D-Wave Quantum Optimization

Invited Session

Exhibitor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Dr Ste 200, Catonsville, MD, 21228, United States

1 - Quantum Optimization

Catherine Potts, D-Wave Quantum Inc, Palo Alto, CA, United States

Quantum computing has gone from the lab to the enterprise, and a recent Hyperion Research study reported that respondents overwhelmingly indicated that quantum computing-based optimization capabilities are seen as integral to optimizing their key business processes. While you may think production use of quantum computers are years away, the first commercial quantum applications in production are using D-Wave's quantum technology. This workshop will cover the following topics: An introduction to quantum computers, quantum annealing, and optimization solvers What kinds of business problems are good candidates for quantum/ hybrid solutions Use case examples: how quantum hybrid is being used for optimization applications such as resource and workforce scheduling, cargo loading and other complex business problems How quantum systems are programmed, and the tools for developers. This will include live demos and an introduction to Leap, D-Wave's real-time cloud service. Leap provides access to a portfolio of hybrid solvers, enabling enterprises to address all kinds of business problems that range in size and complexity. How to get started with quantum for business.

Saturday, October 19, 1:00 PM - 3:30 PM

Summit - 447

GAMSPy and Data APIs for Streamlining Optimization

Invited Session

Exhibitor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Dr Ste 200, Catonsville, MD, 21228, United States

1 - GAMSPy and Data APIs for Streamlining Optimization

Atharv Bhosekar, GAMS Development Corp, Fairfax, VA, United States

GAMS (General Algebraic Modeling System) is an algebraic modeling language that provides users a way to write optimization models using intuitive algebraic syntax. However, as optimization becomes an integrated step within larger decision-making pipelines, modelers face two significant challenges: (1) the inconvenience of switching out of a preferred programming language (such as Python) solely for optimization purposes, and (2) the difficulty of efficiently transferring data between GAMS and other tools and platforms within a diverse software ecosystem. In this presentation, we will tackle these challenges using our latest solutions. First, we will present GAMSPy, our new product that brings algebraic modeling capabilities to Python. GAMSPy allows users to enjoy an intuitive algebraic syntax without compromising on the performance. We will also highlight our suite of data APIs to streamline data exchange with GAMS. In particular, we will focus on GAMS Transfer, a data API that enables users of R, MATLAB, and Python to efficiently read, modify, analyze, and write GAMS data. These tools significantly enhance the interoperability of GAMS within multi-platform decision pipelines, facilitating smoother and more efficient optimization workflows.

Summit - 445

Elevate your Optimization Practice with latest Advances in FICO® Xpress Solver and Xpress Insight

Invited Session

Exhibitor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Dr Ste 200, Catonsville, MD, 21228, United States

1 - Elevate your Optimization Practice with latest Advances in FICO® Xpress Solver and Xpress Insight

Dinakar Gade, FICO, Bozeman, MT, United States, Michael Perregaard, Leona Gottwald, Tristan Gally, Majid Bazrafshan, Bruno Vieira, Alexander Biele

Join our workshop to discover the cutting-edge innovations in Xpress Solver 9.5 and our new object-oriented APIs! Get a firsthand look at how Xpress Insight empowers business users to harness the full potential of analytical models faster than ever before.

Experience the latest features and performance enhancements in FICO® Xpress Solver, including groundbreaking advances in mixed-integer linear and nonlinear optimization. These include a new, first-order hybrid gradient algorithm for linear optimization problems, new heuristics, cutting and branching techniques. Furthermore, we discuss updates to Xpress Global to solve general mixed-integer nonlinear, and nonconvex problems to proven global optimality.

The new FICO Xpress Solver API leads to a dramatically reduced overall model building time and increased memory efficiency. It supports modern programming concepts such as Collections, Streams, Lambdas, and operator overloading. All in an interface that guarantees a consistent user experience across different programming languages.

The session will cover advancements in the Python API, outlining recent updates to modelling capabilities and discussing best practice for developing readable and yet efficient implementations of large-scale optimization models.

FICO® Xpress Insight is a rapid application development and deployment framework that integrates with Xpress Solver and your own analytics. We will show how you can rapidly convert Python models into complete business applications with Xpress Insight to make your analytical models available to thousands of business users.

Summit - 446

Analyzing Multidimensional Data and building Predictive Models in an Interactive No Code Environment

Invited Session

Exhibitor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Dr Ste 200, Catonsville, MD, 21228, United States

1 - Analyzing Multidimensional Data and building Predictive Models in an Interactive No Code Environment

Kevin Potcner, JMP Statistical Discovery, San Francisco, CA, United States

Fully analyzing data requires an analyst to generate a wide variety of visualizations, analyses, and models. The insights gleaned from each step leads the analyst to a next set of analyses to try, and so on. This exploratory approach can become very cumbersome in a coding environment. Without strong proficiency in programming, students often get frustrated finding themselves unable to run many different analyses and visualization quickly. In this presentation, a statistical scientist from JMP will illustrate how easy it can be to explore multi-dimensional data through interactive visualizations, analyses, and prediction models in a “no code” environment. The audience will see how this approach not only greatly expedites data analysis efforts, but provides students with a much richer and more engaging experience to learning analytics. The content presented is most relevant to: Professional (Mid-Career); Associate (Early Career); and Executive (Senior Level).

Summit - 448

Hexaly, a New Kind of Global Optimization Solver

Invited Session

Exhibitor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Dr Ste 200, Catonsville, MD, 21228, United States

1 - HEXALY, A New Kind of Global Optimization Solver

Fred Gardi, Hexaly, Brooklyn, NY, United States

Hexaly is a new kind of global optimization solver. Its modeling interface is nonlinear and set-oriented. It also supports user-coded functions, thus enabling black-box optimization and, more particularly, simulation optimization. In a sense, Hexaly APIs unify modeling concepts from mixed-linear programming, nonlinear programming, and constraint programming. Under the hood, Hexaly combines various exact and heuristic optimization methods: spatial branch-and-bound, simplex methods, interior-point methods, augmented Lagrangian methods, automatic Dantzig-Wolfe reformulation, column and row generation, propagation methods, local search, direct search, population-based methods, and surrogate modeling techniques for black-box optimization. Regarding performance benchmarks, Hexaly distinguishes itself against the leading solvers in the market, like Gurobi, IBM Cplex, and Google OR Tools, by delivering fast and scalable solutions to problems in the space of Supply Chain and Workforce Management like Routing, Scheduling-Packing-Clustering-Matching-Assignment-Location problems. For example, on notoriously hard problems like the Pickup/Delivery Problem with Time-Windows or Flexible Job Shop-Scheduling with Setup Times, Hexaly delivers solutions with a gap to the best solutions known in the literature smaller than 1% in a few minutes of running times on a basic computer. In addition to the Optimizer, we provide an innovative development platform called Hexaly Studio to model and solve rich Vehicle-Routing and Job-Shop Scheduling problems in a no-code fashion. The user can define its problem and data, run the Optimizer, visualize the solutions and key metrics through dashboards, and deploy the resulting app in the cloud – without coding. The content is most relevant to: Associate (Early Career), Professional (Mid-Career), and Executive (Senior Level).

Summit - 444

Linking Logistics Models: Combining ML and OR Through Ensembling and Horizontal Computing

Invited Session

Exhibitor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Dr Ste 200, Catonsville, MD, 21228, United States

1 - Linking logistics models: Combining ML and OR through ensembling and horizontal computing

Carolyn Mooney, Nextmv.io Inc, Philadelphia, PA, United States

Conceptually, the connection between machine learning (ML) and operations research (OR) is intuitive: order demand predictions feed into scheduling delivery operations, consumer buying behavior influences inventory management, and so on. But in practice, seamlessly blending the two disciplines can be more challenging than expected due to technical implementation and the ability to manage uncertainty. This interactive session will explore foundational ML and OR logistics models (forecasting, scheduling, routing, etc.) alongside the tooling and techniques to link, solve, and orchestrate them for real-world, operational settings. We will demonstrate ways to manage uncertainty, employ ensembling to aggregate multiple forecasts, run multiple model scenarios, and derive consensus across model output to feed downstream applications. Join us for an interactive session that will explore foundational logistics models, best practices for operations such as model testing and CI/CD, and tooling such as OR-Tools, Pyomo, HiGHS, Gurobi, AMPL, Statsmodels, Prophet, and more. This content is most relevant to Associate (Early Career); Professional (Mid-Career); and Executive (Senior Level).

Saturday, October 19, 4:00 PM - 6:30 PM

Introducing ChiAha – the Smart Manufacturing Digital Twin Toolkit

Invited Session

Exhibitor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Dr Ste 200, Catonsville, MD, 21228, United States

1 - Introducing ChiAha – the Smart Manufacturing Digital Twin Toolkit

Amber Siprelle, Chiaha.ai, Tallassee, TN, United States

ChiAha can predict production line performance and OEE within 1% accuracy. High-fidelity modeling constructs with statistically modeled data-driven behavior. Provide answers to many of the questions related to the design, operation and improvement of lines for optimum OEE. This content is most relevant to Associate (Early Career); Professional (Mid-Career); and Executive (Senior Level).

Summit - 444

What's New in Gurobi 12.0: Helping You to Build, Solve, and Deploy Optimization Models

Invited Session

Exhibitor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Dr Ste 200, Catonsville, MD, 21228, United States

1 - What's New in Gurobi 12.0: Helping You to Build, Solve, and Deploy Optimization Models

Xavier Nodet, Gurobi Optimization, LLC, Antibes, France, Gregory Glockner, Ed Klotz, Rodrigo Fuentes, Zed Dean, Maliheh Aramon

Our pre-conference workshop will cover a wide range of updates and practical tips, including a preview of new features that will be available with Gurobi 12.0, an overview of our new massive open online course (MOOC), and an interactive panel on GenAI and Optimization. Gurobi 12.0 Overview: This talk will provide a preview of notable features in the upcoming Gurobi 12.0 release. Besides the usual performance comparisons against previous releases, we will consider advances in the global MINLP solver that was first introduced in the current version, 11.0. These include direct support for compound multivariate nonlinear expressions that eliminate the need for users to create auxiliary variables and constraints. Major advances in the efficiency of the Web License Server will also be discussed, as well as other features that improve the usability of the optimizer. A Groundbreaking MOOC: We'll also be presenting a short overview of "Introduction to Optimization Through the Lens of Data Science," a groundbreaking massive-open online course (MOOC) developed by Gurobi in partnership with Dr. Joel Sokol, professor at Georgia Tech. This course provides a unique opportunity for anyone to enhance their skill sets and for educators to bring cutting-edge, practical knowledge into their classrooms. Panel–Generative AI and Optimization: The workshop will conclude with a panel discussion featuring optimization experts from across industries, academia, and Gurobi as they discuss generative AI and optimization. All attendees will receive a special Gurobi t-shirt. The content presented is most relevant to: Associate (Early Career); Professional (Mid-Career); and Executive (Senior Level).

Summit - 448

Littlefield 2.0: A New Version of the Online Game for Operations Management Courses

Invited Session

Exhibitor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Dr Ste 200, Catonsville, MD, 21228, United States

1 - Littlefield 2.0: A New Version of the Online Game for Operations Management Courses

Samuel Wood, Responsive Learning Techologies, Los Altos, CA, United States

After 25 years there is a new version of Littlefield! Littlefield is a competitive online simulation of either a factory or a medical laboratory that has been by more than half a million students in 500+ universities in 60+ countries to excite and engage students in operations management topics like process analysis and inventory control. This presentation will introduce a newly updated version 2 of the game that was released this past summer. Participants are encouraged but not required to bring a laptop. This content is most relevant to: Executive (Senior Level); Professional (Mid-Career); and Associate (Early Career).

Summit - 446

SAS Analytics

Invited Session

Exhibitor Workshop

Chair: Loraine Coleman, INFORMS, 5521 Research Park Dr Ste 200, Catonsville, MD, 21228, United States

1 - SAS Analytics

Yan Xu, SAS Institute, Cary, NC, United States, Rob Pratt, Laci Ladanyi, Bochuan Lyu

SAS offers extensive analytic capabilities, including machine learning, deep learning, natural language processing, statistical analysis, optimization, and simulation. SAS analytic functionality is also available through the open, cloud-enabled design of SAS® Viya®. You can program in SAS or in other languages – Python, Lua, Java, and R. SAS Analytics is equipped with AI-enabled automations and modern low-code or no-code user interfaces that democratize data science usage in your organization and offer unparalleled speed to value. We will first review the SAS analytics portfolio, then highlight recently added optimization features (including automated Benders decomposition and support for Pyomo and PuLP), and finally explore several case studies in optimization. The content presented is most relevant to Associate (Early Career); Professional (Mid-Career); and Executive (Senior Level).

Healthcare Data Analytics

Invited Session

Service Science

Chair: Mohammad Fili, Oklahoma State University, Stillwater, OK, United States

1 - Improving Menu Selection in Assisted Living Facilities by Considering Residents' Behavior

Sadan Kulturel-Konak, Penn State Berks, Reading, PA, United States

The proportion of the US population residing in assisted living facilities is steadily rising. Often, elderly individuals in these facilities depend solely on the meals provided to fulfill their nutritional requirements. Studies indicate that many seniors in assisted living have deficits in several crucial macro- and micronutrients, alongside overconsumption of sodium, fat, cholesterol, and saturated fat relative to their age demographic. This study is centered on devising nutritious menus for assisted living facilities while juggling multiple objectives and intricate nutritional limitations. The proposed approach considers a range of factors in menu development, encompassing USDA healthy eating guidelines, input from chefs based on their expertise and preferences, menu diversity, cost considerations, and the varying dietary needs and preferences of residents. One significant advancement over prior research lies in integrating individuals' menu selection behaviors, thereby enhancing the menus' practicality upon implementation and fostering a sense of autonomy among residents.

2 - Pain Quantification: A Novel Decision-Support System Benefitting from Multi-Attribute Decision-Making Techniques and Large Language Models

Mohammad Alipour Vaezi, Virginia Tech, BLACKSBURG, VA, United States, Kwokleung Tsui, Huaiyang Zhong

Historically, various approaches have been employed for pain assessment. Nevertheless, none of the existing methodologies can capture the comprehensive extent of the patient's pain due to their intrinsic limitations. In this research, for the first time in history, a novel approach is introduced for pain quantification considering various aspects of pain gathered from different sources to determine the real pain level of the patients suffering from acute or chronic pains. In this research, first, each pain assessment technique is reviewed, and its limitations are identified. Then, a novel method is conducted by integrating two Multi-Attribute Decision-Making (MADM) Techniques (Bayesian Best-Worst Method and Weighted aggregated sum product assessment) based on experts' opinions. The experts in this study include both humans (physicians) and artificial intelligence (Chat GPT 4 and Google Gemini). To validate the proposed method, it is applied to two different groups of patients suffering from acute (group I) and chronic (group II) pain as a real-life case study. The results indicate the reliability of the proposed approach for both groups. This research provides an interactive tool that can be helpful for every healthcare system in which patients are suffering from acute or chronic pain.

3 - GANCQR: Estimating Prediction Intervals for Individual Treatment Effects with GANs

Jiaxing Wang, North Carolina State University, Raleigh, NC, United States, Hong Wan, Xi Chen

Evaluating individual treatment effects (ITE) poses challenges due to the lack of access to counterfactuals, especially when dealing with biased data. Currently, there is a growing interest in harnessing the generative capabilities of Generative Neural Networks (GANs) and Variational Autoencoders (VAEs) for ITE estimation. However, few methods effectively tackle uncertainty quantification of the estimated ITE. In this work, we introduce GANCQR, a GAN-based conformal prediction approach aimed at providing prediction intervals of ITE with acceptable coverage. Numerical evaluations on synthetic and semi-synthetic datasets underscore GANCQR's superiority in handling datasets with selection bias compared to state-of-the-art methods.

1 - 4DYNAMO: Analyzing and Optimizing Process Parameters in 4D Printing for Dynamic 3D Shape Morphing Accuracy

Michael Biehler, Georgia Institute of Technology, Atlanta, GA, United States, Daniel Lin, Reinaldo Mock, Jianjun Shi

Additive manufacturing (AM), commonly referred to as 3D printing, has undergone significant advancements, particularly in the realm of stimuli-responsive 3D printable and programmable materials. This progress has led to the emergence of 4D printing, a fabrication technique that integrates AM capabilities with intelligent materials, introducing dynamic functionality as the fourth dimension. Among the stimuli-responsive materials, shape memory polymers have gained prominence, notably for their crucial applications in stress-absorbing components. However, the exact 3D shape morphing of 4D printed products is affected by both the 3D printing conditions as well as the stimuli activation. Hence it has been hard to precisely control the 3D shape morphing accuracy. To model and optimize the dynamic 3D evolution of the 4D printed parts, we conducted both simulation studies and real-world experiments and introduced a novel machine-learning approach extending the concept of normalizing flows. This method not only enables the process optimization of the dynamic 3D profile evolution by optimizing the process conditions during 3D printing and stimuli activation but also provides interpretability for the intermediate shape morphing process. This research contributes to a deeper understanding of the nuanced interplay between process parameters and the dynamic 3D transformation process in 4D printing.

Naichen Shi, University of Michigan, Ann Arbor, MI, United States, Hao Yan, Shenghan Guo, Raed Al Kontar

coming soon

3 - Real-time Transfer Active Learning for Functional Regression and Prediction based on Multi-output Gaussian Process

Zengchenghao Xia, University of Iowa, Iowa City, IA, United States, Zhiyong Hu, Qingbo He, Chao Wang

Active learning provides guidance for the design and modeling of systems with highly expensive sampling costs. However, existing active learning approaches suffer from cold-start concerns, where the performance is impaired due to the initial few experiments designed by active learning. In this paper, we propose using transfer learning to solve the cold-start problem of functional regression by leveraging knowledge from related and data-rich signals to achieve robust and superior performance, especially when only a few experiments are available in the signal of interest. More specifically, we construct a multi-output Gaussian process (MGP) to model the between-signal functional relationship. This MGP features unique innovations that distinguish the proposed transfer active learning from existing works: i) a specially designed covariance structure for characterizing within-and between-signal inter-relationships and facilitating interpretable transfer learning, and ii) an iterative Bayesian framework to update the parameters and prediction of the MGP in real-time, which significantly reduces the computational load and facilitates the iterative active learning. The inter-relationship captured by this novel MGP is then fed into active learning using the integrated mean-squared error (IMSE) as the objective. We provide theoretical justifications for this active learning mechanism, which demonstrates the IMSE is monotonically decreasing as we gather more data. The real-time updating and the monotonically decreasing objective together provide both practical efficiency and theoretical guarantees for solving the cold-start concern in active learning. The proposed method is compared with benchmark methods through various numerical and real case studies, and the results demonstrate the superiority of the method.

4 - Spatial In-Profile Monitoring via Latent Tensor-variate Gaussian Process with Mixed Effects

Peiyao Liu, Tsinghua University, Beijing, China, People's Republic of, Chen Zhang

Nowadays advanced sensing technology enables real-time data collection in two or higher-dimensional coordinate systems, known as spatial profiles. These data have attracted significant efforts toward anomaly detection and quality control in manufacturing. However, most of the existing monitoring methods face detection delays as they require complete profiles before implementation. To accommodate the sequential nature of the data, Gaussian Process (GP) modeling offers a promising approach. Yet, the high-dimensional covariance matrix associated with densely sampled spatial profiles pose challenges in estimation accuracy. Additionally, they often treat spatial locations as the GP inputs, neglecting numerous latent factors involved in the generation of spatial profiles. This article proposes an in-profile monitoring (INPOM) control chart for spatial profiles based on a latent tensor-variate GP with mixed effects (LTGP-ME) model. The random effects component is constructed by a LTGP, which preserves the multiway structure of spatial profiles in the tensor domain while capturing underlying nonlinear variations through latent factors. Fixed effects component can be further incorporated to capture the relationship between spatial profiles and input variables. We develop an expectation maximization algorithm for parameter estimation, exploring model identifiability and convergence properties. Based on the prediction errors of LTGP-ME, a Hotelling T^2 statistic is further constructed for INPOM. The effectiveness and applicability of the proposed approach are demonstrated through extensive simulation studies and a real case study in additive manufacturing.

Knowledge Fusion for Modeling and Decision-making in Complex Systems

Invited Session

Quality, Statistics and Reliability

Chair: Shancong Mou, Georgia Institute of Tehnology/University of Minnesota Twin Cities, Minneapolis, MN, United States

1 - Local Transfer Gaussian Process for Surrogate Modeling of Expensive Computer Simulators

XINMING WANG, Peking University, Beijing, China, People's Republic of, John Miller, Jianguo Wu, Simon Mak

A critical bottleneck for scientific progress is the costly nature of computer simulations for complex systems. Surrogate models provide an appealing solution: such models are trained on simulator evaluations, then used to emulate and quantify uncertainty on the expensive simulator at unexplored inputs. In many applications, one often has available data on related systems. For example, in designing a new jet turbine, there may be existing studies on turbines with similar configurations or geometries. A key question is how to transfer information from such ``source" systems for effective surrogate training on the ``target" system. We thus propose a new LOcal transfer Learning Gaussian Process (LOL-GP) model, which leverages a carefully-designed GP to transfer such information for surrogate modeling. The key novelty of the LOL-GP is the use of a data-learned regularization model, which learns regions where transfer should be performed and where it should be avoided. This ``local transfer" property is desirable in scientific systems: for certain parameters, the systems may behave similarly and thus transfer is beneficial; for others, the systems may be considerably different and thus transfer is detrimental. In accounting for local transfer, the LOL-GP can remedy an important limitation of ``negative transfer" in existing transfer learning models, where the transfer of information worsens predictive performance. We derive a Gibbs sampling algorithm for efficient posterior predictive sampling on the LOL-GP. We then show, via a suite of numerical experiments and an application to jet turbine design, the improved surrogate performance of the LOL-GP over the existing state-of-the-art.

2 - Uni-3Dad: Gan-Inversion Aided Universal 3D Anomaly Detection on Model-Free Products

Jiayu Liu, Rensselaer Polytechnic Institute, Troy, NY, United States, Shancong Mou, Yinan Wang

Anomaly detection is a long-standing challenge in manufacturing systems, which aims to identify the location of surface defects and critically impact product quality. 3D point clouds have started to attract practitioners’ attention due to their robustness to environmental factors and

capability of geometric representation. The existing 3D anomaly detection lies in two branches. One line of work directly compares the scanned 3D point cloud with the design file, which assumes the design file is always available. However, there are many model-free products, such as fresh produce (i.e., cookies, bagels, potatoes), dentures, etc. The other line of work is to compare the patches of scanned 3D point clouds with a dictionary of normal patches. However, when detecting incomplete shapes of the target product (i.e., missing pieces of cookie and denture), there is no representation of the missing regions in the collected 3D point cloud due to the nature of 3D scanning, which fails the existing methods of identifying such type of anomaly. To resolve these two challenges, we proposed a unified, unsupervised 3D anomaly detection framework for model-free products. Specifically, GAN-inversion is firstly adapted in the 3D anomaly detection to accurately identify the missing regions. In addition, the One-class Support Vector Machine is tailored to fuse the detection results from feature-based and GAN-inversion-based branches. The results demonstrated that (1) our proposed method receives comparable performance with the state-of-the-art (SOTA) methods on detecting anomalies except for incomplete shapes and (2) it outperforms the SOTA methods on identifying incomplete shapes.

3 - Classifying Phase Behavior of Soft Materials using Spectral Data

Xuerui Song, Virginia Tech, Blacksburg, VA, United States

Understanding soft material composition-phase-property relations is essential for predicting material processability and part quality, such as for additive manufacturing and biomanufacturing applications using hydrogels. This work is driven by the challenge of predicting the composition-phase-mechanical property relation data for hydrogels using spectral data generated by autonomous experimentation (AE) workflows. While AE workflows can efficiently generate spectral data, the data quality and characteristics are material- and application-dependent. We hypothesize that deep learning can help address the challenges of classifying spectral data that exhibit variance in signal-to-noise ratio, sparsity, and class imbalance, which are common to practical experimental applications. Here, we examine the performance of a one-dimensional Convolutional Neural Network (1D-CNN) for understanding and predicting the phase behavior of sustainable α-cyclodextrin (α-CD) hydrogels using impedance spectra data from piezoelectric cantilever sensors. Spectral data dimensionality was first reduced using principal component analysis (PCA) followed by clustering algorithms, identifying the spectral data labels and class distribution (i.e., solid, transition, or liquid states). The unsupervised learning studies indicated that α-CD hydrogels exhibited a third class associated with a 'transition' region in the gel mechanical properties. Supervised learning with a 1D-CNN model outperformed traditional non-deep methods with respect to prediction accuracy and precision. This work highlights the applicability and effectiveness of 1D-CNN models to overcome challenges of classifying spectral data generated in practical sensing and AE-driven materials science and chemistry applications and advances our understanding of the composition-phase-property behavior of a sustainable hydrogel

4 - Spatio-temporal modeling and its applications to extreme environmental processes

Guanzhou Wei, Georgia Institute of Technology, Atlanta, GA, United States, Xiao Liu

In this presentation, we showcase two wildfire applications using the advanced spatio-temporal models. In the first application, motivated by the significant impacts of wildfire aerosols on solar energy production, we propose a physics-informed statistical modeling approach for wildfire aerosol propagation using heterogeneous satellite remote sensing data streams. The model has successfully integrated multi-source remote sensing data streams with the underlying physical advection-diffusion process and is able to handle the heterogeneity among multi-source data streams (e.g., missing data, systematic biases, etc.). In the second application, to quantify the wildfire risks for the power delivery infrastructures, we develop a new spatio-temporal point process model, known as the Convolutional Non-homogeneous Poisson Process (cNHPP) on linear networks. This model incorporates both the topology of power delivery networks and the cumulative effects of real-time environmental factors, surpassing the performance of conventional NHPP models.

5 - Multistage Net: Learning Continuous Multistage Manufacturing Processes of Liquid Products without Intermediate Output and Lead Time Labels

Chiehyeon Lim, Ulsan National Institute of Science and Technology (UNIST), Ulsan, Korea, Republic of

Manufacturers have implemented the continuous multistage manufacturing processes (MMPs), in which raw materials are processed through multiple stages without interruptions, based on efficiency and flexibility compared to discrete MMPs. While there are numerous methods of using machine learning to estimate conditions and outputs of manufacturing processes, applying this approach to continuous MMPs of liquid products is challenging for the following reasons: First, obtaining intermediate output labels is very difficult because the process is originally designed to operate without interruptions. Second, determining lead times between stages is also difficult for liquid products, which are mixed between stages during production. To address these challenges, we propose "Multistage Net," a novel machine learning model designed for continuous MMPs of liquid products. Multistage Net is composed of several "interstage blocks" organized in a hierarchical structure within a "multistage module", with these modules being stacked in the model. The interstage block captures sequential dependency between previous and current stages without requiring intermediate output and concurrently explores lead-time relationship via attention and gated mechanisms. The multistage module effectively learns the sequential nature of MMPs across all stages without requiring intermediate outputs through interconnected interstage blocks. Validation studies on liquid sugar and lube base oil manufacturing with real-world datasets demonstrate the superior performance of Multistage Net compared to existing models, showing its effectiveness in both production yield forecasting and quality prediction tasks. Further analyses not only confirm the exclusive utilities of components within Multistage Net but show it delivers impressive performance without need for lead time labels.

1 - Federated Automatic Latent Variable Selection in Multi-output Gaussian Processes

Jingyi Gao, University of Virginia, Charlottesville, VA, United States, Seokhyun Chung

This paper explores a federated learning approach that automatically selects the only necessary number of latent processes in multi-output Gaussian processes (MGPs). The MGP has seen great success as a transfer learning tool when data is generated from multiple sources/units/entities. A common approach in MGPs to transfer knowledge across units involves gathering all data from each unit to a central server and extracting common independent latent processes to express each unit as a linear combination of the shared latent patterns. However, this approach poses key challenges in (i) determining the adequate number of latent processes and (ii) centralized learning which leads to potential privacy risks and significant computational burdens on the central server. To address these issues, we propose a hierarchical model that places spike-and-slab priors on the coefficients of each latent process. These priors help automatically select only needed latent processes by shrinking the coefficients of unnecessary ones to zero. To facilitate federated inference, we propose a variational inference-based approach, formulating model inference as an optimization problem compatible with federated learning algorithms. This approach allows units to jointly select and infer the common latent processes without sharing their data. We also discuss an efficient learning approach for a new unit within our proposed federated framework. Simulation and the case studies on Li-ion battery capacity degradation and air temperature data demonstrate the advantageous features of our proposed approach.

2 - A General Second-Order Augmented Primal-Dual Framework for Distributed Optimization

Runxiong Wu, University of Wisconsin, Madison, Madison, WI, United States, Andi Wang

We develop a general second-order augmented primal-dual method for distributed optimization, specifically designed for problems where the objective function is composed of a strongly convex twice differentiable term and a possibly non-differentiable convex regularizer. Our approach leverages the proximal operator of the regularizer to transform the augmented Lagrangian of the dual problem into a novel minimax optimization problem, making it highly suitable for distributed optimization algorithms. By incorporating a generalization of the Hessian, we define second-order updates that enhance the convergence rates and solution quality. We demonstrate the efficiency and robustness of our method, even when dealing with non-smooth regularizers such as the ℓ_1 penalty. To improve practical applicability, we employ a line search strategy to automatically tune the step sizes, which incurs no additional communication overhead. Extensive experiments on real distributed datasets validate our framework, showing significant performance improvements over state-of-the-art methods. Our results highlight the framework's ability to handle complex optimization problems efficiently, making it a valuable tool for researchers and practitioners in distributed optimization.

3 - Domain-Informed Reinforcement Learning for Multi-Component Preventive Maintenance Planning under Economic Dependence

Jaesung Lee, Texas A&M University, College Station, TX, United States, Tatthapong Srikitrungruang, Salman Jahani

Many engineering systems consist of multiple components working simultaneously. These components undergo gradual and irreversible degradation, leading to failure, at varying rates. Preventive maintenance is essential to mitigate these failures and reduce costs.
In multi-component systems, maintenance actions are economically interdependent, influenced by factors such as operational shutdowns and shared labor, resulting in high setup costs.
Our goal is to identify an optimal preventive maintenance policy that minimizes total costs in multi-component systems with economic dependence, where each component degrades stochastically at randomly varying speeds.
Preventive maintenance in multi-component systems is challenging, as the action space grows exponentially with the number of components, further complicated by economic dependencies.
Existing decision-making methods, including deep reinforcement learning, fall short in addressing such challenges.
Naturally, most studies have considered a single or a few components in a system for maintenance planning.
To bridge this gap, we introduce a domain-informed reinforcement learning approach, integrating domain knowledge via a sparsity-enhanced stochastic hierarchical policy and reward shaping with Bayesian degradation predictions.
Our carefully designed policy function successfully characterizes the sporadic nature of maintenance events.
Extensive numerical studies and a real-world case study on frying machines demonstrate the significant benefits and substantial cost savings of our method.

INFORMS JFIG Best Paper Competition II

Award Session

Junior Faculty Interest Group

Chair: Albert Berahas, University of Michigan, Ann Arbor, MI, United States

1 - Incentivizing Resource Pooling

Chen Chen, New York University Shanghai, Shanghai, China, People's Republic of

Resource pooling improves system efficiency drastically in large stochastic systems, but its effective implementation in decentralized systems remains relatively underexplored. This paper studies how to incentivize resource pooling when agents are self-interested, and their states are private information. Our primary motivation is applications in the design of decentralized computing markets, among others. We study a standard multi-server queueing model in which each server is associated with an M/M/1 queue and aims to minimize its time-average job holding and processing costs. We design a simple token-based mechanism where servers can earn tokens by offering help and spend tokens to request help from other servers, all in their self-interest. The mechanism induces a complex game among servers. We employ the fluid mean-field equilibrium (FMFE) concept to analyze the system, combining mean-field approximation with fluid relaxation. This framework enables us to derive a closed-form characterization of servers' FMFE strategies. We show that these FMFE strategies approximate well the servers' rational behavior. We leverage this framework to optimize the design of the mechanism and present our main results: As the number of servers increases, the proposed mechanism incentivizes \emph{complete} resource pooling---that is, the system dynamics and performance under our mechanism match those under centralized control. Finally, we show that our mechanism achieves the first-best performance even when helping others incurs higher job processing costs and remains nearly optimal in settings with heterogeneous servers.

2 - Sample Complexity of Inventory Control with Setup Costs Beyond Plug-in Demand Estimation

Xiaoyu Fan, Stern School of Business, New York University, New York, NY, United States

We show in this work that a class of structured MDPs admits more efficient learning (i.e., lower sample complexity bounds) compared to the best possible/known algorithms in generic RL. We focus on the MDPs describing the inventory control system with fixed ordering costs, a fundamental problem in supply chains. We develop an algorithm applied to the inventory MDPs, which leads to strictly lower sample complexity bounds compared to the optimal or best-known bounds recently obtained for the general MDPs. We improve on those ``best-possible'' bounds by carefully leveraging the structural properties of the inventory dynamics in various settings.

3 - Designing Payments Models for the Poor

Bhavani Shanker Uppari, Singapore Management University, Singapore, Singapore, Sasa Zorc

Several basic services, such as energy, clean water and cooking gas, are currently out of reach for millions of people living in poverty. There has been an emergence of private firms that offer these services by, for example, selling solar home systems or clean cooking packages with remote lockout capabilities. These firms deploy a pay-as-you-go model in which consumers are given the flexibility to manage the amount and frequency of their payments based on their own erratic cash flows. However, because a firm under this model cannot observe how much money the consumers have, they can pay less to the firm and turn their income to other needs. We employ an optimal contracting approach to investigate the incentives that can mitigate such misuse of payment flexibility.

Location Analysis for Electric Vehicle Charging

Invited Session

Location Analysis

Chair: Ibrahim Capar, University of North Carolina Wilmington, Bowling Green, OH, United States

1 - Improving Disadvantaged Communities by Locating EV Chargers

Ibrahim Capar, University of North Carolina Wilmington, Wilmington, NC, United States, Michael Lash, Ozgur Araz

In this research, we investigate some of the characteristics of disadvantaged communities defined by the “Justice 40” initiative. Justice 40 is a US Federal Program to improve communities around the US by allocating forty percent of a certain Federal Investment. By analyzing historical data, we explore the impact of setting up EV charging locations on disadvantaged communities. Finally, we formulate a mathematical model to maximize EV coverage while selecting disadvantaged communities.

2 - Location-allocation problem with semi-discrete optimal transport

Nanshan Chen, The Ohio State University, Columbus, OH, United States, Cathy Xia, Guzin Bayraksan

Solving facility location-allocation problems in modern transportation settings can be computationally challenging when the demand is dense. We formulate the allocation problem as a semi-discrete optimal transport (OT) problem under a continuous demand density. We then develop a decomposition algorithm combined with Stochastic Gradient Descent (SGD) to solve the two-stage location-allocation problem. We demonstrate the efficiency of our approach in the context of micro-transit services. The applications can be easily extended to EV charging stations and E-Scooter rental stations.

3 - Integrating Intermediate and Destination Charging to Enhance Electrification for Lake Michigan Circuit Tourism Trips

Amirali Soltanpour, Michigan State University, East Lansing, MI, United States, Alireza Rostami, Mehrnaz Ghamami, Ali Zockaie

This study focuses on developing electric vehicle (EV) charging infrastructure within the Lake Michigan area, aiming to provide convenient and efficient charging options, particularly for tourists. The primary objective is to devise an integrated, cost-effective, and convenient charging network to enhance ecotourism within this region. To achieve this, a framework is proposed to integrate and optimize both Level-2 and Direct Current Fast Charging (DCFC) networks. The Level-2 network planning incorporated a 4-step modeling approach including estimations of EV and energy demand, and charger allocation. Conversely, the DCFC network planning considers charging buffer ranges and an algorithm for assigning EVs to charging stations, stochastic queuing delays, and realistic charging behavior for tourism purposes. The Level-2 problem is solved using both mixed-integer linear programming and heuristic approaches, while the DCFC solution approach is proposed based on simulated annealing, dynamic penalty methods, and two-stage decision-making techniques. The study explores intricate trade-offs between capital investment and user costs, and reveals that budget constraints significantly affect infrastructure allocation and user experience. The study suggests dedicating a minimum of 30% of the budget to the DCFC network to maintain an acceptable level of service. An optimal allocation of 60% of the budget to Level-2 charging and 40% to DCFC can effectively meet energy demands and proves to be the most cost-efficient configuration. Overall, the study offers actionable guidance for creating a resilient and user-focused charging infrastructure in the Lake Michigan Circuit area, contributing to the region’s sustainable development and tourism industry growth.

4 - CAST: A Correlation-based clustering-Assisted Sparse auToregressive model based on Lasso

Muting Ma, University of Alabama, Tuscaloosa, AL, United States, Mesut Yavuz, Matthew Hudnall, Qin Wang

We address an electric vehicle (EV) adoption prediction model for charging station planning. Based on the Least Absolute Shrinkage and Selection Operator (Lasso), the prediction model can accurately estimate future EV adoption at a core-based statistical area (CBSA) granularity level. One of the predictors is the public charging station density (#/square miles). Given the historical density and the predicted

EV adoption, future charging station planning can be advised. We test the spatial discrepancy between the expected station density and the density of newly constructed ones in 2023.

5 - Optimizing Urban Infrastructure Planning for Electric Vehicles Considering Stochastic User Charging Behavior

Alireza Rostami, Michigan State University, East Lansing, MI, United States, Ali Azockaie, Mehrnaz Ghamami, Amirali Soltanpour

The rapid adoption of electric vehicles (EVs) presents a promising avenue for reducing fossil fuel dependency and mitigating the environmental impacts of transportation systems. However, many major cities still lack adequate charging infrastructure to support the mass adoption of EVs for urban trips. Existing research on charging infrastructure planning often oversimplifies user charging behavior by assuming charging events occur only when a user's state of charge drops below a minimum threshold, overlooking the complexities and stochastic nature of user charging patterns. This study proposes an innovative approach to model the spatiotemporal decision-making of EV users during public charging and assess its impact on optimal charging infrastructure configuration. Since urban travel is usually a part of trip chains, EV users can have a wide range of options on where and when to charge their vehicles. This study considers dynamic factors such as charging price, trip urgency, proximity to the station, and state of charge to influence users' decision-making process. The study adopts a solution approach based on simulated annealing to minimize charging station placement cost and EV users' time and cost spent during public charging. To model users' daily activities, trip schedules, and traffic flows, this research adopts the agent-based transportation model of POLARIS. The proposed framework is applied to the Chicago regional area network, considering various EV ownership and charging behavior scenarios. The results of this study provide valuable guidance for policymakers in designing efficient charging infrastructure that captures users' charging behavior to support the widespread adoption of electric vehicles.

1 - Robotic Sorting Systems: Robot Management and Layout Design Optimization

Tong Zhao, Tsinghua University, Beijing, China, People's Republic of, Xi Lin, Fang He, Hanwen Dai

In the contemporary logistics industry, automation plays a pivotal role in enhancing production efficiency and expanding industrial scale. Autonomous mobile robots, in particular, have become integral to the modernization efforts in warehouses. One noteworthy application in robotic warehousing is the robotic sorting system (RSS), distinguished by its characteristics such as cost-effectiveness, simplicity, scalability, and adaptable throughput control. While previous research has focused on analyzing the efficiency of RSS, it often assumed an ideal robot management system ignoring potential queuing delays by assuming constant travel times. This study relaxes this assumption and explores the quantitative relationship between RSS configuration parameters and system throughput. We introduce a novel robot traffic management method, named the rhythmic control for sorting scenario (RC-S), for RSS operations, equipped with an estimation formula establishing the relationship between system performance and configurations. Simulations validate that RC-S reduces average service time by 10.3% compared to the classical cooperative A* algorithm, while also improving throughput and runtime. Based on the performance analysis of RC-S, we further develop a layout optimization model for RSS, considering RSS configuration, desired throughput, and costs, to minimize expenses and determine the best layout. Numerical studies show that at lower throughput levels, facility costs dominate, while at higher throughput levels, labor costs prevail. Additionally, due to traffic efficiency limitations, RSS is well-suited for small-scale operations like end-of-supply-chain distribution centers.

2 - An Examination of Artificial Intelligence Technologies for Healthcare

Shuyu Lai, Westwood High School, Austin, TX, United States

By leveraging vast amounts of data and efficient learning methods, artificial intelligence (AI) equips machines with human-like intelligence and problem-solving capabilities. Within the healthcare industry, AI presents unique opportunities to assist medical professionals in various aspects, including interacting with patients, collecting information, interpreting medical images, diagnosing medical conditions, and proposing treatment plans. This study delves into these roles, offering a comprehensive review of the latest AI applications and research in healthcare. It demonstrates AI's potential to enhance both efficiency and quality in healthcare delivery, while also highlighting avenues for further research and practical implementation.

3 - RecoCheC: Enhancing Employee Health with Personalized Check-Up Recommendations via Machine Learning

Siwapol Techaratsami, Carnegie Mellon University, Pittsburgh, PA, United States, Saranya Thongsawaeng, Jidapa Hanvoravongchai, Napatsorn Thewaran, Piyawat Kantagowit, Krit Pongpirul

RecoCheC represents a breakthrough in personalized healthcare, leveraging advanced machine learning algorithms to optimize health check-up recommendations based on historical health data. As healthcare costs continue to rise and the demand for personalized medical care increases, RecoCheC offers a strategic, data-driven solution to enhance the effectiveness and efficiency of health assessments.

Utilizing a robust dataset collected from mobile health services over a six-year period (2016-2022), which includes 7,518 records of 3,198 individuals (average 3.4 follow-up years, age 39.3±9.6 years old, male 29.3%) across seven different business entities, RecoCheC integrates demographic and biometric data with historical health outcomes. This innovative platform prioritizes health check-up items through the Individual Historical Lab Score (IHLS), demonstrably outperforming traditional methods based solely on prevalence data or randomized approaches.

The efficacy of RecoCheC was rigorously tested using a Receiver Operating Characteristic (ROC) curve, achieving an impressive Area Under the Curve (AUC) of 0.82. This performance significantly surpasses that of the prevalence model (AUC = 0.77) and the baseline model (AUC = 0.50), underscoring RecoCheC's superior capability in tailoring health check-up schedules to individual needs, thereby potentially reducing unnecessary procedures and focusing resources more effectively.

RecoCheC not only promises significant benefits for individual users but also offers substantial implications for healthcare policy by suggesting a scalable model for reducing overall healthcare expenditures while improving outcomes. The platform's application extends beyond individual health management to include optimizing corporate health strategies, marking a significant advance in the application of machine learning in healthcare.

4 - Generalized Machine Learning Models for Forecasting Extended Length of Stay in Hospitals: Insights from Nationwide Data

Marzieh Amiri Shahbazi, RIT, Rochester, NY, United States, Nasibeh Azadeh Fard

In hospitals, the length of time patients stays (known as "length of stay" or LOS) is an important health outcome metric. LOS can help to analyze the patient’s level of illness, healthcare resource usage, and hospital efficiency. Typically, hospitals categorize patients into cohorts based on their illness or treatment to estimate how long they will stay. However, this method can make it difficult to accurately predict LOS for everyone. Therefore, we aim to develop a new approach that can predict LOS effectively for all patients, regardless of their circumstances. Using different machine learning techniques, we analyze a nationwide dataset with various patient information, such as age, demographics, clinical characteristics, comorbidities, treatment procedures, and hospital-specific factors. By incorporating this information, our goal is to develop and validate a generalized LOS prediction model.

5 - IVExplorer: Interactive Exploration of Causality within Causal Graphs

Ye Ji Chun, Seoul National University, Seoul, Korea, Republic of, Hyunwoo Park

The paper presents an IVExplorer, an interactive visualization system specialized for exploring the causal effect between a given dependent and independent variable. Finding causal effects within a regression equation is an extremely frequent as well as crucial task in many business, economic, and social analysis. One of the most popularly used methods to investigate the causal effect between social variables is using an instrumental variable, which aims to capture the causal effect that x has on y, is assumed to be related with y only through the effect of the independent variable x and only aims to capture the effect x has on y. However, according to Linear Structural Causal Models in the field of causal inference, the causal effect that variable x has on y can be derived through the regression coefficient equation depending on the causal graph of the covariates. The IVExplorer allows the user to create various causal graphs which generates a regression model that calculates the causal effect of variable x on y given the causal graph. By incorporating the causal inference theory to investigate causal effects in social or business analysis, we introduce an intuitive and interactive interface to support decision making for social analytics.

1 - Deep Ritz Method with Fourier Feature Mapping: a Deep Learning Approach for Solving Variational Models of Microstructure

Ensela Mema, Kean University, Union, NJ, United States, Ting Wang, Jaroslaw Knap

This work presents a novel approach that combines the Deep Ritz Method (DRM) with Fourier feature mapping to solve minimization problems comprised of multi-well, non-convex energy potentials. These problems present computational challenges as they lack a global minimum. Through an investigation of three benchmark problems in both 1D and 2D, we observe that DRM suffers from spectral bias pathology, limiting its ability to learn solutions with high frequencies. To overcome this limitation, we modify the method by introducing Fourier feature mapping. This modification involves applying a Fourier mapping to the input layer before it passes through the hidden and output layers. Our results demonstrate that Fourier feature mapping enables DRM to generate high-frequency, multiscale solutions for the benchmark problems in both 1D and 2D, offering a promising advancement in tackling complex non-convex energy minimization problems.

2 - Neural Network Cryptography

Lubjana Beshaj, Army Cyber Institute at West Point, West Point, NY, United States

A number of research papers have been published using the architecture of adversarial neural networks to prove that communication between two neural nets based on synchronized input can be achieved, and without knowledge of this synchronized information these systems cannot be breached. In this paper we will try to evaluate these adversarial neural net architectures when a third party gains access to a partial or noisy secret key, has knowledge about a loss function or loss values, or activation functions used during the training of encryption layers. We explore the cryptanalysis side of it in which we will focus on vulnerabilities a neural net-based cryptography network can face. This can be used in the future to improve the current neural net-based cryptography architectures. In this paper we show that while the encryption key is necessary to decrypt the messages in a neural network domain, the adversarial neural networks can occasionally decrypt messages or raise a concern which will require further training.

3 - Bayesian Networks for Predicting Cyber Actor Behaviors

Alicia Bridges, ITA International, LLC, Dayton, MD, United States, Dennis Buede, Charles Burdick

Imagine having a crystal ball to tell you what an adversary's next move might likely be, so that you could prepare to defend against those possible actions. Far too many adversaries target unsuspecting organizations, businesses and other entities with vulnerabilities in their IT networks and are successful at gaining access. Possibly, this is followed by exfiltration of data or worse, launching ransomware attacks that bring their operations to a screeching halt. However, the exploits of many of the cyber actors can be studied as a pattern of behaviors (human or otherwise) and modeled to identify the likely, often repeated steps employed. The ordered attack steps can be arranged into a Bayesian network, which is a probabilistic model where the steps are nodes connected by edges that represent their conditional probabilities via a directed acyclic graph. Through Bayesian network analysis, we can explore modeling the step-by-step patterns of attack behaviors of cyber adversaries and use observed trends in real attacks as a proxy for the probability of those steps occurring and sometimes, given explicit conditions. The steps themselves are represented by the tactics, techniques and procedures (TTPs) that adversaries perform. Through this type of exploratory analysis, entities can use predictive analysis, following the principals of Bayesian analysis, to prepare for predicted cyber behaviors and better defend their networks.

4 - Text Document Triage Using Semantic Embedding, Clustering and Topic Labeling

Kyle Bender, USAF, Baltimore, MD, United States

In this research, we delve into the exploration of advancements in the field of document semantic embedding and clustering techniques. These techniques are pivotal in understanding and interpreting large volumes of data, particularly in the context of sentiment analysis. We further investigate the role of topic labeling, a crucial component in the organization and categorization of data, which aids in the extraction of meaningful insights. The application of these advanced techniques allows for the creation of a hierarchical, two-dimensional visual representation, essentially a canvas that visually maps and organizes data. This visual representation serves as a powerful tool for efficient data analytics, enabling quicker and more accurate interpretation of complex data sets. Our exploration is aimed at broadening the usage of these techniques, with a particular focus on their application in military analysis.

5 - Resilience Measurement for Security Organizations

Paul Goethals, Department of Defense, Columbia, MD, United States

The study of organizational resilience brings with it a host of complexities in derivation, application, interpretation, and perhaps most of all, measurement. The concept has grown significantly in popularity over the last 25 years. Achieving greater resilience is tied closely to increased sustainability and durability; for defense-minded organizations, this translates to higher levels of survivability and adaptability, as well as diminished degrees of risk. This work examines the problem of measuring organizational resilience either in quantitative or qualitative terms through an investigation of various models in the literature. An argument is then presented for ‘why’ challenges exist in establishing such measurement frameworks. Alternative methods for measuring organizational resilience are subsequently offered with explanations on use and their interpretation. The observations and findings tied to this study may be used to further inform efforts in decision analysis or metrics formulation where resilience is a primary attribute of interest.

1 - Optimal Stopping with Interdependent Values

Divyarthi Mohan, Boston University, Tel Aviv University, Boston, MA, United States

We study online selection problems in both the prophet and secretary settings, when arriving agents have interdependent values. In the interdependent values model, introduced in the seminal work of Milgrom and Weber [1982], each agent has a private signal and the value of an agent is a function of the signals held by all agents. Results in online selection crucially rely on some degree of independence of values, which is conceptually at odds with the interdependent values model. For prophet and secretary models under the standard independent values assumption, prior works provide constant factor approximations to the welfare. On the other hand, when agents have interdependent values, prior works in Economics and Computer Science provide truthful mechanisms that obtain optimal and approximately optimal welfare under certain assumptions on the valuation functions. We bring together these two important lines of work and provide the first constant factor approximations for prophet and secretary problems with interdependent values. We consider both the algorithmic setting, where agents are non-strategic (but have interdependent values), and the mechanism design setting with strategic agents. All our results are constructive and use simple stopping rules.

2 - Pareto-Optimal Algorithms for Learning in Games

Eshwar Ram Arunachaleswaran, University of Pennsylvania, Philadelphia, PA, United States

We study the problem of characterizing optimal learning algorithms for playing repeated games against an adversary with unknown payoffs. In this problem, the first player (the learner) commits to a learning algorithm against a second player (the optimizer), and the optimizer best-responds by choosing the optimal-dynamic strategy for their payoff. Classic learning algorithms provide some counterfactual guarantees for the learner, but might perform much more poorly than other learning algorithms against particular optimizer payoffs. In this paper, we introduce the notion of asymptotically Pareto-optimal learning algorithms. Intuitively, if a learning algorithm is Pareto-optimal, then there is no other algorithm which performs asymptotically at least as well against all optimizers and performs strictly better (by at least $\Omega(T)$) against some optimizer. We show that well-known no-regret algorithms such as Multiplicative Weights and Follow The Regularized Leader are Pareto-dominated. However, while no-regret is not enough to ensure Pareto-optimality, we show that a strictly stronger property, no-swap-regret, is a sufficient condition for Pareto-optimality. Proving these results requires us to address various technical-challenges specific to repeated play, including the fact that there is no simple characterization ofhow optimizers who are rational in the long-term best-respond against a learning algorithm over multiple rounds of play. To address this, we introduce the idea of the asymptotic menu of learning algorithm: the convex closure of all correlated distributions over strategy profiles that are asymptotically implementable by an adversary. Interestingly, we show that all no-swap-regret algorithms share the same asymptotic menu, implying that all no-swap-regret algorithms are ``strategically-equivalent''.

3 - Efficient Prior-Free Mechanisms for No-Regret Agents

Natalie Collina, University of Pennsylvania, Philadelphia, PA, United States

We study a repeated Principal Agent problem between a long lived Principal and Agent pair in a prior free setting. In our setting, the sequence of realized states of nature may be adversarially chosen, the Agent is non-myopic, and the Principal aims for a strong form of policy regret. Following Camara, Hartline, and Johnson, we model the Agent's long-run behavior with behavioral assumptions that relax the common prior assumption (for example, that the Agent has no swap regret). Within this framework, we revisit the mechanism proposed by Camara et al., which informally uses calibrated forecasts of the unknown states of nature in place of a common prior. We give two main improvements. First, we give a mechanism that has an exponentially improved dependence (in terms of both running time and regret bounds) on the number of distinct states of nature. To do this, we show that our mechanism does not require truly calibrated forecasts, but rather forecasts that are unbiased subject to only a polynomially sized collection of events -- which can be produced with polynomial overhead. Second, in several important special cases -- including the focal linear contracting setting -- we show howto remove strong ``Alignment'' assumptions by specifically deploying ``stable'' policies that do not have any near ties that are payoff relevant to the Principal. Taken together, our new mechanism makes the compelling framework proposed by Camara et al. much more powerful, now able to be realized over polynomially sized state spaces, and while requiring only mild assumptions on Agent behavior.

4 - Algorithmic Precision and Human Decision: A Study of Interactive Optimization for School Schedules

Arthur Delarue, Georgia Institute of Technology, Atlanta, GA, United States

In collaboration with the San Francisco Unified School District (SFUSD), this paper introduces an interactive optimization framework to tackle complex school scheduling challenges. The choice of school start and end times is an optimization challenge, as schedules influence the district's transportation system, and limiting the associated costs is a computationally difficult combinatorial problem. However, it is also a policy challenge, as transportation costs are far from the only consequence of school schedule changes. Policymakers need time and knowledge to balance these considerations and reach a consensus carefully; past implementations have failed because of policy issues despite state-of-the-art optimization approaches. We first motivate our approach with a micro-foundation model of the interplay between policymakers and researchers, arguing that limiting their dependency is key. Building on these insights, we propose a framework that includes (1) a fast algorithm capable of solving the school schedule problem that compares favorably to the literature and (2) an interactive optimization approach that leverages this speed to allow policymakers to explore a variety of solutions in a transparent and efficient way, facilitating the policy decisionmaking process. The framework led to the first optimization-driven school start time changes in the US, updating the schedule of all 133 schools in SFUSD in 2021 with annual transportation savings exceeding $5 million. A comprehensive survey of approximately 27,000 parents and staff in 2022 provides evidence of the approach's effectiveness.

