivering the necessary service.

36 - Patched Vulnerability Disclosure and Hacker Participation in Bug Bounty Programs

Ali Ahmed, Louisiana State University, Baton Rouge, LA, United States

In cybersecurity, bug bounty programs (BBP) have emerged as an effective method of finding hidden vulnerabilities in a system. In this method, ethical hackers discover and report hidden vulnerabilities to the organizations. In return, these hackers receive rewards for their valid discoveries. The emergence of bug bounty programs has enabled the practice of Patched Vulnerability Disclosure (PVD), where firms disclose vulnerability information after they have been patched. Currently, there is little understanding of how PVD affects ethical hackers' participation in BBPs. We collected a dataset from a leading bug bounty platform and conducted empirical analyses to analyze the effect of PVD on hacker participation. Leveraging multiple specifications, including an instrumental variable approach, difference-in-differences, and data collected from third-party websites, our analysis reveals that as firms disclose more patched vulnerabilities, hacker participation in their programs decreases. To further explore the mechanism, we found that disclosing valid vulnerability reports discourages hacker participation, whereas disclosing invalid reports leads to more hacker participation. We found that PVD influences uncertainty in the bug bounty process, which can simultaneously impact the risk and ambiguity in hacking. Valid disclosures can escalate hackers' risk and discourage participation, whereas disclosing invalid submissions can reduce the ambiguity in the bug bounty process and increase the hacker's participation in BBP. We also found that reduced ambiguity is most salient for hackers with experience working with other firms on the platform. Overall, our study makes theoretical contributions to the literature on vulnerability disclosure, ethical hacking, and the management of bug bounty programs.

37 - Methods, Analysis, and Insights from a State-Of-The-Art Large Glucose Model

Abhimanyu Kumbara, Welldoc, Inc., Columbia, MD, United States, Junjie Luo, Anand Iyer, Mansur Shomali, Guodong Gao

Proactive self-management of diabetes requires accurate glucose value prediction and automated, in-the-moment AI-driven coaching based on those predictions. We created a large glucose model (LGM) trained exclusively on millions of glucose values from continuous glucose monitoring devices (CGM). This model can achieve state-of-the-art (SOTA) results in predicting glucose trajectories in type-1 and type-2

diabetes (T1D, T2D) populations at 30min, 60min, and 2-hour time intervals. In the current analysis, we developed a new SOTA LGM that used both glucose values and time series inputs to predict glucose trajectories at the time intervals above. We also analyzed the results of the LGM across different population subgroups.

When comparing the average root mean square error (RMSE) in T1D and T2D populations associated with the hour of the predicted glucose values, the LGM performed better when predicting glucose trajectories between 12am – 5am, with RMSE increasing during breakfast (6am – 10am), lunch (12pm – 3pm), and dinner (5pm – 9pm). For the T1D population, the RMSE of the model was inversely correlated with age group, and for T2D population, the RMSE of the model was positively correlated with age group. When looking at total engagement levels across medication, education, diet, activity, and labs (MEDAL) categories, engagements between 20-30 entries per month minimized the RMSE for both populations. Analysis and insights from LGM enable us to understand subgroup level differences in managing diabetes and can be used to develop smarter personalized coaching applications that can ultimately be used to improve health outcomes.

38 - Distributed Learning Dynamics for Coalitional Games

Aya Hamed, University of Illinois Urbana-Champaign, Champaign, IL, United States, Jeff Shamma

In the framework of transferable utility coalitional games, a scoring (characteristic) function determines the value of any subset/coalition of agents. Agents decide on both which coalitions to form and the allocations of the values of the formed coalitions among their members. An important concept in coalitional games is that of a core solution, which is a partitioning of agents into coalitions and an associated allocation to each agent under which no group of agents can get a higher allocation by forming an alternative coalition. We present distributed learning dynamics for coalitional games that converge to a core solution whenever one exists. In these dynamics, an agent maintains a state consisting of (i) an aspiration level for its allocation and (ii) the coalition, if any, to which it belongs. In each stage, a randomly activated agent proposes to form a new coalition and changes its aspiration based on the success or failure of its proposal. The coalition membership structure is changed, accordingly, whenever the proposal succeeds. Required communications are that: (i) agents in the proposed new coalition need to reveal their current aspirations to the proposing agent, and (ii) agents are informed if they are joining the proposed coalition or if their existing coalition is broken. The proposing agent computes the feasibility of forming the coalition. We show that the dynamics hit an absorbing state whenever a core solution is reached. We further illustrate the distributed learning dynamics on a multi-agent task allocation setting.

39 - Transparent differential diagnosis using ensemble of simple structures models

Gaurav Arwade, Iowa State University, AMES, IA, United States, Sigurdur Olafsson

Heart failure remains a prevalent global health concern, with 6.5 million diagnosed cases in the United States alone and an annual increase of 960,000 new cases. The complexity of this clinical syndrome, often intertwined with various comorbidities, presents challenges in accurate diagnosis. Factors such as cardiac dysfunction stemming from conditions like ischemic heart disease, atrial fibrillation, valvular heart disease, and uncontrolled systolic blood pressure can contribute to undiagnosed heart failure. Conversely, symptom overlap with related conditions such as obesity and respiratory diseases can lead to both over and misdiagnosis, particularly in primary care settings where resources for comprehensive evaluation are limited. Breathlessness is one of the common symptoms between heart failure and its differential diagnosis; thus, primary patients presenting this symptom can be misdiagnosed. Predictive models may help improve diagnostic accuracy, but in this domain transparency and explainability of the models is also critical. To address these diagnostic challenges, we propose an ensemble approach utilizing simple models constructed upon underlying data structures. These models leverage subsets of patients exhibiting similar characteristics, where redundant complex feature interactions are minimized. While deep learning and complex algorithms like XGBoost have demonstrated impressive diagnostic performance, their lack of explainability has led to skepticism among physicians regarding recommendations from 'black box' algorithms. Our approach offers improved explainability without compromising accuracy, making it more accessible and trustworthy for clinicians. By harnessing the inherent simplicity within the data, our ensemble of simple models suggests a pragmatic solution for accurate heart failure prediction in primary care settings.

40 - Minimax Rate Optimal Algorithms for High-Dimensional Stochastic Linear Bandits

Jingyu Liu, Queen's University, Kingston, ON, Canada, Yanglei Song

We consider the stochastic linear bandit problem with multi-arms over T rounds, where the dimension d of the covariate vectors is potentially larger than T, however each arm-specific parameter vector has at most s_0 non-zero components. First, we study the single-arm case, focusing on the cumulative estimation error of the parameter vector. We show that Lasso has a sub-optimal dependence on d,T in terms of worst-case error in the online estimation setup. Further, we establish the minimax optimality of the OLS post Lasso, which first estimates the support of the parameter vector by thresholding the Lasso estimator and then runs least squares on the selected support. Second, we consider the bandit setup, using the OLS post Lasso as the main estimation method. We propose a three-stage algorithm for arm selection and derive an upper bound of order $s_0 (\log s_0) (\log d + \log T)$ on its cumulative regret. Finally, we establish a matching lower bound up to a $\log s_0$ multiplicative term, which shows the near minimax optimality of the proposed method. We note that our analysis avoids the restrictive "beta-min" condition.

41 - Enhanced Detection of Unknown Defect Patterns on Wafer Bin Maps Based on Open-Set Recognition Approach

jinsu shin, Department of Semiconductor and Display Engineering, Sungkyunkwan University, Suwon-si, Korea, Republic of, Dong-Hee Lee

Detecting and classifying defect patterns on wafers in semiconductor manufacturing processes is crucial for wafer quality management and prompt analysis of defect causes. However, due to the continuous technological innovation and advancement in semiconductor industry processes, the likelihood of unknown defect patterns emerging is increasing. These unknown defect patterns present a challenge that traditional classification and clustering methods, relying solely on existing training data, struggle to effectively address. To overcome this challenge, this study proposes a novel methodology based on Open-Set Recognition (OSR) using EEOC-SVM (Entropy Estimation One-Class SVM) to accurately detect unknown defect patterns. This methodology introduces unique preprocessing steps, including C-Mean filtering and Radon transformation, to remove noise and efficiently extract features from wafer bin maps (WBM). Through this approach, the study demonstrates the successful detection of unknown defect patterns in test data using only known defect pattern data. These results validate the proposed method as a robust tool for effectively detecting and addressing unexpected defect patterns, thereby expecting to significantly impact quality management and maintenance in future semiconductor manufacturing processes.

42 - Optimal Sensor Placement Using Denoising Autoencoder and Discrete Optimization for Heat Transfer Digital Twins

Chaeyun Yeo, Kyung Hee University, Department of Artificial Intelligence, Giheung-gu, Korea, Republic of, Jin-Gyun Kim, Younghoon Kim

This study introduces a methodology for Optimal Sensor Placement (OSP) in constructing digital twins of heat transfer systems. By combining Denoising Autoencoder (DAE) with discrete optimization techniques, our approach aims to accurately reconstruct real-time heat transfer simulation results using a limited number of sensors. The OSP optimization employs a projection function driven by discrete optimization. This identifies the minimal sensor array necessary for precise temperature monitoring, thereby reducing installation and operational costs in industrial systems. Additionally, the DAE effectively processes noisy data, enhancing the robustness of OSP decisions. Comparative evaluations against previous methods demonstrate the superior efficiency of the DAE in processing thermodynamic data. Our proposed approach is expected to significantly enhance the performance of temperature monitoring and control system designs within heat transfer digital twins.

43 - Electrons to electrons? Matching objectives with stakeholder-driven metrics for equitable power systems planning

Ogechi Vivian Nwadiaru, University of Massachusetts, Amherst, Amherst, MA, United States, Paola Furlanetto, Krista Harper, Erin Baker

With the energy transition at the forefront of policy objectives, it is important to ensure that the system planning models capture community needs and are guided by equitable metrics. We develop a game for eliciting these metrics from various stakeholders. The game, which is inspired by apples to apples, calls on stakeholders to match a set of energy equity metrics to a predefined list of objectives, and a judge selects the most favorable metric. This work extends the hierarchical framework of value-focused thinking by actively involving stakeholders in the decision-making process.

44 - Analysis of Power System Impacts Due to Power-to-Heat Energy Conversion

Ye Ha Yang, Korea university, Seoul, Korea, Republic of

To achieve the 2050 carbon neutrality target and accelerate the deployment of renewable energy, power system issues such as curtailment, and the rapid electrification of heat demand due to distortion in the relative prices of energy causes excessive demand, exacerbating power system problems. To address these issues, the conversion between electric and heat energy can induce fluctuations in electricity demand, acting like a flexible resource. Currently, a significant portion of South Korea's electricity demand includes heat energy demand; therefore, separation of electric and heat energy is necessary for efficient energy consumption. However, study in the context of Korea is still lacking. Thus, it is necessary to analyze the effects of power-to-heat conversion for future policy implementation. For this purpose, a power system model capable of predicting generation, surplus electricity, system operating costs, and carbon emissions according to future scenarios in Korea was developed. The effects of the power-to-heat scenarios on the economic, environmental, and system stability aspects of the power system were calculated. Applying a 10% power-to-heat conversion by 2035 resulted in a reduction of fuel costs by about 5% economically, and a decrease in output limitation rates in terms of system stability. These results demonstrate that power-to-heat conversion can reduce base load and be used as a flexible resource in an increasingly unstable power system due to the continuous increase in renewable energy and the electrification in various industries.

45 - You Are What You Like: the Relations Between Daily Preferences and Higher Order Risk Attitudes

Peng Du, Southwestern University Of Finance And Economics, Chengdu, China, People's Republic of, Lin Zhao, Hua Chen

Higher order risk attitudes, including risk aversion, prudence, and temperance, play a fundamental role in economic decision-making, significantly influencing daily consumption/saving behaviors, portfolio allocation, and retirement planning. Their importance has stimulated a growing interest in gauging individuals' risk preferences using easily observable and reliable data. While extant literature has suggested that some easily identifiable basic daily preferences, such as specific diets and exercise preferences, can reflect an individual’s risk attitudes, theses relations have not been thoroughly investigated, with existing evidence predominantly restricted to the second-order risk preference. We, therefore, conduct a systematical survey among University students, encompassing thirty-six basic daily preferences across six common categories (food, clothing, exercise, reading, music, and video), along with three risky lottery-choice experiments to separately assess subjects' intensity of risk aversion, prudence and temperance. Our results indicate that, even after accounting for individual characteristics, certain basic daily preferences exhibit robust correlations with higher order risk attitudes. We also find that cognitive ability and personal traits serve as important mediating factors. Our study are the first to systematically investigate the relations between basic daily preferences and higher order risk attitudes. Additionally, our research provides a valuable demonstration of the potential for identifying risk attitudes through the analysis of individuals’ behavioral data in the era of big data.

46 - Deep Galerkin Method for Mean Field Control Problems

Jingruo Sun, Stanford University, Stanford, CA, United States

We consider an optimal control problem where the average welfare of weakly interacting agents is of interest. We examine the mean-field control problem as the fluid approximation of the N-agent control problem with the setup of finite-state space, continuous-time, and finite horizon. The value function of the mean-field control problem is characterized as the unique viscosity solution of a Hamilton-Jacobi-Bellman (HJB) equation in the simplex. Adapted from the classical Galerkin method, we construct a Deep Galerkin Method (DGM) to solve the HJB equation. Instead of seeking the reduced form of linear combinations, DGM approximates the solution using a deep neural network which is trained to satisfy the differential operator and boundary conditions of the high-dimensional nonlinear PDE. The accuracy of DGM results is validated through various numerical experiments. We also establish theoretical support by proving the convergence result for DGM. Specifically, we show that the loss function can be made arbitrarily small given that the value function possesses sufficient regularity. Based on that, we further demonstrate that if the loss function converges to zero, the corresponding neural network approximators must converge uniformly to the true value function on the simplex. Therefore, we propose a comprehensive framework for the high-dimensional mean-field control problem, leading to a reliable and efficient methodology for decision-making.

47 - Data Value in Distribution System Operations

Mehrnoush Ghazanfariharandi, Rutgers University, Piscataway, NJ, United States, Robert Mieth

The rise of advanced data technologies in electric power distribution systems enables operators to optimize operations but raises concerns about data security and consumer privacy. Resulting protection mechanisms that alter or obfuscate datasets may invalidate the efficacy of data-driven decision-support tools and impact the value of these datasets. This paper derives tools for distribution system operators to enrich data-driven operative decisions with information on data quality and, simultaneously, assess data usefulness in the context of this decision. To this end, we derive an AC optimal power flow model for radial distribution systems with data-informed stochastic parameters that internalize a data quality metric. We derive a tractable reformulation and discuss the marginal sensitivity of the optimal solution as a proxy for data value. Our model can capture clustered data provision, e.g., from resource aggregators, and internalize individual data quality information from each data provider. We use the IEEE 33-bus test system, examining scenarios with varying photovoltaic penetration, to demonstrate the application of our approach and discuss the relationship between data quality and its value.

48 - A (not so) Typical Day at Work for an Emergency Medical Services Crew Member

Nico Ornelas, Wichita State University, Wichita, KS, United States, Laila Cure

Emergency Medical Services (EMS) play a vital role in providing care to patients in need of urgent medical attention outside of the hospital. Most Operations Research/Management Science (ORMS) research on EMS systems focuses on optimizing operational decisions, such as station location, dispatching, and redeployment, in terms of some system-level performance measure, such as coverage or response time reliability. The impact of these decisions on individual crewmembers is rarely considered. Nevertheless, the tasks performed by these crews are extremely diverse and vary widely from shift to shift. This research uses data analysis techniques to describe the dynamics of EMS systems from the perspective of crewmembers. We start with a qualitative analysis of a single workday to use as a baseline. Then, we analyze one year's worth of emergency dispatch data to investigate deviations from this baseline and explore the amount of variation in the frequency and duration of the tasks performed. In addition, we use probability theory to analyze documentation expectations of ambulance crewmembers. The descriptive analysis provides a shared understanding of the work performed by paramedics and emergency medical technicians and the probabilistic analysis provides insight on how likely these crewmembers are to meet the articulated and unarticulated expectations of their profession. We conclude the analysis with future research directions for ORMS professionals as a way to consider the experience of crew members in the modeling and analysis of EMS operational decisions.

49 - End-to-End Asset Allocation Optimization with Convolutional Neural Network and Stock Chart Images

Inyeol Choi, Kyung Hee University, Giheung-gu, Korea, Republic of, Younghoon Kim

Optimizing dynamic asset allocation poses significant challenges but offers promising avenues for portfolio management. While prior research has utilized Convolutional Neural Networks (CNNs) to analyze stock chart images and forecast price movements within portfolios, our study introduces a new extension. We propose that chart images can effectively predict not only individual stock performance but also optimal asset allocation ratios. Our methodology entails developing a CNN-based end-to-end portfolio model trained on diverse allocation strategies. Through out-of-sample testing, the model autonomously generates optimal allocation weights without relying on predefined optimization processes. Leveraging visual data, our approach aims to enrich dynamic asset allocation strategies. This study highlights the potential of CNN-based models to effectively enhance portfolio management practices.

50 - Hierarchical Forecasting for Amazon EC2 demand

Yiming Wang, Amazon, Seattle, WA, United States, Ebrahim Nasrabadi

Amazon's Stores, Digital, and Other (SDO) is the largest user of AWS EC2 capacity. This poster introduces our in-house Hierarchical Bayesian and Hierarchical Reconciliation forecasting methods to forecast SDO EC2 demand. The demand forecasts are published at bi-monthly cadence, covering a rolling 2-year horizon, and at granularity of business group (Stores, Digital, Other), availability zone (e.g., us-east-1a), and instance type (e.g., c5.12xlarge) level. The forecasts can be used for AWS capacity planning to drive operational and financial decisions on global AWS data center infrastructure and space plan. To address the cold-start challenges in forecasting new instance generation and availability zones's demand, we developed a novel Hierarchical Bayesian time series forecasting model. In back-testing, our model was proven to reduce the forecast error measured in Weighted Absolute Percentage Error (WAPE) to 18.6% from 30.0% using Meta's open-source Prophet package for new AWS EC2 instances launched in 2023.

51 - Determinants of Patterns of Outpatient Care in Patients with Chronic Kidney Disease

Somi Kim, Seoul National University, Seoul, Korea, Republic of, Song-Hee Kim, Hyung Woo Kim

Regular outpatient visits by patients with chronic kidney disease (CKD) are crucial to manage patients' prognosis. Although the Kidney Disease Improving Global Outcomes (KDIGO) guidelines provide appropriate testing frequencies based on the patient's stage of CKD, actual visit frequencies do not strictly follow these guidelines due to influencing factors of outpatient visit patterns. This study conducted a retrospective analysis comparing visit frequency of the outpatient visit patterns of patients with CKD to the guideline and identified factors impacting visit frequency.

52 - Neural Forecasting Layer: Straightforward connected interpretable neural forecaster for multivariate time-series.

Wonkeun Jo, Chungnam National University, Daejeon, Korea, Republic of, Dongil Kim

Within the machine learning community, diverse neural network-based methodologies deployed in multivariate time-series forecasting applications have demonstrated commendable efficacy. Despite advancements in model performance, comprehending the rationale behind the model's behavior remains an enigma. Our proposed model, the Neural Forecasting Layer (NFL), employs a straightforward amalgamation of neural networks. This uncomplicated integration ensures that each neural network contributes inputs and predictions independently, devoid of interference from other networks. Consequently, our model facilitates a transparent explication of forecast results. This paper introduces NFL along with its diverse extensions. Empirical findings underscore NFL's superior performance compared to nine benchmark models across 15 available open datasets. Notably, NFL not only surpasses its competitors but also provides elucidation for its predictions. In addition, rigorous experimentation involving diverse model structures bolsters the justification of NFL's unique configuration.

53 - Tree ensemble-based data denoising technique for sparse dynamic system identification

Junhyeok Choi, Kyung Hee University, Giheung-gu, Korea, Republic of, Younghoon Kim

SINDy (Sparse Identification of Nonlinear Dynamics) is a widely used method for identifying nonlinear dynamical equations from data. However, its sensitivity to data noise presents challenges, especially in noisy environments like manufacturing processes. This study proposes a novel approach that combines denoising filters with tree ensemble algorithms to enhance robustness against noise and facilitate sparse equation identification. Comparative evaluations against basic SINDy demonstrate the superior robustness of our method when applied to various dynamical equations with Gaussian noise. These findings suggest that our approach shows promise for obtaining more reliable results in noisy environments, with potential applications in system identification and control. By mitigating the impact of noise, this study contributes to advancing the applicability of data-driven engineering methods in real-world settings, particularly in improving manufacturing processes and other practical applications.

54 - End-to-end portfolio optimization model using transformer

Jiyeon Lee, Kyung Hee University, Giheung-gu, Korea, Republic of, Younghoon Kim

In quantitative finance, portfolio optimization traditionally involves separate prediction and optimization stages, potentially leading to sub-optimal asset allocation decisions due to inaccuracies in parameter estimation. Recent advancements have introduced end-to-end portfolio optimization models, consolidating these steps into a single feedforward neural network. Our study extends this approach, focusing on a model-based strategy to enhance explainability and performance. We propose a method leveraging a transformer model for constructing an end-to-end portfolio optimization framework. We evaluate the performance of these models in maximizing the Sharpe ratio using U.S. financial data. Comparative analysis demonstrates the efficacy of our expanded model in improving portfolio optimization outcomes. This research contributes to advancing portfolio optimization techniques in quantitative finance, offering insights into more effective decision-making processes.

55 - Combining Shortcut3-ResNet and Gated Attention BiLSTM for Wafer Defect Classification

GYU MIN KANG, Kyung Hee University, Giheung-gu, Korea, Republic of, Younghoon Kim

Classifying wafer map defect patterns is crucial in semiconductor manufacturing to increase production yield. While previous methods rely on image analysis models like convolutional neural networks, they face performance limitations. To address this, we propose a composite model that integrates image and sequence information. Wafer image data undergoes preprocessing by resizing and distributionally gridding to facilitate model processing. We employ a combination of Shortcut3-ResNetBlock and MaxPool2d to transform high-dimensional image data into low-dimensional features. These features are processed using Gated Attention BiLSTM, enabling precise defect discrimination by merging image and sequence data characteristics. Our method capitalizes on the strengths of both data types, enhancing defect identification accuracy. FocalLoss is used in the learning process to effectively manage class imbalance. Experimental results demonstrate the superiority of our approach in achieving higher classification accuracy compared to existing methods. This advancement holds promise for significantly improving defect detection efficiency in semiconductor wafer fabrication processes, ultimately enhancing production yield.

56 - Development of One to One Marketing using AI in an Energy utility company

Takahiro Sekoguchi, Tokyo Gas, Tokyo, Japan, Shoma Hino, Kazuki Isshiki, Toshinori Sasaya

It has become more important for Japanese energy retailers to improve customer experience in the electricity and gas liberalization market.

Our marketing activities have faced challenges in understanding customers' needs, offering the optimal solutions, and communicating from customers' perspective.

We developed functions that integrate and analyze various types of customer data, estimate effective information for marketing using machine learning, such as customers' values, product needs and life events, and recommend products that meet the needs of each individual customer at the appropriate time and through the appropriate channels with customized communication tailored to individuals.

We verified the effectiveness of these marketing functions through individual use case such as estimating the timing of relocation and appealing electricity and gas bundle contracts, achieving significant improvement in conversion compared to our previous marketing methods.

We will systematize these marketing modules to deploy in both B2C and B2B, progressing with business implementation.

57 - A data-driven optimization for customized shuttle bus on the metro network with well-developed branch lines

Jiguang Wang, The University of Hong Kong, Hongkong, China, People's Republic of, Changyue Xu

Metropolitan subways are facing a serious connectivity issue among branch lines in the process of continuous development and expansion, especially at stations in the sub-centers of branch lines or at transfer stations, which leads to long travel distances frequent transfers. These problems not only reduce passenger travel efficiency and satisfaction but also burden rail transit operation agencies. Additional train shifts are often used on-site to alleviate the problem, but this method has limitations due to the inherent number of trains and the maximum departure frequency, and it may also worsen the supply-demand mismatch of other off-peak stations, resulting in high-cost waste. To tackle this problem, this study concentrates on metropolitan subway stations with great passenger demand between branch lines by utilizing big data mining and introducing a new customized subway-shuttle bus mode. The proposed mode aims to delivery passengers directly between O-D pairs of the ends in the subway network branches in a shorter period of time and improve passenger travel efficiency. To maximize the number of additional customers that can be served, a mixed integer programming model is established based on a temporal-spatial network to improve this issue. Numerical experiments validate the effectiveness and robustness of the proposed strategy, and some management suggestions for rail transit operation agencies are also discussed.

58 - Seawater Desalination: Exploring Alternative Water Resources and Addressing Water Scarcity through Discrete Choice Experiment in South Korea

Suk-Hoon Lee, Kyunghee University, Seoul, Korea, Republic of, Hyunhong Choi

Rising temperatures and climate change-induced precipitation variability are reducing the availability of freshwater resources. In response, seawater desalination plants are expanding globally, including in China, Spain, and the Middle East. Meanwhile, South Korea, with its manufacturing industry at its core, faces critical industrial water supply challenges, leading to shortages in household drinking water.

To address the conflict between industrial and domestic water scarcity, dam facilities have played a primary role in South Korea. However, with decreasing freshwater availability, solely relying on dams has become insufficient. Therefore, there's increasing consideration in South Korea to expand seawater desalination facilities. Public and corporate opinions on this transition are crucial, yet proper surveys regarding their views have not been conducted. Hence, this study comprehensively evaluates public and corporate preferences and acceptance through a Discrete Choice Experiment (DCE) survey targeting 1,000 citizens and 409 coastal businesses, predicting market share for seawater desalination facilities using choice simulation.

According to the research findings, seawater desalination facilities utilizing renewable energy significantly improve alternative choice probabilities and acceptance compared to traditional inland dams. This study emphasizes the importance of seawater desalination facilities in addressing domestic industrial and drinking water scarcity issues and suggests that integrating renewable energy facilities enhances their effectiveness.

Such research is perceived as an essential strategy involving the nation, businesses, and households. The success of seawater desalination projects will lead to stable industrial water supply for businesses, promoting national development and economic growth while ensuring future generations' access to drinking water.

59 - The effect of patient-to-nurse ratios and patient outcomes: Intensive Care Units versus Medical and Surgical Units

MARBELLY DAVILA, Tampa General Hospital, Tampa, FL, United States

The issue of nurse-to-patient ratios has gained significant attention due to the inadequate staffing levels in healthcare settings across the country. In large academic hospitals, nurses are frequently burdened with caring for more than expected patients at a time, amidst a shortage of nursing assistants. It is imperative to recognize that evidence-based practice strongly supports the notion that lower nurse-to-patient ratios lead to improved patient outcomes. However, it is essential to acknowledge that current policies often do not align with this best practice.

60 - Proposing a Time-to-Event Analysis for Assessing Supply Chain Disruption Severity and Occurrence Using a Competing Risk Model

Ronald Rineer, Widener University, Chester, PA, United States, Amin Keramati

Supply chain disruptions, ranging from minor delays to complete cessation of operations, can significantly impact a business's operations, leading to increased costs and revenue loss. To mitigate these effects, it is essential to predict the likelihood, timing, and severity of such disruptions. Previous models mostly used time series predictive approaches to assess supply chain disruptions. However, in this study, we consider supply chain disruptions as unexpected events, making their prediction more complex than analyzing repetitive patterns of event occurrence. To address this gap, this study treats supply chain disruptions as a time-to-event problem and employs a type of survival analysis known as the Competing Risk Model (CRM). The proposed predictive model can assist supply chain and logistics decision-makers in redefining committed delivery times, determining which products to invest in, and making informed decisions about suppliers, transportation modes, and other logistics considerations.

61 - The Benefit of Interpersonal Uncertainty: On the Design of Reward Allocation Mechanism in Online Referral Reward Programs

Huijie Jin, Renmin University of China, Beijing, China, People's Republic of, Shouwang Lu, Kanliang Wang

The online referral reward program (ORRP) is a topline marketing strategy for businesses to grow the customer base, in which firms promote their business via existing customers' online social networks and reward both the “referrer” and the “referee”. As a key component of the ORRP, rewards play an indispensable role in motivating users to engage in referral behaviors. However, inappropriate reward allocation design might harm the relationship between referrers and referees, ultimately reducing referring. We seek to explore the effect of the uncertain reward allocation, a novel reward allocation design in ORRP practice. Compared to the certain allocation, in the uncertain allocation context, both referrer and referee are only aware of the total referral reward, with the respective allocated reward amounts ex-ante unknown. Given that ORRP participants primarily perceive and evaluate rewards through comparisons, this research proposes the impact of uncertain reward allocation on referrers' referral intentions from the theoretical perspective of social comparison. The proposed hypotheses were investigated by three experiments. The results indicate that the uncertain (vs. certain) reward allocation of ORRP increases the referrers' referral intention by reducing their psychological barriers associated with explicitly comparing rewards with the referee. Furthermore, compared to large social distances (acquaintances), when the referrer considers making referrals to small social distances (friends) where they generally have low psychological concerns, the positive impact of uncertain reward allocation on the referral intention is weakened. The research findings provide new insights for both theory and practice.

62 - Tracing Sedimentary Origins in Multivariate Geochronology via Constrained Tensor Factorization

Naomi Graham, University of British Columbia, Vancouver, BC, Canada, Nicholas Richardson, Michael Friedlander, Joel Saylor

Tracing the origins of sediment over time can increase our understanding of the formation of geological structures as well as help to predict the presence of precious minerals. Detrital zircon grains serve as discrete carriers of information as their durability allows them to maintain elemental compositions over large time scales. These elemental concentrations can be measured and used to study sedimentary data, namely in relation to how it is comprised of sediments travelling from different sources. Current quantitative methods for analyzing sedimentary data are limited to studying up to two elemental features simultaneously, thus limiting their applications. We develop a model based in tensor decomposition and implement a coordinate descent algorithm for processing sedimentary data using an arbitrary number of features, while scaling linearly in the number of features. Our experiments indicate that a larger number of features increases our accuracy of identifying sedimentary sources, and we test our method on real data, achieving over 85% accuracy.

63 - Regression and Time Series Mixture Approaches to Predict Resilience

Priscila Silva, University of Massachusetts Dartmouth, Dartmouth, MA, United States, Gaspard Baye, Mindy Hotchkiss, Gokhan Kul, Nathaniel Bastian, Lance Fiondella

Resilience engineering is the ability to build and sustain a system that can deal effectively with disruptive events. Previous resilience engineering research focuses on metrics to quantify resilience and models to characterize system performance. However, resilience metrics are normally computed after disruptions have occurred and existing models lack the ability to predict one or more shocks and subsequent recoveries. To address these limitations, this research presents three alternative approaches to model system resilience with statistical techniques based on (i) regression, (ii) time series, and (iii) a combination of both to characterize system performance under multiple shocks and stresses of different intensity and duration, provide structure for planning tests to assess system resilience against particular degradations and guide data collection necessary to conduct tests effectively. These modeling approaches are general and can be applied to systems in multiple domains. A historical data set on job losses during the 1980 recessions in the United States is used to assess the predictive accuracy of these approaches. Goodness-of-fit measures and confidence intervals are computed to assess how well the models perform on the data set considered. The results suggest that resilience models based on statistical methods such as multiple linear regression and multivariate time series models are capable of modeling and predicting resilience curves exhibiting multiple shocks and subsequent recoveries. However, models that combine regression and time series account for changes in performance due to current and time-delayed effects from disruptions most effectively, demonstrating superior performance in long-term predictions despite increased parametric complexity.

64 - Automation design to support multitasking performance

Jiaxin Li, University of Washington, Seattle, WA, United States, Zishu Ling, Karine Suryatna, Ji-Eun Kim

Automation, a complete or partial transfer of operators’ tasks to a machine or computer, has reportedly reduced operators’ workload, resulting in enhanced performance in high-demand multitasking environments. Yet, little is known about when and how to use automation in consideration of task-related factors associated with multitasking performance. In this empirical study, we aim to evaluate the effect of two task-related factors: sensory modality (intra- vs. cross-modality) and task priority (absent vs. present) on multitasking performance employing the Multi-Attribute Task Battery, a computer-based in-flight task designed to simulate multitasking environments. Our results show that automation improved multitasking performance by reducing reaction time and error counts in cross-modality conditions, while only reaction time improved in intra-modality conditions. Reduced eye fixation entropy in the cross-modality condition indicates that reduced attention diversion was associated with automation support. Assigning higher priority to the automated task led to faster detection of automation failure, regardless of modality. Our findings offer insights into designing automation taking into account contextual factors in various work settings where operators need to perform multiple tasks under high workload situations.

65 - Deciphering NFTs: Understanding Decision-Making with Interpretable Machine Learning

LANQING DU, Drexel University, Philadelphia, PA, United States, Tianyi Ren

Non-Fungible Tokens (NFTs) stand as distinctive digital assets, each bearing a singular digital identifier denoting ownership, facilitated through blockchain technology.
In December 2021, the digital artwork "Merge," crafted by the renowned artist Pak, commanded a staggering $91.8 million on the NFT platform Nifty Gateway. NFTs have garnered significant attention due to their record-breaking sales prices, underscoring their importance within the digital economy. Our aim is to elucidate the decision-making processes involved in NFT (Non-Fungible Token) transactions through the lens of an interpretable machine learning approach.

66 - Stochastic contextual bandits with graph feedback: from independence number to MAS number

Yuxiao Wen, New York University, New York, NY, United States, Yanjun Han, Zhengyuan Zhou

We consider contextual bandits with graph feedback, a class of interactive learning problems with richer structures than vanilla contextual bandits, where taking an action reveals the rewards for all neighboring actions in the feedback graph under all contexts. Unlike the multi-armed bandits setting where a growing literature has painted a near-complete understanding of graph feedback, much remains unexplored in the contextual bandits counterpart. In this paper, we make inroads into this inquiry by establishing a regret lower bound $\Omega(\sqrt{\beta_M(G) T})$, where M is the number of contexts, G is the feedback graph, and $\beta_M(G)$ is our proposed graph-theoretic quantity that characterizes the fundamental learning limit for this class of problems. Interestingly, $\beta_M(G)$ interpolates between $\alpha(G)$ (the independence number of the graph) and $\mathsf{m}(G)$ (the maximum acyclic subgraph (MAS) number of the graph) as the number of contexts M varies. We also provide algorithms that achieve near-optimal regret for important classes of context sequences and/or feedback graphs, such as transitively closed graphs that find applications in auctions and inventory control. In particular, with many contexts, our results show that the MAS number essentially characterizes the statistical complexity for contextual bandits, as opposed to the independence number in multi-armed bandits.

67 - Exploring equitable accessibility for a foodbank network

Rashik Intisar Siddiquee, North Carolina State University, RALEIGH, NC, United States, Julie Ivy, Lauren Davis, Osman Ozaltin, Dwight Lewis

Food insecurity is a significant humanitarian challenge, with 12.8% of U.S. households experiencing food insecurity in 2023. Food banks play a crucial role in addressing this issue with their wide network of partner agencies, but ensuring equitable distribution and accessibility remains a complex challenge. This study examines the transportation accessibility of a food bank network using Geographic Information Systems (GIS) and data visualization tools. The objective is to identify underserved areas by considering food-insecure populations and food bank agencies that lack adequate public transport access. This analysis can better inform food banks to make additional interventions, ensuring more effective and equitable service distribution.

68 - Near-Optimal Cost Function Approximation for Multi-Period Technician Routing and Scheduling

Kaiwen Li, Beijing Foreign Studies University, Beijing, China, People's Republic of, Xi CHEN

We study the problem of designing near-optimal formulation of cost function approximation (CFA) for multi-period technician routing and scheduling problem in an online learning setting. Prior works using CFA design the parameterized model based on domain knowledge and tune parameters in an offline setting without providing error analysis. However, when the impact of uncertainty is easy to recognize, we propose an approach to find a near-optimal formulation of CFA a prior. More precisely, we first build Kullback-Leibler ambiguity set of future cost incurred by certain action, then we use the relationship between regularization and robust optimization to construct an equivalent regularization term, which leads to the modified cost function in CFA. Next, the performance gap between our proposed approach and optimal policy is given by error analysis of state aggregation. Numerical experiment demonstrates that the proposed approach (without tuning parameters) performs close to optimal in various settings of urban delivery.

69 - Breaking or Exacerbating the Cocoon: Exploring the Impact of Personalized Recommendations on Users’ Information Cocoons

Molin Yang, Peking University, Beijing, China, People's Republic of, Lin Wang, Chong Wang, Jiayin Zhang, Sean Xu

Information cocoon refers to the phenomenon where people are selectively exposed to information consistent with their beliefs or preferences. Literature on social media platforms primarily attributes the formation of information cocoons to filtering algorithms. However, the significant role of individual self-selection has largely been overlooked. This study distinguishes between two primary processes involved in information cocoon formation: algorithmic filtering and individual self-selection. We define two types of cocoons: recommendation cocoons, arising from algorithmic filtering, and selection cocoons, stemming from the self-selection process. Collaborating with one of the most popular social media platforms in China, we investigate how these two cocoons co-evolve and form the ultimate cocoons. This platform introduced a function that allows users to disable personalized recommendations. Our analysis delves into the impact of disabling personalized recommendations on recommendation cocoons, selection cocoons, and the ultimate cocoons.

Our findings reveal that disabling personalized recommendations directly reduces the extent of users’ recommendation cocoons while increasing the extent of selection cocoons. A possible explanation is that disabling personalized recommendations reduces the effectiveness of recommended content, which may lead to information overload and increased search costs, therefore exacerbating information narrowing in self-selection process. For users with higher degree of information cocoons, the extent of ultimate cocoons is reduced after disabling personalized recommendations. However, for users with lower degree of cocoons, disabling personalized recommendations increases the extent of ultimate cocoons, indicating the potential of recommender systems to break cocoons. Moreover, across all users, disabling personalized recommendations reduces engagement, highlighting the importance of personalized recommendations.

70 - A Reinforcement Learning-Based Model for Venture Capital Financing Rounds Investment

Guanrou Deng, University College London, London, United Kingdom

Investing in Venture Capital (VC) staged financing involves high risks and price volatility. Existing theoretical methods based on real options theory often simplify uncertainties and lack risk-averse considerations. Additionally, industry practitioners' decisions often involve personal biases and may not be analytically optimal. This paper introduces a novel reinforcement learning-based method to enhance venture capitalists' decision-making. Our policy-based agents are trained to leverage high payoffs and risks throughout the VC rounds of the financing period, which can allocate investments in proper rounds and identify optimal candidates to exit with the aim of maximising financial returns. Using Pitchbook data, we propose suitable exit multiples for different industries, and on average recommend an exit multiple of 10. Additionally, we find that prioritizing higher-performing companies enhances payoffs, though excessive selectivity may limit exits. These findings underscore the potential of reinforcement learning in optimizing VC-staged financing strategies, providing insights for informed decision-making in staged financing investments.

71 - Mixed-Effect Models for Assessing Variable Speed Limit (VSL) Signs

Julio Cesar Jurado, University of Maine, Orono, ME, United States, Mohammad Razaur Rahman Shaon, Niloufar Shirani, John Ivan, Naveen Eluru, Ali Shirazi

This study aims to assess driver responses to Variable Speed Limit (VSL) signs using mixed-effect linear and logistic regression models. The mixed effect models account for the impact of the VSL location and repeated observations. The data collected from the Vehicle Speed Sensor (VSS), and Road Weather Information Systems (RWIS) along Interstate 80 in Utah (between Salt Lake City and Kimball Junction) were consolidated to create a uniform dataset for analysis. This dataset covers a stretch of 14 miles of highway, from November 2021 to April 2023. First, a linear mixed-effect model is constructed to analyze the relationship between the speed downstream of the VSL sign and several factors, including upstream speed, traffic count per lane, weather conditions, and dummy variables indicating the time of day (morning peak hours, evening peak hours, and off-peak), roadway surface conditions (Frost-Slushy or Ice-Snow versus Dry-Damp-Wet), and the VSL activation. Second, a binary response model is developed using mixed-effect logistic regression to examine compliance with the speed limit when the VSL sign is activated. Our results show that these signs are effective in speed reduction during adverse weather conditions. The findings of this study provide valuable insights for decision-makers, demonstrating the real-world applications of VSL signs during adverse weather conditions.

72 - Enhancing Sample Diversity in Deep Convolutional GANs Using a Bayesian Framework

Mahsa Valizadeh, Texas A&M University, College Station, TX, United States, Rui Tuo, James Caverlee

Generative Adversarial Networks (GANs) are proficient at creating artificial data, but the persistent challenge of mode collapse during the optimization process necessitates innovative solutions. In our endeavor to address mode collapse in Deep Convolutional Generative

Adversarial Networks (DCGAN) and foster greater sample diversity, we introduce a Bayesian framework applied to DCGAN, referred to as Bayesian DCGAN. This framework involves the integration of a weight distribution within the network, achieved through the application of the Bayes by Backprop method. This method employs a mean-field variational inference approach to approximate the posterior distributions of weights. In addition to the incorporation of a weight distribution, we put forth a mathematical approach to quantify the diversity present in the samples generated by Bayesian DCGAN, contrasting it with the output of conventional DCGAN. Our experimental results showcase that Bayesian DCGAN generates more diverse samples compared to its conventional counterpart, thereby significantly reducing uncertainty in neural networks. This enhancement in diversity is pivotal for creating robust and adaptable models, particularly in scenarios where a broader spectrum of data representations is essential for effective learning and generalization.

73 - Smart Cities, Happier Lives? Big Data and Deep Learning Insights in China

Hongyu Zhang, Tsinghua University, Beijing, China, People's Republic of, Yidi WANG, Hongyu Liu

As sustainable urban development prioritizes improving residents' quality of life, smart cities, empowered by advancements in information technology, offer comprehensive management and service platforms that could enhance living conditions. However, the broader impacts and definitions of smart cities are often unclear due to limited data availability. This study addresses these gaps by analyzing big data from 300,000 smart city government procurement projects to categorize and quantify smart city investments. Utilizing deep learning techniques, specifically a RoBERTa fine-tuning classification model trained on manually labeled data, this research explores the correlations between different types and intensities of smart city investments and life satisfaction, considering the influence of political dynamics in China. The findings reveal a non-linear positive relationship between the intensity of smart city investments and residents' life satisfaction, with varying impacts depending on the type of investment. Investments targeting residents' livelihood services demonstrate the most substantial benefits, whereas infrastructure-focused projects yield less immediate improvements. Additionally, the analysis highlights how the career trajectories of government leaders can disrupt the alignment of long-term smart city investments, undermining their effectiveness and the welfare of the residents. This study not only advances understanding of smart cities through the lens of big data and deep learning but also offers critical insights for shaping future urban policies for sustainability.

74 - A Clinical Language Model to Detect Acute Traumatic Intracranial Injury from Free-Text Radiology Reports

Hayley Falk, University of Michigan, Ann Arbor, MI, United States

In acute traumatic brain injury (TBI), free-text brain computed tomography (CT) radiology reports contain detailed information regarding injury severity. This information is critically important for guiding clinical decision making and informing prognosis. However, the information contained within the radiology reports is unstructured and manual extraction of the relevant information is error-prone, difficult to scale, and requires significant resources (e.g., domain expertise, time, financial). Therefore, we developed and validated a clinical language model using radiology reports from 1531 emergency department (ED) patients evaluated for acute TBI. We developed our model using supervised finetuning of a clinical knowledge enriched large language model (LLM). The task was formulated as a binary text classification task (presence or absence of acute traumatic intracranial injury) and annotations were completed by a board certified neuroradiologist. We used a stratified 10 fold cross validation approach and selected the optimal hyperparameters based on performance in the validation set. Our final model demonstrated strong performance and had an area under the receiver operating characteristic curve (AUROC) of 0.99 and an F1 score of 0.90. Our results suggest that this is a promising approach that may help mitigate some of the limitations inherent in manual chart review. Additional analyses are needed to examine the generalizability of our model and to determine whether our model can be adapted to new tasks through finetuning.

75 - ADVANCED PREDICTIVE MODELS FOR DIABETIC RETINOPATHY: A MULTI-LAYERED ENSEMBLE APPROACH WITH HYPERPARAMETER TUNING

Mahyar Mahmoudi, Oklahoma State University, Stillwater, OK, United States

Diabetes is a prevalent chronic condition that often leads to severe complications such as diabetic retinopathy (DR), the leading cause of vision impairment in diabetic individuals. Our study analyzed data from over 1.4 million individuals to develop a predictive model for DR using demographic and laboratory data. This approach circumvents the need for specialized ophthalmic equipment and expertise. We employed a novel multilayered ensembling technique involving five algorithms: Linear Discriminant Analysis, Passive Aggressive Classifier, LinearSVC, Logistic Regression, and SGDClassifier. Through stack generalization, each model was fine-tuned across various hyperparameters to optimize performance metrics like precision, recall, and accuracy. The outputs from each algorithm were then aggregated through the second layer of ensembling, enhancing the interpretability and efficiency of the predictions. Our findings indicate that variables such as diabetic neuropathy, serum creatinine, blood urea nitrogen, glucose, and hematocrit are crucial for detecting DR. This insight allows for more targeted and efficient early screening, which could significantly improve intervention strategies. Our multilayered ensembling method, simpler and more interpretable than deep learning approaches, demonstrates how advanced analytics can be effectively integrated into clinical practices, setting the stage for further refinement and real-world application. This model offers a robust alternative for medical diagnostics, reducing computational demands while maintaining competitive accuracy.

76 - Knowledge Distillation-based Incremental Learning with Integration of Transformer and Its Applications in Online Process Monitoring

Boris Oskolkov, Oklahoma State University, Stillwater, OK, United States, Zhangyue Shi

The pursuit of ever-larger models for incremental learning raises concerns regarding computational cost and environmental sustainability. This work proposes a novel approach that prioritizes efficiency without compromising performance. We introduce a lightweight framework leveraging the knowledge preservation capabilities of transformers to facilitate effective yet sustainable incremental learning. The proposed method employs a compact, pre-trained transformer model as a "teacher." This teacher, despite its relatively smaller size, retains a wealth of knowledge from its initial training. Instead of directly participating in the computationally expensive incremental learning process, the teacher imparts its knowledge onto a smaller, more adaptable student model. This distilled knowledge acts as a stabilizing force, mitigating catastrophic forgetting as the student learns from new data. By offloading long-term memory onto the static teacher, the student model can be kept lightweight and computationally efficient during incremental training. The experimental results demonstrate that this approach achieves competitive performance on simulated dataset while significantly reducing computational demands compared to conventional methods. This work highlights a pathway towards incremental learning by combining the power of transformers with a focus on resource efficiency for future application in manufacturing.

77 - Complete formulation of the capability curve of synchronous generators in OPF models

Rafael Zarate-Minano, University of Castilla - La Mancha, Almadén, Spain, Miguel Carrion

This work addresses the limitations in the current modeling of synchronous generators in optimization problems, where power production limits are often simplified with independent maximum and minimum bounds on active and reactive power outputs. The study proposes a more comprehensive model that includes the complete capability curve of the machine, accurately representing its stability limits. The effectiveness of this model is validated through a maximum loading condition problem, using a homotopy modeling technique to push the generator to its operating limits. This approach offers a more precise representation of generator operation, enhancing the accuracy of optimal power flow solutions.

78 - Connected Vehicles Feature Analytics using Generative AI and Intelligent Sampling

Oleg Gusikhin, Ford Global Data Insight & Analytics, Dearborn, MI, United States, Omar Makke, Syam Chand, Vamsee Batchu, Svidenko Vicky

The increase of connected vehicles has led itself to having an unsurmountable amount of data. Analyzing connected features can become computationally expensive, or even impossible. This necessitates the need for a system that assists in properly sampling the signals using either classical methods or more recent Intelligent Sampling methods. In many cases selecting the correct vehicle signals and a proper sample for the given feature is not trivial. By leveraging Generative AI, this complexity can be efficiently managed. This is due to the ability of Generative AI to process design documents and combine them with general knowledge, to guide the users in collecting the proper data. This system has wide applications such as in engineering, design, and marketing.

79 - Tensor-Based Multi-modal Data Fusion

Mason Li, Chapman University, Orange, CA, United States

Machine learning is widely adopted but often requires substantial computational resources. This research addresses the need for more efficient models by exploring tensor decomposition as a method to reduce computational load. We aim to perform tensor decomposition on convolutional layer weights, therefore reducing dimensionality and enhancing computational efficiency. We aim to achieve this efficiency without sacrificing accuracy. The proposed model integrates multi-modal inputs, combining X-ray imagery and patient demographics, to perform length-of-stay regression and mortality classification. Experimental results indicate a significant reduction in model parameters and inference time, demonstrating the potential of tensor decomposition in real-time clinical applications.

80 - Stochastic Approximation with Delayed Updates: Finite-Time Rates under Markovian Sampling

Arman Adibi, Princeton University, Princeton, NJ, United States, Nicolò Dal Fabbro, Luca Schenato, Sanjeev R. Kulkarni, H. Vincent Poor, George J. Pappas, Hamed Hassani, Aritra Mitra

Motivated by applications in large-scale and multi-agent reinforcement learning, we study the non-asymptotic performance of stochastic approximation (SA) schemes with delayed updates under Markovian sampling. While the effect of delays has been extensively studied for optimization, the manner in which they interact with the underlying Markov process to shape the finite-time performance of SA remains poorly understood. In this context, our first main contribution is to show that under time-varying bounded delays, the delayed SA update rule guarantees exponentially fast convergence of the \emph{last iterate} to a ball around the SA operator's fixed point. Notably, our bound is \emph{tight} in its dependence on both the maximum delay τ_{max}, and the mixing time τ_{mix}. To achieve this tight bound, we develop a novel inductive proof technique that, unlike various existing delayed-optimization analyses, relies on establishing uniform boundedness of the iterates. As such, our proof may be of independent interest. Next, to mitigate the impact of the maximum delay on the convergence rate, we provide the first finite-time analysis of a delay-adaptive SA scheme under Markovian sampling. In particular, we show that the exponent of convergence of this scheme gets scaled down by τ_{avg}, as opposed to τ_{max} for the vanilla delayed SA rule; here, τ_{avg} denotes the average delay across all iterations. Moreover, the adaptive scheme requires no prior knowledge of the delay sequence for step-size tuning.

81 - Feature Subset Selection Framework for Endometriosis Diagnostics

Carolina Arroyo-Roldan, University of Puerto Rico - Mayaguez, Anasco, PR, United States, Wandaliz Torres-Garcia

Endometriosis is a gynecological disease characterized by the growth of endometrial tissue outside of the uterus. It is known to cause pelvic pain, dyspareunia, and dysmenorrhea, and has been linked to infertility. The diagnosis of endometriosis takes various years, partly because the gold standard for diagnosis is an invasive laparoscopic surgery which poses both a physical and financial burden on women. Previous research studies to identify potential molecular biomarkers face statistical and computational limitations due to small sample sizes with high dimensionality. Additionally, there is no standardization regarding factors that should be considered when analyzing the gene expression of endometrial tissue, such as disease severity and the phase of the menstrual cycle. Though experiments with large sample sizes are not available, many new and upcoming experiments are being generated to bridge the gap in understanding the biological mechanisms of this largely uncharacterized disease affecting many women worldwide. Therefore, we propose the development of a consensus framework to extract the best feature subsets to discriminate between endometriosis patients versus women without the disease using gene expression of endometrial tissue, as well as clinical information such as the stage of the menstrual cycle. This framework aims to identify and rank feature subsets using (1) optimization-based search algorithms coupled with classification methods and (2) queries of functional processes from gene-annotated databases across multiple publicly available experiments from the Gene Expression Omnibus repository to evaluate consensus.

82 - When Are Combinations of Humans and AI Useful?

Michelle Vaccaro, MIT, Cambridge, MA, United States, Abdullah Almaatouq, Thomas Malone

Inspired by the increasing use of AI to augment humans, researchers have studied human-AI systems involving different tasks, systems, and populations. Despite such a large body of work, we lack a broad conceptual understanding of when combinations of humans and AI are better than either alone. Here, we addressed this question by conducting a meta-analysis of over 100 recent experimental studies reporting over 300 effect sizes. First, we found that, on average, human-AI combinations performed significantly worse than the best of humans or AI alone. Second, we found performance losses in tasks that involved making decisions and significantly greater gains in tasks that involved creating content. Finally, when humans outperformed AI alone, we found performance gains in the combination, but when the AI outperformed humans alone we found losses. These findings highlight the heterogeneity of the effects of human-AI collaboration and point to promising avenues for improving human-AI systems.

83 - Ensuring Fair Prediction with Group-Aware Priors

Tim G. J. Rudner, New York University, New York, NY, United States

We consider the problem of training neural network models that make fair predictions in settings where certain subpopulations, or groups, are highly underrepresented in the training data. To address this problem, we develop a family of group-aware prior distributions over neural network parameters explicitly designed to favor models that are fair. Priors in this family assign high probability density to parameter values that induce models that are robust across groups. We show how to construct group-aware priors and derive a tractable optimization objective that incorporates them into model training. We demonstrate empirically that training with group-aware priors yields fair models on several challenging prediction tasks. Our evaluation shows that group-aware priors outperform state-of-the-art methods on vision and language classification tasks while only requiring access to a small amount of group information. Group aware-priors are conceptually simple, complement alternative approaches for fair prediction, and allow harnessing Bayesian inference to further improve model robustness.

84 - Enhanced Prediction of Hospital Readmission in Heart Failure Patients: Model Validation and Methodological Improvements Using Sepsis Patient Data

Sonia Jahangiri, Rochester Institute of Technology, Rochester, NY, United States, Nasibeh Azadeh-Fard

Predicting hospital readmissions is a major challenge in healthcare, particularly for heart failure patients, due to the complex interplay of clinical and demographic factors. Reducing readmission rates is crucial for improving patient outcomes and minimizing healthcare costs. This study focuses on developing a predictive model for hospital readmission in heart failure patients, which is then validated and refined using data from sepsis patients. By employing advanced machine learning techniques and various validation methods, the research enhances the model's accuracy and robustness. The process includes incorporating diverse patient variables, performing cross-validation, bootstrapping, and holdout methods, and fine-tuning hyperparameters. The results show significant improvements in prediction accuracy, demonstrating the effectiveness of these methodological enhancements for predicting hospital readmissions across different patient populations.

85 - Predicting Hospital-Acquired Conditions Among Children with Multiple Chronic Conditions: Individual Disparity and Structural Racism Effects

Ajit Appari, Northeastern University, Boston, MA, United States

Hospital-acquired conditions (HACs) are mostly preventable risk to the safety of hospitalized children, especially with multimorbidity that can result in elevated mortality & morbidity, longer hospitalization, and higher cost of care. Machine learning modeling is becoming an important tool for delivering equitable health care and ensuring better health outcomes.

In my study, I focused on building prediction model for composite risk of multiple hospital acquired conditions (MHAC) among chronically ill children having different multimorbidity patterns adjusting for individual disparity factors {age, sex, race/ethnicity, insurance}, structural racism factors {Neighborhood Disadvantage (e.g., poverty, unemployment, households on state income support, and higher proportion of Blacks), Neighborhood Affluence (highly educated, high income population) and Hispanic & Immigrant Concentration}, and provider factors (hospital characteristics).