Online Markets and Platforms

Invited Session

Auctions and Market Design

Chair: Rene Caldentey, The University of Chicago, Chicago

Co-Chair: Farbod Ekbatani, Chicago Booth School of Business, Chicago, IL, United States

1 - A Stochastic Growth Model for Online Platforms

Farbod Ekbatani, The University of Chicago, Chicago, IL, United States, Rene Caldentey

We propose a growth model of platforms operating as market markers in two-sided matching markets. The growth of these platforms, often dubbed the “chicken and egg dilemma” in the literature, poses an inherent challenge; service providers find value in joining the platform due to the presence of customers, while customers are drawn to the platform by the availability of diverse services. This endogenous network effect influences the growth trajectory and propels emerging platforms towards “get big fast” strategies to rapidly achieve critical mass on both sides. To address the limitation in the literature, we propose a dynamic model that explicitly accounts for the stochastic dynamics by which a two-sided platform gradually grows over time. We model the platform as a Markovian system, with its state space defined by s_t, the number of active service providers at time t. Service providers join the platform according to a Poisson process with an intensity $\mu(s_t)$, which is indirectly influenced by the compensation offered by the platform. Customers, on the other hand, are transitory and arrive following a Poisson process with state-dependent intensity $\lambda(s_t)$ that captures consumers' preferences for larger platforms. Under some mild conditions, we show that there are upper bounds on how fast and large the platform can grow. We also show that simple compensation rules, such as uniform payments, fail to achieve this optimal expansion. Instead, an optimal compensation mechanism must take into account the ``{\em seniority}'' of each individual active server, as measured by the time they joined the platform.

2 - Signaling Competition In Two-Sided Markets

Yuri Fonseca, Columbia University, New York, NY, United States, Omar Besbes, Ilan Lobel, Fanyin Zheng

We consider decentralized platforms facilitating many-to-many matches between two sides of a marketplace. In the absence of direct matching, inefficiency in market outcomes can easily arise. For instance, popular supply agents may garner many units from the demand side, while other supply units may not receive any match. A central question for the platform is how to manage congestion and improve market outcomes. We study the impact of a detail-free lever: the disclosure of information to agents on current competition levels. Disclosing competition reduces the perceived value of popular units, but, at the same time, it can help agents on the other side better elect across options. How large are such effects, and how do they affect overall market outcomes? We answer this question empirically. We partner with the largest service marketplace in Latin America, which sells non-exclusive labor market leads to workers. We propose a structural model which allows workers to internalize competition at the lead level and captures the equilibrium effect of such reaction to competition at the platform level. We estimate the model by leveraging agents' exogenous arrival times and a change in the platform's pricing policy. Using the estimated model, we conduct counterfactual analyses to study the impact of signaling competition on workers' lead purchasing decisions, the platform's revenue, and the expected number of matches. We find that signaling competition is a powerful lever for the platform to reduce congestion, redirecting demand, and ultimately improving the expected number of matches for the markets we analyze.

3 - Feature-Based Dynamic Matching

Akshit Kumar, Columbia Business School, New York, NY, United States, Yilun Chen, Yash Kanoria, Wenxin Zhang

Motivated by matching platforms that match agents in a centralized manner, we study dynamic two-sided matching in a setting where both customers (demand) and service providers (supply) are heterogeneous and the pool of service providers is limited. We model heterogeneity on the two sides of the market by demand weight vectors drawn i.i.d. from some distribution, and supply feature vectors drawn i.i.d. from a (possibly) different distribution. The matching of a demand-supply pair generates a matching value that depends on their weight and feature vectors. We adopt a notion of regret, specifically the additive loss relative to the value (per match) achievable in the continuum limit, as our performance metric for matching policies. Simple myopic policies suffer non-vanishing regret in large markets. We propose a forward-looking supply-aware policy dubbed Simulate-Optimize-Assign-Repeat (SOAR) which balances between producing high match value for the current match and preserving valuable supply for future customers. We prove that SOAR achieves the optimal regret scaling under different assumptions on the demand and supply distributions. En-route to proving our guarantees we develop a novel framework for analyzing the performance of our SOAR policy which may be of broader interest. As a corollary of our techniques, we also resolve an open problem posed in Kanoria 2022.

4 - Optimal Design of Recommended Donations

Francisco Castro, UCLA Anderson School of Management, Los Angeles, CA, United States, Scott Rodilitz

Nonprofit fundraising websites often display a set of recommended donation amounts, allowing prospective donors to effortlessly select an amount from this menu of recommendations instead of manually inputting their ideal donation. Although this strategy is effective at shaping behavior, it can also backfire: recommended amounts attract donors with both lower and higher ideal donations, potentially leading to a net decrease in revenue. To address this challenge, we present a comprehensive framework for designing a menu of recommendations to maximize fundraising revenue in the presence of heterogeneous donors. Our analysis reveals the limitations of a greedy approach. Instead, we design an algorithm based on dynamic programming principles that efficiently finds an optimal menu. Additionally, we shed light on the value of information by comparing against a benchmark that knows the largest amount that each donor would select. If the nonprofit has information about each donor’s ideal donation, it can obtain a constant-factor guarantee with respect to this full-information benchmark. If the nonprofit only has distributional information, we characterize how the guarantee depends on donor heterogeneity and the size of the menu. Our results highlight the value of market segmentation as well as the potential advantages of larger menus. As a case study, we apply our end-to-end methodology to experimental data from Altmann et al 2019. Our counterfactual analysis suggests that the optimal menu would increase revenue by more than 3%.

1 - Forest Expression of Networks

Yipeng Wang, University of Florida, 32608, FL, United States, Peihua Qiu

Complex networks, showing hierarchical relationships and the sparse structures between nodes, are ubiquitous in social and physical science. A common question in many studies is to visualize or analyze the network hierarchy. Currently, this is addressed by limited analytical tools, usually using ego networks or designed features to depict the network structures. For a network, we present a novel method to express connected components as trees. Thus, the network can be viewed as the forest. The 3D visualization and features based on a forest expression provide insights into network structures. Furthermore, both the 3D visualization and extracted features are compared to identify structural changes between two networks. For a dynamic network, we achieve the scalable overview by using pixel-based visualizations of the chosen features. In various cases considered, numerical studies show that proposed graphical and analytical tools are effective and flexible for network analysis.

2 - Network Clustering and Machine Learning for Predicting Bacterial Protein Functions

Mishkatur Rahman , North Dakota State University, Fargo, ND, United States, Harun Pirim, Hasan Tekedar, Larry Hanson, Matt Griffin

Understanding the complex network of protein interactions is key to uncovering cellular functions and genetic foundations. This study introduces a thorough approach that includes bacterial protein network clustering leveraging functional similarity and a predictive machine learning model to identify the functions of bacterial proteins. The methodology centers around developing mixed integer linear programming (MILP) clustering model to reveal groups of proteins that interact with each other by maximizing their functional similarity within the cluster. The parameters of the MILP model are predicted using node embeddings from protein-protein interaction network for a bacterial protein generated from STRING database. Validation through gene sequence alignment further demonstrated the effectiveness of the functional similarity-based MILP clustering method, revealing a notable increase in the homogeneity of gene sequences within clusters. In parallel, a predictive model is developed to determine the molecular function of bacterial proteins. This model extracts features from protein sequences, annotations, motifs, and physicochemical properties to accurately predict associated GO terms. By employing advanced machine learning techniques, the model optimizes the accuracy of protein function predictions for newly characterized bacterial proteins. The integration of network clustering and predictive modeling creates a strong foundation for investigating gene functionalities and predicting protein functions in bacterial systems, thus advancing the field of bioinformatics and providing valuable insights for genetic research and molecular biology. This study highlights the importance of computational methods in understanding the complex relationships and functionalities within genetic networks.

3 - Machine Learning and Network Analysis to Predict Hypothetical Protein Functions of Aeromonas hydrophila

Zaidur Rahman, University of Arkansas, Fayetteville, AR, United States

Aeromonas hydrophila, antibiotic resistant gram negative bacteria, is a major fish pathogen. Moreover, A. hydrophila is considered to cause 13% of gastroenteritis cases in the United States. Therefore, it is important to identify groups of proteins that are effective in antibiotic resistance and causing mortality in aquaculture. We train machine learning models on existing A. hydrophila genomes to predict functions of 83 carefully filtered hypothetical proteins. Network analysis is conducted to cluster these proteins based on their similarities. Both ML and network analysis inform about possible roles of these proteins in antibiotic resistance and fish mortality.

1 - Control and Enforcement in a Public Sector Direct Delivery Supply Chain, Considering Horizontal Interaction and Supply Disruption

Matan Shnaiderman, Bar-Ilan University, Ramat-Gan, Israel, Liron Ben-Baruch

Our research deals with Direct Vendor Delivery Supply Chains - common in public and government sector organizations and agencies, such as hospitals, universities and public offices. We consider multiple retailers/facilities and the possibility of limited supply available to a supplier, and we consider behavioral operations factors affecting a supply chain member's performance and decisions. The retailers cannot directly enact sanctions on the supplier and need to persuade the purchasing department's representative to penalize the supplier, due to contract breaches, by investing time in enforcement efforts. We review different scenarios, featuring supply disruptions, different inventory allocation methods, and different attentiveness levels of the organization's purchasing department representative to the retailers' enforcement efforts against the supplier. When the supplier has a limited amount of inventory available for retailers, informing the retailers about the expected shortage and the chosen inventory allocation method enables them to prepare for the shortage and set the optimal values in their decision parameters. Competition between the retailers may create horizontal competition in the supply chain, which benefits the supplier but creates excess costs for the retailers. On the other hand, cooperation between retailers allows reducing inventory costs and lowering the risk of shortages among retailers. The collaboration includes determining a centralized strategy for the level of each retailer's safety stock order, and a plan for stock sharing between the retailers. Cooperation between retailers lowers the risk of shortages and improves the profitability of the retailers, usually at the expense of the supplier.

2 - Incentives on Green Supply Chain considering Product Design and Channel Encroachment

lin li, Beijing Jiaotong University, Beijing, China, People's Republic of

We consider the problem of determining the online channel encroachment decision and the product's greenness level of the manufacturer when the retailer can adopt different product incentive contracts. Both for the encroachment and non-encroachment setting, we formulate a green dual-channel supply chain composed of a manufacturer and a retailer. We find that for manufacturers, when the online channel's invasion cost is small and the green technology cost coefficient is large, or when the invasion cost is large and the green technology cost coefficient is moderate, the retailer adopting green reinvestment strategy and the manufacturer entering the online channel dominates. When the invasion cost is large or the green technology cost coefficient is small, the retailer adopting green reinvestment strategy and the manufacturer no entering the online channel dominates. When the invasion cost is moderate and the green technology cost coefficient is large, the retailer adopting wholesale price strategy or cost-sharing strategy and the manufacturer entering the online channel dominates. When both the invasion cost and the cost coefficient are small, the retailer adopting wholesale price strategy and the manufacturer entering the online channel dominates. For the retailer, if the manufacturer decides not to enter the online channel and the green technology cost coefficient is small or large, the retailer benefits the most from green reinvestment strategy. Conversely, the retailer benefits the most from cost-sharing strategy.

3 - Distributionally Robust Optimization for Overseas Warehouse Location Problem under Decision-Dependent Demand Uncertainty

xiaona zhang, Harbin Engineering University, Harbin, China, People's Republic of

In global supply chain management, the decision-making process for the location of overseas warehouses plays a crucial role in enhancing logistical efficiency, optimizing costs, and improving customer satisfaction. However, the uncertainty of market demand and its interaction with the decision-making process for warehouse location present challenges to the site selection issue.This paper constructs a decision-dependent demand ambiguity set based on moment information, interpreting the demand moments as a function of the location decision, and proposes a distributionally robust optimization model under decision-dependent demand uncertainty.To solve this model, the paper employs robust counterpart theory, transforming the complex distributionally robust optimization problem into a mixed-integer linear programming problem, thereby simplifying the solution process and enhancing solution efficiency.Through extensive computational studies, we have found that the method proposed in this paper exhibits outstanding performance in uncertain environments. Not only can it enhance the overall benefits and service quality of the supply chain, but it also provides decision support for the rational layout of overseas warehouses under uncertain conditions.

1 - Real-time driver behavior monitoring using the integration of transfer learning and Extended Reality

Amirarash Kashef, Mississippi State University, Starkville, MS, United States, Junfeng Ma

According to the World Health Organization (WHO) about 1.19 million individuals lose their lives annually due to road traffic accidents, while between 20 and 50 million others sustain non-lethal injuries, often resulting in disabilities. In fact, one of the main reasons is distracted drivers and the distraction caused by mobile phones is a growing concern for road safety. In this study, we have made use of the image-based distracted driver dataset V2 with 44 different drivers in 10 different classes. The data used is in RGB format and belongs only from the side-view camera that captured the driver’s body. Additionally, we have extended the dataset by adding a class for drowsy drivers which statistics show an estimated 17.6 percent of fatal car crashes between 2017 and 2021 involve a drowsy driver. Transfer learning was then implemented on the dataset for classification purposes. Our proposed Deep Convolutional Neural Network (DCNN) model which is based on MobileNet has shown %93.60 accuracy and 0.94 F1-score. Subsequently, the trained AI model is then installed on Extended Reality (XR) device through a series of procedures to enable real-time driver behavior monitoring.

2 - Go Smart and Green: A Sustainable Traffic Management Framework Utilizing Vehicle Energy Consumption and Emission Patterns

Sudenaz Ozvural, Drexel University, Philadelphia, PA, United States, Liang Zhang, Shiyi Zhang

The increasing number of vehicles on roads has reduced mobility, increased energy consumption, and emphasized environmental concerns. Especially in congested urban areas, vehicles tend to consume more gasoline and emit higher levels of pollutants. In this research, we introduce a traffic signal control system that utilizes vehicle energy consumption and emission data. Our primary objective is effectively balance and reduce vehicle energy consumption and emissions at signalized intersections while ensuring equitable allocation of resources (such as green time and "travel credits") among different vehicle types. Specifically, the system collects vehicle energy consumption and emission data through sensors installed on vehicles, which transfer this information to the control center as the input. The control center outputs signal timing plans based on resource allocation algorithms. Additionally, fairness indices are established for various vehicle types (including trucks, regular vehicles, and electric vehicles). Each vehicle is allocated "travel credits" for future use. Simulation experiments have demonstrated that our proposed method can significantly reduce both energy consumption and emissions simultaneously.

3 - Preventing Pedestrian Road Fatalities on Indian Reservations

Bukola Bakare, Middle Tennessee State University, Murfreesboro, TN, United States, Chris Bic Byaruhanga

Due to cultural, economic, and historic factors, American Indians tend to walk to their destinations more frequently than other populations in the United States. They also have a very high rate of pedestrian deaths due to crashes involving motor vehicles. Contributing factors in these crashes include limited sight zones, alcohol consumption, lack of sidewalks, and uncontrolled intersections. This research investigates crashes on American Indian lands and in other rural locations to provide insight into how to curtail future pedestrian injuries in tribal communities. We utilized National Highway Traffic Safety Administration (NHTSA) and the Bureau of Indian Affairs (BIA) data from the years 2016 to 2020. Descriptive analysis of crash records is used in a diagnostic process to distinguish elements associated with motor vehicle crashes involving pedestrians on tribal lands and those who are indigenous. The pedestrian-involved crashes will be compared to similar incidents on other roads, to distinguish significant differences in the driver involved, vehicle, environment, and roadway elements. Gaining a better understanding of the circumstances surrounding pedestrian/vehicle crashes on American Indian lands will help decision makers to select the most appropriate, evidence-based solutions to these incidents.

4 - Location-Allocation of Emergency Service Systems in Light Traffic: Application to Lift-Trap Rescue

Xin Wang, National University of Singapore, Singapore, Singapore, Weiliang Liu, Zhisheng Ye

This work addresses location-allocation challenges in emergency service systems (ESSs) under light traffic conditions. Typically, assessing ESS performance relies on response time metrics, complicated by the distribution of queued calls. We tackle this complexity by analyzing spatial queues as arrival rates approach zero, yielding simple performance expressions. Leveraging these insights, we formulate tractable optimization models for ESS location-allocation, demonstrating significant improvements over benchmark approaches. Real-world application in Singapore's lift-trap rescue highlights a circa 60% reduction in annual penalized incidents compared to the status quo.

5 - A Robust Time-dependent Green Location-Routing Problem with Time Windows

Seyedehsaba Siadati, Eindhoven University of Technology, Eindhoven, Netherlands, Virginie Lurkin, Mehrdad Mohammadi, Tom Van Woensel

This study addresses the dynamic challenges of urban transportation in logistics caused by time-varying traffic congestion, introducing the Robust Time-Dependent Green Location-Routing Problem with Time Windows (R-TDGLRP-TW). A key innovation is incorporating a time-dependent speed function, strategically capturing the nuanced dynamics of urban transportation. Additionally, the inherent uncertainty in travel speed (time), which significantly impacts the system'sperformance, is considered in a robust optimization context.

The R-TDGLRP-TW optimizes hubs, vehicle routes, and delivery schedules, minimizing economic and environmental costs. To tackle this, we develop a mixed-integer linear programming model for R-TDGLRP-TW, incorporating the linearization of dynamic programming recursive equations proposed in the literature into a deterministic formulation. A matheuristic solution algorithm is then used to solve large-scale instances efficiently within a reasonable computation time. Our focus on the dynamic aspects of urban transportation aims to efficiently provide practical insights, helping service providers navigate the complex trade-offs encountered in logistics planning.

6 - Delay management in transit vehicle scheduling

Tristan Ford, University of British Columbia, Vancouver, BC, Canada, Julia Yan, Amy Kim

Disruptions from congestion, construction, and weather are a major source of primary delay in public transit networks. These delays may then propagate along a vehicle's schedule if there is not sufficient buffer time to absorb delay. In this work, we model a vehicle scheduling problem with propagated delay, using stochastic optimization to minimize operating costs while being robust to propagated delay. We analyze a small network in British Columbia, Canada to highlight best practices and guidelines for transit agencies in managing delay.

1 - Equilibrium Dividend and Capital Policy Under TIME-Inconsistent Preferences

SANG HU, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of

This study investigates the dividend payment and capital injection problem under time-inconsistent preferences. The objective of shareholders is to maximize expected total discounted dividends, while the capital injection with cost is to reduce the likelihood of the insurance company being bankruptcy. The problem is time-inconsistent with non-exponential discounting and we employ the definition of weak equilibrium in stochastic control to be the equilibrium strategy. The extended system of HJB equations are established for general non-exponential discounting. We also consider the pseudo-exponential discounting as an example and derive the analytical treatment.

2 - Inverse Leverage Effect for Cryptocurrencies and Meme Stocks: A Comprehensive Framework

Steven Kou, Boston University, Boston, MA, United States

Although the leverage effect, i.e., a negative correlation between the return and volatility, and the inverse leverage effect have been suggested for equities and commodities, respectively, the existing studies suffer from an endogeneity problem because they only model one asset. By using a comprehensive multivariate model with jumps and heavy tail distribution for both an equity index and the asset, we find inverse and threshold inverse leverage effects for cryptocurrencies and meme stocks. Network effects cannot explain this finding. To handle over 18,000 latent variables in the model, a particle Gibbs with an ancestor sampling algorithm is extended to estimate parameters efficiently.

3 - Price Discovery on Decentralized Exchanges

Agostino Capponi, Columbia University, New York, NY, United States, RUIZHE JIA, Shihao Yu

How would informed traders trade if they have to publicly compete for execution? Decentralized exchanges (DEXs) provide an ideal laboratory to answer this question, as they require traders to publicly submit fees to prioritize their orders. We provide empirical evidence that informed traders do not bid low fees to hide their trading intentions. Rather, they publicly bid high fees to signal their information, even if private bidding is an option. Using a unique dataset of Ethereum mempool orders, we show that informed traders do so by employing a “jump bidding” strategy, where they place high initial bids to deter potential competitors.

4 - Asset Pricing with A-Maxmim Expected Utility Model

Xuedong He, The Chinese University of Hong Kong, Shatin, Hong Kong, Jiacheng Fan, Ruocheng Wu

We study an asset pricing problem in which a representative agent trades a risky stock, a risk-free asset, and human capital to maximize her preference value of consumption represented by the α-maxmin expected utility model. This preference model is known to lead to time inconsistency, so we consider intra-personal equilibrium for the representative agent and define the market equilibrium to the set of asset prices under which the intra-personal equilibrium strategy clears the market. We prove that there exists a unique market equilibrium and the asset prices are determined by the solution to a second-order ordinary differential equation. Finally, we conduct comparative statics to study the effect of the agent's ambiguity attitude on the asset prices.

1 - Vc Theory for Inventory Policies

Yaqi Xie, University of Chicago, Chicago, IL, United States, Will Ma, Linwei Xin

Advances in computational power and AI have increased interest in reinforcement learning approaches to inventory management. This paper provides a theoretical foundation for these approaches and investigates the benefits of restricting to policy structures that are well-established by decades of inventory theory. We prove generalization guarantees for learning several well-known classes of inventory policies, including base-stock and (s, S) policies, by leveraging the celebrated Vapnik-Chervonenkis (VC) theory. We apply the concepts of the Pseudo-dimension and Fat-shattering dimension from VC theory to determine the generalizability of inventory policies. We focus on a classical setting without contexts, but allow for an arbitrary distribution over demand sequences and do not make any assumptions such as independence over time. We corroborate our supervised learning results using numerical simulations.

Managerially, our theory and simulations translate to the following insights. First, there is a principle of “learning less is more” in inventory management: depending on the amount of data available, it may be beneficial to restrict oneself to a simpler, albeit suboptimal, class of inventory policies to minimize overfitting errors. Second, the number of parameters in a policy class may not be the correct measure of overfitting error: the class of policies defined by T time-varying base-stock levels exhibits a generalization error comparable to that of the two-parameter (s, S) policy class. Finally, our research suggests situations where it could be beneficial to incorporate the concepts of base-stock and inventory position into black-box learning machines, instead of having these machines directly learn the order quantity actions.

2 - Learning An Inventory Control Policy with General Inventory Arrival Dynamics

Sohrab Andaz, Amazon, New York, NY, United States, Carson Eisenach, Dhruv Madeka, Kari Torkkola, Randy Jia, Dean Foster, Sham Kakade

In this work, we address the problem of learning and backtesting inventory control policies in the presence of general arrival dynamics, which we term as a quantity-over-time arrivals model (QOT). We also allow for order quantities to be modified as a post-processing step to meet vendor constraints such as order minimum and batch size constraints, a common practice in real supply chains. Building upon recent work, we similarly formulate the periodic review inventory control problem as an exogenous decision process, where most of the state is outside the control of the agent. Madeka et al. (2022) show how one can construct a simulator that replays historic data to solve problems in this setting via deep reinforcement learning. In our case, we incorporate a deep generative model for the arrivals process as part of the history replay. By formulating the problem as an exogenous decision process, we can apply results from Madeka et al. (2022) to obtain a reduction to supervised learning. Via simulation studies, we show that this approach yields statistically significant improvements in profitability over production baselines. Using data from a real-world A/B test, we show that Gen-QOT generalizes well to off-policy data and that the resulting buying policy outperforms traditional inventory management systems in real-world settings.

3 - Neural Inventory Control in Networks via Hindsight Differentiable Policy Optimization

Matias Alvo, Columbia University, New York, NY, United States, Daniel Russo, Yash Kanoria

We argue that inventory management presents unique opportunities for reliably applying and evaluating deep reinforcement learning (DRL). Toward reliable application, we emphasize and test two techniques. The first is Hindsight Differentiable Policy Optimization (HDPO), which performs stochastic gradient descent to optimize policy performance while avoiding the need to repeatedly deploy randomized policies in the environment—as is common with generic policy gradient methods. Our second technique involves aligning policy (neural) network architectures with the structure of the inventory network. Specifically, we focus on a network with a single warehouse that consolidates inventory from external suppliers, holds it, and then distributes it to many stores as needed. In this setting, we introduce the symmetry-aware policy network architecture. We motivate this architecture by establishing an asymptotic performance guarantee and empirically demonstrate its ability to reduce the amount of data needed to uncover strong policies. Toward rigorous evaluation, we create and share new benchmark problems, divided into two categories. One type focuses on problems with hidden structures that allow us to compute or bound the cost of the true optimal policy. Across four problems of this type, we find HDPO consistently attains near-optimal performance, handling up to 60-dimensional raw state vectors effectively. The other type of evaluation involves constructing a test problem using real time series data from a large retailer, where the optimum is poorly understood. Here, we find HDPO methods meaningfully outperform a variety of generalized newsvendor heuristics. Our code can be found at https://github.com/MatiasAlvo/Neural_inventory_control.

4 - Massive Speedups for Policy Simulation in Supply Chain Reinforcement Learning

Aryan Khojandi, Massachusetts Institute of Technology, Cambridge, MA, United States, Joren Gijsbrechts, Vivek Farias, Tianyi Peng, Andrew Zheng

Simulating a single trajectory of a dynamical system under some state-dependent policy is a core bottleneck in policy optimization (PO) algorithms. The many inherently serial policy evaluations that must be performed in a single simulation constitute the bulk of this bottleneck. To wit, in applying PO to supply chain optimization (SCO) problems, e.g. in inventory-management settings, simulating a single month of a supply chain can take several hours. We present an iterative algorithm for policy simulation, which we dub Picard Iteration. This scheme carefully assigns policy-evaluation tasks to independent processes. Within an iteration a single process evaluates the policy only on its assigned tasks while assuming a certain 'cached' evaluation for other tasks; the cache is updated at the end of the iteration. Implemented on GPUs, this scheme admits batched evaluation of the policy on a single trajectory. We prove that the structure afforded by many SCO problems allows convergence in a small number of iterations *independent* of the horizon. We demonstrate practical speedups of 400x on large-scale SCO problems using a single GPU, and also demonstrate practical efficacy in other RL environments.

1 - Deep-Learning-Based Causal Inference for Large-Scale Combinatorial Experiments: Theory and Empirical Evidence

Heng Zhang, Arizona State University, Tempe, AZ, United States, Zikun Ye, Zhiqi Zhang, Dennis J. Zhang, Renyu Zhang

Large-scale online platforms conduct numerous A/B tests daily, but not all treatment combinations are tested, posing challenges in estimating causal effects and identifying optimal combinations. We introduce debiased deep learning (DeDL), a framework that combines deep learning with doubly robust estimation to estimate the causal effects of unobserved treatment combinations using limited data. DeDL provides efficient, consistent, and asymptotically normal estimators. We validated the framework through collaboration with a video-sharing platform. DeDL outperformed benchmarks in estimating ATEs and identifying the optimal combination.

2 - Decoupling Learning and Decision-Making: Breaking the O(\sqrt{T}) Barrier in Online Resource Allocation with First-Order Methods

Chunlin Sun, Stanford University, Stanford, CA, United States, Wenzhi Gao, Chenyu Xue, Dongdong Ge, Yinyu Ye

Online linear programming plays an important role in both revenue management and resource allocation, and recent research has focused on developing efficient first-order online learning algorithms. Despite the empirical success of first-order methods, they typically achieve a regret no better than $\mathcal{O}(\sqrt{T})$, which is suboptimal compared to the $\mathcal{O}(\log T)$ bound guaranteed by the state-of-the-art linear programming (LP)-based online algorithms. This paper establishes several important facts about online linear programming, which unveils the challenges for first-order-method-based online algorithms to achieve beyond $\mathcal{O}(\sqrt{T})$ regret. To address these challenges, we introduce a new algorithmic framework that decouples learning from decision-making. For the first time, we show that first-order methods can attain regret $\mathcal{O}(T^{1/3})$ by this new framework. Lastly, we conduct numerical experiments to validate our theoretical findings.

3 - Workforce scheduling and pricing problem in crowdsourced delivery under uncertainty

MINGYAO QI, Tsinghua University, Shenzhen International Graduate School, Shenzhen, China, People's Republic of, Haoyue Liu, Sheng Liu, Zuo-Jun Max Shen

Crowdsourced labor has significantly changed the on-demand delivery market, as gig workers can supplement in-house couriers to fulfill orders. Motivated by the high level of uncertainty in on-demand instant delivery, we model and solve a joint optimization on workforce scheduling and pricing problem (WSPP) with three types of labor, namely in-house couriers, scheduled couriers, and ad hoc couriers for last-mile delivery system. We propose an integrated stochastic programming, robust optimization, and learning model on scheduled couriers' employment, order assignment, and compensation pricing for ad hoc couriers while considering three types of uncertainties, including order patterns, the location of ad hoc couriers, and travel time. We devise an improved logic-based benders decomposition nested column-and-constraint generation algorithm based on stepwise tightening relaxation to solve WSPP exactly, accelerated by a series of valid inequalities and strategies. We also design various approximation algorithms encompassing shift separating, rolling horizon, and rolling horizon with lookahead, which deliver high-quality solutions in a shorter amount of time. As indicated by the numerical experiments, our approach outperforms the solver and provides optimal solutions within the time limit for most instances. The proposed integrated model has more robustness and lower cost compared to deterministic model when faced with uncertainty. The results on real-world datasets show that the uncertainty of ad hoc courier locations significantly impacts decisions for the number of scheduled couriers, leading to several managerial insights.

4 - Model Stacking with Flexible Data Aggregation: Inventory Management in Meituan’s Flash Sales Mode

Zhenkang Peng, The Chinese University of Hong Kong, Hong Kong, China, People's Republic of, Chengzhang Li, Ying Rong, Zichao Luo, Mingyong Zhao, Guangrui Ma, You Li

Given the rapid pace of product launches and shortened product cycles, although the company accumulates a substantial volume of data overall, the data available per product remains limited on average. Consequently, the task of decision-making across thousands of products, each with scant historical data, has emerged as an urgent and new challenge. To tackle this challenge, we have devised a strategy known as Model Stacking with Flexible Data Aggregation (MOST-FLEXDA). This approach includes data aggregation from multiple perspectives, coupled with the selection of specific models customized for these distinct partitions. Subsequently, we utilize a linear model to stack the outputs from these diverse models. Finally, our methodology is put to the test on the Meituan Youxuan platform, which primarily evaluates performance based on two metrics: the first being the ratio of potential profit loss to maximum profit (LSR), and the second being the ratio of remaining inventory to total demand (IR). The results demonstrate that, compared to the existing algorithms utilized by Meituan, our proposed method achieves an average reduction of 42% in IR and a 14% decrease in LSR for newly launched products. Additionally, for standard new products, it also yields reductions of approximately 10% in both IR and LSR.

5 - Bayesian dynamic pricing and the optimality of incomplete learning

Meixi Wu, National University of Singapore, Singapore, Singapore, Yifan Feng, Zhenyu Hu

In this paper, we introduce a dynamic pricing model with demand learning. We consider a setting where a monopolist makes pricing decisions facing a stream of customers over an infinite horizon. The customers are short-lived and homogenous, all of whom share the same private valuation for the product. Initiating with a prior on the valuation, the monopolist updates her belief through observation of customers' purchase decisions. By formulating this problem as a Bayesian dynamic programming problem, we characterize the optimal pricing policy that notably identifies an absorbing region of beliefs. Within this region, it becomes optimal for the monopolist to cease further learning and adopt a static, myopic pricing strategy. This cessation hinges on the discount factor being less than one, and, under a uniform prior, there is a positive probability of transitioning into this no-learning region.

Emerging Topics in Revenue Management: Digital Innovation, Estimation and Optimization

Invited Session

Revenue Management and Pricing

Chair: Guang Li, Queen’s University, Kingston, ON, Canada

Co-Chair: Elaheh Fata, Queen's University, Kingston, ON, Canada

1 - Demand Estimation with Product Bundles

Xianfeng Meng, Smith School of Business, Queen's University, Kingston, ON, Canada, Sumit Kunnumkal, Murray Lei, Guang Li, Anton Ovchinnikov

Traditionally, firms estimate product demand elasticity by varying prices and observing demand changes. However, this method poses challenges for firms such as chain stores and restaurants, where price alterations can be impractical. This study introduces a novel method under the multinomial logit (MNL) consumer choice model, where firms can infer the demand elasticity of new products through discounted product bundles without adjusting individual item prices. We analytically demonstrate that this method can sometimes yield more accurate estimations than direct item discounts. Through numerical analysis with synthetic data, we investigate the accuracy of direct discount estimators versus bundle discount estimators, examining their performance across various product choice set (menu) sizes and their robustness to differences between the firm’s model and actual consumer behavior. An upcoming empirical study in collaboration with a local restaurant will further explore the practical application of bundle discounts in estimating the real-world demand elasticity.

2 - Content-Centered OR Creator-Centered? An Economic Analysis of Fan Loyalty on User-Generated Content Platforms

Meilin Gu, Tsinghua University, Beijing, China, People's Republic of, Zizheng Liu, Dengpan Liu

The loyalty of fan communities to content creators significantly impacts stakeholders on user-generated content (UGC) platforms. Notably, major UGC platforms exhibit varying stances on creators’ cultivation of fan loyalty. For instance, Douyin (the Chinese version of TikTok) hinders creators from building robust fan followings, while Kuaishou (another major UGC platform in China) takes active measures to encourage and support creators in cultivating fan loyalty on its platform. This stark contrast has sparked an ongoing debate about the role of UGC platforms in the cultivation of fan loyalty. In this paper, using a game-theoretic model, we explore the optimal strategies embraced by platforms in managing creators’ cultivation of fan loyalty and their implications for key stakeholders. Our findings challenge the conventional wisdom that suggests UGC platforms should always facilitate creators in cultivating fan loyalty, as such assistance may sometimes hurt the platforms. Furthermore, our study generates meaningful implications by providing guidelines for UGC platforms to strategically manage creators’ cultivation of fan loyalty and for creators to balance their efforts between cultivating fan loyalty and enhancing content quality.

3 - Assortment Planning with N-Pack Purchasing Consumers

Ying Cao, Penn State University - Erie, Erie, PA, United States, Dorothee Honhon

For many product categories, consumers often buy multiple differentiated products on a given store visit for staggered consumption until the next store visit. In this paper, we study the assortment planning problem for a single product category when a retailer faces multi-item purchasing, so-called “n-pack” consumers as introduced by Fox et al (2018). We obtain interesting properties of the product demand functions and the optimal assortment. We also find the optimal assortment structures in four settings which correspond to four ways by which the retailer could misjudge the demand from consumers. In addition, we conduct a numerical study to investigate the differences in optimal assortment variety and calculate optimality gaps from the retailer misjudging consumer demand. Finally, we evaluate our model on a real-life data set and find that the demand proportions predicted by our model can be made extremely close to the actual proportion of sales; then we provide recommendations regarding the introduction of new flavors.

4 - Competitive Pricing in the Presence of Manipulable Information in Online Platforms

Yuqi Yang, Arizona State University, Tempe, AZ, United States, Harish Guda, Hongmin Li

To entice customers to purchase, sellers on online platforms often misrepresent the quality of their goods/services, e.g., by manipulating consumer opinion. We analyze an oligopoly where sellers, heterogeneous in their true quality, compete by jointly choosing their prices and the extent of manipulation. We solve for the unique equilibrium when price-setting firms can manipulate their perceived quality and characterize the set of sellers that manipulate in equilibrium. We identify an index called the propensity to manipulate, based on model primitives to identify the set of sellers who have greater incentive to manipulate, and show that the set of sellers that manipulate in equilibrium is upward-closed in the propensity to manipulate. The extant literature has been mixed in its findings on which sellers have greater incentive to manipulate. Our work helps reconcile the differing viewpoints in the extant literature by providing a unified perspective. We demonstrate the practical relevance of our model by mapping it to an environment consisting of sellers who are differentiated in a star-rating system based on their true rating and the volume of ratings. Depending on a seller’s rating and volume of ratings, we identify three distinct regions that arise: a cost-prohibitive region, a cost-dominant region, and a benefit-dominant region. The ability to map a seller to one of these regions allows platform managers to understand a seller’s tendency to manipulate consumer opinion dynamically over time.

Revenue Management and Pricing

Chair: Evelyn Xiao-Yue Gong, Carnegie Mellon University, Pittsburgh, PA, United States

1 - Two-Sided Flexibility in Platforms

Jiayu (Kamessi) Zhao, MIT, Cambridge, MA, United States, Daniel Freund, Sebastien Martin

Flexibility is a cornerstone of operations management, crucial to hedge stochasticity in product demands, service requirements, and resource allocation. In two-sided platforms, flexibility is also two-sided and can be viewed as the compatibility of agents on one side with agents on the other side. Platform actions often influence the flexibility on either the demand or the supply side. But how should flexibility be jointly allocated across different sides? Whereas the literature has traditionally focused on only one side at a time, our work initiates the study of two-sided flexibility in matching platforms. We propose a parsimonious matching model in random graphs and identify the flexibility allocation that optimizes the expected size of a maximum matching. Our findings reveal that flexibility allocation is a first-order issue: for a given flexibility budget, the resulting matching size can vary greatly depending on how the budget is allocated. Moreover, even in the simple and symmetric settings we study, the quest for the optimal allocation is complicated. In particular, easy and costly mistakes can be made if the flexibility decisions on the demand and supply side are optimized independently (e.g., by two different teams in the company), rather than jointly. To guide the search for optimal flexibility allocation, we uncover two effects, flexibility cannibalization, and flexibility abundance, that govern when the optimal design places the flexibility budget only on one side or equally on both sides. In doing so we identify the study of two-sided flexibility as a significant aspect of platform efficiency.

2 - How Not to Overpackage? -- Towards a Sustainable HelloFresh Service Supply Chain.

Evelyn Xiao-Yue Gong, Carnegie Mellon University, Pittsburgh, PA, United States, Michael Johnson

Meal kit services have been hot and trending, especially among the younger generation. However, overpackaging is a common major challenge in these services. Packaging materials, including ice packs and liners, ensure the quality of the meal-kits delivered; yet too much packaging would leave a large carbon footprint and impose psychological burdens on many customers. This paper investigates artificial intelligence solutions to adaptively make the packaging decision for each box and mitigate potential overpackaging for HelloFresh, the world’s largest meal-kit company and integrated food solutions group. We design contextual bandit algorithms that take advantage of the special structures we find in the packaging problem and various contextual information such as transit conditions and box contents. Theoretically, our algorithm Contextual One-Sided Arm Elimination achieves the optimality guarantee with an $O(\sqrt{T})$ regret bound. Practically, we experiment with HelloFresh's real delivery datasets that contain hundreds of millions of records, identify and correct for issues such as confounding, and test our algorithm's performance. Given the enormous scale of HelloFresh's operations, our contextual bandit algorithm could potentially save millions of units of packaging materials per year, as well as the associated cost, energy and labor.

3 - LEGO: Optimal Online Learning under Sequential Price Competition

Shukai Li, Northwestern, Evanston, IL, United States, Cong Shi, Sanjay Mehrotra

We consider price competition among multiple sellers over a selling horizon of T periods. In each period, sellers simultaneously offer their prices and subsequently observe their respective demand that is unobservable to competitors. The realized demand of each seller depends on the prices of all sellers following a private unknown linear model. We propose a least-squares estimation then gradient optimization (LEGO) policy, which does not require sellers to communicate demand information or coordinate price experiments throughout the selling horizon. We show that our policy, when employed by all sellers, leads at a fast convergence rate $O(1/\sqrt{T})$ to the Nash equilibrium prices that sellers would reach if they were fully informed. Meanwhile, each seller achieves an optimal order-of-$\sqrt{T}$ regret relative to a dynamic benchmark policy. Our analysis further shows that the \emph{unknown individual price sensitivity contributes to the major difficulty of dynamic pricing in sequential competition} and forces regret to the order of $\sqrt{T}$ in the worst case. If each seller knows their individual price sensitivity coefficient, then a gradient optimization policy can achieve an optimal order-of-$\frac{1}{T}$ convergence rate to Nash equilibrium as well as an optimal order-of-$\log T$ regret.

4 - Queueing Matching Bandits with Preference Feedback

Jung-hun Kim, Seoul National University, Seoul, Korea, Republic of, Min-hwan Oh

In this study, we consider multi-class multi-server asymmetric queueing systems consisting of N queues on one side and K servers on the other side, where jobs randomly arrive in queues at each time. The service rate of each job-server assignment is unknown and modeled by a feature-based Multi-nomial Logit (MNL) function. At each time, a scheduler assigns jobs to servers, and each server randomly serves at most one job based on its preferences over the assigned jobs. The primary goal of the scheduler is to stabilize the queues in the system while learning the service rates of servers. For this purpose, we propose algorithms based on UCB and Thompson Sampling, which achieve system stability with a time average queue length bound of $O(N/\epsilon)$ for large enough horizon time T. Furthermore, the algorithms achieve sublinear regret bounds of $\tilde{O}(\min\{\sqrt{T}Q_{\max},T^{3/4}\})$ where $Q_{\max}$ represents the maximum queue length over agents and times. Lastly, we provide experimental results to demonstrate the performance of our algorithms.

5 - A Hybrid Sampling-Based and Gradient Descent Learning Method and Its Applications in Inventory Management

Kairen Zhang, University of Science and Technology of China, Hefei, China, People's Republic of, Zhanyue Wang, Xiangyu Gao, Sean Zhou

We propose an algorithm that marries Sample Average Approximation and Stochastic Gradient Descent for some structured online learning problems. The special structure of these problems manifests itself in important online inventory control problems where the demand distribution is unknown to the decision maker. In particular, the online control of two-echelon series systems and that of dual sourcing systems with lead time difference equal to one. For the above two problems, our algorithm yields regrets growing at the order of log T times square root of T at most where T is the length of the planning horizon. These upper bounds of regrets differ from the corresponding lower bounds by a factor of log T asymptotically. We establish these upper bounds of regrets via leveraging the additive convexity hidden in the one-period expected cost functions and constructing bridging problems. If the one period demand is greater than some positive number almost surely, then we can further improve these upper bounds and closing the gaps between upper bounds and lower bounds. In numerical experiments, our algorithm demonstrates superior performance to other algorithms in the literature.

1 - Autobidders with Budget and ROI Constraints: Efficiency, Regret, and Pacing Dynamics

Mengxiao Zhang, University of Southern California, Los Angeles, CA, United States, Brendan Lucier, Sarath Pattathil, Alex Slivkins

We study a game between autobidding algorithms that compete in an online advertising platform. Each autobidder is tasked with maximizing its advertiser’s total value over multiple rounds of a repeated auction, subject to budget and/or return-on-investment constraints. We propose a gradient-based learning algorithm that is guaranteed to satisfy all constraints and achieves vanishing individual regret. Our algorithm uses only bandit feedback and can be used with the first- or second-price auction, as well as with any "intermediate" auction format. Our main result is that when these autobidders play against each other, the resulting expected liquid welfare over all rounds is at least half of the expected optimal liquid welfare achieved by any allocation. This holds whether or not the bidding dynamics converges to an equilibrium and regardless of the correlation structure between advertiser valuations.

2 - Dynamic control under non-stationarity: Stochastic and Robust perspectives

Varun Gupta, Northwestern University, Evanston, IL, United States, Yuwei Luo, Jing Yu, Mladen Kolar, Adam Wierman

We will present two vignettes on the problem of online control of the Linear Quadratic Regulator (LQR) problem when the dynamics are non-stationary and unknown. LQR is arguably the simplest Markov Decision Process, and serves as a fertile ground for developing new frameworks for studying online and robust control policies. In the first part of the talk, we will present a minimax dynamic regret optimal policy under two somewhat strong assumptions: (i) the noise process is independent across time steps, and (ii) the total variation of the dynamics over T time steps is sublinear in T (we do not assume this variation is known). In the second part, we will relax both these assumptions. Since dynamic regret minimization is too strong a goal, we propose a policy that guarantees bounded-input-bounded-output stability in the closed loop. The talk will highlight how different perspectives for studying online control under non-stationary dynamics lead to novel statistical and algorithmic questions.

3 - Asymptotically Efficient Distributed Experimentation

Ankur Mani, University of Minnesota - Twin Cities, Minneapolis, MN, United States

Sequential decision making by a large set of independent agents who are not interested in experimentation, either because they are short lived or because experimentation is costly, has gained significant attention over the past decade. Even a little amount of experimentation from a few agents would benefit all others but coordinating such experimentation is challenging for a central planner. Academic literature has focused on mechanisms for promoting experimentation through monetary incentives and persuasion through careful information disclosure. We study a simple control that the central planner can use to coordinate experimentation. We consider a set of agents that observe their own history but not the histories of other agents. The central planner however can observe the history of all agents. In a continuous-time stochastic multi-armed bandit model, myopic agents observe their history, pick an arm and receive a reward at each time instant. In the proposed class of policies, the central planner, using the information it knows, at times unknown apriori, removes arms irrevocably that it considers inferior to other arms with sufficient confidence, thus forcing the agents to choose from a smaller set of remaining arms. We show that an appropriately chosen policy within this class can generate the needed experimentation and match the regret bounds for a centralized problem thus mitigating the cost of decentralization. We also quantify the minimum number of agents that are needed for such a policy to be asymptotically optimal and the impact of the number of agents on the speed of learning.

1 - Defense Critical Supply Chain Networks and Risk Management with the Inclusion of Labor: Dynamics and Quantification of Performance and the Ranking of Nodes and Links

Anna Nagurney, University of Massachusetts Amherst, Amherst, MA, United States

The efficient and effective performance of defense critical supply chain networks is essential to both national and global security. Disruptions to supply chains, heightened in the COVID-10 pandemic, and now further exacerbated because of growing geopolitical and other risks, as well as Russia’s war against Ukraine, have garnered the attention of decision-makers and policymakers, including those in the defense sector. In the paper, a rigorous methodological framework is presented for defense critical supply chain networks in the form of a defense supply chain network economy that captures the behavior of defense firms, which care about revenues as well as risk, and which includes the important labor resources and associated constraints. Variational inequality theory is used to provide alternative formulations of the governing

Nash Equilibrium conditions, with a dynamic model counterpart used for the construction of an easy to implement algorithm that yields closed form expressions at each iteration of the defense product path flows and the Lagrange multipliers associated with the bounds on labor hours available on supply chain links. A defense supply chain network efficiency /performance measure is proposed and an associated importance indicator for supply chain network components. A resilience measure is also given that quantifies the resilience of the defense supply chain network economy to disruptions in labor. The modeling and algorithmic framework, as well as the measures proposed, are then illustrated via numerical examples.

2 - The Weak Core, Partition-Based Universal Stability, and Their Risk Associations Through a Partial Order

Jian Yang, Rutgers University, Newark, NJ, United States

We are concerned with the stability of a coalitional game, i.e., a transferable-utility cooperative game. First, the concept of core can be weakened so that the blocking of changes is limited to only those with multilateral backings. This principle of consensual blocking, as well as the traditional core-defining one of unilateral blocking and one straddling in between, can then be applied to partition-allocation pairs. Each such pair is made up of a partition of the grand coalition and a corresponding allocation vector whose components are efficient and individually rational for the various constituent coalitions of the given partition. Among the resulting stability concepts, two are universal in that any game, no matter how ``poor'' it is, has its fair share of stable solutions. For a game possessing strictly positive values, furthermore, its imputations possess fractional interpretations. These would allow a certain ranking between games, which we deem as in the sense of ``centripetality'', to imply a clearly describable shift in the games' stable solutions. When coalitions' values are built on both random outcomes and a common positively homogeneous reward function characterizing players' enjoyments from their shares, this comparative static could help explain why it so often happens that aversion to risk promotes cooperation.

3 - Scalar Equilibria for Normal Form Games

Herbert Corley, The University of Texas at Arlington, Arlington, TX, United States

A scalar equilibrium (SE) is an alternative type of equilibrium usually in pure strategies for an n-person normal-form game G. It is defined using optimization techniques to obtain a pure strategy for each player of G by maximizing an appropriate utility function over the acceptable joint actions. The players' actions are determined by the choice of the utility function. Such a utility function could be agreed upon by the players or chosen by an arbitrator. An SE is an equilibrium in the sense that no players of G can increase the value of this utility function by changing their strategies. SEs are formally defined, and examples are given. In a greedy SE, the goal is to assign actions to the players giving them the largest individual payoffs jointly possible. In a weighted SE, each player is assigned weights modeling the degree to which he helps every player, including himself, achieve as large a payoff as jointly possible. In a compromise SE, each player wants a fair payoff for a reasonable interpretation of fairness. In a parity SE, the players want their payoffs to be as nearly equal as jointly possible. Finally, a satisficing SE achieves a personal target payoff value for each player. The vector payoffs associated with each of these SEs are shown to be Pareto optimal among all such acceptable vectors, as well as computationally tractable.

4 - Stochastic Differential Games for Designing Water Conservation Incentives

Behnam Momeni, George Mason University, Fairfax, VA, United States, Shima Mohebbi

Global concerns about water scarcity are intensifying due to poor freshwater management. This study develops stochastic differential games to obtain dynamic incentive strategies for water users located throughout river networks. Two networks of water users are considered: those who utilize groundwater and those who rely on surface water for agricultural purposes. A non-governmental organization (NGO) participates as another key player, providing conservation incentives to encourage water users to reduce their consumption. The NGO aims to offer an incentive scheme to each water user based on their unique characteristics, while addressing potential scalability challenges that may arise with an increasing number of players. Stochastic elements are captured by incorporating a Standard Wiener process into the state variables (volume of water in river and Aquifer). The Hamilton-Jacobi-Bellman equation and Ito lemma are then employed to determine the optimal decision variables for the water users and to analyze how the mean and variance of the state variables evolve when following the optimal decisions. Finally, an algorithm is proposed to solve large-scale convex and non-convex optimization problems. The Red River, the second-largest basin in the south-central United States, serves as the case study for the proposed model. Keywords: Stochastic decision games, Incentives, Freshwater management

1 - Optimizing Drone Depot Location and Routing for Last-Mile Delivery: A Novel Application and Extension of the Black and White Traveling Salesman Problem

Juan Zhang, University of Wisconsin - Eau Claire, Eau Claire, WI, United States, Ozgur Kabadurmus, Haitao Li

As drone technology continues to revolutionize last-mile delivery, the challenges of limited flight range and payload capacity necessitate innovative solutions for efficient logistics. This research aims to address the critical question of how to strategically locate drone depots to mitigate the impact of constrained drone capabilities and optimally schedule drone routes to minimize drone facility and delivery costs. A location-routing optimization model is developed, which leverages and extends the unique modeling of the Black and White Traveling Salesman Problem. A case study for last mile healthcare delivery illustrates the usefulness of the model. This optimization framework has the potential to enhance the overall performance and scalability of drone delivery systems, making them more viable and effective in real-world applications.

2 - Unveiling the Influence of Blockchain Technology on ESG Indexes Across Supply Chains: An Empirical Investigation

Sahar Bajgani, WORCESTER POLYTECHNIC INSTITUTE, Worcester, MA, United States, Sara Saberi

This research project critically examines the effects of Blockchain Technology (BCT) on Environmental, Social, and Governance (ESG) metrics and financial indices within firms that have adopted this technology. The aim is to establish whether the integration of BCT leads to improved sustainability practices and enhances financial performance.

Quantitative data from a range of industries will be analyzed to compare the pre- and post-adoption performance of companies that have implemented blockchain solutions. This analysis will help isolate BCT's impact from other variables. Additionally, qualitative assessments will explore how the intrinsic features of blockchain—such as increased transparency, enhanced security, and decentralization—contribute to variations in ESG scores and financial outcomes.

The project will also investigate the potential of blockchain to facilitate compliance with regulatory standards and to foster trust among stakeholders, which are critical components of ESG criteria. Preliminary findings suggest that BCT can significantly influence corporate governance practices and operational efficiencies.

3 - Dispatching Drones after a Disaster Using a Team Orienteering Approach

Amir Hossein Moadab, Washington State University, Pullman, WA, United States, Chuck Munson, Arman Hosseini

We model the use of drones to aid in locating victims following a major disaster. Employing a two-phase approach, we integrate k-means clustering to identify potential hub locations. In the first phase, we optimize hub selection and drone allocation to each hub using a heuristic algorithm. The second phase focuses on efficient routing to ensure timely coverage, thereby enhancing search and rescue operations. We tested this model in three scenarios considering no threshold coverage for clusters, a specific percentage of threshold, and maximal covering hub selection. We identify important trade-offs for decision makers to consider when planning for and responding to major disasters.

4 - Reducing Search Advertisement Spending Through a Two-Stage Term Embedding and Optimization Approach

Vasileios Pavlopoulos, The University of Alabama in Huntsville, Huntsville, AL, United States, Hieu Pham, Ravi Patnayakuni

In the realm of e-commerce, efficient allocation of advertising budgets is crucial for maximizing profitability. This paper presents a novel approach to reducing search advertisement spend by leveraging negative exact matching of search terms that do not lead to conversions. Traditional methods often rely on waiting for a predetermined number of searches without clicks before negative-exacting a search term, which can be time-consuming and inefficient. To address this issue, we introduce a similar text-matching algorithm that utilizes word embeddings to identify similar queries, enabling proactive negative-exacting before incurring significant ad costs.

1 - A Stochastic Dynamic Approach for Task Assignment and Volunteer-Based Delivery Routing in Non-Profit Food Rescue Operations

Leila Hajibabai, North Carolina State University, Raleigh, NC, United States, Mehr Salami, Kuangying Li, Ali Hajbabaie

This research develops a stochastic dynamic program to optimize food rescue logistics for non-profit organizations. It aims to reduce hunger and food waste by maximizing demand coverage and minimizing routing costs, thereby improving the efficiency of food distribution networks. Characterized by fluctuating demand, variable volunteer availability, and constrained transportation resources, the problem suffers from extensive action space and highly random requests due to stochastic dynamics inherent in food rescue operations. A Markov decision process is employed that is enhanced by a Monte Carlo tree search technique to effectively navigate the stochasticities. The proposed integrated methodology dynamically assigns delivery tasks and designs optimal routes for delivery volunteers, incorporating new requests into the solution in real-time. To tackle the complexities due to the extensive action space, a set of heuristics is implemented that help prioritize and sample promising actions, enhancing the operational effectiveness of the proposed tree search algorithm. The effectiveness of the proposed approach is evaluated through comparative experiments using real-world data obtained from a collaborating food rescue agency. The preliminary results indicate that our methodology significantly outperforms existing state-of-the-art solutions in terms of operational efficiency and robustness. It not only improves the distribution of perishable food items to agencies and food-insecure households but also offers a scalable solution that can be adapted to other domains facing similar logistical challenges.

2 - The Many Faces of Equity? Food Bank Operations Through a Multi-Dimensional Equity Lens

Naurin Zoha, University of Michigan, Ann Arbor, MI, United States, Tanzid Hasnain, Julie Ivy

According to Feeding America, there are persistent disparities in food insecurity levels among different racial and ethnic groups in the US. In 2021, while about 10.2% of the US population were food insecure, 19.5% of the African American and 16.2% of the Hispanic populations were food insecure, compared to 7% of the White population. The level of food insecurity also varies among different population groups with different socio-demographic dimensions. As food banks develop distribution policies, they should be aware of the disparities in food insecurity that may exist among different demographics and may adversely impact equitable distribution. This study develops a single-period deterministic network flow model to explore the impact of different equity measures across multiple dimensions, namely geographic and demographic, on food bank's distribution in the presence of effectiveness (undistributed food minimization) criterion under efficiency (distribution cost minimization) constraint. We apply the model to our partner food bank's data to (i) explore the trade-off between dimensions of equity, and (ii) identify policy insights.

3 - Addressing Barriers to Food Access: A Comprehensive Study of Fresh Mobile Market Distribution in Low-Income Communities

Motunrayo Ogunmola, North Carolina A&T State University, Greensboro, NC, United States, Shona Morgan, Dwight Lewis, Lauren Davis

Food insecurity remains a global public health obstacle, highlighting inequalities vulnerable populations face. Using data collected from participants at several fresh mobile market (FMM) locations in a North Carolina (USA) county, combined with other US Census and geospatial datasets, we performed a case study examining FMMs' impact on their beneficiaries and serviced neighborhoods. More specifically, we examined the commute patterns of participants who visited FMMs and the sociodemographic characteristics of participants' residences and mobile market-serviced communities. Lastly, using contemporary spatial modeling, we enumerate the improvements in physical access to food assistance programs by looking at the impact of current FMM scheduling given the spatial distribution of existing food banks and pantries. To address remaining disparities in access to food assistance, we propose a spatial optimization approach for strategically positioning FMMs to minimize the travel burden to food assistance among vulnerable populations. The findings in this research can guide the strategic placement of FMMs in low-income communities tailored to their target communities' specific needs and constraints.

4 - Mapping Agri-Food Distribution onto Real-World Transportation Infrastructure in the United States

Deniz Berfin Karakoc, Arizona State University, Tempe, AZ, United States

Agricultural and food supply chains within the United States are essential for both global and local food security. These complex systems are subject to threats imposed by various economic, political, environmental, and infrastructural factors. Here, we focus on the transportation of agri-food commodities, which is a less well-studied feature, but necessary for connecting production to consumption. In this study, we develop a unified framework of data analytics, network science, and geographic information science techniques to map agri-food distribution within the United States onto real-world highway, railway, and waterway networks. We evaluate how the agri-food load on each transportation mode varies by the distribution of domestic, import, and export flows within the U.S. We also quantify the trade-off between economic efficiency, adaptability, and sustainability of agri-food distribution across transportation modes. We conclude that highways enable the greatest re-routing capacity for agri-food distribution, but it comes at the highest cost and carbon emissions; whereas waterways have the lowest cost and carbon emissions, but with the lowest adaptive capacity to disturbance. Our findings can inform efforts to balance affordability, resilience, and sustainability in agricultural and food transportation.

Multiobjective Optimization Under Uncertainty

Invited Session

Multi Criteria Decision Making

Chair: Margaret Wiecek, Clemson University, Clemson, SC, United States

Co-Chair: Akshita Gupta, Purdue University, West Lafayette, IN, United States

1 - Two-Stage Stochastic Multiobjective Linear Programs and Their Properties

Akshita Gupta, Purdue University, West Lafayette, IN, United States, Susan Hunter, Margaret Wiecek

To address decision making under conflict and uncertainty, we consider a two-stage stochastic multiobjective linear program (TSSMOLP). As a generalization of its single-objective counterpart, the two-stage stochastic linear program, the TSSMOLP may have more than one conflicting objective in each stage. Thus, the second stage is modeled with a set-valued map resulting in a nondominated set rather than a real optimal value that is provided in a single-objective setting. In the first stage, the global Pareto set for the TSSMOLP is the set of nondominated points belonging to the union of the translated expected second-stage nondominated sets. Solving the TSSMOLP requires (a) proving properties of the TSSMOLP and (b) developing a theory to estimate the expected value of the second-stage nondominated set. We discuss structural properties of TSSMOLPs and recent theoretical advances for solving TSSMOLPs using a sample average approximation framework.

2 - Confidence Regions for Multi-Objective Stochastic Convex Programs with Uncertain Parameters

Susan Hunter, Purdue University, West Lafayette, IN, United States, Ziyu Liu, Raghu Pasupathy

We consider the context of constructing confidence regions on the efficient and Pareto sets of multi-objective stochastic convex programs with uncertain parameters. We first derive an asymptotically exact central limit theorem in the parameter space. Then, using the multiple objective functions as push-forwards, we construct asymptotically valid confidence regions on the efficient and Pareto sets. We illustrate projections of the confidence regions in the decision and objective spaces through an example.

3 - Upper Bounds on Scalar and Set-Based Regret for Online Multiobjective Optimization

Kristen Savary, Clemson University, Davenport, FL, United States, Margaret Wiecek

In online multiobjective optimization (OMO), solutions are computed before the objective functions are revealed. As a result, these solutions are not Pareto for the associated offline multiobjective problem and incur a cost, measured by regret.

Scalar regret and set-based regret are defined for OMO and used to evaluate the performance of the Online Gradient Descent Algorithm (OGDA). Using the scalarized OMO problem, the OGDA computes a single solution in every iteration and its success is measured by the scalar regret. Minimizing the generational distance associated with the OMO problem, the OGDA computes a set of solutions at every iteration and its success is measured by the set-based regret. A theoretical and numerical comparison of the upper bounds on the two regrets is presented.

1 - *Wildfire Rescue Missions Utilize Air Drone Carriers Planning*

Aoran Cheng, The University of Hong Kong, Hong Kong, Hong Kong, Shijie Pan, Yiqi Sun, Yulun Zhou, Kai Kang, Cristobal Pais, Zuo-Jun Shen

Preventing wildfires is an extremely important task and safeguard measure in this era. The primary objective of current forest fire management is to find effective methods to extinguish wildfires. However, when facing severe wildfires, we still lack an effective approach that can efficiently suppress the wildfire while ensuring the safety of forest firefighters. Therefore, this research explores the deployment, allocation, and near-optimal mechanism design of emerging drone swarms, as a substitution of traditional human based-firefighting, in the early stages of wildfire outbreaks. Specifically, we aim to optimize the path planning of each individual base during their firefighting missions to achieve the shortest possible time for wildfire suppression. Next, we will utilize geographic information projection and optimization methods to effectively allocate resources and devise scheduling strategies to address the coordination and scheduling challenges of limited resources and time-constrained drones and trucks. Through extensive research and practical experience, our goal is to enhance the efficiency promise of task execution. Furthermore, by integrating optimal strategies for individual drones and drawing inspiration from collective behaviors observed in nature, we could improve the overall firefighting efficiency of the drone swarm. Based on these models, we will explore the practical application of the proposed approach in real firefighting scenarios, providing innovative solutions for wildfire prevention and control.

2 - Enhanced Modeling of Fan Speed Effects on Greenhouse Climate and Agricultural Product Drying

Linda Orjaroen, Chiang Mai University, Chiang Mai, Thailand, Chulin Likasiri

This study advances latest research on the effectiveness of solar greenhouse drying, concentrating on a refined dynamic model that simulates the impact of fan speed adjustments on internal greenhouse conditions—temperature, humidity—and the drying kinetics of bananas. Utilizing comprehensive data from an ongoing banana drying case study, including measurements of air temperature, humidity, irradiance, and the temperature and weight of the bananas, the model employs advanced Ordinary Differential Equations (ODEs). The equations are coupled with sophisticated unconstrained optimization methods to enhance the empirical fit. Enhanced correlation analysis explores the intricate relationships between fan speed adjustments and key environmental variables. All parameters have been rigorously validated using root mean squared error minimization techniques to ensure the model's accuracy and reliability. The refined mathematical model provides more precise predictions of the final weight of dried bananas and recommends optimal fan speed settings to improve drying efficiency. This focused project contributes significantly to optimizing greenhouse drying processes for bananas and promoting more efficient and sustainable local agricultural practices.

3 - A framework to identify and prioritize key performance indicators: assessment of the effectiveness of inclusive climate actions for nature-based solutions

Sara Torabi, Politecnico di Torino, Turin, Italy

Nature-based Solutions (NbS) are increasingly acknowledged as vital strategies against climate change. However, citizens and ecosystems benefit differently from the functions that NbS provide. To better account for NbS trade-offs, theory and practice have embraced Inclusive Climate Actions (ICAs) that simultaneously tackle climate change and urban inequalities. Currently, there is a notable gap in a comprehensive assessment of the environmental, economic, and social implications of ICAs for NbS. This research develops a novel evaluation and monitoring (E&M) framework to identify Key Performance Indicators (KPIs) for evaluating the effectiveness of ICAs for NbS. The methodology is structured into three distinct phases: (i) identification, (ii) refinement, and (iii) prioritization. This approach integrates both quantitative and qualitative techniques and actively involves stakeholders in the process. A set of 13 KPIs is proposed consisting of 2 economic, 5 environmental, and 6 social indicators was identified. Furthermore, these results can be further enhanced engaging local stakeholders to select, when necessary, supporting indicators that are tailored to address specific contextual challenges. The E&M framework assesses the effectiveness of completed or ongoing projects, or to design and evaluate future scenarios. Results will help cities to implement ICAs that incorporate fairness and distribute NbS impacts as equitably as possible. This step is pivotal for empirically evaluating the effectiveness, design, and planning of future scenarios of ICAs within the Urban Living Labs of five European cities. This study is part of the broader European project GREEN-INC, growing effective and equitable nature-based solutions through inclusive climate actions.

4 - Pareto Optimization for Selecting Discriminating Test Locations in Plant Breeding

Mohammadreza Kiaghadi, Iowa State University, Ames, IA, United States, Sigurdur Olafsson

Developing new and better cultivars of food crops is an important challenge that requires expensive and time-consuming field trials. In early-stage experiments thousands of experimental cultivars may be planted in a small number of locations with the goal of only continuing trials with only a small fraction of the very best cultivars in the next season. The selection of experimental planting locations thus plays an important role in plant breeding, and in early-stage experiments a key consideration is to include locations that have the best ability to discriminate the main genotype effects of cultivar, that is, to screen the potential high performers from the average to poor cultivars. Traditionally, this discriminative ability of locations has focused on precision, but recent work also suggests that some locations may be more sensitive to changes in the main genotype effect, that is, have what we will refer to as higher relative discriminative value. We show that while these are both valuable, they are competing measures of discriminative ability, that is, that no location will maximize both precision and relative discriminative value, and there is therefore a tradeoff that should be considered by plant breeders. We further show how this tradeoff can be addressed by proposing how a set of discriminating location can be constructed using ideas based on pareto optimization.

5 - When does green technology diversification affect firms in catching up with industry leaders? The role of environmental policy coordination

yunze li, Harbin Engineering University, Harbin, China, People's Republic of, Weiwei Liu, Ruby Lee

Inspired by the conference calling for more research on smarter decisions for a better world and organizational learning theory, we examine green technology (GT) diversification among firms from an emerging economy (EE) and propose that an increase in GT diversification can facilitate EE firms to catch up with a global industry leader in different ways. GT diversification reflects the number of GT domains out of seven scopes classified by the World Intellectual Property Organization, and thus, the more GT domains an EE firm has, the more diverse it is. We theorize that when GT diversification increases, learning from a wide range of knowledge enables EE firms to catch up with the industry leader's economic performance more closely. However, owing to a wider range of environmental regulations connected to various scopes of GT, compliance with many regulations can slow down EE firms' learning and catch-up with industry leaders. We further explore the role of environmental policy coordination. Using textual analysis of public policies, we develop a novel measure to capture the extent of environmental policy coordination between government departments. We further collect longitudinal data (2012-2023) from publicly traded firms in China to examine the effect of GT diversification and find that GT diversification affects economic catch-up performance positively but environmental catch-up performance negatively. However, when a province's environmental policy between government units is more coordinated, it attenuates the effects of GT diversification on catch-up performance in different ways. Our findings provide novel implications for theory and practice.

6 - Revisiting the Impact of Renewable Energy on PPAs

Subas Acharya, Johns Hopkins University, Baltimore, MD, United States, Benoit Chevalier-Roignant, Helyette Geman

The rise of green businesses and renewable energy marks a pivotal shift in the global pursuit of net zero emissions. Power Purchase Agreements (PPAs) allow corporations and businesses to source green energy. In the long run, the larger share of cost-effective renewable sources in the overall power generation mix will lead to lower electricity prices. This price dynamics will prompt offtakers to withdraw from a PPA signed at a time where the energy producer could charge a premium on green energy and the generation of solar and wind was limited. Assuming a mean reverting price process with a decreasing level of mean reversion, we analyze the date at which an offtaker is likely to renegotiate on a PPA and key statistics on this stopping time to understand better the PPA average duration and revenues producers can expect when defining the contract price at date 0.

Chair: Devansh Jalota, Stanford University, Stanford, CA, United States

1 - Exploring the Role of Generative AI in Transforming the Analytics Education in Business School

Qizhang Liu, National University of Singapore, Singapore, Singapore

The emergence of generative AI technologies, exemplified by innovative platforms like ChatGPT, has catalyzed widespread disruption across various sectors, with education standing as no exception. Educators worldwide are actively engaged in discussions, brainstorming sessions, and experimental endeavors, seeking short-term mitigative measures and long-term adaptation strategies in response to the transformative impact of generative AIs. However, despite the palpable urgency surrounding this issue, the existing scholarly discourse on the efficacy of such measures or strategies remains notably sparse.

This study presents a comprehensive analysis of the transformative interventions implemented within an analytics course at the Business School of the National University of Singapore. Spanning two academic semesters, these interventions encompassed a spectrum of modifications, including the redefinition of teaching objectives, a paradigm shift in teaching philosophy, and the overhaul of assessment methodologies. The efficacy of these interventions was assessed through surveys administered to students, revealing a discernibly positive reception to the implemented changes.

In light of these findings, a series of proactive recommendations are proffered to circumvent the potential pitfalls associated with overreliance on generative AI technologies. These recommendations serve as pragmatic guidelines for educators seeking to harness the transformative potential of generative AIs while concurrently fostering the cultivation of essential analytical competencies among students.

2 - Talk Me Into It: Evaluating Advertising Through GenAI Chatbots

Parto Tavassoli, Simon Fraser University, Burnaby, BC, Canada, AIshwarya Shukla, JM Goh

The introduction of Generative AI technologies has significantly transformed digital interactions, with profound implications for marketing practices. Every day, millions of users across the globe engage with GenAI chatbots, highlighting their widespread popularity and significant potential. Recently, both marketers and AI development firms have recognized the potential of GenAI chatbots as a novel medium for reaching potential customers through personalized and interactive communication. In this study, we aim to examine the implications of embedding advertisements within interactions with GenAI chatbots. We propose that such advertisements may diminish trust in the chatbots' responses, as they may be perceived to be biased toward sponsored products. Additionally, the perception of brands utilizing this marketing strategy could be adversely affected, especially if the presence of advertisements is not transparently disclosed to users. These factors may influence user engagement metrics, such as *click-through rates*, which entails further investigation into how people react to this advertising approach. We will also explore the moderating effect of *task complexity* on these potential negative outcomes. Our hypotheses suggest that higher search costs and perceived complexity in finding the right products might mitigate users' sensitivity to receiving sponsored recommendations from these chatbots. We propose that by nudging users about the complexity of searching, people may become more likely to be receptive to the chatbot's suggestions when they include sponsored material. The proposed hypotheses will be empirically tested through a lab experiment in subsequent phases of this research.

3 - Understanding Human-AI Collaboration in Generative AI Text Detection

Fairy Gandhi, University of Colorado Boulder, Boulder, CO, United States, David Dobolyi, Julian Lehmann, Matthew McCarthy

Recent advancements in generative artificial intelligence have led to a surge in machine-synthesized content in a wide array of fields. AI-generated text has often proven indistinguishable from human-written text, presenting challenges across industries. Although much focus has been on distinguishing text as either human- or AI-generated, many instances involve a blend of both human and AI contributions. AI-text-detection tools, while showing promise in identifying AI-generated content, struggle to detect mixtures of human and AI writing. Humans collaborating with such tools may misplace their trust in the tools' recommendations during their decision-making process. We aim to understand the influence of AI-text-detection tools on human decision-making in a three-way text classification task. First, through a large-scale, classroom-based field study, we collected prompt-based student responses that were self-reported as human-written, AI-written, or a mixture of both. Second, we are currently conducting an online experiment that has participants evaluating these student responses with or without the assistance of a real-world, commercial AI-text-detection tool. We hypothesize that individuals collaborating with recommendations from the tool will generally outperform those without it. Critically, however, our findings from the field study suggest that accuracy will be higher only in the human-written and AI-written conditions when relying on the tool's recommendations, whereas accuracy will be significantly lower in the mixed condition due to flawed tool recommendations present in the mixed condition. This research will provide important insights into the augmented human/AI decision-making process in education, which will apply to other settings such as content moderation, cybersecurity, and beyond.

4 - When Simple is Near-Optimal in Security Games

Devansh Jalota, Stanford University, Stanford, CA, United States, Michael Ostrovsky, Marco Pavone

Fraudulent or illegal activities are ubiquitous across many applications and involve users bypassing the rule of law, often with the strategic aim of obtaining some benefit that would otherwise be unattainable within the bounds of lawful conduct. However, user fraud is detrimental, as it may compromise safety or impose disproportionate negative externalities on particular population groups.

To mitigate the potential harms of users engaging in fraudulent activities, we study the problem of policing such fraud as a security game between an administrator and users. For this security game, we study both welfare and revenue maximization administrator objectives. In both settings, we show that computing the optimal administrator strategy is NP-hard and develop natural greedy algorithm variants for the respective settings with constant factor approximation ratio and resource augmentation guarantees.

We further study several model extensions, including incorporating contracts into our framework and generalizing our model to incorporate additional constraints beyond an overall resource constraint. While greedy approaches do not, in general, work well for arbitrary constraints, we identify sufficient conditions on the constraint structure under which our proposed greedy algorithms can still achieve constant factor approximation ratios to the optimal policy.

Finally, we present experiments based on real-world data obtained from Stanford University's Department of Public Health and Safety on monitoring parking violations on Stanford's campus. Our results demonstrate that our proposed algorithms can increase campus revenues from parking permit purchases by over $300,000 every year relative to the status-quo parking enforcement policy.

Managing in High Technology Environments

Invited Session

New Product Development

Chair: John Angelis, University of Lynchburg, Lynchburg, VA, United States

Co-Chair: Juliana Hsuan, Copenhagen Business School, Frederiksberg, DK-2000, Denmark

1 - The Effects of Blame Shifting and Shopping Intensity on Revisit Likelihood in Data Breaches

John Angelis, University of Lynchburg, Lynchburg, VA, United States, Rajendran Murthy

Data thefts have increased in frequency and cause a loss of customer trust and business. Previous research has studied how the public assigns blame for the crime, and how different individuality levels of data breaches affect revisit intention. In addition, the negative emotional response of the public to data breaches has been frequently studied, finding that fear is highly correlated with revisit intentions. However, previous research has been inconclusive on whether frequent shoppers will be more likely to shift blame away from the business, and whether they will be more likely to return. Our survey of 315 individuals provides insight into how frequent customers differ from the general public. Specifically, the relationship between placing greater proportion of blame on data breach victims (relative to the hacked business) and revisit intention is moderated by prior shopping intensity. Those who placed greater blame on the data breach victims were more likely to return to the breached business. Frequent shoppers are indeed more likely to return to the breached business, indicating that their previous experience does affect their revisit intention. We put this result in context with the literature on customer loyalty, and recommend that businesses monitor public sentiment carefully and match their crisis response to their target customer audience.

2 - On Syntactic and Semantic Attention Summary (SSAS): An Approach to Improve Summary Generation through LLM's

Nitin Mayande, Tellagence, Naperville, IL, United States, Sharookh Daruwalla, Sumedh Khodke, Nitin Joglekar, Charles Weber

In today's information age, the ability to efficiently extract key points from vast amounts of text is crucial. Automatic summarization, a subfield of NLP, tackles this challenge by generating condensed versions of documents while preserving essential information. However, achieving accurate summaries requires models to go beyond simple word frequencies.

Accurate summarization hinges on effectively bridging the gap between syntax and semantics. Syntactic cues often point towards semantically relevant information. Syntactic alignment provides a roadmap, identifying where to look for important information within a sentence structure. Semantic alignment then interprets the identified elements, extracting their meaning and relationships. In this paper we propose a combined approach leads to a more nuanced understanding of the text, enabling the generation of summaries that are not just grammatically sound but also semantically accurate. It also ensures that the broader context of the dataset is captured.

3 - Real-Time Product Development using Generative Artificial Intelligence

Charles Weber, Portland State University, Portland, OR, United States, Antonie Jetter, Dahm Mongkol Hongchai, Ameeta Agrawal, Yufei Tao

A workshop was conducted to train practitioners in real-time new product development (NPD) utilizing AI. Three teams of managers and engineers were allotted six hours to develop a marketing plan prototype using ChatGPT and other AI tools. The plans included customer identification, market analysis, persona creation, and a 15-minute presentation aimed at inspiring a sales force. A panel of judges, including the authors and an external marketing professional, assessed the teams' strengths, weaknesses, and overall viability. The workshop validated the efficacy of AI in NPD across various industries, with the outputs deemed "highly creative" and potentially viable. The primary takeaway was the demonstrated acceleration of product development activities.

4 - Five Pivotal Practices for Leaders to Cultivate Empathy within Virtual Scrum Teams

Dahm Mongkol Hongchai, Portland State University, Portland, OR, United States, Charles Weber

In today's digital and global economy, it's essential for business leaders to possess not only business and technology skills but also empathy. Yet, there is a significant lack of research focusing on the role of empathy within Agile product development, particularly when using the Scrum Framework. A qualitative, empirical study conducted at a professional accounting firm uncovered critical insights into how leaders can foster empathy within virtual Scrum teams. Actionable approaches to leadership involve five themes: Scrum fundamentals, meditation, self- and other-analysis, healthy interactions, and informal connections.

5 - Measuring servitization configurations through modularity

Juliana Hsuan, Copenhagen Business School, Frederiksberg, Denmark

Servitization is enabled through product and service configurations to offer value propositions that are attractive to customers. Modularity can provide powerful insights on how to measure the configuration options and respective implications for business model innovations.

Summit - 347

Product and Business Model Innovation

Invited Session

Technology, Innovation Management and Entrepreneurship

Co-Chair: Niyazi Taneri, Cambridge Judge Business School, Cambridge, United Kingdom

1 - Leveraging Suppliers for Innovation: Sourcing and Investment Strategies

Pascale Crama, Singapore Management University, Singapore, Singapore, Gaoyan Lyu, Yi Xu

Manufacturers benefit from supplier innovation that creates value for their customers. Yet because suppliers only appropriate a fraction of the value created, their investment level may not match the manufacturer's preferences. We show that the manufacturer prefers single sourcing for highly profitable innovations but exploits the competition effect of dual sourcing for less profitable innovations. Furthermore, the manufacturer may opt to co-invest in supplier innovation to increase supplier effort. Interestingly, we find that even in the face of symmetric suppliers and under dual sourcing, the manufacturer may prefer to invest asymmetrically in the two suppliers. Finally, we find that the structure of the optimal sourcing and investment strategy differ depending on whether the innovation leads to product introduction or product improvement. Innovations that lead to new product introduction never lead to dual sourcing with asymmetric investment, whereas product improvement innovations not only favor dual sourcing with or without manufacturer investment, but may also lead to asymmetric investment under dual sourcing with symmetric suppliers.

2 - Unraveling the Implications of Silent Labor TIME (Slt) in the Gig Economy

Srishti Arora, INSEAD, Singapore, Singapore, Vivek Choudhary, Sameer Hasija

The gig economy has become integral to the global economy, driven by the labor flexibility it affords companies and the self-scheduling options available to workers. However, it also introduces an additional discretion for workers; they need to search for tasks during downtime, i.e., intervals when the platform does not assign them tasks. This period of uncompensated task-seeking, which we call “Silent Labor Time (SLT),” necessitates balancing effort between searching and executing tasks, impacting execution time. Our research aims to establish how the effort allocated during SLT affects workers’ performance and earnings and identify factors that moderate this relationship. In food delivery, the distance drivers travel to find the next order, called “relocation distance,” represents the effort allocated during SLT.

Collaborating with a food delivery platform, we find that, on average, drivers relocate 2.6 km before each order, and a km increase in relocation distance reduces order allocation by 5.4%, order speed by 2.7%, and earnings by 14.8% in the subsequent hour. The primary reason for this decline is drivers allocating significant effort to searching for tasks during SLT, subsequently conserving energy when executing tasks. Relocations that are not towards familiar clusters and reduce supply-demand balance are most detrimental to workers' performance and earnings. Our findings suggest that relocation adversely affects drivers' earnings and operational performance in subsequent orders, ultimately impacting the platform's efficiency. We offer actionable insights by suggesting strategies for the management of effort allocation during SLT by different driver groups.

3 - How Do Robots Affect Firms&Rsquo; Innovation Performance? Evidence from Spanish Manufacturers

Yiyao Zhou, UCL School of Management, London, United Kingdom, Bilal Gokpinar

This paper examines the impact brought by robot use on manufacturing firms' innovation performance. The analysis uses a rich panel dataset of Spanish manufacturing firms over 27 years (1990-2016). Our findings document, the first time in the literature, that robot use has a negative effect on firms' process innovation. However, we do not observe a similar effect on firms' product innovation. We also explore mechanisms by which robot use may affect process innovation. We find that the negative effect of robot use on process innovation is only salient for complex manufacturing, rather than light manufacturing or heavy manufacturing. In addition, we find that the negative effects brought by robots on process innovation are smaller for older firms. These results point to a potential mechanism whereby robots may impede process innovation through reducing human involvement. Our findings highlight possible disadvantages brought by robots in manufacturing firms, a notion neglected by the previous literature.

4 - Shifting Targets: How Funding Goal Changes Influence Donation-Based Crowdfunding Success

Xiahua Wei, University of Washington, Bothell, Bothell, WA, United States, Weijia You, Xiaoya Xie

In the dynamic world of crowdfunding, the ability to pivot and adjust fundraising goals can make or break a campaign. With limited research on this topic in the literature, our study delves into the intriguing phenomenon of modifying fundraising targets mid-campaign and its impact on donor behaviors. Utilizing panel data from China's largest donation-based crowdfunding platform, we uncover that announcing changes in funding goals significantly boosts donations on the same day, increasing both the number of participants and the average donation per person. Interestingly, increasing fundraising targets has a more pronounced effect on donor behaviors compared to reducing them. Text analysis further reveals distinct motivations behind these adjustments. Beyond immediate impacts, our study investigates the overall performance of projects with modified goals, finding they achieve higher completion rates, daily fundraising averages, and cumulative funds raised. These insights offer valuable guidance for fundraisers on setting and adjusting funding targets to enhance donation-based crowdfunding campaign success.

5 - The Effects of Robots on the Workplace

FNU Adrianto, University of Minnesota, Minneapolis, MN, United States, Avner Ben-Ner, Ainhoa Urtasun

This paper examines the effects of robots across various occupations in U.S. manufacturing plants, extending extant research conducted at the firm and industry levels. We use a difference-in-differences approach matched on industry, commuting zone, and plant size to estimate how employment and skill demand for various occupations change after robot adoption. We find that the introduction of robots is associated with a 150 percent increase in the number of job postings and an increase in employment of 15 percent; the increase is larger in production than in support jobs. Comparing effects across plants within adopting firms, we show that the expansion only occurs in the robotic plants, suggesting that prior firm-level studies overlooked the distinction between adopter and (majority) nonadopter plants within firms, underestimating the robotization effect. We find a negligible employment effect at the industry level as the positive effect in adopters is counterbalanced by the loss of workers in nonadopters. The majority of jobs do not change skill composition following the adoption, but the robotized part of the plant requires more design, production, maintenance, repair, and programming skills. We provide credible evidence that the productivity and robot-human complementarity effects dominate any displacement effect and that loss of employment is limited to outcompeted nonadopters.

Recycling, Repurposing and Rebalancing in Precision Agriculture and Sustainable Systems

Invited Session

MSOM: Sustainable Operations

Chair: Metin Cakanyildirim, The University of Texas at Dallas, Richardson, TX, United States

Co-Chair: Lingling Shi, McMaster University, Hamilton, ON, Canada

1 - Circular Economy of EV Batteries: Economic and Environmental Impacts of Repurposing

Lingling Shi, McMaster University, Hamilton, ON, Canada, Metin Cakanyildirim, Sila Cetinkaya

The fast growth of electric vehicle (EV) and the increased energy storage markets stimulate the demand for batteries and in turn the critical minerals, which face high supply uncertainty. We investigate the economic and environmental impacts of repurposing spent EV batteries for energy storage in addition to recycling.

2 - Fighting the Plastic Pollution: Product Ban Regulation and Voluntary Compliance

Natalie Huang, University of Minnesota, Minneapolis, MN, United States, Wenli Xiao, Feifei Shan, Aditya Vedantam

We study a firm's voluntary recycling efforts as a proactive compliance strategy for future regulation to ban the sales of its products. We study the economic and environmental implications of the product ban regulation and the firm's compliance incentives.

3 - Equitable Supply-Demand Balancing: Tailoring Equitable Incentives for Demand Response Programs in Power Grids

Solmaz Abbaspour, University of Massachusetts, Amherst, MA, United States, Senay Solak

Demand response programs aim to shift electricity consumption from peak periods to off-peak periods to better match supply with demand, typically through prices or monetary incentives. We investigate equitable incentivization policies in demand response programs by considering diverse characteristics of various demographic groups. We model the trade-offs between equity and efficiency in such incentivization policies, and propose mechanisms that achieve efficiency while ensuring social equity among different customer profiles. The results are expected to provide utility companies with actionable insights for tailoring their demand response strategies more effectively, thus promoting a more sustainable and equitable energy management system.

4 - Evaluating the Trade-Offs Between Safety and Sustainability in a Supply Chain

Gal Raz, Ivey Business School at Western University, London, ON, Canada, Pantea Saremi, Jason Nguyen

This paper examines the impact of investing in safety for sustainable products. We consider a market with two competing manufacturers, one selling a conventional product, and the other a more environmentally sustainable one that could have some safety concerns as a result of altered material and/or production process. Examining the market, we evaluate the tradeoff between safety and sustainability for sustainable products and their economic and environmental impact. This evaluation entails examining sustainable product manufacturer's optimal strategy given the safety threshold they aim to attain.

5 - Outcome-based pricing for precision agriculture services

Heng Chen, University of Nebraska-Lincoln, Lincoln, NE, United States, Ying Zhang

Precision agriculture has been promoted by agricultural technology providers through the use of outcome-based pricing (OBP). In this paper, we examine the effects of OBP on the adoption rate of precision agriculture, and the benefits it offers to both farmers and service providers. We develop a two-period game model that incorporates providers' learning from experience. We also explore the implications of government intervention when the service provider switches to OBP from traditional pricing.

Advances in Network Optimization & Design

Invited Session

OPT: Integer and Discrete Optimization

Chair: Luca Wrabetz, University of Pittsburgh, Pittsburgh, United States

1 - Exploiting players' sub-optimal strategies in multi-level interdiction games.

Rafal Muszalski, University at Buffalo, Buffalo, NY, United States, Jose Walteros, Prashant Sankaran

In a two-player interdiction game, an exploitative strategy consists of a set of moves conducted by the leader to exploit the follower's inability to play optimally. Exploitative strategies can arise when there are imbalances in the game setup across the players, such as when the follower, due to some technological limitation, is restricted to conducting heuristic moves instead of optimal ones. In this work, we formulate an exploitative framework for solving multi-level interdiction games, leveraging a hybrid deep learning optimization approach. Our framework implements a Graph Neural Network (GNN) component that predicts sub-game solutions based on the structural characteristics of the game, as well as historical observations of previous iterations of the game, including the players' previously used strategies. We show that, by sampling solutions generated by the GNN, our approach can generate an estimated characterization of the follower's decision space and use it to parameterize an optimization model tailored to produce exploitative strategies. We test the performance of our framework by solving several three-level interdiction games, including a shortest path interdiction problem with fortification.

2 - Simple Randomized Rounding for Max-Min Eigenvalue Augmentation

Haeseong Yang, University of Pittsburgh, Pittsburgh, PA, United States, Jourdain Lamperski, Oleg Prokopyev

We consider the max-min eigenvalue augmentation problem: given an n × n symmetric positive semidefinite matrix M , vectors a1, . . . , am ∈ R^n, and a positive integer k ≤ m, the goal is to choose a subset I ⊂ {1, . . . , m} of cardinality at most k to maximize the minimum eigenvalue of the matrix M + ∑_{I∈I} a_ia^⊤_i . The problem captures both the maximum algebraic connectivity augmentation and E-optimal design problems. There are two distinct research streams dedicated to these problems that develop approximation algorithms based on rounding optimal semidefinite programming relaxation solutions. Interestingly, both research streams empirically evaluate the performance of "simple" randomized rounding methods but do not establish theoretical approximation guarantees for them. In this paper we establish approximation guarantees for a simple randomized rounding method applied to the general max-min eigenvalue augmentation problem. Furthermore, we investigate its empirical performance through computational experiments.

3 - Commit or defer shortest path interdiction

Shuai Shao, Oklahoma State University, Stillwater, OK, United States, Juan Borrero, Oleg Prokopyev

We study commit or defer interdiction problems when the interdictor has partial initial information about the network and the evader has complete knowledge of the network, including its structure and arc costs. The interdictor has limited resources for interdiction which cannot be renewed after being used. In each time period, the interdictor chooses to block some arcs, and observes feedback from the shortest path used by the evader. By observing the evader's feedback, the interdictor improves her knowledge about the network and adjusts her strategy for the later time periods accordingly to maximize the cumulative cost incurred by the evader. We show that in the worst-case, for arbitrary sets of initial information, interdicting one arc at a time is an optimal worst-case policy. For specific sets of initial information, however, this is not true. For these cases we consider optimistic and pessimistic policies that balance performance and resource expenditures by using Pareto frontiers. We formulate and compute these policies using mixed-integer programming, and show that they can outperform other benchmark policies in our numerical experiments. In particular, these policies as many arcs as the resources permit whenever the interdictor has a reasonably good estimate of the costs of the network, and interdict only one arc whenever the estimates are not good.

4 - Adaptive shortest-path interdiction of multiple followers

Luca Wrabetz, University of Pittsburgh, Pittsburgh, PA, United States

In this work, we define and describe a novel interdiction problem, the Adaptive Shortest-Path Interdiction of Multiple Followers Problem. In this problem, a decision maker selects multiple policies (subsets of arcs to attack or remove) in order to robustly interdict multiple followers who have different costs on the network. We develop three exact algorithms, as well as an approximation algorithm for the problem.

Modeling Problem Structure for Large Optimization Problems

Invited Session

OPT: Computational Optimization and Software

Chair: Alan King, IBM Research, Yorktown Heights, NY, United States

1 - Modeling Uncertainty in Mosdex

Alan King, IBM Research, Yorktown Heights, NY, United States

The Stochastic MPS format (S-MPS) is the go-to data format for Stochastic Programming, which applies optimization-based models and algorithms to address decision-making under uncertainty. This talk discusses the implementation of S-MPS in the MOSDEX framework.

2 - Representing Structured Optimization Models in Mosdex

Jeremy Bloom, self, Sunnyvale, CA, United States, Alan King, Matthew Saltzman, William Hart

MOSDEX (Mathematical Optimization Solver Data Exchange) is a new standard for representing optimization models that has many capabilities including independence from solvers, modeling languages, and programming languages, and end-to-end support of the application data flow. In particular, MOSDEX uses Structured Query Language (SQL) to specify compactly and efficiently the data transformations that feed the highly specialized artifacts that comprise an optimization model. Critically, existing formats poorly capture models' higher-level structure, limiting their usefulness in specialized domains such as stochastic programing and algorithms such as decomposition. This presentation presents extensions of MOSDEX to reflect such structure including: 1) modules to represent subproblems, 2) structure tables to represent relationships among modules, and 3) replication of modules on subsets of the data. The presentation will include explicit examples of their use in MOSDEX .

3 - Enabling Performant Optimization Modeling Languages

William Hart, Sandia National Laboratories, Berlin, MA, United States

We revisit the design of optimization modeling languages to reassess their role in the formulation and analysis of large, complex applications. Modeling languages like AMPL, Coek, GAMS, JuMP and Pyomo simplify the process of expressing complex mathematical expressions in an optimization formulation, and they automate the translation of these models to automate the execution of solvers and related model evaluations (e.g. gradient and Hessian calculations). Here, we consider the implications of modeling language design on the total computational cost for solving complex applications. Specifically, we discuss how a compact but restricted expression of complex equations can be exploited to enable nontrivial performance optimizations. Further, this idea supports the parallel generation of models, generation of LaTeX model descriptions, and interfaces to high-level representations like MOSDEX. We illustrate this idea using examples from Pyomo and Coek, and describe Smoek, a new python-based modeling language that explicitly exploits compact expressions.

4 - Mosdex for the Coin-or Open Solver Interface

Matthew Saltzman, Clemson University, Clemson, SC, United States

We describe a C++ library for reading and writing MOSDEX files from the COIN-OR Open Solver Interface (OSI). The library provides the capability of communicating problem instance data and structure to solvers supported by the OSI.

Summit - 422

Machine Learning for Optimization - I

Invited Session

OPT: Machine Learning

Chair: Gonzalo Constante Flores, Purdue University, West Lafayette, IN, United States

1 - Ensuring Neural Network Solution Feasibility for Constrained Optimization

Minghua Chen, City University of Hong Kong, Hong Kong, Hong Kong

There has been growing interest in employing neural network (NN) to directly solve constrained optimization problems with low run-time complexity. However, it is non-trivial to ensure NN solutions strictly satisfying problem constraints due to inherent NN prediction errors. Existing feasibility-ensuring methods either are computationally expensive or lack performance guarantee. In this talk, we present homeomorphic projection as a low-complexity scheme to guarantee NN solution feasibility for optimization over a general set homeomorphic to a unit ball, covering all compact convex sets and certain classes of nonconvex sets. The idea is to (i) learn a minimum distortion homeomorphic mapping between the constraint set and a unit ball using an invertible NN (INN), and then (ii) perform a simple bisection operation concerning the unit ball so that the INN-mapped final solution is feasible with respect to the constraint set with minor distortion-induced optimality loss. We prove the feasibility guarantee and bound the optimality loss under mild conditions. Simulation results, including those for non-convex AC-OPF problems in power grid operation, show that homeomorphic projection outperforms existing methods in solution feasibility and run-time complexity, while achieving similar optimality loss. We will also discuss open problems and future directions.

2 - Safe Learning Control of Inverter-Based Power Systems with Stability and Safety Constraints

Zixiao Ma, University of Washington, Seattle, WA, United States

As we strive for decarbonization, the power system is evolving to integrate more renewable energy resources, contributing to a cleaner and more sustainable energy landscape. Nevertheless, renewable resources such as wind and solar power typically exhibit low system inertia and have inherently variable output. Consequently, systems with a high penetration of renewable energy are more vulnerable to disturbances and fluctuations in power quality. To improve system reliability, it is crucial to control the critical states such as voltage, frequency, and current to stay within the safety constraints. Conventional computational methods require solving a constrained optimization problem to calculate the control signal iteratively. Such a method is computation-costly for high-order or nonlinear systems and is too slow to be applied in real-time. To overcome the above problems, I proposed a safety-critical voltage control method for inverter-dominated renewable energy systems to improve online computational efficiency while guaranteeing safety constraints. The key idea is to leverage the learning ability of neural networks to cast the online iterative constrained optimization into the offline training. Instead of using the neural network as a black box, we substitute it explicitly into the closed-loop system for deriving the stability and safety constraints. Then, the neural network is trained to optimize the control performance and the size of the stability region under the constraints. The well-trained controller is a static function of system states, such that it can be computed rapidly for online implementation.

3 - Ac-Network-Informed DC Optimal Power Flow for Electricity Markets

Gonzalo Constante Flores, Purdue University, West Lafayette, IN, United States, André Quisaguano, Antonio Conejo, Can Li

The DC optimal power flow (DC-OPF) problem is the workhorse for power systems and market operations in the power industry. The growth in electric demand due to data centers and electrification in the transportation and industrial sectors has driven the operation of power systems to conditions where the solution of the DC-OPF problem could be inaccurate with respect to its nonconvex counterpart. This talk presents a parametric quadratic approximation for the AC-OPF model that reduces the dispatch approximation error with respect to its nonconvex formulation while targeting desirable market properties. The parametric approximation preserves the physics-based formulation provided by the DC-OPF model and leverages the market and physics information encoded in the data-driven demand-dependent parameters. To enable the use of the considered model for real-time applications, we propose a supervised-learning approach to predict near-optimal parameters, given a certain metric with respect to the dispatch outcome and locational marginal prices. The training dataset is generated based on solutions of the AC-OPF problem and a bilevel optimization problem, which identifies parameters satisfying two market properties: cost recovery and revenue adequacy. We demonstrate the performance of the proposed approach using a variety of test systems in terms of cost and dispatch approximation errors, distance to feasibility, and generalizability with respect to N-1 network topologies.

4 - Data-driven robust optimal design and control of floating offshore windfarms

Natalie Isenberg, Pacific Northwest National Laboratory, Richland, WA, United States, Bruno Jacob, Jan Drgona, Draguna Vrabie

The unpredictable nature of wind resources presents significant challenges in planning and operating floating offshore wind farms. Efficient wind farm design must account for the uncertainty in wind conditions to prevent substantial efficiency losses and ensure reliable power generation. While many studies have focused on deterministic models and uncertainty quantification for wind farm planning, fewer have addressed optimal design under uncertainty. This work aims to identify robust optimal designs and control policies for floating offshore wind farms that can withstand uncertainty in wind characteristics. We first derive a fully equation-oriented, continuous, nonlinear, and non-convex steady-state model of a wind farm based on parametric wake effect models. A robust optimization methodology is then paired with data-driven approaches to construct uncertainty sets, aiming to find the best wind farm design and control under worst-case wind characteristic scenarios. This is particularly important for floating wind farms, which face greater variability and challenges due to their offshore environments and mobility.

Co-Chair: Mahyar Fazlyab, Johns Hopkins University, Baltimore, MD, United States

1 - SimFBO: Towards Simple, Flexible and Communication-efficient Federated Bilevel Learning

Kaiyi Ji, University at Buffalo, Buffalo, NY, United States, Yifan Yang

Federated bilevel optimization (FBO) has shown great potential recently in machine learning and edge computing due to the emerging nested optimization structure in meta-learning, fine-tuning, hyperparameter tuning, etc. However, existing FBO algorithms often involve complicated computations and require multiple sub-loops per iteration, each of which contains a number of communication rounds. In this paper, we propose a simple and flexible FBO framework named SimFBO, which is easy to implement without sub-loops, and includes a generalized server-side aggregation and update for improving communication efficiency. We further propose System-level heterogeneity robust FBO (ShroFBO) as a variant of SimFBO with stronger resilience to heterogeneous local computation. We show that SimFBO and ShroFBO provably achieve a linear convergence speedup with partial client participation and client sampling without replacement, as well as improved sample and communication complexities. Experiments demonstrate the effectiveness of the proposed methods over existing FBO algorithms.

2 - Single-loop Projection-free and Projected Gradient-based Algorithms for Nonconvex-concave Saddle Point Problems with Bilevel Structure

Mohammad Mahdi Ahmadi, University of Arizona, Tucson, AZ, United States, Erfan Yazdandoost Hamedani

In this talk, we investigate a broad class of constrained saddle point problems with a bilevel structure. Here, the upper-level objective function is nonconvex-concave and smooth over compact and convex constraint sets, subject to a strongly convex lower-level objective function. To contribute to the existing literature, we consider a more general setting where the upper-level function is not necessarily strongly concave or linear in the maximization variable. Moreover, we propose a one-sided projection-free method employing a linear minimization oracle. In particular, through regularization and nested approximation techniques, we introduce one-sided projection-free and projected gradient-based algorithms capable of achieving an ε-stationary solution within $O(\varepsilon^{-4})$ and $O(\varepsilon^{-5}\log(1/\varepsilon))$, respectively. When the upper-level objective function is linear in the maximization component, our results improve to $O(\varepsilon^{-3})$ and $O(\varepsilon^{-4})$, respectively.

3 - Prediction-Correction Bilevel Optimization in Continuous Time Models

Nazanin Abolfazli, University of Arizona, Tucson, AZ, United States, Mahyar Fazlyab, Erfan Yazdandoost Hamedani

This Work introduces an advanced continuous-time dynamical system framework designed to address bilevel optimization problems, which are characterized by interdependent decision-making across two levels and are prevalent in disciplines such as engineering, economics, and transportation. The proposed approach leverages continuous-time dynamics to simultaneously resolve upper and lower-level objectives, providing a potent alternative to conventional discrete-time methods.In this study we obtain the convergence rates of our algorithm, both with and without lower-level constraints. Additionally, we conduct extensive numerical experiments to demonstrate the efficacy and superior performance of our method compared to existing solutions.

Advances in Data-driven Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Hoda Bidkhori, George Mason University, Fairfax, VA, United States

1 - Robust Quickest Change Detection in Non-Stationary Processes

Yingze Hou, University of Pittsburgh, Pittsburgh, PA, United States

Exactly and asymptotically optimal algorithms are developed for robust detection of changes in non-stationary processes. In non-stationary processes, the distribution of the data after change varies with time. The decision maker does not have access to precise information on the post-change distribution. It is shown that if the post-change non-stationary family has a distribution that is least favorable in a well-defined sense, then the algorithms designed using the least favorable laws are robust optimal. This is the first result where an exactly robust optimal solution is obtained in a non-stationary setting, where the least favorable law is also allowed to be non-stationary. Examples of non-stationary processes encountered in public health monitoring and space and military applications are provided. Our robust algorithms are also applied to real and simulated data to show their effectiveness.

2 - Optimizing Inventory Policies in a Multi-echelon Inventory System Using a Lead Time Approximation

Sharmine Akther Liza, Lehigh University, Bethlehem, PA, United States, Larry Snyder

This study discusses a heuristic for determining an inventory policy for each stage in a general multi-echelon inventory system, which exhibits stochastic lead times because of random stock-outs throughout the system. Stochastic lead times pose challenges not only for general multi-echelon inventory systems but even for simpler, serial systems. Dynamic programming (DP) has mostly been used in single-stage or serial inventory systems considering deterministic lead times. But with stochastic lead times it becomes impossible to solve because of the larger state space. Our proposed heuristic addresses this problem by approximating the lead time distribution based on stock levels of each stage in the inventory system. Ultimately, the DP algorithm uses this approximate lead time distribution to approximate the demand distribution, which facilitates optimizing the optimal inventory policy for each stage.

3 - Effective Scenarios in Distributionally Robust Optimization with Wasserstein Distance

Guzin Bayraksan, The Ohio State University, Columbus, OH, United States, Chennan Zhou

We investigate *effective scenarios* in Distributionally Robust Optimization (DRO) problems where the ambiguity set of distributions are defined on a finite number of realizations (also called scenarios) of the uncertain parameters using the Wasserstein distance. *Effective scenarios* are critical scenarios in DRO in the sense that their removal from the support of the considered distributions alters the optimal value. *Ineffective scenarios* are those whose removal do not alter the optimal value. We first link the effectiveness of a scenario to its worst-case probability being always positive or uniquely zero under a general ambiguity set. We then narrow our focus to DROs with ambiguity sets formed via the Wasserstein distance (DRO-W) and provide easy-to-check sufficient conditions to identify the effectiveness of scenarios for this class of problems. When the Wasserstein distance is equivalent to the total variation distance (i.e., when the transportation cost between scenarios is zero if they are the same and one if they are different), the easy-to-check conditions for DRO-W presented in this talk recover the ones presented in the literature for DRO formed via the total variation distance as a special case. The numerical findings highlight the relationship between scenario effectiveness and the attributes of the transportation cost between scenarios that constitute the Wasserstein distance, revealing useful insights.

4 - Data-Driven Optimization in Partially Observable Environments

Hoda Bidkhori, George Mason University, Fairfax, VA, United States

Missing data is a common issue for many practical data-driven stochastic programming problems. The state-of-the-art approaches first estimate the missing data values and then separately solve the corresponding stochastic programming. Accurate estimation of missing values is typically inaccessible as it requires enormous data and sophisticated statistical methods. Therefore, this paper proposes an integrated approach, a distributionally robust optimization (DRO) framework, that simultaneously tackles the missing data problem and data-driven stochastic optimization by hedging against the uncertainties of the missing values. This paper adds to the DRO literature by considering the practical scenario where the data can be incomplete and partially observable; it particularly focuses on data distributions with finite support.

We construct several classes of ambiguity sets for our DRO model utilizing the incomplete data sets, maximum likelihood estimation method, and different metrics. We prove the statistical consistency and finite sample guarantees of the corresponding models and provide tractable reformulations of our model for different scenarios. We perform computational studies on the multi-item inventory control problem and portfolio optimization using synthetic and real-world data. We validate that our method outperforms the traditional estimate-then-optimized approaches

New Advances in Large-Scale Non-Linear Optimization

Invited Session

OPT: Nonlinear Optimization

Chair: Miaolan Xie, Cornell University, Ithaca, NY, United States

1 - Sample Sizing for Function Estimation in Stochastic Derivative-Free Optimization

Luis Nunes Vicente, Lehigh University, Bethlehem, PA, United States

We introduce a new tail bound condition for function estimation which allows for an improvement in the required sample sizing for derivative-free optimization of the order delta^{-2q} (non-correlated errors) and delta^{2-2q} (correlated errors), where delta is the step size or trust-region radius and the error is assumed to have a momentum of order q/(1-q). We also introduce simple stochastic non-smooth direct-search and trust-region methods, sharing the following principles: generate a direction; generate the new iterate by either search along the direction or by solving a trust-region subproblem (where the linear term is the direction); use a sufficient decrease acceptance test to decide if the trial point can be accepted or not. The methods are shown to globally converge almost surely under the new tail bound condition. We will also report more recent results on sequential sampling. Joint work with F. Rinaldi and D. Zeffiro.

2 - Searching for Optimal Per-Coordinate Step-Sizes with Multidimensional Backtracking

Frederik Kunstner, University of British Columbia, Vancouver, BC, Canada, Victor Sanches Portella, Mark Schmidt, Nicholas Harvey

The backtracking line-search is an effective technique to automatically tune the step-size in smooth optimization. It guarantees similar performance to using the theoretically optimal step-size. Many approaches have been developed to instead tune per-coordinate step-sizes, also known as diagonal preconditioners, but none of the existing methods are provably competitive with the optimal per-coordinate step-sizes. We propose multidimensional backtracking, an extension of the backtracking line-search to find good diagonal preconditioners for smooth convex problems. Our key insight is that the gradient with respect to the step-sizes, also known as hyper-gradients, yields separating hyperplanes that let us search for good preconditioners using cutting-plane methods. As black-box cutting-plane approaches like the ellipsoid method are computationally prohibitive, we develop an efficient algorithm tailored to our setting. Multidimensional backtracking is provably competitive with the best diagonal preconditioner and requires no manual tuning.

3 - First-Order Methods for Bilevel Optimization

Zhaosong Lu, University of Minnesota, Minneapolis, MN, United States, Sanyou Mei

Bilevel optimization, also known as two-level optimization, is an important branch within mathematical optimization. It has found applications across various domains, including economics, logistics, supply chain, transportation, engineering design, and machine learning. In this talk, we will present first-order methods for solving a class of bilevel optimization problems using either single or sequential minimax optimization schemes. We will also discuss the first-order operation complexity of these methods and present preliminary numerical results to illustrate their performance.

4 - On Existence of Solutions to Non-Convex Minimization Problems

Rohan Rele, ASU, Tempe, AZ, United States, Angelia Nedich

We describe sufficient conditions for existence of a solution to a general minimization problem of a closed, proper objective function on nonempty, closed feasible set. We introduce a novel relaxation of coercivity and exploit the asymptotic geometry of unbounded feasible regions to unify previously known existence results of Frank-Wolfe-type. We show that our conditions apply to a broad class of objective functions and feasible regions in both convex and non-convex settings.

Chair: Amro El-Adle, Strome College of Business, Old Dominion University, Norfolk, VA, United States

1 - Fairness in Drone Delivery Flight Paths

Amro El-Adle, Strome College of Business, Old Dominion University, Norfolk, VA, United States, Ahmed Ghoniem, Blake Steiner

We investigate the impact of noise pollution on flight path planning for last-mile delivery via drone. Over an extended planning horizon, the proposed mathematical model optimizes the selection of flight paths used to mitigate noise pollution for residents in the path of the drones. Our results reveal that a set of operational strategies may greatly mitigate not only the overall level of noise pollution, but may also result in a more equitable distribution of the noise from drone flights.

2 - A decomposition approach for parcel delivery by vehicle and drone over ordered neighborhoods

Ahmed Ghoniem, Isenberg School of Management, UMass Amherst, Amherst, MA, United States, Semih BOZ, Amro El-Adle

We examine a multi-vehicle last-mile delivery problem with companion drones over pre-ordered residential neighborhoods. The problem is formulated as a mixed-integer program that is enhanced with valid inequalities. Alternatively a decomposition technique is proposed and tested over problem instances based on the town of Amherst, MA. Computational results are discussed.

3 - Parcel Consolidation In Last Mile Delivery by Vehicle and Drone

Semih BOZ, Isenberg School of Management, UMass Amherst, Amherst, MA, United States, Ahmed Ghoniem, Amro El-Adle

We study parcel consolidation within the context of last-mile delivery, employing both a vehicle and a companion drone to efficiently serve customers across multiple time periods. We present a mixed-integer program enhanced with RLT based valid inequalities and an optimization-based heuristic to address large-scale instances. The efficacy of our methodology is assessed through computational experiments on randomly generated instances, focusing on a residential network in Amherst, Massachusetts. Additionally, a sensitivity analysis is conducted with respect to selected parameters.