I used administrative data on more than 700,000 pediatric hospitalizations (age: up to 17years) during 2015Q4-2016Q4 across 642 hospitals in Texas. Patients were coded for 69 chronic condition categories (reflecting 4400+ ICD10 diagnosis-and-procedure codes) and grouped into 10 different multimorbidity patterns using unsupervised learning method- Block Clustering with Bernoulli Mixture Models that leverages block classification expectation maximization algorithm. Subsequently, patients were coded for multimorbidity pattern complexity (number of chronic conditions from each pattern) to quantify potential complexity of care needs for presence of such patterns. Finally, I build and evaluate composite risk prediction model for MHACs using Zero-Inflated Negative Binomial Regression, and XGBoost Hurdle Model accounting for multimorbidity pattern complexity, individual disparity factors, structural racism factors, and provider factors.

86 - On the Adversarial Robustness of Benjamini Hochberg

Louis Chen, Naval Postgraduate School, Monterey, CA, United States, Roberto Szechtman

The Benjamini-Hochberg (BH) procedure is widely used to control the false detection rate (FDR) in (large-scale) multiple testing. Applications of this control abound in drug discovery, forensics, candidate screening, anomaly detection, and, in particular, machine learning, ranging from nonparametric outlier detection to out-of-distribution detection, and one-class classification methods. Considering this control is relied upon in some critical (safety/security) contexts, we investigate its adversarial robustness. More precisely, we study under what conditions BH does and does not exhibit adversarial robustness, we present a class of simple and easily implementable adversarial data-perturbation algorithms, and we perform computational experiments. With our algorithms, we demonstrate that it is possible for BH's control to be significantly broken with relatively few (even just one) test score perturbation(s), and provide non-asymptotic guarantees on the expected adversarial-adjustment to FDR. Our technical analysis involves a combinatorial reframing of the BH procedure as a ``balls into bins'' process, and drawing a connection to generalized ballot problems to facilitate an information-theoretic approach for deriving non-asymptotic lower bounds.

87 - Estimation of Waiting Time for Employment-Based Permanent Residency in the US: A Machine Learning Framework

Meghan Aerick, California Polytechnic State University, San Luis Obispo, CA, United States, Puneet Agarwal

The United States receives a substantial number of green card applications from individuals seeking permanent residency each year. The processing time for these applications varies significantly based on a variety of factors, causing much uncertainty and anxiety for applicants. This study presents the development and implementation of a predictive application using machine learning (ML) models to estimate U.S. employment-based green card waiting times. Our model leverages historical data from the United States Department of Labor and current processing times from the United States Department of State Bureau of Consular Affairs to predict waiting times. The predictive tool, developed using machine learning algorithms including Decision Trees, Random Forest, AdaBoost, and XGBoost, is hosted on a user-friendly Streamlit application. It offers an intuitive user interface that guides users through data input, model selection, and visualization of predictions and explanatory analyses. The best-performing ML model achieved an F1-score macro of 0.92 and an accuracy of almost 93%, indicating high reliability. Aimed at assisting applicants in effectively planning their futures, this application simplifies complex ML predictions into accessible insights, thereby democratizing access to predictive analytics. Additionally, it includes pages for model performance metrics, feature importance analyses, and general data insights to educate users about the underlying processes and factors influencing wait time predictions. This poster outlines the development process of the application, offers a thorough descriptive and predictive analysis of the data, and highlights the key functionalities of the Streamlit-based decision analysis tool.

88 - An Analytical Model for Assessing Factors Influential in Long- Versus Short-Term Survival after Kidney Transplantation

Mostafa Amini, California State University Long Beach, Long Beach, CA, United States, Aayush Doshi, Hassan Ahmed Qureshi

The significant gap between the availability of organs and the number of patients on transplant waitlists necessitates an equitable and optimized organ allocation system. This system should aim to minimize waitlist mortality and enhance the benefits of transplantation, such as improved survival time and quality of life. This project introduces the development of an explanatory analytics framework designed to uncover the key factors potentially influencing long-term survival following kidney transplantation. Utilizing data from the United Network for Organ Sharing registry, which includes over 100 thousand unique kidney transplant patients in the US since 1987, the framework will employ a variety of machine learning (ML) algorithms for initial classification. The optimal algorithm will subsequently be supplemented with advanced explainable artificial intelligence techniques to allow for comprehensive model explanation and interpretation. A crucial component of our approach involves extensive feature engineering to discover more nuanced relationships among variables, including interaction effects and non-linearities, which are often overlooked in traditional analyses. This framework aims to identify and analyze potentially critical but underexplored factors. By offering a detailed examination of these factors, the proposed framework seeks to significantly enhance the kidney allocation process, potentially leading to improved outcomes for recipients. The insights generated from this research could provide invaluable guidance for medical scholars and practitioners, informing future enhancements to organ transplantation management strategies.

90 - Fixing the Broken Rung: On The Interactions of Allyship and Microaggressions for Women ICT Professionals

Shiyi Wang, Nanyang Technological University , Singapore, Singapore, Anandasivam Gopal, Sierin Lim

The persistent underrepresentation of women at senior and mid-career levels in the information systems (IS) sector—the "*broken rung*" problem—is extensively recognized. However, the understanding of its underlying causes and effective solutions is still lacking. Through collaboration with four multinational technology firms in Singapore, we recruit high-quality participants to explore the broken rung problem. Our findings reveal that microaggressions substantially diminish the psychological safety of mid-career women in the ICT field, reducing promotability perceptions and lower job satisfaction. Concurrently, allyship is identified as a potential mitigating factor, buffering the adverse effects of microaggressions by bolstering mid-career women's psychological safety. Interestingly, our results indicate that men overlook these dynamics, which suggests that "privilege blindness" exists in the ICT field. This calls for further efforts to enhance organizational awareness and create actionable strategies such as cultivating allyship within organizations to solve the broken rung problem.

91 - Revenue Management, Loyalty Program, and Online Travel Agency in Hotel Chains

Shuxian Xiao, State University of New York-Buffalo, Buffalo, NY, United States, Charles Wang, Mingcheng Wei

We study the hotel's optimal designs of the premium-status loyalty programs in two alternative channels selling rooms to strategic consumers: direct channel versus dual channels. In the direct-channel scenario, the hotel sells rooms directly to consumers, while in the dual-channel scenario, the hotel sells rooms both in its direct channel and through an independent channel owned by an online travel agency (OTA). Note that the hotel excludes OTA bookings from the premium-status rewards. We characterize the consumers' purchasing behavior as well as the hotel's optimal pricing and premium-status loyalty program design decisions in both direct-channel and dual-channel scenarios. In the direct-channel model, we relax the restriction of the qualification threshold in a prior work, derive a complete spectrum of consumer segmentation, and find that the hotel can significantly improve its profit by offering a low qualification threshold to make its premium status more achievable by customers. We also numerically compare the hotel's optimal decisions and profits between direct- and dual-channel scenarios, and we find that the hotel can improves its profit by up to 2.57% with the dual-channel model.

92 - Return Based Risk Parity

Viraat Singh, Columbia University, New York City, NY, United States

- Traditional risk parity provides a way of diversifying a portfolio while preventing excessive risk concentration, providing a way to construct portfolios good risk diversification. The volatility of risk parity portfolio lies somewhere between the minimum variance and the 1/n portfolio that has extensively been studied. However, risk parity portfolios or equal risk contribution portfolios (ERC) depend only on the covariance matrix of the asset universe and is agnostic to the returns of the assets. Efforts have been made to incorporate returns into risk parity and other risk budgeting methods, but these methodologies produce non-convex optimization problems that are difficult to solve or relaxations that have no guarantees on the portfolio obtained. This not only makes them hard to solve using numerical heuristics, but these heuristics give no guarantees on the risk diversification. In this paper, we adopt the principle of diversifying risk contributions to improve returns, by satisfying approximate risk parity whilst providing bounds on risk spread and taking returns into account. Mathematically, we provide algorithms (RAH, RAC, AERC), that bound the gap between the risk contributions or risk spread (RS) and allows profitable assets to contribute more to a portfolio than would be allowed through regular risk parity.

93 - A fast nonparametric process monitoring scheme in fully decentralized systems

Jiahui Zhang, University of Wisconsin- Madison, Madison, WI, United States, Ziqian Zheng, Kaibo Liu

Along with the development of big-data technologies, multi-sensor systems have become more and more prevalent in manufacturing industries. To ensure the production process is in normal condition, process monitoring algorithms have been applied to multi-sensor systems, in which a central server aggregates information from all sensors and make decisions about the process condition. This kind of centralized systems, however, highly relies on the central server and cannot protect the privacy of the sensor data. This leads to the need of decentralized systems, in which each edge device can communicate with each other and individually raise the system alarm. The goal of this paper is to develop a fully decentralized process monitoring scheme for fast online change detection. Our monitoring framework includes the design of a nonparametric device-level statistic, a smart strategy for inter-device communication, and an alarm-raising mechanism which responds quickly to mean shifts and is resilient to partial function failures of the devices. The proposed method enjoys good theoretical properties which enables its effectiveness and efficiency. The outperformance of the proposed method is shown in numerical experiments and a case study.

94 - Integration of renewable energy sources in electricity price formation in Pakistan through Merit-Order Effect.

SULEMAN MUHAMMAD, Xi'an Jiaotong University, Xi'an, China, People's Republic of

We examine how the integration of renewable energy sources has impact extensive electricity price in Pakistan. Our main concern is scheduling of electricity power plants to full fil demands via merit order effect. Through merit order effect the most cost-effective indicator is given into service, then the next one most cost effective, and so on. Renewable energy sources are preferred over conventional power plants more and more often due to their less operation costs. This is overall resulting in very cheaper production of electricity. In this article the merit order impact is analyzed using different data sets. This study uses daily data from 2010 to 2022 to view the merit order effect and SARMAX/EGARCH methods has been applied. if renewable energy sources have added to the country's electricity mix, the results explain that electricity price in Pakistan have fall down significantly. In some marketplaces the merit order effect appears stronger than others. The integration of renewable energy sources is affecting the electricity price formation in Pakistan with positive gesture, shown by this study. Utility rates are reducing through merit order effect, it shows progressive development for both consumers and entrepreneurs.

Keywords: Merit-Order effect, extensive electricity price, Renewable energy source, Exponential GARCH, Integration.

95 - A Linearized Branch Flow Model Considering Line Shunts for Radial Distribution Systems and its Application in Volt/VAr Control

Hanyang Lin, Tsinghua University, Beijing, China, People's Republic of, Ye Guo, Hongbin Sun

In the process of modernizing power distribution networks, one common change is the replacement of overhead lines with underground cables. Traditional linear power flow models, assuming zero shunt elements, become inadequate for modern distribution systems where line shunts are non-negligible. To address this, a linearization method for branch flow model considering line shunts (LBFS) is proposed. This model effectively captures the errors introduced by line shunts while maintaining a linear structure of π equivalent circuit. The model's utility is demonstrated in a two-stage stochastic Volt/VAr control framework to manage network voltages, with the uncertainty in active power generation from renewable energy sources.

96 - Designing Sparse Flexibility Structures: What to do when the Long Chain Fails?

David Corredor, Amazon, Boston, MA, United States, Ling Zhang

When designing sparse flexibility structures, the long chain is the best candidate. Theoretical results and empirical evidence show that the long chain structure can achieve a really good performance. This performance is compromised when assumptions presented in the literature are relaxed. The most restrictive assumption when designing flexibility structures in real-world applications is that the demands in the network are identically distributed. In this paper we intend to relax that assumption and consider arbitrary demand distributions. We leverage our methodology on existing results and build sparse flexibility structure with at most O(2n) and O(3n). The proposed structures show promising results by achieving almost optimal performance over several systems with arbitrary distributions.

97 - Predicting Kidney Transplant Success and Risk Factors

Guldasta Hajizade, The University of Tulsa, Collins College of Business, Tulsa, OK, United States, MD Talha Mohsin, Narges Salehin, Kazim Topuz

This study seeks to enhance kidney transplant outcomes by integrating machine learning (ML) techniques for predictive analytics. We employ feature selection algorithms, including RF-RFE (Random Forest Recursive Feature Elimination), DT-RFE (Decision Tree Recursive Feature Elimination), Lasso-RFE (Lasso Recursive Feature Elimination), and LR-RFE (Logistic Regression Recursive Feature Elimination), to identify critical predictors influencing transplant risk. These selected features inform the development of predictive models using Gradient Boosting, AdaBoost, and Artificial Neural Networks (ANNs). The performance of these models is evaluated using metrics such as accuracy, precision, recall, and Area Under the Curve (AUC), providing a comprehensive assessment of model accuracy and reliability. Furthermore, a feature importance analysis is conducted using SHapley Additive exPlanations (SHAP) to gain deeper insights into the factors significantly impacting transplant outcomes. Through a combination of careful feature selection, advanced modeling techniques, and thorough performance evaluation, this research aims to demonstrate the potential of ML to improve predictive accuracy in kidney transplantation. The application of these methodologies aspires to support better clinical decision-making and optimize patient outcomes in kidney transplantation procedures.

98 - Dynamic Interlay and Intraday Scheduling

Christos Zacharias, University of Miami, Coral Gables, FL, United States

The simultaneous consideration of appointment day (interday scheduling) and time of day (intraday scheduling) in dynamic scheduling decisions is a theoretical and practical problem that has remained open. We introduce a novel dynamic programming framework that incorporates jointly these scheduling decisions in two timescales. Our model is designed with the intention of bridging the two streams of literature on interday and intraday scheduling and to leverage their latest theoretical developments in tackling the joint problem. We establish theoretical connections between two recent studies by proving novel theoretical results in discrete convex analysis regarding constrained multimodular function minimization. Grounded on our theory, we develop a practically implementable and computationally tractable scheduling paradigm with performance guarantees. Numerical experiments demonstrate that the optimality gap is less than 1% for practical instances of the problem.

99 - Metamodel Initialization of a Search Algorithm for Repair Kit Application

Xueying Wang, Boston University, Boston, MA, United States, Liying Zhang, Ruthairut Wootisarn

The “repair kit problem” in inventory management involves optimizing the storage and delivery of parts that are used to repair replacement. This parts have interdependencies because the repair cannot be done until all the parts are available. This problem is particularly challenging because of the necessity of maintaining a balance between carrying costs and the risk of delaying the repair when one or more parts are unavailable. It exists in different industries, such as on-site repairs, submarines, space stations, and public transportation systems. This poster presents an approach to initialize an empirical stochastic branch-and-bound search algorithm using metamodels. The algorithm is included in a simheuristics framework, which combined with simulation and heuristics methods, to create periodic review inventory policies for parts in a warehouse that holds intermittent demand spare parts. The simulation mimics a repair kit, while the heuristic model calculates annual total cost slopes on a part-by-part basis. Initialization metamodels are derived from results that use a deterministic model to start the search. Metamodels of service level and order quantity were used to calculate the reorder points and order-up-to levels. This approach shows good accuracy when based on validation using a small repair kit.

100 - Research on the dynamic pre-sale strategy of fresh agricultural products considering supplier risk avoidance

yuxiu liang, southeast university, nanjing jiangsu province, China, People's Republic of, Lindu Zhao

Study the dynamic pre-sale strategy of fresh agricultural products when suppliers face planting risk (out of stock or overplanting) under the risk avoidance behavior of suppliers. The supply chain includes a supplier and a retailer. The supplier makes pre-sale decisions before planting and maturity, and the retailer makes sales decisions at the present sale stage. As strategic consumers, consumers decide which stage to buy according to their own utility maximization. Suppliers reduce the uncertainty of planting risk through pre-planting booking and pre-mature booking, while their risk aversion behavior is modeled through the CARA utility function. Retailers sell spot after the crops mature and optimize their sales strategies based on market demand and supply. In this paper, we analyze the optimal decision of supply chain members at each stage by establishing a multi-stage dynamic game model. The results show that the degree of risk aversion of suppliers and the uncertainty of market demand significantly affect their pre-sale quantity and price strategy. The numerical simulation shows that the higher the risk aversion, the lower the pre-sale quantity and the higher the price; as strategic consumers, the purchase time is affected by the price and available quantity. The research in this paper provides theoretical basis and practical guidance for the formulation of pre-sale strategy in the supply chain of fresh agricultural products

101 - Investment, partial irreversibility, and competition

Takashi Shibata, Tokyo Metropolitan University, Hachioji, Japan, Michi Nishihara, Yuan Tian

This study considers the optimal investment timing decision when the investment is not completely irreversible in a competitive market. As shown in Section 8.2 of Dixit and Pindyck (1994), the optimal investment decision is independent of the degree of competition when the investment is completely irreversible. This study finds that the optimal investment decision depends on the degree of competition when the investment is not completely irreversible. As an extreme case, if the competition is strongly intense, the firm never invests. The weaker the competition, the later the investment is exercised.

102 - Liquidity Identification and Trading Strategies at Dark Pools

Ruijing Yang, Stevens Institute of Technology, Hoboken, NJ, United States, Somayeh Moazeni, Ricardo Collado

To limit the adverse price impact of large orders and to realize more favorable prices, institutional investors may resort to Dark pools for block trading. However, due to the low execution rate of submitted limit orders, identifying liquidity patterns within dark pools is challenging. Building on massive data sets of 200 million orders for 7000 stocks across 43 venues, we investigate liquidity patterns in different dark pools and present several machine learning models to predict the likelihood of executing a submitted limit order within a specific dark pool at any time. Leveraging our feature selection results, we then develop trading strategies and assess their performance.

103 - Building Trust in Digital Twin Through Verification and Validation

Julia Bitencourt, Auburn University, Auburn, AL, United States, Gregory Harris

Digital Twin (DT) is a topic of growing interest, as it combines many technologies, such as Internet-of-Things, simulation, and machine learning to support decision-making in constantly changing environments. As the landscape of DT grows, it is fundamental to trust in all components of a DT, especially in manufacturing environments where DTs support decisions that directly impact cost and safety. Model trust is traditionally viewed from the perspective of Verification and Validation (V&V). In this context, establishing trust includes performing verification and validation activities to demonstrate how the V&V evidence can be applied to support the use of the DT. Even though the importance of V&V is extensively recognized as a fundamental step in developing DTs that can be trusted and used in real-world environments, very few works report implementing such activities. In this research, we uncover the status of V&V for digital twins. A methodology to support practitioners in developing trusted DTs is proposed. The methodology is applied to a case study in a fused deposition modeling additive machine to demonstrate how V&V can support the development of trusted DTs.

104 - Unveiling Shippers' Behavior through a Two-Sided Market Approach

Matthew Roorda, University of Toronto, Toronoto, ON, Canada, Azin Golrizkhatami, Chi-Guhn Lee

The online food delivery sector's rapid growth has been paralleled by the adoption of crowd shipping models, where delivery tasks are outsourced to individuals utilizing their idle transportation capacity. This paper presents a novel mathematical framework within the Markov Decision Process (MDP) to examine crowd shippers' behaviours, particularly focusing on decision-making processes in platforms like UberEATS. The study aims to identify optimal strategies for crowd shippers to maximize long-term earnings by determining which delivery offers to accept or reject. By implementing reinforcement learning algorithms, the findings suggest strategies that could enhance profitability for crowd shippers while providing insights into effective pricing policies for crowd shipping services. This research contributes to the broader discourse on optimizing gig economy operations, emphasizing the need for equitable compensation models.

105 - Multi-physics Guided Diffusion Models with Manufacturing Applications

Naichen Shi, University of Michigan, Ann Arbor, MI, United States, Hao Yan

We present a generic physics-data fusion generative model called MGDM that integrates multi-fidelity physics simulations with diffusion processes. MGDM categorizes multi-fidelity physics simulations into inexpensive and expensive simulations, depending on the computational costs. The inexpensive simulations, which can be obtained with low latency,
directly inject contextual information into diffusion models that effectively learn the conditional distribution through first-order optimization methods. Furthermore, when results from expensive simulations are available, MGDM refines the quality of generated samples via a guided diffusion process. This design separates the training of a denoising diffusion model from a physics conditional probability model, thus lending flexibility to practitioners.
MGDM builds on Bayesian probabilistic models and is equipped with a theoretical guarantee that provides upper bounds on the KL-divergence between the sample and underlying true distribution. We use a numerical simulation in fluid dynamics and a case study in laser-based metal powder deposition additive manufacturing to demonstrate how MGDM achieves a delicate balance between multi-fidelity physics knowledge and statistical
patterns from observations.

106 - Explainable AI in Transport Logistics: Enabling Smarter Decision-Making in Crash Mitigation

Shamkhal Mammadov, The University of Tulsa, Tulsa, OK, United States, Ismail Abdulrashid

Traffic accidents threaten global public safety and kill countless people each year. This poster presents an explainable artificial intelligence (XAI) artifact design that includes accident data for stakeholders and decision-makers. It proposes responsible, explanatory, and interpretable models using a systems-level taxonomy to categorize driver-related behaviors by injury severity, thereby contributing to transport logistics decision making. To determine and analyze risk factors influencing injury severity, we used advanced techniques such as data missing at random (MAR) with Bayesian dynamic conditional imputation for missing records, synthetic minority oversampling for data imbalance, and categorical boosting (CatBoost) with SHapley Additive exPlanations (SHAP). In addition, exploratory feature analysis revealed spatiotemporal elements that influence traffic accidents and injury severity. The second phase involved creating predictive models using XGBoost, RF, DNN, and fine-tuned parameters. Using the SHAP approach, we employed model-agnostic interpretation techniques to separate explanations from models. In the final phase, we provided an analysis and summary of the system-level taxonomy across feature categories. This involved classifying crash data into high-level causal factors using aggregate SHAP scores, illustrating how each risk factor contributes to different injury severity levels.

107 - Optimal Fulfillment and Transshipment Strategies in Omnichannel Retailing with Cross-Channel Returns

Yuchi Guo, University of Michigan- Dearborn, Dearborn, MI, United States, Armagan Bayram

To satisfy customer demand and maintain their competitiveness, retailers are exploring ways to exploit rising online sales, such as by investing in cross-channel strategies. Addressing the challenges in operating both the online and offline channels efficiently, in this study, we build a dynamic programming model and investigate optimal fulfillment and transshipment strategies in omnichannel retailing with cross-channel returns. With the objective of maximizing the total profit of the retailer, we investigate (i) from where to fulfill a home delivery order when it occurs, (ii) when and how to transship returns to balance inventory. In order to develop the optimal omnichannel fulfillment and transshipment policy, we accommodate the uncertainty in the customer demand, returns, and the product per unit cost of shipping and transshipping.

108 - Blame attribution when crowdsourced delivery fails: consumer perceptions in tetradic arrangements in online grocery shopping

Annibal Sodero, The Ohio State University, Columbus, OH, United States, Vince Castillo, Arianna Seghezzi, Chiara Siragusa, Angela Tumino

Crowdsourced delivery of online grocery purchases takes place in a tetradic arrangement, where a consumer purchases grocery made available by a retailer; a worker performs the physical tasks of picking the purchase order, selecting substitutes whenever necessary, and delivering the order, while a crowdsourcing platform coordinates the grocery purchase and the delivery, while exchanging information with both consumer and a worker. This study investigates to whom the consumer attributes blame whenever a failure occurs in a service encounter involving all four entities. Results shed light on design and execution of crowdsourced delivery of online grocery purchases.

Scheduling and Its Contemporary Applications

Invited Session

Scheduling and Project Management

Chair: Zhixin Liu, University of Michigan-Dearborn, Dearborn, MI, United States

1 - Strengthening Priority Supply Chains: ***A Case of Candidate Supply Chains Selection Through Data Analytics Methods***

Charu Chandra, University of Michigan - Dearborn, Dearborn, MI, United States, Jorge Laboy-Bruno, Sam Le

In early 2023, the United States President's Management Agenda proclaimed a commitment to identify government-wide supply chains for prioritization due to diversity, economic, or national security risk. Among various objectives identified for this initiative were, (a) for federal procurement agencies identifying and giving attention to market segments within their own supplier base, where they have experienced challenges, identifying small disadvantages business (SDB) contractors, (b) establishing Government-wide priorities for strengthening strategic product and service supply-chains for such small businesses, and (c) implementing these priorities to better position federal government in building a strong breadth and depth of small business entity participation in different market segments. The first and foremost research question to be answered was developing a formal methodology on identifying priority supply chains. We describe a data-driven methodology that, (a) mines government-wide procurement databases for North American Industry Classification System (NAICS) and Product and Service Codes (PSC) for historical data related to small, disadvantaged business (SDB) participation, involving a large data set representing more than 1000 six-digit NAICS and 3000 PSC codes corresponding to SDBs, for a 12 year time-series reaching more than 20,000 at the end of the period, (b) analyzes it utilizing an ensemble of data processing, statistical, and economic analysis techniques to come up with a list of candidate supply chains. Further detailed business processes evaluation of these supply chains in the next phase of this research is intended to recommend best practices to be implemented for enhancing SDB participation in federal procurement activities.

2 - Retention Optimization in Maintenance Training Programs

Yifu Li, University of Science and Technology of China, Hefei, China, People's Republic of, Qiuwei Guo, Lindong Liu, Lifei Sheng

Training is an important business in the service sector. Although performance-enhancement training programs receive considerable attention from operations management researchers, there is a lack of guidance on designing maintenance training programs. We close this gap by investigating the modeling and optimization of a maintenance training program, considering the behavior that a customer may abandon the program if the training experience is overstressed. Customers make the participation decision of the training program based on the remembered holistic utility of the training activities. We formulate the maintenance training program design problem (MTDP), which maximizes overall service retention across all training episodes through activity selection and scheduling. By our analysis, the MTDP is a 0-1 constrained exponential sum problem (0-1 CESP), which is NP-hard. To resolve the MTDP, we introduce a novel geometric branch and bound (GB&B) algorithm that searches for the optimal solution by computing the bound of multiple dimensions over a box area. The GB&B algorithm is proven to be efficient in solving the MTDP through our computational studies, and it has the potential to resolve other 0-1 CESPs, which cannot be resolved by the branch and bound algorithm. With the optimal solution obtained by the GB&B algorithm, we investigate the properties of optimal program design. We contribute to the literature by discussing the mathematical model, solution method, and managerial insights of maintenance training program design.

3 - Strategic use of Deadlines to Counteract Present Bias

Zhixin Liu, University of Michigan-Dearborn, Dearborn, MI, United States, NICHOLAS G. HALL

We study utility loss from present bias in decision-making, resulting from procrastination and suboptimal task choice, by utilizing deadlines. Our backward recursion method for task scheduling under variable self-awareness levels yields a well-defined schedule framework. We demonstrate that task completion and utility loss respond to deadlines through self-awareness. Our model also presents a learning approach for recognizing and managing present bias. We highlight the effectiveness of deadlines, the varying impact of deadline strictness on utility, and the influence of self-awareness on self-control. Moreover, we offer practical recommendations for deadline setting and motivate managers to consider employees' present bias when allocating tasks.

4 - Online Platform's Store Brand Encroachment: the Role of Spillover Effect

Niu Yu, Wuhan Textile University, Wuhan, China, People's Republic of

In the platform economy, many online e-commerce platforms consider whether to employ the store brands to improve profits. When the national brand of the upstream manufacturer has spillover effect on the store brand, we construct a stylized model to investigate the store brand introduction choice of the online platform. By developing a framework of game theory, two common selling modes are considered: The reselling mode and the agency selling mode. Our findings indicate that when taking into account the spillover effect between the two brands, regardless of adopting a reselling or agency mode, it is always profitable for the platform to introduce the private label. Moreover, within a certain range of spillover effects, the national brand manufacturer can still benefit from the encroachment of the platform's store brand. Interestingly, we identify that in equilibrium, there exists a Pareto improvement zone wherein both the platform and the manufacturer are better off under the agency format.

5 - Uniform Parallel Machine Scheduling Game with Non-splitting Jobs

Guohua Wan, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Jin Yu

We analyze the cooperative game of the $Q_m| |\sum C_j$ problem with non-splitting-jobs for a set $N=\{1, 2, \ldots, n\}$ players, where the player i has N_i jobs. We prove the existence of the core of the game by linear program duality and characterize the core of the game. We also extend some results of Alon and Anily (2023) on the uniform parallel machine scheduling game with splitting-jobs.

1 - Multi-Physics Analysis for Additive Friction Stir Deposition (AFSD) using PINN

Zhenyu Kong, Virginia Tech, Blacksburg, VA, United States, Raghav Gnanasambandam

Metal additive manufacturing (AM) is attractive for its flexibility in designing complex parts. Additive Friction Stir Deposition (AFSD) is a solid-state AM process that deposits material by rotating a feed rod over the substrate. AFSD has several advantages over other AM techniques, including building large emissions-free parts. Modeling, monitoring, and quality control in AFSD is challenging due to the complex physics of the process. Coupled Partial Differential Equations (PDEs), particularly the heat equation and the Navier-Stokes equation, model the process to predict the thermal distribution and material flow during the process, respectively. The solutions of coupled PDEs are typically approximated with numerical simulations that consume much computational power and time. Physics-informed neural Networks (PINNs) are increasingly used to learn these solutions in a discretization-free framework. PINNs leverage the automatic differentiation of neural networks to discover the solutions of partial differential equations (PDEs). Despite their popularity, most applications do not consider multi-physics systems modeled by coupled PDEs. This work proposes coupled PINNs to learn the solutions of multi-physics systems. For AFSD modeling, the coupled PINNs have sub-networks for the heat equation and Navier Stokes, respectively. The inputs of the sub-networks are shared spatial-temporal locations, and the outputs are the corresponding thermal distribution and the material flow velocities. The loss functions of the sub-networks include the respective PDEs and corresponding boundary conditions. The proposed approach is a promising simulator for AFSD and applies to other complex systems.

2 - Selective maintenance optimization for large-scale systems with homogeneous units

Young Myoung Ko, Pohang University of Science and Technology, Pohang, Korea, Republic of, Jaehyoung Ju, Eunshin Byon

We present a novel fluid model to represent the degradation dynamics across the system, allowing for a condition-based maintenance (CBM) strategy. This strategy triggers maintenance actions when the cumulative health state of the units reaches a predetermined threshold, optimizing the long-term cost-effectiveness of maintenance operations.

Unlike typical regenerative processes where all units are restored to an 'as good as new' state, this study's selective maintenance approach repairs or replaces only those units in specific degraded states, leaving others unchanged. This non-regenerative nature presents unique analytical challenges, addressed by the proposed fluid model which effectively captures and predicts system behavior over time.

Numerical experiments validate the model's accuracy and efficiency, showing that the proposed CBM strategy outperforms traditional periodic maintenance approaches by minimizing the long-run average cost, providing significant improvements in maintenance planning for systems with many units. This approach is particularly relevant to industries like wind farms or solar parks, where many small generators require efficient maintenance management.

3 - An Adaptive Sampling Strategy for Online Monitoring of Partially Observed Networks

Yue Jiang, Purdue University, West Lafayette, IN, United States, Ana Maria Estarda Gomez

Rapid advancements in sensing and communication technologies have necessitated monitoring data streams with a network structure in various applications, including power grid maintenance, drought monitoring, and cyber-attack detection. In some applications, the network system can only provide partial information in real time due to limited data acquisition, transmission, and processing resources. In this case, it is critical to decide which node in the network to collect data at each time epoch to maximize the change detection capability. This paper proposes an adaptive sampling strategy for online monitoring of partially observed networks. First, a Gaussian process with a novel spatial kernel that exploits the global network structure is developed to capture the spatio-temporal information within the network. This information is used to guide the monitoring scheme and the adaptive sampling strategy. The main idea of the adaptive sampling strategy is to balance exploration and exploitation by designing a sampling distribution function based on the network topology to decide where to collect data at each acquisition time. The performance of the proposed framework is demonstrated through simulations and case studies.

4 - Dynamic Sensor Selections from In-Field Units for Remote Prognostics in a Cloud-Based System Center

Ying Fu, University of Wisconsin-Madison, Madison, WI, United States

The precise prognostics of operational units are crucial to avoiding catastrophic events. Units in sectors like automotive and aviation, often operating remotely, are equipped with advanced computing systems and wireless sensors for tracking, monitoring, and control. The computing systems can autonomously evaluate maintenance needs or make decisions using local sensor data, which is also transmitted to central or cloud-based systems for continuous improvement. However, high transmission costs, bandwidth constraints, and privacy concerns restrict data transmission frequency, necessitating sensor selection. Additionally, the changing operating environment requires dynamic sensor selection to enhance system robustness. In this study, we strategically select sensors to minimize prediction errors between full and partial sensor sets by utilizing the computational capabilities of the onboard system within bandwidth constraints. Due to the lack of a reliable prediction model, we propose a pilot model that starts with minimal data and dynamically updates as new data is collected on the server. Given the objective function is a complex neural network, we adopt a local linear approximation method to facilitate an effective solution. Our approach is empirically validated with a dataset from an aircraft gas turbine engine.

1 - A Reinforcement Learning Framework for Dynamic Watermarking in the Industrial Machine Tool Controllers

Navid Aftabi, Clemson University, Clemson, SC, United States

With worldwide growth in industrial automation and digitalization of the manufacturing environment, the manufacturing plants are no longer isolated from cyberattacks. Consequently, the industrial machine tool controllers (MTCs) are increasingly integrated with cloud applications, external sensors, and other data sources. While this transformation holds immense potential for efficiency and innovation, it simultaneously presents formidable cybersecurity challenges. The interconnectedness of MTCs with external networks makes them more vulnerable and primary attack targets for cyberattacks. This paper addresses the problem of secure MTCs by designing dynamic physical watermark signals using reinforcement learning (RL). We study the detection of replay attacks on MTCs, and introduce a watermarking RL framework for joint optimization of detection of replay attacks and control performance.

2 - Statistical Inference for Software Reliability Constrained by the Shape of the Mean Value Function

Kangan Chen, AMSS， Chinese Academy of Science, Beijing, China, People's Republic of

While parametric Software Reliability Growth Models (SRGMs) serve as a cornerstone in software reliability assessment, their reliance on known fault-detection time distributions often presents a significant limitation in practical software testing. In this study, we develop a novel shape-restricted spline estimator for quantifying software reliability, which enjoys the following advantages: 1) This estimator not only shares a key characteristic with parametric SRGMs, a feature largely underexplored in existing literature, but also obviates the need for specifying fault-detection time distributions; 2) It effectively utilizes the critical shape information of the mean value function (MVF) of fault-detection process, a detail seldom considered in prior work; 3) Unlike common non-parametric software reliability models, our shape-restricted spline estimator is capable of predicting the future behavior of failures. Furthermore, we investigate the predictive performance of the proposed methods by employing the so-called one-step look-ahead prediction method. In numerical experiment, we show that spline estimators under restriction demonstrates competitive performance compared to parametric and certain non-parametric models.

3 - Using Analytics and Streaming Data to Prioritize Vulnerability Patching and Remediation

Theodore Allen, The Ohio State University, Columbus, OH, United States, Garett Fogel, John McCarty

4 - Smart and Secure Manufacturing: Maintainable Digital Twins (DTs) via Bayesian Optimization and Active Learning

Abhishek Hanchate, Texas A&M University, College Station, TX, United States, Satish Bukkapatnam

This work proposes an implementation of Bayesian Optimization (BO), specifically an extension on Efficient Global Optimization (EGO), in an active learning context for developing maintainable Digital Twins (DTs). The motivation is driven by the challenges of effectively obtaining high-quality data for training DTs, often leading to significant deterioration in the reliability and performance of them. This becomes especially relevant for noisy environments wherein the physical system itself might change. For a given manufacturing recipe (G-code) for a machine, a residual matrix is generated by comparing the actual machine trajectory with the one followed by an initial DT in the form of an emulator. BO is then employed in order to approximate and regenerate the residual surface in least number of BO iterations, resulting in regenerated trajectories based on sampled points that follow the machine's spatial constraints. Additionally, the intermediate points between the trajectories are also employed in the next BO iteration to accelerate the convergence process, usually tracked via a criterion such as Sum of Squared Errors (SSE). The sampled points are then employed to probe the system, allowing for recursive and iterative generation of additional G-codes by stitching the points together, allowing for continuous training of the DT. Due to the noise-robust nature of EGO, the data generated are resistant to any physical system changes and are grounded in real-world machinery. The work demonstrates the novelty and potential of such frameworks for enhancing data quality and quantity for DTs.

5 - Maintenance Optimization for Multi-Station Manufacturing Systems with Quality-Reliability Chain

Kani Fu, University of Florida, GAINESVILLE, FL, United States, Minhee Kim

In many multi-station manufacturing systems, the system reliability is affected by both station reliability and product quality. Specifically, the incoming quality of the product can affect the reliability of the station. Meanwhile, the degradation of the station can cause deterioration of the product, resulting in bad quality. This interaction between product quality and station reliability is called the Quality-Reliability Chain (QR-chain). However, when studying the maintenance policy of multi-station manufacturing systems, little research has considered this dependency. Considering the characteristics of QR-chain, we formulate this problem as a mixed observability Markov decision process (MOMDP) model, in which the station's reliability is observable but the product's quality is unobservable except in the last station. By minimizing the long-run average cost from both station maintenance and product failure, we obtain the optimal maintenance policy. Several structural results are derived by the value iteration algorithm to find the optimal maintenance thresholds. A numerical study is conducted to illustrate the control insight of the optimal maintenance policy.

Models for Supply Chain Resilience and Disruption

Contributed Session

Chair: Brent Moritz, Penn State University, University Park, PA, United States

1 - *Digital Technology Adoption Impact on Supply Chain Resilience*

Chunxia (Trisha) Zhang, Kennesaw State University, Marietta, GA, United States

Supply chain resilience has garnered significant attention from scholars and practitioners, particularly in the face of global environmental disasters and pandemics like COVID-19. This study delves into the drivers behind firms' technology adoption to fortify their supply chain resilience, the hurdles faced during this adoption process amidst complexity and uncertainty, and the integrated role of technology, human capital, and organizational structure in augmenting resilience.

Drawing on the resource-based view theory, my research investigates the intricate relationship between adopting digital supply chain technologies, the capabilities of supply chain integration, and the resulting impact on supply chain resilience. Through in-depth interviews with top-level supply chain executives, I identify four key constructs shaping firms' resilience strategies:

Fit: The alignment between customer demands and technological competencies influences technology adoption decisions, subsequently impacting resilience strategies.

People – Labor: Labor constraints significantly influence technology adoption decisions, thus shaping resilience strategies.

Technology Competencies: Proficiency in digital supply chain technologies correlates with organizational structure and workforce capabilities, affecting resilience.

Supply Chain Integration: Integrating traditional and emerging technologies internally and externally contributes to customer satisfaction, consequently influencing technology adoption and resilience strategies.

My study contributes theoretically and practically by offering insights into the complex interplay between technology adoption, supply chain integration, and resilience. It provides actionable guidance for managers in navigating technology adoption decisions to enhance supply chain resilience. Additionally, while acknowledging the study's limitations, such as sample scope, I suggest avenues for future research, including exploring the impact of contextual factors on the technology adoption-resilience relationship.

2 - Sustainable Supplier Selection Decisions: Choices and Tradeoffs of Practicing Managers

Brent Moritz, Penn State University, University Park, PA, United States, Ben Fahimnia, Andrew Collins

Selecting environmentally sustainable suppliers is a vital and visible supply chain function. However, suppliers differ in cost and performance across different dimensions of sustainability. In addition, suppliers are selected by managers with heterogenous preferences. Little is known about how these factors interact. Using a large sample of experienced supply chain managers, we conduct a discrete choice supplier selectin experiment to investigate how practitioners value five key supplier attributes: *cost, waste management, carbon efficiency, green product and process design, and organizational support for environmental sustainability*. We assess the willingness to pay (WTP) for different dimensions of sustainability. Our results show that experienced practitioners were willing to pay the most for supplier improvements to waste management and carbon efficiency, and somewhat less for green product and process design, and organizational support for sustainability. We found modest differences by organizational level, education, and gender, and find that individuals with sustainability experience were willing to pay substantially more for higher environmental performance. Surprisingly, the WTP is highly non-linear: Managers with the highest individual environmental preferences were willing to pay nearly ten times more for improvements to sustainability. We show which key dimensions of sustainability are favored by practitioners, and that they are favored more (or much more) by individuals with high environmental performance orientation.

3 - Lean Management in Supplier Selection Process

Edward Lee, Hong Kong Polytechnic University, Hong Kong, Hong Kong, Edward Lee

Lean Management in Supplier Selection Process

Supplier selection has played a significant role in supply chain management. A trustful and reliable supplier is essential to the success of a business. An effective and efficient supplier selection process is therefore critical. To provide the products to satisfy the customers, the quicker to conclude a supplier the better. Selecting and evaluating qualified suppliers is complicated. The longer the selection process, the more logistics cost will be consumed. The lean management approach can help companies save costs in the selection process, such as using the lowest cost to evaluate the availability and adaptability of potential suppliers and reducing costs in investigating competitiveness and capability. This paper aims at introducing how lean management techniques can be applied to the supplier selection process. The lean tools discussed in the paper not only result in cost savings, but effects of long-term supplier relationships. New supplier selection strategies will also be considered within the value stream to ensure excellence in selection procedures, in terms of improvement within quality, cost, delivery, and design processes.

Emerging Markets: Challenges and Opportunities

Contributed Session

Chair: N ravichandran, IIM Ahmedabad, C 501 casa Vyoma Vastrapur, Ahmedabad, 380015, India

1 - Balancing Productivity Growth and Environmental Efficiency Goals in Indian Manufacturing: Some Alternative Scenarios

Kankana Mukherjee, Babson College, Wellesley, MA, United States

Soon after Prime Minister Narendra Modi came into power in 2014, the ‘Make in India’ initiative was launched by the Government of India which aimed at increasing the share of manufacturing in the Indian economy to help propel economic growth and create millions of jobs. But an increasing manufacturing production places very large demand on energy. As most industries in India still use traditional sources of energy, they are big contributors to overall greenhouse gas emissions. The goals of increasing manufacturing production and employment while at the same time reducing energy use conflict with each other. This study investigates these tradeoffs by examining data for the major energy intensive industries across the states in India over the period 2013-14 to 2019-20. Using data from Annual Survey of Industries, Government of India as well as other sources to create industry specific data and utilizing Data Envelopment Analysis and directional distance functions, I propose several alternative models for reconciling the conflicting goals in Indian manufacturing. Results show that significant potential for simultaneous increase in output and reduction in energy use exists in several states. The results from the empirical analysis should be helpful in providing policy directions for the government as well as strategic insights for the firms in the energy intensive industries in India.

2 - Does Corporate Governance Improve the ESG performance? Evidence From an Emerging Market

Surya Bhushan Kumar, Indian Institute of Management Indore, Indore, India

Corporate firms disclose their ability and performance through various mandatory and non-mandatory reports. While Annual reports are mandatory, there is a rising trend of disclosing more with some non-traditional reports. ESG report is one such non-mandatory report that provides enriched information to all firm stakeholders. The usability of such ESG reports is more important for firms in emerging markets due to constrained environment for information disclosure and other regulatory challenges. It also aggravates the problem of information asymmetry for investors in their decision-making. Here it will be interesting to see the role of improved corporate governance. In this line, I am exploring in this study the role of corporate governance as an antecedent for ESG performance in emerging markets. Academic literature also suggests that components of ESG vary in their information content and importance. Additionally, it explores the specific element that contributes more to ESG performance. The findings will be helpful to all stakeholders for better decision-making. As mandatory ESG performance in emerging markets is relatively rare compared to developed markets, the finding of this study could enrich the extant related literature.

3 - Digitisation and its impact on the largest employment insurance scheme in the world

Ravichandran Narasimhan, Indian Institute of Management-Ahmadabad, Ahmedabad, India, Balaraman Rajan

The largest employment insurance in the world operating in India has enhanced consumer focus by digitisation of their process. This inhouse effort consisted of Business process reengineering, structural changes, automation and structural changes in the operations. The change management involved working with employees of the organisation and other stake holders like members and member employers .The impact of the digitisation was ease of doing business by members and rapid response time. This paper documents this experience as a unique case study in under managed sectors.

Data Science in Healthcare and Policy

Flash Session

Chair: Alireza Boloori, University of Washington, Tacoma, WA, United States

1 - Comparative Analysis of Comorbidity Networks Before and During the COVID-19 Pandemic

nguyen phan, university of Arkansas, fayetteville, AR, United States, Shengfan Zhang

The COVID-19 pandemic has caused unprecedented impacts on a global scale, including public health system exhaustion, supply chain disruption, economic downturn, service industry decline, lasting behavioral changes, and many more. The pandemic can cause a significant and rapid impact because of the lack of preparedness and tools to detect abnormal changes. To develop such tools, we propose a comorbidity network analysis (CNA) approach, using the National (Nationwide) Inpatient Sample (NIS) to map the interconnections between various comorbidities within patient cohorts. In our analysis, we include diverse demographic and socioeconomic factors, giving us a detailed view of the pandemic’s disparate effects on different populations. To examine how the pandemic has changed the complex comorbidity network dynamics, we constructed and compared different comorbidity networks for each quarter of the year 2020 and pre-pandemic years 2018-2019. Through our observation study, we seek to observe any correlations and trends among concurrent diseases, providing valuable insights into how the pandemic has changed the complex comorbidity network dynamics. Understanding the nature of the virus and how the pandemic‘s effect on different populations can contribute to practical healthcare applications and strategic responses to pandemics.

2 - AI-Powered Tool For Early Prevention Of Type 2 Diabetes In Adolescents

Mahima Naznin, University Of Missouri- Columbia, Columbia, MO, United States, Sharan Srinivas

Early interventions during adolescence and young adulthood are crucial to averting over 50% of Type 2 Diabetes (T2D) cases, which are expected to nearly triple in the US by 2060. Unfortunately, there is currently no screening tool available to predict adolescents' future T2D risk. This research aims to develop a machine learning-based screening tool for predicting short-term and long-term T2D risk among adolescents by accounting for their lifestyle choices and socioecological, physiological, and psychological factors. We evaluated and compared the area under the receiver operating characteristic curve (AUC-ROC) for several state-of-the-art machine learning algorithms. Results indicate XGBoost to yield the best performance with an AUC-ROC of 0.72, suggesting good discriminating capability in predicting high-risk cases up to 15 years in advance.

3 - Identifying Genetic Variants for Obesity Incorporating Prior Insights: Quantile Regression with Insight Fusion for Ultra-high Dimensional Data

Jiantong Wang, University of Cincinnati, Cincinnati, OH, United States, Heng Lian, Yan Yu, Heping Zhang

Obesity is widely recognized as a critical and pervasive health concern. We strive to identify important genetic risk factors from hundreds of thousands of single nucleotide polymorphisms (SNP) for obesity. We propose and apply a novel Quantile Regression with Insight Fusion (QRIF) approach that can integrate insights from established studies or domain knowledge to simultaneously select variables and modeling for ultra-high dimensional genetic data, focusing on high conditional quantiles of body mass index (BMI) that are of most interest. We discover interesting new SNPs and shed new light on a comprehensive view of the underlying genetic risk factors for different levels of BMI. This may potentially pave the way for more precise and targeted treatment strategies. The QRIF approach intends to balance the trade-off between the prior insights and the observed data while being robust to potential false information. We further establish the desirable asymptotic properties under the challenging non-differentiable check loss functions via Huber loss approximation and nonconvex SCAD penalty via local linear approximation. Finally, we develop an efficient algorithm for the QRIF approach. Our simulation studies further demonstrate its effectiveness.

4 - Analysis of Social Determinants of Health to Risk-Stratify Type II Diabetes Pathways

Yukti Kathuria, University of Massachusetts Amherst, Amherst, MA, United States, Muge Capan, Kristen Miller, Elizabeth Selden, William Gallagher

Type II diabetes is a significant public health burden with high prevalence and high cost. Non-clinical factors, such as demographics (e.g., race, ethnicity, gender) and social determinants of health (SDOH) (e.g., insurance, marital status, health literacy) have a strong influence on individuals' diagnostic trajectories in primary care. However, most decision analytical models focus on clinical factors to determine the risk of missed opportunities and undesired health outcomes. This study focuses on quantifying and categorizing patient subpopulations within primary care settings to study the impact of these SDOH factors and demographics on patient outcomes. Descriptive and statistical analyses were applied to de-identified retrospective longitudinal Electronic Health Record (EHR) data (e.g., demographics, labs, vital signs, diagnoses, and health care utilization) of adult patients in selected primary care practices over a 6-year study period (01/2017-12/2023) derived from a healthcare delivery system in the mid-Atlantic, serving a racially, ethnically, and socioeconomically diverse patient population residing in urban, rural, and suburban settings. By employing clustering techniques, we identified distinct subpopulations and their trajectories based on their SDOH characteristics and Type II diabetes pathways. This approach not only enhances our understanding of how social factors influence each other and diabetes diagnosis pathways, but also aids in risk prioritization in primary care diagnostic decision processes. Our preliminary findings suggest significant variance in risk of adverse diagnostic trajectories among subpopulations. These insights will help providers to identify at-risk patients more effectively, thereby optimizing resource allocation and improving primary care diagnostic decision making.

5 - Benchmarking Fairness of Genetic Risk Score Models for Early-stage Prediction of Type 1 Diabetes from the TEDDY study

Feng Lin, University of Washington, Seattle, WA, United States, Congjing Zhang, Kendra Vehik, Hemang Parikh, Mingqian Li, Richard Oram, Xiaoning Qian, Shuai Huang

Type 1 diabetes (T1D) is one of the most prevalent and serious chronic immune-mediated diseases in childhood which has a great impact on the patients' life expectancy and their quality of life. The rapid advances in machine learning (ML) have fostered the use of various ML models for building prediction genetic risk score (GRS) models for the onset of T1D in an early stage. However, the existence of ethnoracial inequity has cast a shadow over the use of these GRS models in practice. Thus, it is important to comprehensively evaluate the potential unfairness in these algorithms across different ethnoracial groups. By performing a secondary analysis of the The Environmental Determinants of Diabetes in the Young (TEDDY) study data with the state-of-the-art ML models, we show that current ML GRS models demonstrated considerable disparities across ethnic groups. Our findings highlight the importance of considering fairness in the development of ML GRS models for T1D prediction as well as in future study design of T1D research.

6 - An interpretable and deterministic model to improve legal decision-making in criminal justice reform

Aparna Komarla, Redo.io, Berkeley, CA, United States

In 2018, California became the first state to pass a Prosecutor-Initiated Resentencing (PIR) law, which grants prosecutor offices the power to revisit multi-decade and life sentence cases. But given that there are over 100,000 people in California's prisons, lawyers and county officials need efficient and accurate ways to identify eligible candidates for PIR instead of manually reviewing piles of paperwork. Redo.io (github.com/redoio) is solving this problem with an open-source eligibility model to filter cases and apply legal expertise efficiently. We designed a rules-based and deterministic model as opposed to a black-box predictive model that embodies the principles of fairness, accountability and transparency. Legal experts help design and fine-tune eligibility rules in an iterative review process. Our model therefore augments legal knowledge about the applicability of PIR as opposed to replacing such expertise. Redo.io has deployed the eligibility model for the Three Strikes Project at the Stanford School of Law (https://law.stanford.edu/three-strikes-project/), a legal clinical seminar where law students represent individuals serving life sentences for nonviolent crimes under California's Three Strikes Law. By supplementing a lawyer's decision to examine a case for resentencing instead of automating the end-to-end process, our model helps stakeholders make high-impact decisions efficiently while preventing existing biases in our society from being exacerbated. It therefore exemplifies a framework for meaningful human-computer interaction in high-stakes and high-risk decision making processes.

7 - Early Detection of Problematic Cannabis Use Among Young Adult Users in Los Angeles Using a Recurrent Neural Network Approach

Jiyang He, University of Southern California, Los Angeles, CA, United States, Shinyi Wu, Carolyn Wong

The increasing prevalence of cannabis use worldwide underscores the need for a thorough understanding of cannabis dependence, highlighting the importance of early detection to mitigate long-term health consequences. This study aims to detect problematic cannabis use (PCU) in the dynamic environment of Los Angeles County, one of the nation's largest markets for liberalized cannabis use. These findings could assist healthcare professionals in cannabis intervention programs by identifying risk factors and warning signs of PCU, thus facilitating the implementation of early intervention strategies.

This research employs a Recurrent Neural Network (RNN) model using data from a longitudinal study of cannabis-using young adults aged 18-26 from 2014 to 2023, which includes eight waves of data collection. The dataset incorporates sociodemographic data, self-reported substance use, and psychosocial assessments. The determination of cannabis dependence among participants utilizes a diagnostic criterion based on the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5).

Our approach integrates these multi-dimensional data sources with a deep learning architecture to model the potential onset of PCU. The RNN model processes time-variant features through multiple layers to capture dynamic changes over time. Additionally, we use a Lassonet-RNN model to reduce input feature dimensions and determine the importance rankings of characteristic variables. We further evaluate the effectiveness of the RNN model by comparing it with traditional machine learning methods.

These analyses provide insights to inform preventive health strategies and practical decision-making in clinical settings, highlighting the potential of deep learning models and the value of utilizing a longitudinal data structure.

8 - Analyzing the Impact of Cannabis Legalization on Health, Societal, and Workplace Outcomes

Alireza Boloori, University of Washington, Tacoma, WA, United States, Iman Attari, Michael Freeman, Rupinder Jindal

The recreational use of cannabis has been legalized in several U.S. states over the last decade. Utilizing patients' claims data, we investigate the impact of these legalizations across states on various healthcare (e.g., hospital resources utilization), societal (e.g., domestic violence), and workplace (e.g., injuries/disabilities) outcomes. We employ a staggered Difference-in-Differences method to test whether or not such legalizations have impacted the foregoing outcomes (and, if so, under what circumstances). Leveraging findings from our numerical experiments, we provide various insights for Federal/state-level healthcare policy makers that could help them in approaching cannabis-related legislation.

1 - Risk Optimization in Food Supply Chains

Ryan Jackovic, Purdue University, West Lafayette, IN, United States

Current methodologies in supply chain risk assessment often overlook the interconnectedness and cumulative impacts of risks across the supply chain. This paper proposes a novel methodology that addresses these gaps by integrating supplier selection and order allocation into a comprehensive supply chain risk assessment framework. The proposed model evaluates potential suppliers based on their production capacities, costs, and risks, considering factors such as location risks, transportation vulnerabilities, and financial stability. The technique identifies optimal paths that balance resilience and efficiency using an optimization model that minimizes shutdown costs, purchasing expenses, and carbon emissions. Traditional multi-criteria approaches may complicate decision-making with multiple trade-offs, while our model simplifies the process by providing a single, interpretable solution. This approach is demonstrated through a case study on food supply chains.

2 - Stochastic Military Port Selection

Lennon Conson, Air Force Institute of Technology, Wright-Patterson AFB, OH, United States, Brian Lunday, Matthew Robbins

The military seaport selection problem involves determining the seaports of embarkation (SPOEs) for the transshipment of military cargoes from home stations to theaters of operation to minimize cumulative travel times. Whereas conventional, commercial seaport selection for transshipment has primarily focused on reducing economic costs, this research examines a military-focused, temporal-domain optimization of seaport selection for military cargo. This problem has several complicating factors of interest: shipments originating at respective home stations traverse either rail or road networks to reach an SPOE; transporting ships must be managed to carry shipments from SPOEs to seaports of debarkation; and the identification of seaports are first-stage decisions, whereas shipment routing and timing entail second-stage decisions subject to parametric uncertainties. This study examines model tractability for a representative scenario, identifying robust, resource-efficient strategic deployment decisions.

3 - Supplier Selection in DoD Supply Chains

D'Andre Tobias, Georgia Institute of Technology, Atlanta, GA, United States

Plant closures have always been a point of concern for supply chain purchasers within the Department of Defense (DoD). At any time, a supplier plant could close due to factors such as natural disasters, strikes, pandemics or financial distress. In times of crisis, the risks of such factors can increase exponentially. When identifying annual contracts, it is important for supply chain purchasers to assess the risk of potential suppliers. In this paper, we apply a supplier risk assessment model proven in literature to a case study within the DoD during a time of crisis – the COVID-19 pandemic. In this case study, we use Cox Proportional Hazards Model to analyze the potential factors that influence a plant closure for at-risk suppliers determined by the supplier risk assessment. Our results demonstrate that applying the cox-proportional hazards model can aid the DoD by reducing plant closures and saving taxpayer-dollars.

1 - Cooperation for Scalable Supervision of Autonomy in Mixed Traffic

Cathy Wu, Massachusetts Institue of Technology, Cambridge, MA, United States, Cameron Hickert, Sirui Li

Advances in autonomy offer the potential for dramatic positive outcomes in a number of domains, yet enabling their safe deployment remains an open problem. This work's motivating question is: In safety-critical settings, can we avoid the need to have one human supervise one machine at all times? The work formalizes this scalable supervision problem by considering remotely located human supervisors and investigating how autonomous agents can cooperate to achieve safety. This article focuses on the safety-critical context of autonomous vehicles (AVs) merging into traffic consisting of a mixture of AVs and human drivers. The analysis establishes high reliability upper bounds on human supervision requirements. It further shows that AV cooperation can improve supervision reliability by orders of magnitude and counterintuitively requires fewer supervisors (per AV) as more AVs are adopted. These analytical results leverage queuing-theoretic analysis, order statistics, and a conservative, reachability-based approach. A key takeaway is the potential value of cooperation in enabling the deployment of autonomy at scale. While this work focuses on AVs, the scalable supervision framework may be of independent interest to a broader array of autonomous control challenges. This work is published in the Transactions on Robotics in 2023.

2 - Supply and Capacity Planning For Autonomous Delivery Vehicles

Neda Mirzaeian, The University of Texas at Dallas, Richardson, TX, United States, Milind Dawande, Soraya (Nadia) Fatehi, Ganesh Janakiraman

We investigate optimal staffing and pricing strategies for a food delivery platform incorporating both human drivers and autonomous delivery vehicles (ADVs) under a maximum delivery time guarantee. Modeling the platform's objective of minimizing its operational costs as an optimization problem, we show nuanced interplays between drivers' wages, vehicle wear and tear, and ADV leasing costs. A comparison is then drawn between the feasibility and optimal number of servers in this case and a benchmark where the platform solely relies on human drivers. We further analyze the potential of ADVs to entirely replace human drivers in the food delivery industry. Our findings suggest that optimal resource allocation may require the simultaneous utilization of both human drivers and ADVs, even in the presence of an abundant supply of ADVs. Our study highlights scenarios where human drivers remain indispensable, challenging assumptions about the future dominance of ADVs. In addition, we explore strategic staffing and pricing for non-peak and peak demand periods. Our results challenge conventional beliefs regarding resource utilization during non-peak and peak periods, demonstrating the advantages of employing human drivers even during non-peak hours. Our findings offer valuable insights for food delivery platforms, ADV suppliers, and human drivers, assisting in optimal resource deployment and providing foresight into the evolving landscape of food delivery services.

3 - On the Supply of Autonomous Vehicles in Platforms

Ilan Lobel, New York University, New York, NY, United States, Daniel Freund, Jiayu (Kamessi) Zhao

The likely large-scale deployment of autonomous vehicle (AV) technology in the near future has the potential to fundamentally change the transportation landscape. Due to the high cost of AV hardware, the most likely path to widespread AV use is via platforms that can sustain high utilization, such as ride-hailing and delivery services. In this paper, we consider four potential operational models to commercialize AVs, which we model as a supply chain game between a platform, an AV supplier, and human drivers that join as individual contractors (ICs). We find that apart from an AV-only platform, all deployment models are subject to a risk of AV underutilization due to the need to maintain the ICs' utilization sufficiently high to ensure ICs remain engaged. In non-integrated models, this risk can propagate backwards in the supply chain and thereby negatively affect its efficiency. For the open platform the efficiency loss compared to an integrated platform can be unbounded. We then study how usage commitments between the platform and the supplier can overcome the unbounded efficiency loss. Though the uncontracted open platform may perform worse than the other models, an open platform equipped with a usage contract offers substantial efficiency benefits compared to the AV-only/AV leasing platforms.

4 - Getting out of Your Own Way: Introducing Autonomous Vehicles on a Ride-Hailing Platform

Andrew Frazelle, The University of Texas at Dallas, Richardson, TX, United States, Francisco Castro

We consider a ride-hailing platform's strategy to recruit human drivers while also operating a private fleet of AVs. The platform sets the human-driver wage and its AV fleet size, and human drivers make strategic joining decisions based on a rational anticipation of their expected earnings. We show that having the option to augment its AV fleet after observing human participation levels can, counterintuitively, hurt the platform's bottom line. Human drivers anticipate that the platform may reactively acquire more AVs; this reduces their expected earnings, so the platform must offer higher wages to attract a given number of drivers. The higher wage implies that the platform should acquire even more AVs, leading to a feedback loop or "race to the top" of increasing wages and increasing AV acquisition. The race to the top hurts the platform's profits by effectively preventing it from attracting more than a limited number of human drivers and increasing the cost of attracting a given number. Our findings reveal the importance of the platform's credibility with its drivers. The ride-hailing platform can succeed in avoiding the race to the top only to the extent that it can convince human drivers that it will not reactively acquire a large number of AVs. Otherwise, significant profit losses await.

Co-Chair: Qinyi Chen, MIT, Cambridge, MA, United States

1 - Nearly Minimax Optimal Regret for Multinomial Logistic Bandit

Min-hwan Oh, Seoul National University, Seoul, Korea, Republic of, Joongkyu Lee

In this paper, we study the contextual multinomial logit (MNL) bandit problem in which a learning agent sequentially selects an assortment based on contextual information, and user feedback follows an MNL choice model. There has been a significant discrepancy between lower and upper regret bounds, particularly regarding the maximum assortment size K. Additionally, the variation in reward structures between these bounds complicates the quest for optimality. Under uniform rewards, where all items have the same expected reward, we establish a regret lower bound of $\Omega(d\sqrt{T/K})$ and propose a constant-time algorithm, OFU-MNL+, that achieves a matching upper bound of $\tilde{O}(d\sqrt{T/K})$. Under non-uniform rewards, we prove a lower bound of $\Omega(d\sqrt{T})$ and an upper bound of $\tilde{O}(d\sqrt{T})$, also achievable by OFU-MNL+. Our empirical studies support these theoretical findings. To the best of our knowledge, this is the first work in the contextual MNL bandit literature to prove minimax optimality --- for either uniform or non-uniform reward setting --- and to propose a computationally efficient algorithm that achieves this optimality up to logarithmic factors.

2 - Online Learning for Increasing Parental Engagement On Ed Tech Platforms

Divya Singhvi, New York University, New York, NY, United States, Alex Akira Okuno, Somya Singhvi

Ensuring universal access to quality education, particularly in developing countries, remains a formidable challenge. A key issue that affects educational outcomes among low-income households is limited parent involvement in their kids' education. However, EdTech platforms can help develop cheap and effective solutions to resolve this problem. In this work, we discuss our collaboration with Rocket Learning, one of India's leading non-profit EdTech organization that collaborates with various states- and the central-government of the country to create and manage digital communities (WhatsApp Groups) to deliver educational content to parents. In collaboration with Rocket Learning, we run a series of experiments to design, implement and optimize nudges to increase parental engagement on these digital groups using various data-driven online and offline learning methods. Our findings suggest that carefully delivered nudges can substanitally improve parental engagement. Furthermore, we also present practical insights from implementing data-driven methods on the field.

3 - Learning in Multi-Unit Pay-as-Bid Auctions

Rigel Galgana, Massachusetts Institute of Technology, Cambridge, MA, United States, Negin Golrezaei

Motivated by Carbon Emissions Trading Schemes, Treasury Auctions, Procurement Auctions, and Wholesale Electricity Markets, which all involve the auctioning of multiple homogeneous units, we consider the problem of learning how to bid in repeated multi-unit pay-as-bid auctions. In each of these auctions, a large number of(identical) items are allocated to the largest submitted bids, where each agent's payment is the sum of their winning bids.

The problem is challenging due to the combinatorial nature of the action space. We first focus on the simpler offline setting, where the bidder optimizes their vector of bids with respect to the past submitted bids by other bidders. We solve this via a polynomial time dynamic program (DP) that essentially decouples the utility across units. We leverage the DP structure to design online learning algorithms with polynomial complexity and regret. We accompany these results with a regret lower bound, which matches the linear dependency in the number of units.

Our numerical simulations show that the market dynamics generally converge to a welfare maximizing equilibrium where bidders submit uniform bids when bidders behave according to our proposed learning algorithms. Additionally, we find that the pay-as-bid auction consistently generates significantly higher revenue compared to the more popular uniform price auction. This advantage positions the pay-as-bid auction as an appealing auction format in settings where earning high revenue holds significant social value, such as in Carbon Emissions Trading Schemes.

4 - Stochastic Multi-armed Bandits with Strongly Reward-Dependent Delays

Yifu Tang, University of California, Berkeley, Berkeley, CA, United States, Yingfei Wang, Zeyu Zheng

There has been increasing interest in applying multi-armed bandits to adaptive designs in patient-centric clinical trials. Existing literature either assumes no delay in observing a patient’s treatment reward, or considers delays that are independent or weakly correlated with the reward. However, certain applications give rise to situations where the delay is strongly correlated with the reward, or even that the delay is exactly the same as the reward (e.g., survival response). We formulate a new set of stochastic multi-armed bandit (MAB) problem with strongly reward-dependent delays, and provide algorithm design and associated theoretical guarantees in terms of upper and lower bounds. We show the central limit theorems with respect to the rewards for post-experiment inference.

5 - Achieving $\tilde{O}(1/\epsilon)$ Sample Complexity for Constrained Markov Decision Process

J Jiang, Hong Kong University of Science and Technology, Hong Kong, China, People's Republic of, Yinyu Ye

We consider the reinforcement learning problem for the constrained Markov decision process (CMDP), which plays a central role in satisfying safety or resource constraints in sequential learning and decision-making. In this problem, we are given finite resources and a MDP with unknown transition probabilities. At each stage, we take an action, collecting a reward and consuming some resources, all assumed to be unknown and need to be learned over time. In this work, we take the first step towards deriving optimal problem-dependent guarantees for the CMDP problems. We derive a logarithmic regret bound, which translates into a O(κϵ·log^2(1/ϵ)) sample complexity bound, with κ being a problem-dependent parameter, yet independent of ϵ. Our sample complexity bound improves upon the state-of-art O(1/ϵ^2) sample complexity for CMDP problems established in the previous literature, in terms of the dependency on ϵ. To achieve this advance, we develop a new framework for analyzing CMDP problems. To be specific, our algorithm operates in the primal space and we resolve the primal LP for the CMDP problem at each period in an online manner, with adaptive remaining resource capacities. The key elements of our algorithm are: i). an eliminating procedure that characterizes one optimal basis of the primal LP, and; ii) a resolving procedure that is adaptive to the remaining resources and sticks to the characterized optimal basis.

Digital Platform Applications

Contributed Session

Chair: Ajit Pratap Singh, IIM Rd, Prabandh Nagar,, 226013

1 - Resolving Copyright Infringement of Derivative Videos

Ying Wang, Northeastern University, Liaoning, China, People's Republic of, Jennifer shang

Short video platforms have witnessed a remarkable growth in recent years. Derivative video, a specific type of short video created from longer-form content, appeals to a segment of the long video audience but also poses a risk of copyright infringement. In a stylized model we investigate whether a long video platform should collaborate with a short video platform when facing potential competition from derivative short videos. We evaluate two scenarios: collaboration, where the short video platform compensates for long video copyrights; and competition, where the two parties compete and the long video platform actively detects and addresses infringement on the short platform. Our research generates valuable managerial insights for the video industry, empowering decision-makers to make informed strategic choices.

2 - A Game Theoretic Analysis of Content Provision Strategies for Video Streaming Services

Kengo Kakimizu, Keio University, Yokohama, Japan, Nobuo Matsubayashi

In recent years, competition in the video streaming service industry has intensified. As a result, Netflix, which initially only offered ad-free content, has recently launched a new ad-supported plan as part of its competitive strategy. Motivated by such real-world examples, this study conducts game-theoretic analysis to investigate under which conditions adding an ad-supported plan to an ad-free plan is profitable in a duopolistic market where the rival firm also offers its own ad-supported plan. We assume that consumers are heterogeneous in their sensitivity to advertising, which implies that plans offered at different levels of ads are vertically differentiated. We find that unlike in a standard vertical differentiation model for information goods, where a product line is never optimal due to severe cannibalization effects, the addition of an ad-supported plan can be sustained in equilibrium. Specifically, the firm benefits from adding this plan when the content quality of the ad-supported plan is moderately low and the intensity of the network effect on advertisers is high relative to that of the rival's plan.

3 - Privacy, Data and Competition: The Case of Apps For Young Children

Grazia Cecere, Institut Mines Telecom , Evry Courcouronnes, France, Catherine Tucker, Vincent Lefrere

This study examines the impact of firm size on the privacy protections offered to consumers, particularly through apps targeted at young children—a group for whom privacy concerns are paramount. Using weekly data from the Google Play Store over a three-year period, we explore whether larger firms exploit their scale to amass more data or if smaller firms exhibit less rigorous data protection practices. Our findings indicate that larger app developers implement more robust privacy protections, requesting less sensitive data from users compared to smaller developers. Large developers originated from developing countries with low privacy regime show a tendency to adopt similar levels of data collection. This pattern suggests a trend towards a universal standardization of privacy practices among large developers, who maintain consistent privacy standards across various regulatory environments.

4 - Optimizing Profitability in Platform Ecosystems: Integrating Pricing, Differentiation, and Cross-Network Effects

Ajit Pratap Singh, Indian Institute of Management, Lucknow, Lucknow, India, Suresh Jakhar

Our research delves into the optimal pricing strategy within a duopolistic media platform market, considering the interplay of cross-network effects among viewers, content creators, and advertisers. Employing a game-theoretical linear city model, we analyze the dynamics among these interconnected stakeholders across three sides. Our investigation examines how platform pricing adjusts with the presence of multi-homing on one or more market sides. The insights obtained from our study underscore strategic opportunities for competitive platforms to leverage pricing, differentiation, and cross-network effects effectively to optimize their profits. Further, we evaluate the relevance of existing literature findings within our context, identifying instances of both alignment and deviation across various scenarios. Our findings suggest that under specific conditions, multi-homing can yield benefits for both market agents and platforms. We explore scenarios wherein multiple sides of the market engage in multi-homing concurrently, proposing that platforms should incentivize one side to multi-home only when other sides also participate in multi-homing. Furthermore, we outline criteria for offering free access or implementing subscription fees for market agents, offering practical guidance for platforms operating within a competitive landscape in the presence of cross-network effects and multi-homing.

Pricing Strategies and Consumer Insights

Flash Session

Chair: Heddy Barale

1 - Flexibility in an Integrated Green Hydrogen/Ammonia Production Facility to Interface with Volatile Electricity Prices

Heddy Barale, MIT, Cambridge, MA, United States

This study explores the integration of nuclear power plants (NPPs) with thermal energy storage (TES) systems on an integrated green hydrogen/ammonia production system to facilitate participation in multi-commodity markets, thereby improving economic competitiveness. The research focuses on two types of NPPs: a light-water reactor (LWR) and a Molten Salt Reactor (MSR). These were analyzed to demonstrate the economic viability of thermally balanced energy storage coupling designs for thermal power extraction. The coupling of each reactor with a TES system was evaluated within the Electric Reliability Council of Texas (ERCOT) market framework.

A stochastic optimization approach was employed, utilizing an autoregressive moving average (ARMA) model to interpret price signals from the ERCOT market. Advanced simulation tools, including the Risk Analysis Virtual Environment (RAVEN) and its dispatch optimization plugin, the Holistic Energy Resource Optimization Network (HERON), were used for dispatch and capacity optimization. These tools leveraged data from the ARMA model to optimize system design and operations.

The findings will guide the design and characterization of an integrated system, assessing the potential of flexible operation in selling electricity. Furthermore, the feedback from market participation will influence the sizing of the reactor, thermal storage, and power block. Future work will extend to optimizing thermal storage in conjunction with water, hydrogen, and ammonia production, as well as managing the storage of these intermediate products.

2 - Sock Matching with Loss

James Crumpacker, University of Illinois, Champaign, IL, United States, Zachary Hornberger, Sheldon Jacobson

The classic Sock Matching Problem states: consider a set N whose elements (e.g., socks) are partitioned into two distinct but equal sized complementary classes (e.g., left and right socks), where the elements within one class have a unique corresponding item in the other class. Elements are selected from N sequentially at random and held (e.g., on a laundry table). Once a matching pair has been obtained, the pair is removed from the table. The problem’s traditional framing seeks the expected number of unmatched elements held over the course of the drawing process. To extend the applicability of the sock matching problem, this research considers a generalization where items in N are subject to random loss and determines exactly the expected number of draws until the first match is obtained. We present a formulation of the classic sock matching problem as a Markovian process, which offers additional insights relative to existing approaches. The model is then extended to account for random loss and calculate the expected number of draws until a match is obtained. This problem models the process of collectors seeking to acquire matching sets of collectible items such as rare coins and banknotes; this problem may be considered as a variation of the coupon collector problem.

3 - Determining the Optimal Range of a Revenue-sharing Ratio for Multiperiod Consignment Contracts under Retailer Competition

SEONG-HYUN NAM, University of North Dakota, Grand Forks, ND, United States

A Consignment Contract with Revenue Sharing model has been one of the strategic business methods used worldwide for decades as it provides manufacturers with a shared risk/reward-based revenue-generating approach to selling products through intermediary retailers. Our study aims to develop a quantitative analysis model in which the manufacturer designs a multi-period consignment contract that includes retailer pricing and volume decisions. Eligible retailers can participate in this consignment arrangement by proposing a revenue share ratio contract. However, retailers must compete with each other to reach an agreement with the manufacturer, and negotiations between the manufacturer and retailers are necessary to establish acceptable terms. Under these circumstances, our study focuses on the following questions: How does competition among retailers affect the upper bound of the range of revenue-sharing rates in multi-period consignment arrangements? Can sharing demand information between the manufacturer and selected retailers increase supply chain efficiency by improving the manufacturer's forecasting accuracy? If so, how can this lead to adjustments in the revenue share range for the benefit of all parties in recurring contractual relationships? How can sales volatility caused by demand uncertainty in multi-period contracts affect the financial risks associated with future profit and revenue sharing between the parties? This study also specifically examines a scenario where increased market uncertainty leads to panic buying or overstocking, as observed during the COVID-19 pandemic.

4 - Unveiling the Dynamics of Pricing Strategies and Framing Feedback Mechanisms on Consumer Satisfaction: A Laboratory Experiment

Kyaw Zay Ya, National Cheng Kung University, Tainan, Taiwan, Wei-Shiun Chang

In e-commerce, pricing strategies play a critical role in shaping consumer satisfaction. Since consumers rely on online review and rating to learn about products for making purchase decisions, retailers are under pressure to maintain a good record of rating. This study investigates the effect of pricing strategies and feedback mechanisms on consumer satisfaction in the context of online retail. We executed laboratory experiment with a 2x2x2 between subject factorial design, manipulating pricing strategy (partitioned vs. all-inclusive), feedback mechanism (reward vs. penalty framing), and delivery outcome (success vs. failure). The results of the study depict that when the carrier successfully delivered the product on time, consumers in the all-inclusive pricing strategy are always more satisfied with the service. When the carrier fails to deliver the product on time, free shipping is favorable to carrier in reward framing and partitioned pricing is favorable to carrier in penalty framing. The lack of transparency related to shipping fees in the all-inclusive pricing strategy may induce greater dissatisfaction to consumers, particularly when coupled with the penalty framing mechanism. Consumers feel a sense of unfairness and distrust, impacting their satisfaction negatively. This contrasts with those under partitioned pricing, who have a clearer understanding of the cost breakdown. These insights contribute to understanding the relationship between pricing strategies, feedback mechanisms, and consumer satisfaction in e-commerce.

Keywords: Pricing strategy, Framing feedback mechanism, Delivery outcome, Consumer satisfaction

5 - Fast and Frugal Heuristic Decisions for Pricing Truckload Delivery Services in Reverse Auctions

Michael Haughton, Wilfrid Laurier University, Waterloo, ON, Canada

Given the uncertainties and time pressures that carriers encounter in deciding the prices to charge for their truckload delivery services, fast and frugal heuristics (FFHs) represent a natural option for the pricing decision. Using behavior experiments and mathematical modeling, we examine the logic and efficacy of FFH-based pricing decisions. Our findings on matters such as how FFHs perform relative to mathematical optimization have practical implication for small carriers who are assessing whether their FFH-based decisions are good enough or whether to invest in pricing optimization tools.

6 - Identifying the Synergic Effect of Topics in Different Segments and Rate Prediction- Case Study of Physicians' Review

Reza Jazemi, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, Ensieh Alidadiani

Online reviews wield significant influence over consumer decisions, shaping perceptions and choices across diverse sectors. But the extent to which online ratings convey information about service provider quality and impact consumers' decisions remains uncertain. This study aims to investigate the synergistic effect of topics within different segments and its influence on rating predictions, focusing on physicians' reviews sourced from various online platforms. The primary objectives include exploring topic variability across specialties, identifying synergic effects between topics, and examining their correlation with star ratings.

The research employs a robust methodology combining text analytics techniques with machine learning algorithms. Leveraging Latent Dirichlet Allocation (LDA) for topic extraction, the study categorizes reviews into common topics and segment-specific topics. Supervised learning methods are then utilized to prioritize topics within each specialty segment. Additionally, sentiment analysis and Generalized Random Forest are employed to detect interactions between topics and predict rating outcomes.

The study is uncovering insightful patterns regarding the dynamics of topics and their interactions within physician segments. Certain topics exhibit varying importance across specialties, with synergistic effects between topics influencing overall ratings. By evaluation of these relationships, the research offers practitioners action plans for service improvement and empowers prospective patients with informative review summaries in specific segments. Ultimately, the findings contribute to the optimization of decision-making processes within the healthcare industry.

7 - Fare Ladder Optimization: Airline Revenue Management in a Volatile Environment

Yan Chen, National University of Singapore, Singapore, Singapore, Changchun Liu, Gang Guo, Hong-ming Tan, Chung-piaw Teo

Airline fare ladder pricing is a strategy used by airlines to optimize revenue by offering various seat prices on the same flight, catering to different customer segments. Traditionally, this has relied on historical sales data and competitor pricing. However, the COVID-19 pandemic has disrupted the industry, prompting a need for new revenue management approaches.

This study presents a novel framework for ladder pricing in unstable environments, allowing airlines to adapt forecasting models to handle fluctuations better. The framework identifies changepoints in booking volumes and incorporates them into sales prediction and price elasticity assessments. Additionally, a pricing engine is developed to assist analysts in crafting optimized fare ladders.Collaborating with a leading airline, we conduct a large-scale field experiment, using the Difference-in-Differences strategy, assesses the impact on revenue and booking metrics. Overall, this approach addresses the fare optimization challenge amidst instability.

1 - Revolutionize Cold Chain: An AI/ML Driven Approach to Overcome Capacity Shortages

Ilya Jackson, MIT, Cambridge, MA, United States, Jafar Namdar, Maria Jesus Saenz

This research investigates how Artificial Intelligence (AI) and Machine Learning (ML) forecasting methodologies can be leveraged for cold chain capacity planning, specifically utilizing Prophet and Seasonal Autoregressive Integrated Moving Average parametrized through grid search. In collaboration with Americold, the world’s second-largest refrigerated logistic service provider, the study explores the challenges and opportunities in applying AI/ML techniques to complex operations covering 385 customers and a capacity of 73,296 pallet positions. We train and test several AI/ML and traditional statistical models using extensive data for every customer over 3.5 years. Based on the results, MAPE of 5% was achieved on the whole site level, and SARIMA outperformed ML models in most cases. Next, we show that developing and applying a Customer Segmentation Matrix has enabled more accurate forecasting and planning across various customer segments, addressing the issue of forecasting inaccuracies. This approach effectively improves forecasting inaccuracies, underscoring the significance of tailoring AI/ML models for demand forecasting within the cold-chain industry. Ultimately, this research presents an AI-driven approach that transcends mere forecasting, offering a practical pathway to manage capacity in light of the constraints.

2 - Optimizing Closed-Loop Location-Inventory Problem Under Dynamic Demand

Sungjune Lee, Korea University Business School, Seoul, Korea, Republic of, Daeki Kim

This study examines the closed-loop supply chain, where distribution centers deliver, collect and reprocess returned products. Returnable transport items such as pallets are the representative, with the central operator playing a crucial role. Effective control over the location of distribution centers and inventory management is essential to fulfill this role. Initially formulated as a nonlinear mixed-integer problem, the model is reformulated into a conic quadratic mixed-integer program with valid cuts. We employ a scenario tree generated by Latin Hypercube Sampling and k-means clustering to address multi-period demand uncertainty and multi-stage stochastic programming is utilized to address different timing of strategic and operational decisions. Our analysis reveals that higher inventory costs complicate the problem. Inventory mediates the demand under the inventory ceiling constraint of distribution centers. The branch-and-cut process is beneficial under certain model characteristics, such as a smaller number of distribution candidates relative to customers. While the stability of the scenario tree generation is proved, the solution from the scenario tree and the deterministic model are compared and it is found that the dynamic demand does not affect the number of opened distribution centers as the demand could be handled by the inventory order amount.

3 - Matheuristic algorithms for the Inventory Routing Problem with Split Deliveries

Luca Bertazzi, University of Brescia, Brescia, Italy, Minh Nho Dinh, Demetrio Laganà

We propose new matheuristic algorithms for the Inventory Routing Problem with Split Deliveries, for both the Order-Up-to Level and the Maximum Level replenishment policies. The first matheuristic is based on the Capacitated Concentrator Location problem, while the second is based on a MIP model, in which all routes are built on the basis of a giant TSP tour serving all customers from the depot. These matheuristics are very fast with respect to the original model, and have a very good performance on average. The routes found by these matheuristics, together with other routes generated on the basis of different criteria, are then used as input data in a route-based formulation, able to improve the quality of the final solution on well-known benchmark instances.

4 - Machine learning algorithms for the design and operation of facilities in future logistics systems: A Survey

Dilhani Marasinghe, The University of Tennessee at Chattanooga, Chattanooga, TN, United States, Pubudu Jayasekara

This survey paper provides an exploration of the utilization of machine learning (ML) algorithms in the design and operation of facilities within logistics systems. By synthesizing a diverse range of research literature, academic papers, and industry reports, the survey offers a comprehensive overview of the various ML techniques utilized in optimizing facility design and operations for logistics purposes. Key areas covered include the application of ML algorithms for facility location optimization, layout design, capacity planning, and demand forecasting. The survey highlights successful implementations of ML algorithms in improving efficiency, reducing costs, enhancing decision-making, and increasing overall performance in logistics operations Ultimately, this study aims to provide insights into how ML can continue to revolutionize the design and operation of facilities in future logistics systems.

5 - Leveraging Graph Neural Networks for Enhanced Supply Chain Network Design and Optimization

Seyed Ahmad Torabzadeh, University at Buffalo, Buffalo, NY, United States, Sabrina Casucci, Robert Dell

This talk presents an innovative approach to dynamic supply chain network design by integrating Graph Neural Networks (GNNs) with optimization techniques. The proposed framework leverages GNNs to make decisions regarding facility location and allocation within the supply chain network. Using historical data, demand forecasts, and candidate locations for suppliers, distribution centers, and demand zone locations, the GNN generates recommendations for facility locations and assignments based on learned spatial relationships, demand patterns, and transportation costs. Based on the recommendations made by the GNN, the optimization model prescribes optimal strategies to fulfill different customers' demands and inventory management strategies in different layers of the supply chain network. We present results for several scenarios.

1 - A characterisation of cross-impact kernels

Mathieu Rosenbaum, Ecole Polytechnique, Mumbai, India

Trading a financial asset pushes its price as well as the prices of other assets, a phenomenon known as cross-impact. We consider a general class of kernel-based cross-impact models and investigate suitable parametrisations for trading purposes. We focus on kernels that guarantee that prices are martingales and anticipate future order flow (martingale admissible kernels) and those that ensure there is no possible price manipulation (no-statistical-arbitrage-admissible kernels). We determine the overlap between these two classes and provide formulas for calibration of cross-impact kernels on data. We illustrate our results using SP500 futures data. This is joint work with Mehdi Tomas.

2 - Inference Preferences from Behaviors

Haoyang Cao, Johns Hopkins University, Baltimore, MD, United States, Renyuan Xu, Zhengqi Wu, Samuel Cohen, Lukasz Szpruch

In 1964, Kalman raised the question of whether it is possible to recover quadratic cost function from an optimal linear policy. Since then, generations of economists have been studying viable ways to reveal meaningful utility functions from rational decisions. About three decades ago, computer scientists started to look at this field of inverse reinforcement learning (IRL), where algorithms are designed to effiiciently derive possible reward functions that have motivated an observed optimal policy; in the 2010's, Ziebart's "MaxEnt IRL" pushed this field to the spotlight, followed by GAIL, guided cost learning and many other influential IRL algorithms. However, there is always this nagging question of how to guarantee the IRL-identified reward function truely reflects the preferences of the demonstrating agent. This question becomes even more relevant today given the growing popularity of robo-advising: in order to provide suitable investment plans, the robo-advisor needs to learn about the clients' preferences of the investment strategies, the growth of wealth, and the timing. Such needs motivate us to re-examine IRL, its identifiability and the inference of preferences for an investor.

3 - Legislator Tweets about the Environment and the Returns of Green versus Brown Stocks

Milind Goel, London Business School, London, United Kingdom, Victor DeMiguel, Javier Gil-Bazo, Roberto Gomez-Cram

We study the impact of legislator tweets (X posts) that discuss environmental topics on the returns of green versus brown stocks. We use natural language processing (NLP) methods to identify tweets that discuss climate-related issues and to establish their sentiment towards green transition. We then study price changes of stocks in the minutes around each tweet to show that the prices of green (brown) stocks increase (decrease) in a statistically significant manner when legislators support green transition. Our high-frequency identification approach enables us to establish a causal relation between the opinions expressed in the tweets and the returns of green versus brown stocks. Our focus on legislator tweets suggests that the effect takes place via a regulatory channel. Progressively expanding the event horizon (over which we compute returns) from five minutes after the tweet to one day increases the economic relevance of our findings by an order of magnitude and reveals that it takes at least one day for the market to absorb the information contained in the tweets. Finally, we analyse the economic mechanism underlying the observed effects by studying how our findings depend on investor attention, institutional ownership, macroeconomic variables, the topic of the environmental tweet, and the legislator direct involvement in environmental regulation.

Revenue Management and Pricing

Chair: Vahideh Manshadi, Yale, Westwood, United States

Co-Chair: Rad Niazadeh, Chicago Booth School of Business, Chicago, IL, United States

1 - Magnolia: Matching Algorithms via Gnns for Online Value-to-Go Approximation

Anders Wikum, Stanford University, Stanford, CA, United States, Alexandre Hayderi, Amin Saberi, Ellen Vitercik

Online Bayesian bipartite matching is a central problem in digital marketplaces and exchanges, including advertising, crowdsourcing, ridesharing, and kidney exchange. We introduce a graph neural network (GNN) approach that emulates the combinatorially-complex optimal online algorithm. This optimal algorithm selects actions (e.g., which nodes to match) by computing each action's *value-to-go (VTG)*, which is the expected weight of the matching if the algorithm takes that action, and then chooses each subsequent action optimally. We train a GNN to estimate VTG and show empirically that this GNN returns high-weight matchings across a variety of tasks. Moreover, we identify a common family of graph distributions in spatial crowdsourcing applications, such as rideshare, under which VTG can be efficiently approximated by aggregating information within local neighborhoods in the graphs. This structure matches the local behavior of GNNs, providing theoretical justification for our approach.

2 - An Application of Online RL in Matching at Lyft

Mehdi Golari, Lyft, Seattle , WA, United States, Vijay Narasiman

To better match drivers to riders in our ridesharing application, we revised Lyft's core matching algorithm. We use a novel online reinforcement learning approach that estimates the future earnings of drivers in real time, and we use this information to find more efficient matches. This change was the first documented implementation of a ridesharing matching algorithm that can learn and improve in real time. We evaluated the new approach during weeks of switchback experimentation in most Lyft markets and estimated how it benefited drivers, riders, and the platform. In particular, it enabled our drivers to serve millions of additional riders each year, leading to more than $30 million per year in incremental revenue. Lyft rolled out the algorithm globally in 2021.

3 - Online Algorithms with Predictions

Debmalya Panigrahi, Duke University, Durham, NC, United States

In this talk, I will give an overview of the emerging area of online algorithms with predictions, where machine-learned predictions about the future are used to overcome information-theoretic barriers in online decision-making. I will describe the motivation behind the emergence of this research area, tell some of the early success stories, and outline some possible directions for further exploration in the near future.

4 - Best of Many in Both Worlds: Online Resource Allocation with Predictions Under Unknown Arrival Model 翻译 搜索 复制

Lin An, Carnegie Mellon University, Pittsburgh, PA, United States, Andrew Li, Benjamin Moseley, Gabriel Visotsky

Online decision-makers today can often obtain predictions on future variables, such as arrivals, demands, inventories, etc. These predictions can be generated from simple forecasting algorithms for uni-variate time-series, all the way to state-of-the-art machine learning models that leverage multiple time-series and additional feature information. However, the prediction quality is often unknown to decisions-makers a priori, hence blindly following the predictions can be harmful. In this talk, we address this problem by giving algorithms that take predictions as inputs and perform robustly against the unknown prediction quality.

We consider the online resource allocation problem, one of the most generic models in revenue management and online decision-making. In this problem, a decision-maker has a limited amount of resources, and requests arrive sequentially. For each request, the decision-maker needs to decide on an action, which generates some rewards and consumes some resources, without knowing the future requests. The decision-maker's objective is to maximize the total rewards subject to resource constraints. We take the shadow price of each resource as prediction. Prediction quality is naturally defined to be the l_1 distance between the prediction and the actual shadow price. Our main contribution is an algorithm which takes the prediction of unknown quality as an input, and achieves asymptotically optimal performance under both requests arrival models (stochastic and adversarial) without knowing the prediction quality and the arrival model beforehand. Our algorithm's performance matches the best achievable performance of any algorithm had the arrival models and the accuracy of the predictions been known.

Revenue Management and Pricing

Chair: A. Serdar Şimşek, The University of Texas at Dallas, Richardson, TX, United States

1 - Algorithmic Self-Preferencing on E-Commerce Platforms: Evidence from JD.Com

Zihan Zhao, Washington University in St. Louis, St. Louis, MO, United States, Dennis Zhang, Renyu Zhang

E-commerce platforms that are both designers and participants of a marketplace, such as Amazon and JD.COM, might leverage recommendation algorithms to preferentially promote their own products, a phenomenon termed "algorithmic self-preferencing." In response to the increasing scrutiny from both regulatory bodies and the academic community, our study introduces a comprehensive framework to define, predict, and detect instances of algorithmic self-preferencing within such e-commerce platforms.

We define algorithmic self-preferencing as the platform's excessive promotion of its own products over equivalent ones sold by third-party sellers, and establish the necessary and sufficient conditions for such a self-preferencing phenomenon. Our theoretical model predicts that a self-preferencing algorithm is characterized by higher consumer traffic (i.e., the number of clicks) but a lower conversion rate for the platform-owned product.

We then leverage a large public dataset from JD.COM to empirically identify algorithmic self-preferencing. Utilizing coarsened exact matching for causal identification, our empirical findings reveal that platform-owned products receive 55.65% more clicks yet exhibit 23.77% lower conversion rates compared to their identical third-party counterparts. This disparity not only evidences algorithmic self-preferencing on JD.COM but also validates our theoretical predictions.

Our extensive robustness checks confirm that the presence and magnitude of algorithmic self-preferencing are robust with respect to different identification strategies and model specifications. Finally, we further demonstrate the generalizability of our framework with data from Amazon, revealing similar patterns of self-preferencing.

2 - Price-You-See vs. Price-You-Pay: Field Experiments for Event Ticket Pricing

Serkan Mehder, University of Colorado Boulder, Boulder, CO, United States, Maxime Cohen, Ovunc Yilmaz

Drip pricing, which involves advertising only a portion of a product's price with additional charges revealed later in the purchasing process, is becoming increasingly popular in various industries. Despite academic research showcasing the profitability of drip pricing, significant public debate surrounds the issue of price transparency. Partnering with an event ticket reseller, we conduct multiple field experiments and examine consumer behavior under various levels of concealed fees.

3 - Assortment and Fulfillment Optimization in Online Grocery Retail

Renjun Hu, University of Michigan, Ann Arbor, MI, United States, Hyun-Soo Ahn, Lennart Baardman

Despite the rapid growth of online grocery retail, most supermarkets have not turned this growth into profit. A key reason is the excessively high picking and delivery cost in an industry with low profit margins. Technological innovation, in the form of the Micro Fulfillment Center (MFC), has great potential to reduce costs by improving the efficiency in picking operations. The MFC is a small local warehouse, often attached to a brick-and-mortar store or regular fulfillment center, which efficiently fulfills a subset of the assortment. For a grocery retailer with an online store and an MFC, it is important to decide which items are offered in the assortment of the online store and which items are fulfilled from the MFC. This is especially important in online grocery retail where cart abandonment is ubiquitous. If customers cannot find the items that they are looking for, they can abandon their shopping cart and move to another online grocery retailer. In this work, we formulate the assortment and fulfillment problem for an online grocery retailer with an MFC whose customers exhibit cart abandonment behavior. We show that the problem is difficult to solve and that its parameters can be complicated to estimate. Hence, we reformulate the optimization problem such that its parameters are estimable with readily available data in the industry, and we develop an algorithm to quickly compute near-optimal decisions at large scale. Both in theory and computations, we can show that our algorithm generates good approximations.

4 - Blessing or Curse? An Investigation of Free-Return Services in E-Commerce

Ahmet Serdar Simsek, University of Texas at Dallas, Richardson, TX, United States, Jiarui (Gary) Wei, Ozalp Ozer

Third-party sellers on e-commerce marketplaces can choose to fulfill their orders through the marketplace’s fulfillment service , referred to as Fulfillment by Platform (FBP), or by managing their own fulfillment operations, referred to as Fulfillment by Seller (FBS). We investigate the effects of the free-return services offered by the FBP service on consumers’ purchase decisions and sellers’ revenues. To do so, we develop a stochastic model that captures the dynamics of consumer purchasing behavior and return decisions under the influence of the return policy. The leniency of return policies impacts product sales, return rates, and sellers' profits. On the one hand, a lenient return policy encourages consumers to purchase products with a reduced sense of risk, boosting overall sales. On the other hand, it increases return rates, potentially eroding sellers’ profitability. We examine how the relative profitability of FBP compared with FBS varies for retailers as product uncertainty and heterogeneity in consumers' valuation across the population change. We find that FBP is more profitable for sellers with products exhibiting high consumer heterogeneity or low product uncertainty. Our findings provide guidance to sellers on which fulfillment option is better suited for different types of products.

New Trends in Discrete Choice Models

Invited Session

Revenue Management and Pricing

Chair: Gustavo Vulcano, Universidad Torcuato Di Tella, Ciudad Autónoma Buenos Aires, Argentina

1 - Revenue Management with Flexible Products

Huseyin Topaloglu, Cornell University, New York, NY, United States, Wenchang Zhu

We consider revenue management problems with flexible products, where we decide which set of resources to use to serve a customer during the service period at the end of the selling horizon. Flexible products allow firms to pool resource capacities and increase their resource utilization. We build on the earlier work on revenue management problems without flexible products to give a constant-factor approximation.

2 - Personalized Substitution Suggestions in Online Grocery Retailing

Luigi Laporte, UTDT - Universidad Torcuato Di Tella, Buenos Aires, Argentina, Srikanth Jagabathula, Daniel Corsten

Online grocery retailers have recently adopted presenting customers with personalized substitution suggestions during the ordering stage to avoid the costs associated with out-of-stocks. Selecting three products to offer as substitution suggestions to maximize the probability of the customer selecting one is a difficult problem because assortments are large, customer data are very sparse, and product availability must be considered both to infer customer preferences from past transactions and to decide which suggestions to present, accounting for the lag between the ordering stage and the picking stage in the online retail setting. We investigate the application of discrete choice models to the problem. We develop and test a three-component framework in which a ranking-generating component is followed by a relevancy filter and a operational filter. We tested the prediction power of our ranking-generating component -- based on a partial order, DAG-based choice model -- and found that it outperforms MNL and LC-MNL choice models in an extensive numerical experiment with offline data. We performed a large-scale field experiment with a European online grocery retailer. The results show that the relevancy filter is essential to counterbalance the unobservability of the customers' consideration sets. They also show that our proposed framework outperforms a machine learning-based model and that the performance improvement is more pronounced for customers with few transactions in the focal category. Our study results indicate that retailers can employ our proposed framework in practice as a general approach to provide personalized substitution suggestions.

3 - Exact Logit-Based Product Design

Velibor Misic, UCLA Anderson School of Management, Los Angeles, CA, United States, Irem Akcakus

The share-of-choice product design (SOCPD) problem is to find the product, as defined by its attributes, that maximizes market share arising from a collection of customer types or segments. When customers follow a logit model of choice, the market share is given by a weighted sum of logistic probabilities, leading to the logit-based share-of-choice product design problem. In this paper, we develop a methodology for solving this problem to provable optimality. We first analyze the complexity of this problem, and show that this problem is theoretically intractable: it is NP-Hard to solve exactly, even when there are only two customer types, and it is furthermore NP-Hard to approximate to within a non-trivial factor. Motivated by the difficulty of this problem, we propose three different mixed-integer exponential cone programs of increasing strength for solving the problem exactly, which allow us to leverage modern integer conic program solvers such as Mosek. Using both synthetic problem instances and instances derived from real conjoint data sets, we show that our methodology can solve large instances to provable optimality or near optimality in operationally feasible time frames and yields solutions that generally achieve higher market share than previously proposed heuristics.

4 - The Mallows Model of Discrete Choice in Operational Contexts

Gustavo Vulcano, Universidad Torcuato Di Tella, Ciudad Autónoma Buenos Aires, Argentina, Srikanth Jagabathula

We study the Mallows discrete choice model, which is well-known in the machine learning community, and novel in the operations management community. .

We first introduce the Mallows model and present some well known results in the literature inferred from the rank-based definition of the model. Then, we derive some new results related to the computation of Mallows probabilities over partial order structures, which generalize the results over rank lists. These new results are fundamental to develop different estimation algorithms to calibrate a Mallows model from anonymous data. We present three variants of the estimation algorithm founded on different ways to envision the input data. Finally, we show how to extend the estimation method to the case of preferences described by partial orders.

Our numerical experiments on synthetic transaction data and real-world panel data identify frameworks where the model allows more accurate predictions compared to state-of-the-art alternative methods.

Advances in Experimentation and Policy Learning in Managerial Settings

Invited Session

Revenue Management and Pricing

Chair: Spyros Zoumpoulis, INSEAD, Fontainebleau, France

Co-Chair: Stefanos Poulidis, INSEAD, Fontainebleau, 77300, France

1 - Policy Evaluation and Policy Learning Under the F-Sensitivity Model

Zhimei Ren, University of Pennsylvania, Philadelphia, PA, United States, Ying Jin, Sharon Wang, Ruohan Zhan, Zhengyuan Zhou

In this talk, I will introduce the f-sensitivity model, a new sensitivity model that characterizes the violation of unconfoundedness in causal inference. It assumes the selection bias due to unmeasured confounding is bounded “on average”; compared with the widely used point-wise sensitivity models in the literature, it is able to capture the strength of unmeasured confounding by not only its magnitude but also the chance of encountering such a magnitude.

Then, I will talk about policy evaluation and policy learning under our new model based on a distributional robustness perspective. For policy evaluation, our estimators are asymptotically normal under mild conditions. We also propose a learning algorithm returning the policy that maximizes the policy value estimator, for which we provide theoretical guarantees on the sub-optimality gap. The proposed methods are implemented and evaluated in numerical simulations, demonstrating substantial improvement compared with existing benchmarks.

2 - Detecting Service Slowdown Using Observational Data

Kuang Xu, Stanford Graduate School of Business, Stanford, CA, United States, Gal Mendelson

Being able to detect service slowdowns is crucial to many operational problems. We study how to use observational congestion data to detect service slowdown in a multi-server system, and in particular, the statistical implications of running adaptive congestion control mechanisms in such settings. We show that a commonly used summary statistic that relies on the marginal congestion measured at individual servers can be highly inaccurate the presence of adaptive congestion control. We propose a new statistic based on potential routing actions, and show it provides a much more robust signal for server slowdown in these settings. Unlike the marginal statistic, potential action aims to detect changes in the routing actions, and is able to uncover slowdowns even when they do not reflect in marginal congestion. Our work highlights the complexity in performing observational statistical analysis for service systems in the presence of adaptive congestion control. Our results also suggest that practitioners may want to combine multiple, orthogonal statistics to achieve reliable slowdown detection.

3 - Estimating Treatment Effects Under Recommender Interference: a Structured Neural Networks Approach

Ruohan Zhan, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, Shichao Han, Yuchen Hu, Zhenling Jiang

Recommender systems are essential for content-sharing platforms by curating personalized content. To evaluate updates of recommender systems targeting content creators, platforms frequently engage in creator-side randomized experiments to estimate treatment effect, defined as the difference in outcomes when a new (vs. the status quo) algorithm is deployed on the platform. We show that the standard difference-in-mean estimator can lead to a biased treatment effect estimate. This bias arises because of recommender interference, which occurs when treated and control creators compete for exposure through the recommender system. We propose a “recommender choice model” that captures how an item is chosen among a pool comprised of both treated and control content items. By combining a structural choice model with neural networks, the framework directly models the interference pathway in a microfounded way while accounting for rich viewer-content heterogeneity. Using the model, we construct an estimator of the treatment effect that is consistent and asymptotically normal. We demonstrate its empirical performance with a field experiment on Weixin short-video platform. Besides the standard creator-side experiment, we carry out a costly blocked double-sided randomization design to obtain a benchmark estimate without interference bias. We show that the proposed estimator significantly reduces the bias in treatment effect estimates compared to the standard difference-in-mean estimator.

4 - Vague Price Optimization

Wen yun, columbia university , new york , NY, United States, Assaf Zeevi

Price experimentation is increasingly used by firms across different industries and has become an integral part of revenue management practices. Because of sensitivity and potential impact on customer relationship management, prices are often set and modified by pricing specialists in a manual manner driven by various heuristics. We report on work with a large global manufacturing company that focuses on the design of a data-driven "price recommendation" engine. This engine provides pricing specialists with "vague" pricing suggestions: the objective is not to precisely identify the "best" action but rather to provide a recommendation that also incorporates and is driven by real world practices and constraints. We demonstrate the system's effectiveness when pricing specialists adhere to the provided suggestions, and investigate the losses associated with various forms of noncompliance. This analysis offers insights into possible trade-offs between practical constraints and algorithmic design principles and will be illustrated on synthetic as well as real sales data.

Strategic Dynamics and Optimization in Crowdfunding and Start-Ups

Contributed Session

Chair: Dowon Lee, University at Buffalo, The State University of New York, Williamsville, NY, United States

1 - Effect of a Wholesale Price Contract on the risk of Delivery Failure in a Crowdfunding Campaign.

Joyaditya Laik, Bucknell University, Lewisburg, PA, United States, Qian Zhang, Nabita Penmetsa

We study how a traditional wholesale price contract affects the optimal target and pledge amount in a crowdfunding campaign, when an entrepreneur depends on his supplier for components. A crowdfunding campaign is a verifiable signal that a supplier may use to gauge the demand of the product and adjust her wholesale price, in response to the prices the entrepreneur sets for a product both in the crowdfunding campaign and post-campaign market. We find that the efficiency of the crowdfunding market, in predicting post-crowdfunding demand affects the parameters set in this transaction. We contribute to the less studied field of a nascent supply chain, where the entrepreneur is in a weaker bargaining position, and therefore depends on the outcome of market signals, like crowdfunding, to provide evidence about the future prospect of the product. Through this paper we model the benefits that an entrepreneur gets from engaging in a crowdfunding campaign, by using the subscription levels to set prices. Furthermore, our study also shows that the target and pledge amounts are a consequence of contracts set with the suppliers.

2 - The Time-Varying Effects of Knowledge Diffusion in Open Source Projects

Orcun Temizkan, Ozyegin University, Istanbul, Turkey, Ram Kumar

Knowledge diffusion among software developers facilitates knowledge creation in Open Source (OS) projects. Prior research has illustrated that connectivity between software developers is related to knowledge creation in OS projects. However, the effect of knowledge diffusion over time is under researched. We illustrate that knowledge diffusion among software developers depends on the connectivity of software developers within projects and that the effect of developer connectivity on knowledge creation is time-dependent. Data collected from real-world OS projects is used in order to illustrate these effects. Research and managerial implications will also be discussed.

3 - Managing Start-up Growth Before Facility Investments

Yuanyuan Li, ESSEC Business School, Cergy, France, Riccardo Mogre, Felix Papier

We study the growth of the startup before it purchases its own plant. With limited capital, startups often leverage contract manufactures until they gain enough traction to secure facility investments. Herein lies a key question: whether to grow rapidly to buy the plant earlier, risking excessive capacity adjustment costs with contract manufacturers, or to grow slowly and then acquire the plant later. To find the tradeoff, we first analyze a stochastic model with the stochasticity in the number of new growths generated by sales efforts. Then we analyze a static convex model, assuming a deterministic number of growths resulting from a certain sales effort, where we derive closed-form solutions for the optimal sales effort in each period and the optimal number of periods. This study provides insights for startups navigating the path to facility investment while optimizing their growth strategies.

4 - Optimal Product Launch and Innovation Investment Decisions for a Niche Firm

Akhil Singla, Northwestern University, Evanston, IL, United States, Izak Duenyas, Seyed Iravani, Jacqueline Lane

We consider the product launch and innovation investment decisions for a niche firm that produces a single product in the presence of a multi-product rival firm. The rival continuously launches its new product generations, which increases its competitive advantage compared to the niche product, consequently reducing the niche firm's revenue. However, to gain higher revenues, the niche firm may launch its R&D product into the market by incurring a launch cost or, to gain competitive advantage against the rival, the niche firm may innovate by investing in R&D. The novel aspect of this problem is that the niche firm’s product is an auxiliary or peripheral part of a multi-product firm’s business; therefore, only the niche firm views the multi-product firm as a direct competitor. We develop a MDP model to analyze the niche firm’s decisions on when to launch and how to innovate, incorporating stochastic innovation gains. We characterize the structure of the optimal launch decision policy and study its sensitivity with respect to model parameters. Due to non-monotonicity in the structure of the optimal policy driven by the innovation investment decisions, we partially characterize the optimal policy that informs product launch and innovation investment decisions. Therefore, we propose a triple-threshold heuristic policy that performs very close to the optimal solution and provides a simpler decision rule for the product launch and innovation investment decisions. We identify the conditions under which the commonly used policy to launch the product after fixed time intervals can incur huge costs for the firm.

5 - Scheduling ground-to-satellite communications with cislunar orbits and interception risk

Dowon Lee, University at Buffalo, Amherst, NY, United States, Moises Sudit, Christopher Nebelecky, Jeremy Dening, Chase Murray

The Moon has gained significant attention recently as indicated by NASA's Artemis missions, with the goal of establishing a long-term presence for exploration. Satellites in lunar or cislunar orbit will be necessary to enable communications from the surface of the Moon. The scheduling of communication requests on ground stations to satellites will need to be optimized. The scheduling of ground to satellite communications to maximize the profit from scheduled requests is the Satellite Range Scheduling Problem. However, it is also of interest to ensure the communications are secure. When another satellite is also within the cone of visibility during a transmission, there is a risk that the transmission is intercepted. With the goal of secure communications, the risk from scheduled requests may need to be limited or minimized. Two discrete time integer programming models are introduced to solve the satellite range scheduling problem with different perspectives: (1) maximize profit with a risk limit, and (2) minimize risk with a profit requirement. An analysis on the performance is conducted using a variety of lunar and cislunar orbit combinations. This work is funded by the AFOSR through the Space University Research Initiative (SURI).

Decision Analysis Through Information Sharing

Invited Session

Decision Analysis Society

Chair: Behnam Malmir, Georgia Southern University, Savannah, GA, United States

Co-Chair: Aram Bahrini, University of Illinois Urbana-Champaign, Champaign, IL, United States

1 - Online Opinion Leadership during Crises

Behnam Malmir, Georgia Southern University, Savannah, GA, United States

During pandemics like COVID-19, public health officials face challenges disseminating guidance. Opinion leaders (OLs) serve as trusted sources, aiding guideline adoption. This study presents the Pandemic OL Analyzer (POLA), identifying OLs on Twitter. Trust emerges as the most influential trait, followed by expertise, uniqueness, innovation, and reputation. OLs include organizational and individual types, with organizational ones exerting more influence. OL activity spans eight domains: government planning, blood issues, reports, public actions, organizational aid, vaccination, community solutions, and general health. POLA aids in efficient OL identification for effective pandemic communication.

2 - Information Sharing in Closed Loop Supply Chains

Aram Bahrini, University of Illinois Urbana-Champaign, Champaign, IL, United States, Robert J. Riggs, Maryam Esmaeili

In this study, we explore how information sharing affects the performance of a two-level closed-loop supply chain consisting of one manufacturer and one retailer, where the manufacturer is the leader and the retailer is the follower. The manufacturer sells products through the retailer in the forward supply chain and collects used products in the reverse supply chain. Despite demand uncertainty, both manufacturers and retailers possess private information about demand. We determine the Stackelberg equilibrium for retail price, wholesale price, and the rate of collecting used products. We then compare their profits under scenarios with and without information sharing. Our findings reveal that information sharing in this leader-follower closed-loop supply chain model does not always enhance the profits of both the manufacturer and the retailer.