Innovative Strategies in Freight and Logistics: From Air Mobility to Electric Trucks

Invited Session

TSL: Freight Transportation

Chair: Ruiting Wang, University of California, Berkeley, Berkeley, CA, United States

1 - Optimal Dispatching in Two-Sided Spatial Queues

Ang Xu, University of California, Berkeley, Berkeley, CA, United States, Chiwei Yan

We study an optimal dispatching problem in two-sided spatial queues motivated by ride-hailing platforms. The platform aims to maximize the system throughput (or revenue) penalized by waiting cost by controlling the matching process through a Markov Decision Process framework. Under some mild conditions, we give closed-form state-dependent dispatching policies. In the general case, we develop an efficient dynamic programming algorithm for finding optimal policy within a sub-class of dispatching policies.

2 - A TIME-Invariant Network Flow Model for Ride-Pooling in Mobility-on-Demand Systems

Fabio Paparella, Eindhoven University of Technology , Eindhoven, Netherlands

This paper presents a framework to incorporate ride-pooling from a mesoscopic point of view, within time-invariant network flow models of Mobility-on-Demand systems. The resulting problem structure remains identical to a standard network flow model, a linear problem, which can be solved in polynomial time. In order to compute the ride-pooling assignment, which is the matching between two or more users so that they can be pooled together, we devise a polynomial-time knapsack-like algorithm that is optimal w.r.t. the minimum vehicle travel time with users onboard. Finally, we conduct two case studies of Sioux Falls and Manhattan, where we validate our models against state-of-the-art results, and we quantitatively highlight the effects that maximum waiting time and maximum delay thresholds
have on the vehicle hours traveled, overall pooled rides and actual delay experienced. Last, we show that allowing for four people ride-pooling can significantly boost the performance of the system.

3 - Integrating Unmanned Aircraft Vehicles into Grid

Jiaman Wu, UC Berkeley, Berkeley, CA, United States

The rapid growth of e-commerce, coupled with the urgent need for decarbonization and advancements in technology, is revolutionizing urban package delivery. Among various innovations being considered, delivery by Unmanned Aircraft Vehicles (UAVs) is increasingly seen as a component with great potential for future urban freight movement, as it offers rapid and point-to-point deliveries. With a potentially significant demand for UAV delivery in the future, there is a growing need to efficiently manage UAV operations in urban environments. Since UAV operations rely heavily on battery charging and fast-charging capabilities, optimizing their charging schedules is crucial for integrating UAVs into the grid effectively. This study aims to improve the balance of loads on the electric grid and minimize the impact on power grid loads, voltage, frequency, and power losses by controlling UAVs' charging schedules.

4 - Joint Optimization of Charging Infrastructure Placement and Operational Schedules for a Fleet of Battery Electric Trucks

Juan Pablo Bertucci, Eindhoven University of Technology, Eindhoven, Netherlands, Theo Hofman, Mauro Salazar

In the immediate advent of zero-emission zones, fleet operators are transitioning to electric fleets. To maintain their current operations, a clear understanding of the required charging infrastructure and its relationship to existing power grid limitations and fleet schedules is essential.

In this context, we introduce an optimization framework for designing the charging infrastructure and creating routing and charging schedules for a logistic distribution network. We validate our results using agent-based simulations.

Specifically, we start by formulating the joint infrastructure design and operational scheduling problem as a mixed-integer linear program. Next, we develop an agent-based model that acts as a virtual experimental replica to evaluate various design and operational solutions.

Finally, we conduct experiments comparing rule-based approaches to optimized design and operation strategies across key operational metrics, as well as power requirements. Our case study focuses on the logistics network in The Netherlands.

The results reveal that distributed vehicle charging rules mitigate the impact of consumption uncertainties, thereby enhancing logistics reliability. However, central coordination leads to more cost-efficient solutions (16.1% to 35.4% energy cost reductions) and less stringent power requirements (22.8% to 47.9% less time operating at peak consumption).

Explainable optimization and simulation frameworks, incorporating real-case reliability metrics, play a crucial role in improving decision-making and facilitating a smoother transition to battery electric trucks.

Semiconductor Industry and Batch Production

Contributed Session

Contributed

Chair: julien Maurice

1 - Reinforcement Learning-based Facility Layout Redesign to Improve Logistics Efficiency on a Semiconductor FAB

Ha Neul Kim, Korea University, Seoul, Korea, Republic of, Junghoon Kim, Subin Oh, Sangmin Lee, Taesu Cheong

This research aims to improve logistics efficiency through M:N exchange of facilities based on the existing facility layout in a semiconductor FAB. To produce a semiconductor, multiple processes must be performed along the processing sequence. After each process is completed, work in progress (WIP) is transported to the next process facility, thus the flow of logistics has a significant effect on productivity. However, the facility layout within a FAB is typically oriented towards maximizing production capacity within a limited space, and optimizing the flow of logistics is often disregarded. Our goal is to minimize the sum of the distances between any two facilities, each belonging to consecutive processes, through the exchange of interchangeable facility sets based on the existing layout. This problem is characterized by changes in distances between exchanged facilities and remaining facilities after any exchange occurs. Therefore, we propose a dynamic programming algorithm, and in addition, an attention network-based deep reinforcement learning model is proposed to consider the computational complexity. Through experiments, we compare the performance between our proposed reinforcement learning model and other heuristic algorithms.

2 - Continual learning-based remaining useful life prediction of machining tools under varying operating conditions

Gyeongho Kim, Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of, Yun Seok Kang, Sang Min Yang, Jae Gyeong Choi, Gahyun Hwang, Hyung Wook Park, Sunghoon Lim

Data-driven prediction of the remaining useful life (RUL) of equipment and assets has become one of the most important tasks in manufacturing. Accurate RUL prediction not only helps prevent unexpected failures but also enables maximal utilization of available life, thus contributing to improved process efficiency. However, in practice, the use of multiple operating conditions that vary by time impedes performing an efficient data-driven RUL prediction. Unlike conventional supervised learning setups, varying operating conditions generate heterogeneous data of which the generating distribution also is time-varying. Thus, existing approaches cannot be effectively applied due to linearly increasing modeling and memory costs. One of the domains that suffer from this issue is machining, where accurate RUL prediction of cutting tools is extremely important for productivity. Considering the realistic circumstances where operating conditions vary over time, this work proposes Fisher-informed continual learning (FICL), which enables an efficient tool RUL prediction by using a single model that adaptively learns as condition changes without the need to store previous data and models. In particular, Fisher information is used to improve generalization via sharpness-aware minimization and to transfer informative knowledge between operating conditions through regularization-based continual learning. Experiments are performed using datasets collected from real-world machining processes under five distinct operating conditions. The results prove the efficacy of the proposed FICL, indicating its superior RUL prediction performance to existing data-driven approaches for all operating conditions. In addition, the proposed FICL has shown the least catastrophic forgetting, implying that it effectively retains informative knowledge from previous operating conditions.

3 - The concept of Hyperconnected Mobile Supply Chains to address the distributed production near customers problem.

julien Maurice, H. Milton Stewart School of Industrial and Systems Engineering,Georgia Institute of Technology, Atlanta, GA, United States, Simon Kwon, Benoit Montreuil

In a world where consumers demand high-quality products at minimum cost and with rapid delivery, traditional production and delivery models are challenged, especially when considering large-sized products such as modular building units. As a solution, the concept of Hyperconnected Mobile Production was developed by Montreuil and Marcotte (2016). This strategy leverages the concepts of modularization, standardization, interfaces, and protocols of the Physical Internet, to allow businesses to dynamically expand and contract their production capacity in a network of open certified facilities. In their paper, they limit to a single-tier setting. However, supply chains are oftentimes multi-tier multi-party systems that require interaction between multiple production networks. The gap leads us to introduce the concept of Hyperconnected Mobile Supply Chains, extending from single-tier multi-party production networks to multi-tier multi-party supply chains, linking multiple mobile production networks with plug-and-play modular mobile production units across the supply tiers and enabling creation of flexible, responsive, and environmentally friendly supply chains.

Several criteria impact the pool of facilities to consider, such as cost, environmental, or societal objectives. We propose a multi-objective mixed integer programming formulation for the strategic network design of hyperconnected mobile supply chains to serve a dynamic set of customers across a wide territory, leveraging existing open production facilities and proposing location and capacity of supplementary facilities. We propose a solution approach leveraging the epsilon-constraint method. We present experimental results from an industrial case to assess the computational performance and the economic and environmental benefits brought by Physical Internet enabled Hyperconnected Mobile Supply Chains.

1 - Deploying Next Generation Technologies for Aerial Urban and Rural Delivery

Mark Moore, Whisper Aero, Crossville, TN, United States

Aerial delivery is an emerging direct delivery option for smaller packages that leverages flying drone technologies. The operational aspects for these deliveries are highly complex, as significant environmental constraints are present, especially in densely populated urban areas for the final 100' distance. Varied approaches are being operationally tested, including use of parachutes, winches, building attachment, portals, car rooftop, and ground landing - each facing their own obstacles towards achieving high reliability, minimum risk, and maximum community acceptance. The author's involvement in the UberEats drone delivery project provided valuable insight across these options that included test deliveries with partners. A common obstacle across all approaches is drone noise as one of the most significant obstacles for community acceptance. Another community acceptance obstacle is the perceived safety of operations, particularly in the event of a component failure. New technology approaches offer methods to mitigate both of these concerns. Ensuring the merging of new technologies, opportunities and operational approaches can achieve not only reliability, risks and community acceptance - but also meet aggressive platform and delivery costs, which is critical for drone delivery to reach scaled operations. The presentation will focus on an overview of the drone delivery opportunity, existing developers and their specific approaches, a requirement perspective for what's needed, and Whisper Aero's electric electric ducted fan technology that eliminates exposed blades to achieve high efficiency and ultra-quiet operations.

2 - Noise Analysis for Drone Delivery Operations

Raphael Gautier, Georgia Institute of Technology, Atlanta, GA, United States, Holger Pfaender, Dimitri Mavris

The unmanned aircraft system (UAS) market, which includes drone package delivery, is expected to grow rapidly in the coming years, possibly leading to large-scale operations whose environmental impact will have to be assessed to be authorized. However, UAM operations bring unique requirements that are not addressed by today’s noise assessment capabilities, which focus on commercial aviation operations around airports during the departure and arrival phases of flights. UAM operations are expected to be denser than current general or commercial aviation operations, requiring the ability to analyze many flights simultaneously. UAM vehicles are expected to be relatively small and quiet, leading to more localized noise footprints than traditional aviation operations, calling for higher spatial resolution of analyses. Finally, UAM operations are expected to be stochastic in nature with day-to-day variations stemming from demand. The objective of this research is to develop a novel noise estimation method that supports the computation of noise resulting from the stochastic operation of UAS with irregular locations and operations in large numbers. To achieve this, we propose a multi-step approach: 1) demand estimation, leveraging publicly available US census data, 2) planning of operations, accounting for diverse concepts of operations and the presence of multiple operators, 3) path planning, to estimate the actual trajectory followed by vehicles, 4) noise propagation, where source noise from operating vehicles is propagated to a dense grid of virtual receivers. We demonstrate the proposed approach on a notional use case featuring multiple operators over the Atlanta urban area.

3 - Towards safe and fluent interactions for autonomous systems

Karen Leung, University of Washington, Seattle, WA, United States

Autonomous robots are becoming increasingly prevalent in our daily existence, from navigating our roads and sky, assisting in households and warehouses, conducting daring search and rescue missions, and even exploring the frontiers of space. Yet building robots that can safely and fluently interact with humans in a trusted manner remains an elusive task. Ensuring robots can keep a sufficiently safe distance from humans is at odds with fluent interactions, yet humans are remarkable at seamlessly avoiding collision in crowded settings. In this talk, we will study how humans engage in safe and fluent multi-agent interactions and how this can be applied to robot decision-making and control. With a few relatively simple tweaks to a general trajectory optimization formulation, we can induce legible and proactive robot behaviors that can lead to prosocial interactions. This talk aims to rethink how safety and fluency can be more compatible with one another, leading to more natural and trusted autonomous operations.

4 - Walmart Drone Delivery

Coline Ramee, Walmart, Sunnyvale, CA, United States, Yuqian Dong, Xinyue Peng, Precia Carraway

With 90% of the US population located within 10 miles of one of its stores, Walmart is uniquely positioned to provide drone delivery service to its customers, making a large assortment of products available in less than 30 minutes without leaving the comforts of home.

Initial pilots have proven the feasibility, interest and acceptance from the local communities. Walmart is currently expanding aggressively around Dallas and plans to cover 75% of single-family homes in this market by early 2025. This will be used to prove the economic viability of the drone delivery service and observe customer behavior.

To identify the best markets to launch drone deliveries, feasibility, demand, and coverage were considered.

Today, drones can only operate in fair weather and are restricted to operate away from airports, removing 25% of potential locations.

A granular demand model, accounting for customers affinity for drone delivery based on their distance to stores, was developed. Current customer orders were used to estimate the basket value that could be expected for drone orders based on the payload weight and dimensions.

Store selection was optimized based on operational constraints to maximize satisfied demand while minimizing operating costs. Other Walmart initiatives, such as increasing fulfillment automation in the stores, are being leveraged during the selection to reduce the cost to serve.

This approach allowed us to define a coherent strategy for drone in a rapidly evolving technological and regulatory landscape. The assumptions and results of the model will be validated in the coming year in Dallas.

Behavior in Queueing and Service Systems

Invited Session

Behavioral Operations Management

Chair: Blair Flicker, University of South Carolina, Columbia, SC, United States

1 - Give Me a Choice! a Field Experiment on Task Choice Enabled by Wearables

Daniel Kwasnitschka, University of South Carolina, Columbia, SC, United States, Henrik Franke, Torbjorn Netland

Considering human motivation, is it more effective to delegate work tasks to shop floor workers or let them choose among a set of open tasks? This paper reports the results of a field experiment conducted with a manufacturer that uses wearable devices to distribute shop floor tasks. We show that a system that allows workers to choose their next task outperforms a task delegation system in productivity but does not affect work speed and decreases workers' task responsiveness. We measure the effect of giving workers the choice to choose the next task using a Difference-in-Difference approach in a 13-week-long field experiment. We collect data from 65,348 machine status reports and 49,050 work tasks completed in two manufacturing plants in Germany and Italy. Our results indicate a productivity increase of 6.9%, which corresponds to an estimated annual savings potential of USD 98,168. In summary, our results both align with and challenge aspects of organizational theories on human motivation in work settings. This offers interesting implications for production managers considering the implementation of digital task-distribution systems.

2 - Experienced and Prospective Wait in Queues: a Behavioral Investigation

Jing Luo, University of Science and Technology Beijing, Beijing, China, People's Republic of, Leon Valdes, Sera Linardi

Problem definition: The relative contribution of the length, speed, and wait time of a queue to people’s disutility is not well understood. Empirical studies show deviations from hyper-rationality, but the impact of each factor—separate from one another and differentiating their effects in the experienced (elapsed) vs. prospective (remaining) queue—is unclear. This problem is compounded by the fact that the continuous cost of completing a queue, V , is often studied only indirectly through binary, censored decisions like balking or reneging. Methodology/results: Using a series of controlled experiments, we introduce the use of the Becker-DeGroot-Marschak (BDM) method to directly measure V in deterministic, visible queues. With it, we study the effects of our key parameters of interest concurrently, hence avoiding omitted- variable biases. We find that customers consider the length and speed of the queue ahead of them additively, not multiplicatively as they would if they were responding proportionally to total wait time. Regarding the experienced queue, we observe that in most cases, it does not affect completion costs. The only exception is in the slowest of our queues, and only when participants have made significant progress, when we find signs of commitment through lower completion costs. Managerial Implications: Organizations regularly offer customers paid options to shorten their wait time, present them with alternatives to joining a line, or use incentives to manage congestion. Our work provides them with a granular metric of completion costs, measured in monetary terms, as well as an understanding of their dependence on queuing factors.

3 - How a Wait's Presentation Affects Its Perceived Cost

Blair Flicker, University of South Carolina, Columbia, SC, United States, Charlie Hannigan

Physical queues are being replaced by virtual waiting systems. Managers must now decide how to communicate wait characteristics to customers, and we show that their choice of presentation scheme can substantially influence behavior. This paper describes two controlled experiments. The first focuses on customers’ accuracy in forecasting the duration of hypothetical waits while the second studies customers’ preferences over real waits. In both, we study two wait presentation formats: Clocks and Queues. Clocks (e.g., apps displaying expected waiting times) excel at clearly communicating total wait time to customers, but they emphasize wait duration which increases people’s perceived disutility of the wait. Queues (e.g., wait lists showing a position in line), in contrast, make it difficult for customers to derive total wait time. When facing Queues, people’s wait time forecasts are systematically too short which makes Queue-framed waits appear more attractive than Clock-framed analogs. We that estimate the perceived cost waiting is twice as high for Clocks vs. Queues. We also find that people are risk averse with their time and that this has a large influence on disutility. Finally, we organize our results into a parsimonious behavioral utility function to add more nuance to queueing models.

4 - Multitasking over TIME: the Time-Dependent Effects of Multitasking

Bob Batt, Wisconsin School of Business, UW-Madison, Madison, WI, United States, Santiago Gallino

This paper explores agent multitasking over time in customer service environments, particularly within livechat settings. Multitasking, a ubiquitous occurrence in various professional sectors, is typically assumed to have a constant effect conditional on the multitasking level. We go beyond this conventional approach by examining the temporal dynamics of multitasking and their effects on performance. Through a collaboration with a third-party customer contact center, we analyze livechat interactions across different retail brands, focusing on both multitasking and multibranding, where agents manage tasks for multiple brands simultaneously. Our findings reveal that handling multiple chats simultaneously increases the average chat duration, with diminishing marginal increases as the number of concurrent tasks grows. We explore the implications of these insights by proposing a “pile-on” heuristic, which assigns new tasks to agents already engaged in multitasking, rather than evenly distributing tasks across agents. This method can lead to a reduction in average chat duration and increased agent idle time. Our study contributes to the operations management literature by illustrating the dynamic nature of multitasking, challenging traditional perceptions and suggesting that the duration and intensity of multitasking play crucial roles in shaping operational efficiency, and we show how work assignment strategies can influence operational outcomes.

Co-Chair: Zhi Wang, University of Texas at Austin, Austin, TX, United States

1 - A Unified Analysis for Assortment Planning with Marginal Distributions

Xiaobo Li, National University of Singapore, Singapore, Singapore, Zeyu Sun, Selin Ahipasaoglu

In this paper, we examine assortment planning using the marginal distribution model (MDM), a semiparametric choice model that relies solely on information about the marginal noise in alternative utilities without assuming noise term independence. While previous literature has established the multinomial logit (MNL) model as part of the MDM framework, we extend this to include other multi-purchase choice models like the multiple-discrete-choice (MDC) and threshold utility model (TUM), despite MDM not explicitly addressing multi-purchase behavior. Within the MDM framework, we establish a condition for optimal strictly profit-nested assortments for assortment problems. Although NP-hard, we demonstrate that the best strictly profit-nested assortment provides a 1/2-approximate solution for all MDMs, with an example illustrating this bound's tightness. These findings either expand or refine previous insights on assortment optimization under MNL, MDC, and TUM. We also show how these bounds extend naturally to mixtures of MDM models. Furthermore, empirical experiments on a real-world dataset with multi-purchase behavior compare the predictive capabilities of various MDM choice models. Our results indicate that, beyond MDC, several other MDMs exhibit promising predictive power in multi-purchase scenarios, emphasizing the benefits of analyzing multi-purchase behavior within the MDM framework.

2 - When Online Resource Allocation Meets Watermarking LLMs

Xiaocheng Li, Imperial College Business School, London, United Kingdom, Hanzhao Wang, Shang Liu, Huaiyang Zhong, Zhongze Cai

We study the problem of watermarking LLMs, where a watermark for LLMs is a hidden pattern injected to the generated text that is imperceptible to humans but can be algorithmically detected as generated by AI. We consider the trade-off between model distortion and detection ability, and formulate the watermarking procedure as a constrained optimization problem based on the green-red algorithm of Kirchenbauer et al. (2023). We show that the optimal solution to the optimization problem enjoys a nice analytical property. This analytical structure renders the formulation fall under the framework of online optimization with constraints where the existing online resource allocation algorithms in OR/MS literature can be naturally applied. These developments also shed light on the properness of model distortion metrics and the repetition phenomenon for the watermarking algorithms.

3 - Consider OR Choose? the Role of Consideration Sets in Discrete Choice Modeling

Yi-Chun Akchen, University College London, London, United Kingdom, Dmitry Mitrofanov

Consideration sets play an crucial role in discrete choice modeling, where a large class of non-parametric models can be understood as a two-stage decision making process. In this process, customers first form consideration sets and then follow a choice mechanism, such as a ranking system or a decision tree, to navigate their way towards a purchase decision. Rather than delving into a more sophisticated second-stage choice mechanism, this paper takes a step back and focuses on the fundamental properties of the decision making process based on the consideration sets. We consider a class of nonparametric choice models that is only specified by a distribution over consideration sets and has a bounded rationality interpretation. We call it the *consideration set model*. Intriguingly, we show that this class of choice models can be characterized by the axiom of symmetric demand cannibalization and enable full statistical identification. We further consider the model's downstream assortment planning as an application. We first provide an exact characterization of the optimal assortment and show that it is revenue-ordered on the blocks defined with respect to the consideration sets. Despite the existence of the exact structure, we prove that the optimal assortment is NP-hard to approximate. This result shows that the existence of consideration sets inevitably cause inapproximability in assortment planning, despite that the consideration set model does not involve a sophisticated second-stage mechanism. Finally, using a real-world dataset, we show that the consideration set model offers comparable prediction power to other advanced choice models.

4 - Learning Mixed Logit Choice Model with Neural Network: Global Convergence and Generalization Bound

Zhi Wang, University of Texas at Austin, Austin, TX, United States, Rui Gao

The mixed logit model is an expressive class of discrete choice models that have been widely studied in operations, marketing, and econometrics. However, estimating the mixing distribution presents significant challenges. Existing nonparametric methods often lack global convergence guarantees (such as the Expectation-Maximization algorithm), or necessitate non-convex optimization subroutines to secure global convergence (such as the Frank-Wolfe algorithm).

This study explores the efficacy of a one-hidden-layer neural network model to approximate the mixing distribution. Leveraging recent advances in the mean-field analysis of neural networks, we demonstrate that the gradient descent algorithm can identify the globally optimal estimator, subject to an approximation error. This error is inversely proportional to the neural network's width and becomes negligible in over-parameterized models. Furthermore, we prove that over-parameterization does not compromise generalization on unseen data, by deriving width-independent generalization bounds for finite-width networks. Using both synthetic and real datasets, we validate our algorithm's superior in-sample and out-of-sample performance against existing benchmarks.

Our findings underscore the potential of even shallow neural networks, armed with efficient training algorithms, to effectively learn complex choice models. The resultant model not only boasts high predictive accuracy but also exhibits guaranteed generalization capabilities.

1 - Computationally Efficient Reinforcement Learning with Linear Bellman Completeness

Noah Golowich, MIT, Cambridge, MA, United States, Ankur Moitra

One of the most natural approaches to reinforcement learning (RL) with function approximation is value iteration, which inductively generates approximations to the optimal value function by solving a sequence of regression problems. To ensure the success of value iteration, it is typically assumed that Bellman completeness holds, which ensures that these regression problems are well-specified. We study the problem of learning an optimal policy under Bellman completeness in the online and offline models of RL with linear function approximation:

- In the online setting, while statistically efficient algorithms are known under Bellman completeness, these algorithms all rely on the principle of global optimism which requires solving a nonconvex optimization problem. In particular, it has remained open as to whether computationally efficient algorithms exist. We give the first polynomial-time algorithm for online RL under linear Bellman completeness when the number of actions is any constant.

- In the offline setting, we give the first algorithm which finds a near-optimal policy under a single-policy coverage condition. Our algorithm is also computationally efficient and generalizes to the setting with small inherent Bellman error, for which the suboptimality of our output policy scales with the square root of the Bellman error. We also prove a matching lower bound, showing that no algorithm can achieve better than square-root dependence on the Bellman error. This lower bound stands in contrast to many other settings in reinforcement learning with misspecification, where one can typically obtain performance that degrades linearly with the misspecification error.

2 - Offline Reinforcement Learning: Role Of State Aggregation and Trajectory Data

Zeyu Jia, Massachusetts Institute of Technology, Cambridge, MA, United States

We revisit the problem of offline reinforcement learning with value function realizability but without Bellman completeness. Previous work by Xie and Jiang (2021) and Foster et al. (2022) left open the question whether a bounded concentrability coefficient along with trajectory-based offline data admits a polynomial sample complexity. In this work, we provide a negative answer to this question for the task of offline policy evaluation. In addition to addressing this question, we provide a rather complete picture for offline policy evaluation with only value function realizability. Our primary findings are threefold: 1) The sample complexity of offline policy evaluation is governed by the concentrability coefficient in an aggregated Markov Transition Model jointly determined by the function class and the offline data distribution, rather than that in the original MDP. This unifies and generalizes the ideas of Xie and Jiang (2021) and Foster et al. (2022), 2) The concentrability coefficient in the aggregated Markov Transition Model may grow exponentially with the horizon length, even when the concentrability coefficient in the original MDP is small and the offline data is admissible (i.e., the data distribution equals the occupancy measure of some policy), 3) Under value function realizability, there is a generic reduction that can convert any hard instance with admissible data to a hard instance with trajectory data, implying that trajectory data offers no extra benefits over admissible data. These three pieces jointly resolve the open problem, though each of them could be of independent interest.

3 - Selective Sampling and Imitation Learning via Online Regression, and Implications for Unlearning

Ayush Sekhari, MIT, Cambridge, MA, United States

We consider the problem of Imitation Learning (IL) by actively querying noisy expert for feedback. While imitation learning has been empirically successful, much of prior work assumes access to noiseless expert feedback which is not practical in many applications. In fact, when one only has access to noisy expert feedback, algorithms that rely on purely offline data (non-interactive IL) can be shown to need a prohibitively large number of samples to be successful. In contrast, in this work, we provide an interactive algorithm for IL that uses selective sampling to actively query the noisy expert for feedback. Our contributions are twofold: First, we provide a new selective sampling algorithm that works with general function classes and multiple actions, and obtains the best-known bounds for the regret and the number of queries. Next, we extend this analysis to the problem of IL with noisy expert feedback and provide a new IL algorithm that makes limited queries. I will conclude by discussing the implications of selective sampling for the problem of machine unlearning with limited memory.

4 - Instance-Dependent Complexity of Contextual Bandits and Reinforcement Learning: A Disagreement-Based Perspective

Yunzong Xu, Microsoft Reseach, New York, NY, United States

We introduce a family of complexity measures that are both sufficient and necessary to obtain instance-dependent regret bounds in contextual bandits. We then introduce new oracle-efficient algorithms which adapt to the gap whenever possible, while also attaining the minimax rate in the worst case. Finally, we provide structural results that tie together a number of complexity measures previously proposed throughout contextual bandits, reinforcement learning, and active learning and elucidate their role in determining the optimal instance-dependent regret. Additionally, we compare our results to some more recent work on instance-dependent complexity measures.

5 - Near-Optimal Pure Exploration in Matrix Games: A Generalization of Stochastic Bandits & Dueling Bandits

Kevin Jamieson, University of Washington, Seattle, WA, United States

We study the sample complexity of identifying the pure strategy Nash equilibrium (PSNE) in a two-player zero-sum matrix game with noise. Formally, we are given a stochastic model where any learner can sample an entry (i,j) of the input matrix A ∈ [−1,1]^n×m and observe Ai,j + η, where η is a zero-mean 1-sub-Gaussian noise. The aim of the learner is to identify the PSNE of A, whenever it exists, with high probability while taking as few samples as possible. Zhou et al. [21] present an instance-dependent sample complexity lower bound that depends only on the entries in the row and column where the PSNE lies. We design a near-optimal algorithm whose sample complexity matches the lower bound, up to log factors. The problem of identifying the PSNE also generalizes the problem of pure exploration in stochastic multi-armed bandits and dueling bandits, and our result matches the optimal bounds, up to log factors, in both settings.

1 - Machine Unlearning via Simulated Oracle Matching

Seth Neel, Harvard, Boston, MA, United States

Despite increasing interest in machine unlearning, recent work

shows that under strong evaluations, existing techniques largely fail to
unlearn in non-convex settings.
In this paper, we introduce a new technique for machine unlearning in such settings.
Key to our method is a reduction from the problem of machine unlearning
to that of data attribution.
In particular,
we show theoretically (in an underdetermined regression setting)
and empirically (in a standard deep learning setting)
that given access to the outputs of a perfectly unlearned model
(i.e., a model trained from scratch on the non-unlearned data),
we can quickly fine-tune an existing model on these predictions
and match the target model predictions out-of-sample.
Meanwhile, predicting such ``oracle''
outputs is precisely the goal of a recent line of
work in data attribution called {\em datamodeling}.
Combining these two insights yields an end-to-end unlearning
algorithm in which one first {\em predicts the output}
of a model re-trained from scratch, then {\em fine-tunes}
an existing model to match these predicted outputs.
Across different types and sizes of forget sets on standard classification tasks,
we show that this two-stage
algorithm results in strong unlearning performance being close to indistinguishable from the fully-retrained ``oracle'' model in some cases.
As an added benefit, our reduction means that future improvements
to data attribution---whether in accuracy or efficiency---yield better unlearning algorithms.

2 - Black-Box Counterfactual Auditing Using LLMs

Chara Podimata, MIT, Boston, MA, United States, Sarah Cen, Andrew Ilyas

Auditing of social media platforms has become increasingly important, given the impact that these platforms have in shaping beliefs and opinions. For all its importance, auditing remains hard to implement properly and rather costly; an auditor needs to find a lot of users that would be willing to give their data and even in that case, it's unclear how to create proper counterfactuals. In this work, we present a new framework for doing black-box and counterfactual auditing using Large Language Models (LLMs). Our approach is "black-box" in that we only assume query access to the platform (i.e., we don't have access to the platform's algorithm). At a high level, our framework creates different LLM agents that are seeded with original personalities from data from PEW research. Each of these agents is then allowed to interact with the contents of the social media platform according to their personality. We collect and analyze data about how the algorithm recommends content to different users and audit for a variety of different metrics.

3 - Formalizing Fairness With Respect To Stereotypes

Judy Hanwen Shen, Stanford University, Palo Alto, CA, United States

Machine learning algorithms used for high-stakes decision-making such as hiring must be carefully examined for unintentional biases. While existing group notions of fairness allow discrimination to be formally examined across groups, representational harms can also arise from outcomes determined by stereotypical features. Despite the plethora of empirical examinations of stereotypes and their harms, current literature offers no formal characterization of fairness with respect to stereotypes. In our work, we address this gap by introducing notions of fairness with respect to stereotypes that extend existing notions of group fairness. We examine how to achieve fairness with respect to stereotypical associations when there are multiple stereotypes under different fairness notions. We also present impossibility results characterizing when stereotype-based fairness notions are mutually exclusive.

Recent Development in Simulation Analysis Methodology

Invited Session

Simulation Society

Chair: Linyun He, Georgia Institute of Technology, Atlanta, United States

1 - Digital Twin Validation with Multi-Epoch, Multi-Dimensional Data

Linyun He, Georgia Institute of Technology, Atlanta, GA, United States, Luke Rhodes-Leader, Eunhye Song

This paper studies validation of a simulation-based process digital twin (DT). We assume that at any point the DT is queried, the system state is recorded. Then, the DT simulator is initialized to match the system state and the simulations are run to predict the key performance indicators (KPIs) of the system at the end of the time epoch of interest. Our validation question is if the distribution of the simulated KPIs matches that of the system KPIs at every epoch. Typically, these KPIs are multi-dimensional random vectors and are non-identically distributed across epochs making it difficult to apply the existing validation methods. We devise a multiple hypothesis test that compares the marginal and joint distributions of the multi-dimensional KPI vectors, separately, by transforming the multi-epoch data to identically distributed observations. We empirically demonstrate that the test has good power when the system and the simulator sufficiently differ in distribution.

2 - Efficient Uncertainty Quantification and Reduction for Over-Parameterized Neural Networks

Haofeng Zhang, Columbia University, New York, NY, United States, Ziyu Huang, Henry Lam

Uncertainty quantification (UQ) is important for reliability assessment and enhancement of machine learning models. In deep learning, uncertainties arise not only from data, but also from the training procedure that injects substantial noises and biases. These hinder the attainment of statistical guarantees and, moreover, impose computational challenges on UQ due to the need for repeated network retraining. Building upon the recent neural tangent kernel theory, we create statistically guaranteed schemes to principally characterize, and remove, the uncertainty of over-parameterized neural networks with very low computation effort. In particular, our approach, based on what we call a procedural-noise-correcting (PNC) predictor, removes the procedural uncertainty by using only one auxiliary network that is trained on a suitably labeled dataset, instead of many retrained networks employed in deep ensembles. Moreover, by combining our PNC predictor with suitable light-computation resampling and simulation-based ideas, we build several approaches to construct asymptotically exact-coverage confidence intervals using as low as four trained networks without additional overheads.

3 - Effective Training and Optimization of Neural-Network-Based Simulation Metamodels

Peter Haas, University of Massachusetts Amherst, Amherst, MA, United States, Wang Cen

In prior work we introduced simulation metamodels based on graph and generative neural networks (NNs). Such metamodels can capture the effect of both input-parameter values and simulation-model structure on the simulation output, and allow fast approximation of a range of performance measures using a single metamodel. We describe a novel procedure for efficiently training a NN metamodel and also describe improvements to our original NN architecture that both improve accuracy and allow exact solution of mixed continuous-discrete optimization problems via an MILP solver.

4 - Machine Learning-Assisted Stochastic Kriging Metamodel for Offline Simulation Online Application

Haoting ZHANG, University of California, Berkeley, Berkeley, CA, United States, Jinghai He, Rhonda Righter, Zuo-Jun Shen, Zeyu Zheng

For many real-time decision problems in complex stochastic systems, a decision-maker observes the system status online in real time and needs to immediately evaluate the performance of alternative decision choices based on the observed system status. Simulation metamodels can effectively support these needs by constructing a fast-to-evaluate mapping from the system status and decision to system performance, using offline-generated simulation samples. However, when the system status involves high-dimensional information and a large number of simulated samples, classical simulation metamodeling approaches, such as stochastic kriging, may face challenges in terms of model specification, computational complexities, and computer storage demands. To address these challenges, we propose using machine learning models to assist stochastic kriging in building metamodels offline, that then can support online applications. The machine learning models can capture the potential nonlinear dependence of the stochastic kriging parameters on the high-dimensional system status. We analyze standard properties, such as mean squared errors and uncertainty quantification, for the proposed machine learning-assisted metamodel, and show its consistency and asymptotic validity. We demonstrate its comparative advantage of our approach through numerical experiments.

5 - Optimizing Discrete Event Simulations for Urban Transport: Subgraph Parallelization via the Kemeny constant in New York City's Citi Bike Network

Silvano Bernabel, The Graduate Center, City University of New York, New York, NY, United States, Felisa Vazquez-Abad

Simulating multiple vehicles in a realistically city-sized model is a challenging problem. While discrete-event or agent-based models are appropriate, execution times for long simulations can be prohibitive. Our research explores an intriguing alternative that admits parallelization of the discrete event simulations to increase overall efficiency. We use the simulation of Citi Bikes in New York city as a case study. Our approach divides the graph that describes the topology of the stations into subgraphs. Simulations on the subgraphs, executed in parallel, represent mobility within the corresponding region. Since the various subgraphs have interconnections, we must reconstruct the overall dynamics to approximate the original problem. Rather than dividing the space arbitrarily, we propose a novel approach based on the origin destination (OD) matrix. In the case of public bikes, these circulate around the city from station to station as different passengers ride them. We consider the normalized OD matrix as a Markov kernel that describes the movement of the vehicles and use the Kemeny constant to assess the subgroups that describe the stationary distribution as a singularly perturbed Markov chain. Reconstruction of the original system depends on the type of measurement chosen. We provide mathematical analysis and prove the validity of the approach via simulation. We highlight through a real-world application in transportation under various scenarios for system layout, capacity, and demand, enabling stakeholders to make quicker decisions for financial and social benefits.

1 - Understanding Queue Abandonment: The Role of Wait Information and Distraction

Adam Arveson, University of Cincinnati, Cincinnati, OH, United States, Kanix Wang, Yinghao Zhang, Craig Froehle

Despite significant advancements in predictive analytics and service delivery enhancement, individuals face long wait times in Emergency Departments. The continued presence of queues underscores an ongoing need for researchers and practitioners to extend their focus beyond merely enhancing efficiency practices to improving the waiting experience itself. Inadequate management of customer waiting periods can significantly diminish satisfaction levels and increase abandonment, so developing effective strategies to mitigate the adverse effects of these experiences is imperative. Drawing on Maister's (1985) well-known principles, two predominant strategies have emerged: enhancing transparency through communication about the wait, and employing distraction techniques to divert attention from the wait.

While these commonly used approaches are well-established, there is something of a trade-off: more communication about the wait tends to draw customers' attention to their waiting, potentially increasing displeasure, while distraction necessarily lowers the firm's ability to communicate specifically about the wait. Many firms attempt to find a balance, using a bit of both tactics. But is this the best approach? This as-yet-unanswered question underscores a nuanced challenge in deciding how to best balance information transparency with distraction techniques within the context of wait management.

To investigate this phenomenon, we designed an online, between-subjects experiment where individuals engage in a waiting task. The study design incorporated six treatments, each varying in the degree of wait time information and the level of distraction. This experimental setup, which used a declining payment structure, enabled a detailed observation of participants' abandonment behaviors in response to each specific treatment scenario.

2 - Utilizing Specialists and Nurse Practitioners on Improving Accountable Care Organizations Efficiency: An Optimization Framework

Mayukh Majumdar, University of San Diego, San Diego, CA, United States, Anupam Agrawal, Arun Sen, Chelliah Sriskandarajah

Accountable Care Organizations (ACOs) are networks of primary care providers or PCP-led operating under shared savings or loss arrangements. They focus on delivering high-quality care while effectively managing costs. Over time, while some ACOs have demonstrated success in cost and quality performance, others have struggled. Additionally, the shortage of PCPs has been a long-standing concern for them and is expected to worsen. In response to this and the growing demand for healthcare access, ACOs leverage the expertise of specialists and nurse practitioners (NP) to ensure that patients receive comprehensive healthcare services. To better understand how ACOs can effectively utilize them, we study the care provided by specialists and NPs in single and multi-period settings using an optimization framework. Under the single-period setting, we simplify the formulation and propose an algorithm. Using a computational experiment, we find that (i) an increase in specialists and overreliance on NPs beyond an optimal threshold can compromise ACO efficiency, and (ii) under two-sided contracts, ACOs prioritize NPs as costs fluctuate. To reduce analytical complexity and provide an actionable solution, we introduce a simple algorithm for the multi-period setting to maximize efficiency in every period. Our study offers valuable insights for practitioners and policymakers to improve the performance of ACOs.

3 - A Machine Learning Model to Predict Heart Failure Readmission: Toward Optimal Feature Set

Sonia Jahangiri, Rochester Institute of Technology, Rochester, NY, United States, Masoud Abdollahi, Ehsan Rashedi, Nasibeh Azadeh-Fard

Hospital readmissions for heart failure patients remain high despite efforts to reduce them. In this study, we aimed to develop a machine learning based prediction model leveraging a nationwide hospitalization database to predict 30-day heart failure readmissions and to find the optimal feature set that leads to the highest AUC value in the prediction model. Heart failure patient data was extracted from the 2020 Nationwide Readmissions Database. A heuristic feature selection process incrementally incorporated predictors into logistic regression and random forest models, which yields a maximum increase in the AUC metric. Discrimination was evaluated through accuracy, sensitivity, specificity, and AUC. A total of 566,019 discharges with heart failure diagnosis were recognized. The feature selection method resulted in the identification of optimal feature sets including 20 and 22 variables from a pool of 30 and 31 features for the same-cause and all-cause datasets. Key predictors included age, payment method, chronic kidney disease, disposition status, number of comorbidities, and post-care encounters. This study provides meaningful insights into predictive modeling methodologies and influential features for forecasting heart failure readmissions.

1 - Optimizing Vehicle Routing and Nurse Scheduling for Mobile Vaccine Team Units in Los Angeles

Jing Jin, University of Southern California, Los Angeles, CA, United States, Suyanpeng Zhang, Sze-chuan Suen

Mobile Vaccination Team (MVT) units in Los Angeles County Department of Public Health (LACDPH) must simultaneously assign nurses to teams and route these teams to geographically dispersed homes to vaccinate patients. We formulate a mixed integer linear program (MILP) to minimize nurse travel time while constrained by appropriate nurse staffing requirements, nurse availability, patient scheduling preferences, and traffic congestion on LAC roads. Despite the inherent NP-hard nature of such scheduling and routing problems, we speed up the optimization process by using Big-M constraints and efficient formulation of constraints. We create code that takes inputs including the numbers of nurses, their home addresses, depot location, home visit addresses, and available time windows and durations for each home visit. It outputs a detailed scheduling sheet that specifies time windows, assigns nurse teams, and designates a team leader for each event. We parameterize the model with example data provided by the LACDPH and solve using Gurobi in Python. Our model efficiently solves scenarios ranging from small-scale (three nurses and five events) in seconds to larger real-world situations (50 nurses and over ten events) within 20 minutes. This indicates that typical weekly LACDPH scheduling could use this tool to find results in reasonable time.

2 - Non-Monotonicities in Variation with Transmission Rates in Risk-Stratified Compartmental Models: Implications for Infectious Disease Modeling

Jinghong Miao, University of Southern California, Los Angeles, CA, United States, Sze-chuan Suen

Compartmental models are widely employed to describe infectious disease transmission dynamics, and extreme value analysis with respect to transmission rates are often conducted as a follow-up step to predict the best- and worst- case scenario under model assumptions. We consider a stratified compartmental SIS (susceptible-infectious-susceptible) model with high-risk and low-risk subpopulations with the same clearance rate in both groups. We prove analytic properties and conduct sensitivity analyses given a known range for the number of contacts for high- and low-risk cohorts, which linearly influences intra- and inter-group transmission rates. We consider four metrics of epidemic severity – basic reproduction number R_0, the marginal increase in incidence per infected case (a proxy for the effective reproduction number R_t), endemic steady state prevalence, and cumulative prevalence. We establish that while R_0 and steady-state prevalence are monotonic with respect to intra- or inter-group transmission rates, R_t proxy and cumulative prevalence are non-monotonic with respect to transmission rates. It is thus not sufficient to only consider the minimum and maximum transmission rates for extreme value analyses for disease outcomes.

In this project, we highlight the counterintuitive fact that some reasonable metrics for epidemic severity are non-monotonic with respect to intra- or inter-group transmission rates in the two-group-risk-stratified SIS compartmental model. We believe this result can provide insights for epidemic control and cost-effectiveness analysis.

3 - Targeted Priority Mechanisms in Organ Transplantation

Ruochen Wang, Virginia Tech, Blacksburg, VA, United States, Sait Tunc, Burhaneddin Sandikci, Matthew Ellis

The persistent imbalance between organ supply and demand poses a significant challenge for the life-saving treatment of transplantation. This study introduces innovative targeted priority mechanisms inspired by the Eurotransplant Senior Program (ESP), designed to bridge the supply-demand gap while optimizing the matching between organs and recipients without mandating offer acceptance. Using a comprehensive queueing model, our study analyzes the strategic decisions of candidates under targeted priority mechanisms in equilibrium, establishing the optimal program design. Our evaluation of these mechanisms' impact on social welfare underscores their potential to improve overall welfare without adversely affecting any patient group. Furthermore, our simulation findings highlight the mechanisms' potential to increase yearly transplants by 1,000 and prevent up to 200 waitlist deaths annually.

4 - Predicting Eventual COVID-19 Vaccination Uptake by Vaccination Attitudes over TIME

Citina Liang, University of Southern California, Los Angeles, CA, United States, Sze-chuan Suen

Our study aims to predict COVID-19 vaccine uptake as of May 2023 by analyzing self-reported vaccination likelihood scores from April to December 2020. Utilizing the Understanding America Survey data, we assessed the predictive power of various machine learning methods, including Latent Transition Analysis (LTA), and compared these to a naive approach based on average likelihood scores. Our findings indicate varying performances among the models; notably, some models demonstrated high sensitivity, suggesting a greater ease in predicting individuals who will eventually opt for vaccination over those who will not. This study highlights the potential of advanced analytical techniques in forecasting public health behaviors, thereby informing targeted vaccine promotion strategies.

5 - Multi-Class Prediction of Missed Appointments in Primary Care Considering Health Impact

Yifang Yan, The Pennsylvania State University, University Park, PA, United States, Qiushi Chen, Wen-Jan Tuan

Missed appointments in primary care not only waste healthcare resources but also disrupt the continuity of care in clinical workflows, adversely impacting patient health outcomes. We utilized machine learning models to predict three mutually exclusive appointment outcomes: completed visit, late cancellation, and no-show. The model demonstrated outstanding performance in predicting the probabilities of three-class outcomes. However, determining the risk thresholds at which these probabilities are sufficient to make practical classification decisions is non-trivial, especially when balancing the utility of correct and incorrect decisions for hospitals and patients. This challenge is further amplified with three-class prediction, which involve multiple risk thresholds and interactions between thresholds. To address this, we developed a multi-class prediction and decision model. We established support vector machine (SVM) model with hinge loss function modified to incorporate two threshold problems (TTP). TTP includes an "inconclusive zone" to focus on the individuals with sufficient evidence. We extended the hinge loss in SVM from two-segment piecewise linear function into three-segment to accommodate the "inconclusive zone." Loss function was also tailored to balance the waste in healthcare resources and the impact on health outcomes. We formulated a convex optimization problem and solved it in dual space. We applied our model to patients with type II diabetes. Health outcome impact was estimated using a microsimulation model by simulating the effects of missed appointments on HbA1c levels and subsequent complications and measured by loss in quality-adjusted life years. We compared our model with existing decision models by simulating the total cost during operations.

Stochastic Modeling for Decision Making in the Cancer Care Continuum

Invited Session

Health Applications Society

Chair: Iakovos Toumazis, The University of Texas MD Anderson Cancer Center, Houston, TX, United States

Co-Chair: Sayaka Ishizawa, The University of Texas MD Anderson Cancer Center, Houston, TX, United States

1 - Designing Tertiary Cancer Services Under Burden Uncertainty

Abel Sapirstein, Georgia Institute of Technology, Atlanta, GA, United States, Lauren Steimle, Mathieu Dahan

Cancers are a growing cause of morbidity and mortality in low- and middle-income countries (LMICs). Geographic access plays a key role in both treatment and diagnosis - however a dearth of existing facilities often means that the demand for cancer services is not well understood. Using Rwanda as a case study, we adopt a distributionally robust optimization approach to simultaneously identify existing burdens and maximize access to treatment. First, we present a novel-path based formulation of two stage decision problem. In this problem's first stage a decision maker must simultaneously choose a set of facilities at which to add a set of tertiary cancer services and design a transportation network to improve patient access. In the second stage, patients use the transportation network to seek care at the place facilities. We then extend this formulation to instances in which demand is unknown and present preliminary work on solving large scale instances of this problem using Branch and Price and strengthening cuts.

2 - AI for Clinical Decision-Making in Oncology

Issam El Naqa, Moffitt Cancer center, Tampa, FL, United States

Artificial intelligence (AI) and Machine learning (ML) algorithms are revolutionary technologies that have captured the imagination of the public recently. They are currently transforming biomedical research, especially in the context of decision-making outcome modeling in cancer. These technologies have tremendous potentials for automating workflow, personalizing care, and reducing health disparity, to name a few prospects. Despite this excitement, only a few AI/ML models have been properly validated and fewer have become regulated products for routine clinical use. This can be attributed to multitude of concerning issues regarding the deployment of AI/ML driven technologies into the clinic. These concerns include technical, practical, ethical, and legal issues. In addition to skepticism related to commercialization hype, under representative data, inherent implementation bias, lack of robustness, and absence of prediction transparency. In this work, we will discuss some of these impending challenges, present general requirements for successful AI/ML implementation in the clinic, and highlight different approaches for detecting and mitigating explicit and implicit bias. We further show examples of applying these approaches in oncology applications from our work and others and discuss their implications to pave the way for safe and beneficial AI/ML decision making in clinical practice.

3 - Estimating sojourn time and sensitivity of screening for ovarian cancer using a Bayesian framework

Sayaka Ishizawa, The University of Texas MD Anderson Cancer Center, Houston, TX, United States, Jiangong Niu, Martin Tammemagi, Ehsan Irajizad, Yu Shen, Karen Lu, Larissa Meyer, Iakovos Toumazis

Background: Ovarian cancer is the second leading cause of cancer-related deaths among all gynecologic cancers. Previous ovarian cancer screening trials failed to show significant mortality benefit. Estimating sojourn time, the time length from when the cancer becomes screen-detectable until clinical detection, is key to developing more effective future screening programs.

Methods: We modeled ovarian cancer progression as continuous-time Markov chain. The modality-specific sojourn time and screening's sensitivity were estimated from model parameters using a Bayesian approach to reproduce the outcome of the Prostate, Lung, Colorectal, and Ovarian (PLCO) cancer screening and the United Kingdom Collaborative Trial of Ovarian Cancer Screening (UKCTOCS) trials. The quality of the estimates was validated using the posterior predictive p-value (PPPV). We also derived histology-specific sojourn times by adjusting the overall sojourn time based on their corresponding survival from SEER.

Results: The overall ovarian cancer sojourn time was estimated as 2.1 years (PPPV=0.469) in PLCO, and 2.0 years (PPPV=0.532) in the multimodal arm of UKCTOCS. The overall sensitivity of screening was 65.7% in the PLCO and 93.2% in the UKCTOCS. The stage-specific sensitivities of multimodal screening in PLCO were estimated as 39.1% and 82.9% for early and advanced stage disease, respectively. The histology-specific sojourn times ranged from 0.8-1.8 years for Type II and 2.9-6.6 years for Type I ovarian cancers.

Conclusions: Stochastic modeling and the Bayesian approach estimated reliable estimates of sojourn time and screening sensitivity. Annual screening is not effective in reducing ovarian cancer mortality because the sojourn time of the disease is too short.

4 - Personalized Rescheduling of Adaptive Organ-at-Risk-Sparing Radiation Therapy for Head and Neck Cancer under Re-planning Resource Constraints: A Novel Application of Markov Decision Processes

Fatemeh Nosrat, Rice University, Houston, TX, United States, Cem Dede, Lucas B. McCullum, Raul Garcia, Abdallah S. R. Mohamed, Jacob G. Scott, James E. Bates, Brigid A. McDonald, Kareem A. Wahid, Mohamed A. Naser, Renjie He, Amy C. Moreno, Lisanne V. van

Dijk, Kristy K. Brock, Jolien Heukelom, Seyedmohammadhossein Hosseinian, Mehdi Hemmati, Andrew Schaefer, Clifton D. Fuller

Background and Purpose: The purpose of this study was to determine personalized optimal timing for re-planning in adaptive organ-at-risk-sparing radiation therapy under limited re-planning resources in patients with head and neck cancer (HNC).

Materials and Methods: A novel Markov decision process (MDP) model was developed to determine optimal timing of re-plannings based on the patient's expected toxicity, characterized by normal tissue complication probability (NTCP), for four toxicities: xerostomia, dysphagia, parotid gland dysfunction, and feeding tube dependency at 6 months post-treatment. The MDP parameters were derived from a dataset comprising 52 HNC patients treated at the University of Texas MD Anderson Cancer Center between 2007 and 2013. Optimal re-planning strategies were obtained when the permissible number of re-plannings throughout the treatment was to 1, 2, and 3.

Results: The model recommended re-planning when the difference between the planned and actual NTCPs (ΔNTCP) was greater than or equal to 1%, 2%, 2%, and 4% at treatment fractions 10, 15, 20, and 25, respectively, exhibiting a temporally increasing pattern. The ΔNTCP thresholds remained constant across the number of re-planning allowances (1, 2, and 3). This result underscores the importance of re-planning for patients experiencing a slight change in ΔNTCP at fraction 10.

Conclusions: In contrast to prior work that relies on a single re-planning allowance or predetermined time intervals using a one-size-fits-all approach, the MDP model proposed in this paper offers a personalized, resource-aware, and scalable decision-making tool to identify optimal dynamic re-planning schedules, tailored to individual patients's needs.

1 - A Heuristic for near-Optimal Advertising Waterfalls

Jiamei Zhang, University of California, Irvine, Irvine, CA, United States, John Turner

Digital display advertising constitutes a significant source of revenue for online publishers. In cases when premium advertisers have priority over impressions, allocating ads using a waterfall strategy may be used. Through waterfall protocol, publishers sequentially solicit acceptance from advertisers at pre-set prices until the first acceptance. This study introduces a heuristic method to optimize the solicitation sequence under waterfall mechanisms. Given the exponential increase in potential strategies with more advertisers, optimizing these strategies is essential yet challenging for maximizing publisher revenue.

To address the need for rapid ad placement decisions upon content requests, we propose a stochastic optimization framework subject to complexities of uncertain response latencies and stringent loading time constraints for each impression. Our methodology incorporates dynamic programming and analytical models to structure waterfall strategy, and devise a heuristic scoring system for adaptive ranking of ad-slot requests.

By integrating several computationally efficient upper bounds, our approach is demonstrated to yield near-optimal revenue results. striking a balance between performance and computational efforts. This work provides a practical solution that can enhance publisher revenue under sequential decision environments.

2 - Using Influencers to Persuade

Zi (Elaine) Ling, Booth School of Business, University of Chicago, Chicago, IL, United States, Christopher Ryan, Mengzhenyu Zhang

The practice of cooperating with social media influencers has become a mutibillion-dollar industry. In this paper, we show how companies can use influencers with their own independent reputations as a vehicle to indirectly persuade target consumers (followers of the influencer) to make purchase. The followers act as Bayesian learners, gathering information from both the influencer and other consumers who have already made purchases before deciding to buy or not. This means the followers' decisions are interconnected and not made independently. Our study provides insights into how this indirect persuasion works and its implications for marketing strategies.

3 - Can Producers be Testers? A Peer-to-Peer Testing Framework for Milk Cooperatives

Liying Mu, University of Delaware, Newark, DE, United States, Sameer Mehta, Milind Dawande, Vijay Mookerjee

In the milk supply chain in developing countries, the production process and the testing process have traditionally been separate -- individual farmers produce milk and sell it to milk cooperatives, and the cooperative employs a dedicated entity to test the quality of milk. Since individual testing is costly, the cooperatives often do not conduct comprehensive testing of individual milk samples -- this creates incentives for farmers to free-ride. In this paper, we examine the viability of the idea of milk producers (i.e., individual farmers) also performing the role of testers. To this end, we develop and analyze a peer-to-peer testing framework. We exploit the fact that, as a community, farmers possess a significant amount of institutional knowledge about milk quality and the common ways in which milk can be adulterated. Further, potential concerns related to farmers' rudimentary testing instruments are addressed by multiple peers conducting independent tests on each milk sample. We show that peer-to-peer testing can increase farmers' income -- this incentivizes more farmers to join the cooperative and improve the milk quality, which in turn further increases their income, thus generating a ``beneficial virtuous cycle''.

4 - Microgrid Generation and Storage Investments: Scenarios of Price-Demand Independence and Dependence

Jiarui Wei, The University of Texas at Dallas, Richardson, TX, United States, Fariba Farajbakhsh Mamaghani, Metin Cakanyildirim

In today's energy transition, microgrids (MGs) emerge as vital components of the electricity landscape, offering profitable and reliable energy solutions, particularly for institutions like universities, airports, and hospitals. These localized energy systems, comprising local generators and consumers, act as alternative and supplementary suppliers alongside the grid, supported by short-term battery storage capabilities. However, determining optimal generation and storage capacities for MGs presents significant challenges due to uncertainties in demand, market prices, and their interdependence. This paper addresses these complexities by maximizing MG profit through closed-form formulas for optimized capacity levels under various price-demand scenarios. Notably, it reveals the impact of positive dependence between price and demand on MG profitability and investment decisions, highlighting the importance of incorporating interdependencies in sustainable energy planning.

5 - Optimal Inspection and Maintenance Planning for Utility Power Grids to Reduce Wildfire Risk

Abolfazl Taghavi, UCLA Anderson School of Management, Los Angeles, CA, United States, Ali Fattahi, Sriram Dasu, Reza Ahmadi

Wildfires have a significant impact on the environment, society, and infrastructures. During the last decades, the behavior of wildfires has changed significantly and become more severe. In addition, climate change and wildland-urban interface expansion made the wildfire problem even more challenging than it was in the past. As a result, wildfire management is becoming significantly important in the US and other countries. In 2018, PG&E, the largest utility company in California, almost went bankrupt because of igniting the campfire. Since then, utility companies have initiated several programs to reduce the fire ignition probability across their power grid, including maintenance and inspection of the power grid elements. In this project, we present an optimal inspection and maintenance policy for the utilities' power grid.

Empirical Analysis of New Retail Models

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Antonio Moreno, Harvard Business School, Boston, MA, United States

1 - Hyper-Local Fulfillment Services: Consumer Demand and Service Design

Natalie Epstein, Harvard Business School, Cambridge, MA, United States, Santiago Gallino, Antonio Moreno

In this paper, we study the emerging industry of ultrafast grocery delivery services. Using data from a platform that provides ultrafast grocery delivery services in Latin America via a network of local micro-fulfillment centers, we find empirical evidence that customer demand is highly responsive to changes in delivery times (even when those times are short) and to the offline options available to the customer. Drawing from queuing theory and using a very granular dataset of ultra-fast grocery delivery operations, we study the tradeoffs associated with the design of the network of micro-fulfillment centers supporting ultrafast grocery delivery services. Our analysis provides a framework that retailers and platforms can use to evaluate their network design and how such decisions depend on the offline characteristics of the region.

2 - Expedited Service Promises: Evidence from a Food Ordering Platform

Simin Li, Tulane University, New Orleans, LA, United States, Nil Karacaoglu, Luyi Yang

We empirically investigate the intended and unintended consequences of expedited service promises on a food ordering platform. Employing a quasi-experimental design, we discover that the expedited service promise (ESP) leads to an increase in sales. However, it also alters the mix of order urgency, resulting in more ASAP orders and fewer advance-scheduled orders being placed. Indeed, utilizing change-in-changes analysis, we observe a leftward shift in the distribution of purchase to request delivery times. Consequently, we find an increase in the probability of customers receiving ASAP orders later than their requested time, as well as an increase in the probability of customers receiving advance-scheduled orders at least 15 minutes earlier than their requested time, resulting in food becoming cold.

This observation suggests that, in order to avoid delays for more urgent orders, servers may need to prioritize clearing out advanced orders early to accommodate urgent order processing. Nevertheless, the probability of late orders still increases. Furthermore, we empirically demonstrate that missed delivery time windows—both too late and too early—diminish customer retention on the platform. These findings carry significant managerial implications regarding how platforms should implement ESP to maximize profit increase. For example, leveraging admission controls or pricing delivery promises in conjunction with ESP could be effective strategies.

3 - The Value of Online Interactions for Store Execution

Borja Apaolaza, The Wharton School - University of Pennsylvania, Philadelphia, PA, United States, Felipe Caro, Victor Martínez-de-Albéniz

Problem definition: Omnichannel retailers interact with customers both online and offline. So far, they have used this richer information to optimize the sales process by designing the right channel and supply chain structures, and by personalizing offer, pricing and promotions. We advance an additional dimension of omnichannel value: retailers can use online clickstreams to better understand customer needs and optimize store layouts to maximize conversion. **Methodology/results:** We develop a model where in-store purchases depend on the customer's shopping list, and the effort required to locate and reach the products within the store. Category location in the store thus drives conversion. We then apply our model to a large home improvement retailer and find that shoppers' preferences are revealed by nearby online traffic, and hard-to-reach locations lead to lower conversion. Finally, we optimize category-location assignments using our demand model and find that putting higher-interest and higher-price items in the most effective locations can increase revenues by about 2% in comparison with models that ignore online clicks. **Managerial implications:** We show how using online clickstream information for optimizing offline operations can create significant value. More fundamentally, our results provide a word of caution that in some retail segments like home improvement, longer in-store paths might not necessarily be better.

4 - Disclosing Low Product Availability: An Online Platform&Rsquo;S Strategy for Mitigating Stockout Risk

Dmitry Mitrofanov, Boston College, Chestnut Hill, MA, United States, Benjamin Knight

Ensuring product availability and the successful fulfillment of orders are key priorities for any company operating in the retail industry. In this paper, we investigate how sharing information regarding the low availability of certain items can influence customers' purchase decisions, both preventing stockouts and mitigating the negative effects of stockouts with respect to customer long-term behavior. It is hard to predict the net impact of sharing item availability information on business metrics ex-ante because there are multiple effects that might act in opposite directions. The information-sharing policy could lead customers to not purchase items that are low in availability because those customers are averse to stockouts. Contrariwise, this approach might increase the popularity of low-availability items because consumers' cognitive bias leads them to place a higher value on items that are scarce.

In a field experiment, we exogenously share low item availability information with a random subset taken for a sample of more than 840K customers using Instacart. We find evidence that customers are 25% less likely to purchase low-availability items when item availability information is disclosed. In addition, we show that low product availability disclosure positively affects the platform's fundamentals in the context of our field experiment both in the short and long run. More specifically, our results indicate that this innovative and cost-free approach leads to a 5.33% increase in revenue per customer and a 4.9% increase in order frequency over the long term.

Emerging-Market Retail Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Jiwen Ge, Dongbei University of Finance and Economics, Dalian, 116025

1 - Integrating Prediction and Optimization to Improve In-store Fulfillment Operations for Online Orders

Yang Zhan, Zhejiang University of Technology, Hangzhou, China, People's Republic of, Xueqi Wu, Zhi-Long Chen

This study addresses the critical challenge of optimizing order fulfillment in fast-paced online grocery markets. We develop an innovative integrated approach combining machine learning prediction (GBDT) with advanced optimization techniques to tackle heterogeneous picker efficiency and varying batch priorities. Our method includes a polynomial-time algorithm for a special case with a proven worst-case scenario and a heuristic with a theoretical worst-case bound for the general problem. Computational experiments using real-world data demonstrate significant improvements over current practices, reducing objective values by up to 23% and enhancing batch completion times. We provide crucial managerial insights on workforce strategies, emphasizing the value of experienced, full-time workers in boosting operational efficiency.

2 - Last-Mile Efficiency in Emerging Markets

Camilo Mora, Tecnologico de Monterrey, Monterrey, Mexico, Leopoldo Eduardo Cardenas-Barron, Jan Fransoo

Urbanization in emerging markets has led to market fragmentation, meaning a retail landscape dominated by nanostores that rely on distributors to serve them frequently to restock their businesses. In this context, a better understanding of last-mile operations is crucial to improving the efficiency of the distribution of goods. This article aims to advance research by providing data-driven evidence on the factors influencing dwell time in last-mile distribution for nanostores in emerging markets. We employed an observational research design in which 1000+ undergraduate students were trained to observe and document last-mile operations for nanostores without interfering with them, collecting over 4.5K observations. This research uses statistical analysis to shed light on the factors influencing dwell time and provides insights into freight vehicle composition in emerging markets. Our results show evidence that nanostores are served by a heterogeneous fleet, with over half being more than ten years old. We also capture that one third of the freight vehicles come from the informal sector. Regarding the operations, freight drivers were found to illegally park in 22% of the cases and that legal parking increases dwell time by 23%. These findings suggest a correlation between parking behavior and dwell time efficiency, emphasizing the impact of parking practices on logistics operations. We also found that companies can reduce 45% dwell time by prioritizing van sales over pre-sales strategies and using side doors to speed up unloading. The results hold implications for policymakers and companies seeking to elevate the efficacy of last-mile operations to serve nanostores.

3 - value of exclusive doorstep delivery in the last-100-meter distribution

Jiwen Ge, Dongbei University of Finance and Economics, Dalian, China, People's Republic of, Yang Zhan, Zheng Zhang

This paper investigates the value of exclusive doorstep delivery in the last-100-meter distribution service on e-commerce sales via a natural experiment conducted by Alibaba. By leveraging difference-in-differences models, we show significant sales change for Alibaba and its competitors. We also uncover the mechanism which drives the sales change.

Emerging Topics in iFORM

Invited Session

MSOM: iForm

Chair: Yuqian Xu, UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC, United States

Co-Chair: Youngsoo Kim, Loyola University Chicago, Tuscaloosa, AL, United States

1 - The Role of Late Payment Flexibility in Supply Chains

John Birge, University of Chicago, Chicago, IL, United States

Trade credit is an important source of financing in supply chains but the observed contractual terms are often not followed explicitly. Instead, terms of payment are often flexible and allow supply chain partners to share risk. This talk will review the role of this flexibility in supply chains and present empirical findings demonstrating its value.

2 - When the Dust Settles: Financing the Future of Land Reclamation

Qi Wu, Case Western Reserve University, Cleveland, OH, United States, Peter Ritchken

A key method to ensure that mining and oil companies restore land after use involves collecting taxes from operating firms, which are then placed in trust funds specifically designed to finance cleanup efforts once extraction activities end. This study examines regulatory frameworks designed to establish these funds. The sources of these contributions could be constant annual fees, payments tied to the volume of production, or royalty fees based on the revenue or profit generated by the operation. We analyze the four prevalent regulatory alternatives, all designed to be actuarially fair. The mining firms respond to each of these policies by adjusting their operating policies. Consequently, they are not indifferent between the policies. We characterize the properties of the firm's value and social welfare that lead to preferences over the four policies. We show that these preferences depend on firm's financial leverage and characteristics of production technology.

3 - Financing Supply Chain Resilience

Sriraman Sairam, Technical University of Munich, Heilbronn, Germany, David Wuttke, Andreas Kilian Gernert, Volodymyr Babich

We examine how financing arrangements and frictions affect supply chain resilience investments. In our game-theoretic model of a buyer, a supplier, and a bank, the supplier can invest in resilience, which reduces the supplier's production losses in case of a shock. The supplier is financially constrained and faces two financing frictions: moral hazard costs (the resilience investment is unobservable) and bankruptcy costs (future cash flows are lost in bankruptcy). We compare two financing arrangements: Under commercial loan financing, the supplier requests a loan from the bank; under buyer-intermediated financing (BIF), the supplier also obtains a loan from the bank, but the buyer guarantees the repayment and proposes the loan terms. Under commercial loan financing, we find that moral hazard costs can lead to credit rationing, limiting the supplier's resilience investments. In contrast, bankruptcy costs can accentuate these investments and change the direction of the moral hazard effect on investments. Bankruptcy costs can even motivate the supplier to invest more in resilience than she would without financing frictions. The buyer benefits from resilience and offers BIF only if it mitigates credit rationing. When BIF is offered, it always increases resilience. Surprisingly, financing frictions can increase the expected value for one of the firms: either the buyer or the supplier. The supplier's bankruptcy costs benefit the buyer when the supplier uses a commercial loan. Moral hazard costs can benefit the supplier when they motivate the buyer to offer BIF.

4 - Role of Liquidity in Retail Settings

Panos Kouvelis, Washington University in St. Louis, St.Louis, MO, United States, Naveed Chehrazi, Wenhui Zhao

We present an interesting model capturing consumer liquidity concerns on retail pricing and inventory decisions.

Reinforcement Learning and Causal Inference with Applications in Service Systems

Invited Session

MSOM: Service Operations

Chair: Yao Xie, Georgia Institute of Technology, Atlanta, GA, United States

Co-Chair: He Wang, Georgia Tech, Atlanta, GA, United States

1 - Reinforcement Learning in Latent Heterogeneous Environments

Elynn Chen, New York University, New York City, NY, United States, Rui Song, Michael Jordan

Reinforcement Learning holds great promise for data-driven decision-making in various social contexts, including healthcare, education, and business. However, classical methods that focus on the mean of the total return may yield misleading results when dealing with heterogeneous populations typically found in large-scale datasets. To address this issue, we introduce the K-Value Heterogeneous Markov Decision Process, a framework designed to handle sequential decision problems with latent population heterogeneity. Within this framework, we propose auto-clustered policy evaluation for estimating the value of a given policy and auto-clustered policy iteration for estimating the optimal policy within a parametric policy class. Our auto-clustered algorithms can automatically identify homogeneous subpopulations while simultaneously estimating the action value function and the optimal policy for each subgroup. We establish convergence rates and construct confidence intervals for the estimators. Simulation results support our theoretical findings, and an empirical study conducted on a real medical dataset confirms the presence of value heterogeneity and validates the advantages of our novel approach.

2 - Different Faces of Difference-in-Differences

Anqi Zhao, Duke University, Durham, NC, United States

In many social science applications, researchers use the difference-in-differences (DID) estimator to establish causal relationships, exploiting cross-sectional variation in a baseline factor and temporal variation in exposure to an event that presumably may affect all units. This approach, often referred to as generalized DID (GDID), differs from canonical DID in that it lacks a "clean control group" unexposed to the event after the event occurs. In this paper, we clarify GDID as a research design in terms of its data structure, feasible estimands, and identifying assumptions that allow the DID estimator to recover these estimands. We frame GDID as a factorial design with two factors: the baseline factor, denoted by G, and the exposure level to the event, denoted by Z, and define effect modification and causal interaction as the associative and causal effects of G on the effect of Z, respectively. We show that under the canonical no anticipation and parallel trends assumptions, the DID estimator identifies only the effect modification of G in GDID, and propose an additional generalized parallel trends assumption to identify causal interaction. Moreover, we show that the canonical DID research design can be framed as a special case of the GDID research design with an additional exclusion restriction assumption, thereby reconciling the two approaches. We illustrate these findings with empirical examples from economics and political science, and provide recommendations for improving practice and interpretation under GDID.

3 - Multi-Agent Reinforcement Learning for Joint Police Patrol and Dispatch

Matthew Repasky, Georgia Institute of Technology, Atlanta, GA, United States, He Wang, Yao Xie

Modern service systems are often composed of patrol and dispatch phases. Many methods for optimizing service system operations focus on optimizing the patrol or dispatch actions alone, neglecting to consider a joint decision-making process. In this work, we develop a joint optimization scheme for patrol and dispatch decision makers. Our method targets a flexible objective using deep multi-agent reinforcement learning (RL) and mixed-integer programming, formulating the patrol and dispatch problem in terms of patrollers and incidents on a graph. Our work builds upon prior RL approaches focused on selecting within combinatorial action spaces, extending such approaches to learn a dispatcher which pairs patrollers to incidents. Simultaneously, Q-learning with parameter sharing is conducted to optimize cooperative patrol agents. An alternating procedure is developed to jointly optimize the parameters of the dispatcher and patrollers.

We demonstrate that this approach results in more rapid response than optimizing the patrol or dispatch policies alone when optimizing an efficiency-based objective. Furthermore, the flexible reward definition also permits targeting alternative objectives, such as those encouraging equity. We show that optimizing with respect to equity may yield policies which are more fair than those optimized naively for efficiency, resulting in less disparity in response time to disproportionate groups. Finally, our method is applied to a realistic setting based upon three Atlanta Police Department (APD) beats in Southwest Atlanta. We further exhibit the benefit of our method by comparing it to a realistic policy based upon GPS data of APD patrollers.

4 - Counterfactual Generative Models for TIME-Varying Treatments

Shixiang Woody Zhu, Carnegie Mellon University, Pittsburgh, PA, United States

Estimating the counterfactual outcome of treatment is essential for decision-making in public health and clinical science, among others. Often, treatments are administered in a sequential, time-varying manner, leading to an exponentially increased number of possible counterfactual outcomes. Furthermore, in modern applications, the outcomes are high-dimensional and conventional average treatment effect estimation fails to capture disparities in individuals. To tackle these challenges, we propose a novel conditional generative framework capable of producing counterfactual samples under time-varying treatment, without the need for explicit density estimation. Our method carefully addresses the distribution mismatch between the observed and counterfactual distributions via a loss function based on inverse probability re-weighting, and supports integration with state-of-the-art conditional generative models such as the guided diffusion and conditional variational autoencoder. We present a thorough evaluation of our method using both synthetic and real-world data. Our results demonstrate that our method is capable of generating high-quality counterfactual samples and outperforms the state-of-the-art baselines.

5 - Optimal Policy Learning in Nonstationary Markov Decision Processe

Liyan Xie, CUHK-SZ, Shenzhen, China, People's Republic of, Jie Meng, Minshuo Chen, Mengdi Wang, Vincent Poor

We consider a piecewise stationary Markov Decision Process in which different pieces are segmented by unknown change-points. We propose the Detection-UCBVI Algorithm, which introduces online change detection methods into an Upper Confidence Bound Value Iteration (UCBVI) type algorithm. The Detection-UCBVI algorithm can effectively identify change-points and thus allows the learning algorithm to restart more quickly after changes. We analyze regret in the finite-time episodic setting with K episodes for arbitrary sizes of changes. Numerical results are provided to demonstrate the advantage of Detection-UCBVI as compared with the vanilla UCBVI algorithm without detection.

1 - Multi-Product Pricing and Multi-Channel Budget Allocation for E-Commerce Retailers: a Data-Driven Target-Oriented Robust Optimization Framework

Qiyuan Deng, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Yue Zeng

As multi-channel marketing in online platforms becomes increasingly popular, e-commerce retailers face challenges in effectively distributing their budget across multiple marketing channels and setting prices for multiple products to maximize their total return. To tackle these challenges, we propose a data-driven decision-making framework using robust optimization to improve an e-commerce retailer's profitability through optimized multi-product pricing and multi-channel budget allocation. Based on data from a world-renowned retailer selling skincare products, we empirically construct a demand prediction model capturing two essential features of multi-channel marketing in online platforms – spillover effect and promotion effect. By incorporating the demand model, we develop a data-driven framework to optimize the e-commerce retailer's pricing and budget allocation decisions. Facing demand uncertainty, we adopt a target-oriented robust optimization (TRO) approach to absorb as much uncertainty as possible in our solutions while ensuring a target total return. Based on the same data set, the TRO approach substantially outperforms a deterministic policy, yielding an approximately 24% increase in the retailer's daily average return. The TRO approach is especially promising, yielding approximately 31% higher daily average return, during promotion phases when it is more difficult to predict demand. By analyzing the retailer's optimal pricing and budget allocation decisions, we provide practical guidance to e-commerce retailers. Specifically, retailers should lower product prices to increase their competitiveness in online platforms. Besides, during promotion phases, we recommend to allocate more budget to marketing channels that can increase product exposure to potential consumers, instead of marketing channels functioning as search ads.

2 - Managing the Personalized Order-Holding Problem in Online Retailing

Yun Fong Lim, Singapore Management University, Singapore, Singapore, Shouchang Chen, Zhenzhen Yan

A significant percentage of online consumers place consecutive orders within a short duration. To reduce the total order arrangement cost, an online retailer may consolidate consecutive orders from the same consumer. We investigate how long the retailer should hold the consumer's orders before sending them to a third-party logistics provider (3PL) for processing. In this order-holding problem, we optimize the holding time to balance the total order arrangement cost and the potential delay in delivery. We show that the optimal order-holding decisions follow a threshold-type policy: Hold any pending orders if the holding time is within a threshold, or send them to the 3PL otherwise. Whenever the consumer places a new order, the holding time is reset and the threshold is updated based on a cumulative set of her past consecutive orders in her shopping journey. Using a consumer's sequential decision model, we personalize the threshold by finding its closed-form expression in the consumer's order features. We determine the model's coefficients and evaluate the threshold-type policy using the data of the 2020 MSOM Data Driven Research Challenge. Extensive numerical experiments suggest that the personalized threshold-type policy outperforms two commonly-used benchmarks by having fewer order arrangements or shorter holding times. Furthermore, personalizing the order-holding decisions is significantly more valuable for "enterprise" customers. The threshold is higher for "plus" consumers, female consumers, and consumers in the age group of 16-25. The threshold for tier-1 cities is lower than that for tier-2 to tier-4 cities but higher than that for tier-5 cities.

3 - Optimal Growth of a Two-Sided Platform with Heterogeneous Agents

Yixin ZHU, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Hongfan Chen, Renyu Zhang, Sean Zhou

We consider the dynamics of a two-sided platform, where the agent population on both sides experiences growth over time with heterogeneous retention and new adoption. The compatibility between buyers and sellers is captured by a bipartite network. The platform strategically sets commissions to optimize its total profit over a horizon of T periods, considering the trade-off between short-term profit and growth as well as the spatial imbalances in supply and demand. We design an asymptotically optimal commission policy with the profit loss upper-bounded by a constant independent of T. To obtain this policy, we first develop a single-period benchmark problem that captures the optimal steady state of the platform, then delicately control the growth of the agent types with the lowest relative population level compared with the benchmark in each period. We further examine the impact of the growth potential and the market network structure on agents' payment/income, and the platform's optimal commissions and profit. We first show that for each agent type, higher ratios of their compatible counterparts' long-term growth potential to their own cause lower payments (higher income) at the optimal steady state. In addition, the impact of the relative long-run growth potential on the platform's optimal commissions in a submarket depends on the convexity/concavity of the value distribution function of agents. Finally, we show that a ``balanced'' network, where the relative long-run growth potential between sellers and buyers for all submarkets is the same as that for the entire market, allows the platform to achieve maximum profitability.

4 - To Keep Prices Consistent OR Not: Multi-Channel Retailing with Consumers' Fairness Concerns

Guang Xiao, Hong Kong Polytechnic University, Hong Kong, Hong Kong, Xiaomeng GUO, Yumeng Li, Wenxin Xu

In this talk, we study a stylized game-theoretic model to investigate a multi-channel retailer's optimal pricing strategy in the presence of consumers' fairness concerns. We investigate the impact of such concerns on the firm's pricing strategy, profitability, and consumer surplus. Our results can provide useful managerial insights for multi-channel retailers to adopt proper pricing strategies when facing fairness-concerned consumers (This research is supported by the Research Grants Council of Hong Kong [General Research Fund Grant: PolyU 15505621]).

5 - Learning and Forgetting in Gig Work: Behavior-Based Task Allocation in An on-Demand Grocery Platform

Reeju Guha, CUNEF Universidad, Madrid, Spain, Daniel Corsten, Maqbool Dada

Online platforms operating on a gig-contractor model rely on self-scheduling gig workers to meet real-time demand, while maintaining desired performance levels. Most platforms allocate tasks randomly based on proximity of the worker to the store, or based on prior ratings. However, such allocations are often not useful as gig workers frequently have gaps in continuity of their service, thereby leading to a 'forgetting' effect, especially when they visit unfamiliar stores after a long service-gap. Furthermore, allocating tasks on the basis of prior ratings could cause an 'experience-mismatch' where higher-ranked workers gather more experience than their 'inexperienced' counterparts. Therefore, we investigate whether recent (intra-day) experience could mitigate the detrimental effects of 'forgetting' on workers' performance, and therefore be utilized as a ranking parameter in task allocations. Utilizing data from an online grocery platform, we develop an econometric model to analyze workers' performance, based on their intra-day and prior task experience, while accounting for selection bias and endogeneity. We further examine the moderating effects of task batching, complexity, and discretion. Our findings reveal that as intra-day and prior experience increase, both productivity and service quality improves. We further observe that excessive batching can improve productivity, but increase delays. Lastly, when complexity or discretion increases, productivity improves, but service quality reduces if intra-day experience crosses a threshold-limit. Utilizing our results, we rank gig-workers and develop a task-allocation algorithm to allocate work based on workers' rank, and task complexity, while adjusting for compensation. Finally, we calculate predicted improvements in performance from the new allocations.

Invited Session

MSOM:Technology, Innovation, and Entrepreneurship

Chair: Tu Ni, Harvard Business School, Boston, United States

1 - Online Uniform Risk TIMES Sampling: First Approximation Algorithms, Learning Augmentation with Full Confidence Interval Integration

Xueqing Liu, Duke-NUS Medical School, Singapore, Singapore, Kyra Gan, Esmaeil Keyvanshokooh, Susan Murphy

In digital health, the strategy of allocating a limited treatment budget uniformly across risk times is crucial to reduce user fatigue. This strategy, however, encounters a significant obstacle due to the unknown actual number of risk times, a factor not adequately addressed by existing methods lacking theoretical guarantees. This paper introduces, for the first time, the online uniform risk times sampling problem within the approximation algorithm framework. We propose a randomized approximation algorithm that enjoys robust theoretical guarantees across all problem instances or sample paths. Next, we extend our algorithm to the setting where a confidence interval [L,U] for the true risk time is provided, potentially through a machine learning algorithm. We conduct the competitive ratio analysis for our proposed learning-augmented approximation algorithm, demonstrating its consistency in the strong sense - optimal performance is achieved when the confidence interval width is zero - and robustness - the learning-augmented algorithm performs no worse than the non-learning augmented counterpart. We assess the performance of our proposed algorithms through numerical experiments conducted on both synthetic and real-world datasets. Without learning augmentation, our randomized algorithm outperforms the benchmark b/T. With learning augmentation, our learning-augmented algorithm performs no worse than both the naive benchmark b/U and the randomized algorithm.

2 - Adaptively Learning to Select-Rank in Online Platforms

Sharon Wang, Stern School of Business, New York University, New York, NY, United States, Perry Dong, Ying Jin, Ruohan Zhan, Zhengyuan Zhou

Ranking algorithms are fundamental to various online platforms across e-commerce sites to content streaming services. Our research addresses the challenge of adaptively ranking items from a candidate pool for heterogeneous users, a key component in personalizing user experience. We develop a user response model that considers diverse user preferences and the varying effects of item positions, aiming to optimize overall user satisfaction with the ranked list. We frame this problem within a contextual bandits framework, with each ranked list as an action. Our approach incorporates an upper confidence bound to adjust predicted user satisfaction scores and selects the ranking action that maximizes these adjusted scores, efficiently solved via maximum weight imperfect matching. We demonstrate that our algorithm achieves a cumulative regret bound of $O(d\sqrt{NKT})$ for ranking K out of N items in a d-dimensional context space over T rounds, under the assumption that user responses follow a generalized linear model. This regret alleviates dependence on the ambient action space, whose cardinality grows exponentially with N and K (thus rendering direct application of existing adaptive learning algorithms -- such as UCB or Thompson sampling -- infeasible). Experiments conducted on both simulated and real-world datasets demonstrate our algorithm outperforms the baseline.

3 - Optimal Statistical Inference in Adaptive Experiment Design: Private, Robust and Efficient

Jiachun Li, Massachusetts Institute of Technology, Cambridge, MA, United States, David Simchi-Levi

It's widely known that using adaptive experimental design can use the historical data to enhance data efficiency and improve statistical power. However, the adaptive nature of data collection process makes the traditional statistical analysis fails. In this work, we try to understand the question of what's the statistical limit of any experimental design and whether we can design an adaptive experiment which attains this statistical lower bound. Besides, we investigate the privacy and robustness issue in adaptive experimental design and analyze their impact on the statistical power.

4 - Design-Based Confidence Sequences: A General Approach to Risk Mitigation in Online Experimentation

Dae Woong Ham, Michigan Ross Business School, Ann Arbor, MI, United States, Iavor Bojinov, Martin Tingley, Michael Lindon

Randomized experiments have become the standard method for companies to evaluate the performance of new products or services. In addition to augmenting managers' decision-making, experimentation mitigates risk by limiting the proportion of customers exposed to innovation. Since many experiments are on customers arriving sequentially, a potential solution is to allow managers to "peek" at the results when new data becomes available and stop the test if the results are statistically significant. Unfortunately, peeking invalidates the statistical guarantees for standard statistical analysis and leads to uncontrolled type-1 error. Our paper provides valid design-based confidence sequences, sequences of confidence intervals with uniform type-1 error guarantees over time for various sequential experiments in an assumption-light manner. In particular, we focus on finite-sample estimands defined on the study participants as a direct measure of the incurred risks by companies. Our proposed confidence sequences are valid for a large class of experiments, including multi-arm bandits, time series, and panel experiments. We further provide a variance reduction technique incorporating modeling assumptions and covariates. Finally, we demonstrate the effectiveness of our proposed approach through a simulation study and three real-world applications from Netflix. Our results show that by using our confidence sequence, harmful experiments could be stopped after only observing a handful of units; for instance, an experiment that Netflix ran on its sign-up page on 30,000 potential customers would have been stopped by our method on the first day before 100 observations.

5 - Geometry-Aware Approaches for Balancing Performance and Theoretical Guarantees in Linear Bandits

Yuwei Luo, Stanford University, Stanford, CA, United States

Recent research in the d-dimensional stochastic linear bandit literature highlights a discrepancy: algorithms like Thompson sampling and Greedy perform well empirically but have pessimistic theoretical regret bounds. This discrepancy arises because these algorithms may perform poorly in certain instances but excel in typical ones. To address this, we propose a data-driven technique that tracks the geometric properties of the uncertainty ellipsoid around the main problem parameter. This enables us to formulate an instance-dependent frequentist regret bound, incorporating geometric information, for a broad class of algorithms, including Greedy, OFUL, and Thompson sampling. Our approach identifies and corrects poorly performing instances, achieving minimax optimal regret of order $d\sqrt{T}$ for a T-period decision-making scenario, up to logarithmic factors, while maintaining the algorithms' empirical efficacy. We validate our findings with simulation results using synthetic and real data.

Humanitarian and Disaster Operations Management

Invited Session

Public Sector OR

Chair: Christopher Zobel, Virginia Tech, Blacksburg, VA, United States

Co-Chair: Andrew Arnette, Virginia Tech, Blacksburg, VA, United States

1 - Vulnerability-Based Prioritization in Disaster Response Efforts

Feyza Guliz Sahinyazan, Simon Fraser University, Vancouver, BC, Canada, A.Irfan Mahmutogullari, Halenur Sahin

Humanitarian logistics literature commonly uses Equity, Efficiency and Effectiveness (3E) objectives. The equity objective strives to minimize differences among individual treatments by assuming that everyone is equally affected by a disaster. Efficiency measures aim to reduce the costs of aid programs, while effectiveness focuses on the quality of humanitarian aid, measured by factors such as response time, reduced risk, or human suffering. The inherent assumption of 3E objectives is the homogeneity of the beneficiaries. However, it is essential to acknowledge that disasters disproportionately affect individuals from socioeconomically disadvantaged backgrounds. Vulnerable groups, including the low-income, elderly, disabled, or marginalized, typically encounter unique challenges and heightened risks during disasters. Any measure assuming homogeneous demand will overlook the intersectionalities experienced by vulnerable communities. This paper introduces an alternative measure prioritizing vulnerable populations in disaster response, aiming for a more inclusive and compassionate disaster management strategy. To compare the performance of this approach against the traditional 3E measures, we study the emergency assembly point allocation problem and use Istanbul's neighborhood-level vulnerability and population characteristics for our computational analyses. Our results demonstrate that the vulnerability-based prioritization approach can single-handedly achieve more inclusive results for vulnerable populations without significantly deteriorating 3E objectives and non-vulnerable population outcomes.

2 - An Information-Theoretic Framework for Tracking Changes in 311 Calls Using Transformer-Based Hierarchical Topic Modeling

Onur Seref, Virginia Tech, Blacksburg, VA, United States, Christopher Zobel, Michelle Seref

311 services provide a channel to connect municipal agencies with the public. 311 calls are typically recorded and organized under pre-defined categories. However, during events such as crises, natural language usage among affected individuals change significantly, and may render the existing categories insufficient due to the unforeseen changes in context. Transformer-based hierarchical topic models capture context through deep semantic relationships and organize them into hierarchical clusters as topics. These topics may naturally change over time while the categories remain static, which causes a disconnect. To study this problem, we introduce an information-theoretic framework to establish a relationship between the topics and the categories. We study 311 calls from Orlando, FL and the surrounding municipalities within a six month time period that spans three months before and three months after the onset of the COVID-19 outbreak. We track changes under each category and each topic to match them based on their mutual information. Using the hierarchical structure of the topics, we identify expansions, reductions, or shifts in context under affected categories, and suggest new alternatives for organizing categories.

3 - Efficiency Criteria for National Public Private Emergency Collaborations: Findings from the German Food Emergency Preparedness System

Marcus Wiens, Technical University Freiberg, Freiberg, Germany

The secure supply of essential goods to the population in the event of a crisis has been of great relevance even before Covid-19 and the war in Ukraine. The article provides information on the experiences and findings from the four-year NOLAN research project (as well as follow-up projects and ongoing stakeholder exchanges), which identified opportunities to make emergency food provision in Germany more robust and reliable with the help of a public-private emergency collaboration. It is shown that both companies and authorities place high value on efficiency in addition to the robustness and effectiveness of structures and processes.

On the basis of empirical surveys, network optimization and game-theoretical analyses, two focal domains are analyzed from the point of view of efficient structures and processes of emergency supply. The first focus is on the optimal design of emergency storage and examines the costs of different levels of integration of public emergency storage into the commercial system. The second focus examines the incentives of private companies to integrate relief processes required in an emergency into the commercial retail system. These include an early warning system, strategic co-location of warehouses, rush orders and the implementation of emergency deliveries through re-routing as well as the voluntary provision of a minimum emergency stock capacity.

4 - To Donate OR Not to Donate: Optimal Policies for Supermarket In-Kind Donations to Food Banks

Shabnam Salehi, The University of Alabama, Tuscaloosa, AL, United States, Irem Orgut, Emmett Lodree

Food waste is a significant problem with economic, environmental, and social impacts. Supermarkets view the donation of perishable items close to their expiration date to food banks as a mean to reduce waste-related costs and improve their social image. Food banks, as non-profit organizations, depend greatly on receiving these perishable donations promptly to manage their operations effectively and distribute food efficiently to those in need. However, supermarkets, with the goal of maximizing sales and minimizing waste, often donate perishable goods as close to their expiration date as possible, even though they receive tax credits for these donations. Our study focuses on the food bank supply chain from the standpoint of supermarkets, with the goal of maximizing their profit by developing a multi-period stochastic dynamic programming model that identifies the optimal timing and quantity for donating perishables under stochastic demand. The analysis reveals that delaying donations until the last minute is not always optimal for supermarkets. Under certain conditions, early donation strategies can lead to better outcomes, enhancing the supermarkets' profitability while simultaneously reducing food waste in the food bank supply chain more effectively. The paper emphasizes the importance of aligning the donation strategies of supermarkets with the objectives of food banks to maximize the efficiency and societal benefits of the hunger relief supply chain.

5 - A Multi-Commodity Approach to Long-Term Climate-Induced Displacement

Deniz Emre, University of Oklahoma, Norman, OK, United States, Kash Barker, Andrés David González

The visible effects of climate change are increasing and are expected to escalate over time. One significant consequence is the displacement of populations due to climate-induced events, a process that has already started and is projected to lead to mass movement in the foreseeable future. With this motivation, we focus on long-term relocations caused by climate-induced events such as drought and sea level rise. We develop a multi-commodity model representing distinct groups of individuals as separate commodities. By distinguishing different groups as "commodities", we analyze displacement patterns and provide tailored long-term planning strategies.

Revolutionizing Patient Care: The Fusion of Machine Learning and Optimization Techniques

Invited Session

Health Applications Society

Chair: Gian-Gabriel Garcia, Georgia Institute of Technology, Atlanta, GA, United States

Co-Chair: Himadri Pandey, Georgia Institute of Technology, Atlanta, 30308, United States

1 - A Monotonic Policy Q-Learning Algorithm for Hypertension Management

Mina Yi, Dartmouth College, West Lebanon, NH, United States, Wesley Marrero

Reinforcement learning algorithms offer a promising approach for addressing treatment planning in healthcare applications. Within the context of hypertension treatment, traditional algorithms often fail to generate policies that align with clinical intuition. Clinicians commonly favor treatment plans that adjust medication intensity over time in response to the patient's health status, gradually increasing it as needed. To address this requirement, we introduce a monotonic Q-learning algorithm to provide online, treatment policies that adapt to individual patients. This algorithm is evaluated over a set of patients and demonstrates comparable efficacy to traditional offline algorithms using mixed-integer programming.

2 - Robust AI-Assisted Radiotherapy Planning

Arkajyoti Roy, The University of Texas at San Antonio, San Antonio, TX, United States, Justin Boutilier, Ruiqi Li

Artificial intelligence (AI) based auto-contouring offers a quick and cost-effective solution for delineating structures on CT scans, and has the potential to increase standardization and accessibility of radiation therapy by lowering the time costs of the planning process. However, AI-based auto-contouring can produce errors, especially when the training data quality and/or quantity is limited. This can degrade the precision of each contour and reduce the effectiveness of the resulting treatment plan. Our solution to this problem is a predictive-prescriptive framework that fuses the AI-based predictions and its errors with a subsequent robust treatment planning model to produce plans that can withstand auto-contouring errors. Our results show sizable plan improvements in using the proposed framework, compared to deterministic approaches.

3 - Learning Optimal Prescriptive Trees for Substance use Treatment: Trade-Offs Between Fairness, Interpretability, and Accuracy

Han Kyul Kim, University of Southern California, Los Angeles, CA, United States, Phebe Vayanos

Substance abuse poses a significant societal challenge in the United States, particularly among adolescents and young adults. Despite the urgency, most treatment facilities assign treatments based on resource availability, often overlooking individual needs or backgrounds of patients.

In this work, we explore the impact of data-driven personalized treatment assignments using prescriptive trees. Based on the assumptions of causal inference, we train an optimal prescriptive tree from the GAIN dataset, the largest longitudinal dataset capturing real treatment outcomes. This approach allows for a more personalized treatment assignment policy that considers patient-specific needs while maintaining model interpretability.

Furthermore, we introduce the concept of the “price of interpretability", which quantifies the difference in expected treatment outcomes between black-box models and interpretable models, highlighting the trade-off between model performance and interpretability. Our work reveals disparities in the price of interpretability among gender groups in our dataset, indicating that some groups may face a higher cost in expected outcomes when using interpretable models. To address this disparity, we propose a modified prescriptive tree that aims to distribute the price of interpretability more equally among protected groups, balancing fairness with model interpretability in treatment assignments.

Our research seeks to empower clinicians and social workers by integrating data-driven decision-making into fair and interpretable treatment assignment policies. The ultimate goal is to enhance the effectiveness of treatment for adolescents and young adults battling substance abuse, fostering a more fair and personalized approach to care.

4 - Advancing Patient Monitoring Strategies in Tuberculosis Treatment Using Reinforcement Learning

Maryam Kheirandish, University of Arkansas, Fayetteville, AR, United States, Shengfan Zhang

Health systems are currently facing unprecedented financial challenges. Both the overuse and underuse of tests deplete essential health resources and impede timely diagnosis and treatment. A primary driver of test overuse is the inherent uncertainty in medical decision-making. Merely ordering additional diagnostic tests does not necessarily prevent physicians from missing a condition. To counteract test overuse, a predictive model can assist physicians by providing insights into a patient's current health status, based on existing test results and associated uncertainties. This enables physicians to make informed decisions about whether additional tests are necessary or if treatment can proceed based on the existing data, ensuring conditions are not overlooked. Test overuse occurs in both disease diagnosis and treatment processes. While predictive uncertainty may be sufficient for decision-making at the diagnosis stage, a sequential decision-making approach is crucial for ongoing treatment monitoring. In this study, we introduce a contextual reinforcement learning framework that integrates uncertainty quantification in outcome prediction models to improve treatment monitoring strategies. This framework aims to identify scenarios where additional monitoring tests can enhance the predictive uncertainty of treatment outcomes. The model considers the impact of test ordering on current predictive uncertainty and on subsequent predictions used in future patient follow-ups. We apply this model to enhance the treatment monitoring of tuberculosis patients.

5 - Resource Allocation

Himadri Pandey, Georgia Institute of Technology, Atlanta, GA, United States

Concussions, the most prevalent form of traumatic brain injuries, pose a significant public health concern, contributing to 1.6-4 million sports and recreation-related incidents annually. Alarmingly, half of these incidents remain unreported or undetected. Swift and precise concussion diagnosis is imperative for effective injury management, as it reduces the potential for severe short-term and long-term consequences like cognitive impairment, depression, and neurodegenerative disorders. Baseline testing has emerged as a promising tool in diagnosing concussions. Although it is particularly beneficial for certain subgroups, there is a scarcity of such resources. Often, they are allocated to high-impact sports like football, disregarding other demographics that may have a greater need. Baseline testing is especially useful for specific populations compared to standard reference points. This presents a dilemma: given the limited availability of baseline testing, which groups should be prioritized for allocation? We designed a model that can optimally assign these resources.

Summit - Terrace Suite 2

Severe Trauma

Invited Session

Health Applications Society

Chair: Dimitris Bertsimas, Massachusetts Institute of Technology, Cambridge, MA, United States

Co-Chair: Vasiliki Stoumpou, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States

1 - Treatment of hip fragility fractures

Lisa Everest, Operations Research Center, Massachusetts Institute of Technology, Cambridge, MA, United States, Catherine Ning

We develop machine learning models trained on multimodal sources of data to predict hip fragility fractures at the Hartford HealthCare (HHC) hospitals in Connecticut. In particular, we leverage tabular data, timeseries data, vision data, and language data to predict three main targets as identified by HHC orthopedic surgeons - readmission after surgery, post-operative complications within 3 days of surgery, and time to surgery after admission.

2 - Using Holistic AI to Diagnose AAST Injury Grade for Blunt Splenic and Liver injuries on CT scan and Direct Optimal Treatment

Carol Gao, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas, Ikram Chairi, Muhammad Maaz

Liver injury is a critical concern in trauma care. As management depends on the severity of liver injury, cases are graded according to the American Association for the Surgery of Trauma (AAST) classification on a scale from I to V. However, recent literature has shown that CT reads by humans can misclassify liver injuries, leading to inappropriate management. We introduce a multimodal approach combining CT scans, as 3D images, unstructured clinical notes, vitals, and past medical history to predict the grading of liver injury for trauma patients. We then build a prescriptive model using patient management and outcome data to recommend operative versus non-operative approaches to patients with liver or spleen injuries. We apply our approach to n=3,331 trauma patients at Hartford Hospital in Connecticut to demonstrate the accuracy of our method.

3 - Prediction of Chronic Subdural Hematoma

Rohan Kumar, Boston University, Boston, MA, United States

A subdural hematoma is a type of intracranial bleed that occurs on the surface of the brain. Aging, trauma in the head, use of anticoagulants and alcohol, and coagulopathies have been associated with the occurrence of subdural hemorrhages. Subacute/chronic subdural hematoma, the main focus of this study, is expected to emerge as a predominant neurosurgical concern in the United States by 2030, primarily attributed to increasing life expectancy and the expanding utilization of antiplatelet and anticoagulation medications. The present work evaluates the efficacy of machine learning (ML) approaches used to predict the existence of chronic subdural hematoma. We perform these tasks using demographics, labs, medications and image data, by extracting embeddings from images, combining them with the tabular data and then training an XGBoost model to learn each task. We demonstrate that the combination of modalities is beneficial in successfully performing both tasks.

4 - OPOM 2.0: Continuity and Accuracy for an Optimized Prediction of Mortality for Candidates Awaiting Liver Transplantation

Maura Hegarty, Massachusetts Institute of Technology, Cambridge, MA, United States, Theodore Papalexopolous, Dimitris Bertsimas, Nikolaos Trichakis

In 2019, an Optimized Prediction of Mortality (OPOM) model was developed to predict the probability that a candidate awaiting liver transplant dies on the waitlist or is removed for being too sick within 90 days. OPOM, a machine-learning optimal classification tree-based model, demonstrated improved performance and equity in simulation and AUC over the then-current policy MELDNa which similarly predicts mortality in 90 days. However, OPOM predictions were found to be very sensitive to noise added to the data given its discrete decision-making process. As certain lab measurements are prone to noise, in particular creatinine and bilirubin, this is a significant drawback of OPOM. In 2023, the new and improved MELD3.0 was introduced and implemented into policy. MELD3.0 improves upon the performance and equity of MELDNa, in particular, for sex. An area of weakness of the MELD3.0 model is its poor predictive performance among patients diagnosed with hepatocellular carcinoma (HCC) which accounts for about 20-25% of patients waiting for liver donation each year. To address the issues resulting from the discontinuous nature of OPOM and the weak performance of MELD3.0 among HCC patients, we introduce OPOM 2.0 which employs the novel machine-learning method called deep trees. As deep trees are continuous, our predictions are more robust in the face of noise. We also observe enhanced overall model performance and most notably, for HCC patients.

Summit - Ballroom 2

Optimizing Last Mile Efficiency at Amazon

Invited Session

The Practice Section of INFORMS

Chair: Julie Poullet, Amazon - Last Mile, Seattle, WA, United States

1 - GPU based Route Planning with Cuopt

Bhargav Kunkulagunta, Amazon, Austin, TX, United States

Cuopt is a GPU based route solver, we have done benchmark to identify the potential oppurtunity with GPU based route solver and building a GPU based last mile stack for a potential GPU based GIS analytics system.

2 - Energy Aware Last-Mile Route Planning

André Snoeck, Amazon, Luxembourg, Luxembourg, Aniruddha Bhargava, Daniel Merchan, Mahmood Zangui

Amazon co-founded The Climate Pledge in 2019. As part of that Pledge, Amazon also announced to bring 100,000 electric delivery vehicles on the road by 2030. This goal presents challenges across multiple planning spaces including but not limited how to optimize the deployment of the EV fleet and how to plan EV routes. In this talk, we address the problem of predicting and incorporating energy estimates into last-mile planning systems. We show the need to move away from thinking about range and we propose that we should use energy as the basic unit of analysis for battery electric vehicles. Furthermore, we illustrate how incorporating EVs at large scale requires energy-aware planning throughout all decision making processes.

3 - Route time estimate optimization with non-linear opportunity cost awareness

Ivan Tereshchenko, Amazon, San Francisco, CA, United States

Last mile delivery services leverage machine learning models that predict delivery route duration at multiple stages of the route planning process. In this work we demonstrate the methodology for determining the duration of planned routes that uses quantile regression estimates and the newsvendor model with a generalized underage and overage cost functions. We derive approximate cost functions that reflect important business objectives. We show how our methodology can be used to simultaneously minimize late deliveries, driver dissatisfaction and route underutilization in ultra-fast delivery operations.

4 - Handling multi-objective contiguous unit allocation problems through Resources in a graph modeling

Julie Poullet, Amazon - Last Mile, Seattle, WA, United States, Andre Snoeck

In Amazon Logistics (AMZL), most of our deliveries are made by Delivery Service Partners (DSPs) which are independent local businesses. Typically, each Last Mile node is covered by a couple of DSPs operating on a daily basis. DSPs are assigned to an area in which they are operating the majority of their deliveries. Optimally assigning such areas to DSPs is a complex problem incorporating many dimensions, e.g., affinity and complexity, that are subject to change as the business evolves. We introduce a flexible and scalable graph-based approach that models these dimensions as resources in a Resource Constrained Shortest Path (RCSP) framework. We propose a Column Generation approach to solve the graph model, whose pricing problem is modeled as RCSP problem. We introduce a novel and extended A* algorithm leveraging these resources to discretize bounds and promising paths, reducing the number of enumerations by 96% and the run-time by 62% in complex instances. To demonstrate the modeling flexibility and business relevance of the approach, we optimize area assignments for the feasibility, fairness, and efficiency dimensions.

Summit - Ballroom 3

Cutting-Edge Research in Federated Learning

Invited Session

OPT: Machine Learning

Chair: Chhavi Sharma, Southern Methodist University, Dallas, TX

1 - Federated Learning with Data Heterogeneity

Jingrui He, University of Illinois at Urbana-Champaign, Champaign, IL, United States

Federated learning allows multiple clients to collaborate in training a machine learning model with the orchestration of a central server, without requiring them to share the raw data. In real applications, it is usually the case that clients exhibit various types of data heterogeneity. In this talk, I will introduce some of our recent works modeling such data heterogeneity, including (1) clustered federated learning, which explores the optimal collaboration structure among clients; (2) personalized federated learning, aiming to generalize the global model to both participating and unparticipating clients; (3) robust federated learning against Byzantine clients. Towards the end, I will also share my thoughts regarding future directions.

2 - Communication-Efficient Federated Group Distributionally Robust Optimization

Zhishuai Guo, Northern Illinois University, DeKalb, IL, United States, Tianbao Yang

Federated learning faces significant challenges due to the heterogeneity in data volume and distribution across different clients. This heterogeneity often undermines the model's ability to generalize effectively across various data distributions including unseen ones. Previous methods to tackle this issue, particularly those based on group distributionally robust optimization (GDRO), tend to incur high communication and/or computational costs. To this end, our work introduces a suite of novel algorithms designed for communication-efficient Federated Group Distributionally Robust Optimization (FGDRO). Our contributions are threefold: Firstly, we introduce the FGDRO-CVaR algorithm, which optimizes the CVaR-constrained GDRO loss that focuses on the top-K clients with highest losses. Secondly, we present the FGDRO-KL algorithm, which optimizes a KL-regularized weighted loss. Lastly, we introduce FGDRO-KL-Adam that uses Adam updates local steps. Our theoretical results demonstrate that our methods achieve low communication and computational costs. We have validated the effectiveness of our algorithms through experiments in natural language processing and computer vision.

3 - Communication-Efficient Algorithms for Federated Bilevel Optimization

Junyi Li, University of Maryland, College Park, College Park, MD, United States

Bilevel Optimization has witnessed notable progress recently with new emerging efficient algorithms. However, its application in the Federated Learning setting remains relatively underexplored, and the impact of Federated Learning's inherent challenges on the convergence of bilevel algorithms remain obscure. In this talk, we investigate Federated Bilevel Optimization problems and propose a communication-efficient algorithm, named FedBiOAcc. The algorithm leverages an efficient estimation of the hyper-gradient in the distributed setting and utilizes the momentum-based variance-reduction acceleration. Remarkably, FedBiOAcc achieves the near-optimal sample and communication complexity and the linear speed up with respect to the number of clients.

4 - Multi-agent Sequential Decision Problems under Uncertainty

Chhavi Sharma, Southern Methodist University, Dallas, TX, United States, Harsha Gangammanavar

Sequential decision problems under uncertainty are ubiquitous and arise in various applications such as healthcare, energy infrastructure, and supply chains. Several efforts have been made to solve these problems in a distributed computing environment tailored to specific applications. However, a comprehensive tool for addressing multi-agent sequential decision problems under uncertainty remains elusive. This talk will delve into a particular class of such problems: multi-agent two-stage stochastic programming problems in which all agents have their own private two-stage stochastic program and are connected through a graph. We will present solution methods and analyze the behavior of the solutions obtained from them. We will also highlight the challenges when agents collaborate to approximate the recourse function.

Nanoretail Operations in Developing Markets

Invited Session

TutORial

1 - Nanoretail Operations in Developing Markets

Jan Fransoo, Tilburg University, Tilburg, Netherlands, Rafael Escamilla, Jiwen Ge

Across much of the developing world, family-operated nanostores provide daily grocery needs to billions of poorly paid consumers. This highly fragmented retail channel is of critical importance to consumer brands as in many markets this is the largest retail channel. We characterize the empirical context in which these stores operate, as well as the intricate operations that manufacturers and distributors put in place to supply them with their goods. We then elaborate on modeling operations execution and operations strategies to expose critical tradeoffs that are distinct from those in organized retail in developed markets. We discuss research results that have demonstrated why many manufacturers choose to serve this market directly and at high frequency, why manufacturers invest considerable effort in deploying sales agents networks, how this channel manages to remain competitive with modern organized retail such as convenience store chains, and how digitization and novel financing solutions provide a further competitive advantage to the nanoretail channel. Finally, we discuss how to conduct research in this retail segment and provide examples of novel contexts and business models that may open up new areas of nanoretail research.

Technological Transformation: AI's Role in Shaping Future Societies

Invited Session

Information Systems

Chair: Che-Wei Liu, Arizona State University, Tempe, AZ, United States

1 - When AI Showcases: Comparing Human and Ai Streamer Effectiveness in Live E-Commerce

Meixian Wang, Temple University, Philadelphia, PA, United States, Guohou Shan, Keran Zhao, Jason Thatcher

Live Streaming E-commerce (LSE) is a synchronic format that embeds live streaming into e-commerce, where streamers sell products and interact with viewers synchronously. Many stores have launched LSE channels to attract traffic and increase sales. As competition for effective human streamers is intense, platform owners have developed artificial intelligence (AI) streamers as an alternative. However, it is unclear whether human or AI streamers are more effective at engaging viewers and selling products. Drawing on naturalness theory, we develop a research model that examines the differences between human and AI streamers' sales competency. Using collected data from Taobao Live, we found that human and AI streamers have different sales efficiency in different product categories (i.e., search and experience products). To further investigate the underlying mechanism, we conducted an experiment to link the roles of human and AI streamers, their different sales efficiency, and product categories. Our study provides insights for platforms and store owners seeking to utilize AI technology better to sell products and for designers interested in developing more effective AI.