3 - Irrigation Decisions in a Game-Theoretic Landscape: Strategic Risk Dominance and Topology Design

Mobin Zarreh, Arizona State University, Tempe , AZ, United States, Paul Grogan

This research investigates the pivotal role of constructed water infrastructures in enhancing societal well-being and economic development, with a specific focus on the design and user dynamics of infrastructure systems. The study centers on flood irrigation systems managed by the Salt River Project (SRP) in Arizona—a communal infrastructure that enables both utility customers and homeowners to efficiently irrigate crops and lawns through an extensive canal network. This investigation treats system design as a bi-level problem featuring three asymmetric decision-makers engaged in a strategic design game. It incorporates metrics of risk dominance and operational choices to deepen the understanding of strategic interactions and their effects on both the resilience of the infrastructure and the benefits to users. Through the modeling of various scenarios, this study examines differing infrastructure topologies and their impact on collaborative decision-making processes. It specifically contrasts collaborative flood irrigation designs with those using city (municipal) water resources for irrigation. An agent-based model (ABM) is developed to simulate these scenarios, providing insights into the interplay between infrastructure design and user strategies, and assessing the robustness of collaborative designs. This methodological framework not only identifies optimal design and operational strategies but also supports policy development aimed at ensuring the sustainability and long-term viability of water infrastructure systems, thus promoting sustainable development, and enhancing quality of life.

4 - Design of a Distribution Network in a Multi-product, Multi-period Green Supply Chain System Under Demand Uncertainty

Azam Boskabadi, Washington State University, Pullman, WA, United States, Mirpouya Mirmozaffari

This paper proposes a novel fuzzy mathematical model for a distribution network design problem in a multi-product, multi-period, multi-echelon, multi-plant, multi-retailer, multi-mode of transportation green supply chain system. The three purposes of the model are to minimise total network cost, maximise net profit per capita for each human resource, and diminish CO2 emission throughout the network. P-hub median location with multiple allocations is used for locating the distribution centres. One scenario is designed for fuzzy customer demands with a trapezoidal membership function. Furthermore, the model determines the design of the network (selecting the optimum numbers, locations of plants, and distribution centres to open), finding the best strategy for material transportation through the network with the availability of different transportation modes, the capacities level of the facilities (plants or distribution centres (DCs)), and the number of outsourced products. Finally, all uncertain customer demands for all product types can be satisfied based on the methods mentioned above. This multi-objective mixed-integer non-linear mathematical model is solved by NSGA-II, MOPSO and a hybrid meta-heuristic algorithm. The results show that NSGA-II is the exclusive algorithm that obtains the best result according to the evaluation criteria.

5 - Intervention in Collaborative System Design to Increase Efficiency: A Communication Channel for Technical and Social Information Exchange

Alkim Avsar, Arizona State University, Tempe, AZ, United States, Paul Grogan

Collaborative systems involve multiple actors pooling their resources and efforts to achieve a complex goal that surpasses the capabilities of any single entity. Distributed Satellite Systems (DSS) exemplify this, where numerous spacecraft collaborate with diverse functionalities to fulfill a shared objective. However, while collaborations offer promising outcomes, their failure can lead to substantial sunk costs for involved parties. In such systems, actors often prioritize their self-interest, selectively sharing or withholding information, resulting in reduced transparency and lack of control over decision variables, leading actors to make strategic decisions. Consequently, risk emerges from both technical and social sources, making actor interactions critical. Facilitating effective communication among actors and providing a more transparent technical picture might help actors make more effective strategic decisions. This study proposes an intervention: a *system mediator*, to enhance information exchange among actors and provide a more transparent technical picture within collaborative systems. The study conducts a human experiment with a bi-level collaborative system problem to assess the impact of the system mediator. In the experimental process, designers represent decision-making authorities of different product design companies and engage in a design and strategic decision-making process. Experimental groups, with and without the system mediator, are compared to evaluate its efficacy. Results indicate that the system mediator significantly enhances overall system efficiency by augmenting actors' access to technical and social information. Understanding the mechanisms underlying this intervention's success and refining the system mediator can facilitate the development of management strategies conducive to optimizing complex collaborative systems.

Making Army Installations More Resilient

Invited Session

Decision Analysis Society

Chair: Gregory Parnell, University of Arkansas, Fayetteville, AR, 72702, United States

1 - Leveraging Data and Artificial Intelligence for Supporting Installation Planning and Resilience Strategies

Randy Buchanan, USACE - ERDC, Vicksburg, MS, United States

An all-hazards risk approach to military installation planning increasingly requires a significant effort toward understanding climate change impacts. Climate change threatens physical and operational security of U.S. military bases around the world. Threats include sea level rise, droughts, wildfires, floods, and numerous extreme weather events, with each installation possessing unique vulnerabilities. Weather and climate intelligence efforts support the modernization of installation decision-making processes by applying complex computational analytics and in some cases high-performance computing assets to inform decision makers for making real-time holistic weather-related decisions as well as supporting long-term climate resilience planning. This presentation discusses these hazards and their impacts, and the return on investment for resilient strategies, as well as emerging capabilities such as artificial intelligence being leveraged to support large historical and real-time data set analytics.

2 - Incorporating Military Installation Resilience Plan (MIRP) Resilience and Risks/hazards into Installation Planning

Mary Mitchell, US Army Information Technology Laboratory, Vicksburg, MS, United States, Su Wolters, Tim Perkins, Shelia Barnett, Matt Swanson, John Richards

Military installations need to modernize to mitigate threats from increased complexity and potential risks. Central to future military installations is revolutionizing installation master planning. Installation master planning is the process to plan out infrastructure projects and prepare for upcoming mission requirements and risks, mandated by UFC 2-100-01. PLANNER is an Army Installation Modernization Pilot Program (AIMP2) project managed by ERDC under leadership of the Assistant Secretary of the Army for Installations Energy & Environment's Strategic Integration (ASA-IE&E(SI)) and powered by the Virtual Toolbox for Installation Mission Effectiveness (VTIME). Through the data lake provided by VTIME, PLANNER digitizes and operationalizes integrated installation planning, allowing the Army to overcome information stovepipes, and move away from late-to-need, time-intensive static plans developed at high-cost. As weather and climate threats impact installations, and impacts are forecasted to continue to increase, a key component of transforming installation planning includes an all-hazards approach to risk analysis to form clearer pictures of individual installations' resilience. Our team conducted a Business Process Reengineering (BPR) study to understand the processes, people, policies, technology, and information necessary for establishing All-Hazards-Risk-Analysis (AHRA) and deliver it as a PLANNER component of VTIME. The AHRA component will assist with incorporating resilience, risks, and hazards and linking them to resilience strategies for integrated installation resilience planning process and enable continuous risk/deficiency assessments to allow installations to better prepare for potential threats and hazards. This presentation will focus on the development of the AHRA and its potential to connect risks and hazards to the installation planning process.

3 - ROI Model to Evaluate Options to Make Installations Resilient to Extreme Weather

Gregory Parnell, University of Arkansas, Fayetteville, AR, United States

As the Department of Defense recognizes the potential for severe weather events caused by climate change, they plan to develop options to mitigate the impact on installation facilities and reduce the disruption in operations. While the Army recognizes that climate change will require adaptation costs, the data surrounding imposed costs to installations has not been integrated across the department. We are working to support the HQDA and G-9 by developing a Return-on-Investment (ROI) model for PLANNER (the Army's new data-driven master planning tool), to inform cost-effective modernization of installation infrastructure to make the facilities more resilient to the impacts of extreme weather.

4 - LLM-assisted Support for Infrastructure and Installation Resilience Planning

George Gallarno, US Army Engineer Research and Development Center, Vicksburg, MS, United States, Jaylen Hopson

The quick retrieval of information is important for informing consistent, transparent, and data-driven decision making during the development and execution of an installation resilience plan. Specifically, being able to reference standards, guidelines, and regulations is necessary to develop and execute an appropriate infrastructure strategy. In this study a large language model (LLM) is enhanced with domain-specific knowledge to quickly provide information to the end user on U.S. Army Corps of Engineers construction management-related topics. Specifically, retrieval augment generation and prompt engineering techniques were used to develop and deploy a proof-of-concept LLM using cloud-based tools. This proof-of-concept capability provided at least a 20x time savings for the test user group, helping provide quick reference to many applicable standards, guidelines, and regulations related to their various queries. This research shows the applicability of LLMs to the field of resilience planning by improving the quality and consistency of documentation as well as, more generally, enhancing the productivity of planning-related personnel.

This presentation will overview the methodology used to develop and deploy the proof-of-concept LLM, discuss Department of Defense-related constraints and limitations, and summarize the lessons learned from deployment of the proof-of-concept capability. Applications to broader infrastructure resilience planning and decision support will also be discussed.

5 - AI for Installation Decision Support

Patrick Ables, US Army Information Technology Laboratory, Vicksburg, MS, United States, George Gallarno, Randy Buchanan

This presentation delves into the transformative potential of artificial intelligence (AI) in enhancing decision-making processes within government installations across various domains. As an administrative tool, AI demonstrates exceptional effectiveness in aiding decision-making by automating and optimizing tasks such as summarizing internal documentation, scheduling, and predictive maintenance. AI-powered natural language processing (NLP) techniques streamline decision-making by automating the summarization of extensive internal documentation, extracting key insights from reports, policy documents, and meeting minutes, facilitating efficient information retrieval and trend identification enabling decision-makers to prioritize critical issues effectively. AI also plays a crucial role in analyzing vast datasets to uncover patterns and predict future conditions, thereby informing strategic decisions related to other administrative functions. For example, in environmental management, AI algorithms can analyze weather and climate data to inform infrastructure planning and disaster preparedness. More broadly, AI optimizes maintenance schedules by leveraging predictive analytics to forecast equipment failures based on historical performance data, usage patterns, and environmental factors. By implementing proactive maintenance strategies, government installations minimize downtime, reduce maintenance costs, and prolong asset lifespan. Through the integration of AI technologies, government installations can enhance decision-making processes, improve operational efficiency, and mitigate risks across diverse operational domains. By harnessing the power of AI to analyze data, extract insights, and provide actionable recommendations, decision-makers can navigate complexities, allocate resources effectively, and achieve their organizational objectives with greater agility and foresight, ultimately benefiting citizens and stakeholders.

Co-Chair: Ming Yin, Princeton University, Princeton, NJ, United States

Co-Chair: Ming Yin

1 - Efficient Reductions for Reinforcement Learning from Human Feedback

Gokul Swamy, Carnegie Mellon University, Pittsburgh, PA, United States

RL from human feedback (RLHF), also known as preference-based RL (PbRL), has emerged as a critical component of the fine-tuning procedure for large language models (LLMs). The standard recipe for RLHF involves first fitting a reward model from preference data before optimizing the learned reward via some RL algorithm. However, such an approach makes a key assumption: that the preferences we observe exhibit none of the intransitivity that frequently occurs in practice when aggregating preferences across a diverse population of raters. In this talk, we will discuss how taking a game-theoretic perspective on this problem (https://arxiv.org/abs/2401.04056) allows us to design efficient reduction-based algorithms that handle complex, intransitive preferences in a robust manner, match (and sometimes supersede) the performance of traditional approaches under idealized conditions, and elide reward modeling as well as adversarial training.

2 - Adapting Foundation Models Using Reinforcement Learning and Imitation Learning

Joey Hejna, Stanford University, Stanford, CA, United States

Modern foundation models are often trained to simply mimic a distribution of data. Such approaches, however, cause models to exhibit the same sub-optimalities present in their training dataset, which is particularly detrimental in sequential decision making settings. In this talk I will discuss how ideas from reinforcement learning an imitation learning can be used to mitigate this problem. First, I will discuss how we can use human feedback to directly optimize sequential policies, instead of myopically considering a bandits setting as usually done in LLMs. Next, I will show how ideas in inverse reinforcement learning can be used to quickly adapt models in the low-data regime. Finally, I will discuss how similar insights can transfer to foundation models in the robotics domain, and discuss our recent progress in this area.

3 - Crispr-GPT: An LLM Agent for Automated Design of Gene-Editing Experiments

Kaixuan Huang, Princeton University, Princeton, NJ, United States, Yuanhao Qu, Henry Cousins, William Johnson, Di Yin, Mihir Shah, Denny Zhou, Russ Altman, Mengdi Wang, Le Cong

The introduction of genome engineering technology has transformed biomedical research, making it possible to make precise changes to genetic information. However, creating an efficient gene-editing system requires a deep understanding of CRISPR technology, and the complex experimental systems under investigation. While Large Language Models (LLMs) have shown promise in various tasks, they often lack specific knowledge and struggle to accurately solve biological design problems. In this work, we introduce CRISPR-GPT, an LLM agent augmented with domain knowledge and external tools to automate and enhance the design process of CRISPR-based gene-editing experiments. CRISPR-GPT leverages the reasoning ability of LLMs to facilitate the process of selecting CRISPR systems, designing guide RNAs, recommending cellular delivery methods, drafting protocols, and designing validation experiments to confirm editing outcomes. We showcase the potential of CRISPR-GPT for assisting non-expert researchers with gene-editing experiments from scratch and validate the agent's effectiveness in a real-world use case. Furthermore, we explore the ethical and regulatory considerations associated with automated gene-editing design, highlighting the need for responsible and transparent use of these tools. Our work aims to bridge the gap between beginner biological researchers and CRISPR genome engineering techniques, and demonstrate the potential of LLM agents in facilitating complex biological discovery tasks.

4 - Do LLM Agent have regret?

Chanwoo Park, MIT, Cambridge, MA, United States, Xiangyu Liu, Asuman Ozdaglar, Kaiqing Zhang

Large language models (LLMs) have been increasingly employed for (interactive) decision-making, via the development of LLM-based autonomous agents. Despite their emerging successes, the performance of LLM agents in decision-making has not been fully investigated through quantitative metrics, especially in the multi-agent setting when they interact with each other, a typical scenario in real-world LLM-agent applications. To better understand the limits of LLM agents in these interactive environments, we propose to study their interactions in benchmark decision-making settings in online learning and game theory, through the performance metric of \emph{regret}. We first empirically study the {no-regret} behaviors of LLMs in canonical (non-stationary) online learning problems, as well as the emergence of equilibria when LLM agents interact through playing repeated games. We then provide some theoretical insights into the no-regret behaviors of LLM agents, under certain assumptions on the supervised pre-training and the rationality model of human decision-makers who generate the data. Notably, we also identify (simple) cases where advanced LLMs such as GPT-4 fail to be no-regret. To promote the no-regret behaviors, we propose a novel \emph{unsupervised} training loss of \emph{regret-loss}, which, in contrast to the supervised pre-training loss, does not require the labels of (optimal) actions. We then establish the statistical guarantee of generalization bound for regret-loss minimization, followed by the optimization guarantee that minimizing such a loss may automatically lead to known no-regret learning algorithms. Our further experiments demonstrate the effectiveness of our regret-loss, especially in addressing the above ``regrettable'' cases.

5 - Reinforcement Learning from Human Feedback: From Theory to Algorithm

Wei Xiong, UIUC, Urbana, IL, United States

Reinforcement Learning from Human Feedback (RLHF) is the leading technique to align foundation large language (LLM) model with the human preferences, and achieves tremendous successes in the application of Chat-GPT, Gemini, and Claude. We consider a standard mathematical formulation, the reverse-KL regularized contextual bandit for RLHF. Despite its widespread practical application, a rigorous theoretical analysis of this formulation remains open. In this presentation, we first establish the mathematical foundation of RLHF by proposing statistically efficient algorithms, which enjoy finite-sample guarantee under standard assumptions. We then move toward practical applications and show that the proposed algorithms can be practically implemented and empirically outperform existing strong baselines like DPO and RSO in real-world LLM experiments.

Summit - 343

On the Fairness for Optimization and Learning

Contributed Session

Chair: Eklavya Sharma, ISE, UIUC, Urbana, IL, United States

1 - Improving Approximation Guarantees for Maximin Share

Eklavya Sharma, ISE, UIUC, Urbana, IL, United States, Hannaneh Akrami, Jugal Garg, Setareh Taki

We consider fair division of a set of indivisible goods among n agents with additive valuations using the fairness notion of maximin share (MMS). However, since MMS allocations do not always exist [Kurokawa et al., JACM'18], the focus shifted to investigating its multiplicative approximations. Here the goal is to show the existence of α-MMS allocations (for the largest possible $\alpha < 1$), i.e, allocations that guarantee each agent at least α times her MMS value. A series of works in the last decade led to the state-of-the-art factor of $\alpha = 3/4 + 3/3836$ [Akrami and Garg, SODA'24].

We introduce a general framework of approximate MMS with agent priority ranking. We order the agents, and agents earlier in the order are considered more important. An allocation is said to be T-MMS, for a non-increasing sequence $T := (\tau_1, \ldots, \tau_n)$ of numbers, if the agent at rank i in the order gets a bundle of value at least τ_i times her MMS value. We show the existence of T-MMS allocations where $\tau_i \geq \max(3/4 + 1/12n, 2n/(2n+i-1))$ for all i. Furthermore, by ordering the agents randomly, we can get allocations that are (3/4 + 1/12n)-MMS ex-post and (0.8253 + 1/36n)-MMS ex-ante. We also investigate the limitations of our algorithm and show that it does not give better than (0.8631 + 1/2n)-MMS ex-ante

2 - Trading-off price for data quality to achieve fair online allocation

Vianney Perchet, ENSAE, Palaiseau, France, Patrick Loiseau, Nicolas Gast, Mathieu Molina

We consider the problem of online allocation subject to a long-term fairness penalty. Contrary to existing works, however, we do not assume that the decision-maker observes the protected attributes -- which is often unrealistic in practice. Instead they can purchase data that help estimate them from sources of different quality; and hence reduce the fairness penalty at some cost. We model this problem as a multi-armed bandit problem where each arm corresponds to the choice of a data source, coupled with the online allocation problem. We propose an algorithm that jointly solves both problems and show that it has a regret bounded by O(T^{1/2}). A key difficulty is that the rewards received by selecting a source are correlated by the fairness penalty, which leads to a need for randomization (despite a stochastic setting). Our algorithm takes into account contextual information available before the source selection, and can adapt to many different fairness notions. We also show that in some instances, the estimates used can be learned on the fly.

3 - Symmetrically Fair Allocations of Indivisible Goods

Connor Johnston, University of Florida, Gainesville, FL, United States, Aleksandr Kazachkov

We consider the allocation of indivisible goods with provable fairness guarantees which are satisfied regardless of which bundle of items each agent receives. One such fairness guarantee is envy freeness up to one good (EF1), under which an agent is permitted to envy another agent's bundle, but the amount of envy is no more than the value of the agent's favorite good in the envied bundle. When this fairness criteria is satisfied regardless of which bundle an agent receives, we call this allocation symmetrically envy free up to one good or symEF1. We discuss theoretical results about the existence of symEF1 allocations and computational results related to the frequency at which symEF1 allocations exist and model the problem as an integer program to verify if a symEF1 allocation exists. The main theoretical result of our paper is for 2 agents, there always exists a symEF1 allocation. This theorem is proved with a sufficient condition for the existence of symEF1 allocations which relates the valuation matrix to a graph. If this graph is n-colorable, then there exists a symEF1 allocation. We solve the integer program if our greedy algorithm cannot find a feasible allocation. The percentage of cases that needed the IP ranged from 7% to 99%. Our computational testing for cases of 3, 4, and 5 agents involved varying the number of items. Our results show that the proportion of allocations that satisfy the symEF1 constraint quickly tends to 1 with more items but it is not monotonically increasing.

4 - On-Demand Delivery: Estimation, Routing and Last Mile Solutions

Tayo Fabusuyi, University of Michigan, Ann Arbor, MI, United States, Majid Mirzanezhad, Yangyang Wang

This research develops a nationally scalable approach that estimates and forecasts the volume of on-demand delivery at fine geographic scales and implements an optimization model that fulfills the delivery with a focus on last mile solutions. Utilizing public use microdata sample files, we estimate demand using extreme gradient boosting and generate representative demand profiles through population synthesis. Additionally, we employ nearest-neighbor matching to fill data gaps and maintain the consistency of our estimates over time. This combination of methods enhances our understanding of the changing e-commerce landscape and urban freight patterns, informing strategic operations and policymaking in the urban delivery sector. We motivate the balance of the research by hypothesizing that last mile deliveries are mainly fulfilled by autonomous sidewalk robots (ASDRs) and propose energy-efficient GPS use in these robots by adjusting their data retrieval rate in response to new local conditions. This strategy, managed through a linear predictive filter, could be adapted for various delivery and location-based services.

5 - Assessing Fairness in the Presence of Missing and Mislabeled Sensitive Attributes

Hyungrok Do, NYU School of Medicine, New York, NY, United States

It is well-documented that sensitive attributes–which are often socio-economic status or demographic information–such as gender, race, and age, are frequently reported inaccurately in many databases. This is a significant challenge in the context of investigating predictive performance disparity since the metrics are calculated with the assumption that correct sensitive attribute information are provided. There is a relatively small amount of prior work in algorithmic fairness on handling of missing and mislabeled sensitive attributes. We propose a methodology to estimate per-patient probability distributions for sensitive attributes such as gender, race, and age, based on other known features of the patient. Using these estimated probability distributions, we calculate prediction disparity metrics, such as differences in accuracy or true positive rates between groups, robust to the missing and mislabeled sensitive attributes are. This will enable us to achieve robust estimates of fairness metrics and avoid misleading assessments of predictive disparities.

6 - Ensuring Fair Prediction with Group-Aware Priors

Tim G. J. Rudner, New York University, New York, NY, United States

We consider the problem of training neural network models that make fair predictions in settings where certain subpopulations, or groups, are highly underrepresented in the training data. To address this problem, we develop a family of group-aware prior distributions over neural network parameters explicitly designed to favor models that are fair. Priors in this family assign high probability density to parameter values that induce models that are robust across groups. We show how to construct group-aware priors and derive a tractable optimization objective that incorporates them into model training. We demonstrate empirically that training with group-aware priors yields fair models on several challenging prediction tasks. Our evaluation shows that group-aware priors outperform state-of-the-art methods on vision and language classification tasks while only requiring access to a small amount of group information. Group aware-priors are conceptually simple, complement alternative approaches for fair prediction, and allow harnessing Bayesian inference to further improve model robustness.

Optimizing Digital Content, Revenue, and Education Strategies

Contributed Session

Chair: Amrita Thomas, University of North Texas, 3832 Greenhills Ct E, Denton, TX, 75038, United States

1 - Revenue Sharing Strategies among Digital Content Creators

Icheng Chiang, Fordham University, New York, NY, United States, Jhih-Hua Jhang-Li

Social media platforms foster creativity by helping creators monetize their content. During content creation, however, copyright disputes could arise when prior uploads were used as base materials for derivative work. One way to obtain copyright is to pay recurring royalty or a steep fee upfront—propositions that could be cost-prohibitive for many content creators. Recently, a major social media platform unveiled a revenue-sharing mechanism in which content creators split the ad revenue from their derivative works with copyright owners according to a predefined revenue-sharing ratio. We propose a mechanism to optimize the revenue-sharing ratio and to suggest when/whether the copyright owner should file the copyright claim. Upon receiving a claim, the content creator can cancel the upload, agree to revenue sharing, or dispute the claim within a time window. We show how our approach can complement flat-fee licensing and help reduce the likelihood of litigation.

2 - Managing the Digital Advertising Economy: Balancing Generated Content and Profitability

Na Liu, Cornell University, Ithaca, NY, United States, Chris Forman

This paper examines the influence of digital monetization strategies on user-generated content (UGC) platforms like YouTube and TikTok, which play a crucial role in facilitating collaborations between content creators and industrial sponsors for online media curation. We investigate the effects of commission fee deductions on various platform outcomes, including revenue sharing, total profits, ad selection, and users' activities. Through DID Models with ex-ante classification and robustness checks spanning over years, we find surprisingly that advertisers are shifting towards goods-selling links that experienced the fee deductions, resulting in the substitution of ad types. This transition concentrates the goods-selling market on specific popular products, bolstering direct sales on major online retailing sites. However, the platform does not witness a substantial increase in total profits despite decreased commission fees on certain ad links, prompting shifts in user behavior regarding ad types. On the creators' side, content quality declined on average for untreated groups, signified by a drop of 2 interactions per 100 viewers, while it remains the same for treated creators with deducted commission fees' ads. In summary, while the platform's design does not directly escalate profits, it channels advertisers towards specific ad types and goods, intensifying competition among creators and sustaining content quality, informing "smarter decision" for the UGC platforms. This paper is the first to empirically analyze the strategic implications of UGC platform commission fees at scale from a multi-sided perspective.

3 - Are Recruitment Postings Believable? A Theory-Driven Supervised Learning and Interpretable Analysis for Digital Fraudulent Recruitment Posting Behavior

Tianteng Wang, City University of Hong Kong, Hong Kong, Hong Kong, David Xu, Keng Siau

The number of recruitment postings on digital recruitment-hiring platforms has increased after the COVID-19 pandemic. However, the weak surveillance of these platforms, combined with the fact that most recruitment seekers have relatively low vigilance and strong desire for recruitment offers enables scammers to easily deceive recruitment seekers for their money and confidential information. The existing manual experience-based fraud recruitment posting detection approach is labor intensive, inefficient, and prone to misdetection. Therefore, how to efficiently detect the fraudulence of digital recruitment postings without human interventions becomes a major operational challenge. Guided by the design science approach, we are informed by a kernel theory of interpersonal deception theory and propose a novel text analytic framework to extract theoretically important and managerially meaningful constructs, such as completeness, association, clarity, and relevance, from textual recruitment postings as operationalized and contextualized features with textual statistics, lexicon-based methods, named entity recognizer, topic modeling, information entropy, sentiment analysis techniques, pre-trained large language model, and Generative Pre-trained Transformer (GPT) model to predict the fraudulence. In terms of evaluations, we empirically compare our designed framework with state-of-the-art general-purpose algorithms that can be adapted to tackle the fraud recruitment detection problem. Our extensive analysis demonstrates the efficiency and interpretability of our proposed framework in detecting the fraudulence of recruitment postings. Using an illustrative example, we further quantify the economic value of our theory-inspired design via a cost-revenue analysis. We also highlight the academic contributions and practical implications of our work to recruitment seekers, recruiters, and third-party recruitment-hiring platforms.

4 - Innovating Classrooms: Leveraging AI for Engaging Educational Experiences

Amrita Thomas, University of North Texas, Denton, TX, United States

In the evolving landscape of educational innovation, integrating digital technologies into academic frameworks stands at the frontier for advancement. This presentation explores the incorporation of digital tools within a university curriculum. By utilizing these tools to enhance creative processes such as brainstorming and media production, we highlight the synergistic potential between theoretical knowledge and practical digital application. We aim to offer a view on how we can amplify creativity and innovation and provides insights and strategies for embedding these technologies into educational practices to foster a new era of creative excellence.

5 - Membership Pricing Strategies for Digital Content Platforms: Balancing Native and Traditional Advertising

Wan Xiong, Shanghai University of Finance and Economics, ShangHai, China, People's Republic of, Lu Wang

We consider ad-supported media platforms with incomplete information about the disutility consumers' experience from exposure to advertising. We characterize the platform's optimal subscription fees and the level of two kinds of advertising respectively (i.e. traditional advertising and sponsored advertising, also known as native advertising), exploring whether the decision-making power regarding the level of native advertising should be ceded to content creators. Employing mechanism design and Kuhn-Tucker conditions enables us to systematically analyze the key factors influencing market outcomes. We demonstrate that the introduction of sponsored content advertising reduces the level of traditional advertising and increases the subscription fees. However, the platform's profit increases when the ratio of aversion to advertisements among type H consumers, as compared to type L consumers, is very high or moderate high. Additionally, we find that the platform should allow the creator to decide the level of sponsored ads under certain conditions.

Technology Showcase

1 - Techno-economic Analysis with MATLAB: Microgrid Planning for Green Hydrogen Production

Chris Lee, MathWorks, Natick, MA, United States

Techno-economic analysis of microgrids is essential for assessing the financial viability and technical feasibility of integrating renewable energy sources. This analysis enables cost-effective strategies and technological innovations to enhance energy resilience, reduce carbon footprints, and accelerate the transition to sustainable energy.

In this session, we will present a live demonstration of how to develop a techno-economic analysis framework using optimization tools in MATLAB. We will cover the following:

- Modeling using the problem-based optimization workflow
- Solving using the linear programming solver
- Performing sensitivity and statistical analysis

As a case study, we will focus on planning a microgrid for green hydrogen production. We will explore how to determine the optimal power and energy ratings within a microgrid system incorporating renewable energy and energy storage. The goal is to power an electrolyzer to produce green hydrogen at the lowest cost and highest return on investment over a 20-year period.

2 - Introducing ChiAha – the Smart Manufacturing Digital Twin Toolkit

Andrew Siprelle, ChiAha, Tallassee, FL, United States

ChiAha can predict production line performance and OEE within 1% accuracy. High-fidelity modeling constructs with statistically modeled data-driven behavior. Provide answers to many of the questions related to the design, operation and improvement of lines for optimum OEE.

AI Process Innovation: Connection to the Human Element

Invited Session

Technology, Innovation Management and Entrepreneurship

Chair: Abhishek Deshmane, Georgia Institute of Technology, Atlanta, GA, United States

1 - The Uneven Impact of Generative AI on Entrepreneurial Performance

David Holtz, UC Berkeley, Berkeley, CA, United States, Nicholas Otis, Rowan Clarke, Solene Delecourt, Rembrand Koning

There is a growing belief that scalable and low-cost AI assistance can improve firm decision-making and economic performance. However, running a business involves a myriad of open-ended problems, making it hard to generalize from recent studies showing that generative AI improves performance on well-defined writing tasks. In our field experiment with 640 Kenyan entrepreneurs, we as- sessed the impact of AI-generated advice on small business revenues and profits. Participants were randomly assigned to a control group that received a standard business guide or to a treatment group that received a GPT-4-powered AI busi- ness mentor via WhatsApp. We are unable to reject the null hypothesis that generative AI access has no impact, but are able to rule out the large effect sizes reported by other studies of generative AI's economic impact. Our over- all null result masks treatment effect heterogeneity with respect to the baseline business performance of the entrepreneur: our point estimates suggest that high performers benefited by just over 15% from AI advice, whereas low performers did about 8% worse with AI assistance. Exploratory analysis of WhatsApp in- teraction logs shows that both groups sought the AI mentor's advice, but that low performers did worse because they sought help on more challenging business tasks. Our findings highlight the potential and limitations of generative AI to enable entrepreneurs across the globe.

2 - The Impact of AI-Enabled Technology on The Learning of The Gig Workers

Youngsoo Kim, University of Alabama, Tuscaloosa, AL, United States, Dmitry Mitrofanov, Yuqian Xu

This paper investigates the relationship between AI-enabled technology and the learning dynamics of gig workers, through a large-scale randomized field experiment partnered with a major US delivery platform. Specifically, we look into the balance between leveraging AI-enabled technology for immediate productivity gains and fostering a learning environment that ensures the sustainable development of gig workers' skills. We believe that understanding this interaction is important for platform operators to design user-supporting technologies and systems that consider both short-term productivity gains and long-term skill development in the gig economy.

3 - Can Machine Learning Target Health Care Fraud? Evidence from Medicare Hospitalizations

Shubhranshu Shekhar, Brandeis University, Waltham, MA, United States, Jetson Leder-Luis, Leman Akoglu

The US spends more than $4 trillion per year on health care, largely conducted by private providers and reimbursed by insurers. A major concern in this system is overbilling and fraud by hospitals, who face incentives to misreport their claims to receive higher payments. In this work, we develop novel machine learning tools to identify hospitals that overbill insurers, which can be used to guide investigations and auditing of suspicious hospitals for both public and private health insurance systems. Using large-scale claims data from Medicare, the US federal health insurance pro- gram for the elderly and disabled, we identify patterns consistent with fraud among inpatient hospitalizations. Our proposed approach for fraud detection is fully unsupervised, not relying on any labeled training data, and is explainable to end users, providing interpretations for which diagnosis, procedure, and billing codes lead to hospitals being labeled suspicious. Using newly collected data from the Department of Justice on hospitals facing anti-fraud lawsuits, and case studies of suspicious hospitals, we validate our approach and findings. Our method provides an 8-fold lift over random targeting of hospitals. We also perform a post-analysis to understand which hospital characteristics, not used for detection, are associated with suspiciousness.

4 - Enhancing Emergency Department Patient Flow with Artificial Intelligence

SeungJin Wang, Siena College, Loudonville, NY, United States, Ratna Chinnam

This study aims to optimize patient flow and reduce length of stay (LOS) in the emergency department (ED) through early task initiation. An artificial intelligence (AI) model is developed using real ED electronic health record data to predict LOS and admission decisions. A reinforcement learning (RL) approach determines the optimal timing to disseminate patient information to facilitate resource allocation. The RL agent leverages predictions on LOS and admission, as well as virtual ED environment data in simulations. By continuously learning the most effective broadcasting actions, the RL mechanism optimizes patient flow. Outcomes demonstrate timely patient updates through the AI-enabled orchestration can reduce wait times. This not only improves care delivery but also enhances healthcare provider productivity and satisfaction while minimizing costs. Future work includes extending early task initiation techniques to other hospital departments for comprehensive patient flow optimization.

Leveraging Access to Data to Improve Access to Social Services

Invited Session

Service Science

Chair: Opher Baron, University of Toronto, Toronto, ON, Canada

Co-Chair: Shany Azaria, University of Toronto, Toronto, ON, Canada

1 - From Docket to Data: Unpacking Judicial Congestion Using Process- and Queue-Mining

Shany Azaria, University of Toronto, Toronto, ON, Canada

The court system, pivotal for social justice, is overflowed by congestion affecting social welfare, economic development, and access to justice. Despite its significance and operational complexity, being characterized by constrained resources, increasing demand, long in-process waiting time, impatient customers, and LOS measured in years, empirical research on court operations remains limited. This scarcity is largely attributable to challenges in accessing reliable and comprehensive data. This study employs NLP and AI tools to transform two decades of US Federal District Court case dockets into a detailed event log, leveraging process- and queue-mining to explore judicial congestion. By scraping, labeling, and analyzing millions of docket entries through operations management lenses, we are able to observe the case flow in the system and assess congestion impacts on case processing. Our findings illuminate the judicial workflow, offering insights for reducing congestion and enhancing system efficiency. This pioneering approach underscores the potential of data-driven analysis in court systems operations.

2 - Service Operations for Justice-on-TIME: a Data-Driven Queueing Approach

Ramandeep Randhawa, USC Marshall School of Business, Los Angeles, CA, United States, Nitin Bakshi, Jeunghyun Kim

We study judicial delays in the Supreme Court of India by applying concepts from service operations. Our goal is to elucidate the drivers of congestion, focusing on metrics such as the expected case-disposition time (delay) and the expected number of cases awaiting adjudication (pendency), and leverage this understanding to recommend operational interventions. We employ data-driven calibrated simulations to model the analytically intractable case-management queue. The life cycle of a case comprises two stages: pre-admission (before determining its merit for detailed hearings) and post-admission. Our methodology allows us to capture the queueing dynamics in which the judges are shared resources across the two stages. The sources of inefficiency that drive congestion include a misalignment between scheduling guidelines and judicial capacity, coupled with the requirement to schedule hearings in advance. Together, these factors inhibit utilization of shared capacity across the two-stage judicial queue. We demonstrate how interventions that account for these inefficiencies can successfully tackle judicial delay. In particular, scheduling to improve the allocation of time across pre- and post-admission cases can cut down the expected delay by as much as 65%.

3 - Modeling and Evaluating Policy Impacts on the United States Immigration Court System: An Application of Simulation and Data Science

Geri Dimas, Bryant University, Smithfield, RI, United States, Andrew Trapp, Renata Konrad

There is a significant and growing backlog in the United States immigration court system with over 2 million cases waiting to be heard. Due to large influxes of immigrants together with limited design and resources, the court system struggles to manage this growing backlog, resulting in delays that unnecessarily tax governmental and community resources. Leveraging data science and discrete event simulation we model the intricacies of this court system, deconstructing different elements and their respective complexity. We extend the baseline model to investigate alternative policies, seeking more efficient and equitable solutions to address the growing backlog.

4 - Neural Network Version of Mixed Effect Models

Mian Adnan, University of Northern Colorado, Greeley, CO, United States

The neural network structure for the mixed effect models has been developed.

5 - How Driving Automation Will Save Demand Responsive Transit

Antonio Antunes, Universidade de Coimbra, Coimbra Codex, Portugal, Amir Brudner, Anne Patricio, Gonçalo Gonçalves Duarte Santos, Moshe Ben-Akiva

This research investigates the viablility and potential advantages of deploying a Demand-Responsive Transit (DRT) service in low-demand areas, with a particular emphasis on how
driverless technology could influence this service. The analysis employs a three-step process.Inttially, it estimates the demand function based on service characteristic like fares and travel time. Subsequently, an integer linear programming (ILP) model is applied to optimize aspects such as fleet sized, vehicle routing, and the number or drivers/supervisors to achieve profit maximization. The final step involves assessing key performace indicators (KPIs) tp evaluate the service from multiple stakeholder perspectives. Findings reveal that although human-operated DRT services can improve consumer surplus, they are economically inefficient due to high operational costs and required subsidies, which can explain their frequent failure. In contrast, driverless DRT services emerge as a viable alternative, with substantially lower costs and improved social welfare
compared to human-operated DRT, especially when using low-capacity vehicles. Therefore,
policymakers and transit agencies should explore the potential of driverless technology as a means to provide a successful public transportation solution in rural and low-density areas where conventional fixed-route services fall short.

ONR Program Review: Integer and Discrete Optimization

Invited Session

OPT: Integer and Discrete Optimization

Chair: David Phillips, Office of Naval Research, University of New Mexico, Catonsville, MD, United States

1 - Mixed-Integer Programming Approaches to Generalized Submodular Optimization and Its Applications

Simge Kucukyavuz, Northwestern University, Evanston, IL, United States

Submodularity is an important concept in integer and combinatorial optimization. A classical submodular set function models the utility of selecting homogenous items from a single ground set, and such selections can be represented by binary variables. In practice, many problem contexts involve choosing heterogenous items from more than one ground set or selecting multiple copies of homogenous items, which call for extensions of submodularity. We refer to the optimization problems associated with such generalized notions of submodularity, Generalized Submodular Optimization (GSO). GSO is found in wide-ranging applications, including infrastructure design, healthcare, online marketing, and machine learning. Due to the often highly nonlinear (even non-convex and non-concave) objective function and the mixed-integer decision space, GSO is a broad subclass of challenging mixed-integer nonlinear programming problems. In this tutorial, we first provide an overview of classical submodularity. Then we introduce two subclasses of GSO, for which we propose polyhedral theory for the mixed-integer set structures that arise from these problem classes. Our theoretical results lead to efficient and versatile exact solution methods that demonstrate their effectiveness in practical problems using real-world datasets.

2 - Dyadic Linear Programming

Gerard Cornuejols, Carnegie Mellon University, Pittsburgh, PA, United States, Ahmad Abdi, Bertrand Guenin, Levent Tuncel

A rational number is *dyadic* if it has a finite binary representation. Dyadic rationals are important for numerical computations because they have an exact representation in floating-point arithmetic on a computer. A vector is *dyadic* if all its entries are dyadic rationals. We study the problem of finding a dyadic optimal solution to a linear program, if one exists. We show how to solve dyadic linear programs in polynomial time. We give bounds on the size of the support of a solution as well as on the size of the denominators. To illustrate this theory, we present recent computational results obtained in collaboration with PhD students Anthony Karahalios and Vrishabh Patil. In a different direction, we present results on directed graphs obtained in collaboration with PhD students Olha Silina and Siyue Liu. The work of Gerard Cornuejols, Vrishabh Patil, Siyue Liu and Olha Silina is supported by ONR grant N00014-22-1-2528.

3 - Sensitivity Analysis for Mixed Binary Quadratic Programs

Santanu Dey, ISyE Georgia Tech, Atlanta, GA, United States, Diego Cifuentes, jingye xu

In many applications it is necessary to solve challenging Mixed Binary Quadratic Programming (MBQP) instances repeatedly. These instances typically have the same constraint matrix, representing data corresponding to some invariant physical infrastructure, but varying objective function and right-hand-side (rhs). This motivates the need to develop methodology for conducting sensitivity analysis of MBQPs. In this talk, we consider sensitivity analysis for MBQPs with respect to changing rhs. We show that even if the optimal solution of a given MBQP is known, it is NP-hard to approximate the change in objective function value with respect to changes in rhs. Next, we study algorithmic approaches to obtaining dual bounds for MBQP with changing rhs. We leverage Burer’s completely-positive (CPP) reformulation of MBQPs. Its dual is an instance of co-positive programming (COP) and can be used to obtain sensitivity bounds. We prove that strong duality between the CPP and COP problems holds if the feasible region is bounded or if the objective function is convex, while the duality gap can be strictly positive if neither condition is met. We also show that the COP dual has multiple optimal solutions, and the choice of the dual solution affects the quality of the bounds with rhs changes. Finally, we provide an algorithmic approach to find ``best values" of optimal dual solutions, and present preliminary computational results on sensitivity analysis for MBQPs.

4 - Representing Integer Program Value Function with Neural Networks

Andrew Schaefer, Rice University, Houston, TX, United States, Tu Nguyen, Joey Huchette

We study the value function of an integer program (IP), which characterizes its optimal objective as a function of its right-hand side. We show that the IP value function can be approximated to any desired degree of accuracy using neural networks (NNs). We do this by deriving a connection between Chvatal-Gomory (CG) cuts and the IP value function, resulting in a novel NN architecture that interprets the weights of the NN as CG multipliers. Using this NN architecture, we propose a new unsupervised training method specialized for learning the IP value function. Preliminary computational results show that our training method on data without labels is comparable with supervised training.

Optimization Software Session II

Invited Session

OPT: Computational Optimization and Software

Chair: Hans Mittelmann, Arizona State University, Tempe, AZ, United States

1 - What's New in Fico Xpress Solver

Michael Perregaard, FICO, Birmingham, United Kingdom, Alexander Biele

We will give an overview of the latest enhancements, the newest features, and the most recent performance improvements in the FICO Xpress Solver for mixed-integer linear and nonlinear optimization problems. These include new heuristics, cutting and branching techniques, a more streamlined API, and updates to our global MINLP solver.

2 - Latest Developments in the Artelys Knitro Optimization Solver

Richard Waltz, Artelys, Los Angeles, CA, United States

Artelys Knitro is the premier solver for nonlinear optimization problems. Knitro offers both interior-point and active-set algorithms for continuous models, as well as tools for handling problems with integer variables and other discrete structure. This talk will highlight the latest developments in Knitro, focusing on some of the recent advances in solving mixed-integer nonlinear problems (both convex and non-convex), and heuristics for global optimization. We will also present Knitro results on large-scale models demonstrating speedups achieved with the latest Knitro releases.

3 - Latest Progress in Optimization Software

Hans Mittelmann, Arizona State University, Tempe, AZ, United States

An overview will be given on the performance of the latest optimization software based on our benchmarks

4 - Recent Developments in Optimization with MATLAB

Steve Grikschat, MathWorks, Natick, MA, United States

We will present an overview of the latest developments in MATLAB optimization. MATLAB has solvers for engineering and scientific applications where problems range from linear to nonlinear, mixed-integer, and non-smooth.

Learning and Applications of Mean Field Models and Multi Agent Systems

Invited Session

OPT: Machine Learning

Chair: Gokce Dayanikli, University of Illinois Urbana-Champaign, Champaign, IL, United States

Co-Chair: Mathieu Lauriere, New York University Shanghai, Shanghai, N/A

1 - Synchronization Games

H. Mete Soner, Princeton University, Princeton, NJ, United States

Building on Winfree's work, the Kuramoto model (1975) has become the corner stone of mathematical models of collective synchronization, and has received attention in all natural sciences, engineering, and mathematics. While the classical model postulates the dynamics of each oscillator in the form of a system of nonlinear ordinary differential equations, Yin, Mehta, Meyn, & Shanbhag (2010) use the mean-field game (MFG) formalism of Lasry & Lions, and Huang, Caines, & Malhame. In this talk, in addition to the Yin et.al model, we also introduce a simpler two state model which can be seen as a discretization of the original one. We outline results showing that the mean field approach also delivers same type of results including the phase transition from incoherence to synchronization. In particular, in the discrete setting we provide a comprehensive characterization of stationary and dynamic equilibria along with their stability properties. In all models, while the system is unsynchronized when the coupling is not sufficiently strong, fascinatingly, they exhibit an abrupt transition to a full synchronization above a critical value of the interaction parameter. In the subcritical regime, the uniform distribution representing incoherence is the only stationary equilibrium. Above the critical interaction threshold, the uniform equilibrium becomes unstable and there is a multiplicity of stationary equilibria that are self-organizing. The discrete model with discounted cost present dynamic equilibria that spiral around the uniform distribution before converging to the self-organizing equilibria. With an ergodic cost, however, unexpected periodic equilibria around the uniform distribution emerge.

2 - Stochastic differential games on graphs

Haosheng Zhou, University of California, Santa Barbara, Santa Barbara, CA, United States, Ruimeng Hu, Jihao Long

In this talk, we present our recent study unveiling the connection between graph properties and stochastic differential games. We begin by introducing a game modeled on graphs and derive the Markovian Nash equilibrium via Riccati equations. We then analyze the iterative scheme – fictitious play – for solving the Riccati equations and demonstrate its convergence rate, which is highly correlated with the underlying graph structure. Additionally, we present a semi-explicit expression for the Markovian Nash equilibrium in games played on vertex-transitive graphs. This expression serves as a benchmark to test our proposed deep learning algorithms.

3 - Partially-observable and major minor mean field control for multi-agent reinforcement learning

Kai Cui, Technische Universität Darmstadt, Darmstadt, Germany

In this talk, we consider mean field control in discrete time with partial observability and major agents for multi-agent reinforcement learning. Here, partial observability refers to limited information available to agents under a deterministic limiting mean field, whereas major agents refer to additional arbitrary, general agents under limiting stochastic mean fields. We begin by presenting standard mean field control and associated learning algorithms. Then, we relax the two limitations of full observability and weak interaction via novel mean field control models. We also give associated multi-agent reinforcement learning policy gradient algorithms and analyze the error in the policy gradient estimation. Finally, we briefly give an outlook on possible future extensions and current limitations.

4 - Stochastic filtering equations for diffusions on infinite graphs

Ichiba Tomoyuki, University of California-Santa Barbara, Santa Barbara, CA, United States

We discuss stochastic filtering problem for diffusions on infinite graphs and its applications to machine learning. A prototypical example we consider here is the problem for diffusions which are described by the stochastic differential equations of directed chain interaction and mean-field interactions on the infinite directed graph. We derive the linear and non-linear systems of the corresponding filtering equations and examine its solvability and properties which include the smoothness of the solution. In this talk we introduce its applications to the generative adversarial network problem.

MD32

Summit - 423

Advances of Reformulation Methods in General Integer Programming

Invited Session

OPT: Global Optimization

Chair: Ningji Wei, Texas Tech University, Lubbock, TX, United States

1 - Rank-One Convexification for Quadratic Functions with Sign-Controlled Variables

Soobin Choi, University of Southern California, Los Angeles, CA, United States, Valentina Cepeda, Andres Gomez, Shaoning Han

In this talk, we study the epigraph of a quadratic form, whose variables are ``sign-controlled'' by indicator variables. We describe the convex-hull for a special case of the set, in which the quadratic term is defined by a rank-one matrix. From the rank-one convexification, we derive a convex relaxation for general quadratic functions defined by positive semi-definite matrices.

2 - Binary Integer Program Reformulation: a Set System Approximation Approach

Ningji Wei, Texas Tech University, Lubbock, TX, United States

We present a generic reformulation framework for binary integer programs (BIPs) without imposing additional specifications for the objective function or constraints. To facilitate such generality, we introduce a set system approximation theory designed to identify the tightest inner and outer approximations for any binary solution space using special types of set systems. This development leads to an exact reformulation framework for general BIPs, centered around set covering and subtour elimination inequalities. We investigate the implications of this methodology on various instance problems, uncovering new solution strategies and structural insights. Building upon these advancements, we also extend the classic max-flow min-cut theorem into a broader context of set system duality. Overall, our framework explores a new direction in the field of integer programming by examining the algebraic properties of set systems and their operators, which may spur additional research questions and further enrich the field.

3 - A New Branching Rule for Optimizing Range and Other Order-Based Objective Functions

Rui Chen, Cornell Tech, Cornell University, New York, NY, United States, Bart van Rossum, Andrea Lodi

We consider range minimization problems featuring exponentially many variables, as frequently arising in fairness-oriented or bi-objective optimization. While branch-and-price is successful at solving cost-oriented problems with many variables, the performance of classical branch-and-price algorithms for range minimization is drastically impaired by weak linear programming relaxations. We propose range branching, a generic branching rule that directly tackles this issue and is compatible with any problem-specific branching scheme. We show several desirable properties of range branching and show its effectiveness on a series of fair capacitated vehicle routing instances. Range branching significantly improves multiple classical branching schemes in terms of computing time, optimality gap, and size of the branch-and-bound tree, allowing us to solve many more large instances than classical methods. We also consider a generalization of range branching to deal with more general order-based objective functions such as Gini deviation.

4 - Optimal Piecewise Quadratic Approximations for Enhancing Deterministic Global Optimization

Yingkai Song, Princeton University, Princeton, NJ, United States, Christos Maravelias

A range of process systems engineering problems can be formulated as mathematical optimization models, though the resulting, often nonlinear, models are computationally challenging. A common solution strategy involves simplifying nonlinearities through piecewise linear (PWL) approximations. However, due to the linearity of each approximation segment, this method may require many segments to achieve a desired accuracy, subsequently increasing the number of necessary binaries and thus complexity. Given recent advances in numerical solvers such as Gurobi, which can solve mixed-integer quadratically constrained programs (MIQCP) efficiently, there's a motivation to use piecewise quadratic (PWQ) approximations instead. Employing PWQ approximations enables using significantly fewer segments, which has the potential to outperform models/solvers using PWL approximations.

This presentation introduces new approaches for constructing optimal PWQ approximations with both the placement of break points and the approximation coefficients being decision variables. The objective is either to minimize approximation error given a maximum number of segments or minimize the number of segments given a maximum approximation error. Our approach builds upon existing studies for PWL approximation and introduces mixed-integer models to construct optimal PWQ approximations for two-dimensional discrete data. A sampling-and-refining strategy subsequently extends these models to approximate univariate scalar functions. Numerical examples show how using the proposed PWQ approximation can lead to improved computational performance compared to using state-of-the-art PWL approximations or the original models.

Distributional Robustness and Sequential Decision-Making

Invited Session

OPT: Optimization Under Uncertainty

Chair: Mohammed Amine Bennouna, Massachusetts Institute of Technology, Cambridge, MA, United States

1 - Multistage Distributional Robustness, TIME Consistency and Optimal Policy

Rui Gao, University of Texas at Austin, Austin, TX, United States

In this talk, I will discuss distributional robustness in a dynamic setting, where the deviation is measured by the causal transport distance between stochastic processes. Such a choice accounts for information evolution, making it hedge against a plausible family of data processes. I will present a recursive reformulation to evaluate the worst-case risk of any given random sequence and explore the intricacies of time consistency in dynamic risk measures. Furthermore, I will present dynamic programming reformulations for finding the optimal robust policy.

2 - The Curious Price of Distributional Robustness in Reinforcement Learning with a Generative Model

Yuting Wei, University of Pennsylvania, PHILADELPHIA, PA, United States

In this talk, we investigate model robustness in reinforcement learning (RL) to reduce the sim-to-real gap in practice. We adopt the framework of distributionally robust Markov decision processes (RMDPs), aimed at learning a policy that optimizes the worst-case performance when the deployed environment falls within a prescribed uncertainty set around the nominal MDP. Despite recent efforts, the sample complexity of RMDPs remained mostly unsettled regardless of the uncertainty set in use. It was unclear if distributional robustness bears any statistical consequences when benchmarked against standard RL. Assuming access to a generative model that draws samples based on the nominal MDP, we characterize the sample complexity of RMDPs when the uncertainty set is specified via either the total variation (TV) distance or χ^2 divergence.

3 - Sample Complexity of Inventory Control with Fixed Ordering Cost

Xiaoyu Fan, Stern School of Business, New York University, New York, NY, United States, Zhengyuan Zhou

We show in this work that a class of structured MDPs admits more efficient learning (i.e., lower sample complexity bounds) compared to the best possible/known algorithms in generic RL. We focus on the MDPs describing the inventory control system with fixed ordering costs, a fundamental problem in supply chains. We develop an algorithm applied to the inventory MDPs, which leads to strictly lower sample complexity bounds compared to the optimal or best-known bounds recently obtained for the general MDPs. We improve on those ``best-possible'' bounds by carefully leveraging the structural properties of the inventory dynamics in various settings.

4 - Statistical Learning of Distributionally Robust Stochastic Control in Continuous State Spaces

Shengbo Wang, Stanford University, Stanford, CA, United States, NIAN SI, Jose Blanchet, Zhengyuan Zhou

We explore the control of stochastic systems with potentially continuous state and action spaces, characterized by the state dynamics $X_{t+1} = f(X_t, A_t, W_t)$. Here, X, A, and W represent the state, action, and exogenous random noise processes, respectively, with f denoting a known function that describes state transitions. Traditionally, the noise process $\{W_t, t >= 0\}$ is assumed to be independent and identically distributed (i.i.d.), with a distribution that is either fully known or can be consistently estimated. However, the occurrence of distributional shifts, typical in engineering settings, necessitates the consideration of the robustness of the policy. This paper introduces a distributionally robust stochastic control paradigm that accommodates possibly adaptive adversarial perturbation to the noise distribution within a prescribed ambiguity set. We examine two adversary models: current-action-aware and current-action-agnostic, leading to different dynamic programming equations. Furthermore, we characterize the optimal finite sample minimax rates for achieving uniform learning of the robust value function across continuum states under both adversary types, considering ambiguity sets defined by f_k-divergence and Wasserstein distance. Finally, we demonstrate the applicability of our framework across various real-world settings.

Game Theory and Optimization: Minimax and Variational Inequality Approaches

Invited Session

OPT: Nonlinear Optimization

Chair: Afrooz Jalilzadeh, The University of Arizona, Tucson, United States

1 - Variance Reduced Halpern Iteration for Finite-Sum Monotone Inclusions

Xufeng Cai, University of Wisconsin-Madison, Madison, WI, United States, Ahmet Alacaoglu, Jelena Diakonikolas

Machine learning approaches relying on such criteria as adversarial robustness or multi-agent settings have raised the need for solving game-theoretic equilibrium problems. Of particular relevance to these applications are methods targeting finite-sum structure, which generically arises in empirical variants of learning problems in these contexts. Further, methods with computable approximation errors are highly desirable, as they provide verifiable exit criteria. Motivated by these applications, we study finite-sum monotone inclusion problems, which model broad classes of equilibrium problems. Our main contributions are variants of the classical Halpern iteration that employ variance reduction to obtain improved complexity guarantees in which n component operators in the finite sum are “on average” either cocoercive or Lipschitz continuous and monotone, with parameter L. The resulting oracle complexity of our methods, which provide guarantees for the last iterate and for a (computable) operator norm residual, is $\tilde O(n + \sqrt{n}L \epsilon^{-1})$, which improves upon existing methods by a factor up to $\sqrt{n}$. This constitutes the first variance reduction-type result for general finite-sum monotone inclusions and for more specific problems such as convex-concave optimization when operator norm residual is the optimality measure. We further argue that, up to polylogarithmic factors, this complexity is unimprovable in the monotone Lipschitz setting; i.e., the provided result is near-optimal.

2 - Projection-free Methods for Solving Nonconvex-concave Saddle Point Problems

Morteza Boroun, The University of Arizona, Tucson, AZ, United States, Erfan Yazdandoost Hamedani, Afrooz Jalilzadeh

This study addresses constrained saddle point (SP) problems with nonconvex-(strongly) concave and smooth objective functions, which are widely applicable in problems arising in machine learning such as robust multi-class classification and dictionary learning. While projected gradient-based primal-dual methods exist, those with projection-free oracles are limited. In this work, we propose new projection-free primal-dual algorithms with convergence rate guarantees in both deterministic and stochastic scenarios.

3 - Linear Convergence Rate for Quadratic Functional Growth Saddle Point Problems

Cody Melcher, The University of Arizona, Tucson, AZ, United States, Erfan Yazdandoost Hamedani, Afrooz Jalilzadeh, Conner Alubowicz

In this talk, we consider a convex-concave saddle point problems and how to incorporate quadratic functional growth assumptions into them. Saddle point problems arise in a variety of areas such as machine learning, signal processing, and Nash equilibrium. While it has been shown that strongly convex-strongly concave setting leads to a linear convergence guarantee, we consider a weaker assumption based on the quadratic functional growth to ensure the same guarantee. Finally, we present numerical experiments to validate theory.

4 - First-order Methods for Stochastic Variational Inequality Problems with Function Constraints

Mohammad Khalafi, Southern methodist university, DALLAS, TX, United States, Digvijay Boob

The monotone Variational Inequality (VI) is a general model with important applications in various engineering and scientific domains. In numerous instances, the VI problems are accompanied by function constraints that can be data-driven, making the usual projection operator challenging to compute. This paper presents novel first-order methods for the function-constrained VI (FCVI) problem under various settings, including smooth or nonsmooth problems with stochastic operators and/or stochastic constraints. First, we introduce the AdOpEx method, which employs an operator extrapolation scheme of the KKT operator of the FCVI in a smooth deterministic setting. This operator is not uniformly Lipschitz continuous in the Lagrange multipliers. We show that an adaptive selection of stepsizes leads to bounded multipliers and achieves the optimal O(1/T) convergence rate. A direct application of such techniques to nonsmooth and stochastic FCVIs is challenging. Hence, we introduce design changes to the AdOpEx method and propose a novel P-OpEx method that takes a partial extrapolation. We show a convergence rate of $O(1/\sqrt{T})$ for P-OpEx when both the operator and constraints are stochastic. This method has suboptimal dependence on the noise and Lipschitz constants of function constraints. We propose a constraint extrapolation type approach leading to the OpConEx method that improves this dependence by an order of magnitude. Moreover, all our algorithms can easily extend to saddle point problems with function constraints that couple the primal and dual variables. For such problems, our algorithms maintain the same complexity results for the aforementioned cases.

1 - Traffic Signal Optimization with Connected Vehicle Trajectories

Xingmin Wang, University of Michigan, Ann Arbor, MI, United States

Traffic light optimization is known to be a cost-effective method for reducing congestion and energy consumption in urban areas without changing physical road infrastructure. However, due to the high installation and maintenance costs of vehicle detectors, most intersections are controlled by fixed-time traffic signals that are not regularly optimized. To alleviate traffic congestion at intersections, we present a large-scale traffic signal re-timing system that uses a small percentage of vehicle trajectories as the only input without reliance on any detectors. We develop the probabilistic time-space diagram, which establishes the connection between a stochastic point-queue model and vehicle trajectories under the proposed Newellian coordinates. This model enables us to reconstruct the recurrent spatial-temporal traffic state by aggregating sufficient historical data. Optimization algorithms are then developed to update traffic signal parameters for intersections with optimality gaps. A real-world citywide test of the system was conducted in Birmingham, Michigan, and demonstrated that it decreased the delay and number of stops at signalized intersections by up to 20% and 30%, respectively. This system provides a scalable, sustainable, and efficient solution to traffic light optimization and can potentially be applied to every fixed-time signalized intersection.

2 - TSL information on the data-driven research challenge

Hai Wang, Singapore Management University, Singapore, Singapore, Lei Zhao

TSL and Meituan, a platform offering location-based consumer products and services including entertainment, dining, delivery, travel, and more, are partnering to provide researchers and practitioners worldwide with access to Meituan’s operational-level food delivery data in the first INFORMS TSL Data-Driven Research Challenge. This initiative aims to foster data-driven research on real-world challenges. Participants are expected to develop data-driven optimization models using the real data provided by Meituan to address some of the suggested questions or to explore questions of their own interest.

In this information session, we aim to cover the following aspects: (1) the academic and industry background of the research challenge; (2) the general administration of the challenge; (3) some descriptive analysis results and insights from the data provided; and (4) answer any questions from the attendees.

Behavioral-informed Analytics and Decision-making for Urban Transportation Systems

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Tianming Liu, University of Michigan, Ann Arbor, United States

1 - On the Economic Value of Electric Vehicle Charging Infrastructure

Daniel Vignon, New York University, New York, NY, United States, Yanchao Li, Prakrith Raja

In 2021, the Infrastructure Investment and Jobs Act (IIJA) allocated $7.5 bn for the construction of a national network of electric vehicle (EV) chargers. These are to be distributed to States according to a set of criteria which includes: "(…) meeting current and anticipated market demands for electric vehicle charging infrastructure, including with regard to power levels and charging speed, and minimizing the time to charge current and anticipated vehicles". Satisfying such a criterion naturally involves tradeoffs which must balance costs and benefits of a given charging deployment strategy. However, evaluating these tradeoffs when it comes to EV charging infrastructure is non-trivial and involves accounting for the interactions between multiple forces: activity scheduling, parking competition, and adoption dynamics. Our proposed research seeks to tackle that challenge. We propose and estimate a dynamic equilibrium framework that allows us, through counterfactuals in the context of New York City, to assess the economic value of charging infrastructure. Our insights shed light not only on behavioral patterns that may help--or hinder--EV adoption but also on efficient infrastructure policy.

2 - Principled Data Fusion to Infer Sociodemographic Variables from Big Mobility Data: a Semi-Supervised Bayesian Gp-Lvm Approach

Ekin Ugurel, University of Washington, Seattle, WA, United States, Khoa Dang, Prateek Bansal, Cynthia Chen

The widespread use of mobile devices and the omnipresence of network connectivity have led to an enormous volume of timestamped spatial data. While longitudinal, this passively collected mobile (PCM) data lacks the rich contextual insights of the more traditional household travel survey (HTS). We propose a principled method to impute latent factors (such as sociodemographic variables) into GPS-based datasets for a variety of use cases, like enhancing the performance of predictive models or enabling generalizable travel behavior inferences over time. Our method is both behaviorally- and spatially-informed—for the former, it uses a set of "labeled" trajectories (i.e., ones with the latent factors we seek to impute) to learn the relationship between travel behavior and various sociodemographic variables, whereas for the latter, it considers the underlying census tract at which the individual resides. Additionally, the word "principled" refers to our model's handling of uncertainty—rather than predicting point estimates, we propagate the uncertainty inherent in our learning of latent factors forward. We achieve this with a Bayesian treatment of the Gaussian Process latent variable model (GP-LVM), which allows us to report confidence bounds in any of our use cases. We demonstrate the robustness of our approach in two case studies.

3 - Cyberattack Impacts in Mixed-Flow Traffic: Driving Simulator Study

Yangjiao Chen, Georgia Institute of Technology, Atlanta, GA, United States, Shubham Agrawal, Srinivas Peeta

Connected and autonomous vehicles (CAVs) are expected to generate safety and efficiency benefits for the transportation system. However, CAVs are vulnerable to cyberattacks, potentially creating mixed-flow traffic of human-driven vehicles (HDVs), normal CAVs and compromised CAVs. To understand the associated network-level impacts, there is a need to analyze the interactions between HDVs and compromised CAVs and how they differ from the interactions between HDVs and normal CAVs. In this context, a driving simulator-based study is designed to investigate HDV car-following (CF) behavior in mixed-flow traffic when the predecessor CAV is normal or compromised. The effects of cybersecurity awareness and perception on CF behavior are considered. Statistical analysis and CF model calibration are performed based on the trajectory data collected from the driving simulator experiments to examine impacts on string stability and safety. The results also provide insights for CF behavior prediction under cyberattacks and mitigation measures to enhance CAV cybersecurity to assure putative traffic flow benefits.

1 - Optimizing TIME of Arrival Rather than Estimation: Joint Operation with Pricing for on-Demand Food Delivery Systems

Kaihang Zhang, The University of Hong Kong, Hong Kong, China, People's Republic of, Jintao Ke

The on-demand food delivery (OFD) system relies highly on time-sensitive operations and well-designed pricing policies. Therefore, these two aspects are crucial factors in the decision-making process for OFD operations. Optimizing pricing policy is a common practice in on-demand service operations including OFD as it influences the delivery supply-demand relationship and ultimately the platform's profitability or other metrics. On the other hand, the estimated time of arrival (ETA) is not typically regarded as a decision variable but rather as a prediction. However, it is the direct implementation of time sensitivity because it tells customers when their food will arrive and also shows delivery deadlines to drivers. As a result, the change in ETA decision may impact both customer demand and drivers' willingness to deliver. This paper considers the ETA as one of the platform's decision variables together with pricing. We present a joint optimization model of OFD which uses the unique characteristics of the OFD market, i.e., the order bundling behavior of drivers, as a medium to analyze the supply and demand equilibrium of delivery requests. We present insights into the operations of the OFD market in terms of ETA and pricing using the proposed mathematical model and show the non-monotonic impact of both decision factors.

2 - Analysis of Microhubs for Three-Sided Meal Delivery Services

Linxuan Shi, The George Washington University, Washington, DC, United States, Zhengtian Xu

In recent years, online food ordering and delivery platforms, such as DoorDash, Uber Eats, and Meituan, have experienced rapid growth in their three-sided market form. These platforms connect a range of restaurant suppliers to the people in surrounding neighborhoods and enable efficient meal delivery through a network of crowdsourced deliverers. This study examines the operational mechanism of microhubs in meal delivery services, acting as transshipment points where meal packages can be temporarily stored and consolidated for batch delivery. We develop aggregate analytical models for delivery operations with and without microhubs and compare their relative performances under various market conditions. Critical system metrics, with a specific focus on customers' and deliverers' experiences, are formulated to analyze and evaluate the potential efficiencies achievable through microhubs.

3 - The Parcel Delivery Problem Considering Crowd-Shipping and Uncertainty of Customer Demands

Sisi Jian, The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Shixuan Tang, Wentao Huang

Express companies are faced with lower economic efficiency if they continue offering direct delivery service to customers because of the expensive fulfillment cost of last-mile delivery and the rapid growth of parcel volume. This paper therefore introduces an emerging logistic service, crowd-shipping, to the problem. Packages destined for remote areas can be dropped at predetermined service points to avoid costly delivery expense, and crowd-shipping drivers in the nearby regions will be designated as relay couriers from the service points to customers. A mixed-integer linear programming (MILP) model is then formulated with the crowd-shipping technique to determine decisions on the fleet size, the crowd-shipping service, and the routing choice. Due to the computational complexity of the problem, a heuristic algorithm based on the adaptive large neighborhood search (ALNS) is tailored to solve large-scale instances. Numerical experiments are conducted in comparison with other solution means and a deterministic model to validate the effectiveness and efficiency of the proposed method. This paper is expected to offer an economic delivery approach for express companies.

4 - On-Demand Food Delivery with Compensation Services

Yanling Zhuang, McMaster University, Hamilton, ON, Canada, Elkafi Hassini, Yun Zhou, Yufei Yuan

In food delivery services, on-time delivery is critical because customers base their orders on estimated arrival times and delivery fees. Failure to meet these promises results in delivery delays and potential loss of future orders. To counteract these issues, platforms may offer compensation to customers for delays. This paper presents an analytical model that examines how promised delivery times affect the decisions of platforms, customers, and drivers, and the impact of customer compensation policies.

Chair: Wayne Ng, Singapore University of Technology and Design, Singapore, Singapore

1 - Modeling Demand Competition in Long-haul Aviation Markets

Nuno Ribeiro, Singapore University of Technology and Design, Singapore, Singapore, Mingmei Li, Sebastian Birolini

We look at the strategic hub competition problem in long-haul markets at a global scale. We identify itinerary attributes affecting passengers' choices and integrate them into demand models combined with optimization to analyse competition across airport hubs.

2 - Predicting Convective Weather in the Terminal Airspace of Singapore

Jetanat Datephanyawat, Singapore University of Technology and Design, Singapore, Singapore, Nuno Ribeiro

We develop probabilistic models to predict lightning occurrences in the terminal airspace of Singapore. Leveraging geostationary data, including cloud contours and lightning occurrences, we construct a suite of spatial tracking features to enhance the prediction of convective weather movements. Subsequently, we design algorithms to optimize aircraft trajectories, incorporating the calculated lightning risk probabilities to ensure safer and more efficient routing.

3 - Optimizing Aircraft Flows and Fuel Savings in Terminal Airspace Operations

Wayne Ng, Singapore University of Technology and Design, Singapore, Singapore, Sebastian Birolini, Nuno Ribeiro

In this research, we aim to optimize aircraft flows in the terminal airspace, also taking into account environmental considerations through minimizing fuel consumption, at a strategic level. To optimize aircraft flows, we previously developed an integrated optimization approach that utilizes matheuristic algorithms to optimize runway aircraft sequencing and decisions in the terminal airspace, including aircraft speeds, utilization of holding stacks, and vectoring. This model combines a Linear Programming model with metaheuristics, such as a Genetic Algorithm, to give near-optimal solutions in reasonable computation times. In order to also optimize fuel consumption, we propose 2 models, i) an extension of the LP to also consider altitude and speeds and ii) a data-driven approach to estimate fuel consumption between waypoint-pairs, which can also account for uncertainty. We utilize one year of high quality satellite data of flights in the congested terminal airspace of Changi Airport in Singapore, to calibrate both the parameters for the first model and the data-driven fuel estimation in the second model. Using a real flight schedule of Changi Airport, we test and discuss the applicability of our models. In this study, we also investigate the potential trade-offs between flight delays and total fuel consumption.

4 - Vehicle Routing Models for Efficient Airside Operations

Marcus Koh, Singapore University of Technology and Design, Singapore, Singapore, Peter Jackson, Nuno Ribeiro

In this research, we aim to develop a mesoscopic simulation tool to analyse airside operations and optimise resource planning for related operations. As a starting point, we focus on the development of vehicle routing programs to model the aircraft turnaround operations for purposes of resource optimization.

1 - Trade Credits and Visit Frequency: the Role of Order Financing on Nanostore Logistics Efficiency

Rafael Escamilla, Arizona State University, Tempe, AZ, United States, Jan Fransoo, Marcos Mogollon

Millions of mom-and-pop nanostores dominate the grocery retail landscape in emerging markets. As nanostores are cash and storage space constrained, their suppliers tend to visit them with a high frequency, causing high operational costs. It is unclear if credit could mitigate such costs by allowing for a lower visit frequency. To investigate this, we conduct a randomized field experiment on nanostores that have not made recent use of supplier credit, with the objective to uncover how trade credits interact with the visit frequency and with the available storage space to shape shopkeepers' ordering behavior. We find that trade credits moderate the positive relationship between visit frequency and bi-weekly order size, with credit effects being salient under low frequency visits. Storage space, by contrast, does not directionally shape shopkeepers' ordering behavior. While trade credits may more than offset the negative effect of low frequency visits among adopting nanostores, credit adoption remains challenging, with only 24% of nanostores assigned to the credit condition actually adopting the credit. Remarkably, not a single credit line was defaulted over the entire duration of the intervention. In terms of assortment, trade credit is mostly used to acquire nanostores' core assortment of popular, low-price items with low physical volume. We contribute to the extant literature by showing that the gesture by the supplier to extend trade credit may only partly legitimize a reduction of the visit frequency.

2 - Pay Models and Transparency on On-Demand Service Platforms

Swanand Kulkarni, Dartmouth College, Hanover, NH, United States, Basak Kalkanci, Chris Parker

On-demand service platforms have been experimenting with models to determine compensation for their workers. While some use commission- or effort-based pay models that are intuitive to workers, others, in their efforts to better match customer demand, have transitioned to models where pay is not strictly tied to effort, but depends on other, potentially exogenous factors. Platforms have also kept these pay models opaque. Workers' reactions to such practices, however, are not systematically examined or understood. Through incentivized experiments, we examine how a pay model's intuitiveness to workers, its transparency, and a change that reduces the model's intuitiveness affect workers' participation on the platform. Results show the promise and limits of pay model intuitiveness and transparency in managing worker participation.

3 - The Role of Explainable Artificial Intelligence in Influencing Loan Officer Behaviour

Stephanie Kelley, Sobey School of Business, Saint Mary's University, Halifax, NS, Canada, Anton Ovchinnikov

Little is known about whether explainable artificial intelligence (XAI) can help drive practitioners to increase the use of AI models for decision-making. We conduct a series of field and lab experiments to determine whether XAI can influence loan officer behaviour with respect to granting consumer credit.

4 - Coarsening in Human-AI Interaction

Ruru Hoong, Harvard Economics / Harvard Business School, Cambridge, MA, United States

AI signals are increasingly deployed as aids to human decision-making aids, yet various human cognitive biases can hinder their effectiveness. Coarsening at optimized thresholds—partitioning the signal space into fewer cells—can improve outcomes while keeping humans in the loop and adapting to any bias or context. Using a Bayesian persuasion framework, we determine the optimal partitioning of signals and characterize the conditions under which coarsening can help. We empirically show in a randomized experiment with loan underwriters that the provision of AI signals coarsened at the right thresholds improves overall decision-making outcomes.

1 - Estimating Individual Treatment Effects Using Nonlinear Methods in Panel Data

Qingyin Ge, NUS IORA, Singapore, Singapore, Jussi Keppo, Jinglong Zhao

Synthetic control is one of the most popular methods in policy evaluation using panel data. The most classical synthetic control method proposes to use a convex combination of the untreated units to create the counterfactual for the treated units. In this paper, we propose to generalize the convex combination to nonlinear functions when doing synthetic control.

2 - Quantifying the Effect of Interference on Platform Decisions

Anushka Murthy, Stanford University, Stanford, CA, United States, Hannah Li, Ramesh Johari, Gabriel Weintraub

There has been a recent and rapidly developing literature on studying bias in A/B tests resulting from interference on marketplaces. We study the impact of bias on decision-making using a hypothesis testing viewpoint.

3 - Treatment Effect Quantiles in Stratified Randomized Experiments and Matched Observational Studies

Yongchang Su, University of Illinois, Urbana-Champaign, Urbana, IL, United States, Xinran Li

Evaluating the treatment effect has become an important topic for many applications. However, most existing literature focuses mainly on average treatment effects. When the individual effects are heavy-tailed or have outlier values, not only may the average effect not be appropriate for summarizing treatment effects, but also the conventional inference for it can be sensitive and possibly invalid due to poor large-sample approximations. In this paper we focus on quantiles of individual treatment effects, which can be more robust in the presence of extreme individual effects. Moreover, our inference for them is purely randomization-based, avoiding any distributional assumptions on the units. We first consider inference in stratified randomized experiments, extending the recent work by Caughey et al. (2021). We show that the computation of valid p-values for testing null hypotheses on quantiles of individual effects can be transformed into instances of the multiple-choice knapsack problem, which can be efficiently solved exactly or slightly conservatively. We then extend our approach to matched observational studies and propose sensitivity analysis to investigate to what extent our inference on quantiles of individual effects is robust to unmeasured confounding. The proposed randomization inference and sensitivity analysis are simultaneously valid for all quantiles of individual effects, noting that the analysis for the maximum or minimum individual effect coincides with the conventional analysis assuming constant treatment effects.

4 - Flexible sensitivity analysis for causal inference in observational studies subject to unmeasured confounding

Sizhu Lu, UC Berkeley, Berkeley, CA, United States, Peng Ding

Causal inference with observational studies often suffers from unmeasured confounding, yielding biased estimators based on the unconfoundedness assumption. Sensitivity analysis assesses how the causal conclusions change with respect to different degrees of unmeasured confounding. Most existing sensitivity analysis methods work well for specific types of statistical estimation or testing strategies.

We propose a flexible sensitivity analysis framework that can deal with commonly used inverse probability weighting, outcome regression, and doubly robust estimators simultaneously. It is based on the well-known parametrization of the selection bias as comparisons of the observed and counterfactual outcomes conditional on observed covariates. It is attractive for practical use because it only requires simple modifications of the standard estimators. Moreover, it naturally extends to many other causal inference settings, including the causal risk ratio or odds ratio, the average causal effect on the treated units, and studies with survival outcomes. We also develop an R package saci to implement our sensitivity analysis estimators.

Chair: Yilun Chen, CUHK Shenzhen, Shenzhen, N/A

Co-Chair: Jiashuo Jiang, Hong Kong University of Science and Technology, Hong Kong, N/A

1 - Sample Complexity of Posted Pricing for a Single Item

Billy Jin, University of Chicago Booth School of Business, Chicago, IL, United States, Thomas Kesselheim, Will Ma, Sahil Singla

Selling a single item to *n* self-interested bidders is a fundamental problem in economics, where the two objectives typically considered are welfare maximization and revenue maximization. Since the optimal auctions are often impractical and do not work for sequential bidders, posted pricing auctions, where fixed prices are set for the item for different bidders, have emerged as a practical and effective alternative. This paper investigates how many samples are needed from bidders' value distributions to find near-optimal posted prices, considering both independent and correlated bidder distributions, and welfare versus revenue maximization. We obtain matching upper and lower bounds (up to logarithmic factors) on the sample complexity for all these settings.

2 - Near-Optimal Data-Driven Control for Assemble-to-Order Systems

Lun Yu, Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Zhixuan Cai, Tianhu Deng, Zhaoran Wang

The literature on periodic-review assemble-to-order (ATO) systems has long assumed that the demand distribution is exactly known. In practice, this may not be true and only a limited sample of historical demand data is available. In this paper, we study data-driven ATO systems under the criteria of long-run average cost. The task is complicated by the demand learning of multiple products, synchronization between different components' ordering decisions under non-identical lead times, and allocation to different products' assembly. To the best of our knowledge, our work is the first to analyze sample average approximation (SAA) in data-driven ATO systems and the first to propose an algorithm that finds a near-optimal solution.Surprisingly, we prove that the error of SAA in optimizing over the infinite-dimensional space of policies of an ATO problem compares only logarithmically larger than that over a finite-dimensional Euclidean space.We show that the complexities associated with demand learning and high-dimensional policy optimization can be captured by properly combining a specifically designed model-free reinforcement learning (RL) algorithm with SAA, which enriches the classical inventory control literature on ATO systems. To speed up numerical computation, we prove the convexity and asymmetric Lipschitz continuity of the cost-to-go functions and design a specialized model-free RL algorithm. Using an extensive numerical study, we show that our proposed algorithm consistently and notably outperforms existing heuristic policies and an off-the-shelf RL algorithm.Our numerical results suggest that the no-holdback rule---a commonly adopted heuristic in ATO systems---may lead to a double digit performance loss.

3 - On the Limited Representational Power of Value Functions and Its Links to Statistical (in)Efficiency

David Cheikhi, Columbia University, New York, NY, United States, Daniel Russo

Identifying the trade-offs between model-based and model-free methods is a central question in reinforcement learning. Value-based methods offer substantial computational advantages and are sometimes just as statistically efficient as model-based methods. However, focusing on the core problem of policy evaluation, we show information about the transition dynamics may be impossible to represent in the space of value functions. We explore this through a series of case studies focused on structures that arises in many important problems. In several, there is no information loss and value-based methods are as statistically efficient as model based ones. In other closely-related examples, information loss is severe and value-based methods are severely outperformed. A deeper investigation points to the limitations of the representational power as the driver of the inefficiency, as opposed to failure in algorithm design.

4 - Toward Unified Lower Bounds for Statistical Estimation and Interactive Decision Making

Yunbei Xu, MIT, Cambridge, MA, United States

In this paper, we develop a unified framework for lower bound methods in statistical estimation and interactive decision making. Traditional methods such as Fano's inequality, Le Cam's method, and Assouad's lemma have been foundational for statistical estimation. However, the contemporary interactive decision-making framework necessitates new approaches, such as the Decision-Estimation Coefficient (DEC). We bridge these methodologies through a general algorithmic lower bound method, integrating the existing lower bound approaches by relaxing the separation condition using data-dependent quantile and considering an adversarial reference distribution that generates a ghost data set. Based on our general lower bound approach, we introduce a novel complexity measure in the form of a log quantile, which facilitates the derivation of new lower bounds for interactive decision making. In particular, we establish necessary and sufficient complexity measures for convex model classes, which encompass many important contextual bandit classes. Ultimately, we provide a principled unification of existing lower bound methods and enhance them in various applications.

Exciting New Applications in Applied Probability

Invited Session

Applied Probability Society

Chair: Jamol Pender, Cornell University, Ithaca, NY, United States

1 - Modeling Epidemics via Queueing Theory

Jamol Pender, Cornell University, Ithaca, NY, United States

2 - Infectious Disease via Queueing Theory

Laurel Newman, Cornell ORIE, Ithaca, NY, United States

We construct and analyze a new stochastic model for infectious disease spread in service systems. Our model considers a M/M/1 queue where a proportion, p, of the arriving population is infectious and the remaining population is susceptible. When an infectious person overlaps in the queue with a susceptible customer for more than l units of time, then the susceptible person becomes infected. We provide both a personalized perspective of how an individual susceptible customer is infected and a community perspective of how one infectious customer can infect the others around them. From the personalized perspective, we derive the probability that a susceptible person becomes infected and the probability they are infected by at least k different people. From the community perspective we compute the mean and higher moments of the number of susceptible customers that are infected by one infectious individual. Finally, we use stochastic simulation to verify our analytical results and show that our new formulas accurately describe the behavior our stochastic model of infection.

3 - Understanding Bail Funds through Queueing Theory

Yidan Zhang, Cornell University, Ithaca, NY, United States, Jamol Pender

Community bail funds play a crucial role in supporting individuals unable to afford bail, significantly influencing defendants' future quality of life. We show how queueing theory is effective in modeling the dynamics of remaining money in a community bail fund and its allocation to defendants. We will demonstrate how to employ the Skorokhod Map to construct a more realistic model where defendants can be blocked from receiving funds in bail fund operations. Finally, we will discuss how our research can assist bail fund managers and stakeholders in making decisions in choosing recipients to fund.

4 - Optimal Spacing in Queues to Prevent Overlaps

Ruici Gao, Cornell University, Ithaca, NY, United States, Jamol Pender

In this paper, we investigate the probability of overlap between two customers arriving at an infinite server tandem queue with M = {2, 3, 4} stations. Understanding this probability is crucial for designing queue systems that minimize customer interaction, which is significant in a variety of realistic scenarios such as pandemic control. Our main contribution is the derivation of probability of no overlap, and the optimal spacing x between two customers required to ensure that the pair of units do not overlap within the system.

Simulation Optimization and AI

Invited Session

Simulation Society

Chair: Haidong Li, University of Chinese Academy of Sciences, Beijing, N/A

Co-Chair: Gongbo Zhang, Peking University, Beijing, N/A

1 - Compass-Inspired Grid Search Algorithm: a near-Optimal Algorithm for Strongly Convex Simulation Optimization

Jianzhong Du, University of Science and Technology of China, Hefei, China, People's Republic of, Jeff Hong, Ying Zhong

In this work, a grid search algorithm is proposed to solve a class of continuous simulation optimization problems (CSO) where the objective function is strongly convex. When the solution space is one-dimensional, the algorithm exploits the nested structure of grid solutions and borrows the idea from Convergent Optimization via Most-Promising-Area Stochastic Search (COMPASS) to ensure the estimated optimal solution is locally optimal. To solve multi-dimensional CSO, the algorithm adopts the coordinate search method and changes the value of only one coordinate by solving a one-dimensional strongly convex CSO in each iteration. We find that the algorithm has an interesting link with the coordinate descent algorithm for conventional convex programming. We show that the proposed algorithm has a near-optimal convergence rate for strongly convex CSO. Numerical results show the algorithm is efficient.

2 - Optimal Sampling for Best Arm Identification with Gaussian Process Regression

Mingjie Hu, Fudan University, Shanghai, China, People's Republic of, Jie Xu, Chun-Hung Chen, Jian-Qiang Hu

We consider the fixed-budget best-arm identification (BAI) problem in the presence of spatial correlation among arms. The mean reward of each arm can only be evaluated through stochastic simulation or field experiments with heterogeneous noise. Our primary objective is to find an optimal sampling policy that considers the spatial correlation among arms to maximize the probability of correct identification. We propose using Gaussian process regression (GPR) to model the spatial correlation and develop a GPR-based framework to derive an asymptotically optimal sampling policy. Additionally, we analyze the impact of spatial correlation on the sampling policy and quantify its benefits under specific cases. We also introduce a sequential implementation algorithm and establish convergence results. Numerical experiments show that the proposed method significantly outperforms widely used benchmarks in the literature, demonstrating improved efficiency by considering spatial correlation in BAI problems.

3 - Randomized Zeroth-Order Feedback-Based Coordinate Descent Algorithm for Simulation-Embedded Problems

Ruiyang Jin, Peking University, Beijing, China, People's Republic of, Yujie Tang, Jie Song

Complex simulation processes often arise in real-world decision-making scenarios, where only an input-output oracle is available. In such situations, traditional gradient-based algorithms are ineffective as obtaining the gradient relies on access to higher-order information, which may not be observable. Zeroth-order optimization methods offer a solution by estimating gradients using the input-output oracle, which is particularly suited for high-dimensional problems. However, their sample complexity is often unsatisfactory for practical requirements. To overcome this challenge, we propose and analyze the randomized zeroth-order feedback-based coordinate descent (RZFCD) algorithm, comparing it with the conventional zeroth-order feedback-based gradient descent (ZFGD). While ZFGD applies to problems with general convex and compact feasible sets, it exhibits higher oracle complexity, typically bounded by $O(d/\epsilon^2)$. In contrast, RZFCD achieves a lower complexity bound of $O(d/\epsilon)$ but is limited to problems with box constraints. Empirical experiments are conducted to validate the performance of both algorithms.

4 - Offline Contextual Optimization with Correlated Bayesian Beliefs

Fan Zhang, ACADEMY OF MATHEMATICS AND SYSTEMS SCIENCE CHINESE ACADEMY OF SCIENCES, Beijing, China, People's Republic of

For most complex systems, the decision maker needs to make the optimal decision solution in real time with the changing exogenous information in order to minimize cost or maximize profit. While the exogenous information, commonly called contexts, will influence the performance of feasible solutions, which means that the optimal solution varies as covariates. In addition, with the inherent complexity and uncertainty pervasive in them, these complex systems are rendered intractable to analytical modeling and analysis. In this work, we investigate the offline contextual learning in simulation optimization. In offline contextual learning, the optimal design changes with the context. Therefore, the optimal design needs to be carefully determined for each possible context. Existing research has paid little attention to the impact of correlations between different designs' performances on the efficiency of offline contextual learning. In this study, we consider the Bayesian framework and utilize a multi-output Gaussian process to capture correlations between different designs' performances. We verify that considering correlations can accelerate the decay of posterior variance. Taking the KG-type strategy as an example, we construct a new Bayesian sampling policy, CIKG. Finally, we show the effectiveness of CIKG through numerical experiments.

5 - Solving Mixed Integer Linear Programs by Monte Carlo Tree Search

Gongbo Zhang, Peking University, Beijing, China, People's Republic of, Yijie Peng

Mixed Integer Linear Programs (MILPs) are powerful tools for modeling and solving combinatorial optimization problems. Solving an MILP is NP-hard due to the integrality requirement, and the branch-and-bound (B&B) algorithm is a widely used exact solution method. In this work, we explore the use of Monte Carlo Tree Search (MCTS) to guide the search within the space of branching candidate variables, aiming to efficiently find the optimal solution (if it exists) for an MILP. We adapt the Asymptotically Optimal Allocation for Trees (AOAT) algorithm, a recently proposed MCTS approach in the field of simulation and optimization, for solving MILPs. AOAT compares different nodes based on their corresponding posterior mean and posterior variance for the unknown state value. The advantages of AOAT over the commonly used Upper Confidence Bound for Trees (UCT) are that AOAT tends to explore more, achieves asymptotic optimality, and has shown better performance. Numerical results demonstrate the potential benefits of the proposed method.

Data-driven Decision-making in Healthcare.

Invited Session

Health Applications Society

Chair: Vishal Ahuja, Southern Methodist University, Dallas, TX, United States

Co-Chair: Yingchao Lan, University of Nebraska-Lincoln, Lincoln, NE, United States

1 - Personalized Treatment for Opioid use Disorder

Savannah Tang, Southern Methodist University, Dallas, TX, TX, United States, Kyra Gan, Alan Scheller-Wolf, Sridhar Tayur

Wearable devices have the potential to revolutionize treatments for *opioid use disorder* (OUD) by measuring patient responses to different treatment regimens in real-time, enabling the development of personalized treatments. A variety of wearable devices with different features, sensitivities, and costs are available. Whether such devices are practical and cost-effective to incorporate in treatments for OUD, and if so how they should be used, are critical questions. To investigate these questions, we build a finite-horizon, non-stationary *constrained partially observable Markov decision process* (CPOMDP). To facilitate the solution of our model, we provide a novel budget reformulation that finds all optimal solutions lying on the original formulation's solution convex hull. We then show that our reformulation can be solved using a binary search in conjunction with an exact POMDP algorithm. Applying those elements and using parameters estimated from past literature, we perform a numerical study to investigate the values of different wearables in OUD treatments, where we consider different levels of budget, wearable precision, and patient *treatment adherence* (TA). We find that wearables can be valuable when patients react differently to treatments across the entire population. Furthermore, this value is the largest at low or moderate budgets for patients with low or moderate TA. Outside of these settings, the marginal benefit of wearables is negligible relative to their cost.

2 - Empowering Frontline Health Workers to Tackle Stock-Outs

Amir Karimi, The University of Texas at San Antonio, San Antonio, TX, United States, Anant Mishra, Karthik Natarajan, Kingshuk Sinha, Omar Balsara, Barbara Lamphere

In low-income countries, frontline health workers are frequently tasked with the non-clinical responsibility of inventory management for which they are not adequately trained. To address these challenges, several countries have launched initiatives to empower frontline health workers in inventory management by enhancing their skills through training. Through a collaboration with JSI Research & Training Institute, Inc., we gain access to fine-grained, proprietary data from approximately 18,000 health facilities across Indonesia. Leveraging these data, we evaluate the impact of a training program for frontline health workers aimed at reducing the stock-outs of reproductive health commodities.

3 - The Impact of Virtual Visits on Ambulatory Care Utilization and Patient Health Outcomes.

Jane Iversen, The Ohio State University, Columbus, OH, United States, Yingchao Lan, Aravind Chandrasekaran

Despite the widespread introduction of virtual visits within ambulatory care, the impact that the adoption of this new care mode has on the adopting patients remains poorly understood. This study conducts a comprehensive long-term evaluation of patients' uptake of virtual visits across a wide range of medical specialties within the ambulatory care setting at a major U.S. Health System. Namely, we investigate whether virtual visit adoption affects patients' care utilization and health outcomes as reflected in their use of resource-intensive services such as emergency rooms and hospitals. Additionally, given the existing health disparities in the U.S., we seek to understand whether the effect of virtual visit adoption varies with respect to a patient's race, socioeconomic status and gender.

4 - Introducing Healthcare Delivery Equity: A Novel, Actionable Metric Providing Hospitals with Controllable Suggestions for Improvement

Jae Park, University of Central Florida, Orlando, FL, United States, Jiguang Li, Veronika Rockova, Thomas Spiegel, Daniel Adelman

While existing hospital rating systems include health equity as a metric, hospitals often find themselves unable to influence this measure due to numerous uncontrollable factors. To address this challenge from an operations management perspective, we introduce a novel metric named "healthcare delivery equity." Tailored to be under hospitals' control, it aims to facilitate the implementation of equitable care by leveraging improvements in this metric. This study assesses how equitably hospitals treat patients with the same socioeconomic status and health conditions but different races, with the goal of urging underperforming hospitals to provide equitable care. Examining the national CMS Limited Data Set data spanning 2017 to 2022, the study employs a hierarchical Bayesian approach to robustly estimate random hospital effects, considering various hospital attributes and their interactions with patient characteristics. Our Bayesian model utilizes resulting distributions unlike traditional approaches that solely rely on coefficients and classifies hospitals into two categories: equitable care hospitals and racially privileged care hospitals. This innovative rating system provides a nuanced understanding of hospitals' current practices in terms of healthcare delivery equity, thereby assisting in reshaping their decision-making processes to promote equitable care.

Causal Discovery, Fairness, and Learning in Healthcare

Invited Session

Health Applications Society

Chair: Esmaeil Keyvanshokooh, Mays Business School, Texas A&M University, College Station, TX, United States

Co-Chair: Kyra Gan, Cornell Tech, Cornell University, New York, NY, United States

1 - Local Causal Discovery for Structural Evidence of Direct Discrimination

Jacqueline Maasch, Cornell Tech, New York, NY, United States, Kyra Gan, Violet Chen, Agni Orfanoudaki, Nil-Jana Akpinar, Fei Wang

Fairness is a critical objective in policy design and algorithmic decision-making. Identifying the causal pathways of unfairness requires knowledge of the underlying structural causal model, which may be incomplete or unavailable. This limits the practicality of causal fairness analysis in complex or low-knowledge domains. To mitigate this practicality gap, we advocate for the development of efficient causal discovery methods for fairness applications. To this end, we introduce local discovery for direct discrimination (LD3), a polynomial-time algorithm for recovering structural evidence of direct discrimination. Additionally, we propose a graphical criterion for identifying the weighted controlled direct effect (CDE), a qualitative measure of direct discrimination. We prove that this criterion is satisfied by the structural knowledge returned by LD3, increasing the accessibility of the weighted CDE as a causal fairness measure. We numerically validate our approach on custom synthetic data, community benchmarks, and real-world data. Taking liver transplant allocation as a case study, we highlight the potential impact of our method for modeling fairness in complex decision systems.

2 - Hybrid Top-Down Causal Discovery

Sujai Hiremath, Cornell University, Ithaca, NY, United States, Jacqueline Maasch, Mengxiao Gao, Promit Ghosal, Kyra Gan

Learning the unique directed acyclic graph (DAG) corresponding to an unknown causal model via an exact method is a challenging task. Constraint-based algorithms are limited to identifying Markov equivalence classes and often suffer from worst-case exponential runtimes. In contrast, structural equation based methods can identify a unique graph by imposing additional assumptions, but suffer from the curse of dimensionality due to high-dimensional regressions. To address these challenges, we propose a novel hybrid approach for global causal discovery in observational data. We first present a topological sorting algorithm that leverages ancestor-descendant relationships in linear structural equation models to establish a compact top-down hierarchical ordering, encoding more causal information than linear orderings produced by existing methods. We then introduce a nonparametric constraint-based algorithm that eliminates spurious edges with greater sample efficiency than current parametric methods. We provide theoretical guarantees for correctness and polynomial worst-case time complexity, supported by empirical validation on synthetic data. We demonstrate that our approach generalizes to nonlinear settings with arbitrary noise.

3 - Assessing Algorithmic Bias in Clinical Decision Support Tools for Acute Myocardial Infarction Patients: A MIMIC IV Cohort Study

Emily Garcia, Purdue University, West Lafayette, IN, United States, Zachary J. Hass

In recent years, machine learning (ML) algorithms have been increasingly integrated into clinical decision support systems (CDSS), promising to enhance decision-making in healthcare. While ML-based tools can expedite decision-making processes, there are concerns about the possibility of these tools exacerbating health disparities. Previous studies have shown that ML algorithms could inadvertently introduce bias, affecting the access and quality of care for vulnerable populations. However, there is a lack of evidence on whether ML-based CDSSs, used for early discharging of acute myocardial infarction (AMI) patients, contribute to disparities in discharge rates among vulnerable populations with AMI. This study aims to evaluate algorithmic bias and fairness in the Controlled Abciximab and Device Investigation for Lower Late Angioplasty Complications (CADILLAC) CDSS, which uses in-hospital mortality risk scores as a proxy indicator for early discharge. We examine the usage of CADILLAC on a cohort of AMI hospitalized patients to identify cases where it could be optimally used. We also propose strategies to mitigate algorithmic bias. Our findings suggest that a more patient-centered approach, considering the needs and characteristics of individual patient types, can help identify optimal patients for CDSS use. This approach could also facilitate the wider adoption of ML-based CDSSs and reduce post-discharge adverse events from impacting patients disproportionately.

4 - A Proposed Framework to Identify Upstream Sources of Bias Among Racial Subgroups in Artificial Intelligence Models

Rahul Ladhania, University of Michigan, Ann Arbor, MI, United States, Allister Ho, Karandeep Singh, Paramveer Dhillon, Chad Brummett, Anne Fernandez

Upstream biases can be understood as biases introduced into AI models prior to model training and testing. Beyond studying stratified model performance to identify these biases, we propose a framework for evaluating whether observed differences in model performance between subgroups could be due to upstream bias. Our proposed framework comprises two methodological approaches: 1) apply sub-group matching to attenuate modeling disparities and 2) explore characteristic differences between the key sub-groups to assess potential sources of model performance differences. We apply our framework to evaluate observed model performance differences between Black and White patient cohorts in two AI-based opioid use prediction models. Both models exhibited a higher AUC in Black patients as compared to White patients. We found matching Black and White patients reduced the subgroup model performance differences in our study, which was suggestive of selection bias in the unmatched cohorts. We also found that the Black patient population was more heterogeneous than the White population with respect to the distribution of predicted risk, several comorbidities, and measures of socioeconomic disadvantage. This heterogeneity is not explainable simply by our modeling procedure and likely arises from upstream factors such as historical, representation, and measurement bias, the first two of which can manifest as selection bias.

Platform Operations and Retailing

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Leela Nageswaran, University of Washington, Seattle, WA, United States

Co-Chair: Soo-Haeng Cho, Carnegie Mellon University, Pittsburgh, PA, United States

1 - &Ldquo;be the Buyer&Rdquo;&Ndash;Leveraging the Wisdom of the Crowd in E-Commerce Assortment Planning

Leela Nageswaran, University of Washington, Seattle, WA, United States, Yu Kan, Uttara Ananthakrishnan

We study a new business practice of using crowdvoting, wherein a retailer first seeks input from customers on the desirability of the product and then bases the purchasing decision on their votes. We collaborated with a subscription-based apparel rental platform and obtained a proprietary dataset comprised of the platform's products and users. We find that the initiation of the service improves short- and long-term rental performance outcomes. We also investigate several potential mechanisms that drive this improvement.

2 - Two Sides of Same-Day Delivery: Evaluating the Distributional Effects of Platform Fulfillment on Third-Party Sales

Euro Bae, KAIST, Seoul, Korea, Republic of, Daegon Cho, Soo-Haeng Cho, Jin Soo Han, Yeongwoo Kim

E-commerce platforms have increasingly adopted "Fulfillment by Platform" (FBP) programs, enabling third-party sellers to delegate order fulfillment operations and improve delivery speed. Despite the prevalence of FBP programs, there is a limited understanding of how they affect sales distribution across participating FBP sellers and non-FBP sellers. This paper presents the first empirical evidence of the distributional effects of an FBP program, leveraging a quasi-experimental variation in FBP sellers' delivery speed on a fashion e-commerce platform. Specifically, the platform introduced FBP sellers' same-day delivery to customers in a specific region while keeping FBP sellers' next-day delivery in neighboring regions. Using a difference-in-differences approach, we demonstrate that the platform-driven improvement in delivery speed increases FBP sellers' sales while cannibalizing non-FBP sellers at the aggregate level. However, we find that non-FBP sellers can safeguard their sales against FBP sellers when offering vertically or horizontally differentiated products. Furthermore, our analysis of customer-level transactional data unveils the heterogeneous effects of the faster same-day delivery of the FBP program on customers: Customers who purchase from a diverse set of sellers increase their purchases from FBP sellers while reducing them from non-FBP sellers. In contrast, customers with strong loyalties to few select sellers increase their purchases from FBP sellers while maintaining purchases from non-FBP sellers. Our findings highlight the need for sellers and platforms to recognize the nuanced impacts of faster delivery on sales dynamics and the importance of product differentiation and customer loyalty building as vital countermeasures to mitigate the potential adverse effects of FBP programs.

3 - Algorithmic Pricing, Transparency, and Discrimination in the Gig Economy

Daniel Chen, Boston College, Chestnut Hill, MA, United States, Gad Allon, Kenneth Moon

Algorithms control pricing and match customers and workers in the gig economy. However, algorithms face several critiques: they lack transparency, can be biased, and can be inefficient. We empirically analyze these issues and show that variation in algorithmic pricing incentivizes workers to decline a large portion of trips in practice, significantly decreasing system efficiency. We estimate policy counterfactuals and show that minimum wage and transparent pricing policies can improve efficiency without harming fairness constraints.

4 - Capacitated Spatial Newsvendor

Jinhui Han, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Ming Hu, Xian Yu

This work is motivated by Amazon's practice of distributing a limited supply across various locations to meet random demand. We address a spatial newsvendor problem with the aim of minimizing the total loss from transportation and inventory by optimizing supply redistribution. Employing optimal transport theory, we establish optimality conditions for different scenarios, which guide the corresponding optimal inventory reallocation strategies. Our results extend the classical newsvendor solution by incorporating spatial considerations, strategically reducing inventory levels at locations further from the supply origin. We specifically investigate both semi-discrete and discrete scenarios, offering managerial insights and developing numerical algorithms to support decision-making.

5 - Consumer Profiling via Information Design

Ruslan Momot, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, Itai Fainmesser, Andrea Galeotti

Platforms use purchase histories to profile customers, create consumer segments, and disclose them to sellers. Sellers target price offers to these segments, generating new data that enables further profiling. We characterize the platform's ability to learn consumers' valuations using only information design in constructing the segments disclosed to sellers. We then evaluate the implication for market outcomes. We find that there is a threshold so that the platform cannot accurately profile consumers with valuations above it but can do so for those with valuations below it. The threshold is the seller's optimal uniform price in the no-information case. As a consequence, the use of purchase data to profile customers increases total welfare without harming consumers.

Summit - 441

Recent Advances in Retailing, Healthcare and Manufacturing Research Domains

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Anupam Agrawal, Texas A&M University, College Station, TX, United States

1 - Customized Product Manufacturing and the Role of Complexity

Anupam Agrawal, Texas A&M University, College Station, TX, United States

The production of complex, customized technology products is challenging due to the need for flexibility and frequent changes, with the impact of operational integration on productivity and cost not well understood. Our study examines a major European bus and coach manufacturer, finding that operational integration improves productivity and reduces delays, cycle time, and production costs, especially in high-complexity and high-customization scenarios. Using a novel estimation method on station-level longitudinal data, we show that real-time information sharing and inter-functional communication enhance labor and capital utilization in complex customized manufacturing settings.

2 - Going Local: Authenticity of Retailers' Buy-from-Local-Suppliers Program

Orchi Bhattacharyya, University of Minnesota, MINNEAPOLIS, MN, United States, Necati Ertekin, Mehmet Gumus, Karen Donohue

This study delves into Buy-from-Local-Suppliers (BFLS) programs, a facet of corporate social responsibility wherein grocery retailers source and showcase local food products to support local suppliers and economies. To enhance customer awareness and establish authenticity for local food products in these programs, local suppliers certify their products through third-party certifying agencies and collaborate with retailers to display local certifications on product packages and/or online product pages. Using data from a Canadian online grocery retailer that offers a BFLS program and conducting an online experiment, we assess how displaying local certifications on online product pages influences sales of local food products. Our multimethodology research provides guidance on when and how grocery retailers and local suppliers should display local certifications on online product pages.

3 - The Role of Ease-of-Return Experience on Contingent Free Shipping Policies

Nitish Jain, London Business School, London, United Kingdom, Ashish Kabra, Wedad Elmaghraby

Contingent free shipping (CFS) policies, whereby consumers get free shipping if their orders are greater than a certain amount, are commonplace. Our study documents a novel determinant of financial performance of a CFS policy: the ease-of-return experience (EOR). Our analysis indicates that our collaborating retailer would be better off selecting a (relatively) lenient CFS policy in more convenient EOR markets and a (relatively) stringent CFS policy in less convenient EOR market.

4 - Towards enabling the last-mile logistics of vaccine supply chains: learnings from covid-19 vaccine administration

Bhupinder Juneja, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States, Ujjal Mukherjee, Kingshuk Sinha

Vaccine administration and vaccine coverage are among the primary ways to minimize the impact of a pandemic such as COVID-19. However, policy makers face the challenge of widespread disparity in vaccine coverage across locations. While the significance of vaccine hesitancy and the associated socio-economic factors are well-acknowledged in the extant literature, the factors associated with vaccine delivery and administration – from a supply-chain efficacy perspective – are not well-understood. In this paper, we attempt to fill this gap in the literature and analyze the effect of the enablers of the last mile of vaccine supply chains with respect to three dimensions: (i) logistical connectivity, (ii) delivery infrastructure, and (iii) informational connectivity. Our results suggest that all three dimensions of the last-mile delivery and administration of vaccines improve vaccine coverage. More importantly, there exists a complementarity relationship among the logistical and informational enablers of the last-mile logistics, signifying that focusing on one of the enablers alone is not sufficient. Furthermore, we find that investing in improving the enablers of last mile of a vaccine supply chain is more beneficial for locations characterized by relatively higher prevalence of socio-economic and demographic risk factors. Taken together, the findings of the paper make a significant contribution, theoretically and practically, towards understanding the supply-chain (last-mile) enablers of delivery and administration of vaccines. In conclusion, the paper complements the literature on socio-economic factors associated with vaccine acceptance and hesitancy.

Summit - 442

Recent Advancement in Virtual Care Integration

Invited Session

MSOM: Healthcare

Chair: Yue Hu, Stanford University, Palo Alto, CA, United States

Co-Chair: Lin Zang, University of Rochester, Rochester, NY, United States

1 - The Hybrid Hospital: Balancing On-Site and Remote Hospitalization

Andrew Daw, USC Marshall Data Sciences and Operations, Los Angeles, CA, United States, Noa Zychlinski, Gal Mendelson

Hybrid hospitals offer a blend of on-site and remote hospitalization. These new healthcare models require efficient operational policies to balance costs, efficiency, and patient well-being. Our study addresses two primary operational questions: (i) how to direct patient admission and call-in policies based on individual characteristics and proximity and (ii) how to determine the optimal allocation of medical resources between these two hospitalization options. We develop a model that uses Brownian Motions to capture the patient's health evolution during hospitalization. By optimizing call-in policies, we find that remote hospitalization is cost-effective only for moderately distant patients; the call-in threshold has a non-monotonic relationship with travel time. Additionally, we find that the impact of scarce resources is reflected through simultaneous increase of both remote and on-site costs by the same value, relative to the structure under abundant resources. Lastly, we identify a non-monotonic relationship between the total medical resources and the workload allocation, depending on the recovery rates and the hospital proximity. Contrary to the widely held view that telemedicine can mitigate rural and non-rural healthcare disparities, our research suggests that on-site care may actually be more cost-effective than remote hospitalization for patients in distant locations, due to increased risks for remote patients who are called in to the hospital. This finding may be of particular concern in light of the growing number of "hospital deserts," as these communities may in fact not be well-served through remote care. Such insights can guide decision- and policy-makers in shaping future healthcare delivery and design.

2 - Recent Advancement in Virtual Care Integration

Vijaya Parameswaran, Stanford University School of Medicine, Stanford, CA, United States

Virtual care delivery, including telemedicine systems, can be conceptualized as a sociotechnical system comprising people, processes, and technologies that integrate social and technical elements to provide effective remote healthcare. This approach includes synchronous and asynchronous telehealth, remote patient monitoring, and the collection and interpretation of patient-generated health data, which have the potential to transform healthcare delivery. Since the rise of virtual care, research has highlighted positive outcomes such as high patient satisfaction, reduced travel costs, and improved patient engagement and clinical outcomes, particularly in chronic disease management. However, the utilization of such services varies significantly, influenced by factors at multiple levels within a health system, including individual preferences, clinic specialties, and organizational ideology. The effectiveness and appropriateness of virtual care also depend on patient sociodemographic characteristics, access, comfort with technology, and clinical factors such as diagnosis, clinician preferences, and clinic site. Moreover, inefficiencies arising from legacy practices, such as duplicating in-person workflows, increasing coordination burdens, and reinforcing outdated patterns, curtail the benefits of virtual care and are exacerbated by volume-focused compensation structures and organizational resistance to change. Effective virtual care integration includes identifying the 'right' patient for the 'right' modality and determining the 'right' modality for each clinic specialty, which should be based on patient demographics, technological accessibility, clinician practice patterns, clinic site, and organizational considerations. Furthermore, future research must focus on identifying specific clinical scenarios in which virtual care is most effective for maintaining access to care, guided by clinical appropriateness and utilization patterns.

3 - Sunk Cost Effect in Mitigating Service Incompletion: A Queueing Approach

Jimmy Qin, Columbia Business School, New York, NY, United States, Carri Chan, Jing Dong

Sunk-cost bias is generally recognized as a factor that can lead to suboptimal decisions. In this work, however, we investigate how sunk cost can be used as an operational lever to increase service completion rates in a congested service system. We run a controlled online experiment and find that the abandonment rate is significantly reduced for the group of participants who incur a larger sunk cost. To better capture the dynamics of service systems and their impact on customers' behavior, we study a queueing model with sunk cost and strategic customers, where customers experience a disutility of balking that is proportional to the sunk cost they incur. We characterize the equilibrium behavior of the customers, from which we further derive the optimal strategy for the service provider in terms of whether to provide real-time queue length information to customers as well as the optimal level of sunk cost to impose. Our results show that the sunk cost strategy is effective only when waiting information is provided and that using a non-zero sunk cost is optimal when the queueing system is moderately congested. Through a comprehensive numerical study, we demonstrate that implementing a non-zero sunk cost can substantially improve the throughput of the system. In addition, we reveal an asymmetric pattern in the robustness of the service provider's optimal policy which suggests that if the service provider cannot accurately estimate the customer’s sensitivity to sunk cost, using an underestimated value will give more robust performance improvements.

4 - Hospital Collaboration with Telemedicine: A Viable Solution to Address Rural Health Disparities?