2 - From Seeing to Signing up: the Co-Creative Dance of Humans and AI in Cultivating Symbiotic Uniqueness for Enhanced User Engagement

Che-Wei Liu, Arizona State University, Tempe, AZ, United States, Shenyang Jiang, Jiang Duan

The advent of Generative Artificial Intelligence (AI) heralds a new epoch in which users are not mere consumers but active participants in the creation of digital content. This evolution prompts an inquiry into the distinction between generative AI and its traditional counterparts. We contend that the essence of this difference is encapsulated in the concept of "Symbiotic Uniqueness," which we introduce to underscore the dynamic interplay between human input and the AI's ability to generate unique and random outputs. We argue that the two pillars of this concept are the effectiveness of the AI in meeting user intentions and the inherent randomness that fuels the creation of one-of-a-kind results. We devised a field experiment with a dual-axis framework: content visibility and loss framing. Our findings reveal that displaying AI-generated content upfront significantly boosts user registration. Moreover, a mixed strategy that combines both revelation and concealment of content suggests potential advantages, as it appears to strike a delicate balance between effectiveness and intrigue, slightly enhancing user registration rates. The application of loss framing, which plays on the randomness of AI-generated content, markedly amplified sign-up rates by tapping into the users' fear of missing out on unique creations. Surprisingly, the combination of content visibility and loss framing appeared to dilute the efficacies, pointing to a possible substitution effect. Lastly, we showcase that both content visibility and loss framing would be ineffective without active user participation in the co-creation process. This highlights the critical importance of symbiotic uniqueness in promoting user engagement.

3 - Multimodal Co-Attention Transformer for Video-Based Personality Understanding

Mingwei Sun, University of Maryland, College Park, MD, United States, Kunpeng Zhang

Video has emerged as a pervasive medium for communication, entertainment, and information sharing. With the consumption of video content continuing to increase rapidly, understanding the impact of visual narratives on personality has become a crucial area of research. While text-based personality understanding has been extensively studied in the literature, video-based personality prediction remains relatively under-explored. Existing approaches to video-based personality prediction can be broadly categorized into two directions: learning a joint representation of audio and visual information using fully-connected feed-forward networks, and separating a video into its individual modalities (text, image, and audio), training each modality independently, and then ensembling the results for subsequent personality prediction. However, both approaches have notable limitations: ignoring complex interactions between visual and audio components, or considering all three modalities but not in a joint manner. Furthermore, all methods require high computational costs as they require high-resolution images to train. In this paper, we propose a novel Multimodal Co-attention Transformer neural network for video-based affect prediction. Our approach simultaneously models audio, visual, and text representations, as well as their inter-relations, to achieve accurate and efficient predictions. We demonstrate the effectiveness of our method via extensive experiments on a real-world dataset: First

Impressions. Our results show that the proposed model outperforms state-of-the-art approaches while maintaining high computational efficiency. In addition to our performance evaluation, we also conduct interpretability analyses to investigate the contribution across different levels. Our findings reveal valuable insights into personality predictions.

4 - Group-Sparse Matrix Factorization for Transfer Learning of Word Embeddings

Kan Xu, University of Pennsylvania, Philadelphia, PA, United States, Xuanyi Zhao, Hamsa Bastani, Osbert Bastani

Unstructured text provides decision-makers with a rich data source in many domains, ranging from product reviews in retail to nursing notes in healthcare. To leverage this information, words are typically translated into word embeddings---vectors that encode the semantic relationships between words---through unsupervised learning algorithms such as matrix factorization. However, learning word embeddings from new domains with limited training data can be challenging, because the meaning/usage may be different in the new domain, e.g., the word “positive" typically has positive sentiment, but often has negative sentiment in medical notes since it may imply that a patient tested positive for a disease. In practice, we expect that only a small number of domain-specific words may have new meanings. We propose an intuitive two-stage estimator that exploits this structure via a group-sparse penalty to efficiently transfer learn domain-specific word embeddings by combining large-scale text corpora (such as Wikipedia) with limited domain-specific text data. We bound the generalization error of our transfer learning estimator, proving that it can achieve high accuracy with substantially less domain-specific data when only a small number of embeddings are altered between domains. Furthermore, we prove that all local minima identified by our nonconvex objective function are statistically indistinguishable from the global minimum under standard regularization conditions, implying that our estimator can be computed efficiently. Our results provide the first bounds on group-sparse matrix factorization, which may be of independent interest. We empirically evaluate our approach compared to state-of-the-art fine-tuning heuristics from natural language processing.

Unpacking Inequalities in Social Media Algorithms and UGC

Invited Session

Social Media Analytics

Chair: Xi Wang, Central University of Finance and Economics, Beijing, N/A

1 - Impact of Perceived Personalized Recommendation on Content Novelty and Creative Performance on Content Creation Platforms

Xiji Zhu, Hitotsubashi University, Japan, Tokyo, Japan, Yuhan Zuo, Yu Yang, Junjie Wei

As content creation platforms proliferate and reshape the landscape of creative activities, the role of personalized recommendation in creative activities comes into focus. This study aims to understand how content creators’ perceived personalized recommendation influence their creative strategies and, in turn, their creative performance. We first develop and validate tools to measure perceived personalized recommendation through two samples (n1 = 209, n2 = 388), then use survey data of original video bloggers (n = 195) on a Chinese content creation platform to test our hypotheses. Based on signaling theory, we show that content creators’ perceived personalized recommendation promotes their content novelty and boost creative performance. We also find that these effects are intensified by content creators’ platform embeddedness. Our research advances the current studies on platform algorithmic control by revealing the consequences of an under-investigated algorithmic control form—algorithmic recommendation, and demonstrates the positive side of platform algorithmic control. We also diverge from the existing user-centric studies on platform algorithms and provide preliminary empirical evidence on how content creators’ responses to platforms’ personalized recommendation algorithms influence their subsequent creative outputs.

2 - Does AI Reduce Workplace Gender Inequality?

Pedro Masi, University of Tennessee, Knoxville, Knoxville, TN, United States, Yuanyang Liu, ChuanRen Liu

Many occupations are predominantly occupied by male or female workers. An important reason for such gender inequality in the workforce is the nature of certain tasks within these jobs, which tend to align more closely with either the capabilities or societal expectations of one gender over the other. For example, males are disproportionately represented in industry work while females are in pre-school education.

The purpose of this study is to determine if AI promotes gender diversity in the work-place. Specifically, this study examines whether exposure to AI reduces barriers to occupations traditionally dominated by a certain gender group. In essence, the study tests for the so called "deskilling effect" of AI technology. That is, if AI can perform certain tasks that were historically more challenging for a certain gender group to accomplish, then AI has effectively lowered the barrier of entry for that group. If so, then AI would allow that group to set foot into previously uncharted territory, thus, increasing gender diversity in the workplace.

3 - Analyzing the Dynamics and Dissemination of Gender Inequality on Weibo

Tiantian Liang, Central University of Finance and Economics, Beijing, China, People's Republic of

This study analyzes the dynamics and dissemination of gender inequality on Weibo through the lens of several key phrases, including "unmarried women," "older single women," "single motherhood," and "unmarried motherhood." We examine the differing perspectives on these topics among Chinese individuals to understand how these views diverge and spread across the platform. Our findings reveal significant variances in opinion and highlight the mechanisms through which these viewpoints are disseminated. This research offers valuable insights into social media dynamics and public opinion, with implications for understanding and managing cultural discourse.

4 - Gender Disparity in Expressed Emotions Within Online Health Communities

Yuehua Zhao, Nanjing University, Nanjing, China, People's Republic of

Online support groups offer a new way to users to communicate with others regarding certain health issues. Taking autism-related support groups on Facebook as an example, we examine whether the expressed emotions differ between female and male users in online health-related support groups and whether such gender disparity varied based on the topics of the groups. Experimental results reveal a significant gender difference of expressed emotions in the groups. We find that female users tended to express more positive emotions in the group discussions than the male group members did. In addition, users appeared to express different sentiments within the groups focused on various topics. Male users tend to convey more negative emotions in the group that related to treatment, while female users were more positive when posted in the research-related group than male users were. This study is beneficial for tracking and moderating the emotional environment in online support groups.

1 - Doubly High-Dimensional Contextual Bandits: An Interpretable Model for Joint Assortment-Pricing

Linda Zhao, University of Pennsylvania, Philadelphia, PA, United States

Key challenges in running a retail business include how to select products to present to consumers (the assortment problem), and how to price products (the pricing problem) to maximize revenue or profit. Instead of considering these problems in isolation, we propose a joint approach to assortment-pricing based on contextual bandits. Our model is doubly high-dimensional, in that both context vectors and actions are allowed to take values in high-dimensional spaces. In order to circumvent the curse of dimensionality, we propose a simple yet flexible model that captures the interactions between covariates and actions via a (near) low-rank representation matrix. The resulting class of models is reasonably expressive while remaining interpretable through latent factors, and includes various structured linear bandit and pricing models as particular cases. We propose a computationally tractable procedure that combines an exploration/exploitation protocol with an efficient low-rank matrix estimator, and we prove bounds on its regret. Simulation results show that this method has lower regret than state-of-the-art methods applied to various standard bandit and pricing models. Real-world case studies on the assortment-pricing problem, from an industry-leading instant noodles company to an emerging beauty start-up, underscore the gains achievable using our method. In each case, we show at least three-fold gains in revenue or profit by our bandit method, as well as the interpretability of the latent factor models that are learned.

2 - New Optimization Models for AI Research

Tianyi Lin, Columbia University, New York, NY, United States

In this talk, we present several new results on minimizing a nonsmooth and nonconvex function under a Lipschitz condition. Recent works show that while the classical notion of Clarke stationarity is computationally intractable up to some sufficiently small constant tolerance, the randomized first-order algorithms find an approximate Goldstein stationary point with the finite-time convergence guarantee, which is independent of problem dimension. First of all, we present several motivating examples and explain why the notion of Goldstein stationary is important to the finite-time convergence guarantee. Second, we show that the randomization is necessary to obtain a dimension-independent guarantee, by proving a lower bound of $\Omega(d)$ for any deterministic algorithm that has access to both first-order and zeroth-order oracles. We also show that the zeroth-order oracle is essential to obtain a finite-time convergence guarantee, by showing that any deterministic algorithm with only the first-order oracle can not find an approximate Goldstein stationary point within a finite number of iterations up to sufficiently small constant parameter and tolerance. Finally, we establish the relationship between the notion of Goldstein stationary and the uniform smoothing, and propose several new zeroth-order methods with solid finite-time convergence guarantee.

3 - Dual Active Learning for Reinforcement Learning from Human Feedback

Will Wei Sun, Purdue University, West Lafayette, IN, United States, Pangpang Liu

Aligning large language models (LLMs) with human preferences is critical to recent advances in generative artificial intelligence. Reinforcement learning from human feedback (RLHF) is widely applied to achieve this objective. A key step in RLHF is to learn the reward function from human feedback. However, human feedback is costly and time-consuming, making it essential to collect high-quality conversation data for human teachers to label. Additionally, different human teachers have different levels of expertise. It is thus critical to query the most appropriate teacher for their opinions. In this paper, we use offline reinforcement learning (RL) to formulate the alignment problem. Motivated by the idea of D-optimal design, we first propose a dual active reward learning algorithm for the simultaneous selection of conversations and teachers. Next, we apply pessimistic RL to solve the alignment problem, based on the learned reward estimator. Theoretically, we show that the reward estimator obtained through our proposed adaptive selection strategy achieves minimal generalized variance asymptotically, and prove that the sub-optimality of our pessimistic policy. Through simulations and experiments on LLMs, we demonstrate the effectiveness of our algorithm and its superiority over state-of-the-arts.

Case Competition

Award Session

Case Competition

Co-Chair: Matthew Drake, Duquesne University, Pittsburgh, PA, United States

1 - LandMover Equipment Company: Optimizing Servicizing Product Contract

Saurabh Bansal, Penn State, State College, PA, United States, Dan Guide, Wei Wu, Yinshi Gao, Yinshi (Alice) Gao

LMC is an original equipment manufacturer that sells capital-intensive earth-moving equipment. Recently, LMC decided to move towards a servicizing product model, which it expects to be more profitable and sustainable. Customers receive a product and return it back after use. The customers pay a fixed fee and a variable fee based on product usage. LMC performs extensive remanufacturing on the used product, e.g., taking the machine apart and repair. The remanufacturing cost depends on the customer's usage of the machine. LMC needs to determine the optimal contract for this business model.

2 - Potty Parity: Stadium Restroom Design

Vahid Roshanaei, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Setareh Farajollahzadeh, Ming Hu

Addressing long restroom wait times of women and LGBTQ+ individuals, this case presents tools to evaluate wait time disparities in various restroom setups. A stadium manager aims to enhance efficiency (wait time) and fairness (Totalitarian and Rawlsian Scores) among diverse gender preferences. In three modules, students (1) evaluate queuing parameters for mixed populations, (2) analyze wait-time disparities in restroom layouts, and (3) assess fairness from a DEI perspective. This case helps students understand queuing theory, efficiency-fairness trade-offs, and multi-objective problem-solving.

3 - Pricing Analytics for Porsche Drive Vehicle Subscription Program

Varun Gupta, University of North Georgia, Dahlonega, GA, United States, Vaughan Griffiths, Jing Li, Daniel Manion, Xiao Zhang

This case examines the pricing challenges of a luxury car subscription service: Porsche Drive, amidst a volatile automotive market. Facing unpredictable depreciation rates, a new intern analyzes cost-based, market-based, and value-based pricing models. Customers exhibit a heterogenous willingness to pay for the service, emphasizing the need for segmentation and reevaluation of pricing strategies. This case study explores the complexities of pricing in a rapidly changing industry, focusing on customer segmentation, market dynamics, and adapting pricing models to maximize subscription profit.

1 - Optimizing the Path Towards Plastic-Free Oceans

Baizhi Song, London Business School, London, United Kingdom

Rising ocean plastic pollution has considerable adverse effects on Earth and humans. We partner with a non-profit organization and use optimization to help clean up oceans from plastic faster. Specifically, we optimize the route of their plastic collection system in the ocean to maximize the quantity of plastic collected over time. The algorithm considers complex plastic dynamics and relevant operational constraints. We validate our algorithm on historical ocean data and achieve over 60% improvement over their current method. Our algorithm also informs the design of their new system.

2 - Strengthening Blood Transfusion System in Kenya by Analytic Tools

Yiqi Tian, University of Pittsburgh, Pittsburgh, PA, United States

The PITS-Kenya project has advanced Kenya's blood transfusion services by an integrated OR tool set. We developed the first comprehensive process map and the first large-scale ‘vein-to-vein’ discrete event simulation platform to visualize and interact with the system. These innovations have streamlined operations, evaluated interventions, and are supporting clinical trials in 13 hospitals, impacting over 30,000 patients. Additionally, we are developing a novel blood drive planning tool to boost donor engagement, aiming to increase the annual blood supply from 30% to 50% of the target.

3 - Identification of Hazard Clusters for Priority Landmine Clearance as a Quadratic Knapsack Problem

Mateo Dulce Rubio, Carnegie Mellon University, Pittsburgh, PA, United States

Landmines pose a threat to war-affected communities even after conflicts have ended, in part due to the labor-intensive nature of demining. In this work we propose RELand, in partnership with the UN Mine Action Service, to identify hazard clusters for priority mine clearance under geographic and budget constraints using a novel QKP formulation. Ongoing field testing in actual demining operations in Colombia has so far identified three landmines in one prioritized area. The proposed system provides practical inputs for humanitarian demining with the potential for global application and impact.

4 - Optimizing Health Supply Chains with Decision-Aware Machine Learning

Tsai-Hsuan (Angel) Chung, The Wharton School, UPenn, Philadelphia, PA, United States

We address the problem of allocating limited medical resources in a developing country by combining ML (to predict demand) with optimization (to optimize allocations). A key challenge is aligning the ML model's loss function with the decision loss in optimization. We propose a scalable decision-aware learning framework and successfully deployed in collaboration with the Sierra Leone government across 1,123 healthcare facilities nationwide, leading to a 15-29% increase in medicine consumption and improved real-world patient access to care.

1 - Can Hiding (Dis)like Help? An Investigation of the Impact of Performance Metrics Disclosure on Social Media Platforms

Yi Gao, Texas Tech University, Lubbock, TX, United States, Pei-yu Chen, Dengpan Liu

As social media becomes deeply integrated into daily life, concerns have emerged regarding the potential unintended negative effects on well-being due to social comparison and pressure. To address these concerns, platforms have started experimenting with various measures to safeguard the mental health of content creators. One approach is adjusting the disclosure of performance metrics. In this study, we investigate how changes in performance metric disclosures impact the platforms and creators by constructing a game-theoretic model that takes into account social comparison as well as the platform’s potential long-term loss from demand distortion driven by the disclosure of performance metrics. Our findings reveal that when the creators derive significant utilities or disutilities from social comparison, heightened disclosure can motivate less effective creators to increase their efforts. Interestingly, our analysis of the demand disparity between the two creators suggests that while disclosing more performance metrics may seemingly widen the popularity discrepancy between them, it does not necessarily lead to a greater disparity in demand. Moreover, we find that as the disclosure level increases, platforms may lower their commission rates and experience a decline in their profits. We also find that the optimal disclosure level decreases with the social comparison intensity and may sometimes increase with the platform’s traffic revenue per demand. These findings have significant implications for social media platforms on how to employ technologies for social good and regulators on how to respond to changes in the disclosure level.

2 - Learning for Approval

Xingchen Xu, University of Washington, Seattle, WA, United States, Yumei He, Yong Tan

In online matching platforms, users must exert effort (cost) and face the risk of rejection when seeking to forge connections with others. Beyond the mere absence of a match, there might exist an additional psychological cost borne by those who face rejection, distinct from the silent void left by an inactive counterpart. Concurrently, users exhibit heterogeneous preferences towards various participants on the opposing side of the platform, obfuscating the process of disentangling application costs, rejection costs, perceived probabilities of matching outcomes, and the intrinsic preferences that underpin user behavior. Acknowledging these empirical complexities, we construct a comprehensive Bayesian Learning model that jointly incorporates all the aforementioned mechanisms to characterize user behavior in matching markets. By leveraging a unique dataset from an online dating platform, we calibrate the model and thoroughly depict users' strategic behavior. On top of the estimation results, We develop counterfactual policies that harness the power of matching algorithms and large language models, thereby improving the efficiency of online matching process.

3 - Impact of the Representational Fidelity of AI Explanations and Perceived Bias of Ai Systems on Medical Decision-Making: Cognitive and Emotional Mechanisms

Rongen "Sophia" Zhang, Baylor University, Waco, TX, United States, Karl Werder, Kartikeya Negi, Balasubramaniam Ramesh

While Artificial intelligence (AI)-based decision-making systems have been shown to outperform them, medical experts are often reluctant to follow their recommendations because of the black-box nature of these systems. Explainable AI provides the promise of unpacking the black box of AI. Hence, this study aims to understand the impact of the representational fidelity of different explanations and the perceived bias of the AI system on the informed decisions of medical professionals. Drawing from effective use theory, we propose two mechanisms that mediate these effects: a cognitive learning mechanism and an emotional mechanism. We conducted two studies to test our hypotheses. In the first study, diabetes patients were asked to provide recommendations for their relatives based on their data, AI recommendations, and accompanying AI explanations. In the second study, healthcare providers, including physicians, nurse practitioners, and physician assistants, were asked to make decisions regarding the likelihood of developing sepsis based on patient data, AI recommendations, and various types of AI explanations. Our study provides a new perspective to the scholarly discourse on explainable AI and the effective use of AI by enhancing our understanding of how AI explanations influence medical decision-making and highlighting the importance of designing AI systems that support both the cognitive and emotional aspects of decision-making.

4 - Ground Truth Mechanisms in AI Development: A Conjoined Agency Perspective

Hengqi Tian, University of Colorado Denver, Denver, CO, United States, Arun Rai, Angelos Kostis, Jonny Holmström

Crafting ground truth data labels is instrumental but challenging in AI development. In contrast to the prevailing dominant objective view on ground truth labels and human-centered data labeling approaches, we adopt a conjoined agency perspective to theorize how the complementarities between humans and AI play out in organizing the data labeling process for AI development. We conceptualize ground truth data labeling as a highly iterative process involving reflection in action between human agency and AI agency. We propose that the level of ground truth uncertainty determines the composition of conjoined agency and the degree of reflection in action necessary to get the appropriate labels, which can lead to two different organizing principles emphasizing either accuracy or divergence. Our theoretical framework and propositions are expected to contribute to unpacking the composition and interactive dynamics of humans and AIs in constructing ground truth data labels and how learning occurs within human-AI interactions.

Statistical Learning via Generative Models, Simulation, and Optimization

Invited Session

Data Mining

Chair: Yao Xie, Georgia Institute of Technology, Atlanta, GA, United States

1 - Kernel Learning in Ridge Regression "Automatically" Yields Exact Low Rank Solution

Feng Ruan, Northwestern University, Evanston, IL, United States, Yunlu Chen, Yang Li, Keli Liu

This talk considers a variant of kernel ridge regression which simultaneously optimizes the prediction function and the reproducing kernel Hilbert space (RKHS) parameter. We identify a previously unnoticed phenomenon for this kernel learning objective where — under certain conditions — the global minimizer is exactly low rank with high probability. This phenomenon is interesting because the low rankness property is achieved without using any explicit regularization. Our theory makes correspondence between the observed phenomenon and the notion of low rank set identifiability from the optimization literature. The low rankness property of the finite sample solutions exists because the population kernel learning objective grows "sharply" when moving away from its minimizers in any direction perpendicular to the central mean subspace.

2 - Simulation Calibrated Machine Learning: Minimax Estimation via Hybrid Scientific and Statistical Models

Yiping Lu, Northwestern IEMS, Evanston, IL , IL, United States

Machine learning (ML) has achieved great success in a variety of applications suggesting a new way to build flexible, universal, and efficient approximators for complex high-dimensional data. These successes have inspired many researchers to apply ML to other scientific applications such as industrial engineering, scientific computing, and operational research, where similar challenges often occur. However, the luminous success of ML is overshadowed by persistent concerns that the mathematical theory of large-scale machine learning, especially deep learning, is still lacking and the trained ML predictor is always biased. In this talk, I'll introduce a novel framework of (S)imulation-(Ca)librated (S)cientific (M)achine (L)earning (SCaSML), which can leverage the structure of physical models to achieve the following goals: 1) make unbiased predictions even based on biased machine learning predictors; 2) beat the curse of dimensionality with an estimator suffers from it. The SCASML paradigm combines a (possibly) biased machine learning algorithm with a de-biasing step design using rigorous numerical analysis and stochastic simulation. Theoretically, I'll try to understand whether the SCaSML algorithms are optimal and what factors (e.g., smoothness, dimension, and boundness) determine the improvement of the convergence rate. Empirically, I'll introduce different estimators that enable unbiased and trustworthy estimation for physical quantities with a biased machine learning estimator. Applications include but are not limited to estimating the moment of a function, simulating high-dimensional stochastic processes, uncertainty quantification using bootstrap methods, and randomized linear algebra.

3 - Flow-Based Distributionally Robust Optimization

Chen Xu, Georgia Institute of Technology, Atlanta, GA, United States, Jonghyeok Lee, Xiuyuan Cheng, Yao Xie

We present a computationally efficient framework, called FlowDRO, for solving flow-based distributionally robust optimization (DRO) problems with Wasserstein uncertainty sets while aiming to find continuous worst-case distribution (also called the Least Favorable Distribution, LFD) and sample from it. The requirement for LFD to be continuous is
so that the algorithm can be scalable to problems with larger sample sizes and achieve better generalization capability for the induced robust algorithms. To tackle the computationally challenging infinitely dimensional optimization problem, we leverage flow-based models and continuous-time invertible transport maps between the data distribution
and the target distribution and develop a Wasserstein proximal gradient flow type algorithm. In theory, we establish the equivalence of the solution by optimal transport map to the original formulation, as well as the dual form of the problem through Wasserstein calculus and Brenier theorem. In practice, we parameterize the transport maps by a sequence of
neural networks progressively trained in blocks by gradient descent. We demonstrate its usage in adversarial learning, distributionally robust hypothesis testing, and a new mechanism for data-driven distribution perturbation differential privacy, where the proposed method gives strong empirical performance on high-dimensional real data.

4 - Spurious Stationarity and Hardness Results for Mirror Descent

Jiajin Li, University of British Columbia, Vancouver, BC, Canada

Despite the considerable success of Bregman proximal-type algorithms, such as mirror descent, in machine learning, a critical question remains: Can existing stationarity measures, often based on Bregman divergence, reliably distinguish between stationary and non-stationary points? In this paper, we present a groundbreaking finding: All existing stationarity measures necessarily imply the existence of spurious stationary points. We further establish an algorithmic independent hardness result: Bregman proximal-type algorithms are unable to escape from a spurious stationary point in finite steps when the initial point is unfavorable, even for convex problems. Our hardness result points out the inherent distinction between Euclidean and Bregman geometries, and introduces both fundamental theoretical and numerical challenges to both machine learning and optimization communities.

1 - Gradient Guidance for Diffusion Models: An Optimization Perspective

Hui Yuan, Princeton University, Princeton, NJ, United States, Yingqing Guo, Yukang Yang, Minshuo Chen, Mengdi Wang

Diffusion models have demonstrated empirical successes in various applications and can be adapted to task-specific needs via guidance. This work introduces a form of gradient guidance designed to adapt diffusion models towards user-specified optimization objectives. We study the theoretic aspects of a guided score-based sampling process, linking the gradient-guided diffusion model to first-order optimization. We show that adding gradient guidance to the sampling process of a pre-trained diffusion model is essentially equivalent to solving a regularized optimization problem, where the regularization term acts as a prior determined by pre-training data. Diffusion models are able to learn data's latent subspace, however, explicitly adding the gradient of an external objective function to the sample process would jeopardize the structure in generated samples. To remedy this issue, we consider a modified form of gradient guidance based on a forward prediction loss, which leverages the pre-trained score function to preserve the latent structure in generated samples. We further consider an iteratively fine-tuned version of gradient-guided diffusion where one can query gradients at newly generated data points and update the score network using new samples. This process mimics a first-order optimization iteration in expectation, for which we prove O(1/K) convergence rate to the global optimum when the objective function is concave.

2 - Stronger Together: Marrying Large Language Models with Traditional Symbolic Decision-Making

Yuandong Tian, Facebook, Menlo Park, CA, United States

While Large Language Models have achieved remarkable success, they are still weak for complicated tasks such as planning and optimization that look for optimal solutions for a given objective, subject to multiple constraints. In comparison, traditional symbolic solvers often give precise and guaranteed solutions to well-defined problems. In this talk, we explore a marriage of LLMs and symbolic solvers for better planning for hard optimization problems with natural language interface.

3 - From Minimax Score Matching to Optimal Sampling

Zehao Dou, Yale University, New Haven, CT, United States

Score-based diffusion models have significantly enhanced the performance of image, audio and video generation in the few past years. As a key ingredient, score estimation plays the most important role in the overall quality of diffusion models. In this work, we study the estimation of score function for the noisy probability distribution from n i.i.d observations. Assuming the Hölder smoothness and the compact support set of the original density, we establish the minimax rate of the mean integrated squared error for score estimation under all time steps. Without any additional logarithmic gaps, we perfectly match the upper and lower bounds, and achieve the optimal density estimation by diffusion models with the minimax score estimator plugged in.

4 - Representation-Based Reinforcement Learning

Bo Dai, Georgia Tech, ATLANTA, CA, United States

The majority reinforcement learning (RL) algorithms are largely categorized as model-free and model-based through whether a world model is learned in the algorithm. However, both of these two categories have their own issues, especially incorporating with function approximation: the exploration with arbitrary function approximation in model-free RL algorithms is difficult, while optimal planning becomes intractable in model-based RL algorithms with neural nonlinear world models.

In this talk, I will present our recent work on exploiting the power of representation in RL to bypass these difficulties, while enjoys best of both worlds. Specifically, we designed practical algorithms for extracting useful representations from world model, with the goal of improving statistical and computational efficiency in exploration vs. exploitation tradeoff and empirical performance in RL. We provide rigorous theoretical analysis of our algorithm, and demonstrate the practical superior performance over the existing state-of-the-art empirical algorithms on several benchmarks.

5 - OptiGuide: Language models for supply chain management (and beyond)

Ishai Menache, Microsoft, Redmond, WA, United States

We will provide an overview of our work on applying language model technology for supply chain management. We will also discuss future directions in the intersection of language models and operations.

Waiting Time Prediction using Machine Learning

Invited Session

Data Mining

Chair: Yaron Shaposhnik, University of Rochester, Rochester, NY, United States

1 - Prediction of hospitalization and waiting time within 24 hours of emergency department patients with unstructured text data

Hyeram Seo, Asan Medical Center & Yonsei Univercity, (UTC+09:00) Asia/Seoul, Korea, Republic of

Overcrowding of emergency departments is a global concern, leading to numerous negative consequences. This study aimed to develop a useful and inexpensive tool derived from electronic medical records that supports clinical decision-making and can be easily utilized by emergency department physicians. We presented machine learning models that predicted the likelihood of hospitalizations within 24 hours and estimated waiting times. Moreover, we revealed the enhanced performance of these machine learning models compared to existing models by incorporating unstructured text data. Among several evaluated models, the extreme gradient boosting model that incorporated text data yielded the best performance. This model achieved an area under the receiver operating characteristic curve score of 0.922 and an area under the precision-recall curve score of 0.687. The mean absolute error revealed a difference of approximately 3 hours. Using this model, we classified the probability of patients not being admitted within 24 hours as Low, Medium, or High and identified important variables influencing this classification through explainable artificial intelligence. The model results are readily displayed on an electronic dashboard to support the decision-making of emergency department physicians and alleviate overcrowding, thereby resulting in socioeconomic benefits for medical facilities.

2 - Probabilistic Forecasting of Patient Waiting Times in an Emergency Department

Siddharth Arora, University of Oxford, Oxford, United Kingdom

This study aims to generate probability distribution forecasts of individual patient waiting times in an emergency department (ED). Wait time estimates can offer low-acuity patients and first responders a more comprehensive view of the possible waiting trajectory and provide reliable inputs to inform prescriptive modelling of ED operations. We define wait times as the time elapsed from patient registration at the ED to the start of treatment. Previous studies on modeling wait times have typically focused on generating a point estimate. However, waiting time is inherently uncertain, and the distribution is asymmetric. Thus, communicating only a point forecast can be uninformative and potentially misleading. This motivates us to generate probabilistic estimates of wait times. Using a large patient-level data set, we extract the following categories of predictor variables during the modeling: (1) calendar effects, (2) demographics, (3) staff count, (4) ED workload resulting from patient volumes, and (5) the severity of the patient condition. We demonstrate that publishing probabilistic waiting time estimates can inform patients and ambulance staff when selecting an ED from a network of EDs, leading to a more uniform spread of patient load across the network.

3 - Waiting Time Prediction using Machine Learning

Yashi Huang, University of Rochester, Rochester, NY, United States, Arik Senderovich, Yaron Shaposhnik

We develop a system for a large cancer institute for predicting in real-time patients' waiting times. The system consists of a collection of machine learning and simulation models that are assembled to make predictions (e.g., different models are used in different cases in different stages of the service process). The system is designed to overcome various challenges such as stochasticity (e.g., unexpected cancellations, and random service and arrival times), heterogeneity (e.g., of patients, providers, and workflow), complex service process (e.g., multiple interconnected stages), and limitations of the available data (e.g., noisy data and changes to the schedule that may not be electronically recorded). At the same time, the system is designed to provide the users explanations about why predictions are made and alert them about potentially inaccurate predictions and delays to the schedule. We report on the performance of our models for the various prediction tasks using a real-world data set.

Optimization and Learning for Future Electricity Market Design

Invited Session

ENRE: Electricity

Chair: Rajni Bansal, Johns Hopkins University, Baltimore, MD, 92093, United States

Co-Chair: Patricia Hidalgo-Gonzalez, University of California, San Diego, La Jolla, CA, United States

1 - Balancing Fairness and Efficiency in Energy Resource Allocations

Baosen Zhang, University of Washington, SEATTLE, WA, United States, Jiayi Li, Matthew Motoki

Bringing fairness to energy resource allocation remains a challenge, due to the complexity of system structures and economic interdependencies among users and system operators' decision-making. The rise of distributed energy resources has introduced more diverse heterogeneous user groups, surpassing the capabilities of traditional efficiency-oriented allocation schemes. Without explicitly bringing fairness to user-system interaction, this disparity often leads to disproportionate payments for certain user groups due to their utility formats or group sizes. We addresses this challenge by formalizing the problem of fair energy resource allocation and introducing the framework for aggregators. This framework enables optimal fairness-efficiency trade-offs by selecting appropriate objectives in a principled way. By jointly optimizing over the total resources to allocate and individual allocations, our approach reveals optimized allocation schemes that lie on the Pareto front, balancing fairness and efficiency in resource allocation strategies.

2 - Locational Marginal Price in Electricity Markets

Steven Low, Caltech, Pasadena, CA, United States

In this brief tutorial, I will explain the basic economic dispatch problem in the electricity market and properties of locational marginal prices (LMPs). Specifically, I will present the DC optimal power flow problem that maximizes social welfare over real-time dispatch decisions subject to injection capacity and line flow limits. The resulting LMPs are nodal prices. They balance supply and demand, align individual incentives with social welfare, and are different at different nodes if and only if line congestion prices are nonzero. I will describe how injection limits and line congestion can cause LMPs at some nodes to be negative, but the system operator will never run cash negative. Time permitting, I will extend the basic economic dispatch problem to a security-constrained problem where dispatch decisions must be made under network contingencies.

3 - Fair Allocations of Cooperation Gains in Peer to Peer Electricity Markets

Shmuel Oren, UC Berkeley, Berkeley, CA, United States, Tomas Valencia Zuluaga

The advent of differentiated prices for consuming (buying) and injecting (selling) electricity at the residential level promotes the emergence of local peer-to peer electricity markets for prosumers, which can deliver savings to participants as long as an attractive cost sharing mechanism can be designed. Building on cooperative game theory models that have been proposed in the literature, we define the uniform price core, a class of desirable distribution of savings in this context, and prove constructively that it is not empty. We propose the shadow price imputation, a computationally efficient stable uniform price imputation, which we show to be equivalent to a dual imputation in the sense of cooperative linear production games. We then compare the shadow price imputation to other imputations in the uniform price core through the lens of fairness. To overcome the challenge of computational tractability for large numbers of participants, we employ a statistical sampling methodology for approximating the core and apply it to optimization problems devised to obtain a fair imputation. We present theoretical results and numerical experiments and examples illustrating our approach.

4 - Energy Storage Bidding Mechanism for Temporally-Coupled Electricity Markets

Rajni Bansal, University of California San Diego, San Diego, CA, United States, Patricia Hidalgo-Gonzalez

Electricity markets typically consist of two stages: a day-ahead (forward) market and a real-time (spot) market. This study proposes a market mechanism for a temporally coupled and stochastic two-stage multi-interval electricity market with different types of participants, such as generators and energy storage. Competitive equilibrium analysis is used to examine the impact of day-ahead decisions on the bidding curve of energy storage in the real-time market. Numerical experiments are conducted using New York ISO data to demonstrate the benefits of incorporating day-ahead decisions and uncertainty in the bidding function and to establish limits on the proposed market mechanisms.

Net-Zero Emissions Energy Systems: Equitable Transitions

Invited Session

ENRE: Energy-Climate

Chair: Aleksander Grochowicz, University of Oslo, Oslo, Norway

Co-Chair: Jacqueline Dowling, Carnegie Science, 260 Panama St., Providence, 94305, United States

Co-Chair: Edgar Virgüez, Carnegie Institution for Science, Stanford, CA, United States

1 - Assessing multiple objectives in participatory energy modelling

Aleksander Grochowicz, University of Oslo, Oslo, Norway, Oskar Vågerö, Koen van Greevenbroek, Maximilian Roithner

As climate mitigation efforts focus strongly on decarbonising energy systems, some communities are forced to rapidly transform their fossil-based energy infrastructure.
In many places, the transition to renewable systems can be met with skepticism due to the top-down implementation of national targets.
In this case study, we consider the Arctic settlement Longyearbyen, which is the world's northernmost settlement at 78 degrees latitude.
Founded as a coal mining town, the Norwegian government has shut down its coal power plant and aims to transition to a renewable off-grid

system.

We use a novel participatory modelling approach to investigate the preferences of the local population regarding the future energy system in Longyearbyen.
Based on results from an open energy system optimisation model, we use near-optimal methods to describe many possible outcomes and additionally compare their performance under different metrics and objectives.
We develop a tool through which a significant part of the population interacts with the challenging tasks of weighing off different objectives such as e.g. costs, emission reduction, and vulnerability of energy supply.
We find that generally the local population is willing to accept some higher costs if other priorities can be achieved and acknowledge the trade-offs and challenges in the decision process.
By laying bare the complexities and offering very diverse system alternatives, our approach can bridge the communication and information gap between stakeholders, modellers, and policymakers.

2 - Resilience of Offshore Wind Technologies under Hurricane Landfalling Within the PJM Interconnection

Avery Barnett, Princeton University , Princeton , NJ, United States, Jesse Jenkins

New Jersey (NJ) is not spared from hurricane impacts and will have to work towards ensuring that social and technical impacts are mitigated and that infrastructure is sufficiently hardened. In line with the recent executive orders that mandate 100% clean energy by 2035 and 11,000MW of offshore wind by 2040, my research project focuses on the resilience of offshore wind technologies under hurricane landfall within PJM. Through varying the penetration of offshore wind technologies in the grid, I will investigate the options available to balance resilience and affordability, the impact of offshore wind on the overall system, and the level of electricity supply disruption at different hurricane intensities. By using GenX and an extreme weather model, the impacts of the electric grid within NJ will be assessed and solved for a range of different configurations, including varying offshore wind penetrations and other resilience factors, which will then be impacted by varying intensities of hurricanes where wind speed is used as a proxy. The impact of electricity supply disruption that results from the failure and how much failure is attributed to offshore wind within each configuration will be assessed. This research hopes to provide a first step in understanding the resilience of NJ, and by extension, the PJM grid against hurricanes. Future research can be informed through adaptation to consider other electricity grid threats such as storm surges, flooding, and similar hazards.

3 - Disparities in Per Capita Energy Consumption Within and Between Countries

Edgar Virguez, Carnegie Institution for Science, Stanford, CA, United States

Addressing issues related to equity and poverty requires a better understanding of the more than 1000-fold differences in per capita energy consumption worldwide. Here, we integrate national energy balances, population, income distribution, and gross domestic product data, to identify patterns in the current distribution of per capita energy consumption by quantifying existing disparities within and between countries. Among the profound disparities evident from this analysis, we find that 1% additional primary energy supply worldwide would be sufficient to double the energy available to the 10% of the most energy-impoverished people. In contrast, the 10% of the world's population with the highest energy consumption uses ~41% of the world's energy. The half of the people in the world using the least energy consume about the same amount of energy as 1.6 % of most profligate energy users. To bring the half of people who consume the least amount of energy to the worldwide median would increase global energy demand by 13.4%. Bringing the 1% of people who consume more energy than the 99th percentile level to the 99th percentile level would make enough energy available to bring the 31.1% of people who are most energy-impoverished to the level of the 31.1th percentile. Countries differ more in their mean per capita energy consumption than in the degree of within-country disparity. We conclude that relatively modest increases in global energy production (and/or redistribution of energy use) could produce large fractional increases in energy provision for the most energy-impoverished people in the world

4 - Climate change loss and damages (L&D) and reparations for equitable net-zero transitions.

Kiran Chawla, Stanford University, Palo Alto, CA, United States, Ines Azevedo

We use integrated assessment model based projections to understand what economic losses from climate change will be in different world regions. Even if the world optimally switches to a clean energy economy through global coordination, the impacts of climate change that are going to be baked into a warmer world need to be addressed through financial support from countries most responsible for emissions. We estimate the magnitude of these transfers and show how they are orders of magnitude greater than current international commitments, demonstrating a need to scale up ambition by countries for equity improving transfers.

5 - Air pollution inequity in net-zero targets in United States

Candelaria Bergero, UCI, Irvine, CA, United States

Meeting the target of the Paris Agreement of 1.5°C calls for large amounts of carbon dioxide removals (CDR). The U.S. net-zero GHG emissions target could require as much as 1.9 Gt of CDR by mid-century. Because GHGs and air pollution are commonly co-emitted, net-zero targes generally improve air quality and health outcomes. However, the magnitude and distribution of such health benefits will ultimately depend on the mitigation pathway chosen. Here we combine a series of models and analyze the pollution and health related impacts on local communities of two net-zero targets for the contiguous U.S. with varying amounts of CDR. We find that, while net-zero targets improve air quality and could avoid as much as 84,000 PM2.5-related deaths compared to a business-as-usual case, there are difference between an unrestricted CDR scenario and a restricted one in terms of mortality and its distribution across races and income groups. Meeting the dual goals of mitigating climate change and achieving a more equitable distribution of the benefits of the transition will require purposeful policy planning.

Data-Driven, Human-Centered Decision Making in Stochastic Service Systems

Invited Session

MSOM: Service Operations

Chair: Yueyang Zhong, London Business School, London, N/A

1 - Learning to Defer in Content Moderation: the Human-AI Interplay

Thodoris Lykouris, Massachusetts Institute of Technology, Cambridge, MA, United States, Wentao Weng

Ensuring successful content moderation is vital for a healthy online social platform where it is necessary to responsively remove harmful posts without jeopardizing non-harmful content. Due to the high-volume nature of online posts, human-only moderation is operationally challenging, and platforms often employ a human-AI collaboration approach. A typical machine-learning heuristic estimates the expected harmfulness of incoming posts and uses fixed thresholds to decide whether to remove the post (classification decision) and whether to send it for human review (admission decision). This can be inefficient as it disregards the uncertainty in the machine-learning estimation, the time-varying element of human review capacity and post arrivals, and the selective sampling in the dataset (humans only review posts filtered by the admission algorithm).

We introduce a model to capture the human-AI interplay in content moderation. The algorithm observes contextual information for incoming posts, makes classification and admission decisions, and schedules posts for human review. Non-admitted posts do not receive reviews (selective sampling) and admitted posts receive human reviews on their harmfulness. These reviews help educate the machine-learning algorithms but are delayed due to congestion in the human review system.

We propose a near-optimal learning algorithm that carefully balances the classification loss from a selectively sampled dataset, the idiosyncratic loss of non-reviewed posts, and the delay loss of having congestion in the human review system. To the best of our knowledge, this is the first result for online learning in contextual queueing systems and hence our analytical framework may be of independent interest.

2 - Ambiguous Dynamic Treatment Regimes: A Reinforcement Learning Approach

Soroush Saghafian, Harvard University, Cambridge, MA, United States

Researchers in different domains often want to use observational data and provide recommendations that can yield causal improvements. When using available methods, they often have to rely on assumptions that are violated in real-world applications (e.g., medical decision-making or public policy), especially when (a) the existence of unobserved confounders cannot be ignored, and (b) the unobserved confounders are time-varying (e.g., affected by previous actions). Motivated by a case study of finding superior treatment regimes for patients who underwent transplantation in our partner hospital (Mayo Clinic), we introduce a new methodology termed Ambiguous Dynamic Treatment Regimes (ADTRs), in which the causal impact of treatment regimes is evaluated based on a “cloud” of causal models. We then develop new reinforcement learning algorithms and run detailed experiments using real-world patient level data.

3 - Detecting Service Slowdown Using Observational Data

Gal Mendelson, Faculty of Data and Decision Sciences, Technion, Adi, Israel, Kuang Xu

In this talk, I will discuss the interplay between control and statistical analysis in service systems. The choice of the control mechanism is key for obtaining desired performance and fast, online detection of persistent changes in service speed is key to maintaining desired service quality and availability. I will demonstrate that the choice of control has a substantial impact on the nature of the data that is being generated and consequently changes how it should be used. I will discuss the limitations of using state data (e.g., queue lengths) for detection and present a new statistic, namely action data, and demonstrate that it can be very powerful.

4 - Integrating In-Person Specialists' Care with AI-Driven Telemedicine

Fanying Chen, Boston University, Boston, MA, United States, Opher Baron, Abraham Seidmann

Telemedicine has been slowly gaining popularity, and the COVID-19 pandemic dramatically boosted its usage. With an acute shortage of physicians, large healthcare organizations have been looking at the best ways to integrate virtual, digital, and condition-specific automated care programs to create a unified, comprehensive clinical journey for their members. Working with the leadership of a large HMO, we investigate the option of incorporating an independent third-party service that will offer select patients rapid access to virtual AI-driven dermatological diagnostic systems. We present a novel model of such a hybrid service system designed to shorten waits for this specialty medical care. Under this model, the automated appointment scheduling system dynamically activates the (far more expensive) virtual AI-driven care line only when the primary (in-person) service line becomes overloaded. We use extensive field data analytics to show that our proposed hybrid service-delivery model provides significant service improvements, even when the virtual AI-driven telecare is called to serve only a small proportion of patients.

Logistics under Contested Conditions

Invited Session

Computing Society

Chair: Daniel Bienstock, Columbia University, New York, NY, United States

1 - Dreamcatcher-Operations

Jeff Linderoth, University of Wisconsin-Madison, Madison, WI, United States

Given friendly and adversary Orders of Battle and projected movements, which weapons should be assigned over time to missions to maximize the damage to high-priority targets? Dreamcatcher-Operations (DCOPS) is a mixed-integer programming-based tool for helping decision-makers answer this question.

We will discuss the design and implementation of DCOPS, including its newest features aimed at measuring and mitigating the risk of operations.

2 - Planning Logistics Under Adversarial Conditions

Blake Sisson, Columbia University, New York, NY, United States, Daniel Bienstock, Alexandra Newman, Justin Kilb, Caleb Fluker

We explore multiple mixed-integer programming- and machine-learning-based tools designed to enhance operational planning for contested logistics that rapidly evaluate the results of planning models, making them resilient to adversarial uncertainty and enabling real-time strategic adaptations. Acknowledging the high degree of uncertainty involved in contested logistics, we focus on an iterative algorithm that explores blue and red multi-period action plans. Building on the methods of Stackelberg competition, the process simulates sequences of actions and reactions, generating a large solution space that quantifies the implications of both rational and irrational decisions. By simulating a variety of possible outcomes, in which each iteration finds the best currently available set of decisions, the approach ensures that blue's strategy remains robust, effectively reducing vulnerability regardless of the unpredictable nature of red's actions. These tactical tools are designed to be fast-solving and user-friendly, allowing decision-makers without deep technical expertise to utilize advanced optimization and artificial intelligence capabilities.

3 - Layered Graph Security Games & Contested Logistics

Jakub Cerny, Columbia University, NY, NY, United States, Chun Kai Ling, Christian Kroer, Garud Iyengar

Security games model strategic interactions in adversarial real-world applications. Such applications often involve extremely large but highly structured strategy sets (e.g., selecting a distribution over all patrol routes in a given graph). In this paper, we represent each player's strategy space using a \textit{layered graph} whose paths represent an exponentially large strategy space. Our formulation entails not only classic pursuit-evasion games, but also other security games, such as those modeling anti-terrorism and logistical interdiction. We study two-player zero-sum games played on such graphs, and develop scalable algorithmic approaches for computing optimal plans for each player.

4 - A Fast Algorithm for Dual Decomposition in Vehicle Delivery Networks

Samuel Tan, Cornell University, Ithaca, NY, United States, Peter Frazier, Matthew Ford, Huseyin Topaloglu

We present a fast algorithm for solving dual decomposition in discrete-time vehicle delivery problems. We first use Lagrangian relaxation on a coupling constraint between vehicle movements and inventory levels to yield a dual decomposition, which can be solved with dual ascent. Moreover, the sets of problems can be further grouped into (1) a set of problems corresponding to individual vehicles, and (2) a set of problems corresponding to each item type and location. By appealing to the economic interpretation of the dual variables as prices in a marketplace, we show that the vehicle problems can be solved efficiently with dynamic programming, and that the item/location problems can be solved analytically in closed-form. We also provide an algorithm for generating primal feasible solutions in the case that the dual ascent terminates early. On a variety of realistic test instances, we show that our method yields objective values which are competitive with those produced by a mixed integer programming solver with significantly less computation.

1 - Unveiling Competitive Dynamics: Leveraging Generative Large Language Models for Textual Analysis of Firm Actions and Their Impact on Competitive Advantage

Yuanyuan Chen, University of Alabama Culverhouse College of Commerce, Tuscaloosa, AL, United States

In this study, we delve into the intricate relationship between manufacturers' competitive actions and their resulting competitive advantages. Our focus is on firms' strategic maneuvers in the domains of artificial intelligence and data analytics. Leveraging Generative Large Language Models (GLLMs) and GPT models, we embark on a comprehensive textual analysis of manufacturers' financial filings and press releases. This meticulous analysis enables us to gather pertinent data on firms' competitive actions, product development initiatives, and the phenomenon of servitization. Our investigation extends to assessing the impact of firms' actions in the area of AI and data analytics on key performance indicators that are crucial for business success, including customer relationship management, profitability, and stock market returns. Beyond the empirical findings, this study has significant managerial implications, shedding light on strategic decision-making processes and operational management practices within manufacturing firms. Furthermore, our methodological approach contributes to the field by pioneering an innovative use of GLLMs and GPT in textual mining of large data sets.

2 - Fair Conformal Prediction and Risk Control

Linjun Zhang, Rutgers University, New Brunswick, NJ, United States

Multi-calibration is a powerful and evolving concept originating in the field of algorithmic fairness. For a predictor f that estimates the outcome y given covariates x, and for a function class C, multi-calibration requires that the predictor $f(x)$ and outcome y are indistinguishable under the class of auditors in C. Fairness is captured by incorporating demographic subgroups into the class of functions C. Recent work has shown that, by enriching the class C to incorporate appropriate propensity re-weighting functions, multi-calibration also yields target-independent learning, wherein a model trained on a source domain performs well on unseen, future target domains(approximately) captured by the re-weightings. The multi-calibration notion is extended, and the power of an enriched class of mappings is explored. HappyMap, a generalization of multi-calibration, is proposed, which yields a wide range of new applications, including a new fairness notion for uncertainty quantification (conformal prediction), a novel technique for conformal prediction under covariate shift, and a different approach for fair risk control, while also yielding a unified understanding of several existing seemingly disparate algorithmic fairness notions and target-independent learning approaches. A single HappyMap meta-algorithm is given that captures all these results, together with a sufficiency condition for its success. Time permitting, the application of HappyMap to computer vision and large language models will also be discussed.

3 - Model-Based Clustering Analysis on the Spatial-Temporal and Intensity Pattern of Tornadoes

Rong Zheng, Western Illinois University, Macomb, IL, United States, Yana Melnykov, Yingying Zhang

Tornadoes are one of the nature's most violent windstorms that can occur all over the world. Many papers have been written to analyze tornadoes. However, the developed models fail to consider the dynamic nature of tornado paths and covariates that affect the tornadoes behaviors. In the proposed models, finite mixture models are employed to describe various tornado patterns, and the clustering analysis on the spatial-temporal and intensity patterns of the tornadoes are also conducted.

4 - On Regime Changes in Text Data Using Hidden Markov Model of Contaminated Vmf Distribution

Yingying Zhang, Western Michigan University, Portage, MI, United States, Shuchismita Sarkar, Yuanyuan Chen, Xuwen Zhu

This paper presents a novel methodology for analyzing temporal directional data with scatter and heavy tails. A hidden Markov model with contaminated von Mises-Fisher emission distribution is developed. The model is implemented using forward and backward selection approach that provides additional flexibility for contaminated as well as non-contaminated data. The utility of the method for finding homogeneous time blocks (regimes) is demonstrated two real-life text data sets containing presidential addresses and corporate financial statements respectively.

How OR Helps the United Nations Deliver Food and Hope

Plenary/Keynote Session

Plenary

Chair: Stefan Karisch, Amazon

1 - How OR Helps the United Nations Deliver Food and Hope

Koen Peters, World Food Programme, Utrecht, Netherlands

After years of steady decline, global hunger is on the rise again. Over 309 million people are on the brink of starvation as conflicts escalate worldwide. This alarming increase in food insecurity is driven by the many concurrent challenges the world is facing: the slow post-COVID recovery of global markets, a rise in natural disasters, and deepening conflicts. The United Nations World Food Programme (WFP) has responded by placing Operations Research (OR) at the core of its emergency response, transforming humanitarian work. How can analytics be harnessed to combat the rising tide of global hunger? What does it take to apply these sophisticated tools in WFP’s complex operational environment? Through OR, the WFP has not only streamlined food distribution, cutting delivery times significantly, but also provided a beacon of hope. As we confront these challenges, the continued innovation in OR is not just promising—it is a critical step towards a world without hunger.

1 - Design Multidimensional All-Pay Procurement Auction with Loss-Averse Bidders

Shan Li, City University of New York, New York, NY, United States, Xianghua Wu, Kay-Yut Chen

Procurement auctions involving multidimensional bids, typically consisting of a proposal and a price, are common in various industries. One notable aspect of these auctions is the all-pay component, where bidders must invest time and effort upfront to prepare a proposal, regardless of whether they win the contract. If a bidder loses the auction, the cost of developing the proposal is unrecoverable. Given that individuals tend to be loss averse, meaning they are more sensitive to losses than to gains of the same magnitude, loss aversion is particularly relevant in this setting, especially regarding the all-pay component. We analyze the impact of bidder loss aversion using game theoretical analysis and find that in the unique symmetric equilibrium of this setting, loss aversion consistently reduces equilibrium bid quality. Additionally, the effect on the buyer's equilibrium expected utility depends on the degree of loss aversion and how the buyer values the bidder's proposal. To mitigate the potential negative impact of loss aversion, we investigate two quality compensation policies commonly used in practice and studied in the literature: the proportional and the flat compensation policy. We show that both policies can improve social welfare without harming either side. Furthermore, we find that the flat compensation policy is preferable when the bidder population exhibits low levels of loss aversion.

2 - When the Personal is Professional: the Racialization of DEI Leadership

Rebecca Ponce de Leon, Columbia University, New York, NY, United States, James Carter

Spurred in large part by mega-events that laid bare the persistence of societal inequality, organizations have increasingly sought to demonstrate their commitment to diversity, equity, and inclusion (DEI) in recent years. As part of these efforts, many companies have created new leadership positions, like Chief Diversity Officer, to manage the ever-shifting diversity landscape. Despite this increase in interest, very little is known about the candidate attributes relied upon to select DEI leaders. The work current theorizes that these role are viewed as personal, identity-based roles, resulting in the reliance on personal attributes—like one's identity and background—over professional attributes—like one's work experience—to inform perceptions about candidates' fit and hireability. Further, decision makers use candidate race as a proxy to infer personal fit, resulting in general preferences for candidates of color over White candidates. We demonstrate these effects across six experiments, including studies exploring cognitions about the attributes necessary for success, selection decisions, and leader evaluations for DEI versus non-DEI leadership roles. We conclude by discussing critical implications for both theory and organizations.

3 - The Effect of Social Class Signals on Entry-Level Labor Market

Lai Wei, Boston College, Chestnut Hill, MA, United States, Teng Ye

Candidate evaluation in hiring and recruiting has drawn attention in the literature, specifically due to the prevalent biases within these processes. In this study, we focus on a different channel that could lead to evaluation bias in job interviews: social class. Understanding social class biases in the labor market is especially important since such biases may perpetuate societal inequalities by limiting access to well-paid jobs for people from lower social classes and hindering their upward social mobility.

4 - Hierarchy in Design Reviews: How Power and Status Influence Design Decisions

Yakira Mirabito, University of California, Berkeley, Berkeley, CA, United States, Kosa Goucher-Lambert

Engineers are systematic problem solvers whose decisions are not immune to the influence of biases and organizational dynamics. Authority bias is the tendency to overvalue opinions from the top of the hierarchy and undervalue those from the bottom. Hierarchy—defined here as power and status—has been observed in design education through instructor presence and feedback. Power refers to an individual's capacity to modify others' states via resources, while status denotes the respect others afford an individual. This study investigates the subtle dynamics of hierarchy within the context of a design review, an integral part of the engineering design course. Data from five industry design reviews across three engineering firms serve as the primary source, supplemented by semi-structured interviews and demographic surveys. Thematic analysis was employed to analyze the transcripts from meetings and interviews, explaining how verbal interactions in design reviews convey hierarchy. The act4teams coding schema was used to help map power and status to previously defined interactions. Meeting roles and feedback are two mechanisms through which power and status were wielded and influenced design decisions. Presenting designers, facilitators, and attendees have the potential to drive design decisions through the content under review and the feedback provided. The most influential feedback in guiding design decisions was linked to high-power or high-status individuals. This research deepens our understanding of how hierarchy impacts engineering design processes and proposes organizational changes to enhance equity and inclusion in design decisions.

Invited Session

Quality, Statistics and Reliability

Chair: Chao Wang, University of Iowa, Iowa City, IA, 52242, United States

1 - Transfer Learning of Stochastic Kriging for Individualized Prediction

Jinwei Yao, University of Iowa, Iowa City, IA, United States, Chao Wang, Jianguo Wu, Yongxiang Li

Stochastic Kriging (SK) is a generalized variant of Gaussian process regression, and it is developed for dealing with non-i.i.d. noise in functional responses. Although SK has achieved substantial success in various engineering applications, its intrinsic modeling strategy by focusing on the sample mean limits its flexibility and capability of predicting individual functional samples. Moreover, the performance of SK can be impaired under scarce data scenarios, which are commonly encountered in engineering applications, especially for start-up or just deployed systems. In this paper, we propose a novel transfer learning framework to address the challenges of individualization and data scarcity in traditional SK. The proposed framework features a within-process model to facilitate individualized prediction and a between-process model to leverage information from related processes for resolving the issue of data scarcity. The within- and between-process models are integrated through a tailored convolution process, which quantifies interactions within and between processes using a specially designed covariance matrix and corresponding kernel parameters. Statistical properties are investigated on the parameter estimation of the proposed framework, which provide theoretical guarantees for the performance of transfer learning. The proposed method is compared with benchmark methods through various numerical and real case studies, and the results demonstrate the superiority of the proposed method in dealing with individualized prediction of functional responses, especially when limited data are available in the process of interest.

2 - Federated Multiple Tensor-on-Tensor Regression (Fedmtot) for Multimodal Data Under Data-Sharing Constraints

Zihan Zhang, ISyE Georgia Tech, Atlanta, GA, United States, Shancong Mou, Mostafa Reisi, Massimo Pacella, Jianjun Shi

In recent years, diversified measurements reflect the system dynamics from a more comprehensive perspective in system modeling and analysis, such as scalars, waveform signals, images, and structured point clouds. To handle such multimodal structured high-dimensional (SHD) data, combining a large amount of data from multiple sites is necessary (i) to reduce the inherent population bias from a single site and (ii) to increase the model accuracy. However, impeded by data management policies and storage costs, data could not be easily shared or directly exchanged among different sites. Instead of simplifying or facilitating the data query process, we propose a federated multiple tensor-on-tensor regression (FedMTOT) framework to train the individual system model locally using (i) its own data and (ii) data features (not data itself) from other sites. Specifically, federated computation is executed based on alternating direction method of multipliers (ADMM) to satisfy data-sharing requirements, while the individual model at each site can still benefit from feature knowledge from other sites to improve its own model accuracy. Finally, two simulations and two case studies validate the superiority of the proposed FedMTOT framework.

3 - Fourier Neural Operators for Fast Simulations in Additive Manufacturing

Raghav Gnanasambandam, Virginia Tech, Blacksburg, VA, United States, Zhenyu Kong

Metal additive manufacturing (AM) is a fast-growing technique that solves some unique problems in manufacturing. One of the ubiquitous issues with AM users is the unknown optimal process parameters that can provide high-quality parts. Physics-based simulations, repeated over several process parameter settings, are typically used for finding these optimal parameters. This work proposes to use the Fourier Neural Operator (FNO)-based predictions to optimize the process parameters in metal AM. Compared to standard deep-learning methods, FNO trains with limited physics-based simulations by learning the entire class of Partial Differential Equations (PDEs). Once trained, FNO instantaneously predicts the high-dimensional spatial-temporal output of physics-based simulations, typically the thermal distributions, with the process parameters as input. The accuracy of FNO is significantly better than that of existing methods for predicting simulation outputs. The higher accuracy is due to the lack of a principled way to handle physics-based functional data in standard deep-learning techniques. The case studies show that the proposed method can significantly reduce the simulation costs for optimizing the process parameters.

4 - Privacy-Aware System Failure Prediction Through Joint Longitudinal-Survival Modeling

Yuxin Wen, Chapman University, Orange, CA, United States, Miles Milosevich, Junde Chen

As manufacturing becomes increasingly data-driven, data privacy will become increasingly important for protecting sensitive data and ensuring the security and privacy of manufacturing operations. In this paper, we propose a novel data-driven joint longitudinal-survival modeling framework, which combines statistical survival models and federated learning methodologies to jointly model and extract degradation features, to predict the potential failure just-in-time while keeping the signals private.

5 - On Model Compression for Neural Networks: Framework, Algorithm, and Convergence Guarantee

Chenyang Li, New Jersey Institute of Technology, Newark, NJ, United States, Bo Shen

Model compression is a crucial part of deploying neural networks (NNs), especially when the memory and storage of computing devices are limited in many applications. This paper focuses on two model compression techniques: low-rank approximation and weight pruning in neural networks. However, training NNs with low-rank approximation and weight pruning always suffers significant accuracy loss and convergence issues. In this paper, a holistic framework is proposed for model compression from a novel perspective of nonconvex optimization by designing an appropriate objective function. Then, we introduce NN-BCD, a block coordinate descent (BCD) algorithm to solve the nonconvex optimization. One advantage of our algorithm is that an efficient iteration scheme can be derived with closed-form, which is gradient-free. Therefore, our algorithm will not suffer from vanishing/exploding gradient problems. Furthermore, with the Kurdyka-Łojasiewicz (KŁ) property of our objective function, we show that our algorithm globally converges to a critical point at the rate of $O(1/k)$, where k denotes the number of iterations. Lastly, extensive experiments with tensor train decomposition and weight pruning demonstrate the efficiency and superior performance of the proposed framework.

1 - Nondestructive Fatigue Life Prediction for Additively Manufactured Parts through a Multimodal Transfer Learning Framework

Jia Liu, Auburn University, Auburn, AL, United States, Shehzaib Irfan

Understanding the fatigue behavior and accurately predicting the fatigue life of laser powder bed fusion (L-PBF) parts remain a pressing challenge due to complex failure mechanisms, time-consuming tests, and limited fatigue data. This study proposes a physics-informed data-driven framework, namely, a multimodal transfer learning (MMTL) framework, to understand process-defect-fatigue relationships in L-PBF by integrating various modalities of fatigue performance, including process parameters, XCT-inspected defects, and fatigue test conditions. It aims to leverage a pre-trained model with abundant process and defect data in the source task to predict fatigue life nondestructively with limited fatigue test data in the target task. MMTL employs a hierarchical graph convolutional network (HGCN) to classify defects in the source task. The synergies learned from HGCN are then transferred
to fatigue life modeling in neural network layers. MMTL validation through numerical simulations and real-case studies demonstrates its effectiveness in fatigue life prediction of L-PBF parts.

2 - Block No-U-Turn Samplers for Spatially Correlated Accelerated Failure Time Models

Jie Min, Virginia Tech, Blacksburg, VA, United States, Yili Hong

The spatially correlated accelerated failure time (SC-AFT) model has received increasing attention over the years, due to its ability of utilizing important spatial information provided in time-to-event data. Moreover, Markov Chain Monte Carlo (MCMC) is considered a convenient method for the estimation and inference of SC-AFT models. Among various MCMC samplers, the No-U-Turn Sampler (NUTS) is widely used in practice because of its advantage in generating samples with high effective sample sizes. However, the computing time of NUTS can be long for sampling from SC-AFT models, partially because of the large number of parameters in the model. To solve the problem, we propose Block No-U-Turn Samplers (BNUTS) that are able to generate samples with reasonable auto-correlations within an acceptable amount of time for SC-AFT models. Two blocking schemes are proposed based on the SC-AFT model structure and the derivative computing method used in the sampler. Advantages of BNUTS over NUTS in sampling from SC-AFT models are demonstrated using extensive simulation examples. Important factors that affect the computing time and effective sample sizes of BNUTS and NUTS are further investigated. The proposed BNUTS is applied to analyze a GPU failure time data from the Titan supercomputer, showing the capability of BNUTS in solving real-world research problems.

3 - Detecting Changes in High Dimensional Model Relationship Profiles

Alina Gorbunova, Georgia Institute of Technology, East Brunswick, NJ, United States, Jianjun Shi, Kamran Paynabar

Advancements in sensor and data collecting technology have resulted in data sets that are both high dimensional and heterogeneous, with forms such as scalars, waveform signals, images, videos, and 3D point clouds. These advancements have created the need to construct and monitor statistical models that are able to model the relationship between heterogeneous and high dimensional inputs and a high dimensional output. This project (1) discusses how to model the relationship between such inputs and output using Multiple Tensor-on-Tensor Regression (MTOT) and (2) presents different approaches for how to monitor this model relationship to detect potential changes over time. Monitoring the model relationship can be done either by monitoring the core tensor of the MTOT model and/or by monitoring the residuals of new data samples. This methodology is validated through several case studies including monitoring overlay error from semiconductor wafer shape data and.

4 - Modeling Acute Opioid Event Recurrence with a Covariate-Adjusted Triggering Point Process

Fenglian Pan, University of Arizona, Tucson, AZ, United States, You Zhou, You Zhou, Carolina Vivas-Valencia, Nan Kong, Carol Ott, Mohammad S. Jalali, Jian Liu

Substance use disorder, particularly opioid-related, is a serious public health challenge in the U.S. Accurately predicting events related to opioid use disorder (e.g., overdose, intoxication) and stratifying the risk of having an event are critical to effective prevention and treatment for people with opioid use disorder. Despite a large body of literature investigating various risk factors for the prediction, the existing research to date has not explicitly investigated and quantitatively modeled how an individual's past events related to opioid use disorder affect future occurrences. In this paper, we propose a covariate-adjusted triggering point process to model the occurrence of recurrent acute opioid events that includes opioid use disorder diagnosis with withdrawal, intoxication, and poisoning, wherein an occurred acute opioid event is considered to trigger subsequent acute opioid events. Further, the proposed method is capable of incorporating the influence of identified demographic factors (e.g., age, sex, and race) in acute opioid event prediction. The prediction performance is assessed by a real-world case study. Compared with commonly used prediction models, the proposed method yields the lowest prediction error on 15-, 30-, 60-, and 90-day ahead predictions. In addition, our method can explicitly quantify the expected number of acute opioid events that are due to event triggering. Our results show the statistical significance of considering the triggering mechanism for recurrent acute opioid events prediction.

Chair: Albert Berahas, University of Michigan, Ann Arbor, MI, United States

1 - Disclosing Low Product Availability: An Online Retailer's Strategy for Mitigating Stockout Risk

Dmitry Mitrofanov, Boston College, Chestnut Hill, MA, United States

Ensuring product availability and the successful fulfillment of orders are key priorities for any company operating in the retail industry. In this paper, we investigate how sharing information regarding the low availability of certain items can influence customers' purchase decisions, both preventing stockouts and mitigating the negative effects of stockouts with respect to customer long-term behavior. It is hard to predict the net impact of sharing item availability information on business metrics ex-ante because there are multiple effects that might act in opposite directions. The information-sharing policy could lead customers to not purchase items that are low in availability because those customers are averse to stockouts. Contrariwise, this approach might increase the popularity of low-availability items because consumers' cognitive bias leads them to place a higher value on items that are scarce. In a field experiment, we exogenously share low item availability information with a random subset taken for a sample of more than 840K customers using Instacart. We find evidence that customers are 25% less likely to purchase low-availability items when item availability information is disclosed. In addition, we show that low product availability disclosure positively affects the platform's fundamentals in the context of our field experiment both in the short and long run. More specifically, our results indicate that this innovative and cost-free approach leads to a 5.33% increase in revenue per customer and a 4.9% increase in order frequency over the long term.

2 - Strategic Network Inspection with Location-Specific Detection Capabilities

Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA, United States, Bastián Bahamondes

We consider a two-person network inspection game, in which a defender positions a limited number of detectors to detect multiple attacks caused by an attacker. We assume that detection is imperfect, and each detector location is associated with a probability of detecting attacks within its set of monitored network components. The objective of the defender (resp. attacker) is to minimize (resp. maximize) the expected number of undetected attacks. To compute Nash Equilibria (NE) for this large-scale zero-sum game, we formulate a linear program with a small number of constraints, which we solve via column generation. We provide an exact mixed-integer program for the pricing problem, which entails computing a defender's pure best response, and leverage its supermodular structure to derive two efficient approaches to obtain approximate NE with theoretical guarantees: A column generation and a multiplicative weights update (MWU) algorithm with approximate best responses. To address the computational challenges posed by combinatorial attacker strategies, each iteration of our MWU algorithm requires computing a projection under the unnormalized relative entropy. We provide a closed-form solution and a linear-time algorithm for the projection problem. Our computational results in real-world gas distribution networks illustrate the performance and scalability of our solution approaches.

3 - Learning to Defer in Content Moderation: The Human-AI Interplay

Thodoris Lykouris, Massachusetts Institute of Technology, Cambridge, MA, United States

Ensuring successful content moderation is vital for a healthy online social platform where it is necessary to responsively remove harmful posts without jeopardizing non-harmful content. Due to the high-volume nature of online posts, human-only moderation is operationally challenging, and platforms often employ a human-AI collaboration approach. A typical machine-learning heuristic estimates the expected harmfulness of incoming posts and uses fixed thresholds to decide whether to remove the post (classification decision) and whether to send it for human review (admission decision). This can be inefficient as it disregards the uncertainty in the machine-learning estimation, the time-varying element of human review capacity and post arrivals, and the selective sampling in the dataset (humans only review posts filtered by the admission algorithm).

We introduce a model to capture the human-AI interplay in content moderation. The algorithm observes contextual information for incoming posts, makes classification and admission decisions, and schedules posts for human review. Non-admitted posts do not receive reviews (selective sampling) and admitted posts receive human reviews on their harmfulness. These reviews help educate the machine-learning algorithms but are delayed due to congestion in the human review system.
We propose a near-optimal learning algorithm that carefully balances the classification loss from a selectively sampled dataset, the idiosyncratic loss of non-reviewed posts, and the delay loss of having congestion in the human review system. To the best of our knowledge, this is the first result for online learning in contextual queueing systems and hence our analytical framework may be of independent interest.

Facility/Hub Location

Invited Session

Location Analysis

Chair: Gita Taherkhani, Loyola University Chicago, Chicago, IL, United States

1 - Time-Dependent Decisions in Hub Location and Routing

Francisco Saldanha-da-Gama, Sheffield University Management School, Sheffield, United Kingdom, Afaf Alloulal, Raca Todosijevic

This paper investigates the relevance of time-dependent decisions in hub-location routing problems. A multi-period planning horizon is considered during which the system is to be phased in. In addition to hub location, hub network decisions are also considered. The origin-destination flows are assumed to be time-dependent as well as the costs underlying the problem which include, setup costs for hubs and hub edges and variable operational costs at the hubs. An optimization model is discussed for the problem. For small instances, it can be solved up to proven optimality using a general-purpose solver. For larger instances, a four-phase matheuristic combining principles of relax-and-fix, variable neighborhood descent and local branching schemes is proposed. Two variants of the algorithm are discussed. The model and proposed procedure are tested using data generated by extending existing hub location instances to our problem. The results are analyzed. The major conclusion to draw is that by capturing time in the decision-making process, one may find solutions that better hedge against parameter changes throughout time. Furthermore, the overall procedure presented in this paper is quite general in the sense that it can be easily adapted to other multi-period decision making problems and different objective functions.

2 - Hub Network Design for Platooning

Elif Zeynep Serper, TED University, Ankara, Turkey, Sibel Alumur Alev

In transportation, platooning is a method where multiple vehicles, typically trucks, travel closely together in a convoy led by one vehicle with others following at close distances. This formation is maintained by advanced automated driving systems. Platooning is primarily utilized to enhance both fuel and driver efficiency. Through closely trailing the lead vehicle, subsequent vehicles experience reduced aerodynamic drag, resulting in decreased fuel consumption. Furthermore, as trucks form platoons, driver costs are significantly reduced since drivers can rest in the truck, enabling continuous travel without mandated breaks. The advantages of platooning include cost reduction due to fuel savings and increased driver efficiency, reduced carbon emissions contributing to environmental sustainability, increased safety, driver comfort, and improved traffic flow by reducing the space between vehicles. In platooning applications, hubs serve as roadside locations where trucks can gather, wait, and form or deform platoons. In this study, we focus on the design of hub networks for truck platooning applications in truckload transportation. We develop a mixed-integer programming model to optimize the locations of hubs considering the trade-off between platooning and direct shipment in terms of both service time and cost. The model determines whether a truckload is to be shipped using platooning, the optimal locations of platoon formation, and deformation hubs while adhering to predetermined service time restrictions and platoon capacities. The model is tested on real-life data from U.S. trucking operations.

3 - Service Network Design and Hub Location

Gita Taherkhani, Loyola University, Chicago, IL, United States, Hao Li, Sibel Alumur Aleb, Mike Hewitt

To enhance cost-effectiveness, it is essential that shipments transported by carriers are consolidated within a hub network. Additionally, the movement of these shipments, executed by capacitated trucks, must account for spatial and temporal decisions typically considered in service network design. This paper introduces a profit-maximizing model that integrates hub location and service network design for less-than-truckload (LTL) carriers. The model strategically selects hub locations and makes tactical decisions regarding truck dispatch times, streamlining the process without needing to model every time point explicitly. A deterministic model and its Benders reformulation are presented, enhanced with acceleration techniques. The model is extended to handle variability in shipment volumes through a two-stage stochastic program. To solve this model, a Monte-Carlo simulation-based algorithm integrated with a sample average approximation scheme and a proposed Benders decomposition reformulation is developed. Computational results demonstrate that this formulation can solve instances involving up to 20 nodes over a three-day planning period. Its performance is compared with that of commercial solvers and other algorithms.

4 - Shipment Consolidation in Multi-Period Hub-Arc Location Problems with Stochastic Demand

Jim Bookbinder, University of Waterloo, Toronto, ON, Canada, Khaled Shah, Sibel Alumur Alev

We include inventory holding decisions in hub arc location problems with probabilistic origin-destination demands. A heterogeneous fleet, with varied capacities and costs are used on the hub arcs. Vehicles may be used with different ‘frequencies’, meaning the number of vehicles to be operated on a given arc may vary during different days (periods) of the time horizon. We formulate a mixed-integer model that minimizes the total costs of hub arc establishment, transportation plus inventory holdover, given the demands and a choice of frequencies for the hub arcs. We adopt the sample average approximation approach to deal with demand randomness. The performance of our model and algorithm are evaluated by numerical experiments.

1 - Advancing Carbon Mitigation via U.S. Municipal Green Bond Issuance: Insights from Causal Machine Learning

Dan Li, university of michigan, Ann Arbor, MI, United States, Peter Adriaens

The green bond market provides a vital channel for directing financial resources toward climate-related initiatives that support the Sustainable Development Goals. This study aims to evaluate the influence of the US municipal green bond market on carbon emissions spanning from 2009 to 2019, taking into account the confounding effects of local socio-economic conditions. By employing causal machine learning models, we discerned the effects of increased green bond issuance volume on emission reduction at the county level. Our findings reveal notable heterogeneity across regions, with a maximum impact on emissions reduction two years post-bond issuance. Within the subgroups analyzed in our study, counties characterized by long commute times appear to benefit most significantly. Hence, urbanization and city expansion may result in a notably larger impact from green bond issuances to mitigate CO_2 emissions. Importantly, our findings highlight the effectiveness of certified green bonds, which undergo environmental outcome verification by assurance companies, in catalyzing efforts to reduce emissions. While this verification process undoubtedly incurs costs for the external review, it also enhances the credibility of their environmental commitment. These novel insights can inform the benefit of green bond issuance and strategic allocation of resources for emissions mitigation to regions that most likely to derive benefits from targeted environmental measures and urban planning initiatives.

2 - Evolution of gender pay gap in the 21st century

Jeena Ahuja, Alcuin School, Dallas, TX, United States

The gender wage gap has been studied for years, but it remains an area of active and innovative research. This research strives to better understand the worldwide historical trends in gender wage gap \over the course of two decades -- from 2000 to 2020. In particular, we compare and contrast ten different regions -- Oceania, two in Americas (North, South), four regions in Europe (Eastern, Western, Northern, Southern), Asia, and Middle East. We also benchmark against the average of Organization for Economic Co-operation and Development (OECD) countries. We use the publicly available OECD dataset to conduct our analysis. We use multiple regression models created in *RStudio* and F-tests to conduct our analysis. We find that the gender wage gap follows a quadratic trend in each region. Importantly, the gender wage gap decreased over the course of two decades in all but Oceania, Northern Europe, and South America. Additionally, we showed (using t-tests) how significant the changes in the gender wage gap are between two consecutive years. Specifically, we find that the most significant changes in the evolution of the gender wage gap occurred in the second decade, specifically in the years 2010-2011, 2014-2015, and 2018-2019. In summary, we analyze the evolution of gender wage gap in the first two decades of the 21st century and the associated regional and temporal variation. Our findings highlight the areas that need more attention from policymakers.

3 - Analysis of Corporate Environmental, Social, and Governance Performance

Xinyi Lai, Westwood High School, Austin, TX, United States

Environmental and social responsibilities play pivotal roles in fostering the growth and advancement of our society. With increasing awareness of the pressing need for sustainable practices, there is a widespread belief that companies emphasizing environmental, social, and governance (ESG) factors can not only enhance their reputations but also attract and retain top-tier talent, contributing to a more sustainable and equitable world. However, despite the recognized importance of ESG initiatives, the extent to which companies are effectively addressing these responsibilities remains uncertain. To shed light on this issue, this study collects reported ESG scores from publicly traded companies and evaluates their overall performance in fulfilling their ESG obligations. Additionally, this study explores factors that may influence companies' ESG scores and examines the connections between companies' ESG performance and their financial outcomes.

4 - The Importance of Investment in Electric Cars

Andrew Zheng, Boston Latin School, Boston, MA, United States

It is no secret that vehicle exhaust is extremely harmful for us and the environment. Electric cars can help mitigate this problem as they have low to no tailpipe emissions whatsoever. Pollutants from vehicle exhaust cause at least 100,000 premature deaths per year in the United States alone. Fortunately, the world is aware of this and many countries are rushing to transition into EVs. For example, in Norway, over 80% of new car sales are EVs. Other European countries are catching up, and if the car market follows current predictions, by 2030 Europe could save emissions equivalent to planting one billion trees. If all of the cars on the road become electric, global emissions could be cut by 20%. National policies and incentives can help push EV sales in other parts of the globe. These policies and incentives include subsidies in the form of tax credits to consumers, as this now helps alleviate the higher upfront costs of purchasing EVs. Currently, the U.S. government offers tax credits ranging from $2,500 to $7,500. These tax credits are responsible for about 30 percent of carbon dioxide emissions reductions from the current amount of EVs in the U.S. Mandates could also decarbonize the car industry, as seen in California's Zero Emission Vehicle(ZEV) Sales Requirement program, which forces automakers to gradually make all of their cars electric by 2035. These ideas would definitely reduce our emissions and help save our planet from the irreversible effects of climate change.

5 - The impact of built environment and private car accessibility on transit-oriented-development in urban sub-centres: A case study of Shanghai's sub-centre metro stations

Chenwei Jin, Shanghai Jiao Tong University, Shanghai, China, People's Republic of

A number of studies have suggested that TOD (transit-oriented development) in sub-centres with transit stations is an approach to increase foot traffic and the overall vitality of the area. However, the current development of sub-centres mostly follows the existing well-established TOD model in CAZs (central activity zones), which may not be applicable to sub-centre areas. Additionally, most TOD studies do not deliberately distinguish or emphasise the differences between CAZs and sub-centres. Therefore, this study aims to examine the influence of various factors in the built-up areas of Shanghai's urban sub-centres on the degree of TOD around the stations and to assess the level of development at existing transit stations. The four main factors considered are accessibility to private cars, land use, inner connectivity, and functionality. A regression model was introduced to identify and validate the factors that significantly influence the usage of transit stations, as reflected by the daily passenger flow at transit stations. The results show that almost all factors are associated with transit station usage, while land use diversity is not as significant as it is in urban centres.

Military and Security

Chair: Paul Goethals, Department of Defense, Columbia, MD, United States

1 - Automated Vessel Selection and Combat Load Planning

William Kirschenman, North Carolina State University, Raleigh, NC, United States

In large-scale combat operations, the U.S. military must move and maneuver its forces through intratheater and intertheater modes of transportation. Threat forces exacerbate these demanding requirements through efforts to hinder the flow of friendly forces. Contested landing zones, whether they be fixed ports or beaches, are the starting point for a landing force’s ground combat operations. It is imperative that the landing force expeditiously off-loads in the prescribed order of priority to support the planned scheme of maneuver upon off-loading. We first discuss current and historical methods of load planning while emphasizing the need for more detailed and automated methods driven by the expected nature of future conflicts against near-peer threats. We then present a model that optimizes vessel selection, sequencing, and combat load configurations of a large military force by considering multiple levels of priority and group unity, which enables efficient off-loading into desired tactical formations for follow-on objectives.

2 - Resupply during Dispersed Operations

Mette Wagenvoort, Erasmus University Rotterdam, Rotterdam, Netherlands, Paul Bouman, Martijn van Ee, Kerry Malone

During a military operation, units require supplies such as water, food and fuel. Therefore, during the operation, the units need to be resupplied to ensure they are never without supplies. In a dispersed operation, small units operate at geographically disperse locations, making the resupply task more challenging.

There are different ways in which units can be resupplied. Namely, a large quantity of different supplies can be brought to a location from which units can collect them. Alternatively, smaller quantities of a commodity can be brought to one of the units. However, this is riskier as the supplies have to be brought closer to the area of operations. There is thus a trade-off between offering more tailored services at a higher risk for the resupply operation, and more generic services that require a higher time investment from the units itself.

When the region in which units operate is far from the depot, an intermediate depot can be placed from which units can be resupplied. The intermediate depot will have to be resupplied from the main depot, as it is not desirable to have large quantities of stock in the intermediate depot. However, this might require more vehicles to execute the resupply operation.

It is therefore of interest to model the resupply operation using different types of resupply methods to analyse in which situation one would prefer each of these methods.

3 - Resilient Taksing and Basing Model - an optimization of millitary resources placement in theater

Oluwaseun Ogunmodede, The MITRE Corporation, McLean, VA, United States

The Resilient Tasking and Basing Model (RTBM) is an attacker-defender model that finds the optimal beddown of tactical aircraft in the face of base attacks by a near-peer threat. Optimality here is a saddle-point where Blue can still accomplish its mission while minimizing its casualties. We discuss the structure of the antagonists. Blue has a multi-layered facility location structure: where to base receiver aircraft in order to service missions, which interacts with where to base tankers in order to service aerial refueling points that are servicing the receiver aircraft. Similarly, Red has a fixed inventory of missiles that must choose given launch points from which to attack Blue bases to kill Blue AC, maximizing casualties. We show how to transform this Min - Max Defender-Attacker optimization model into a tractable minimization optimization monolith.

4 - Adversarial Unsupervised Learning in Connected Defense Systems

Tahir Ekin, Texas State University, San Marcos, TX, United States

Traditional unsupervised learning methods typically assume clean and legitimate data streams. However, the presence of changing data, patterns and adversarial influences may impact their performance in dynamic environments. The intersection of dynamic data driven applications systems and adversarial risk analysis presents an opportunity for comprehending and effectively managing dynamic conditions with security and reliability. This manuscript proposes a decision-theoretic framework for clustering based outlier detection within the realm of dynamic unsupervised learning, addressing the challenges posed by adversarial attacks, uncertainty, and incomplete information. We demonstrate the efficacy of our framework within a joint all-domain command and control systems framework.

Design and Analysis of Marketplaces

Invited Session

Auctions and Market Design

Chair: Chen Chen, New York University Shanghai, Shanghai, N/A, China, People's Republic of

1 - Budget Pacing in Repeated Auctions: Regret and Efficiency Without Convergence

Bar Light, Tel Aviv University, Tel Aviv, Israel, Brendan Lucier, Alex Slivkins

We study the aggregate welfare and individual regret guarantees of dynamic \emph{pacing algorithms} in the context of repeated auctions with budgets.
Such algorithms are commonly used as bidding agents in Internet advertising platforms.
We show that when agents simultaneously apply a natural form of gradient-based pacing, the liquid welfare obtained over the course of the learning dynamics is at least half the optimal expected liquid welfare obtainable by any allocation rule.
Crucially, this result holds \emph{without requiring convergence of the dynamics}, allowing us to circumvent known complexity-theoretic obstacles of finding equilibria.
This result is also robust to the correlation structure between agent valuations and holds for any \emph{core auction}, a broad class of auctions that includes first-price, second-price, and generalized second-price auctions. For individual guarantees, we further show such pacing algorithms enjoy \emph{dynamic regret} bounds for individual value maximization, with respect to the sequence of budget-pacing bids, for any auction satisfying a monotone bang-for-buck property.

2 - Trading Flexibility for Adoption: Dynamic Versus Static Walking in Ridesharing

Sebastien Martin, Kellogg School of Management, Northwestern University, Evanston, IL, United States

On-demand ridesharing aims to fulfill riders' transportation needs whenever and wherever they want. Although this service level appeals to riders, overall system efficiency can improve substantially if riders are willing to be flexible. Here, we explore riders' flexibility in space via walking to more accessible pickup locations.
Ridesharing platforms have traditionally implemented *dynamic walking* to optimize rider pickup locations and rider-driver assignment jointly. We propose an alternative that we call *static walking*, which presents a predetermined pickup location to the rider before optimizing rider-driver assignment. Although dynamic walking enables more efficient matching of riders and drivers, we hypothesize that riders prefer static walking because of the certainty of the pickup location before booking the ride. Using simulations on Lyft data, we show that static walking can capture up to 96% of the value of dynamic walking in congested urban networks at a fixed adoption rate. Furthermore, experimentation on Lyft's user interface suggests that providing riders with information on pickup location before an opt-in decision can increase walking adoption --- to the extent that static walking may outperform dynamic walking overall. More broadly, this study highlights the importance of carefully designing flexibility mechanisms on platforms: a little flexibility goes a long way, especially when flexibility presents a barrier to adoption.

3 - Incentivizing Resource Pooling

Chen Chen, New York University Shanghai, Shanghai, China, People's Republic of, Yilun Chen, Pengyu Qian

Resource pooling improves system efficiency drastically in large stochastic systems, but its effective implementation in decentralized systems remains relatively underexplored. This paper studies how to incentivize resource pooling when agents are self-interested, and their states are private information. Our primary motivation is applications in the design of decentralized computing markets, among others. We study a standard multi-server queueing model in which each server is associated with an M/M/1 queue and aims to minimize its time-average job holding and processing costs. We design a simple token-based mechanism where servers can earn tokens by offering help and spend tokens to request help from other servers, all in their self-interest. The mechanism induces a complex game among servers. We employ the fluid mean-field equilibrium (FMFE) concept to analyze the system, combining mean-field approximation with fluid relaxation. This framework enables us to derive a closed-form characterization of servers' FMFE strategies. We show that these FMFE strategies approximate well the servers' rational behavior. We leverage this framework to optimize the design of the mechanism and present our main results: As the number of servers increases, the proposed mechanism incentivizes \emph{complete} resource pooling---that is, the system dynamics and performance under our mechanism match those under centralized control. We also extend our mechanism to settings with heterogeneous servers and show that our mechanism obtains near-optimal performance.

4 - The Welfare Effects of Selling Leads in a Two-Sided Marketplace

Peng Shi, USC Marshall School of Business, Los Angeles, CA, United States

Digital platforms that help customers find suitable service providers often monetize by selling customer leads to interested service providers. Examples of such platforms include Bark, Google Local Services, HomeAdvisor, Modernize, Porch, and Thumbtack. I analyze this platform design using a game-theoretic model and obtain insights on how the pricing of leads affects customer and provider welfare. When the platform raises the fee per lead, providers who buy these leads quote more competitive prices to customers to improve their chances of converting these leads. This benefits the customers whose leads are bought, but more customers may be unmatched because no one buys their lead. For providers, raising the fee per lead allows them to more easily target this customer segment, but those who successfully target receive a lower surplus. For maximizing social welfare, the simple policy of charging a market-clearing fee-per-lead for every customer segment guarantees at least 1/(e-1)≈58.19% of the first-best welfare, and at least 79.15% of the welfare under the optimal fees. Higher welfare can be achieved by paying providers an additional subsidy upon each service, so that experienced providers with cheaper sources of leads do not exit the platform. Understanding the nuances of these welfare effects can help platforms better grow both sides of the marketplace while maintaining an adequate revenue stream.

1 - Two-Sided Feature-Based Choice Modeling via Optimal Transport

Yijie Zheng, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Ming Hu

Conventional choice models typically concentrate on choice decisions from one side, such as consumers' product choices, which makes it hard to handle scenarios where both sides simultaneously make choices. Moreover, these one-sided models generally use feature information solely from the chosen side, failing to accommodate the diversity of both sides involved. Inspired by optimal transport theory, this paper introduces a two-sided feature-based choice modeling approach to tackle the two challenges. Within the two-sided choice model, the interactions between consumers and products are conceptualized as a mutual choice process, akin to a matching mechanism. Consumer attributes are projected onto the product feature space through a random preference matrix, facilitating the matching of consumers with their nearest products. By allowing an arbitrary random preference matrix, our model demonstrates extensive generality, encompassing commonly used choice models. In the context of multi-product pricing, we demonstrate under mild conditions that optimal prices maintain a constant markup over their unit costs and that the profit function exhibits concavity with respect to market shares, enabling efficient price optimization across various scenarios. For assortment planning, we develop an efficient solution method using the shortest path approach, which solves problems in polynomial time. Additionally, we use a nonparametric estimation method based on the conditional gradient descent algorithm to learn the random preference matrix and demonstrate its effectiveness both theoretically and empirically.

2 - Platform Design for the First Mile of Commodity Supply Chains

Sergio Camelo, Stanford University, Stanford, CA, United States, Dan Iancu, Joann de Zegher

We propose a data-driven platform that provides traceability to the first mile of agricultural supply chains by coordinating the transactions of farmers and intermediaries. We model unique aspects of the supply chain, including pre-existing informal relationships between farmers and intermediaries, and we develop algorithms to solve real-world instances. We test the results on data from the palm oil supply chain and show the platform's potential to reduce costs and increase farmers' welfare.

3 - Hicksian Unit-Demand Pricing

Michael Hamilton, University of Pittsburgh, Pittsburgh, PA, United States, Jourdain Lamperski, Kasra Tari

We study single price approximations for the Hicksian unit-demand pricing problem. In the well-studied Bayesian unit-demand pricing problem, two celebrated lines of work show that (i) when valuations are IID, an optimally chosen single price is a two-approximation of the optimal pricing, and (ii) when valuations are independent but not identical and satisfy an MHR condition, a single price is a $\approx$ 2.62 approximation of the optimal pricing. We study the equivalent problem when customers choose items in a Hicksian (sometimes referred to as min-buying) fashion, purchasing the minimum priced item that guarantees a certain level of utility. We find that under Hicksian demand and IID valuations, a single price is always optimal, implying that the paradoxical advantage of non-symmetric prices vanishes in more conservative demand models. We also give improved single price approximations in the case of independent but non-identical valuations, and new results for the case of identical but dependent exchangeable valuations.

4 - Optimal world design in video games

Lifei Sheng, University of Houston Clear Lake, Houston, TX, United States, Yifu Li, Christopher Ryan

Spending time in virtual spaces is a growing part of human experience. We study the design of virtual spaces in a video game context, with an emphasis on understanding how people spend more or less time enjoying these spaces. We model virtual world design as a graph design problem. We show that, in certain cases of virtual world design, the optimal world maps have a ``side-quest'' tree structure that is amendable to an efficient inductive construction using a polynomial-time algorithm. We also show numerically that side-quest trees are ``near'' optimal for more general cases.

5 - Tracking Truth with Liquid Democracy

Daniel Halpern, Harvard University, Cambridge, MA, United States

The dynamics of random transitive delegations on a graph are of particular interest when viewed through the lens of an emerging voting paradigm, *liquid democracy*. This paradigm allows voters to choose between directly voting and transitively delegating their votes to other voters, so that those selected cast a vote weighted by the number of delegations they received. In the epistemic setting, where voters decide on a binary issue for which there is a ground truth, previous work showed that a few voters may amass such a large amount of influence that liquid democracy is less likely to identify the ground truth than direct voting. We quantify the amount of permissible concentration of power and examine more realistic delegation models, showing they behave well by ensuring that (with high probability) there is a permissible limit on the maximum number of delegations received. Our theoretical results demonstrate that the delegation process is similar to well-known processes on random graphs that are sufficiently bounded for our purposes. Along the way, we prove new bounds on the size of the largest component in an infinite P\'olya urn process, which may be of independent interest. In addition, we empirically validate the theoretical results, running six experiments (for a total of $N=168$ participants, 62 delegation graphs and over $11k$ votes collected). We find that empirical delegation behaviors meet the conditions for our positive theoretical guarantees. Overall, our work alleviates concerns raised about liquid democracy and bolsters the case for the applicability of this emerging paradigm.

New Applications of Network Optimization

Invited Session

Telecommunications and Network Analytics

Chair: Rui Zhang, University of Colorado Boulder, Boulder, CO, 80309, United States

Co-Chair: Yunlong Wang, Shanghai Jiao Tong University. University of Colorado Boulder (Visiting), 2300 Arapahoe, Apt 2B 208 Netwon Court , Shanghai, 200030

1 - New Formulations and Valid Inequalities for the Least Cost Influence Problem on Social Networks

Yunlong Wang, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, TaoTao He, S. Raghavan, Ying Rong, Rui Zhang

This work studies the least cost influence problem where the decision maker wants to promote a new product over a given social network, and the goal is to have every individual adopt this product with the least cost. In the given network, each individual receives influence from their neighbors who have adopted the products, and they also may influence others once they become adopted. A threshold is applied to the activation condition. We developed several IP formulations and designed valid inequalities to enhance them. Theoretical results are given, and comprehensive numerical experiments are implemented to certify the promise of the proposed methods. In addition, we conducted a thorough study regarding the optimal promotion strategy on different network structures and gave some managerial insights into this problem.

2 - Compact Mip Formulations for the Minimum Biclique Cover Problem

Hamidreza Validi, Texas Tech University, Lubbock, TX, United States, Bruno Burin, Bochuan Lyu, Illya Hicks

Given a simple graph G = (V, E) with vertex set V and edge set E, the minimum biclique cover problem seeks to cover all edges of the graph with a minimum number of bicliques (i.e., complete bipartite subgraphs). This is an NP-hard combinatorial optimization problem with applications in disjunctive programming, fixing decision variables in mixed integer programming (MIP), and combinatorial geometry. This talk proposes two compact MIP formulations for solving the minimum biclique cover problem on general graphs: (i) a natural formulation in the edge space and (ii) an extended formulation in the edge and vertex spaces. Despite the exponential-size MIP formulation of Cornaz and Fonlup (Discrete Mathematics, 2006), our natural formulation employs only a polysized number of their exponential "no-good" cuts, along with another set of polysize valid inequalities. Although our natural formulation has fewer decision variables, the proposed extended formulation performs better computationally. To accelerate the solving process of the extended formulation further, we propose (i) valid inequalities, (ii) fixing procedures, and (iii) a bounding procedure. Our computational experiments show the proposed framework's efficacy to improve the extended formulation's computational performance.

3 - Cactus Graph Formation Algorithms for Communication Networks with Decentralized Control

Alexander Nikolaev, University at Buffalo, Buffalo, NY, United States, Sangeeth Das, Robert Dell

A directed cactus graph, by definition, is such a graph where any directed edge is part of only one directed loop/cycle. On the theoretical front, this work contributes to the domain of network optimization by presenting computationally efficient heuristic solutions to the graph formation problem where the objective is to form a cactus graph with the minimum number of edges. The solutions obtained with our sub-optimal, low-computational-expense algorithms are shown to compare well to the optimal solutions on a number of cactus formation problem test instances. On the application front, we explain how the cactus graphs we are able to form can be used in communication network design applications, in particular to avoid double-counting in data fusion. Double-counting, or data incest, is a problem that arises in networks when members (sensors) of a decentralized network are tasked to make estimates based on shared signals. Our cactus graph formation-inspired decentralized algorithm is a self-organizing, low complexity approach that any placed sensors can adopt at the stage of establishing network-wide communication, thereby achieving connection structures enabling evidence exchange and aggregation with no double-counting.

4 - Lethal Cliques in Comorbidity Graphs

Parisa Vaghfi Mohebbi, Oklahoma State University, Stillwater, OK, United States, Yajun Lu, Zhuqi Miao, Baski Balasundaram, Pankush Kalgotra, Ramesh Sharda

Mortality rate refers to the overall likelihood of death within a specific population over a defined period. The knowledge of high mortality rate disease clusters can enable healthcare providers and patients to be proactive and develop tailored interventions that improve patient outcomes. In this talk, we discuss the problem of finding a small clique of comorbid diseases that corresponds to the highest mortality rate among a given patient population. We introduce two approaches to solve this problem: (i) an integer programming formulation that maximizes a single fractional objective subject to linear constraints, and (ii) an extension of the classical Bron-Kerbosch enumeration algorithm. We conduct a detailed computational study and report results from our experiments with both approaches on datasets derived from 10.6 million anonymous patient electronic health records.

5 - Routing and re-routing UAV's under Uncertain Disruptions

Jaime Yair Perez Tezoco, Oklahoma State University, Stillwater, OK, United States, Juan Borrero

We consider a UAV routing problem in which the visiting targets are subject to uncertain disruptions. The goal is to find a tour, limited in length, that maximizes the sum of collected information of selected locations. However, information cannot be collected if a target location is disrupted. Initially, the planner is unable to have information regarding the locations in which disruptions will occur, and this information is revealed once a disrupted target is visited. To address this problem, we propose a two-stage robust optimization model where the first-stage problem is to plan a tour under the uncertain environment, and the second stage problem is to optimize the re-routing recourse actions to be taken once the information regarding disrupted locations is revealed. We solve this problem by using a column-and-constraint generation algorithm and a decomposition branch-and-cut method. We present computational results considering both randomly generated networks and instances available in the literature for similar applications, which corroborates the effectiveness of the proposed model and the solution method.

1 - Advancing Decarbonization and Blockchain Integration in the Supply Chain: Strategic Decision-Making under Dual Carbon Regulatory Policies

chang liu, Harbin Engineering University, Harbin, China, People's Republic of

Excessive carbon emissions have led to an exacerbation of environmental issues. This study initially examines how supply chain members develop carbon reduction technology and select carbon reduction pathways under the dual carbon policies of carbon tax and cap-and-trade systems. Furthermore, it conducts a comparative analysis of the profits of supply chain members before and after the development of blockchain technology, quantifies the factors and investment thresholds that affect the maximization of corporate profits, and explores how to optimize the profits of supply chain members. Through the construction of game-theoretic models and numerical simulation analysis, it is found that the impact of carbon tax and cap-and-trade policy formulation on manufacturers' profits is related to the carbon emission values of the original product production and the selection of carbon reduction channels. The development of carbon reduction technology can significantly increase the profits of retailers. Under different market demands and carbon policies, manufacturers adopt different carbon reduction pathways. The choice of manufacturers' carbon reduction channels hinges on the balance between gains and cost investment. A comparison of investment costs and thresholds across different reduction modes guides the selection of the reduction mode. The introduction of blockchain technology has significantly improved the level of carbon reduction, and an optimal investment scheme for the blockchain platform has been identified. That is, when manufacturers and retailers jointly share the costs of blockchain technology within a threshold, a double Pareto improvement can be achieved.

2 - Optimizing Bulk logistics under uncertainty and compatibility constraints

Ashesh Kumar Sinha, West Virginia University, Morgantown, WV, United States

This study explores the optimization of routes for transporting bulk items like oil products, aerosols, and foodstuffs, which are typically loaded directly into tankers or trailers without conventional packaging. Unlike traditional logistics, Bulk logistics entails adhering to prior order restrictions, which are based on compatibility with recent orders (up to the last five), as well as potential requirements for specialized equipment or handling instructions, such as meticulously cleaned and prepared tanks. Furthermore, the research aims to incorporate two types of uncertainty into the model: (i) limited capacity at each wash location after delivery, and (ii) the degradation of order quality over time, resulting in diminished value upon delivery completion. By employing an integrated approach utilizing stochastic models and graph decomposition theories, we tackle the challenges associated with order compatibility and uncertainty. The first stage formulation draws upon graph decomposition theories to manage compatibility relations. We develop specialized graph decomposition-based theories that are proven to be optimal and derive tight lower bounds on the optimal solution to further enhance the decomposition-based approach. The second stage formulation analyzes uncertainty within the system and derives necessary optimality and feasibility constraints. Using numerical experiments, we study the impact of parameters such as number of trailers, wash locations, and various order compatibility scenarios on the optimal routing decisions.

3 - Fleet Scheduling for Distribution Planning of Refrigerated and Non-Refrigerated Loads

Ahmad Bassaleh, Wichita State University, Wichita, KS, United States, ekrem duman, Mehmet Yildirim

Logistical challenges pose a substantial financial burden for distributors worldwide, particularly in light of escalating oil prices and evolving customer demands. This paper addresses a Vehicle Routing Problem (VRP) encountered by a distributor in Turkey. The problem involves a multi-objective function that integrates road tariffs, specific customer constraints, refrigerated and non-refrigerated loads, and features observed in various VRP variants. Our study explores diverse solving approaches, including an exact method developed through a novel Mixed-Integer Linear Program, as well as non-exact solutions employing heuristic and metaheuristic algorithms. Notably, our findings highlight the efficacy of metaheuristic algorithms, especially within a smart two-phase solving strategy designed to tackle the problem's large scale: initially segmenting it into individual sub-problems and subsequently integrating and solving them comprehensively. The study concluded with a noteworthy 5.13% reduction in operational costs compared to the distributor's existing plan, indicating significant potential for enhanced profitability while optimizing the daily scheduling of the vehicle fleet.

4 - Biking the goods... but where?

Carla Tejada, University of Illinois in Chicago, Chicago, IL, United States

Biking in general, has seen an increase in several parts of the world. In addition, as more sustainable freight transportation modes are being developped, biking the goods has taken an interest from researchers and practitioners for the last portion of goods delivery. Additionally, several cities in the U.S. have seen an increase in the bike ridership that requires the development of biking infrastructure. However, the developped infrastructure has yet to be proved safe and it generally is not designed to accomodate for cargo-bikes.

This preliminary study has three specific goals. The first is to assess the perceived safety for cyclists in urban areas, with the already existing bycicle infrastructure. For this, an AI vide recognition model has been developped to recognize all the instances where cyclists pereived a nuissance. The second goal is to assess what is the existing connectivity of bike lanes. To accomplish this goal we have created a connectivity model that will help assess the existing infrastructure. To prove this model, data from the Chicago area was used. Finally, the last goal, is to create a qualitative assessment of whether or not the exisitng infrastructure is ready to accomodate cargo-bikes and what would be the requierements for this implementation in the future.

Initial results show the importance of identifying existing nuissane to improve the existing bike infrastructure, and has shown that a lot of work remains to be done to improve safety and capacity of bike infrastructure in cities.

5 - Bi-Objective Electric Vehicle Routing Problem with Queuing Systems at Charging Stations

Xin Zhang, Tongji University, Shanghai, China, People's Republic of, Jiantong Zhang

With the rise in battery capacities and the expansion of fast-charging infrastructure, electric vehicles (EVs) are increasingly suitable for long-distance travel. However, queues at charging stations may result in extended waiting times, underscoring the importance of efficient route planning. By integrating arrival rules, queuing rules, charging stations, and service times, a queuing system is established. This study aims to investigate the bi-objective Electric Vehicle Routing Problem (EVRP) while considering queuing systems at charging stations. A mixed-integer programming model is formulated to address the problem, and a non-dominated ranking genetic algorithm with an elite strategy is developed to solve it. Test results demonstrate that the model and algorithm proposed in this study efficiently identify the Pareto optimal solution set for the problem.

1 - A Branch-and-Price-and-Cut Type Algorithm for the Collaborative Truck&Ndash;Drone Routing and Scheduling Problem with Flexible Launch and Recovery Locations

SHROUQ GAMAL, KFUPM, Dharhan, Saudi Arabia, Naqeebuddin Mujahid Syed

This study introduces the Collaborative Truck–Drone Routing and Scheduling Problem with Flexible launch and recovery locations (CTDRSP-FL), addressing limitations in current research that restrict drone operations to customer sites only. Unlike restricted Launch and Recovery Operations (LARO) that rely primarily on truck deliveries and result in longer routes and underutilised drones, our model allows the truck to use non-customer locations (flexible sites) for drone operations, enhancing delivery efficiencies.
The proposed Mixed Integer Linear Programming (MILP) model makes three key decisions:
determining whether customer locations should be served by truck or drone; optimising truck and drone routing; and scheduling drone launch and recovery times at various truck stops. This flexibility in drone operation site selection facilitates faster deliveries and improved drone utilisation, particularly advantageous given drones' range limitations.However, the MILP model becomes computationally intractable for large instances. To address this, we developed a new branch-price and cut algorithm that improves scalability and minimises delivery times. Our findings indicate that using flexible sites overcomes the constraints of high-demand density locations and optimises the truck route, significantly enhancing the efficiency of the delivery system. This approach also results in higher drone utilisation compared to the traditional truck–drone setup. The model offers several practical insights for selecting potential flexible stops and the efficient management of a mixed fleet of trucks and drones for last-mile deliveries.

2 - Neural Combinatorial Optimization for Vehicle Routing Problems with Drones

Aigerim Bogyrbayeva, Cal Poly State, San Luis Obispo, CA, United States, Aigerim Bogyrbayeva

Many exact algorithms, heuristics, and metaheuristics have been proposed to solve the Vehicle Routing Problem with Drones (VRPD), which involves using a fleet of trucks and drones to fulfill customer orders in last-mile delivery. In this study, we formulate this problem using the Markov Decision Process (MDP) and propose a Reinforcement Learning (RL) based solution. Our RL model is based on an attention-encoder and a recurrent neural network-decoder architecture. This approach enhances coordination by determining which vehicles should visit specific customers and where vehicles can rendezvous, effectively leveraging drones and reducing the overall completion time. Our proposed RL model has demonstrated competitive performance compared

3 - Optimal Freight-on-Transit Operations Using Drones

Ouyang Yanfeng, University of Illinois Urbana-Champaign, Urbana, IL, United States, Jesus Osorio

This paper investigates the integration of Freight-on-Transit (FoT) with drone operations to optimize urban freight logistics. It develops a mathematical model for optimizing drone-assisted FoT operations, taking into account drone battery limitations, transit vehicle capacities, and the spatial-temporal alignment of transit and delivery schedules. A Lagrangian relaxation with column generation approach is proposed as a solution method to manage the computational complexity. Numerical experiments demonstrate the efficacy of this approach compared to commercial solvers and a simulated annealing metaheuristic. Sensitivity analyses highlight the impact of transit vehicle capacity and drone battery life on the overall system performance. A real-world case study using Chicago's Metra network illustrates practical applications and cost savings compared to truck-only and drone-only operations.

4 - Drone Scheduling Logistics

Srinivasa Prasanna, IIIT-Bangalore, Bengaluru, India

We describe drone scheduling algorithms suitable for agriculture, where crop conditions have to be identified, and appropriate fertilizers, pesticides, ... given. The problem is complex due to the scale and complex flying conditons, with uncertainty.

We desccribe both AIML heruistics and optimal methods. Results on simulated and real situations will be presented.

The worrk builds on earlier work on scheduling under uncertainty.