Yunting shi, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Nan Liu, Sergei Savin, Guohua Wan

Telemedicine offers an innovative way of collaboration between the distinguished hospital and the ordinary hospital in a remote area. We employ a three-stage Stackelberg game to capture the dynamic interactions between the hospitals and patients, and propose a contract to incentivize telemedicine partnership, which specifies capacity allocation portion and a collaboration fee.

5 - The Impact of Information-Granularity and Prioritization on Patients' Care Modality Choice

Lin Zang, University of Rochester, Rochester, NY, United States, Yue Hu, Ricky Roet-Green, Shujing Sun

The past few years have witnessed a significant expansion in telemedicine adoption by healthcare providers. On one hand, telemedicine has the potential to increase patients' access to medical appointments. On the other hand, due to the limitations of remote diagnostic and treatment methods, telemedicine may be insufficient for patients' treatment needs and may necessitate subsequent in-person follow-up visits. To better understand this tradeoff, we model the healthcare system as a queueing network providing two types of service: telemedicine and in-person consultations. We assume that an in-person visit guarantees successful treatment, whereas a telemedicine visit may fail to meet the patient's treatment needs with a probability that is contingent on individual patient characteristics. We formulate patients' strategic choices between these care modalities as a queueing game, and characterize the game-theoretic equilibrium and the socially optimal patients' choices. We further examine how improving patients' understanding of their telemedicine suitability through predictive analytics at the online triage stage affects system performance. We find that increasing information granularity maximizes the stability region of the system but may not always be optimal in reducing the average waiting time. This limitation, however, can be overcome by simultaneously deploying a priority rule that induces the social optimum under specific conditions. Finally, leveraging real-world data from a large academic hospital in the United States, we perform a comprehensive case study that encompasses both the development of a prediction model for in-person follow-up needs and the implementation of effective information provision and prioritization strategies.

Summit - 443

Supply Chain Finance

Invited Session

MSOM: iForm

Chair: Paola Martin, Indiana University, Bloomington, IN, United States

1 - Understanding the Impact of Informational Transparency in Collaborative Ventures

Diwakar Gupta, University of Texas, Austin, TX, United States, Paola Martin, Stephen Gilbert

In many two-party collaborative ventures, such as those between a franchisor (principal) and franchisee (agent), the two firms agree to share the total realized revenue. Typically, such collaborations are subject to two informational frictions. First, while the principal advertises its contribution up front as a magnet to attract agents, it is unable to observe the effort of the agent. Second, while the two firms share the realized revenue, only the agent can observe the realized revenue. The principal may either accept the reported revenue split or choose to verify the agent’s report at a cost. A natural question that arises in this setting is whether these two informational frictions, i.e., the agent's unobserved effort and the sales revenue opacity, lower the principal’s profit. Therefore, we formulate and analyze equilibrium decisions in a game-theoretic model to tease out whether the principal would prefer full transparency if such transparency could be achieved without incurring additional costs. Contrary to intuition, we find that the principal always benefits from not observing the agent's effort. In addition, the principal may prefer positive verification costs to zero such costs provided they are not too high. There also exist parameter settings for which the agent also realizes higher profit when the principal does not observe his effort and when verification costs are positive. Thus, we show that neither of the two collaborating firms may benefit from full transparency even when it is free.

2 - Political Ideology and Global Sourcing

Jie Peng, Advanced Institute of Business, Tongji University, Shanghai, China, People's Republic of, Ben Charoenwong, Jing Wu

We study the relationship between political ideology and corporations' global sourcing strategies. Specifically, we investigate if an amplification in ideological divergence between firms and foreign governments triggers a decrease in the importation of goods from these countries. We assert that political alignment significantly impacts operational risks and regulatory compliance and consequently shapes global sourcing decisions. To empirically explore this, we utilize a difference-in-differences model and unearth a noteworthy correlation: firms that undergo an increase in ideological distance following a foreign election are found to reduce their imports from that respective country. Our findings persist across various robustness tests, thereby strengthening the reliability of our results. This research underscores the palpable effect of political ideology on international sourcing strategies, providing valuable insights for corporations maneuvering through the global political terrain.

3 - Coordination contract for time and material management in project supply chains

Xingxing Chen, University of Richmond, Richmond, VA, United States, Panos Kouvelis

We study the time and material coordination problem faced by project firms in executing project activities. Project activities often have random durations and the dependency between them makes it a challenging task to manage them. One particular challenge is that project firms need to coordinate material delivery times with suppliers in face of the activities' uncertain start time. On another front, project execution is prone to uncontrollable factors that may demand additional materials to be supplied and hence prepared for. To manage both materials' delivery time and consumption uncertainties, we develop a material coordination contract that aligns the incentives of the supplier and the project firm by accounting for both project time and cost implications. Our work bridges the gap between the standard supply chain coordination literature and the project time coordination literature.

4 - Crop Insurance Contract Design under an Intermediary

Sridhar Seshadri, University of Illinois, Champaign, IL, United States, Minyu Ye

Crop insurance is crucial for mitigating agricultural risks, while the involvement of intermediaries and government subsidies introduces complexity into the contract design. Our study revisits the problem of determining welfare-maximizing crop insurance contracts in the presence of an intermediary. We derive the optimal structure of the insurance contract, and the optimal payoffs for farmers and insurers. We also evaluate the cost of the government subsidy required to achieve the optimal welfare outcomes. By introducing the role of intermediary in the contract design, our findings offer valuable insights in designing effective insurance contracts and managing the cost of subsidies for government.

5 - Addressing Drug Shortage with Forward Contracts

Mingxuan Cui, University of Illinois Urbana-Champaign, Urbana, IL, United States, Sridhar Seshadri, Qiong Wang

Drug shortage poses significant challenge for today's healthcare systems. Inadequate capacity, raw material shortage, and production disruption are major contributing factors to the problem. Addressing these issues requires business innovation. To this end, we consider an emerging drug supply chain model in which a third-party intermediary offers producers and buyers forward contracts to align incentives and reduce uncertainty. The business process is formulated as a multi-stage game that involves manufacturers' capacity decisions and subsequent competitions a la Cournot. As a significant feature of the model, random yield of capacity investment not only raises profit risks but also incentivizes manufacturers to take opportunistic behaviors to benefit from drug shortage. By comparing equilibrium outcomes of the game with and without the intermediary, we demonstrate the important role that third-party forward contracts can play to reduce drug shortage.

Pricing and Learning in Retail Operations

Invited Session

MSOM: Service Operations

Chair: Kostas Bimpikis, Stanford University, Stanford, CA, United States

Co-Chair: Vasiliki Kostami, HEC Paris, Jouy-En-Josas, France

1 - Routing in Vendor-Managed Inventory Supply Chains: Efficiency and Assortment Quality

Kostas Bimpikis, Stanford University, Stanford, CA, United States, Salomon Wollenstein-Betech

While the theoretical literature on the optimal and fair allocation of limited inventory to a set of retailers is extensive, there has been little empirical research to explore how inventory allocation strategies perform in real-world supply chains and their impact to downstream retailers. Using a proprietary panel dataset from a major CPG company in Mexico, we uncover a relationship between the order retailers were allocated inventory and the service quality they receive. Specifically, our findings illustrate significant disparities on both the inventory level and the product assortment between retailers depending on their position in the delivery route from the distribution center, which determines the order by which they were allocated inventory. Retailers that receive inventory last tend to receive more inventory of the best-selling products and typically carry higher priced SKUs. This finding had a direct impact on the retailers' sales, profits, and returns.

2 - Managing Acquisition and Retention Dynamics under Demand Learning and Capacity Constraints

Seyed Seyed Ghafouri, London Business School, London, United Kingdom, Oded Koenigsberg, Vasiliki Kostami

This research addresses the critical challenge of managing customer acquisition and retention in environments characterized by demand uncertainty and capacity constraints. We develop a dynamic model that incorporates stochastic approximation techniques to optimize pricing as well as acquisition and retention strategies by leveraging real-time interaction data and capacity constraints in decision-making processes. We demonstrate that our algorithm achieves optimal performance with theoretical guarantees, matching the best achievable regret in the online learning context. Our findings offer valuable insights for marketing and operations managers, addressing the joint interface in customer relationship management.

3 - Incentives in Online Gaming: Optimal Policy Design with Dynamic Causal Machine Learning

Zhikun Lu, Emory University, Decatur, GA, United States, Ruomeng Cui

We study the trade-off between AI and human decisions on reward design under static and dynamic settings in online gaming. We first document the empirical evidence and then develop an optimization framework for optimally assigning treatment under a dynamic setting to maximize user engagement.

4 - Market Fragmentation and Inefficiencies in Maritime Shipping

Giacomo Mantegazza, Amazon, Seattle, WA, United States, Kostas Bimpikis, Salomon Wollenstein-Betech

Maritime transportation is essential for global supply chains, but ballasting—vessels traveling without cargo—imposes significant economic and environmental costs. This paper focuses on the oil transportation industry, where about half of the total traveled miles are sailed empty, and illustrates that market fragmentation is the most important cause to ballasting after demand and supply imbalances, accounting for 17-20% of the total. We find that it is possible to reduce carbon emissions associated with ballasting by as much as 15% by consolidating the market into small shipping pools, i.e., sets of vessels controlled by a single operator, without raising concerns about excessive market power. Consolidation improves utilization due to larger pools coordinating their vessels more efficiently and expanding the set of ports they serve, which reduces the need for vessel relocations. At a broader level, this work shows the extent of the sustainability gains that can be obtained solely by organizing efficiently the resources available in today's supply chains.

Summit - 445

Innovating the Supply Chain: Scientific Advancements at Chewy

Invited Session

MSOM: Supply Chain

Chair: Eric Huang, Chewy, Bellevue, WA, United States

1 - Predicting Purchase Order Fulfillment: Integrating Machine Learning with Supply Chain Optimization

Eric Huang, Chewy, Bellevue, WA, United States, Chong Sun

To optimize the creation of Procurement Orders (POs), we should have an accurate measurement of how many units from the on-order POs will arrive. This motivates us to develop a model to better predict arrival quantity. Further investigation shows that approximately 97% of items in on-order POs arrive either in full (order quantity equals received quantity) or not at all and 3% arrive with a partial quantity. We thus decided to first develop a binary classification machine learning (ML) model that predicts if an item in an on-order PO will arrive. Compared to the multiclass classification or regression models, the binary classification model is easier to develop and test. Should the portion of partial received quantity arise, we will likely develop a different model that predicts the filled quantity directly. We call the current binary classification model, filled-quantity model (FQM), and it is based on a XGBoost method. Using these predictions, we can update the on-hand inventory estimate for an item during its expected receiving week. Once integrated into our PO creation system, we can make more informed decisions on new orders. We also conducted an entitlement study of the FQM based on a simulation method we derived without expensive integration and backtests. This helps us to bring the leadership onboard in implementing our model.

2 - Reinforcement learning based buying decisions in pharmacy business

Baris Kacar, Chewy, Bellevue, WA, United States, Chong Sun

The pharmacy business is complex, as there are certain rules and regulations that impact how and where products can be stored and shipped from. Fulfilling pharmacy orders in a short time is the highest priority and important for our customers, so it is essential that our fulfillment carries the right amount of products in the right places. One level above is the decision to order the correct number of products from our vendors, which keeps the pharmacy locations replenished regularly and enables them to serve with approximately 100% service levels. With the highly complex structure of decision-making in the face of stochastic lead times, fill rate reliability, and other supply chain constraints such as capacity, we explore reinforcement learning in buying decisions for the pharmacy business at Chewy. We compare different strategies in reinforcement learning and show numerical results to highlight how it can be used as an alternative approach to other stochastic or MILP-based models.

3 - Scaling Order Routing Optimization: Integrating MILP with GNN

Venkatesh Manohar, Chewy, Plantation, FL, United States, ChanSeng Pun, Gautham Sunder

Mixed Integer Linear Programming (MILP) is widely adopted for numerous discrete optimization tasks. However, lack of scalability limits their application in large scale use cases such as e-commerce delivery optimization models, which necessitates exploration of alternate methods to solve them efficiently. This study addresses the order routing problem modeled using MILP with an objective that minimizes the overall fulfillment cost and delivery time. We pre-solve the problem using a Graph Neural Network (GNN) to improve the scalability of the problem. The remaining problem is solved following the traditional approach. Our preliminary results tested using Chewy supply chain network suggest that the hybrid approach, which integrates the use of GNN and MILP, addresses the scalability limitation with minimal optimality tradeoffs

Doing good with OR: Responding to the needs of the vulnerable population

Invited Session

Public Sector OR

Chair: Faith Idoko, North Carolina Agricultural and Technical State University, Greensboro, NC, United States

1 - Supply Chain Resilience in the Face of Uncertainty: A Food Bank Case Study

Faith Idoko, North Carolina Agricultural and Technical State University, Greensboro, NC, United States, Chrysafis Vogiatzis, Lauren Davis

Humanitarian logistics has played an essential role in disaster management over the years. However, anticipating and preparing for the aftermath of these events can be very challenging due to its unpredictability. When such situations arise, there is often a notable increase in the number of food insecure individuals within the impacted area. To curb potential food crises after the disaster, food banks need to better prepare by evaluating network vulnerabilities beforehand. Recognizing the magnitude of the disaster, social vulnerability and resilience indices of the affected area can guide distribution efforts in meeting demand effectively and on time. Additionally, possible changes to this anticipated demand, as well as the available supply and physical capacity of the food bank must also be considered. These variabilities can stem from residents' evacuation behavior, or the trajectory and magnitude of the disaster. We propose a decision support approach which accounts for potential uncertainties that may impact preparations made by the food bank, or their ability to respond to the needs of the food insecure during dire times. The proposed approach in this study boosts food bank disaster preparedness, ensuring the food bank still accomplishes its main goal of serving the food insecure population despite the limitations imposed on its network by the disaster. Findings from this work can be adapted to fit food banks of various sizes with comparable network structures while also accounting for varying disaster types.

2 - Collaborative Prepositioning with Postponement and Stock Sharing

Lamia Gulnur Kasap, Ozyegin University, Istanbul, Turkey, Birce Adsanver, Burcu Balcik

We evaluate the impacts of postponement and stock-sharing strategies among humanitarian agencies operating within regional and country-level depots for prepositioning supplies. Our proposed system involves agencies stocking supplies in both branded (final product) and unbranded (shareable standard) forms at the regional depot, while limiting stocks to branded form only at country depots for faster response. To minimize expected response time under fixed total base stock constraints in this setting, we develop a two-stage stochastic model that determines the optimal inventory levels of branded and unbranded items for each agency across these depots. Our model incorporates constraints for facilitating practical stock sharing among agencies and stock mobilization from each agency to countries within its response region. We test our approach using historical hurricane scenarios from the Caribbean region and data from agencies. We demonstrate substantial savings in fill rate, response time, and inventory utilization.

3 - Co-designing solutions to societal issues with lived experts

Kayse Lee Maass, Northeastern University, Boston, MA, United States, Baris Tezcan, Geri Dimas, Yaren Bilge Kaya, Thomas Sharkey, Renata Konrad, Andrew Trapp, Lauren Martin, Kelle Barrick

Operations Research has the potential to help address many of the pressing societal issues facing our world today that increase the vulnerability of people to experience harm. But, how do we know what the needs of people in vulnerable positions actually are? This presentation describes the ways we have partnered with people with lived experience (e.g., homeless youth, human trafficking survivors) to understand their needs, rather than presuming knowledge of their needs without their involvement. The goal of building these community-based research partnerships is to move away from extractive research *on* vulnerable communities to co-creating research and solutions in partnership *with* people with lived experience. Such an approach also helps to understand and mitigate any unintended negative consequences that may come from implementing the policies, technologies, or operational changes suggested by the models. The audience will leave with an understanding of why this approach is necessary and actionable tips for how to create and sustain these partnerships.

4 - Assessing the Relationship between Social Vulnerability and Assessed Housing Damage in Hurricane Michael

Christopher Zobel, Virginia Tech, Blacksburg, VA, United States, Andrew Arnette, Louis Luangkesorn, Michael Whitehead

We discuss a project that combines three large-scale different data sets to better understand the interplay between social vulnerability and housing damage that occurred in Florida as a result of Hurricane Michael. The damage data is drawn from an American Red Cross post-disaster damage assessment. Centers for Disease Control and Prevention / Agency for Toxic Substances and Disease Registry (CDC/ATSDR) social vulnerability data is then included at the county level, where it is subdivided into its four component themes. Detailed weather data is also incorporated into the analysis at the county level in order to examine the relative strength of the storm in each affected area. We discuss preliminary results that confirm the hypothesis that different aspects of social vulnerability, as captured in the CDC/ATSDR themes, have differential impacts on the overall housing damages that resulted from the storm. This serves to further emphasize the importance of addressing the needs of vulnerable populations in order to improve their resilience to natural disasters.

5 - Supply chain network design for not-for-profit food distribution

Christine Nguyen, Northern Illinois University, Dekalb, IL, United States, Gabriela Ibarra, Michael Hewitt

This study describes a two-stage stochastic problem that can be formulated and solved to design a supply chain for a third party logistics (3PL) provider that equitably supports the goals and missions of food banks and food pantries. The primary purpose of this model is to help a 3PL determine which consolidation centers to open to equitably balance food distribution across food banks, and subsequently, food pantries. A secondary decision is to determine the size of the fleet of vehicles owned by the 3PL to hedge against uncertainty in the transportation spot market. In this study, an algorithm is developed and compared with CPLEX results.

Chair: Jin Qi, Hong Kong University of Science and Technology, Hong Kong, Hong Kong

Co-Chair: Aiqi Zhang, Wilfrid Laurier University, Waterloo, ON, Canada

1 - Dynamic Capacity Management for Deferred Surgeries: a Case Study on Hernia

Eojin Han, University of Notre Dame, Notre Dame, IN, United States, Kartikey Sharma, Kristian Singh, Omid Nohadani

We studied 4 years of medical insurance claims of more than 15,000 hernia patients in the United States and observed the presence of uncertainty in surgery demand and patient departure. The endogeneity of these uncertainties to hospital operations renders existing capacity management approaches inapplicable. To this end, we develop two approaches based on robust and distributionally robust optimization. These methods offer sizable improvements over alternative methods for hernia patients. We also discuss multiple operational insights obtained from extensive sensitivity analysis.

2 - Distributionally Robust Group Testing with Correlation Information

Jin Qi, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Zhuoyu Long, Yu SUN, Aiqi Zhang

Motivated by the need for more efficient and reliable methods of group testing during widespread infectious outbreaks, such as the COVID-19 pandemic, this paper introduces a novel operational improvement to Dorfman's widely-used group testing procedure. Our method minimizes a weighted sum of tests and misclassifications, predicated on the known prevalence rates and interindividual Pearson correlation coefficients. Recognizing the inherent ambiguity in the population-level probability of infections that arises from correlations, our approach leverages a distributionally robust optimization (DRO) framework to counteract the worst-case probability distribution. In fully-correlated cases, where each pair of subjects are equally correlated, we establish uniform group sizes and connect our analysis to Nash equilibrium principles. Larger testing groups are generally favored under high correlation, whereas individual testing becomes optimal under high prevalence. In partially-correlated cases, where the population is formed by several intra-correlated but inter-independent clusters, we highlight the effectiveness of mixed-cluster testing strategies, particularly at lower levels of prevalence and correlation. Conversely, scenarios with high prevalence or high correlation tend to favor individual testing or same-cluster pooling. For both fully- and partially-correlated cases, we develop polynomial-time solutions and conduct a thorough exploration on the change of optimal pooling strategy as a function of imperfect tests. We demonstrate the benefits of adopting the DRO framework through a comprehensive comparison with stochastic alternatives, and we illustrate the significant impact of considering correlated infections through a case study on a COVID-19 dataset from Hong Kong.

3 - Satisficing Measure for Extubation Decision Analytics

Jingui Xie, Technical University of Munich, Heilbronn, Germany, Zhiyuan Lou

The process of deciding when to extubate patients who rely on mechanical ventilation for breathing is critical in intensive care settings. This research focuses on determining the optimal timing for extubation by taking into account the risks related to the variability of outcomes. This study introduces a satisficing Markov decision process (MDP) that employs a satisficing measure to blend risk tolerance with a decision-maker-specified target. It unveils the threshold-based nature of the optimal policy, the submodularity of the value function, and a policy structure that is aware of risk. We identify three scenarios of risk-sensitive strategies for decision-making in comparison to the nominal MDP: an aggressive policy when terminal costs are deterministic, a conservative policy, and a mixed strategy that transitions from conservative to aggressive actions. Numerical experiments demonstrate our model's effectiveness, revealing a balance between expected costs and risk profiles (e.g., approximately 1.15% increase in expected cost in exchange for a 22.13% reduction in conditional expected shortage). These findings highlight a key balance between the risk of immediate termination and the ongoing risk associated with continuing treatment. Utilizing our model enables managers to significantly diminish the risk of shortages with a minimal increase in expected costs.

4 - Queueing Causal Models: Comparative Analytics in Queueing Systems

Zhenghang Xu, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Opher Baron, Dmitry Krass, Arik Senderovich, Mark Van der Laan

Simulation is a powerful tool for comparative analysis of queueing models. With expert knowledge of underlying system structure, simulator can be constructed to predict intervention effects. However, such manual construction is time- and skill-demanding. It could also be subjective - if expert failed to note an important system feature (e.g. different customer types receiving different service priorities), the model will not be accurate. As an alternative, we propose a data-driven representation of system building blocks, justified by G-computation formula. We describe the queueing data generation process with causal graphs and apply machine learning models to fit the structural equations. Through numerical experiments, we show that this approach can replace the explicit queueing dynamics and capture intervention effect in overtake-free queues.

Summit - Terrace Suite 2

OR Applications to Improve the Quality of Life of Individuals with Disabilities

Invited Session

Health Applications Society

Chair: Carolina Vivas-Valencia, The University of Texas at San Antonio, San Antonio, TX, United States

1 - Developing Score-Based Risk Assessment for Autism Using Supersparse Linear Integer Model

Yu-Hsin Chen, Penn State University, University Park, PA, United States, Whitney Guthrie, Qiushi Chen

Early diagnosis is crucial to the treatment outcome of Autism Spectrum Disorder (ASD), a developmental disorder that affects 1 in 36 children in the US. The Modified Checklist for Autism in Toddlers (M-CHAT) is the most commonly used screening tool for ASD-specific screening during pediatric well-child visits. However, its effectiveness is limited due to concerns about its accuracy. Although previous research has demonstrated that machine learning models using electronic health record (EHR) data can enhance ASD risk predictions, these models often involve complex computations and are challenging to integrate into clinical practice because they do not incorporate M-CHAT results directly and are difficult to interpret. To address these issues, we have applied a Supersparse Linear Integer Model (SLIM) to develop a score-based risk assessment system. This new model complements the existing M-CHAT by simplifying the calculation process and enhancing the overall accuracy of ASD screening. This approach promises to make advanced risk prediction models more accessible and practical for routine clinical use.

2 - Data Analytics Framework to Evaluate the Risk of Long-Term Side Effects of Psychotropic Polypharmacy in Autism Spectrum Disorder

Paula Andrea Jaimes Buitron, The University of Texas at San Antonio, San Antonio, TX, United States, Leslie Neely, Melissa Svoboda, Carolina Vivas-Valencia

Children with autism spectrum disorder (ASD), particularly those severely affected, are at high risk for challenging behaviors like physical aggression, self-injury, and property destruction. Without proper intervention, these behaviors can worsen over time. It is estimated that up to

65% of individuals with challenging behavior are treated with psychotropic medications, and 35% of them are exposed to polypharmacy, defined as the utilization of two or more prescriptions concurrently for at least 30 days. Psychotropic medications are drugs used to treat various psychiatric and neurological disorders that affect brain function, behavior, mood, and thoughts. Even though the use of psychotropic medications has become more common in the ASD population, there is still a significant gap in our understanding of their utilization in clinical practice. This study aims to determine the utilization and risk of long-term side effects, including metabolic syndromes associated with psychotropic polypharmacy among individuals with ASD. Leveraging a national cohort of commercially insured patients with ASD, we first investigated changes in the utilization of psychotropic medications intended to manage challenging behavior among children, adolescents, and adults with ASD in the US. Second, we conducted a survival analysis to determine the probability of individuals with ASD who did not face metabolic syndrome during the treatment exposure to psychotropic interventions from 2012 to 2021. This study offers insight into the use of psychotropic polypharmacy and the associated risks among various ASD demographic groups, including age, sex, and place of residence, contributing to the development of evidence-based care for individuals with ASD.

3 - Optimizing Patient Outcomes Through Generative Graph Neural Networks for Predictive Modeling of Multi-Chronic Conditions

Julian Carvajal Rico, The University of Texas at San Antonio, San Antonio, TX, United States, Adel Alaeddini, Syed Hasib Akhter Faruqui, Susan P Fisher-Hoch, Joseph B Fisher-Hoch

Predicting the emergence of multiple chronic conditions (MCC) is crucial for early intervention and personalized healthcare, as MCC significantly impacts patient outcomes and healthcare costs. Graph neural networks (GNNs) are effective methods for modeling complex graph data, such as those found in MCC. However, a significant challenge with GNNs is their reliance on an existing graph structure, which is not readily available for MCC.

To address this challenge, we propose a novel generative framework for GNNs that constructs a representative underlying graph structure by utilizing the distribution of the data to enhance predictive analytics for MCC. Our framework employs a graph variational autoencoder (GVAE) to capture the complex relationships in patient data. This allows for a comprehensive understanding of individual health trajectories and facilitates the creation of diverse patient stochastic similarity graphs while preserving the original feature set. These variations of patient stochastic similarity graphs, generated from the GVAE decoder, are then processed by a GNN.

Next, a contextual Bandit is designed to evaluate the stochastically generated graphs and identify the best-performing graph for the GNN model iteratively until model convergence. We validate the performance of the proposed contextual Bandit algorithm against e-Greedy and multi-armed Bandit algorithms on a large cohort (n = 1,592) of patients with MCC. These advancements highlight the potential of the proposed approach to transform predictive healthcare analytics, enabling a more personalized and proactive approach to MCC management.

4 - A Ride-Sharing Platform for Improved Healthcare Access by People with Disabilities

Omar Abbaas, The University of Texas at San Antonio, San Antonio, TX, United States

This study addresses the transportation barrier faced by People with Disabilities (PWD) accessing healthcare services. We propose a novel approach through the development of a ride-sharing program facilitated by a mathematical model and a matching algorithm. This program will connect PWD with volunteer drivers and other community members who can provide transportation assistance. The matching process will consider various factors including the type of disability, geographic location, preferred language, and service type (paid or volunteer). By incorporating these details, the program aims to create efficient and comfortable transportation solutions that cater to the specific needs of PWD. To ensure effectiveness, the program's functionality will be validated using simulation tools. This will allow us to generate alternative recommendations, further optimizing the matching process and ultimately improving healthcare access for PWD.

Summit - Ballroom 2

AI at Amazon Last-Mile

Invited Session

The Practice Section of INFORMS

Co-Chair: Abhilasha Katariya, Amazon, Issaquah, United States

1 - Revolutionizing Last Mile Delivery through Channel Topology Optimization

Gokce Kahvecioglu, Amazon, Bothel, WA, United States, Jin Ye

The expansion of Amazon Last Mile Delivery is one of the key enablers for the continued growth of Amazon's consumer business. Sustaining this growth is dependent on our ability to move beyond our traditional delivery channels, Delivery Service Provider (DSP) and Amazon Flex (Flex), to leverage alternative channels such as Hub Delivery Partners (Hub), walkers and cargo electric bikes (E-Bikes).These alternative delivery methods can help Amazon to overcome capacity constraints, real estate limitations, labor shortages, improve the delivery cost and speed and also support Amazon's sustainability goals. AMZL needs to determine the most suitable combination of delivery methods for a given geography to ensure optimal efficiency and lower cost, yet to meet customer demand and delivery speed, and make progress towards its sustainability commitments. This paper aims to develop an optimized multi-modal transportation model - Channel Topology Optimization (CTO) and proposes an expansion strategy at different phases of planning process of last-mile delivery.

2 - Large Scale Events

Selin Tosun, Amazon, Seattle, WA, United States, Jin Ye, Leah Riley

Large-scale events (LSEs) are not only impacting our scheduling and delivery quality but also many other aspects of pool health. In 2021 in the US, there were deliveries affected by these events, and led to drops in the pool health. Exempting these defects is currently handled manually, and some of these events are not processed on time. Anomaly-based approaches are not able to catch LSE events as effectively due to the non-linear nature of the problem. Here, we present a novel approach on automating LSEs detections by the systemic observations in the environmental factors and defect densities by XGBoost model for classifying LSEs. We are able to auto-capture more than 83% of the events accurately and immediately after the block's defects are posted, resulting in near-real-time Anomaly detection. The initial observations in real operations showed improvement on the timeliness metric to 95%, by automation and dramatically reduces the number of manual processes; the full extent is still being calculated. The LSE-Anomaly detection does not only improve the timeliness of the exemptions, but also standardizes the cases by reducing the inconsistencies coming from the manual investigations and reduces the dependencies on the event exemption intake requests. We see additional benefits of this modeling approach in wider set of applications in the Evaluations space.

3 - Optimizing Last Mile Delivery with Machine Learning: Amazon's Infrastructure and Scaling Strategies

Xiaodong Lan, Amazon, Inc, Seattle, WA, United States, Eliot Hijano, Ram Thiruveedhi, Abhilasha Katariya, Rohit Malshe

This research presents a novel approach leveraging Amazon Web Services (AWS) to enhance forecasting for Amazon's last-mile delivery operations. We describe our methodology for data collection, feature engineering, and developing cutting-edge machine learning models powered by AWS services. By integrating these models into decision-making, we demonstrate the potential for significant cost saving. We provide insights into our debugging and parameter tuning strategies facilitated by the AWS ecosystem, highlighting the value of cloud infrastructure in building high-performance forecasting models. The findings offer practical implications for logistics organizations seeking to optimize operations through data-driven decision-making supported by advanced analytics and cloud computing.

4 - Cold-start Forecasting for Special Events

Arkajyoti Misra, Amazon.com, Bellevue, WA, United States, Abhilasha Katariya, Ram Thiruveedhi

Accurate forecasting for rare events like high-demand, or special sales periods is hampered by limited data availability, leading to suboptimal planning and increased costs. This paper explores multiple solutions to address the cold-start problem, including imputing from relevant scenarios with appropriate adjustments and appending historical data to augment sparse datasets. We evaluate the effectiveness of these approaches in improving forecasting accuracy for key operational metrics during such special events, within the Amazon context. The proposed methodologies enable better capacity planning, mitigating risks associated with understaffing or overstaffing, and ultimately driving cost optimization.

Randomized Rounding Approaches to Online Allocation, Sequencing, and Matching

Invited Session

TutORial

Chair: Jamol Pender, Cornell University, Ithaca, NY, United States

1 - Randomized Rounding Approaches to Online Allocation, Sequencing, and Matching

Will Ma, Columbia University, New York, NY, United States

Randomized rounding is a technique that was originally used to approximate hard offline discrete optimization problems from a mathematical programming relaxation. Since then it has also been used to approximately solve sequential stochastic optimization problems, overcoming the curse of dimensionality. To elaborate, one first writes a tractable linear programming relaxation that prescribes probabilities with which actions should be taken. Rounding then designs a (randomized) online policy that approximately preserves all of these probabilities, with the challenge being that the online policy faces hard constraints, whereas the prescribed probabilities only have to satisfy these constraints in expectation. Moreover, unlike classical randomized rounding for offline problems, the online policy's actions unfold sequentially over time, interspersed by uncontrollable stochastic realizations that affect the feasibility of future actions. This tutorial provides an introduction for using randomized rounding to design online policies,

1 - Incorporating Genetic Data into Outcome Prediction and Treatment Prescription for Ovarian Cancer

Neelkanth Bardhan, Massachusetts Institute of Technology, Cambridge, MA, United States, Alkiviadis Mertzios, Matea Gjika, Xidan Xu, Samayita Guha, Subodha Kumar, Angela Belcher, Georgia Perakis

Ovarian Cancer (OC) is the leading cause of gynecological cancer-related deaths among women, with a 5-year survival rate of about 50% across all stages. To improve patient prognosis, there is an unmet clinical need for advanced Machine Learning (ML) models that utilize genetic data to improve OC outcome predictions and treatment recommendations. Our study addresses this shortcoming by developing new techniques to incorporate genetic information into treatment planning for OC, using data from the Prostate, Lung, Colorectal, and Ovarian Cancer (PLCO) trial. In this work, we transform genotype sequencing data into a tabular format suitable for ML models. By combining this genetic data with clinical parameters and recorded treatment regimens, we estimate treatment effects on mortality and recommend optimal treatments. Compared to models using clinical parameters only, we achieve improved efficacy of our predictive model by including genetic data, as demonstrated by an increased accuracy of prediction. Our ML models enable oncologists to make more informed decisions, potentially leading to improved prognosis and better survival outcomes for OC patients.

2 - On the Vertical Spillover Effect of Online Ratings on Platform Competition

Yulia Vorotyntseva, University of St. Thomas, Minneapolis, MN, United States, Aleksi Aaltonen, Subodha Kumar, Paul Pavlou

The standard 5-star rating system is a key source of information for consumers trying to decide where to eat, what products to buy, or which doctor to visit. Yet, a vendor may have different average rating on different platforms and, consequently, a consumer may observe the same vendor with different average ratings across platforms. Higher average ratings are known to increase vendor sales, but we do not know how differences in average ratings across platforms may affect platform competition.We study the impact of the difference in average ratings for the same vendor across platforms on the choice of a platform in a setting in which vendors offer their products (multihome) on several platforms and consumers can easily switch between platforms. Using incentive-aligned and stated-preferences experiments in a food delivery setting, we show that, all other things being equal, consumers prefer to purchase from a platform that displays a higher average rating for the same vendor---even if the difference in ratings would not signal a real difference in the quality of the product or purchasing experience from the same vendor between the platforms. We explain this by a vertical spillover effect by which consumers allow vendor ratings to bias their platform choice. The results have implications to how platform owners and policymakers should govern the provision of online ratings. When both vendors and consumers multihome across platforms, the management of each platform must govern its rating system strategically to avoid offering a virtual showroom to competitors.

3 - Are Smart Contracts Smart Enough? A Game Theoretic Approach for Implementing Blockchain-Enabled Group Purchasing

Amirhossein Ranjbar, Fox School of Business, Temple University, Philadelphia, PA, United States, Subodha Kumar

While improved supply chain transparency stemming from blockchain adoption can help supply chain members enhance their operational decisions, sharing information can come at the expense of competitive disadvantage. Consequently, firms often face challenges when considering blockchain technology adoption. In this study, we explore the optimal decisions of a single supplier and two competing retailers who face uncertain demand at the end market. Retailers do not know each other's demand, resulting in bilateral asymmetric information. The supplier offers quantity discounts to incentivize retailers to purchase higher values. By adopting blockchain technology, the parties can engage in a group purchasing strategy. Additionally, designing a smart contract, they can automate transactions contingent on realized uncertainties. This setup allows retailers to benefit from discounts across a wider range of orders. However, it requires them to reveal their orders to competitors. We investigate the profitability of supply chain members adopting blockchain technology and smart contracts for group purchasing transactions.

4 - Impact of Average Rating and Number of Reviews on Business Performance on Digital Platform

Samayita Guha, Florida International University, Miami, FL, United States

Consumers increasingly use social media content to make their purchase decisions. Many consumers study online reviews about products or services before purchasing. Online review platforms, such as Yelp and TripAdvisor, provide consumers with reviews and ratings of businesses and service providers. Hence, all types of businesses maintain their presence on online review platforms to improve their performance. To make their presence felt strongly among so many other competitors on online review platforms, businesses need to understand which review characteristic (such as volume, rating value, reviewer identity, texts, etc.) has more influence on consumer purchase decisions and in what ways. In this context, it becomes important to understand the interplay between both review rating and review number. To study this interplay empirically, we use a data set about restaurants on the Yelp platform. The answer to our research question will help restaurants allocate their resources more effectively to improve the number of reviews and ratings.

AI-human Interaction and Applications

Invited Session

Artificial Intelligence

Chair: Yuan Zhang, University of Memphis, Memphis, TN, United States

1 - Delving into Generative AI's Role in Mental Healthcare

Polina Durneva, University of Memphis, Memphis, TN, United States, Yuan Zhang

Mental health is a significant public health concern, which imposes a substantial economic burden on the healthcare system. Mental health disorders reduce quality of life and increase risks of disability, morbidity, and mortality. Limited availability and affordability of mental health services, due to shortages of professionals, geographic barriers, and lack of insurance coverage, pose significant challenges. Consequently, exploring alternative avenues for addressing mental health issues is essential. The advent of ChatGPT represents a transformative leap in self-management of mental health. Generative AI technologies like ChatGPT simulate human-like interactions, generate adaptive responses, and tailor conversations based on individual user inputs. However, the specific ways users interact with ChatGPT for mental health purposes remain unclear. Unlike structured mobile health apps, ChatGPT offers greater versatility and adaptability. Understanding user interactions with ChatGPT is crucial for identifying key variables and behaviors that influence desired outcomes, such as improved mental health. This study conducted 20 semi-structured interviews to explore participants' experiences using ChatGPT for mental health self-management. Using grounded theory and constant comparative methods, the analysis identified the process of user interaction with ChatGPT for mental healthcare as well as various use cases. Our findings provide insights into user interactions with ChatGPT, thereby informing the design of future experimental studies and guidelines for health technology developers. This research aims to enhance the accessibility and effectiveness of mental health support, ultimately improving the well-being and quality of life for individuals facing mental health challenges.

2 - Can Voice-Based AI Help US Feel Less Lonely: a Perspective Beyond Anthropomorphism

3 - Mindfulness in AI Tool Usage Among Software Developers: Impact on Innovation Activities

Yafang Li, University of Memphis, Memphis, TN, United States, Yujie Zheng, Pavankumar Mulgund, Raghvendra Singh

Generative artificial intelligence (AI) has become an integral component in the software development landscape, enhancing productivity and efficiency through capabilities like intelligent searching, recommendation systems, and automated code generation. While these tools facilitate tasks such as generating boilerplate code, explaining complex algorithms, and conducting research, there exists a potential risk of over-reliance which may undermine essential human-centric research qualities such as critical thinking and ethical judgment. Thus, mindful use of AI tools is crucial. This study explores the influence of mindfulness in the use of AI tools on innovation activities among software developers. We categorize the mindfulness states of software developers into high, medium, and low, assessing how each impacts the utilization of AI in two primary innovation activities: exploration and exploitation. Exploration involves using AI tools to delve into unfamiliar territories for diversification, while exploitation focuses on leveraging familiar domains to enhance specialization. This research aims to provide insights into how different levels of AI mindfulness affect the innovative outputs in software development environments, contributing to a balanced approach to AI tool integration in creative and technical processes.

4 - Applying Inverse Reinforcement Learning to Understand User Behavior in Online Health Communities

Yaqi Zhang, Central University of Finance and Economics, Beijing, China, People's Republic of, Xi Wang, Zhiya Zuo

This study seeks to understand how receiving social support influences various motivational types and, consequently, different behavioral patterns. Setting out from the theoretical lens of incentive salience, we posit that user motivations dynamically evolve during their initial support seeking upon joining an OHC, hence adapting their engagement behaviors progressively. Specifically, we applied inverse reinforcement learning to identify the "motivations" of diverse engagement patterns of users by inferring the rewards underlying engagement behavior types contingent on the types of social support received by users. Furthermore, we employed the panel autoregression model to examine the mutual influence among users' behavioral patterns and underlying motivations. Our findings provide valuable insights for community administrators and information system designers to maintain and enhance user activity in OHCs.

5 - Incorporating Human Preferences into Interpretable Reinforcement Learning with Tree Policies

Stephanie Milani, Carnegie Mellon University, Pittsburgh, PA, United States

Interpretable reinforcement learning (RL) seeks to create agents that are efficient, transparent, and understandable to the populations that they impact. A significant gap in current approaches is the underutilization of human feedback, which is typically employed only for post-hoc evaluation. We propose to center the needs of end users by incorporating the feedback that would be obtained in a user study directly into the training of interpretable RL algorithms. Our approach involves preference learning, where we learn preferences over high-level features that are not directly optimizable during the RL training process. We introduce an evolutionary algorithm that leverages user feedback to guide training toward interpretable decision-tree policies that are better aligned with preferences. We demonstrate the effectiveness of our method through experiments using synthetic preference data on three RL environments. We show that our approach not only yields policies that are more aligned with underlying user preferences but does so with sample efficiency in the number of user queries, thereby decreasing the burden on the user in providing such data.

1 - Standing on the Shoulders of a Genai Platform: Examining the Impact of Implementing Customized Gpts

Yinan Yu, University of Oklahoma, Norman, OK, United States, Hua Ye, Yi-Jen Ho

Generative AI (GenAI) is evolving from a B2C-oriented model to a platform-based ecosystem. While previous studies have focused on GenAI's impact on individual users, the effects on other platform stakeholders remain unexplored. This study investigates the impact of GenAI on business stakeholders, specifically through the adoption of customized GPTs on business developers' websites. Using Look-Ahead Propensity Score Matching (LA-PSM) and Differences-in-Differences (DiD) estimations, our observational study reveals that adopting customized GPTs does not influence traffic volume but significantly enhances visitor engagement metrics. These effects are more pronounced for niche websites and desktop users. A survey of ChatGPT Plus users confirms that customized GPTs provide high-quality and specific information, encouraging deeper user interaction on developers' websites. Our study contributes to the GenAI and two-sided platform literature by highlighting the nuanced effects of GenAI on business stakeholders. Practically, it suggests that businesses can achieve substantial improvements in user engagement, particularly for niche websites and desktop users.

2 - Visualizing the Competitive Market Structure - Mapping Products and Customers Using Online Reviews

Yifan Zhang, Kennesaw State University, Kennesaw, GA, United States, Ning Zhong

Online reviews have become an essential tool for businesses to learn about consumer perception of their brand and products. In this research, we develop a dynamic latent factor model that generates a joint spatial mapping of products and brands to provide insights into the underlying competitive market structure. The proposed model combines review text with review rating through a topic model and simultaneously performs market segmentation and brand positioning. We apply our model to car review data and show how the model may be used by managers to identify changes in consumer perception in online platforms and visualize the competitive market structure.

3 - The Philosopher's Stone for Science - The Catalyst Change of AI for Scientific Creativity

Qian Chen, Penn State University, STATE COLLEGE, PA, United States, Ian Ho, Pin Sun, Dashun Wang

The work investigates whether AI is a catalyst for scientific creativity and what theoretical explanations behind observed AI-supported creativity are. Employing the Logical Creative Thinking (LCT) framework, we conjecture that AI enhances scientific creativity by providing faster search algorithms and offering possibilities to explore new search paths for uncovered knowledge. AI is expected to facilitate creative knowledge *hybridization* (i.e., *recombination* in LCT) across fields and serve as a stimulus for knowledge mutation (i.e., *replacement* in LCT) within a field. Accordingly, we consider two measures of scientific creativity: novelty (as hybridization) and disruption (as mutation). To quantify the AI impact, we analyze the publications from 2000 to 2021 and their citation networks. Our findings first inform that AI increases the novelty of mediocre (medium-level) and the top (90th-percentile) papers while enhancing the disruption of the mediocre papers only. Second, we identify nuanced variations in the impact on creativity across fields. Specifically, AI has the strongest and least impacts on basic science and humanity, respectively. Third, our citation-network analyses further uncover the direct and indirect effects of AI. Citing AI-related papers from other fields fosters novelty due to the hybridization of diverse techniques. Yet, citation concentration within specific or own fields leads to an indirect negative impact on novelty. As for disruption, we observe a similar pattern applied to mediocre papers only. For the most disruptive papers, over-emphasizing specific fields and references hurts scientific mutation, whereas the increase in within-field citations deepens the understanding of prior work and illuminates new reasoning paths.

4 - Understanding the Impact of Algorithmic Viewer Targeting in Live-streaming Commerce

Qinping Lin, Tianjin University, Tianjin, China, People's Republic of, Jing Tian, Lei Wang, Ning Jia

In order to attract viewers with high purchase intention and enhance the viewer-to-buyer conversion rate in the live streaming, many firms are increasingly implementing the algorithmic viewer targeting (AVT) strategy. Based on two unique datasets, we conduct three analyses to explore the effectiveness of AVT strategy. Our study has the following findings: (1) the AVT strategy generally associates with the enhanced interaction atmosphere and increases sales revenue of live streaming. (2) targeted viewers acquired from AVT consume more products compared to organic viewers. (3) AVT strategy enhances the purchase from organic viewers through a spillover effect, facilitating an improved shopping atmosphere with increased commenting interaction and order placement notifications. This study contributes to the emerging live streaming literature by unfolding the impacts of AVT strategy. It also helps firms evaluate their usage of the AVT strategy and optimize their budget allocation accordingly.

Advanced Approaches for Network Resilience and Optimization

Contributed Session

Chair: Kedong Chen, Old Dominion University, Norfolk, VA, United States

1 - Restoring a Maximum Flow Network Using Reinforcement Learning

Nayan Chakrabarty, University of Arkansas, Fayetteville, AR, United States, Kelly Sullivan

We examine the problem of restoring network edges that have been disrupted. Specifically, we seek to identify which edges to repair in each time period to maximize the cumulative maximum flow for a given source and sink node. Network restoration problems have been studied from the perspective of designing exact and heuristic solution procedures, but reinforcement learning (RL) algorithms have not been explored extensively for this class of problems. For the deterministic version of the problem, we characterize the necessary conditions for an optimal restoration policy based on structural characteristics of the network. Using this property, we solve the network restoration problem using the maskable proximal policy optimization (PPO) RL algorithm in which masking is used to remove actions that do not meet the necessary conditions. We perform numerical experiments to compare our implementation against benchmark methodologies.

2 - Data-Driven Emergency Medical Service Network Design Models: A Robust Stochastic Dominance Approach

Chun Peng, Beijing Jiaotong University, Beijing, China, People's Republic of, Erick Delage

We study an Emergency Medical Services network design problem and propose two novel data-driven optimization models that account for uncertainty about emergency demand with a time-dependent ambiguity set, leveraging the recent advances on robust optimization. We compare the two models through an out-of-sample analysis using both synthetic and real-life data.

3 - Robust Modeling to Minimize the Total Time of the Process with Random Execution Time and Reduce the Consumption of "Energy Cost" in Parallel Packaging Machines

Samaneh Golara , Northern Illinois's university , Dekalb , IL, United States, Amin Eslampanah , Ziteng Wang

Abstract:

In this research, the problem of minimizing the execution time and the total cost of electricity on a set of parallel batch processing devices where jobs with different sizes are entered dynamically is investigated. To solve this bi-objective problem, an optimization algorithm based on GAMS named "GAMS bi-objective optimization algorithm" is presented. This algorithm is applied using a GAMS programming approach to improve performance in two problem objectives. Based on the delay status of the current batch after the task is added, two candidate lists are generated to limit the search space. In addition, heuristic information is designed for each of the candidate lists to guide the optimal search. Also, targeted local optimization methods are implemented to improve the solution quality. In the end, the performance of the proposed algorithm is compared with the existing GAMS algorithms using comprehensive simulation experiments. The results of experiments show that the proposed algorithm has a significant improvement in performance over other compared algorithms, especially for large problems.

Keywords: Robust modeling, Parallel packaging machines, Random execution time, and energy cost

4 - Improving the Resilience of an Evolving Capacitated Network Using Graph Neural Networks

Seyyed Farid Hashemian, University of Arkansas, Fayetteville, AR, United States, Maryam Aghamohammadghasem, Jose Carlos Hernandez Azucena, Haitao Liao

This research presents a data-driven model that aims to improve the reliability and resilience of a network under stochastic conditions by determining the sequence of operations. To achieve this, an objective function is designed to improve the network's reliability. Surrogate models such as Monte Carlo simulation and Graph Neural Networks (GNN) are utilized to quickly determine the objective function's value based on a sequence of approximate solutions. The GNN model distinguishes itself from previous research by not requiring additional input information like reliability upper bounds or graph features. Instead, the reliability of the network solely depends on data from the network's edges and nodes. However, the data for this model is imbalanced, which presents a challenge, and there is a need to select samples for the prediction model carefully. After computing the objective function using surrogate models, we need to solve the optimization problem to find the best sequence of actions to maximize the reliability and resilience of the network. To do this, heuristic models are developed that are proficient in dealing with complex scenarios and the sequential nature of the design problem. The capability of this type of data-driven model to perform optimization under stochastic settings that are dynamically evolving, as well as the ability to discover extensive decision spaces, led to the decision to use heuristic models.

5 - Clustering in Cardinality-Constrained Portfolio Optimization

Amirmohammad Ebrahimi, University of Florida, Gainesville, FL, United States, Hamed Amini

In portfolio optimization, efficiently managing large pools of assets while adhering to cardinality constraints presents a significant challenge. We propose a novel portfolio optimization framework that combines cardinality constraints with the classical Markowitz mean-variance model, using clustering to reduce dimensionality and achieve an optimal balance of risk and return. We use spectral clustering to group the residual returns of stocks. This method reveals natural groupings of assets based on their returns and correlations and enhances our understanding and categorization of assets, which is crucial for efficiently reducing the optimization space and dimensionality. Our empirical results show that our method is effective in managing portfolios while limiting the number of assets in each group. By optimizing the number of asset clusters, we make the asset selection process easier and achieve performance close to that of an unconstrained portfolio. This demonstrates that clustering strategically can maintain near-optimal performance and provides a robust framework for large-scale portfolio management under real-world constraints. This study shows that our framework improves investment strategies, making portfolio diversification and risk management more efficient and manageable.

6 - Managing Reputational Risks Under Institutional Pressure

Kedong Chen, Rensselaer Polytechnic Institute, Troy, NY, United States

Managing firm reputation risks is imperative as firm reputation impacts its profits, employee and customer loyalty and market value. We posit that supply chain relationships and national culture play important roles on firm reputational risks. We empirically examine the impact of supply network and the moderation role of national culture.

MD69

Regency - 607

Policy and Digital Platforms

Invited Session

eBusiness

Chair: Sameer Borwankar, McGill University, Montreal, QC, Canada

1 - Effects of Corporate Sociopolitical Activism

Sameer Borwankar, McGill University, Montreal, QC, Canada, Shrijata Chattopadhyay

As political polarization deepens across the US, large corporations have a significant role to play in the public discourse regarding political issues. Yet it is uncertain how corporations should react to social issues that have been politicized over the years. We study the politicization of LGBTQ+ rights over the years in the U.S. and its impact on corporate stances on socio-political issues. As corporations go beyond profit maximization and take stances on socio-political issues, it is difficult to satisfy all stakeholders and hence, can result in reduction in firm value. On the other hand, strategic use of socio-political stances by corporations can enhance firm value. We find a decline in public stances by corporations post-politicization of LGBTQ+ rights, although the stock market has a heightened positive reaction to such stances post-politicization.

2 - When Moderators are Moderated: Evidence from an Online Forum

Ilango Guru Muniasamy, Daniels School of Business, Purdue University, West Lafayette, IN, United States, Wreetabrata Kar, Hossein Ghasemkhani, Warut Khern-am-nua

Online communities play a vital role in creating safe and inclusive digital spaces based on shared interests. The success of these communities hinges on cultivating trust and a sense of belonging, with community moderation and disciplinary processes playing a crucial role in building this trust. While research has explored the impact of disciplinary actions like user suspensions on subsequent content contributions, the influence of suspensions on participation in community moderation remains unexplored. Our study fills this gap by examining how suspensions affect users' engagement in upvoting and downvoting, key tools for moderation of online communities.

Utilizing data from a leading Asian online forum, we discover that post-suspension, users tend to downvote more frequently but exhibit no change in upvoting. This behavior is accompanied by a short-term decline in the quality of downvoting and conformity with community consensus, revealing evidence of an antisocial response to suspension. This response is amplified among the set of core users who contribute more content and are longer tenured in the forum, raising additional concerns about the negative effects of suspension.

To interpret these behaviors, we draw on the Multi-motive Model of Reactions to Interpersonal Rejection - a prominent theory that studies individuals' response to rejection, and the Temporal Need-Threat model which evaluates individuals' evolution of the responses over time. Our findings suggest that suspensions, though intended as corrective measures, may inadvertently disrupt platform harmony in the short-term by promoting hostile moderation activities

3 - The Impact of Online City Disclosure

Tiange Li, McGill University, Montreal, QC, Canada, Animesh Animesh, Sameer Borwankar

Studies suggest online communities can mitigate spatial inequality across regions of different development levels and facilitate more equitable discussion. Yet, this digital egalitarianism is at risk in the face of a pervasive trend toward increased transparency, particularly when platforms disclose user location data. Such disclosures may unintentionally exacerbate regional disparities by reinforcing pre-existing tensions and biases. In this study, we aim to fill this gap and investigate how city disclosure influences the network significance of cities in terms of online interactions. Specifically, we investigate how users in higher-tier cities respond to city disclosure (i.e., engage and interact) compared to their lower-tier cities counterparts, in the context of the Chinese city-tier system. By leveraging a natural experiment on China's civil service exam forum, we show that city disclosure introduces location-induced social hierarchy bias into online interactions: users located in higher-tier cities are less likely to engage with or receive responses from others, demonstrated by a decrease in both outdegree and indegree centralities of higher-tier cities. However, our analysis suggests that certain real-world competencies, such as educational attainment or local competitive dynamics, may mitigate this bias. Our robustness checks, including provincial data limitations, region subsample analysis and alternative social hierarchy indicators, confirm the consistency of our results. Additionally, we enrich our study with a dyad-level analysis and show that city disclosure significantly increases same-status competition, be it within the same tier group, tier, or province.

4 - Monetization and Accreditation in Healthcare

Krishna Pothugunta, Michigan State University, East Lansing, MI, United States, Xiao Liu, Anjana Susarla, Rema Padman

Monetization and accreditation in healthcare, particularly on social media with the rapid growth of user generated content, presents a unique opportunity and challenge to maintaining inclusivity on the social media. Since the introduction of YouTube Partner Program in 2007, the program has gone through various changes, notably through 2017 to 2023. Prior literature has shown that monetization models like subscription services or premium content can create access barriers, thereby affecting the representativeness of the platform by excluding certain demographics or socio – economic groups. In May 2020, YouTube announced that all healthcare professionals must disclose their credentials in videos related to health or medical topics. Even though the aim of this policy is to enhance the transparency and credibility of the content creator or presenter, but stringent criteria may exclude valuable contributors who lack formal credentials, thereby negatively affect the representativeness of the platform by limiting the diversity. So, both monetization and accreditation can impact the representativeness of healthcare in social media platforms. The study intends to measure the change in representativeness in the videos from 2018 to 2023 by using multiple channels related to healthcare. The major focus of the study is towards understanding the major difference in representativeness in videos that belong to channels that are accredited and influencers on YouTube, by using a difference – in – difference method. The contribution of the study is to address the change in level of inclusivity and representativeness on social media with the respective modifications in monetization and accreditation policies.

Regency - 701

Leveraging Machine Learning for Advanced Demand-Side Electricity Management

Invited Session

ENRE: Electricity

Chair: Lingxiang Yun, Taxes A&M University Corpus Christi, Corpus Christi, United States

1 - Sample-Efficient Deep Learning for Demand Response

Guangchun (Grant) Ruan, Massachusetts Institute of Technology, Boston, MA, United States

The superior performance of deep learning relies heavily on a large collection of sample data, but the data insufficiency problem turns out to be relatively common in global electricity industry. How to prevent overfitting in this case becomes a fundamental challenge when training deep learning models in different demand response applications. With this in mind, we propose a general framework, namely Knowledge-Augmented Training (KAT), to improve the sample efficiency, and the main idea is to incorporate domain knowledge into the training procedures of deep learning models. Specifically, we propose a novel data augmentation technique to generate some synthetic data, which are later processed by an improved training strategy. This KAT methodology follows and realizes the idea of combining analytical and deep learning models together. Modern learning theories demonstrate the effectiveness of our method in terms of effective prediction error feedbacks, a reliable loss function, and rich gradient noises. At last, we study two popular applications in demand response decision making: user modeling and probabilistic price forecasting. The proposed method outperforms other competitors in all numerical tests, and the underlying reasons are explained by further statistical and visualization results.

2 - Data-Driven Robust Unit Commitment with Statistical Guarantees: An Integrated Forecasting and Optimization Approach

Yue Chen, The Chinese University of Hong Kong, Hong Kong, China, People's Republic of, Rui Xie

The penetration of distributed renewable generation increases the demand side randomness and brings new challenges for unit commitment. Following the idea of predict-and-optimize, this paper proposes a novel robust unit commitment approach that integrates the forecasting and optimization processes. In the forecasting part, besides directly using local load data, horizontal federated learning is adopted to utilize the similarity between loads, and a privacy-preserving vertical federated learning framework is developed to exploit consumers' private data. These three kinds of predictions are combined by a weighted summation, where the weight is adjusted based on the test performance of the optimized unit commitment strategy. In the robust unit commitment part, the uncertainty set is constructed in a data-driven manner based on the combined prediction and the historical forecast error so that it has a statistical guarantee. It is then reconstructed using a shape derived from the robust unit commitment problem to mitigate conservativeness. The problem is formed as two-stage robust optimization and solved by the C&CG algorithm. Case studies on the modified IEEE 30-bus and 118-bus systems demonstrate the effectiveness of the proposed approach.

3 - Enhanced Load Detection with Data-Driven Appliance Signatures Using Mixed Integer Quadratic Programming in Non-Intrusive Load Monitoring

Jay Rosenberger, University of Texas at Arlington, Arlington, TX, United States, Marina Materikina, Victoria Chen, Wei-Jen Lee

Rapidly developing renewable energy sources pose new challenges for utility companies' production and demand response (DR) planning. Studying customers' electricity consumption behavior can enhance the effectiveness of DR programs. Non-intrusive load monitoring (NILM) enables the analysis of individual appliance electricity patterns, fostering the connection between customers and energy providers. A mixed integer quadratic programming algorithm utilizing data-driven appliance signatures was developed for NILM. The algorithm has the ability to study very complex electrical devices, detect their signal with higher accuracy and reconstruct the electricity usage over time. The detailed signatures for modern state-based appliances (EV, AC, solar, washer, dryer) were studied using nonlinear programming and piecewise functions that depend on mode shapes. This approach significantly improved load detection accuracy during the disaggregation phase, and was applied to low-frequency data making NILM process more practical.

4 - Reinforcement Learning for Dynamic and Heterogeneous Incentive-Based Demand Response

Elson Cibaku, New Jersey Institute of Technology, Rutherford, NJ, United States, Bahareh Kargar, SangWoo Park

This paper introduces a Reinforcement Learning (RL) approach for dynamic incentive-based demand response (DR) programs, designed to maximize the operating profit for load aggregators. Our methodology integrates a Markov Decision Process (MDP) model with a Deep Q-Network (DQN)-based RL framework, allowing for sophisticated decision-making that adapts to changing consumer behavior patterns and system states. By simulating interactions between an aggregator and multiple heterogeneous customers, our model dynamically adjusts the optimal incentive pricings at both an individual and appliance-specific level. Additionally, our model incorporates a comprehensive reward function that includes multiple factors such as real-time locational marginal price (LMP), cost of self-owned generators, and cost of battery operations, enhancing the realism of modern load aggregators. We validate our approach through extensive simulations and a real-world dataset, demonstrating its potential to effectively balance energy supply and demand by adapting to real-time market conditions and consumer preferences.

5 - Decentralized DER Integration into Wholesale Energy Markets via Mean-Field Games

Jun He, Purdue University, West Lafayette, IN, United States, Andrew Liu

FERC Order 2222 facilitates the integration of distributed energy resources (DERs) into wholesale energy markets, but specific mechanisms are needed for effective small prosumer participation. A key concern is prosumers' hesitation to relinquish control of their assets to aggregators. Current research primarily focuses on how aggregators can bid into a wholesale market and design contracts for direct load control of the DERs. In response, we propose a decentralized model that allows prosumers, especially those with solar PV panels and energy storage, to make autonomous decisions based on real-time locational marginal prices (LMPs). Our solution employs a mean-field-based algorithm suited for a multi-agent system with a large number of agents. This algorithm enables prosumers to maintain beliefs about LMPs at a long-run equilibrium, solve their own Markov decision problems, and determine their supply or demand bids, which are then aggregated for the wholesale market. System operators continue running multi-settlement systems, including unit commitment and economic dispatch. We prove the existence of a mean-field equilibrium (MFE) and provide a reinforcement-learning-based algorithm for prosumers to learn to converge to an MFE. Numerical results show that LMPs can quickly reach a steady state. Furthermore, numerical comparisons with and without energy storage illustrate that our model can prevent extreme LMP values, fostering a more stable market even with completely decentralized decision-making.

Advances in Data Science: From Description to Prediction and Decision-making

Invited Session

Data Mining

Chair: Naichen Shi, University of Michigan, Ann Arbor, MI, United States

1 - Robust Personalized Design via Bayesian Optimization Under Covariate Uncertainty

Jiacheng Liu, University of Michigan, Ann Arbor, MI, United States, Wenbo Sun, Jingwen Hu, Jionghua Jin

Personalized design is to optimize a functional design policy that assigns the optimal design based on human covariates. Despite the noiseless setting in the computer simulations, applying the optimal design presents reliability concerns due to the potential differences between the selected and true optimal designs. The presence of measurement errors in covariates can further lead to discrepancies in the system response performance. The high computational cost of data collection also limits the ability to build an accurate surrogate model for the entire population. To address these challenges, we propose a robust Bayesian Optimization framework to minimize the discrepancy in system response by imposing penalties on the variation of system responses induced by covariate uncertainties. An appropriate acquisition function is introduced to consider the mixed type of categorical and continuous design variables when searching for new samples. This robust design policy reduces the sensitivity of the optimal design policy against covariate uncertainties as well as maintains system performance. Both the numerical examples based on the synthetic data and vehicle restraint system design demonstrate the efficiency and robustness of the proposed method.

2 - Robust Collaborative Online Learning Under Adversarial Attack

Tanapol Kosolwattana, University of Houston, Houston, TX, United States, Huazheng Wang, Ying Lin

Dealing with multiple different but closely related sequential decision-making problems is usually achieved by the collaborative online learning algorithms. However, many decision-making problems, such as pay-per-click advertisements and recommendation systems, face risk of adversarial attacks, leading to vulnerabilities in existing collaborative online learning algorithms. To the best of our knowledge, there is no robust online learning algorithms developed for a population of dependent sequential decision making under adversarial attack. To mitigate this gap, this study proposes a robust collaborative online learning method that captures latent representative models inherent in the population through representation learning. Additionally, we design a novel robust collaborative UCB algorithm to estimate representative models from sequentially observed data corrupted by adversarial attacks. We demonstrate the effectiveness of our method through theoretical analysis and simulation studies.

3 - Online Optimal Testing Policy Learning

Qiyuan Chen, University of Michigan, Ann Arbor, MI, United States, Raed Al Kontar

Experimentation is one of the most fundamental tools for scientific discovery and operations research for understanding the unknown nature. In many real-world applications like health examination and quality control, a sequence of experiments is often needed to probe the latent state of an object of interest. However, the number of experiments required is often much less than the number of experiments available. For example, a doctor usually does not recommend doing all the medical tests in a hospital, although doing all of them will be sufficient to diagnose a patient. Depending on the results of the previous test, the doctor shall determine the best test to conduct next so that the patient can be diagnosed with the fewest tests possible. However, the goal of saving testing costs poses fundamental challenges to the learning of this optimal testing policy. There are two consequences of not conducting all the tests. First, one will never know the exact quality of a part, meaning the reward associated with the conducted action is not revealed. Second, the missing values in the historical datasets make the empirical estimators heavily biased.

4 - A tractable approach to solve misspecified Predict-then-Optimize Problems

Omar Bennouna, MIT, Cambridge, MA, United States, Jiawei Zhang, Saurabh Amin, Asuman Ozdaglar

We study the predict-then-optimize framework approach, a common application of machine learning, which entails estimating unknown parameters of a linear optimization problem and then solving the optimization task with these estimations. For example, consider an energy allocation problem when the energy cost in different areas is uncertain. Despite the absence of precise energy cost values at the time of problem-solving, machine learning models are employed to predict these costs, and the resulting optimization problem, which consists for example of minimizing energy costs while meeting some minimal requirements, is solved using state-of-the-art optimization algorithms. We focus on the unrealizable setting, i.e. when the used hypothesis set (predictor function class) does not contain the ground truth value. In this case, there is no known algorithm that solves this predict-then-optimize problem. We provide a tractable algorithm which successfully finds an optimal solution in this setting.

5 - Multi-physics Guided Diffusion Models with Manufacturing Applications

Naichen Shi, University of Michigan, Ann Arbor, MI, United States, Hao Yan, Raed Al Kontar

We present a generic physics-informed generative model that integrates multi-fidelity physics simulations with diffusion processes. Our model categorizes multi-fidelity physics simulations into inexpensive and expensive simulations, depending on the computational costs. The inexpensive simulations, which can be obtained with low latency, directly inject contextual information into diffusion models. Furthermore, when results from expensive simulations are available, we refine the quality of generated samples via a guided diffusion process. This design separates the training of a denoising diffusion model from physics conditional probability models, thus lending flexibility to practitioners. Our model builds on Bayesian probabilistic models, which provide a convenient approach for uncertainty quantification in prediction. We use a numerical simulation in fluid dynamics and a case study in laser-based metal powder deposition additive manufacturing to demonstrate how our model seamlessly integrates multi-fidelity physics simulations and observations to obtain superior predictive performance.

Applications of Data Mining Techniques in Biomedical Data Analysis

Invited Session

Data Mining

Chair: Abhidnya Patharkar, ARIZONA STATE UNIVERSITY, Chandler, 85286, United States

Co-Chair: You Zhou, Arizona State University, Tempe

1 - EE-SFE: An Entropy-based Feature Extraction Framework on Subgraphs for Cognitive Disease Classification

Jiajing Huang, Arizona State University, Tempe, AZ, United States, Yiming Che, Teresa Wu

Brain networks play an essential role in cognitive-related disease studies, providing a powerful framework to capture the functional connectivity between different regions of the brain. While existing methods demonstrate prevailing computational efficiency, their lack of transparency hinders the interpretability of the extracted features. Therefore, efficient extraction of meaningful features on these networks for effective brain disease diagnosis is critical yet challenging. To address the challenges outlined above, we introduce a novel two-staged framework named Eigen Entropy-based Subgraph Feature Extraction (EE-SFE) designed for fMRI data. In the initial stage, significant edges, representing pairwise connections between brain regions that exhibit discriminatory power between dysfunctional and healthy groups, are identified through hypothesis testing. Subsequently, these edges are organized into clusters, forming distinct subgraphs. In the second stage, features are extracted from these subgraphs utilizing the Eigen-Entropy (EE) method, a technique previously developed for classification purposes. Our proposed method demonstrates better performances compared to a heuristic approach reported in the literature. More importantly, features extracted by our method retain meaningful interpretation, aligning consistently with findings in neuroscience literature.

2 - Smart Driving: Using Machine Learning for Non-Invasive Detection of Age-Related Cognitive Decline

Firas Al-Hindawi, Arizona State University, Tempe, AZ, United States, Teresa Wu, Erica Forzani, Peter Serhan , Francis Tsow, Yonas Geda

The rise of machine learning techniques has paved the way for innovative approaches in monitoring human health. In this study, we explore the utilization of multi-sensing devices installed in subjects' vehicles to detect age-related cognitive decline. Our focus lies in leveraging various data streams from accelerometer, gyroscope, and GPS sensors to find patterns indicative of cognitive health. We conducted experiments consisting of 20 subjects, including 12 healthy individuals and 8 diagnosed with Mild Cognitive Impairment (MCI). These subjects underwent two distinct sets of experiments: standardized and naturalistic driving scenarios. In the standardized experiments, subjects were instructed to perform specific driving maneuvers within a controlled environment. This controlled setting allowed for the systematic collection of data under various driving conditions. Conversely, the naturalistic driving experiments provided insights into subjects' driving behaviors during their routine travel patterns. By observing their driving habits in real-world scenarios, we aimed to capture a holistic understanding of their cognitive performance during everyday tasks. Through the application of machine learning algorithms to the collected data, we sought to identify subtle deviations in driving behavior that may signal cognitive decline. Our findings demonstrate the potential of non-invasive monitoring techniques in early detection and intervention for age-related cognitive impairments and the advancement of future research in cognitive health assessment through smart driving technologies.

3 - TP-CL: A Novel Temporal Proximity Contrastive Learning Approach for Obstructive Sleep Apnea Detection using Single-Lead Electrocardiograms

Fulin Cai, Arizona State University, Tempe, AZ, United States

Early detection of obstructive sleep apnea (OSA) benefits individuals by improving overall life quality and preventing malignant complications associated with untreated OSA. Deep learning-based applications using single-lead electrocardiograms (ECG) have shown promise in automatic OSA detection. However, most efforts have not fully considered variations in the detected signals of breathing events. A breathing event is highly conditioned to the present sleep context (sleep position and stage), while sleep context varies through time. In addition, the high variance among apnea events, associated with event duration, recovery period after apnea, and respiration pattern, shall be utilized to support OSA detection. Utilizing these two characteristics, a temporal proximity contrastive learning (TP-CL) approach is proposed for OSA detection. TP-CL has three modules: (1) a representation learning module using a DL-based encoder; (2) a temporal delta classification module using the difference between temporal proximities to support OSA detection; and (3) a temporal proximity contrast module employing a novel contrastive-based loss function to form a representation space with minimal contextual influence. Experimental results show that TP-CL can achieve competitive results, outperforming the state-of-the-art OSA detection models, in both subject-dependent and subject-independent settings. A sensitivity analysis showcases the robustness of the proposed approach and provides insight into potential future applications of TP-CL. In addition, using 1-minute ECG signals as input, the proposed TP-CL method provides real-time detection capability and is a potential tool for early OSA detection and in-home OSA monitoring.

Learning Control and Decision-Making of Dynamic Systems

Invited Session

Data Mining

Chair: Shuo Wang, University of Texas at Arlington, Arlington, TX, United States

1 - Learning Control of a Complex Population System

Shuo Wang, University of Texas at Arlington, Arlington, TX, United States

Designing a robust control to steer the collective behavior of ensemble systems has been of significant importance and practical demand in engineering and science, such as quantum control, cancer treatment, neurons' spiking patterns, etc. However, such a robust control may be too restrictive and costly to realize focusing on the entire population of the targeted dynamic systems. Instead, a relaxed control synthesis that aims at controlling only the majority of the population would be more practically appealing. In this work, an optimal control strategy is developed and explored in such a sense, that a partial differential equation is used to describe the collective dynamic behavior of the targeted systems, and machine learning techniques are adopted to be combined with the standard necessary conditions from optimal control theory such as Hamilton-Jacobi- equations. Several numerical applications are included to demonstrate the applicability of this proposed method.

2 - Surrogate model of dynamical systems in effective region

Wei Kang, Naval Postgraduate School, Monterey, CA, United States

In this study, we develop learning-based surrogate model of dynamical systems for efficient state estimation and prediction in a limited area. Our model employs a feedforward neural network for online computation, eliminating the need for integrating high-dimensional limited-area models. This approach offers significant computational advantages over integrating high dimensional system models. Furthermore, our method avoids the requirement of lateral boundary conditions for the limited area model in both online and offline computations. The design of our surrogate model is built upon a robust theoretical framework that leverages two fundamental concepts: observability and effective region. The concept of observability enables us to quantitatively determine the optimal amount of observation data necessary to achieve accurate approximation. Meanwhile, the concept of effective region substantially reduces the computational burden associated with computing observability and generating training data.

3 - Research on the Evaluation of Technological Innovation Capability of Intelligent Manufacturing Enterprises

Mengshan Zhu, Tongji University, Shanghai, China, People's Republic of, Chunyan Duan, Wenyong Zhou

The emerging models of intelligent manufacturing bring new opportunities for enterprise innovation. However, innovation inherently is a high-risk research and development activity. To mitigate losses and transform threats into opportunities, intelligent manufacturing enterprises must effectively control innovation risks. This paper begins by identifying innovation risks and analyzing their sources, constructing a comprehensive evaluation index system that includes dimensions such as technological risk, market risk, and management risk. Subsequently, the multiple intelligent algorithms-based innovation risk evaluation model is developed and applied in a case study. Furthermore, by comparing artificial intelligence evaluation models such as Support Vector Machine (SVM) and Decision Tree (DT), the superiority of the proposed method is demonstrated, showing optimal performance in evaluating innovation risks in intelligent manufacturing enterprises. Finally, relevant risk management measures and recommendations are proposed, aiming to enhance the innovation capacity and market competitiveness of intelligent manufacturing enterprises.

4 - Decision supporting for car sharing platform selection based on risk preferences and heterogeneous uncertain data

Hui Lin, School of Economics and Management, Tongji University, Shanghai, China, China, People's Republic of, Xueyang Zhang, Jianxin You

The choice of car sharing platforms (CSPs) is crucial for users to obtain a high-quality, safe and environmentally friendly car experience. Usually, this selection process involves various CSPs and attributes, which can be regarded as a heterogeneous multi-attribute group decision making (MAGDM) problem. Two methods are proposed for considering risk preferences and heterogeneous uncertain data, as well as two decision scenarios where the decision information is in forms of numerical-linguistic hybrid and linguistic hybrid types. Firstly, to capture the impact of individual risk preferences (IRPs) on multi-granular interval linguistic information in heterogeneous decision making, a semantic representation model and a transformation model of multi-granular interval linguistic terms under IRPs are defined. Secondly, in heterogeneous MAGDM with incompletely known weight information under different IRPs, we formulate some optimization models for solving weights of attributes and decision makers separately. These models are grounded on the deviation maximization and the group compatibility principles. Based on the aforementioned models, an approach to addressing heterogeneous MAGDM problems that involve incomplete weight information and IRPs is presented. Thirdly, in heterogeneous linguistic MAGDM with completely unknown individual attribute weights under IRPs, the best-worst method (BWM) is extended to the case of different individual attribute sets. An optimization model for solving attribute weights in individual attribute sets is constructed. Based on proposed models, a method for heterogeneous linguistic MAGDM problems under diverse IRPs is proposed. Finally, an example of car sharing platform selection and comparative analysis are provided to clarify the effectiveness and feasibility of our proposed methods.

5 - Data asset quality evaluation Framework based on a Hybrid Multi-criteria Decision-making Method

Tao Xu, Tongji University, Shanghai, China, People's Republic of, Jianxin You, Luning Shao, Mengmeng Shan

This paper presents a new framework for evaluating data asset quality using a hybrid Multi-Criteria Decision-Making (MCDM) approach that integrates the Decision Making Trial and Evaluation Laboratory (DEMATEL), Best-Worst Method (BWM), and Fuzzy- Technique for Order of Preference by Similarity to the Ideal Solution (TOPSIS) techniques. Firstly, the framework consider data as both a product and an asset, leading to the quality indicators being developed beyond the traditional dimensions. Subsequently, the interrelationships among indicators are addressed using the DEMATEL method, allowing for the identification of key indicators that significantly influence data asset quality in a given scenario. The BWM method is then employed to determine the weights of these key indicators, enabling a more precise assessment of their importance. After that, the TOPSIS method, incorporating triangular fuzzy numbers, is utilized to rank the data asset quality of different companies. Finally, the effectiveness of the framework is demonstrated by applying it to a group of companies, and the results of the company's evaluation are discussed, along with the corresponding data asset quality improvement initiatives.

Optimization Methods for Grid Operations and Market Clearing

Invited Session

ENRE: Electricity

Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL, United States

1 - Can a Storage System Exercise Market Power in an Electricity Market?

Feng Tu, Ohio State University, Columbus, OH, United States, Antonio Conejo

We analyze the ability of a storage system to exercise market power within an electric energy system. For this, we use three models. The first one represents the storage system as a price taker, the second one as a price maker, and the third one allows the system operator to freely operate the storage system for the best of the power system as a whole (maximum social welfare). Considering analytical outcomes from a stylized model and numerical simulations from a realistic model, we found that the storage system has no ability to exercise market power. Thus, the outcomes of the price-maker model and those of the model in which the system operator is in control of the storage system are equal. In other words, the objective of the storage system as a price maker -- maximum own profit -- and the objective of the system operator -- maximum social welfare -- are aligned, and thus, a bi-level model is not needed. Finally, we note that solving the model in which the system operator is in control of the storage system is simple, but solving the price-maker model, which is bi-level, is complex.

2 - Congestion relief through market-to-market coordination

Feng Qiu, Argonne National Laboratory, Lemont, IL, United States

The growing usage of renewable energy resources has introduced significant uncertainties in energy generation, posing challenges for Regional Transmission Operators (RTOs) in managing transmission congestion. The cost of real-time congestion for the Midcontinent Independent System Operator (MISO), for example, surged to \$3.7 billion in 2022, more than tripling since 2020. To mitigate congestion that affects neighboring regions, RTOs employ a market-to-market (M2M) process, in which they exchange real-time security-constrained economic dispatch solutions and communicate requests for congestion relief. While this method provides some economic benefits, it still struggles with issues like power swings and time delays. In this presentation, we analyze the M2M process to better understand its efficacy and identify potential improvements. We develop an open-source version of the M2M process using UnitCommitment.jl and test it across a comprehensive set of multi-area benchmark instances. To evaluate the potential impact of M2M enhancements, we develop a centralized model that provides a lower bound on congestion costs and compare it against current practice. Additionally, we identify scenarios where the existing M2M process fails to provide solutions. Finally, we explore enhancements and alternative strategies to narrow the efficiency gap in multi-area congestion management.

3 - Solving the security constrained AC unit commitment problem using an enriched Benders decomposition approach

Jorge Orrego, Ohio State University, Clumbus, OH, United States

We address the security-constrained AC unit commitment problem in a corrective manner, considering that only the transmission line fails. We convexify the AC power flow equations using a conic relaxation to achieve tractability. We propose an enriched Bender-type decomposition algorithm to solve large-scale systems, assuming all transmission lines could fail. This algorithm involves three optimization problems: a master problem that provides scheduling decisions, a normal-operation condition problem that dispatches generators, and subproblems that provide operating decisions under contingency conditions. The master problem is a mixed integer linear problem containing normal-operating conditions constraints and a small subset of under-contingency operations. Fixing scheduling decisions from the master problem transforms the normal-operation condition problem and the subproblems into continuous conic optimization problems. In addition, fixing dispatch decisions from the normal-operation condition allows solving the subproblems independently, each corresponding to an under-contingency condition. The master problem is a relaxed version of the original problem, thus providing a valid algorithm lower bound, while the subproblems allow deriving an upper bound. The solution of the subproblems enriches the master problem and the normal-operation condition using (i) Benders' cuts, (ii) incorporating a subset of under-contingency operation in the master and normal-operation condition problem, and (iii) enforcing only congested transmission lines. We solve the master problem, the normal-operation condition problem, and the subproblems iteratively until a convergence condition is satisfied. We illustrate the effectiveness of the proposed algorithm using the Illinois 200-bus system and different demand levels.

4 - Optimal Battery Utilization and Swapping Service Level through Balanced Battery Inventory and Replenishment for an Electric Vehicle Battery Swapping Station Network

Reza Alizadeh, Magna International, Boston, MA, United States

Establishing an ample charging infrastructure is pivotal for the successful deployment of electric vehicles (EVs), mitigating concerns associated with restricted range and extended charging durations. Battery exchange stations arise as a promising remedy to alleviate these waiting periods. These stations act as intermediaries between the power grid and consumers, presenting a rapid alternative to recharging batteries. Ensuring their efficacy and profitability necessitates a robust business and operational model. This endeavor introduces an optimization framework for the operational structure of battery swapping stations, emphasizing balanced battery inventory management. The framework offers features like flexible battery restocking from depots and equitable battery inventory distribution among charging stations. The battery float percentage and battery utilization rate are augmented, eliminating unmet demand and minimizing the overall shipment cost. The findings demonstrate the feasibility of the proposed model as a business case, as well as its efficacy in delivering the necessary service.

Biodiversity Conservation

Invited Session

ENRE: Environment and Sustainability

Chair: Jue Wang, Smith School of Business, Queen's University, Kingston, ON, Canada

1 - Saving Whales with Optimal Control

Yu Gong, Smith School of Business, Queen's University, Kingston, ON, Canada, Jue Wang

Collision with large vessel is the leading cause of whale mortality. The collision risk can be reduced by the establishment of vessel speed reduction (VSR) zone, in which large vessels are asked to reduce speed. However, reducing speed is costly to the mariners by causing shipping delays. Thus, the compliance rate is low in VSR. We develop an optimal control model to optimize the VSR locations based on daily prediction of whales' presence distribution. Our model utilizes the dynamic discrete choice model to capture mariners' strategic response. The goal is to minimize the probability of whale mortality subject to a constraint on the economic impact to the shipping industry.

2 - Site Prioritization for Conservation Planning

Quanmeng Wang, Institute of Operations Research and Analytics, National University of Singapore, Singapore, Singapore, Guodong Lyu, Chung-Piaw Teo

We propose a new approach to prioritize activities in a resource constrained environment, where the resource budget may change across time. This problem arises frequently in spatial conservation planning, a problem in biodiversity protection worldwide. Traditional approach often adopts greedy techniques to develop a priority ranking of all the zones in the conservation site, without considering resource available for execution. We address this gap and provide a systematic approach in this paper to synthesize the impact of resource uncertainty on the optimal prioritization strategy. We use a well-known real life case study in this field to show how our approach can produce a more resilient plan to cushion the impact of budget changes, in realistic size instances with thousands over zones. More interestingly, the prioritization approach generally produces solution that performs close to the scenario-wise optimal solution at each time period, demonstrating a desirable feature of our approach in practice.

3 - Birdbnb: Data-Driven Pitstop Support for Migrating Birds

Li Chen, Cornell University, Ithaca, NY, United States, Jue Wang, Xiaoyue Yan

Wetland stops serve as vital rest and refueling sites for millions of migrating birds. Many of these wetlands, however, have been lost to farmland conversion over the past, posing a serious challenge to bird populations. The BirdReturns program, a biodiversity initiative, runs an open bidding process to acquire temporary wetland habitats from rice farmers during the critical bird migrating seasons. In this talk, we present an optimal data-driven auction mechanism for the program.

Industrial Decarbonization I: Carbon Capture and Hydrogen

Invited Session

ENRE: Other Energy

Chair: Benjamin Leibowicz, The University of Texas at Austin, Austin, TX, 78712, United States

1 - Optimal Subsidies for Carbon Capture Storage

Connor Colombe, University of Texas at Austin, Austin, TX, United States, Benjamin Leibowicz

Carbon capture, utilization, and storage (CCUS), has been widely recognized for its important role in decarbonization. Emerging technologies like CCUS are often adopted slowly until the technology matures and the implementation costs reduce enough for firms to profit from them. Government planners can induce earlier adoption of new technologies through direct and indirect subsidies. In this paper we use a stylized Stackelberg game framework involving a government planner and a CO_2 emitting firm in order to study the impacts of different subsidy levels on CO_2 levels, firm profit, and social-welfare. We analytically derive optimal CCUS subsidy levels under a variety of assumptions and apply our findings to a case study of a coal-fired power plant.

2 - Opportunities and Constraints of Hydrogen Energy Storage Systems

Jacqueline Dowling, Carnegie Institution for Science, Stanford, CA, United States, Tyler Ruggles, Edgar Virguez, Natasha Reich, Zachary Ifkovits, Steven Davis, Anna Li, Kathleen Kennedy, Katherine Rinaldi, Lei Duan, Ken Caldeira, Nathan Lewis

In contrast to battery storage, power-to-hydrogen-to-power (P-H2-P) storage systems provide opportunities to separately optimize the costs and efficiency of the system's charging, storage, and discharging components. The value of capital cost reduction relative to round-trip efficiency improvements of P-H2-P systems is not well understood in electricity systems with abundant curtailed power. We used a macro-energy model to evaluate the sensitivity of system costs to techno-economic characteristics of P-H2-P systems in stylized wind-solar-battery electricity systems with restricted natural gas generation. Assuming current costs and round-trip P-H2-P efficiencies, least-cost wind and solar electricity systems had large amounts of excess variable generation capacity. These systems included P-H2-P in the least-cost solution, despite its low round-trip efficiency and relatively high P-H2-P power discharge costs. These electricity system costs were not highly sensitive to the efficient use of otherwise-curtailed power, but were sensitive to the capital cost of the P-H2-P discharge component. If capital costs of charging and discharging components were decreased relative to generation costs, curtailment would decrease, and electricity system costs would become increasingly sensitive to improvements in the P-H2-P round-trip efficiency. These results suggest that capital cost reductions, especially in the discharge component, should be a key priority for innovation in P-H2-P systems for applications in electricity systems dominated by wind and solar generation. Analysis of underground salt cavern storage constraints in U.S.-based wind and solar scenarios suggests that ample hydrogen storage capacity could be obtained by repurposing the depleted natural gas reservoirs that are currently used for seasonal natural gas storage.

3 - Coordination Problems and Incentive Pass-Through in Carbon Capture, Utilization, and Storage Development

Benjamin Leibowicz, The University of Texas at Austin, Austin, TX, United States, Abdullah Albeladi

Carbon capture, utilization, and storage (CCUS) technologies figure prominently in many proposed pathways for achieving ambitious, economy-wide decarbonization goals. While numerous governments offer subsidies for CCUS, the buildout of CCUS infrastructure has been sluggish to date. In this study, we address two research questions related to policy incentives for CCUS development. First, to what extent do coordination problems among multiple players in the CCUS supply chain hinder CCUS development? Second, how much of the total value of CO_2 capture incentives will pass through to other players downstream in the supply chain? To answer these questions, we develop a game-theoretic model of a CCUS economy formulated as a mixed complementarity problem. It incorporates CO_2 capture subsidies with different levels for geologic storage and utilization applications, in line with the 45Q policy in the United States. We first prove two theoretical results, then apply the model to a case study of the Texas-Louisiana Gulf Coast. On coordination problems, we find that they reduce the total volume of CO_2 capture substantially when the incentive for geologically stored CO_2 is low (by 33% for $50/ton), but have little impact when the incentive is high. On incentive pass-through, we find that CO_2 capturers appropriate the largest share of the subsidies, but greater fractions of the incentives pass through to pipeline operators as the incentives become more generous and CCUS activity expands.

4 - Hydrogen and carbon capture and storage enable the decarbonization of hard-to-abate industries

Alissa Ganter, ETH Zurich, Zurich, Switzerland, Paula Baumann, Veis Karbassi, Giovanni Sansavini

The transition to net-zero emissions proves challenging for industries that inherently rely on carbonaceous feedstocks, such as the chemical industry, steel, cement, and refineries. These hard-to-abate industries are difficult to decarbonize as direct electrification is limited, and cost-efficient decarbonization alternatives are lacking. In this context, the use of low-carbon hydrogen and the coupling with carbon capture and storage emerge as promising solutions that can enable the transition. In addition, biomass feedstocks could provide a cost-efficient low-carbon alternative to fossil fuels. We formulate a linear optimization problem to investigate cost-optimal decarbonization pathways for these hard-to-abate industries in Europe. We consider a multi-year time horizon and use a regional resolution to model the transition pathway from today, 2024, to 2050, and account for the heterogenous availability of renewable energy sources such as wind, solar and biomass. The analysis focuses on synergy effects and trade-offs between the industries and their respective decarbonization pathways. Our findings reveal that low-carbon hydrogen is vital in decarbonizing the chemical industry, where hydrogen is required as a feedstock in production. For high-heat processes in the steel and cement industry its application remains limited, and the utilization of biomass and the coupling with carbon capture and storage are preferred. Our integrated approach reveals that captured carbon can be utilized e.g. for methanol production, thereby reducing the pressure on limited carbon storage capacities. Results also highlight the importance of a European scale hydrogen, carbon, and biomass transport infrastructure by 2040 across all scenarios to achieve net-zero emissions by 2050.

Application of Neural Networks in OR/OM

Invited Session

Computing Society

Chair: Yizhe Huang, University of Texas at Austin, Austin, TX, United States

Co-Chair: Rui Gao, University of Texas at Austin, Austin, TX, United States

1 - Deep Learning for Contextual Stochastic Optimization: Global Convergence and Statistical Guarantees

Jie Wang, Georgia Institute of Technology, Atlanta, GA, United States

Contextual stochastic optimization (CSO), by seeking the optimal decision with side information, has achieved phenomenal success in operations research. In this paper, we investigate theoretical properties of using over-parameterized two-layer neural networks for CSO. From the computational perspective, we leverage mean-field theory to show the global convergence of the training dynamics. From the statistical perspective, we provide finite-sample guarantees of this framework, and showcase its ability to overcome the curse of dimensionality and generalization to unseen data. Our theoretical results are exemplified in the Sepsis prediction task as well as strategic pricing.

2 - Policy Gradient Method for Risk-Sensitive Distributional Reinforcement Learning with Provable Convergence

Minheng Xiao, Ohio State University, Columbus, OH, United States, Xian Yu, Lei Ying

Risk-sensitive reinforcement learning (RL) is crucial for maintaining reliable performance in many high-stakes applications. While most RL methods aim to learn a point estimate of the random cumulative reward, distributional RL (DRL) seeks to estimate the entire distribution of it \citep{bellemare2017distributional}. The distribution provides all necessary information about the reward and leads to a unified framework for handling various risk measures in a risk-sensitive setting. However, developing policy gradient methods for risk-sensitive DRL is inherently more complex as it pertains to finding the gradient of a probability measure. This paper introduces a policy gradient method for risk-sensitive DRL with general coherent risk measures, where we provide an analytical form of the probability measure's gradient. We further prove the local convergence of the proposed algorithm under mild smoothness assumptions. For practical use, we also design an approximate distributional policy gradient algorithm based on categorical DRL policy evaluation \citep{bellemare2017distributional} and trajectory-based gradient estimation. Through experiments on a stochastic cliff-walking environment, we illustrate the benefits of considering a risk-sensitive setting in DRL.

3 - Unlocking the Power of Deep Q-Learning in Operations Management

Yao Wang, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Shao-Bo Lin, Tao Li, Shaojie Tang, Ding-Xuan Zhou

With the help of massive data and rich computational resources, deep Q-learning has received unprecedented success in numerous operations management applications including recommender systems, supply chains management among others. However, there lacks solid theoretical foundations to demonstrate the success. The aim of this work is to present a unified theoretical analysis framework for Q-learning, including oracle inequalities to show the role of hypothesis space, expressive power analysis of deep neural networks in capturing special features of optimal Q-functions and generalization error analysis to quantitatively describe the relationship between size of data and prediction accuracy. Our results reveal that the effectiveness of deep Q-learning lies in the remarkable ability of deep neural networks in capturing some special properties of rewards, namely, spatial sparseness and piecewise constancy. Our theoretical assertions are verified by applying deep Q-learning in three typical applications including the well-known beer game in supply chain management, a simulated recommender system, and the Gridworld game.

4 - Learning Optimal Inventory Policies by Sequential Neural Networks

Zhen Yang, University of Texas at Austin, Austin, TX, United States, Yizhe Huang, Rui Gao

Inventory management problem is crucial for many business and have been extensively studied by previous works. Despite these effort, there remain models that are hard to solve in the sense that the structure of the optimal inventory policy remains unknown. We propose to approximate the policy at each stage by a 2-layer neural network which is a universal approximator, and show convergence results.

1 - Learning Decision Trees and Forests with Algorithmic Recourse

Ken Kobayashi, Tokyo Institute of Technology, Meguro-ku, Japan, Kentaro Kanamori, Takuya Takagi, Yuichi Ike

In this talk, we propose a new algorithm for learning accurate tree-based models while ensuring the existence of recourse actions. Algorithmic Recourse (AR) aims to provide a recourse action for altering the undesired prediction result given by a model. Typical AR methods provide a reasonable action by solving an optimization task of minimizing the required effort among executable actions. In practice, however, such actions do not always exist for models optimized only for predictive performance. To alleviate this issue, we formulate the task of learning an accurate classification tree under the constraint of ensuring the existence of reasonable actions for as many instances as possible. Then, we propose an efficient top-down greedy algorithm by leveraging the adversarial training techniques. We also show that our proposed algorithm can be applied to the random forest, which is known as a popular framework for learning tree ensembles. Experimental results demonstrated that our method successfully provided reasonable actions to more instances than the baselines without significantly degrading accuracy and computational efficiency.

2 - Overcoming the Optimizer's Curse: Obtaining Realistic Prescriptions from ReLU Neural Networks

Asterios Tsiourvas, MIT, Cambridge, MA, United States, Georgia Perakis

We study the problem of obtaining optimal and realistic prescriptions when using ReLU networks for data-driven decision-making. In this setting, the network is used to predict a quantity of interest and then is optimized to retrieve the decisions that maximize the quantity (e.g. find the best prices that maximize revenue). However, optimizing over-parameterized models often produces unrealistic prescriptions, far from the data manifold. This phenomenon is known as the Optimizer's Curse. To tackle this problem, we model the requirement for the resulting decisions to align with the data manifold as a tractable optimization constraint. This is achieved by reformulating the highly nonlinear Local Outlier Factor (LOF) metric as a single linear or quadratic constraint. To solve the problem efficiently for large networks, we propose an adaptive sampling algorithm that reduces the initial hard-to-solve optimization problem into a small number of significantly easier-to-solve problems by restricting the decision space to realistic polytopes, i.e. polytopes of the decision space that contain at least one realistic data point. Experiments on publicly available networks demonstrate the efficacy and scalability of our approach.

3 - Optimization Over Trained Neural Networks: Taking a Relaxing Walk

Thiago Serra, Bucknell University, Lewisburg, PA, United States

Besides training, mathematical optimization is also used in deep learning to model and solve formulations over trained neural networks for purposes such as verification, compression, and optimization with learned constraints. However, solving these formulations soon becomes difficult as the network size grows due to the weak linear relaxation and dense constraint matrix. We have seen improvements in recent years with cutting plane algorithms, reformulations, and an heuristic based on Mixed-Integer Linear Programming (MILP). In this work, we propose a more scalable heuristic based on exploring global and local linear relaxations of the neural network model. Our heuristic is competitive with a state-of-the-art MILP solver and the prior heuristic while producing better solutions with increases in input, depth, and number of neurons.

Service Science

Chair: Zhiwei Qin, Eva AI (foreva.ai), San Jose, United States

1 - Enhancing ETA Reliability at Lyft

Rachita Naik, Lyft, Inc., New York, NY, United States

In the dynamic and competitive landscape of ride-hailing services, the accuracy of Estimated Time of Arrival (ETA) forecasts displayed prior to ride requests is crucial for ensuring customer satisfaction and fostering platform loyalty. Lyft addresses the challenge of predicting accurate ETAs prior to request time by leveraging Machine Learning (ML) to enhance ETA precision. Our strategy employs a classification approach using a tree-based ML Model that integrates a diverse dataset encompassing historical ride data, real-time traffic conditions, driver availability, and marketplace dynamics to enable nuanced predictions of ETA reliability. This methodology facilitates the selection of ETAs that align with strict reliability service levels, thereby improving the likelihood of riders choosing Lyft for their transportation needs. This session will explore the challenges of predicting ETA reliability, detail the architecture and training process of our model, and our ongoing effort to maintain and improve our predictive models and strategies in a dynamic environment, in order to uphold our commitment towards meeting user expectations and delivering service information that is both trustworthy and precise.

2 - SERGI: Similar Entity Retrieval Using Grouped Images

Akshit Sarpal, Walmart, San Bruno, CA, United States

Image data is frequently organized in semantic groups for entities such as e-commerce products, social media users or hotels on travel websites. There are a wide range of applications for retrieving entities based on their images, yet its exploration remains limited. Signals from images are commonly infused with other attributes in form of embeddings, but purely leveraging groups of images for retrieval is relatively unexplored. Drawing inspiration from natural language literature, we developed an efficient and scalable method, SERGI (Similar Entity Retrieval using Grouped Images), for retrieving entities similar to given image groups. We apply SERGI to an e-commerce use-case, aiming to identify products with brand misrepresentation. Despite the scarcity of benchmark methods for comparison, our system demonstrates superior performance compared to a baseline and a commonly used representation-based method, showing high precision in this relatively uncharted domain.

3 - A Deep Learning Approach for Predicting B2B Customers' Online Behavior

Tolunay Alankaya, Eindhoven University of Technology, Eindhoven, Netherlands, Nevin Mutlu, Sarah Gelper, Fred Langerak

As digital marketplaces become central to B2B transactions, the vast amount of data generated on e-commerce platforms offers pivotal insights into customer retention and churn. This study leverages customer clickstream data from a B2B digital marketplace to predict visits and purchases on the e-commerce platform while specifically focusing on the early detection of customer churn. Our model sequentially connects customers' clicks from previous visits to uniquely identify the customers at risk of disengaging from the platform. We use a deep learning modeling approach that improves retention and churn prediction and decreases the number of required previous visits to make an accurate prediction compared to statistical benchmarks. Moreover, the model enables us to test the effect of certain click paths on online customer behavior. Our findings contribute to academic and practical fields by emphasizing the crucial role of clickstream data in predicting B2B customer decisions. Insights from our study help managers anticipate what to expect during the digital transition and underscore the importance of data collection on B2B platform adoption. Thus, our research not only advances scholarly knowledge but also serves as a practical guide for B2B companies moving toward digital commerce.

1 - Semi-Supervised PARAFAC2 Decomposition for Medical Decision Making

Elif Konyar, University of Florida, Gainesville, FL, United States, Mostafa Reisi

High-dimensional data is common in healthcare applications, particularly from the collection of data during clinical visits of patients. This HD data, commonly referred to as electronic health records (EHR), consists of medical conditions and clinical progress of a large cohort of patients over time. Tensor factorization methods are commonly used to extract meaningful patterns from the EHR data. However, challenges arise in analyzing EHR data because of data irregularity due to varying hospital visits and frequencies, and the presence of missing values, such as incomplete test results or erroneous entries. Existing PARAFAC2 frameworks are unsupervised methods and cannot exploit partially labeled data. In this work, we propose a semi-supervised PARAFAC2 decomposition model to extract meaningful patterns from irregular EHR data by also incorporating label information from a subset of instances. Experiments on synthetic and real-world data sets show the superiority of the proposed approach over the benchmarks.

2 - Federated Learning on Distributed and Encrypted Data for Smart Manufacturing

Timothy Kuo, The Pennsylvania State University, state college, PA, United States, Hui Yang

Industry 4.0 drives exponential growth in the amount of operational data collected in factories. These data are commonly distributed and stored in different business units or cooperative companies. Such data-rich environments increase the likelihood of cyber attacks, privacy breaches, and security violations. Also, this poses significant challenges on analytical computing on sensitive data that are distributed among different business units. To fill this gap, this paper presents a novel privacy-preserving framework to enable federated learning on siloed and encrypted data for smart manufacturing. Specifically, we leverage fully homomorphic encryption (FHE) to allow for computation on ciphertexts and generate encrypted results which, when decrypted, match the results of mathematical operations performed on the plaintexts. Multi-layer encryption and privacy protection reduce the likelihood of data breaches while maintaining the prediction performance of analytical models. Experimental results in real-world case studies show that the proposed framework yields superior performance to reduce the risk of cyber-attacks and harness siloed data for smart manufacturing.

3 - High Dimensional Packages' Delivery Times Prediction under Aggregated Quantile Constraints

Yifei Yuan, Amazon.com, Santa Clara, CA, United States, Mederic Motte, Philip Kaminsky

One of the fundamental aspects of the on-line shopping experience is the delivery promise – the estimated order delivery date that is displayed to customers at checkout before they purchase a product. Predicting fast and accurate packages' delivery times helps improving customers' satisfaction and attracting more purchases. For a better customer experience, the predicted delivery date should maintain a high On-time delivery rate (OTDR), which is defined as the percentage of units delivered before the predicted/promised delivery dates. OTDR metric is meaningless for a single package, because one package either meet the predicted/promised delivery date with OTDR 100% or miss the predicted/promised delivery date with OTDR 0%. Instead, there might be different OTDR requirements at different aggregated granularities, e.g. ship-option level, region level, etc. To predict delivery times under different aggregated OTDR constraints, we propose a two-step model, which first predicts delivery times' distribution at package-level and then optimize the predictions with aggregated quantile constraints. The model is tested with historical data, showing a significant reduction of the gap between promised/predicted delivery date and the actual delivery date, while maintaining the OTDR constraints.

4 - Fatigue Reliability of Manufacturing Tools Using Sensor-Based Image Sequences and Material Microstructure Analysis

Pengyan Lu, Wayne State University, Detroit, MI, United States, Qingyu Yang

The fatigue life of manufacturing tools faces extreme challenges as the strength of materials continuously increases, especially for high-strength steel. In this research, a new experimental method was designed to simulate the degradation of manufacturing tools based on image sequences. We proposed a novel methodology to study the fatigue life of both manufacturing tools and repaired tools, considering both image sequences and material microstructure information. The developed methodology was applied and verified for forming dies used with advanced high-strength steel in the auto industry.

1 - The Relationship Between It Spending in Industry 5.0 and Vertical/Horizontal Integration in Us Manufacturing

Fangling Zhu, Old Dominion University, Norfolk, VA, United States, Ling Li

This paper explores the relationship among the spending of Information technology (IT) of industry 5.0, vertical and horizontal integration of the supply chain, and firms' performance. The moderates are the competition and demand uncertainty. The explanation of the findings are follows: (1) IT spending, especially artificial intelligence, blockchain, robots, Internet of Things (IoT), digital twins, is significantly and positively associated with the vertical integration supply chain of manufacturing firms; (2) IT outsourcing and operation costs per full-time employee are positively associated factors that shows in the firms with vertical integration supply chain; (3) the effects of the vertical integration supply chain is positively associated with firms' performance, however, there is no empirical support for horizontal integration supply chain and firms' performance; (4) when uncertainty demand increases, the vertical integration of supply chain is positively correlated with firms' performance, especially for return on assets (ROA).

2 - Enhancing Sustainability in Manufacturing with Machine Learning Ensembles: A Global Empirical Study

Narges Mashhadi Nejad, University of Toledo, Toledo, OH, United States, Paul Hong, Iman Khazrak

In response to the escalating environmental and social challenges faced by the manufacturing sector, there is a growing need for robust methodologies that integrate sustainability into core operations. This paper investigates the efficacy of ensemble machine learning models, such as Random Forest, Boosting, and XGBoost, in optimizing Sustainability Value Articulation (SVA) and enhancing the execution of sustainability business models (SBMs). By analyzing data from a comprehensive survey involving 692 manufacturing firms across 23 countries, this study explores how these advanced predictive models improve upon traditional statistical methods by uncovering complex patterns, optimizing processes, and offering predictive insights into sustainability practices. The research highlights how ensemble methods facilitate a more detailed understanding of the dynamics between various sustainability practices and their impacts, enabling firms to make informed strategic decisions. Additionally, the study assesses the interactions between these predictive models and traditional factors like

Supplier Involvement Practices (SIP) and Technology Systems Integration (TSI), evaluating their combined impact on social, environmental, and economic performance indicators. The expected outcomes include a theoretically and empirically substantiated framework that demonstrates the enhanced accuracy and adaptability of ensemble machine learning in refining sustainability outcomes. This framework provides actionable insights that help businesses not only meet comprehensive sustainability goals but also effectively engage stakeholders in their sustainable operations.

3 - A Note on Drivers and Obstacles to Technology Diffusion and Market Penetration

Makiko Nagaya, Showa Women's University, Tokyo, Japan, Akira Maeda

This study examines drivers and obstacles to the diffusion of new technology. In the economics and management literature, the most commonly cited obstacles to widespread use of a new technology are cost issues, including investment costs, market imperfections and barriers to entry as well as social and psychological factors. This addresses that if the new technology is cost-effective more than before, it will naturally be accepted and implemented to the market. The realty that we observe is, however, not always the case. Cost should be understood as just one factor and there must be more fundamental mechanism.

We focus on underlying obstacles to technology diffusion beyond typical cost discussion. As a model, we consider a simple partial equilibrium of supply and demand. Using basic tools such as consumer surplus, producer surplus, and social welfare, we examine the consequences of use of a new technology through comparative statics analysis. The main results are as follows: Whether or not a new technology is adopted and diffused is determined not by technological factors on the producer side, but only by price elasticity on the demand side. If price elasticity of demand is less than 1, producers have no motivation to promote the new technology while, for any price elasticity, consumers and society as a whole will always benefit from the new technology. The result helps explain why an innovative technology sometimes face difficulties in its market penetration.

4 - Sustainable Circular Supply Chain Network in the Garment Industry: a Bi-Objective Optimization Approach with Supplier Diversity Considerations

Mayssam Tarighi Shaayesteh, University of North Texas, Denton, TX, United States

Justice and social responsibility are the two main pillars in establishing an equitable and sustainable society. Supplier diversity is a social issue that can have a substantial impact on expanding justice and promoting social responsibility. Recently, many businesses have put cooperation with diverse suppliers on their agenda to attain sustainable development goals. In this study, for the first time, a new bi-objective mixed-integer linear programming (MILP) model is formulated to configure a sustainable circular supply chain network by considering the supplier diversity problem. The first objective function (OF) of the proposed model considers the economic facet of sustainability and focuses on minimizing the total costs. The environmental facet of sustainability is included through the minimization of CO2 emissions in the second OF. In addition, cooperation with diverse suppliers is considered as the social facet. We utilize the augmented epsilon constraint method to solve the presented bi-objective MILP model, and validate its efficacy by applying the data of a garment industry in Iran. The results achieved through the practical application of the model affirm its robustness and viability as a framework in configuring a sustainable circular supply chain network.

Locational Analysis for Supply Chain Design

Contributed Session

Chair: Bahram Alidaee, University of Mississippi, School of Business, University, MS, 38655, United States

1 - Solution for The Inbound Load Building-Transporting-Scheduling at Walmart

Ti Zhang, Walmart, Sunnyvale, CA, United States, Ming Ni, Liqing Zhang, Mingang Fu, Nadere Mansouri, Li Ji, Rohan Prakash, Yu Zheng, Pritam Aher, Phani Nandiraju, Bharat Dhanekula, Simon Guo, Ankush Bhargava, Jyothi Madallapalli, Amritayan Nayak, Sunil Singh, Juan Gomez, Rajiv Bhuta, Parvez Musani, Srinivasan Venkatesan

At Walmart inbound transportation, everyday tens of thousands of shipments are moved from multiple thousands of geographically dispersed vendors into Walmart's supply chain network nodes. The goal is to develop an optimization engine that reduces transportation cost, increases truck utilization, and improves on-time service qualities. The mathematical problem is a combination of a variation of set partitioning and a vehicle routing problem with time windows. Walmart's network large scale network makes this problem especially challenging to solve. We deployed a solution by transforming the problems into a divide-and-conquer framework, which employs multiphase solution strategies and algorithms: (1) network partition, a data-driven spatial partitioning scheme to divide network into non-independent subnetworks; (2) load generation, a column generation based solution framework gradually determines shipment profitability and utilizes various tailored metaheuristics including Simulated Annealing and Tabu Search algorithms to create promising candidate loads; (3) load selection, employs a combination of solution methods to select a set of loads from a large pool of candidates; (4) carrier allocation, which optimizes the carrier to load assignment while balancing carrier procurement compliance, carrier service level and transportation cost. Since the pilot launch, this optimization engine has achieved sizable business impacts: (1) better shipment consolidation that reduces trailer usage and reduces miles traveled; (2) improvement in carrier assignment to drive higher level of service; (3) transparency for root cause analysis/resolutions that improves user experience.

2 - Enhancing Walmart's Digital Fulfillment: A Multi-Channel Last Mile Network Design Framework

Amin Aghalari, Walmart, Dallas, TX, United States, Yao Luo, Xinyue Peng, Lingxun Kong, Weifang Li, Sai Mahabhashyam

Optimizing Walmart's last mile delivery (LMD) presents a complex challenge crucial for meeting its diverse, multi-channel demand efficiently. This paper introduces a comprehensive multi-channel network design framework, innovating beyond traditional single-channel planning methods. Our approach integrates scheduled and unscheduled orders, leveraging a variety of last mile nodes including store-attached automated pickup and delivery (APD), delivery stations (DS), dark stores, and direct deliveries from fulfillment centers (FC) and sortation centers (SC) to achieve significant cost savings, enhanced resource utilization, and operational efficiency.

Central to our framework is a two-phase design process. The first phase employs a mixed-integer programming (MIP) model to optimize the node and catchment decisions, minimizing total costs including last-mile delivery, fulfillment, capital costs, and penalties for unmet demand, while balancing node capacity. An innovative hierarchical pixel framework facilitates accurate last mile delivery cost estimation, avoiding the complexities of traditional vehicle-routing problems. The second phase addresses operational optimization in a dynamic environment, introducing mode-mix and last mile delivery simulation models to refine vehicle allocation and routing, ensuring network resilience under varying demand and supply conditions. This holistic framework not only streamlines Walmart's LMD operations but also underpins strategic asset investment and operational decisions, marking a leap towards enhancing customer service and operational efficiency.

3 - Decentralized Online Order Fulfillment in Omni-Channel Retailers

Sinem Savaser, Rotman School of Management, Toronto, ON, Canada, Opher Baron, Andre Cire

We consider an order fulfillment problem of an omni-channel retailer that ships online orders from its distribution center (DC) and brick-and-mortar stores. Stores use their local information to accept or reject fulfillment requests of online orders. We investigate the problem of sequencing requests to stores and inventory rationing decisions at the DC to minimize expected costs under uncertain store acceptance behavior. First, assuming stores are used only when the DC has insufficient inventory, we propose a Markov Decision Process formulation. We show that the performance rate of a myopic approach that orders stores by cost only depends on the number of items in an order, which is small in practice. Using optimality conditions for a special case of the problem, we develop an adaptive degree-based strategy that balances shipping costs and acceptance probabilities. Numerical testing suggests that the best-performing sequencing policy is within 1% of optimality on average. Moreover, using two years of data from a large omni-channel retailer in North America, we observe that adaptive policies, albeit more complex, are beneficial in reducing costs and split deliveries if acceptance rates can be estimated accurately. Second, we determine when the retailer should ship from stores or ration the inventory at the DC. We show that for single-unit orders, the optimal policy has a threshold structure, where the highest priority region is also subject to rationing. We then leverage the structure of this model to develop a heuristic for the multi-unit rationing problem and numerically establish its efficacy.

4 - Multi-Echelon Facility Location Supply Chain Design

Bahram Alidaee, University of Mississippi, University, MS, United States, Haibo Wang

At k-level uncapacitated facility location, ensuring each client is served by a sequence of k facilities is common in complex supply chain design systems. Due to its complexity, when $k > 1$, approximation algorithms are crucial for swiftly obtaining high-quality solutions. This study focuses on a k-echelon supply chain design facility location problem with $k = 5$. The objective is to select markets, distribution centers, warehouses, plants, and suppliers to maximize the total profit of serving selected markets. A Tabu Search with an r-Opt sequence embedded multi-start, and random-key diversification is designed for solution. Extensive experimental results is presented.

1 - Customer Payment Choices in Virtual Reality Retail: Implications for New Sensory Environment in the Metaverse

Yoonsun Jeong, University of Texas at El Paso, El Paso, TX, United States, Nandini Nim, Jessica Felix, Leah Smith

This research explores the nature of customers' payment and transaction method choices in virtual reality (VR) retail settings. Payments present a customer touchpoint that can create a customer experience problem without proper ubiquity and interoperability across various VR and non-VR retail channels. Blockchain-based payments have gained momentum as customer payment methods in the metaverse, leading banks, financial institutions, and technology firms to develop capabilities to provide retailers and customers with more efficient and secure payment technologies. In the past decade, digital wallets such as Apple Pay have become popular across multiple retail channels and have become a preferred method. We study customer payment preferences among – credit cards, digital wallets, platform currency, and cryptocurrency. Using a VR grocery store and online grocery shopping simulation, we study the impact of an immersive sensory environment. Over two experiments and a qualitative study, we find that customers are more likely to choose digital wallets (Study 1) and platform currency (Study 2) over cryptocurrency across both VR and non-VR retail settings. We build a case for retailers and other stakeholders to build blockchain-based digital wallet capabilities with existing technology firms and financial institutions to provide customers with familiarity in the transactions and payments phase of the customer journey in VR retail journeys.

2 - How do gender and ethnic diversity impact consumer returns?

YU Jiang, University of Tennessee, Knoxville, Knoxville, TN, United States, Michael Galbreth, Paolo Letizia, Paolo Roma

In this work we study the impact of gender and ethnicity on consumer returns of online purchases. Our investigation is based on analysis of a unique dataset from a leading global luxury brand operating in the U.S. market. Our analysis confirms that gender and ethnicity both have a significant effect on consumer returns.

3 - Integrated showroom locating, pricing, and inventory management: models and analyses

Dincer Konur, Texas State University, San Marcos, TX, United States

To overcome customers' hesitation to buy online without trying a product, many online-only brands expand with showrooms. A showroom is a physical zero-inventory outlet where customers can try a product; and, if it is a fit, purchase is completed online. Showrooms are shown to increase demand. In this study, we analyze an online-only brand's showroom locating problem. Considering the demand enhancement effect of locating showrooms, pricing and inventory control decisions are integrated with showroom locating decisions. First, we formulate the integrated showroom locating, pricing, and inventory control problem as a mixed-integer nonlinear programming model. We then analyze showroom location decisions given price and pricing decision given showroom locations. These are then used to develop a polynomial time algorithm to solve the problem. The model is then extended to account for shipping fees, borne by either the customers or the brands. We show that both cases can be solved in polynomial time. Furthermore, capacitated versions of the models with demand capacity or budget limit are analyzed. For the capacitated models, we develop linear-relaxation based ranking heuristic approaches. Numerical tests indicate that the heuristic methods are computationally efficient and they return near-optimal solutions.

4 - Leveraging Augmented Reality and Assortment Planning in Omnichannel Retail Systems

Amin Aslani, University of Wisconsin - Whitewater, Whitewater, WI, United States, Borzou Rostami, Mojtaba Araghi

One of the challenges that online retailers face is the lack of physical interaction in online shopping, which can deter customer purchases. To overcome this, several major retailers are adopting augmented reality (AR) technology to enrich online shopping experiences by blending digital imagery with real-world views. This innovation enhances the customer experience through more interactive and accurate purchase decisions. Additionally, in an omnichannel retail framework, physical stores serve dual roles as both sales and information channels, where product assortments enable direct customer interaction with showcased products, complementing online AR enhancements and potentially influencing sales. Our research focuses on identifying the optimal investment in AR technology for online platforms and determining the best product assortment for physical stores to maximize overall retail system profitability. We develop solution algorithms and provide managerial insights into how these decisions are interconnected.

5 - Insights into Returned Orders: the Power of Explainable Analytics

Arno De Caigny, IESEG School of Management, Lille, France

Understanding the dynamics of orders returned by customers is crucial for firms given the significant economic losses and ecological impacts associated with these returns. Traditionally, the focus has been on managing the handling of returns rather than on proactive strategies to minimize them. Previous research has primarily concentrated on predicting the total volume of returns, which aids in managing product returns but does not give insights for preventive actions. This study shifts the focus from reactive to proactive by providing specific insights that could help firms reduce the risk of returns. Leveraging explainable analytics and a comprehensive real-world dataset from a major European e-tailer, we show how specific order- and customer- characteristics contribute to the risk of returns. Our framework offers e-tailers a strategic tool to support decision-making systems aimed at mitigating return risks.

Chair: Zahra Ashrafi, York University, 240 Bantry Ave, Richmond Hill, ON, L4B 4H9, Canada

1 - Adaptive Decision-Making in Human-AI Teaming for Dynamic Driving Environments

Mayuree Binjolkar, University of Washington, Seattle, WA, United States, Yuanjie Tu

This research focuses on the application of adaptive decision-making techniques, specifically bandit algorithms, to facilitate human-AI teaming in dynamic driving environments. As autonomous vehicles become increasingly prevalent, ensuring safe and efficient interactions between human drivers and AI systems remains a critical challenge. Bandit algorithms offer a promising approach to address this challenge by enabling intelligent systems to adapt their decision-making strategies in real-time to changing environmental conditions. We explore various aspects of bandit algorithms tailored for non-stationary environments, including sliding window approaches, online change-point detection, and contextual bandits. By incorporating contextual information such as traffic conditions, road dynamics, and the behavior of surrounding vehicles, these algorithms can enhance decision-making in human-AI teaming scenarios. Moreover, by actively learning from interactions with the environment, bandit algorithms contribute to the development of adaptive and intelligent systems for automated driving. In terms of specific formulation, the bandit algorithms are designed to adjust the exploration-exploitation trade-off dynamically based on an evolving reward structure, which reflects real-time data from the vehicle’s sensors and external sources. The algorithms apply a weighted combination of recent outcomes within a sliding window to prioritize current trends over older data, and use contextual cues to adapt strategies more effectively to specific driving scenarios. Through this research, we anticipate improvements in navigation precision and decision-making efficiency, particularly in complex traffic conditions. These outcomes will demonstrate the practical benefits of adaptive decision-making in improving real-world driving performance and ensuring safer human-AI interactions on the road.

2 - Leveraging Large Language Models for Autonomous Vehicle Operations

Yuming Chang, Georgia Institute of Technology, Atlanta, GA, United States, Chaojie Wang, Qing Tang, Yongyang Liu, Yangjiao Chen, Srinivas Peeta

Autonomous vehicles (AVs) seek to enhance their responsiveness to diverse driving scenarios, especially corner cases, to ensure safety and emulate human driving behaviors. However, unlike human drivers who can react to unusual traffic situations by leveraging experience and inherent skills in such situations, AVs rely on learning models which need extensive real-world data for training. The low frequency and long-tail distributions associated with corner cases makes it impractical and time-consuming to collect sufficient data through real-world field tests and simulations, posing challenges for improving AV operational performance. Recently, Large Language Models (LLMs) have illustrated the potential to conduct human-like thinking and perform tasks beyond their training data. By leveraging LLMs, we develop a generalizable methodology for creating an autonomous driving system to generate maneuvers for diverse traffic scenarios and emulate human behaviors and assess its performance using real-world corner cases. The LLM-based autonomous driving system consists of three core modules: (i) the LLM-based perception module that complements the traditional perception module by generating descriptions of corner cases from the driver's perspective, (ii) the LLM-based planning module, which generates a list of potential maneuvers by integrating the scenario descriptions with information from other sensors, and simulates trajectories to verify the maneuvers' safety, and (iii) the control module, which executes maneuvers confirmed as safe. The LLM-based autonomous driving system is tested using multiple real-world corner cases to validate its usability and reliability, in terms of how AVs respond to unfamiliar driving scenarios.

3 - Simulation Based Optimization of Autonomous Vehicle Model Parameters in Mixed Traffic by Genetic Algorithm

Jinkun Lee, East Carolina University, Greenville, NC, United States

As we observe self-driving technology of SAE level 3 and above are being tested in multiple public-private partnerships, it is generally anticipated that the autonomous vehicles (AVs) will penetrate current human driving transportation network quickly in the near future. As a result, a mixed traffic with human driving vehicles and AVs will show transient system behavior with respect to the penetration rate of AVs. Therefore we may require adaptive optimal AV settings for the overall traffic performance. We are interested in understanding this system behavior over the transitional period to achieve an optimal traffic performance. We investigate the system behavior with an agent-based simulation with different penetration rates and find optimal AV model parameter set per penetration rate by using genetic algorithm (GA). Simulation results with optimal AV parameter values reveal improvement in multiple average traffic performance measures.

4 - Navigating in Mixed-Flow Traffic: Role of Connected and Autonomous Vehicles in Shaping Human Lane-Change Behavior

Yongyang Liu, Georgia Institute of Technology, Atlanta, GA, United States, Srinivas Peeta

Connected and autonomous vehicles (CAVs) and human-driven vehicles (HDVs) will coexist on roads in the future, creating a mixed-flow traffic environment. The heterogeneity in HDVs' lane-change behaviors can significantly impact CAV operations and degrade CAV control performance. This driving simulator-based study investigates HDV lane-change behavior in mixed-flow traffic and analyzes differences in their lane-change behaviors in interactions with HDVs and CAVs. Behavior evolution is also factored as HDVs' lane-change behaviors may evolve after human drivers gain more experience in driving alongside CAVs. Results from driving simulator experiments involving 72 participants indicate significant differences in participants' lane-change behaviors in interactions with HDVs and CAVs. In addition, the learning effects from participants' interactions with CAVs on their lane-change behavior were found be significant. The study provides valuable insights on the evolution of human drivers' lane-change behaviors and the dynamics of CAV-HDV interactions in mixed-flow traffic, illustrating practical implications for developing human-friendly CAV operational systems.

5 - Vehicular Control for Improving Safety and Sustainability in Mixed Traffic of Connected Automated and Human-driven Vehicles

Brian Park, University of Virginia, Charlottesville, VA, United States

Modern vehicles are equipped with adaptive cruise control (ACC) that allows longitudinal control of the ego vehicle based on the speed or distance measured to its preceding vehicle. Some limitations include (i) the ego vehicle takes off when the preceding vehicle changes its lane, and (ii) the ACC requires 2+ seconds of time headway to be string stable, which often induces cut-ins by nearby lane vehicles. Due to these, many drivers do not use the ACC in their day-to-day driving.

When human drivers follow their preceding vehicle, their acceleration/deceleration are not optimal, mainly due to human perception and reaction. They typically do too much or too little acceleration/deceleration. Given more than 50% of new vehicles have connectivity (e.g., GM's OnStar), the ego vehicle will likely run into a connected preceding vehicle. Thus, there is a need to design and develop an algorithm that can use the connectivity from its preceding vehicle and help a human driver in charge of their driving improve their driving. To this end, a human-in-the-loop connected cruise control (hCCC) algorithm that takes advantage of vehicle connectivity and keeps drivers in control of their vehicles was developed. The hCCC takes the driver's acceleration/deceleration, receives the intended acceleration/deceleration of its connected preceding vehicle, and then adjusts the ego vehicle's acceleration/deceleration to be string stable. The hCCC was implemented and evaluated using a virtual driving simulator using an open-source Carla platform. A preliminary result showed significant reductions in fuel consumption and safety distance over human driving alone.

6 - Optimal nonlinear distance toll with mixed equilibrium of human-driven vehicles and connected and autonomous vehicles considering equity issue

Haoming Yang, Carnegie Mellon University, Pittsburgh, PA, United States

The rise of connected autonomous vehicles (CAVs) offers a promising solution to bridge the gap between user equilibrium (UE) and system optimal (SO), enhancing network efficiency and addressing the selfish routing behavior of human-driven vehicles (HDVs). However, before the period of fully CAVs appears, there will be a situation in which both HDVs and CAVs are present. In a mixed autonomy environment, we can control CAVs to follow the SO routing principle to minimize total system travel costs, while HDV users dynamically adjust their routes through day-to-day dynamics to minimize their individual travel costs in response to the CAV routing strategy. This study first solves a mixed equilibrium of HDVs and CAVs, where the mixed flow traffic assignment problem is formulated as a mathematical program with equilibrium constraints (MPEC). One challenge is that the SO routing strategy may result in higher travel times for CAVs compared to HDVs. To address this inherent unfairness, road pricing is used to influence the route choices of HDVs. We designed a piecewise nonlinear distance-based pricing scheme to further improve equity, measured with the Gini coefficient. We formulated the pricing strategy as a bi-level optimization problem, solved using artificial bee colony algorithms. The results demonstrate that the designed pricing scheme, combined with CAV routing in mixed traffic flow, can reduce inequity and total travel time in the network, even when the market penetration rate of CAVs is low.

7 - Impacts of On-board Automated Vehicle Sensors on Traffic Flow: Analysis of Sensor Range, Rate, and Resolution

Zahra Ashrafi, York University, Richmond Hill, ON, Canada, Mehdi Nourinejad, Sina Bahrami

Connected automated vehicles (CAVs) can process and interpret their environment, allowing them to navigate, identify obstructions, and make real-time decisions based on data collected by on-board sensors. CAV sensors are characterized by three features: range, rate, and resolution, commonly referred to as the *3Rs*. Range refers to the sensor's distance perception, rate to the frequency of data capture, and resolution to the data precision. The type and properties of the on-board sensors can affect traffic flow as the CAVs rely on the retrieved sensor data for making driving decisions. This study investigates the impact of the three sensor Rs on traffic flow in congested and uncongested traffic conditions. The proposed model employs car-following principles to express the relationships within the fundamental diagrams of traffic flow and their corresponding properties. The analyses show enhanced range, rate, and resolution increase traffic capacity. However, we observe a nuanced relationship between reaction time and capacity, with a unimodal pattern emerging. While an initial increase in reaction time provides CAVs with additional sensor data, thereby boosting capacity, prolonged reaction times may eventually lead to decreased capacity due to excessive caution.

This research illuminates the critical role of sensor technology in shaping traffic dynamics and highlights the potential benefits of optimizing sensor capabilities for future transportation systems.

Summit - 328

2024 MAS Annual Awards

Invited Session

Military and Security

Chair: Brian Lunday, Air Force Institute of Technology, 2950 Hobson Way, WPAFB, OH, 45433, United States

Co-Chair: Shaun Doheney, Amazon Web Services (AWS), Arlington, VA, United States

1 - Mas President's Introductory Remarks

Shaun Doheney, Amazon Web Services (AWS), Herndon, VA, United States

This session is made possible by the efforts of MAS Past-president, Dr. Brian Lunday, who orchestrated the MAS Annual Awards for 2024, along with the chairs of the respective committees: Dr. David Myers for the Bonder Scholarship; Dr. Tahir Ekin for the Koopman Prize; Dr. Ed Pohl for the J. Steinhardt Prize; and Dr. Matthew Robbins for the MAS Student Paper Competition.

2 - Mas Student Paper Competition

Matthew Robbins, Air Force Institute of Technology, WPAFB, OH, United States

See https://connect.informs.org/militaryandsecurity/awards/studentpapercompetition

3 - Seth Bonder Scholarship for Applied Operations Research in Military and Security Applications (Sponsored by the Bonder Estate) - Presentation by Recipient on Emerging Research Thread

Shaun Doheney, Amazon Web Services (AWS), Herndon, VA, United States, David Myers

See https://connect.informs.org/militaryandsecurity/awards/seth-bonder-scholarship

4 - Koopman Prize (Sponsored by MAS Members)

Ekin Tahir, Texas State University, San Marcos, TX, United States

See https://connect.informs.org/militaryandsecurity/awards/koopman-prize

5 - J. Steinhardt Prize (Sponsored by Cna Corporation) - Presentation by Recipient on Career Insights and Observations

Ed Pohl, University of Arkansas, Fayetteville, AR, United States

The J. Steinhardt Prize is sponsored by the CNA Corporation. The prize is awarded for outstanding contributions to Military Operations Research and is awarded for life work rather than for any particular contribution. The selection Committee is composed of previous award winners. The award is accompanied by a plaque and a $2,000 honorarium.

Matching Markets

Invited Session

Auctions and Market Design

Chair: Sophie Yu, Stanford University, Durham, NC, United States

Co-Chair: Pengyu Qian, Boston University, Boston, United States

1 - Incentives Design for Decentralized Matching

Pengyu Qian, Boston University, Boston, MA, United States, Chen Chen

In decentralized dynamic matching markets, agents can benefit from sharing their supply and demand, but they will collaborate only if properly incentivized. Motivating applications include kidney exchange and ridesharing platforms. This paper explores incentive design to foster collaboration in such markets. We consider a model with multiple self-interested agents, each operating a general multi-way dynamic matching market, aiming to maximize their time-average matching rewards. The agents' states are private information, and items awaiting matches are available for only a limited amount of time. We introduce a simple reward splitting mechanism that specifies the distribution of rewards for inter-player matches, leading to a complex dynamic game. Despite its complexity, we demonstrate that in all market equilibria, the total reward closely approaches that of a centralized matching market, with the gap diminishing to zero as the number of players increases to infinity. This mechanism is straightforward to implement and offers significant economic insights.

2 - Experiment Design for One-Sided Matching Platforms

chenran weng, University of Science and Technology of China, Hefei, China, People's Republic of, Xiao Lei, NIAN SI

One-sided matching markets, where users are matched with other users, are evident in environments like video game platforms and anonymous social networks. Here, participants are matched for interactions such as games or social exchanges. Experimentation (A/B tests) in these markets is challenging due to the interdependence of users' metrics on their counterparts' treatment assignments. In this paper, we build a stochastic market model and develop its mean field limit to analyze such experimental dynamics. Our focus is on two randomization strategies: user and match randomization. We demonstrate that, under Markovian conditions and homogeneous users behavior, match randomization provides unbiased estimations but can lead to significant biases when these conditions are not met. Conversely, user randomization shows greater resilience to model inaccuracies. We further propose an associated linear regression estimator that can halve the bias compared to a naive estimator.

3 - Stochastic Online Metric Matching: Adversarial is No Harder than Stochastic

Mingwei Yang, Stanford University, Stanford, CA, United States, Amin Saberi, Sophie Yu

We study the stochastic online metric matching problem. In this problem, n servers and n requests are located in a known metric, where all servers are available upfront and requests arrive one at a time. In particular, servers are adversarially chosen, and requests are independently drawn from a known distribution. Upon the arrival of a new request, it needs to be immediately and irrevocably matched to a free server, resulting in a cost of their distance. The objective is to minimize the total matching cost. The best competitive ratio achieved for general metrics is $O((\log \log \log n)^2)$, and only the tree metrics are known to admit $O(1)$-competitive algorithms.

In this paper, we show that the problem can be reduced to a more accessible setting where both servers and requests are drawn from a fixed distribution by losing only a constant factor in the competitive ratio. Combined with previous results, we give $O(1)$-competitive algorithms for a broader range of metrics and distributions. For $[0, 1]^d$ with $d \geq 3$, we present an $O(1)$-competitive algorithm for distributions satisfying a mild condition. We further extend our algorithm to the case with at most a linear amount of excess servers and achieve the same competitive ratio guarantee.

4 - Stable Matching as Transport

Joseph Root, University of Chicago, Chicago, IL, United States, Federico Echenique, Fedor Sandomirskiy

We study matching markets with aligned preferences and establish a connection between common design objectives—stability, efficiency, and fairness and the theory of optimal transport. Optimal transport gives new insights into the structural properties of matchings obtained from pursuing these objectives, and into the trade-offs between different objectives. Matching markets with aligned preferences provide a tractable stylized model capturing supply-demand imbalances in a range of settings such as partnership formation, school choice, organ donor exchange, and markets with transferable utility where bargaining over transfers happens after a match is formed.

Co-Chair: Ali Makhdoumi, Duke University, Durham, NC, United States

Co-Chair: Pengyu Qian, Boston University, Boston, United States

1 - Pure Nash Equilibrium Market Recommendations

Shai Vardi, Purdue University, West Lafayette, IN, United States

New business models help sellers make better decisions by communicating information about market prices. However, sellers' inability to coordinate greatly reduces the efficacy of this information and can lead to market failures. We study the feasibility and benefits of providing equilibria as recommendations in economies where sellers face price uncertainty, information scarcity, and an inability to coordinate. We describe a general model in which sellers wish to sell some quantity of a good at one of several markets with elastic prices, and show that while an equilibrium may not necessarily exist, an approximate equilibrium always exists under mild assumptions on the market concentration. %provide an algorithmic framework that a market planner can use to recommend ex-post equilibria to sellers. We describe an algorithm that a market planner can use to recommend approximate ex-post equilibria to sellers, and compare the recommended (approximate) equilibria to selling strategies identified from a survey of onion and potato farmers in India. Using both synthetic data and real data on India's agricultural markets, we show that the recommended strategy outperforms the other strategies in terms of seller welfare, geographic price dispersion, market volume concentration, and several metrics of individual farmer welfare improvements. We also show that the framework is robust to imperfect market penetration, is fair to smaller farmers, and captures nearly all of the welfare from a welfare-maximizing allocation.

2 - Contract Design With Safety Inspections

Alireza Fallah, UC Berkeley, Berkeley, CA, United States

We study the role of regulatory inspections in a contract design problem in which a principal interacts separately with multiple agents. Each agent's hidden action includes a dimension that determines whether they undertake an extra costly step to adhere to safety protocols. The principal's objective is to use payments combined with a limited budget for random inspections to incentivize agents towards safety-compliant actions that maximize the principal's utility. We first focus on the single-agent setting with linear contracts and present an efficient algorithm that characterizes the optimal linear contract, which includes both payment and random inspection. We further investigate how the optimal contract changes as the inspection cost or the cost of adhering to safety protocols vary. Notably, we demonstrate that the agent's compensation increases if either of these costs escalates. However, while the probability of inspection decreases with rising inspection costs, it demonstrates nonmonotonic behavior as a function of the safety action costs. Lastly, we explore the multi-agent setting, where the principal's challenge is to determine the best distribution of inspection budgets among all agents. We propose an efficient approach based on dynamic programming to find an approximately optimal allocation of inspection budget across contracts.

3 - Strategically-Robust Learning Algorithms for Bidding in First-Price Auctions

Rachitesh Kumar, Amazon, Seattle, WA, United States

Learning to bid in repeated first-price auctions is a fundamental problem at the interface of game theory and machine learning, which has seen a recent surge in interest due to the transition of display advertising to first-price auctions. Past work has predominantly treated it as an online learning problem and focused on developing regret-minimizing algorithms. However, such an approach ignores the strategic nature of the market in which such algorithms are deployed---sellers and buyers can manipulate these algorithms for their own benefit. In this work, we go beyond regret minimization and develop bidding algorithms that are robust to manipulations by strategic market participants. We propose a novel concave formulation for pure-strategy bidding in first-price auctions and use it to analyze Gradient Ascent. Unlike previously-proposed algorithms, which attain optimal regret but are manipulable, we show that Gradient Ascent attains optimal regret while being robust to strategic manipulations by the buyer and the seller.

4 - Information Design and Pricing of Supply Competition in Lead-Selling Platforms

Yanwei Sun, Imperial College Business School, London, United Kingdom

We analyze a type of platform common in the service sector, where customers can freely post tasks, and service providers pay a feeto purchase job leads and unlock the ability to communicate with these customers. We adopt a Bayesian persuasion framework to explore how the platform can leverage its informational advantage about the supplier base and pricing to strategically influence the decisions of service providers, aiming to maximize its revenue. We begin the analysis by assuming that prices are exogenously given and characterize the structure of the optimal signaling mechanism. Specifically, the platform recommends all service providers to participate when the pool-size is below a certain threshold. When the pool-size exceeds this threshold, the platform randomizes its recommendations between two consecutive numbers, independent of the pool-size. This behaviour is driven bya unique feature of our model, where the beliefs of the platform and suppliers are non-identical: a supplier's knowledge of their own participation inflates their belief about the total number of service providers. Next, we endogenize the platform's pricing decision and consider the policy space where the signaling mechanism and state-dependent pricing are jointly optimized. Notably, within this space, we findthat the optimal signaling mechanism with a single price remains optimal. This result implies the superiority of the optimal signaling mechanism over the commonly adopted contingent pricing policy, where the price charged by the platform depends on the number of interested suppliers. We show that the performance discrepancy between these two policies is particularly pronounced when supply competition is intense.

Emerging Trends in Financial Risk Management and Market Influence

Contributed Session

Chair: Yusaku Watanabe, N/A

1 - Necessity Analysis of Insurance and Reinsurance in Mitigating Bank Loan Risk -- Based on Multi-Party Game Model

Jinye Du, Southern University of Science and Technology, Shenzhen, China, People's Republic of, Yanhong Guo

The financial vulnerabilities of Small and Medium-sized Enterprises (SMEs) is a vital problem and insurance and reinsurance can be an efficient way of risk mitigation. By employing a game theory framework, our study examines interactions among SMEs, banks, insurers, and reinsurers, focusing on strategic interdependencies and the complexity of financial support mechanisms. Distinct from previous research centred on profitability, our analysis highlights the challenge of transparency in borrowers' financial integrity during initial loan approvals, a factor clarified in subsequent oversight. The proposed model addresses SME financing challenges and efficiently distributes risks among all stakeholders—including enterprises, financial institutions, reinsurance companies, and government regulators—thereby fostering a sustainable financial ecosystem. Our approach enhances banks' lending capacity while effectively managing default risks, contributing to the stabilisation of the national economic order.

2 - Impact of Firm-Level Cyber Risk on Stock Price Informativeness: An Empirical Analysis

Waqas Nawaz Khan, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Shan Liu, Jae Kyu Lee

Cyber risk is a critical aspect of the economy all over the globe. The relationship between firm-level cyber risk and stock price informativeness has become a critical area of research, particularly in an era where cyber threats loom large over corporate governance. This study investigates how the exposure to cyber risk at the firm level influences the informativeness of stock prices in the market. Utilizing a robust dataset of 26252 firms from 2007-2018 that spans several industries, we employ multiple regression analyses to examine the impacts of cyber risk on the efficiency of stock price in reflecting relevant information. Our findings indicate that higher levels of cyber risk are significantly associated with stock price informativeness. This suggests that as firms become more susceptible to cyber threats, the efficient stock prices. Stocks of firms with higher cyber security risk tend to achieve higher informativeness both from managers' and fundamental investors' efforts. High cyber security risk leads to lower earnings management and increased fundamental investors' information acquisition. Our path analyses suggest that decreased earnings management and increased fundamental investors' attention are the key mechanisms of impact through which high stock price informativeness is achieved. The research contributes to the ongoing discussions on corporate transparency and market uncertainty surrounding their future cash flows and operational stability increases, leading to less efficiency, highlighting the importance of robust cyber risk management strategies not only for safeguarding operational integrity but also for maintaining investor confidence and market stability.

3 - Reference Price Effect Model as the Piecewise-Smooth Dynamical System: Dynamic Pricing with Asymmetric Reference Price Effects

Anton Bondarev, Xi'an Jiaotong-Liverpool University, Suzhou, China, People's Republic of, Regis Chenavaz

In this paper we contribute to the study of the well-known reference price effects model, established by Fibich et al. (2003) and subsequent papers.

We make use of recently developed methods in hybrid control of piecewise-smooth dynamical systems to shed light to several aspects of that model which previously were not studied.

We start with the classical symmetric price effects model and next analyze asymmetric effects both under loss aversion and gain seeking assumptions. In the first case we are able to fully replicate previous findings and extend them claiming that there is an additional continuum of equilibria in between two (previously reported) price levels associated with different reference price effects.

For the gain seeking case, we extend the literature by showing that there are additional optimal solutions associated with the existence of the sliding equilibrium and its associated flow. This result is to our best knowledge, novel to the field.

At last we extend our findings to the differential game setup with many players and show that main results survive such an extension. We also discuss further potential development sin the field.

4 - Estimating the Cost of Content Diversification: An Empirical Evidence from Japanese TV Markets

Yusaku Watanabe, Kobe University, Kobe, Japan

Diversity in broadcasting is an important concept that has been set as a primary goal of broadcasting policy in many countries. There are also many studies on media diversity in various academic fields. However, while diversity in media is recognized as important from a social and policy perspective, most studies have overlooked the discussion of the costs associated with content diversification. Scheduling programming is an essential strategic decision for broadcasters and needs to be treated endogenously.

The purpose of this study is to address this gap by examining the impact of broadcasters' content diversity on viewer and advertiser demand, and estimating the marginal cost of content diversification using a structural model based on a two-sided market model. This study utilizes a market-level dataset for the Japanese TV market, including advertising prices, advertising quantities, audience ratings, and detailed program characteristics such as content diversity, to estimate the proposed model. Viewer choice behavior is formulated as a Multiple Discrete-Continuous Extreme Value (MDCEV) model, in accordance with the frequency of data observations, and transformed to be estimated at the market-level. The study shows that the marginal cost can be obtained by combining the structural model and estimated demand parameters.

By quantifying the costs of achieving diversity in broadcasting content, this study offers insights that can inform more effective policymaking to promote a vibrant and pluralistic media landscape.

Radiotherapy and Cardiovascular Health

Flash Session

Chair: Jindong Tong, University of Florida, Gainesville, FL, United States

1 - Determining the Causal Influence of Migraine-Specific Factors on MACE Outcome: A Causal Learning Approach

Asra Aghaei, Arizona State University, Tempe, AZ, United States, Teresa Wu, Catherine Chong

Migraine is a common and debilitating headache disorder that has a one-year prevalence of 12% in the general population. Existing data demonstrate that migraine is associated with an increased risk of cardiovascular disease and stroke, which are commonly referred to as MACE events. The NIH's *All of Us* research program includes over 647,000 participants with approximately 80% of those originating from underrepresented groups. As such, it is one of the most diverse health databases in history and includes participants from demographic groups that are typically underrepresented in human health research. With the *All of Us* database, 34,232 individuals received a migraine diagnosis (female=27,409/80%, male=5,997/18%, other=726/2%; mean age=54.1, std=15.6) and 379,225 did not have a migraine diagnosis (female=222,056/59%, male=149,172/39%, other=7,997/2%; mean age=54.9, std=17.2). We queried ICD-9 and ICD-10 codes for migraines and strokes and compared the prevalence of strokes between individuals with and without migraines. Utilizing relative risk ratios with a 95% confidence interval, results demonstrate Ischemic stroke was 3.38 times higher (95% CI: 3.25 to 3.52; $P < 0.001$), hemorrhagic stroke was 3.18 times higher (95% CI: 2.93 to 3.44; $P < 0.001$) and ill-defined stroke was 5.31 times higher (95% CI: 4.80 to 5.87; $P < 0.001$) in individuals with migraine compared to those without migraine. These results suggest migraines are associated with a higher prevalence of both ischemic and hemorrhagic stroke. This research presents our preliminary study on casual analysis to investigate the cascading relationships amongst migraine-related factors which influence MACE outcome.

2 - Survival Analysis for Risk Stratification of Clinical Events in Heart Failure Patients Using Longitudinal EHR Data

Maryam Jafaripakzad, University of South Florida, Tampa, FL, United States, Jorge A. Acuna Melo, Jose L. Zayas Castro, Joel Fernandez

Heart failure affects approximately 6.5 million Americans over the age of 20, directly causing about 8.5% of all heart disease deaths in the United States. It is also a leading cause of hospitalizations among the Medicare population, emphasizing the urgent need for improved management and predictive strategies. Accurately predicting clinical events in heart failure patients is essential for proactive healthcare management. Advanced predictive models enable clinicians to identify at-risk patients earlier and more reliably, facilitating timely interventions that can prevent deterioration of health and avoid costly hospital admissions. In this study, we aim to predict adverse clinical events in heart failure patients by using longitudinal electronic health record data, which includes repeated measurements of risk factors over time. We applied and compared dynamic prediction models, including time-varying Cox regression, joint modeling of longitudinal and time-to-event data, and recurrent neural networks (RNNs) to assess their predictive accuracy and their ability to adapt to new information. Preliminary analyses indicate that these dynamic models outperform traditional static models in predicting clinical events, particularly in survival data.

3 - Deep Learning-based Bio-signal Multivariate Time-series Forecasting

Seonyeong Park, Ewha Womans University, Seoul, Korea, Republic of, Dongil Kim

Heart disease remains a significant health concern, accounting for a substantial portion of mortality rates worldwide. This underscores the critical importance of early diagnosis and prediction in improving patient outcomes and survival rates. Given the importance of bio-signal data in diagnosing heart conditions, particularly in the context of heart disease, the ability to forecast bio-signal patterns emerges as a critical problem. Recurrent Neural Networks (RNNs) such as Long-short term memory(LSTM) and Gated Recurrent Unit(GRU), designed to handle sequential data with a memory mechanism, are particularly well-suited for modeling temporal dependencies in bio-signal records. By using LSTM and GRU, our study enhances the ability to forecast multivariate time series with bio-signal patterns. We used various open real-world multivariate time series datasets provided by UCI machine learning dataset, PhysioNet and etc.. Various preprocessing methods suitable to bio-signal datasets are used, and time series preprocessing methods are used, too. Through the RNN-based model and various time series preprocessing methods, our study enables the forecasting of patients' future bio-signal patterns based on past bio-signal data. The experimental results of our method showed higher accuracy in forecasting bio-signal patterns than the other models. Our methods not only provide the effectiveness, but also insights to help in the decision-making process of heart disease prevention and treatment strategies. Analyzing bio-signal patterns by our method can provide valuable insights related to healthcare, and help to develop proactive management and prevention strategies for heart disease.

4 - Enhancing Heart Failure Diagnosis: A Transparent Approach with Ensemble of Simple Models

Gaurav Arwade, Iowa State University, AMES, IA, United States, Sigurdur Olafsson

Heart failure remains a significant global health issue, with 6.5 million confirmed cases in the United States alone and an annual increase of 960,000 new cases. The complex nature of this clinical syndrome, often intertwined with various other health conditions, presents challenges in achieving accurate diagnoses. Thus, certain ischemic and valvular heart conditions contribute to heart failure being overlooked. Conversely, symptoms that overlap with conditions such as obesity and respiratory diseases can result in both over and underdiagnoses. Breathlessness, a common symptom shared between heart failure and other conditions, can lead to misdiagnosis, particularly in primary care settings where comprehensive evaluation resources are scarce. Predictive models have the potential to enhance diagnostic accuracy, but transparency and explainability are essential in this field. To address these diagnostic challenges, we propose an ensemble approach that relies on simple models constructed based on the inherent structures of the data. These models utilize subsets of patients with similar characteristics to minimize redundant complex interactions among features. Though deep learning and complex algorithms like XGBoost show promising diagnostic capabilities, their lack of explainability raises physicians' concerns about 'black box' recommendations. algorithms. Our approach prioritizes improved explainability without compromising accuracy, making it more accessible and reliable for clinicians. We demonstrate how the simple structures within the ensemble differ from each other and the global model using causality. This further enhances our understanding of the model's predictions and aids in interpretation, strengthening its utility in clinical practice for precise heart failure prediction in primary care settings.

5 - A Mathematical Framework for Optimizing Immuno-radiotherapy Treatments

Ehsan Salari, Wichita State University, Wichita, KS, United States, Keerthi Venugopal Rakhee

Immunotherapy has recently emerged as an important modality for the treatment of advanced-stage cancers. Despite the encouraging clinical results, the number of patients who durably respond to immunotherapy alone is small. Therefore, there is clinical interest in combining immunotherapy with radiotherapy to achieve better outcomes. The primary goal of this study is to develop novel mathematical models to inform the design of immuno-radiotherapy (IRT) treatments. To that end, we adapt and utilize existing compartmental models available in the literature to explicitly optimize for the dosing and schedule of IRT treatments. Specifically, we consider an extended compartmental model based on differential equations to simulate the population dynamics of cancer and immune cells under the influence of radiation and immune-checkpoint inhibitors (ICI's). We integrate the compartmental model into an optimization framework to optimize the antitumor immune response while limiting the risk of normal-tissue toxicity. The proposed IRT optimization framework determines both a radiation fractionation schedule and an ICI dosing schedule. Additionally, it allows for investigating how variations in disease characteristics such as cancer stage, primary tumor volume, tumor radio-sensitivity, tumor growth rate, and metastatic drivers, may affect the optimal IRT schedule.

6 - Using Zeroth Order IMPT Algorithm Towards Clinic Implementation of the MKM RBE model for Carbon Ion therapy

Jindong Tong, University of Florida, Gainesville, FL, United States, Dong Han, Hongcheng Liu, Yu Yang, Bo Lu

Ion beam radiotherapy, especially using protons and carbon ions, has recently gained significant attention in the field of radiation oncology. The Microdosimetric Kinetic Model (MKM) model utilizes novel expressions to calculate exposure-specific cell survival, considering the full spectrum of microdosimetric information instead of relying on average values. While the MKM model shows promise for describing the

Relative Biological Effectiveness (RBE) in Carbon Ion Radiotherapy (CIRT), its integration into treatment planning for RBE dose optimization has been less visited due to its sophisticated computations involved in the model that prohibits easy access to improving search directions. To address these challenges, we adopt random gradient free method for tractable optimization.

Summit - 333

Supply Chain Risk Assessment

Contributed Session

Chair: Mohamad Darayi, The Pennsylvania State University--Great Valley, Malvern, PA, United States

1 - Value of Information in Analyzing Freight Transportation Resilience Considering Economic Impacts

Mohamad Darayi, The Pennsylvania State University--Great Valley, Malvern, PA, United States

Defining a four-phase disaster life cycle as (i) mitigation, (ii) preparedness, (iii) response, and (iv) recovery, freight transportation resilience literature most focus is on assessing the network's ability to deal with disruption consequences, with less work on holistic analysis of resilience. This work, however, emphasizes resilience analysis considering economic impacts. A systematic framework to analyze freight transportation resilience is proposed by (i) evaluating vulnerability of the interdependent system of freight infrastructure and economic sectors, (ii) seeking strategies to allocate a limited budget to harden the system, and (iii) assessing value of information in decision making under uncertainty. The proposed resilience analysis framework is implemented in a stylized case study of the multi-modal freight transportation network that connects Pennsylvania to the surrounding states.

2 - "Effects of Heterogenous Decisionmakers in Disrupted Supply Chains"

Souri Sasanfar, Northeastern University, Boston,, MA, United States

Title:

"Effects of Heterogenous Decisionmakers in Disrupted Supply Chains"

Disruptions to the supply chain present serious problems, especially in the pharmaceutical industry where reliable and effective delivery is essential. This study examines the effects of decision-maker heterogeneity on supply chain performance during different types of disruptions, with a particular emphasis on three important profiles: followers, hoarders, and reactors. To study the dynamic interactions between these decision-makers and two important information sharing formats, Automated System Information (ASI) and Automated Demand Information (ADI), we created an agent-based simulation model.

The simulation looks at how different decision-maker types react to supply chain interruptions and how their actions interact with ADI and ASI to impact performance. By lowering supply chain expenses, panic purchases, and phantom ordering, the study seeks to determine which information sharing practices could enhance performance and offer suggestions for the best kinds of ADI and ASI for pharmaceutical supply chains.

The goal of the research is to provide a comprehensive understanding of the actions and tactics used by various decision-makers, along with recommendations for improving collaboration and decreasing inefficiencies. By doing so, stability in this important industry will be ensured and pharmaceutical supply chains will become more robust and effective.

3 - Revisiting Supply Chain Response Strategy Under Uncertainty and Asymmetric Information

chuqiao peng, The University of Oklahoma, Norman, OK, United States, Qiong Wang

In supply chain management, uncertainty and asymmetric information pose significant challenges. However, the unique impacts of these challenges on supply chain response strategies remain unclear. Using secondary datasets, this study empirically explored how firms employ supply chain response strategies—specifically, bridging and buffering—to navigate these challenges. Limited the sample size to be publicly traded companies, we are able to control for the firm level variables using Compustat. Utilizing FactSet Revere Relationship dataset, this study measures the supply chain response strategies through the inter-organizational relationship between buyers and suppliers and uses the location as a proxy for asymmetric information. Employing WRDS SEC Readability and Sentiment Data, we are able to explore the supply chain uncertainty using sentimental analysis in the 10-K filing. Additionally, the lengthy time series of these datasets enables us to mitigate the impacts of external policy changes and unobservable noises on the estimation. Drawing upon Information Processing Theory, this study conceptually reveals that uncertainty intensifies the implementation of bridging and buffering strategies. In contrast, asymmetric information generally undermines these strategies' effectiveness. These insights offer valuable managerial implications, underscoring strategic approaches for navigating the complexities of modern, often volatile, business environments. While uncertainty and asymmetric information are often viewed as volatile and challenging, they can be transformed into valuable opportunities for growth and success when firms adopt the appropriate response strategies.

4 - Non-committed cost auditing in supply chain contracts

Jing Li, Renmin University of China, Beijing, China, People's Republic of, Wanshan Zhu, Zhengping Wu

As a widely used means in supply chain practice, audit can be used as an auxiliary means to alleviate the supply chain incoordination problem under asymmetric information that cannot be solved by profit-sharing contract and other means. Although some studies have considered audit issues under supply chain contracts in the literature, few studies are conducted from the perspective of principal-agent theory, not to mention the situation where retailers do not commit to audit strategies under the principal-agent model. In this paper, under the principal-agent theory model, we consider the optimal audit strategy when the retailer makes no commitment to the audit mechanism. We explore the unique features of the audit strategy and the sensitivity of the optimal strategy to various factors.

Quantitative Finance and FinTech

Invited Session

Finance

Co-Chair: Chen Yang, The Chinese University of Hong Kong, Sha Tin, Hong Kong

1 - Implementing a Ramsey Plan

Wei Jiang, Hong Kong University of Science and Technology, Hong Kong, Hong Kong

We study how to induce future governments to continue a fiscal plan chosen by a benevolent government at time 0, an issue analyzed by Lucas and Stokey (1983). We implement a Ramsey plan by adding instantaneous debt to the contractible subspace and requiring each continuation government to preserve that debt's purchasing power over the next instant. After first using a Lagrangian to solve the Ramsey problem, we formulate the problem recursively and then apply that formulation to settings with various debt term structures and government spending processes. We extract implications about tax smoothing and e effcts of fiscal policies on bond markets.

2 - Risk-Sharing Pricing of Variable Annuities within a Principal-Agent Framework

Bin Li, University of Waterloo, Waterloo, ON, Canada, Min Dai, Dongchen Li, Yumin Wang

We propose a new risk-sharing pricing approach of variable annuities within a principal-agent framework where an insurer (principal) is the contract provider and a policyholder (agent) is the follower having the surrender option. While the risk-neutral pricing approach adopted in the existing literature leads to significantly higher fees and more frequent surrendering than market observations, this new risk-sharing pricing approach reconciles the misalignment between theoretical results and market observations. Our risk-sharing framework is flexible to consider the policyholder's outside options such as bond or mutual fund investments, as well as the insurer's financial friction costs. Additionally, we examine the impacts of policyholder discount uncertainty, tax-deferred benefits, and competition among multiple insurers as extensions.

3 - Reinforcement learning to optimal stopping

Yu Sun, The Hong Kong Polytechnic University, Kowloon, Hong Kong, Min Dai, Zuoquan Xu, Xunyu Zhou

We study the optimal stopping problems with unknown model primitives in the continuous-time reinforcement learning framework developed by Wang et al. [Journal of Machine Learning Research 21(1):8145–8178, 2020]. By penalty approximation of the HJB equation, we transform the optimal stopping problems to optimal control ones, for which we randomize the control at each time by a probability measure and introduce an entropy regularizer to encourage exploration. We derive the semi-analytical optimal Bernoulli distribution of the decision regarding stopping or not, and devise reinforcement learning algorithms based on the martingale approach developed by Jia and Zhou [Journal of Machine Learning Research 23(154):1–55, 2022]. Finally, we demonstrate the algorithms in an example of finite-horizon American put option, and both the offline and online algorithms achieve high accuracy in terms of pricing the option and characterizing the associated free boundary.

4 - Optimal Tax-Timing with Transaction Costs

Chen Yang, The Chinese University of Hong Kong, Shatin, Hong Kong, Min Dai, Yaoting Lei, Hong Liu

We develop a dynamic portfolio model incorporating capital gains tax (CGT), financial transaction tax, and transaction costs, where the tax amount is calculated at the end of each year. We find that transaction costs affect loss deferrals much more than gain deferrals, and a lower interest rate makes higher-wealth investors realize losses sooner but makes lower-wealth ones realize losses later. Our model can help explain the puzzle that even when investors face equal long-term/short-term CGT rates or almost zero interest rates, they may still defer realizing large capital losses. In addition, it provides several unique, empirically testable predictions and can shed light on recently proposed tax policy changes.

5 - Corporate Investment and Savings Demand

Ling Qin, Chinese University of Hong Kong, Hong Kong, Hong Kong, Nan Chen, Xavier Giroud, Neng Wang

Why do some firms save more than others? We revisit this important, widely studied question by developing a tractable continuous-time capital-accumulation model for financially constrained firms facing costly external equity. In addition to including the standard building blocks for a q theory of investment (Hayashi, 1982; Abel and Eberly, 1994): capital accumulation, capital adjustment costs, and a persistent stochastic productivity process, we assume that instantaneous profits (cashflows generated by productive capital) are stochastic. This assumption is a key difference between our model and widely used quantitative corporate finance models, e.g., Hennessy and Whited (2007) and Riddick and Whited (2009), in which instantaneous profits (conditional on productivity and capital stock) are deterministic.

Firm value depends on capital stock, cash balance, and productivity. Using the homogeneity property, we analytically characterize the solution with a variational inequality for cash-capital ratio and productivity. Importantly, we show that making instantaneous profits stochastic is key to generating quantitatively meaningful cash holdings. Consider the alternative that instantaneous profits are (locally) deterministic. Then the firm's cash balance at the end of the period would also be deterministic. This substantially reduces its precautionary savings demand, as locally the risk-neutral firm (as long as it is not too cash strapped) faces little liquidation risk and hence holding cash has limited value. Mathematically, whether (conditional) instantaneous profits are stochastic implies whether the second-order derivative of firm value with respect to cash appears in the Bellman equation, and economically this term has a first-order effect on precautionary savings demand.

1 - Online Linear Programming: the Regret Landscape of the Ce Heuristic

Yilun Chen, CUHK Shenzhen, Shenzhen, China, People's Republic of, Wenjia Wang

The Certainty Equivalent (CE) control is a canonical heuristic approach to dynamic resource allocation problems, central to the literature of OR and MS. The CE approach dynamically (re)solves for the optimal solution of a corresponding fluid problem, derived from replacing all the uncertainty by their average values, to guide its decision-making. While CE and its variants are widely applied in practice, the existing theoretical performance guarantees of CE typically require prohibitively strong condition, known as the non-degeneracy conditions. In this work, we analyze the performance of CE within the general framework of online linear programming. Under mild assumptions on problem primitives, we show that CE achieves optimal regret (up to polylog factors) even when the problem is degenerate, thus expanding the existing understanding of the effectiveness of CE for general dynamic resource allocation problems. Furthermore, we characterize the regret landscape achieved by CE in terms of a coefficient describing the smoothness of the problem's underlying probability distribution. Our results essentially relax the non-degeneracy conditions to only requiring the fluid problem to have unique solutions, which has been shown previously (in the special case of multi-secretary problem) to be necessary for CE-type heuristics to succeed.

2 - A Constant Approximation Framework for the Online-Retail Item Placement Problem

Duygu Soylemez, The University of Chicago Booth School of Business, Chicago, IL, United States, Levi DeValve

For online retailers, warehouse assortment planning significantly impacts the profitability of fulfilling multi-item orders. Once items are placed in warehouses, considering item budgets, the challenge is to determine which warehouses will satisfy each order under operational capacity constraints. We propose a modeling framework for this problem, as well as some other related problems, where we establish a novel form of approximate submodularity. This enables us to analyze local search heuristic algorithms that terminate in polynomial time and to propose a general scheme that guarantees new constant factor approximations.

3 - Understanding Group Structure in individual Decision-making

Jessica Dai, U.C. Berkeley, Berkeley, CA, United States, Paula Gradu, Nika Haghtalab, Deborah Inioluwa Raji, Benjamin Recht, Eric Zhao

When consequential decisions are made about individuals, questions of fairness or discrimination in these contexts depend critically on understanding how individuals relate to those groups. In this talk, we share two perspectives on making (online) decisions when per-group performance is fundamental to the problem. In the first, in a sequential hypothesis-testing task, we assume that the group membership of individuals are known; in this case, we show that per-group validity can be guaranteed even when groups are overlapping, and/or the number of groups is very large (possibly exponential in the number of features). In the second, in a prediction task, we show how approximate per-group calibration can be achieved even when group definitions are unknown a priori.

4 - Online Job Scheduling with Uniform Random Arrivals

Jody Zhu, Carnegie Mellon University, Pittsburgh, PA, United States, Benjamin Moseley

Worst-case analysis of the classic single-machine online job scheduling problem with the objective of maximizing weighted throughput has seen limitations due to it being impossible to construct a constant competitive algorithm for it. All subsequent work on this problem either makes assumptions about the input including the release times, processing times, and processing window or leverages resource augmentation. In this paper, we take a beyond worst-case approach and propose the random-order temporal model that samples the release times of jobs from an uniform distribution. Using this new model, we design constant competitive algorithms for both unweighted and weighted throughput maximization.

1 - Consumer Purchase Behavior in Online Grocery: a Structural Modeling Approach Using Generative AI

Sandeep Chitla, NYU Stern School of Business, New York, NY, United States, Srikanth Jagabathula, Vidyadhar Mudium, Shubha Shedthikere

Understanding how customers build their shopping carts can help retailers influence what customers buy and how much they spend. At what cart value should we offer free delivery? Should we offer a cart-level discount or offer a discount on a specific product to increase total spend? To answer these questions, the retailer must understand how customers build their carts and how various factors affect the next item they add to the cart. Building on the recent success of transformer-based models, we propose a generative model to predict the next item a customer will add based on the current items in the cart and the cart value. We train our model on a large dataset obtained from our industry partner, Swiggy Instamart, which is a leading online grocery service in India. Our results showcase the accuracy of our model and its efficacy in helping the firm optimize promotions.

2 - A Robust Approach to Classification and Truth-Validation: Incorporating Human and Large Language Model Decision Making

Chaithanya Bandi, Northwestern University, Evanston, IL, United States

The advent of generative AI and foundational models has opened up promising avenues to enhance the efficiency of many service systems. However, their wider application has been stymied by the persistent presence of model errors and inaccuracies. These errors represent an intrinsic characteristic of current AI models, and not just a transient hurdle. In this talk, we present a Robust Optimization based approach that embraces this reality and seeks to optimize performance within this context.

We present a Robust optimization-based algorithmic framework and develop the Fast Algorithm for Classification and Truth-validation (FACT), which aims to address the critical need for rigorous truth-validation in service systems. FACT is designed to leverage the decision-making competencies of both humans and foundational Large Language Models (LLMs) through a dynamic task routing strategy, informed by task complexity, projected cost, and the capacity of the decision-making entity.

We present our results from a pilot implementation at a customer service portal of an online education company, which demonstrates significant efficiency benefits. This approach offers a promising trajectory for future research and practical implementations, especially in the context of systems where AI and human decision-making must be effectively integrated.

3 - Gpt2 for Operational Decision Making

Shang Liu, Imperial College Business School, London, United Kingdom, Hanzhao Wang, Kalyan Talluri, Guanting Chen, Xiaocheng Li

In this paper, we consider the supervised pretrained transformer for a class of sequential decision-making tasks. The class of considered tasks is a subset of the general formulation of reinforcement learning in that there is no transition matrix, and the class covers bandits, dynamic pricing, and newsvendor problems as special cases. Such a structure enables the use of optimal actions/decisions in the pretraining, and the usage also provides new perspectives for understanding the training and generalization of the pretrained transformer. We first note that the training of the transformer model can be viewed as a performative prediction problem, and the existing methods and theories largely ignore or cannot resolve the arisen out-of-distribution issue. We propose a natural solution that includes the transformer-generated action sequences in the training procedure, and it enjoys better properties both numerically and theoretically. The availability of the optimal actions in the considered tasks also allows us to analyze the properties of the pretrained transformer as an algorithm and explains why it may lack exploration and how this can be automatically resolved. Numerically, we categorize the advantages of the pretrained transformer over the structured algorithms such as UCB and Thompson sampling into three cases: (i) it better utilizes the prior knowledge in the pretraining data; (ii) it can elegantly handle the misspecification issue suffered by the structured algorithms; (iii) for short time horizon such as $T\le50$, it behaves more greedy and enjoys much better regret than the structured algorithms which are designed for asymptotic optimality.

4 - The Choice-Learn Python Package: a Deep Learning Lens on Choice Modeling

Vincent Auriau, CentraleSupélec, Gif-sur-Yvette, France, Ali Aouad, Antoine Desir, Emmanuel Malherbe

Discrete choice models aim at predicting choices made by individuals from a set of options, called an assortment. Such models are used as inputs to operational problems such as assortment optimization and pricing. We develop Choice-Learn, a Python package for choice modeling practitioners and researchers. The package enables processing choice data, and then formulating, estimating, and operationalizing choice models based on the TensorFlow library. We provide a unified implementation of standard parametric families of choice models as well as neural network-based methods. The code combines high-level usage, designed for fast and easy implementation, and low-level usage for customization. Basic post-processing tools that leverage choice models for assortment optimization and pricing are also integrated into the package.

1 - Random-Order Contention Resolution via Continuous Induction: Tightness for Bipartite Matching Under Vertex Arrivals

Calum MacRury, Columbia University, New York, NY, United States, Will Ma

We introduce a new approach for designing Random-order Contention Resolution Schemes (RCRS's) via exact solution in continuous time.
Given a function $c(y):[0,1] \ra [0,1]$,
we show how to select each element which arrives at time $y \in [0,1]$ with probability \textit{exactly} $c(y)$.
We provide a rigorous algorithmic framework for achieving this, which discretizes the time interval and also needs to sample its past execution to ensure these exact selection probabilities.
We showcase