5 - Multi-Depot Drone Arc Routing Problem and Solution Methods

Islam Altin, Eskisehir Osmangazi University, Eskisehir, Turkey, Aydin Sipahioglu, ILGIN ACAR

Recently, drones have gained popularity in the fields of delivery, logistics, and surveillance operations. Researchers have focused on route planning to improve the effectiveness of drones in these fields. While several studies have been conducted on drone routing, a substantial percentage of them have addressed this problem as node-based routing. Only a small number of studies in the literature define this problem as edge-based routing. This study describes an edge-based drone routing problem by taking surveillance drones into account. In this case, there are multiple depots and more than one drone in each depot. Drones have limited energy capacity and must perform edge monitoring operations with their limited energy capacity. The objective of this problem is to obtain optimal drone routes that minimize the total distance traveled. However, it is not mandatory to use all the depots in the problem. Therefore, in addition to getting the optimal drone routes, it is necessary to determine which depots to use. We refer to this problem as the Multi-Depot Drone Arc Routing Problem. We developed a mixed-integer mathematical model to obtain the optimal solution to this challenging problem. Furthermore, we used a metaheuristic algorithm to handle especially large-sized problems in reasonable computation time. The algorithm's local search operators were specifically tailored to the problem. Real test problems of different sizes were generated in order to evaluate the performance of these solution methods. A comprehensive analysis of the computational results is presented.

6 - Optimizing Battery Recharging for Drones in Last-Mile Logistics Under Uncertainty: a Novel Decomposition-Based Approach

Ali Tolooie, Mercer University, Macon, GA, United States

This study addresses the operational challenges in drone logistics, focusing on the optimization of recharging stations, a vital but underexplored area. Our research aims to develop comprehensive strategies for efficient battery management, optimal charging times, and effective inventory control under variable conditions such as fluctuating demand and variable flight and charging times. Our methodology revolves around developing Markov decision process (MDP) models to optimize operations at drone recharging stations, taking into account a range of factors including battery charging strategies, inventory management, and dynamic operational conditions. Theoretically, we identify specific conditions that determine the optimal policy and characterize its structure. A key innovation in our approach is the introduction of a novel decomposition-based method to address the computational complexities of large-scale MDPs. This method segments the original problem into multiple independent processes, each corresponding to a different subsystem within the network, enhancing computational efficiency. Our numerical studies demonstrate the effectiveness of this approach, highlighting how various stochastic factors like flight patterns, demand variability, and inventory and backorder costs impact optimal decision-making. This research contributes to the field of drone logistics by providing actionable strategies for improved last-mile delivery, with broader implications for sustainable, cost-effective, and customer-focused logistics solutions.

1 - A Distributionally Robust Instrumental Variable Estimation Framework

Zhaonan Qu, Stanford University, Stanford, CA, United States

We propose a distributionally robust optimization (DRO) formulation of the classical instrumental variable (IV) regression framework. When the ambiguity set is a Wasserstein ball centered at the empirical distribution of projected variables, the resulting estimator solves a square root version of the standard ridge regularized IV regression. We show that the estimator is consistent whenever the limit of the robustness/regularization parameter is bounded above by an estimable non-zero constant. This novel consistency result differs from existing ones on regularized regression because it allows a non-vanishing regularization parameter. We discuss some interesting features of the problem underlying this phenomenon, namely a projection-based ambiguity set coupled with the unique geometry of the square root ridge regression. We also discuss generalizations to other DRO problems with projection-based ambiguity sets.

2 - Optimal Exiting for Liquidity Provision in Constant Function Market Makers

Brian Zhu, Columbia University, New York, NY, United States, Agostino Capponi

Liquidity provision in exchanges that use constant function market makers (CFMMs) is often unprofitable or unfavorable relative to just holding assets, one major reason being impermanent loss. Using an optimal stopping approach, we show that under mild conditions on the pricing function, there exists an optimal upper threshold policy that yields positive returns in expectation to liquidity providers when they exit the liquidity pool once the price ratio hits the upper price threshold (before transaction and infrastructural fees). We also examine how the pricing function's curvature affects the degree of impermanent loss and the optimal upper threshold.

3 - Asset pricing with supply chain relationships

Jiacheng Zou, Stanford University, Menlo Park, CA, United States

We propose to leverage the comprehensive records of Bloomberg SPLC to study how supply chain (SC) information can help construct better asset pricing models. Asset pricing models explain correlation of stock performances and be used to construct portfolios with desirable properties, such as uncorrelatedness with the market. From the microeconomic perspective, SC data is fundamentally descriptive of firms' input-output relations in terms of production and sales and should contribute to explaining the correlations of their stock performances. However, as a gap between theory and empirics, there is a lack of studies that use SC data for asset pricing, due to 3 key challenges: (i) Large scale. Each year, there may be as high as tens of thousands of relationships in the SC of the SP500 constituent companies; (ii) Pervasive missingness. The SEC only requires disclosing relationships of over 10% revenue, and SC data also contains non-quantitative links; (iii) Lagging updates. Many SC disclosures appear only in annual reports and may dissolve without clear updates. Machine learning offers robust models to extract signals from noisy data, which has been used in the academic literature to construct asset pricing models with firm characteristics and showed promising results. Another gap is that so far the literature focuses on indirectly learning covariances of stocks from price co-movement, rather than directly from production and sales links, partially because the traditional time-series or cross-sectional dimensions of financial market data are easier to model. We aim to close both gaps by comprehensively studying relationships for asset pricing

1 - When Mission Drift Becomes Mission Adaptation for Social Ventures

Leonardo Santiago, Copenhagen Business School, Frederiksberg, Denmark, Sinan Erzurumlu, Juliana Hsuan, Moren Levesque

New ventures with the goal for solving a social problem often face an inherent dilemma: generating sustained profitability vs. generating social value. While a venture's commercial activities generate cash, the venture might be criticized for doing that as it can result in a mission drift whereby the venture's activities drift from directly achieving its social objectives over time. We explore the role of mission drift by developing a stylized welfare-maximization model that combines social value and profits. Our primary interest is in understanding the optimal timing of the mission drift that balances sustained profitability and social value generation.

2 - How do mandated mobile app updates influence user engagement and app performance?

Alejandro Hernandez De la Lanza, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Maria Ibanez

Mobile app developers are commonly believed to have complete discretion over the content they release through updates. However, mobile app marketplaces (i.e., Google Play, App Store) often require developers to release specific updates to ensure ecosystem compatibility. Failure to release them by specific deadlines can have consequences for developers: the app can lose visibility on the platform. In this study, we rely on a natural experiment research design and application of the difference-in-differences methodology to examine the impact of such mandatory updates, versus those at developers' discretion, on user behavior in a freemium app over time. We hope our findings can help developers implement timely updating strategies that minimize user base churn and allow for more efficient promotional campaigns.

3 - Artificial intelligence utilization and collaboration for new product development

Gulru Ozkan-Seely, University of Washington Bothell, Bothell, WA, United States

The utilization of artificial intelligence (AI) in the design and development of new products is rapidly advancing, particularly in technologically oriented fields. We investigate the impact of AI in design and development, focusing on the advantages and challenges of this practice. Specifically, we recognize that while AI can efficiently advance early design ideas or prototypes through task automation, processing large data sets, improving precision, and optimizing features and resource usage, it also poses hurdles. These include the complexity of AI integration, opaque information processing, overfitting to data, and limited creativity opportunities. We examine the trade-off between the benefits of using AI to improve designs and prototypes and the drawbacks associated with these challenges.

1 - A Discretization Framework for Robust Contextual Stochastic Optimization

Cristian Rares, Massachusetts Institute of Technology, Cambridge, MA, United States, Georgia Perakis

In revenue management, businesses often face decision-making challenges based off of optimization problems with uncertain, context-dependent random variables (such as demand). Due to the inherent uncertainty in these problems, one is often interested not only in minimizing expected cost, but also to be robust and protect against worst case scenarios. We propose a novel method that combines the learning stage with knowledge of the downstream optimization task. The method prescribes decisions which aim to maximize the likelihood that the cost is below a (user-controlled) threshold. We provide theoretical guarantees bounding the regret associated with decisions proposed by our method. Furthermore, experimental results demonstrate the competitiveness and robustness of our approach. In particular, our method yields up to 20 times lower worst-case revenue loss compared to other methods in a real-world scenarios, such as electricity generation or inventory allocation, while maintaining comparable average revenue performance.

2 - Platform Competition in Two-Sided Networks

Emin Ozyoruk, University of Chicago, Chicago, IL, United States, John Birge

We study the impact of competition on ride-hailing platforms. The riders are sensitive to price and delay, and the drivers value high wages and utilization. The efficiency of the platforms improves with the density, and the drivers are randomly located in relation to the riders. The platforms simultaneously choose prices, service standards, and wages. The game admits a tractable form where each platform chooses a full price, enabling us to characterize the equilibrium and establish its existence and uniqueness. The results suggest that the ride-hailing industry benefits from economies of scale as the unit cost of attracting drivers decreases with increasing demand. Multiple platforms can enter and co-exist due to the multihoming drivers and variability in the system. However, a limited number of platforms can achieve economies of density and be profitable.

3 - Data-Driven Dynamic Assortment in Online Platforms: Learning about Two-Sides

Rahul Roy, Kenan-Flagler Business School, The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Nur Sunar, Jayashankar Swaminathan

Unlike traditional marketplaces like Amazon, a two-sided online platform allows "active" participants, i.e., they must initiate proposals to interact with agents on the other side to facilitate transactions. With the rise of such platforms (e.g., HomeAdvisor), understanding participants' preferences plays a crucial role in enhancing platforms' financial performance. However, these preferences are unknown to the platform, and must be learned over time. Furthermore, platforms often lack adaptive decision support systems that facilitate transactions between participants under uncertainty. This paper aims to bridge this crucial gap by formulating a dynamic assortment selection problem faced by a two-sided platform, where heterogeneous, active customers sequentially arrive to acquire products, and the platform chooses a subset of sellers from a finite set, tailored to the customer type. Each customer, being active, sends a proposal to at most one seller to initiate a transaction. After recurring intervals, all sellers review their proposals and matches with at most one customer. Platform aims to learn participants' preferences while maximizing the expected reward over time. Unlike extant literature that has solely analyzed one-way learning scenarios where the focus is to learn only customer preferences, our study proposes a novel formulation: "two-way learning." In our study, we develop an asymptotically optimal online algorithm that dynamically learns participants' preferences while optimizing platform's objective. Our algorithm achieves a worst-case regret bound that significantly improves upon the regret bounds in the existing literature. Our study contributes to the advancement of assortment optimization online algorithms, especially within the framework of two-way learning.

4 - Data-driven Population Tracking in Large Service Systems

Morgan Wood, UNC Chapel Hill, Chapel Hill, NC, United States

We develop asymptotically optimal policies to track queue lengths under different loss structures in a setting with inaccurate arrival and departure sensor data. By deriving general lower bounds on any policy's expected cumulative loss, we show that tracking the population in real-time is challenging because of the accumulation of tracking errors. We propose a detection policy with provably good performance guarantees that corrects the estimated population count when the system is believed to be nearly empty. Further, we explore the benefits of augmenting the sensor information with periodic queue inspections at a cost. Our model is motivated by queue tracking implemented at a large airport. Revenue Management and Pricing

Chair: Levi DeValve, Chicago Booth, Chicago, IL, United States

1 - Multi-echelon Batch Inventory Networks

Maximiliano Stock, University of Chicago, Chicago, IL, United States, Levi DeValve

We consider the Multi-echelon Batch Inventory (MEBI) problem, which integrates the challenges of optimizing pallet ordering, breaking down these pallets into inventory units, and allocating these units across a network in anticipation of uncertain demand. We aim to minimize the combined costs of ordering, breaking down, placing inventory, and the expected costs associated with fulfillment and shortages. The research unveils the intrinsic complexity of the problem, demonstrating its inapproximability in terms of lower bounds under non-metric cost assumptions. Under the metric cost assumption, the usual LP relaxation for the two-stage stochastic optimization problem exhibits an unbounded integrality gap. To address this, we propose an improved linear programming relaxation of the two-stage stochastic optimization problem by incorporating additional cuts that help bound the fractional results that may arise from the relaxation of the integer constraints. We develop a constant factor approximation guarantee by implementing a randomized filtering rounding algorithm inspired by approximation algorithm techniques from the facility location literature. The findings enhance the theoretical understanding of the MEBI problem and offer practical insights for large-scale operations in optimizing complex inventory systems under uncertainty.

2 - Landscape of Policy Gradient Objectives for Finite Horizon MDPs: Applications in Operations Models

Minda Zhao, Georgia Institute of Technology, Atlanta, GA, United States, Xin Chen, Yifan Hu

We explore policy gradient methods for finite horizon Markov Decision Processes (MDPs) with continuous state and action spaces. Policy gradient methods for Markov Decision Processes (MDPs) do not converge to global optimal solutions in general due to the non-convexity of the objective functions. We identify several easily verifiable conditions to guarantee the global Kurdyka-Łojasiewicz (KŁ) condition for the objectives of policy gradient optimization problems for a class of MDPs. This allows us to establish that the policy gradient optimization problems can be solved by first-order methods with a sample complexity in the order of $1/\varepsilon$ and polynomial at the planning horizon length to attain ε-global optimal solutions. Our results find applications in a host of operations models including the stochastic cash balance problem and multi-period inventory system with Markov-modulated demand, giving the first sample complexity results in the literature.

3 - Private Optimal Inventory Policy Learning for Feature-based Newsvendor with Unknown Demand

Tuoyi Zhao, University of Miami, Miami, FL, United States, Wenxin Zhou, Lan Wang

The data-driven newsvendor problem with features has recently emerged as a significant area of research, driven by the proliferation of data across various sectors such as retail, supply chains, e-commerce, and healthcare. Given the sensitive nature of customer or organizational data often used in feature-based analysis, it is crucial to ensure individual privacy to uphold trust and confidence. Despite its importance, privacy preservation in the context of inventory planning remains unexplored.
A key challenge is the nonsmoothness of the newsvendor loss function, which sets it apart from existing work on privacy-preserving algorithms in other settings. This paper introduces a novel approach to estimate a privacy-preserving optimal inventory policy within the f-differential privacy framework, an extension of the classical (ϵ, δ)-differential privacy with several appealing properties.
We develop a clipped noisy gradient descent algorithm based on convolution smoothing for optimal inventory estimation to simultaneously address three main challenges: (1) unknown demand distribution and nonsmooth loss function; (2) provable privacy guarantees for individual-level data; and (3) desirable statistical precision.
We derive finite-sample high-probability bounds for optimal policy parameter estimation and regret analysis.
By leveraging the structure of the newsvendor problem, we attain a faster excess population risk bound compared to that obtained from an indiscriminate application of existing results for general nonsmooth convex loss. Our bound aligns with that for strongly convex and smooth loss function.

4 - Beyond Basic Reusability: Joint inventory and online assortment optimization with a network of evolving resources

Yukai Huang, Olin Business School, St. Louis, MO, United States, Jacob Feldman, Heng Zhang

In this study, we consider the joint inventory and assortment optimization when the decision-makers decide the initial capacity of each resource before a finite selling season starts. Then, across the selling horizon, the decision-makers offer personalized assortment in real time based on customer arrivals and remaining inventory to maximize the total expected revenue. Unlike prior work on joint inventory selection and online resource allocation that only considers the perishable resources, our framework can be extended to the reusable resources. Beyond the classic definition of reusable resource, we introduce the new concept of network reusability by allowing for the transformation of resources upon return. This advanced model captures more realistic scenarios, such as products returning to inventory in a different condition or rentals returning to different locations, thereby broadening the applicability of our framework to diverse domains like product returns, fashion rentals, and car-sharing services. The modeling richness introduces new technical hurdles when it comes to solving our joint inventory and online assortment problem. Under the MNL choice model, we propose an inventory refinement procedure that achieves a constant-factor approximate performance. Our computational experiments show that our approximation framework performs well under different application scenarios.

1 - Unveiling Competitive Dynamics in Pricing: Insights from Laboratory Experiments

Bahriye Cesaret, Ozyegin University, Istanbul, Turkey, Armagan Bayram

We conduct a series of controlled laboratory experiments to investigate the dynamic pricing behavior of two capacity-constrained firms under competition. Our experiments initially control for strategic interactions between the sellers and then allow for them. Moreover, we manipulate demand uncertainty and the expected market size to broaden our comprehension. Our findings underscore the significant influence of competitor's behavior on dynamic pricing decisions. We find that the theory predicts a lower level of competition among the sellers than what we observe in the laboratory. The modeling literature indicates that the seller with the lower capacity has a competitive advantage, but our results reveal the opposite. Further, there is potential for high-capacity sellers to benefit from competition. Sellers tend to underprice (resp., overprice) their units at the beginning (resp., end) of a selling season. Also, the duration of competition exceeds theoretical predictions, and customers reap advantages from the biases inherent in strategies of competing sellers. Leveraging our experimental findings, we propose two straightforward heuristics that utilize the competitor's past behavior to improve predictions of sellers' pricing behavior over the normative benchmarks.

2 - Optimal Assortment and Free Shipping Strategies: a Comparative Analysis

Hafila Morais Max Morais, Texas State University, McCoy College of Business, San Marcos, TX, United States, Sahika Sahan Konur

This paper explores optimal assortment decisions of a retailer across various free shipping strategies. Utilizing real-world data, we conduct a computational analysis to compare the expected revenues under two distinct scenarios: one where the retailer incurs all the shipping costs (free shipping), and another where the customer incurs the entire shipping cost (no free shipping). Our study aims to illuminate the impact of different shipping strategies on retailer's revenue and decision-making processes.

3 - The Value of Information Design in Supply Chain Management

Huseyin Gurkan, ESMT GmbH, Berlin, Germany, Ozan Candogan

This paper studies an information design problem of a retailer in a two-tier supply chain that procures a single type of product from a supplier. The supplier needs to decide on a production quantity by balancing the shortage cost and the excess inventory holding cost with respect to the retailer's demand. The retailer's demand is random but the retailer receives an informative signal about the demand before the supplier sets the production quantity, and places orders after learning the demand realization. The retailer wants to reduce the shortage cost, and to this end she can disclose information about her signal to persuade the supplier to increase production levels. For this setup, we characterize the optimal information disclosure policy of the retailer, and shed light on settings where the retailer strictly benefits from carefully designed information disclosure policies relative to a full- or a no-disclosure policy.

4 - Subscription Pricing Strategies for Delivery Services

Shankar Sundaresan, Rutgers University, Camden, NJ, United States, Anantaram Balakrishnan

We study the subscription pricing problem that offers consumers two delivery choices: a pay-per-delivery option and a subscription option with free delivery. We develop and analyze a model that captures consumer heterogeneity in terms of their utility and preference across different firms, lift in consumer demand, possibility of attracting new customers, and order batching by consumers. We characterize the retailer's optimal subscription pricing strategies, and develop interesting insights.

5 - Dynamic pricing with random yields

Srinivasa Puranam, Rutgers University, Camden, NJ, United States, Michael Katehakis

This talk explores the impact of uncertainty surrounding realized capacity on a firm's pricing decisions, particularly in markets where contracts are agreed upon before the actual product delivery. In such markets, if the actual capacity realized at the end of the selling period falls short of the contracted capacity, the seller must adjust existing contracts and may not be able to meet the demand of one or multiple buyers in full. Many firms encounter exogenous factors that influence the final yield of their products, making it challenging to accurately predict yield. Consequently, firms often rely on estimates when selling capacity in advance of their actual yield, which can result in either shortfalls or excesses at the end of the selling season. We present a Markov Decision Process model for this problem.

Mechanism Design Under Uncertainty

Invited Session

Revenue Management and Pricing

Chair: Shixin Wang, The Chinese University of Hong Kong, Hong Kong, N/A

1 - From Doubt to Devotion: Trials and Learning-Based Pricing

Nicholas Wu, Yale University, New Haven, CT, United States, Tan Gan

An informed seller designs a dynamic mechanism to sell an experience good. The seller has partial information about the product match, which affects the buyer's private consumption experience. We characterize equilibrium mechanisms of this dynamic informed principal problem. The belief gap between the informed seller and the uninformed buyer, coupled with the buyer's learning, gives rise to mechanisms that provide the skeptical buyer with limited access to the product and an option to upgrade if the buyer is swayed by a good experience. Depending on the seller's screening technology, this takes the form of free/discounted trials or tiered pricing, which are prevalent in digital markets. In contrast to static environments, having consumer data can reduce sellers' revenue in equilibrium, as they fine-tune the dynamic design with their data forecasting the buyer's learning process.

2 - Pricing with Binary Feedback: the Value of Information Bit by Bit

Omar Mouchtaki, New York University, New York, NY, United States, Omar Besbes, Will Ma

We study a data-driven pricing problem in which a seller offers a price for a single item based on demand observed at a small number of historical prices. Our goal is to derive precise evaluation procedures of the value of the historical information gathered by the seller, along with prescriptions for more efficient price experimentation. Our main methodological result is a reduction which allows us to compute exactly the worst-case performance of a wide range of pricing policies for any sequence of historical prices. This allows us to establish that very few demand observations are sufficient to ensure a near-optimal revenue.

3 - The Power of Simple Menus in Robust Selling Mechanisms

Shixin Wang, The Chinese University of Hong Kong, Hong Kong, Hong Kong

We study the robust screening problem with a finite menu size. Our framework characterizes the optimal selling mechanisms and the corresponding competitive ratio across various menu sizes and ambiguity sets of the buyer's valuation distributions, such as support, mean, and quantile ambiguity sets. We show that a selling mechanism with a small menu already yields a competitive ratio comparable to the optimal robust mechanism with infinite options in the menu. Remarkably, a menu size of merely two can significantly enhance the competitive ratio compared to deterministic pricing, which establishes a favorable trade-off between theoretical performance and implementation simplicity.

Human-Centered AI and Decision Analysis for Social Good

Invited Session

Decision Analysis Society

Chair: Yunyi Li, The University of Texas at Austin, Austin, TX, United States

1 - A Methodological Framework for Human-Algorithm Performance Comparisons Under Uncertainty

Luke Guerdan, Carnegie Mellon University, Pittsburgh, PA, United States, Amanda Coston, Steven Wu, Kenneth Holstein

Predictive models are often introduced to decision-making tasks under the rationale that they improve performance over an existing (e.g., human) decision-making policy. However, it is challenging to compare predictive performance against an existing decision-making policy that is generally under-specified and dependent on unobservable factors. These sources of uncertainty are often addressed in practice by making strong assumptions about the data-generating mechanism. In this work, we propose a method to compare the predictive performance of decision policies under a variety of modern identification approaches from the causal inference and off-policy evaluation literatures (e.g., instrumental variable, marginal sensitivity model, proximal variable). Key to our method is the insight that there are regions of uncertainty that we can safely ignore in the policy comparison. We develop a practical approach for finite-sample estimation of regret intervals under no assumptions on the parametric form of the status quo policy. We verify our framework theoretically and via synthetic data experiments. We conclude with a real-world application using our framework to support a pre-deployment evaluation of a proposed modification to a healthcare enrollment policy.

2 - Mitigating Label Bias via Decoupled Confident Learning

Yunyi Li, The University of Texas at Austin, Austin, TX, United States

Growing concerns regarding algorithmic fairness have led to a surge in methodologies to mitigate algorithmic bias. However, such methodologies largely assume that observed labels in training data are correct. This is problematic because bias in labels is pervasive across important domains, including healthcare, hiring, and content moderation. In particular, humangenerated labels are prone to encoding societal biases. While the presence of labeling bias has been discussed conceptually, there is a lack of methodologies to address this problem. We propose a pruning method—Decoupled Confident Learning (DeCoLe)—specifically designed to mitigate label bias. After illustrating its performance on a synthetic dataset, we apply DeCoLe in the context of hate speech detection, where label bias has been recognized as an important challenge, and show that it successfully identifies biased labels and outperforms competing approaches.

3 - Does a Human-Algorithm Feedback Loop Lead To Error Propagation? Evidence from Zillow's Zestimate

Runshan Fu, New York University, New York, NY, United States, Ginger Jin, Meng Liu

We study how home sellers and buyers interact with Zillow's Zestimate algorithm throughout the sales cycle of residential properties, with an emphasis on the implications of such interactions. In particular, leveraging Zestimate's algorithm updates as exogenous shocks, we find evidence for a human-algorithm feedback loop: listing and selling outcomes respond significantly to Zestimate, and Zestimate is quickly updated for the focal and comparable homes after a property is listed or sold. This raises a concern that housing market disturbances may propagate and persist because of the feedback loop. However, simulations suggest that disturbances are short-lived and diminish eventually, mainly because all marginal effects across stages of the selling process—though sizable and significant—are less than one. To further validate this in- sight in the real data, we leverage the COVID-19 pandemic as a natural experiment. We find consistent evidence that the initial disturbances created by the March-2020 declaration of na- tional emergency faded away in a few months. Overall, our results identify the human-algorithm feedback loop in an important real-world setting, but dismiss the concern that such a feedback loop generates persistent error propagation.

4 - A Machine Learning-Based Approach for Evaluating Experts' Decision Quality in High-Risk Instances

Wanxue Dong, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Weiquan Wang

Experts are fallible, and the repercussions of their decisions can be substantial. For instance, misdiagnoses by physicians in the US annually result in billions of dollars in losses and impact millions of lives. Hence, assessing experts' decisions is vital for guiding managerial tasks and consumer services. However, evaluating decision quality is challenging due to the scarcity and high cost of obtaining ground truth (GT) decisions—those that are correct. While previous studies have attempted to assess experts' decision quality with scarce GT, they often hinge on the assumption that GT and experts' decisions stem from the same distribution. However, such assumptions overlook crucial real-world scenarios. Advanced treatments or medical examinations to uncover GT, for instance, may only be accessible to patients deemed high-risk. Therefore, prior solutions assessing decisions in general may not adequately address the needs of high-risk groups, which are also more susceptible to decision errors. In this study, we concentrate on scenarios where GT data is limited and only accessible for instances with a higher risk of errors. Thus, we propose a Machine Learning (ML)-based approach to assess experts' decision quality in high-risk instances by harnessing a large amount of experts' noisy decisions and scarce GT data from high-risk cases. Our empirical evaluations demonstrate that our method outperforms an alternative that rely solely on independent GT sets with high-risk instances. To our knowledge, this paper is the pioneer in considering high-risk decision evaluation with limited GT available from high-risk groups and achieves state-of-the-art performance.

5 - Elucidating Justice Concerns of Algorithms that Triage Misinformation for Fact-Checkers

Terrence Neumann, University of Texas at Austin, Austin, TX, United States, Maria De-Arteaga, Maytal Saar-Tsechansky, Matt Lease, Sina Fazelpour

Faced with the increasing scale of misinformation, fact-checkers are frequently turning to algorithms to efficiently triage claims in need of verification. However, there is uncertainty regarding the appropriate 'ground truth' for training and evaluating these algorithms given the varied and subjective factors that influence how claims are prioritized for checking. For instance, numerous fact-checking organizations prioritize checking claims that are most likely to go viral and cause harm to the 'general public,' while others have noted the need to prioritize claims that harm vulnerable demographic groups. To better understand the implications of these and other algorithmic design choices on society, we apply the theoretical lens of informational justice to elucidate the often-competing interests of representation, participation, credibility, and the distribution of benefits and burdens among the stakeholders affected by information proliferation, consumption, and fact-checking. Utilizing a new crowdsourced dataset, which we make available for public use, we apply the informational justice framework to a training data audit. We show how algorithmic design choices related to the construction of a 'ground truth' label for claim prioritization can have consequential justice implications for stakeholders affected by misinformation. We propose that an informational justice approach promotes transparency and facilitates more ethical decision-making amidst the unique complexities of claim triage and prioritization of fact-checking resources. Our findings aim to assist researchers, policymakers, and industry professionals in framing the ethical landscape of AI-assisted fact-checking systems.

Reinventing Business Models Amidst New Market Dynamics

Invited Session

Decision Analysis Society

Chair: Yuan Cheng, Cornell University, Jersey City, NJ, United States

1 - Selling Only? Leasing Only? Maybe Selling and Leasing Combined?

Shuya Yin, University of California at Irvine, Irvine, CA, United States, Mobin Ghasempour Nejati

The selling and leasing business models in the automobile industry have been extensively used in practice and studied in literature. With the rising prevalence of electric vehicles, with battery components being a significant part of these products and their depreciation rate being higher than other parts, it seems natural to explore a combined business model where the battery can be leased or rented while the vehicle (excluding the battery) can be sold as usual. This paper examines the trade-offs involved in such considerations.

2 - Fair Contract Design with Agent Rotation

Feng Tian, HKU, Hong Kong, China, People's Republic of, Mingliu Chen, Wei Zhang

We study a dynamic optimal contracting problem when agents have fairness concerns about their earnings. A principal hires agents to run businesses in different markets with different costs. Agents can exert costly private efforts to potentially increase the chance of business success in their markets, and the principal only observes the outcome of the businesses. All agents and the principal are risk-neutral, but the agents have fairness concerns about their earnings due to market differences. The principal can use compensations and agent rotation to alleviate agents' concerns about fairness. At the same time, the principal also wants to induce efforts from the agents to increase the chance of business success and maximize her utility. Note that when subjected to fairness concerns, the principal indirectly provides the agents with some compensation or utility guarantees. As a result, it may be more difficult or costly to motivate agents to exert efforts as the monetary incentives are less effective. On the other hand, a rotation schedule may also serve as an effective incentive or threat to agents, depending on the market conditions, but it may lead to costly logistics. As a result, the principal needs to properly design dynamic contracts for agents involving compensations and agent rotation based on the business outcomes over time to carefully balance their incentives to work hard and fairness concerns.

3 - Using Semantic Network Analysis to Measure the Codification of Occupational Ethics

Jessica Santana, UC Santa Barbara, Goleta, CA, United States, Seonghoon Kim

The institutionalization of occupations tends to assume homogenization of occupational values. This study addresses the question of how members of an occupation with dissenting preferences reach consensus on a code of ethics. We build on prior theorization of occupational institutionalization and institutional discourse to theorize ethical codification as a dynamic discursive process of internal dissent and consensus culminating in a professional code of ethics. We use email data from the IEEE-ACM Software Engineering Ethics and Professional Practice Committee tasked with producing the 1997 Software Engineering Code of Ethics to show how ethical codification follows a process of initial competition followed by semantic convergence. This study demonstrates how natural language processing and semantic network analysis can contribute to discourse analyses of institutional processes.

Wisdom of the Crowd/Forecast Aggregation

Invited Session

Decision Analysis Society

Chair: Zhi Chen, National University of Singapore, Singapore, Singapore

Co-Chair: Long Zhao, NUS DAO, Singapore, Singapore

1 - Bayesian Ensembles of Unlabeled Forecasts: a Rationale for Downweighting Extreme Forecasts

Xiaojia Guo, Robert H. Smith School of Business, University of Maryland, College Park, MD, United States, Casey Lichtendahl

We introduce an ensemble method based on a Bayesian framework that incorporates forecasts and biases from various experts or models. The final uncertainty in the model removes exact knowledge about which expert is best, second best, etc., which in practice is often the case. The final model, then, learns only from the order statistics of the forecasts, as if the forecasts were unlabeled. In other words, the model learns anonymously, without knowing the identity of the experts or how they performed in the past. According to the model, the more extreme a forecast is, the more likely it comes from an overfit or underfit expert or model, and therefore it receives less weight in the ensemble. In two empirical studies of time series forecasts, we demonstrate that our Bayesian ensemble can outperform leading methods.

2 - Regularized Aggregation of Point Predictions from Experts with Different Amounts of past Performance Data

Junnan Wang, INSEAD, Singapore, Singapore, Ville Satopaa

Aggregating point forecasts from multiple experts is a critical challenge, especially in the common context where those experts have contributed a varied number of predictions in the past. Consider the scenario where one expert has provided just two forecasts but with perfect accuracy, and another has offered a hundred predictions with lower accuracy. This situation presents a challenge in balancing accuracy against the risk associated with less data. To address this, our work introduces a novel aggregation method that precisely balances these considerations. Specifically, our aggregator uses Bayesian regularization, estimates each expert's expected bias and noise, factoring in their unique prediction histories, and appropriately shrinks each expert's weight toward equal weight, depending on the expert's skill and how reliably that skill can be estimated. In our empirical study, we apply our aggregator to the data from the European Central Bank's Survey of Professional Forecasters and observe that it outperforms traditional aggregation methods, including the simple average and the performance-based weighted average methods.

3 - From Point Predictions to Probabilistic Aggregate: A Novel Variational Bayes Approach to Harnessing the Wisdom of the Crowd.

Yanwei Jia, The Chinese University of Hong Kong, Shatin, Hong Kong, Jussi Keppo, Ville Satopaa

Decision makers often rely on the combination of many individual judgments, which is known as the wisdom of crowds. In the single-question setting, where there is no past data or other prior information, recent literature finds that using peer predictions, i.e., predictions about others' judgments, can greatly enhance the accuracy of aggregated judgment. However, the methods proposed so far either request individuals provide probabilistic predictions or are restricted to output only an aggregated single-point prediction. The former is difficult to elicit and the latter is not sufficient to inform the decision-making. By using variational Bayes inference techniques, we propose an aggregation method that takes the individual judgments and their peer predictions, both single-point values, as inputs to construct a probability distribution that can be expressed in an analytical form. Under Normal-Gamma information structure, we prove the efficiency of the proposed method. Using simulated data and experimental data collected in previous studies, we demonstrate the proposed method outperforms conventional practices and achieves comparable accuracy to state-of-the-art methods in single-point prediction.

4 - "Information Elicitation from Teams of Privacy-Conscious Experts

Marat Salikhov, New Economic School, Moscow, Russian Federation, Ruslan Momot

Companies often inform their decisions by eliciting votes from teams of internal experts – for example, their employees. However, such experts may vote against their true beliefs if pressured by powerful stakeholders, whose interests may be misaligned with the company's best interest. The experts' desire to protect their true beliefs from such stakeholders presents a privacy concern and makes eliciting their information a challenge. In particular, our results reveal that privacy concerns may undermine the conventional "wisdom of crowds" logic –

in which having a larger pool of experts strictly improves the quality of the firm's decisions. We explore how privacy concerns can be addressed by designing appropriate vote elicitation processes.

5 - Combining Forecasts from Multiple Experts for Multiple Variables

Long Zhao, NUS DAO, Singapore, Singapore, Zhi Chen

We address the challenge of combining point forecasts from multiple experts across multiple variables to draw inferences about an unknown variable. A significant amount of prior research has focused on aggregating forecasts from multiple experts about a single variable into a consensus forecast. However, in practice, each expert frequently provides a forecast for each variable across multiple variables. In this paper, we study how a decision-maker can incorporate forecasts of other variables in addition to those provided for the focal variable.

Multi Criteria Decision Making

Chair: Salvatore Greco, University of Catania, Catania, Italy

Co-Chair: Adiel De Almeida, Universidade Federal de Pernambuco, Recife, Brazil

1 - On solving parametric multiobjective quadratic programs with parameters in general locations

Andrew Pangia, UNC Charlotte, Concord, NC, United States, Pubudu Jayasekara

While theoretical studies on parametric multiobjective programs (mpMOPs) have been steadily progressing, the algorithmic development has been comparatively limited despite the fact that parametric optimization can provide a complete parametric description of the efficient set. This paper puts forward the premise that parametrization of the efficient set of nonparametric MOPs can be combined with solving parametric MOPs because the algorithms performing the former can also be used to achieve the latter.This strategy is realized through (i) development of a generalized scalarization, (ii) a computational study of selected parametric optimization algorithms, and (iii) applications in a real-life context. Several variants of a generalized weighted-sum scalarization allow one to scalarize mpMOPs to match the capabilities of algorithms. Parametric multiobjective quadratic programs are scalarized into parametric quadratic programs (mpQPs) with linear and/or quadratic constraints. In the computational study, three algorithms capable of solving mpQPs are examined on synthetic instances and two of the algorithms are applied to decision-making problems in statistics and portfolio optimization. The real-life context reveals the interplay between the scalarizations and provides additional insight into the obtained parametric solution sets.

2 - An active preference learning approach to aid the selection of validators in blockchain environments

Grzegorz Miebs, Poznan University of Technology, Poznan, Poland, Jonas Gehrlein, Matteo Brunelli, Milosz Kadzinski

We consider a real-world problem faced in some blockchain ecosystems that select their active validators—the actors that maintain the blockchain—from a larger set of candidates through an election- based mechanism. Specifically, we focus on Polkadot, a protocol that aggregates preference lists from an- other set of actors, nominators, that contain a limited number of trusted validators and thereby influence the election's outcome. This process is financially incentivized but often overwhelms human decision makers due to the problem's complexity and the multitude of available alternatives. This paper presents a decision support system (DSS) to help the nominators choose the validators in an environment with frequently changing data. The system structures the relevant multiple attribute problem and incorporates a dedicated active learning algorithm. Its goal is to find a sufficiently small set of pairwise elicitation questions to infer nominators' preferences. We test the proposed solution in an experiment with 115 real nominators from the Polkadot ecosystem. The empirical results confirm that our approach outperforms the unaided process in terms of required interaction time, imposed cognitive effort, and offered efficacy. The developed DSS can be easily extended to other blockchain ecosystems.

3 - Cluster ensemble selection and consensus clustering: A multi-objective optimization approach

Dilay Aktas, KU Leuven Institute for Mobility, Leuven, Belgium, Banu Lokman, Tulin Inkaya, Gilles Dejaegere

Cluster ensembles have emerged as a powerful tool to obtain clusters of data points by combining a library of clustering solutions into a consensus solution. In this paper, we address the cluster ensemble selection problem and design a multi-objective optimization-based solution framework to produce consensus solutions. Given a library of clustering solutions, we first design a preprocessing procedure that measures the agreement of each clustering solution with the other solutions and eliminates the ones that may mislead the process. We then develop a multi-objective optimization algorithm that selects representative clustering solutions from the preprocessed library with respect to size, coverage, and diversity criteria and combines them into a single consensus solution, for which the true number of clusters is assumed to be unknown. We conduct experiments on different benchmark data sets. The results show that our approach yields more accurate consensus solutions compared to full-ensemble and the existing approaches for most data sets. We also present an application on the customer segmentation problem, where our approach is used to segment customers and to find a consensus solution for each segment, simultaneously.

Corporate Governance and Firm Performance

Contributed Session

Contributed

Chair: Fei Li, The Hong Kong Polytechnic University

1 - An Empirical Analysis of Peer Firms Investigates the Relationship Between Corporate Governance Practices and Firm Performance

Tabreez Humayun, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Shuangyan LI, Shahzad Humayun, Gul Rukh

This study demonstrates that peer firms in Pakistan adopt the corporate governance practices that are currently being implemented. Additionally, it investigates the correlation between corporate governance procedures, capital structure, and firm performance in listed companies in Pakistan. Financial resources are essential for companies to achieve their aims. Consequently, we meticulously arrange the elements that can influence financing decisions for all peer firms. In this study, we utilize a sample of 100 peer organizations that are listed on the Pakistan Stock Exchange (PSE) as part of the non-financial industrial sector. The data covers the period from 2015 to 2020. The relationship between corporate governance, capital structure, and business performance is analyzed using Structural Equation Modeling (SEM) and regression approaches. The research study further substantiates the corporate governance ideas. The reliability of our conclusions is ensured by the use of theoretical models, which promote excellent corporate governance practices and ultimately improve the firm's performance and capital structure. The study examines the significance of corporate governance procedures in influencing peer firms to modify their debt strategies and improve overall firm performance. Furthermore, in order to acquire additional resources and cultivate trust from shareholders, organizations must enhance their corporate governance methods.

2 - Will Diversity, Equity, and Inclusion Commitment Improve Manufacturing Firms' Market Performance? A Signaling Theory Perspective on DEI Announcements

Fei Li, The Hong Kong Polytechnic University, Hong Kong, China, People's Republic of, Chris K. Y. Lo, Yi Zhou, Christopher Tang

Despite the escalating emphasis on diversity, equity, and inclusion (DEI), there remains a noticeable gap in empirical research concerning its implications, particularly within the manufacturing sector. This research gap has prompted us to scrutinize DEI commitment's effects on publicly traded manufacturing corporations through the lens of *signaling theory*. To operationalize our study, we employ the event study methodology and apply the structural topic modeling method to analyze 233 DEI commitment announcements issued by 161 firms over a 10-year period between 2013 and 2022. Our findings suggest that DEI commitment announcements can yield positive abnormal stock returns during the announcement period (from day -1 to 0 and from day -1 to 5). Furthermore, the impact will be heightened when the announcements place a stronger emphasis on topics related to DEI as opposed to topics not related to DEI. This is referred to as *signal strength*. The effect is also more pronounced when the focus is on specific subjects within DEI, a concept we term *signal specificity*. We also discuss managerial implications of our findings.

Recent Developments in Innovation Contests

Invited Session

Technology, Innovation Management and Entrepreneurship

Chair: Gizem Korpeoglu, TU/e, Eindhoven, 5632TE, Netherlands

Co-Chair: Konstantinos Stouras, UCD Michael Smurfit GSB, Dublin, Ireland

1 - Technology Contests

Jurgen Mihm, Insead, Fontainebleau, France, Jussi Keppo, Jochen Schlapp

When innovating companies often face the choice of which technology to implement in their product. In particular, firms can typically choose between an established or a more experimental technology. Which one should they choose? And when? And more interestingly, does competition change the optimal choice? And is competition thus good for society? In this paper, we build a formal model of a dynamic technology contest and we study the technology choices of competing firms over time. We find that a firm's technology choice mainly depends on the firm's relative position in the contest as well as the uncertainty embedded in experimenting with a novel technology. We also investigate whether such technology contests are desirable from a societal perspective: Do technology contests promote or hinder innovation? The answer to this question depends on the relative difference between the available technologies and on the intensity of the competition.

2 - Curated Contests

Sina Khorasani, Vanderbilt University, Nashville, TN, United States, Lakshminarayana Nittala, Vish Krishnan

To leverage the contest mechanism for sourcing quality solutions to complex problems, we propose a hybrid approach called the Curated Contest - in which firms benefit from competition among contestants but also engage in curation, by sifting and screening intermediate contestant submissions and potentially offering various forms of support for developing proof of concept and validating ideas. We provide guidance to solution-seeking firms on when and how to organize such curated contests in the presence of information asymmetries between solution seekers and skeptical contestants. We find that screening can stimulate additional effort from contestants. Firms can gain solver credibility by fine-tuning the reward size and other support schemes including late-stage compensation and proof of concept cost-sharing. We present a managerial framework to help design a carefully curated contest, which can help firms realize more effort from contestants.

3 -

Innovating Under Pressure: a New Model for Understanding R&D Competition

Linsheng Zhuang, National University of Singapore Institute of Operations Research and Analytics, Singapore, Singapore, Jussi Keppo, Zhi Chen

In many technological competitions, a firm must develop more superior technology over its rivals to win the entire market. Otherwise, firms simply split the market. We leverage the tug-of-war contest model to study this phenomenon. We show that the equilibrium can be substantially different from the corresponding equilibrium of classical rank-based contests. We discuss the implications of our results in the context of technological competitions.

Online Reviews and Performance

Invited Session

New Product Development

Chair: Morvarid Rahmani, Georgia Institute of Technology, Atlanta, GA, United States

1 - The Bright Side of Lower Quality: Evidence from Restaurant Exploration

Manuel Sosa, INSEAD, Fontainebleau, France, Clara Carrera, Victor Martínez-de-Albéniz

The value derived from hedonic goods is affected by reference effects at the time of consumption, usually in the form of quality standards. Consumption typically involves two steps: first, the consumer chooses a given good, among a pool of available choices; then, the consumer experiences the good and derives a satisfaction from it. Between both steps, consumers might build expectations about the good that might affect the ultimate realized utility. We investigate the role of quality references in this two- stage (choice-outcome) process. We develop a flexible framework for estimating quality references and their effect in choice and outcome, that can include consumers' own past experiences as well as that of others, and can give salience to more recent or more distant past experiences. Using novel longitudinal data from online restaurant reviews, we find evidence of quality loss aversion in the choice decision stage, in accordance with prospect theory. However, in the outcome stage, we do find evidence of the opposite to loss aversion, i.e., satisfaction is affected much less than one would expect when going to a lower quality restaurant. This is consistent with consumers adjusting their expectations downwards and suggests that expectation adjustment protects consumers when they experience a good of lower-than- reference quality. Our results challenge the implicit assumption made by most recommendation systems that the expectation building process after making a choice does not change the outcome, and imply that it may be better to patronize activities by alternating between high- and low-quality choices.

2 - Work-Life Balance Satisfaction and Employee Turnover: A Large-Scale Analysis

Hyunwoo Park, Seoul National University, Seoul, Korea, Republic of, Morvarid Rahmani, Abhishek Deshmane

For firms to be able to compete in the complex and dynamic nature of today's economy, they need to continually innovate. Thereupon, it is important to understand the drivers of innovation at firms. In this paper, we study the effect of employee satisfaction on firms' innovation performance. We examine a social media platform, where employees voluntarily and anonymously share their outlook and opinions on various dimensions of their workplace environment. Using a sample of 905,930 employee reviews and 1,620,229 granted patents of 698 firms, we find that employee satisfaction with their workplace environment can significantly impact firms' innovation performance. More specifically, we find that while employee satisfaction with career opportunities enhances firms' innovation performance, their satisfaction with work/life balance negatively affects firms' innovation performance. Further, we find that employee satisfaction with their compensation and benefits can significantly reduce the value of firms' innovation in terms of both scientific and economic values, but it does not significantly affect the quantity of innovation outcomes. We also conduct analysis on sub-sample of firms based on their characteristics (ie, revenue, geographical location, and industry), and discuss the implications of our findings for research and practice.

3 - Timing the Tide: How the Chronology of External Conflicts Influences the Trajectory of Collaborative Projects (Tbd)

Shizhen Chen, Emory University, Atlanta, GA, United States, Tian Chan, Anandhi Bharadwaj, Gerald Kane

Building on the intriguing dynamics within online communities (OCs) and their ability to mobilize for collaborative action, our study extends the exploration into how external conflicts or crises affect the success trajectory of collaborative projects, especially when considering the timing of such disruptions. Through a comprehensive analysis, we examine the dual-edged nature of external crises, which can either hinder or enhance project outcomes based on their occurrence at different project stages. Drawing on various sources related to Reddit's r/place 2022 event, we delve into the initial devastating impact of early-stage conflicts that can jeopardize project viability, juxtaposed with the late-stage conflicts that can invigorate participation and expedite project success. Our findings highlight the critical role of conflict timing, offering a nuanced understanding of how external pressures can serve as a catalyst for engagement and innovation in collaborative endeavors. This research not only contributes to the discourse on conflict management within project management literature but also offers practical insights for navigating the complexities of collaborative project dynamics in the face of external challenges.

4 - How Women Promote Greater Social Responsibility on Social Media

Kejia Hu, Oxford University, Oxford, United Kingdom, Huibin Du, Lu Kong, Xiang Li

Problem definition: Social media is a platform for equal expression, with women significantly influencing social engagement. However, little research explores whether women's voices on social media lead to greater social responsibility contributions.

Academic/Practical relevance: This research expands the Individual Social Responsibility (ISR) discourse by highlighting ordinary women's role in promoting social responsibility through social media. The findings offer strategic insights for Corporate Social Responsibility (CSR), crisis management, and customer relationship management (CRM).

Methodology: Using two datasets from Sina Weibo, the study employs propensity score matching (PSM) and regression models to analyze gender differences in posting behaviors that promote social responsibility. The primary dataset consists of 225,974 original posts related to 26 public emergencies from 2017 to 2020, while the second captures user characteristics from 10 million historical posts of 138,282 users.

Results: Women post about public emergencies on social media more promptly than men, with posts appearing an average of 29 minutes earlier. Women's posts generate higher engagement, receiving 24.2% more reposts and 18.8% more comments than men's. Higher engagement is due to gender homophily, women's central positions in social networks, and their tendency to create original content, enhancing their effectiveness in promoting social responsibility.

Managerial implications: Firms should involve female employees in public relations and social media teams to enhance communication strategies. Social media platforms and policymakers should refine algorithms and policies to ensure equitable representation of women's voices, especially in discussions on social responsibility, optimizing organizational responses during emergencies.

1 - Should I Curate or Not: A Game-theoretic Analysis of P2P Resale Marketplaces

Aditya Vedantam, State University of New York at Buffalo, Williamsville, NY, United States, Emre Demirezen, Subodha Kumar

The second-hand or resale market (ranging from automotive, luxury watches, clothing, and furniture among others) is growing rapidly. However, the growth of online marketplaces has also come with concerns around increasing amount of low quality and defective products being sold over resale marketplaces. In this paper we contrast two strategies adopted by peer-to-peer (P2P) in third party resale marketplaces: to curate used products by quality (e.g., thredUP), or not curate by quality (e.g., Tradesy, Poshmark). We investigate profitability and social welfare implications of quality curation and provide prescriptions for policymakers debating about regulating low quality and defective items on third party marketplaces.

2 - Sustainability Label: Product Quality Uncertainty and Post-Purchase Behaviors

Hyunsuk Baek, Arizona State University, Tempe, AZ, United States

We study how the quality uncertainty of a CSR-labeled product affects consumer's return and future purchase intention for another CSR-labeled product. We develop an analytical model which describes consumer's three sequential choices, with psychological factors, CSR belief and moral credit. We conduct a sequential discrete choice experiment while measuring participants' CSR belief and moral credit, in order to provide verified insight.

3 - Does Blockchain Facilitate Responsible Sourcing? An Application to the Diamond Supply Chain

Dmitrii Sumkin, University of Illinois at Urbana-Champaign, Urbana-Champaign, IL, United States, Sameer Hasija, Serguei Netessine

Blockchain technology has become widely accepted to demonstrate the provenance of physical goods, but there are open questions about its practical implementation and overall effect on ethical sourcing. In the diamond industry, blockchain enables credibility of the certificate of origin and therefore, allows to charge a premium for responsibly produced goods. Thus, one would expect blockchain to be the enabler of responsible sourcing. Using a stylized economic model, we demonstrate that, counter-intuitively, blockchain implementation may reduce incentives for customers to resell diamonds on the secondary markets and increase the cost of market segmentation. As a result, blockchain implementation could change a retailer's market segmentation strategy by increasing incentives to source from non-responsible suppliers. We also demonstrate that to reduce unintended consequences of blockchain implementation, the social planner should offer blockchain as an option (and not as a requirement) to a retailer. This work shows that caution is needed with wide-scale blockchain implementation. Although it is commonly recognized that blockchain's major application is in enhancing the traceability of durable goods or goods that should have a responsible supplier, we show that, in contrast, when factors of durability and responsibility come together, blockchain may negatively influence the responsibility level.

4 - Playing Fair? Environmental Impacts and Practices of Facilities in Minority Communities

Abhinav Shubham, Georgia Institute of Technology, Atlanta, GA, United States, Ravi Subramanian

Drawing on comprehensive US EPA and Census data, we examine the association between presence of substantial racial minority populations in host communities and facility-level environmental impacts and impact-reduction strategies. Our findings offer evidence for firms and policy makers to consider fairness and equity in managing and regulating environmental risks.

5 - Sustainability ratings in the supply chain

Junfei Lei, INSEAD, FONTAINEBLEAU, France

We study a novel business model in which a rating firm provides sustainability ratings for suppliers upon request of the buyers to minimize business risk under future regulation. The rating firm charges the suppliers and the buyers for the rating and endogenously determines what qualifies a supplier to be sustainable. The suppliers and buyers self-select whether to join the rating firm system. We identify conditions under which the rating firm drives a sustainable performance (by setting a stringent sustainability metric or by helping suppliers improve) and how system parameters (i.e., inherent risk, improvement costs, the magnitude of buyer-supplier transaction, and underlying uncertainty in sustainability performance) affect the same. We provide recommendations for the rating firm, capital markets, and policy.

Optimization

Chair: Oktay Gunluk, Georgia Tech, Atlanta, GA, United States

1 - Wasserstein Distributionally Robust Optimization with Heterogeneous Data Sources

Daniel Kuhn, Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland

We study decision problems under uncertainty, where the decision-maker has access to K data sources that carry biased information about the underlying risk factors. The biases are measured by the mismatch between the risk factor distribution and the K data-generating distributions with respect to an optimal transport (OT) distance. In this situation the decision-maker can exploit the information contained in the biased samples by solving a distributionally robust optimization (DRO) problem, where the ambiguity set is defined as the intersection of K OT neighborhoods, each of which is centered at the empirical distribution on the samples generated by a biased data source. We show that if the decision-maker has a prior belief about the biases, then the out-of-sample performance of the DRO solution can improve with K—irrespective of the magnitude of the biases. We also show that, under standard convexity assumptions, the proposed DRO problem is computationally tractable if either K or the dimension of the risk factors is kept constant.

2 - Fantastic Lifts and Where to Find Them: Using Smooth Parametrizations for Nonsmooth Optimization

Eitan Levin, Caltech, Pasadena, CA, United States

Many optimization problems are reformulated via smooth parametrizations, or lifts, of their domains. Examples include optimization over low rank matrices and tensors by optimizing over a factorization, the Burer--Monteiro approach to low rank semidefinite programs, and training neural networks by optimizing over their weights and biases. Such lifts give rise to two optimization problems, one optimizing a smooth cost function over a nonsmooth domain, and the other minimizing the composition of that cost with a lift map over a smooth manifold. The latter problem is smooth, and can be tackled with standard algorithms which may find various desirable points, like local minima or stationary points. In this talk, we ask when do these desirable points for the smooth problem map to desirable points for the nonsmooth problem. Remarkably, we show that the relationships between the two sets of desirable points is often independent of the cost function, and is rather a geometric property of the lift map itself. We therefore introduce a framework to study the effects of lifts on landscapes, and discuss its implications for the above examples.

3 - Asymptotic Normality and Optimality in Nonsmooth Stochastic Optimization

Liwei Jiang, Georgia Institute of Technology, Atlanta, GA, United States

In their seminal work, Polyak and Juditsky showed that stochastic gradient descent (with averaging) for minimizing smooth strongly convex functions enjoys a central limit theorem. Moreover, it has since been argued that the asymptotic covariance of the method is best possible among any estimation procedure in a local minimax sense of Hájek and Le Cam. A long-standing open question in this line of work is whether similar guarantees hold for important constrained/non-smooth problems, such as stochastic nonlinear programming. In this talk, we show that this is indeed the case.

Network Flows and Parametric Cuts in Machine Learning and Advanced Optimization

Invited Session

OPT: Computational Optimization and Software

Chair: Dorit Hochbaum, UC Berkeley, Berkeley, CA, United States

1 - A Fast and Effective Breakpoints Algorithm for the Quadratic Knapsack Problem

Dorit Hochbaum, UC Berkeley, Berkeley, CA, United States

The maximum Quadratic knapsack problem (QKP) is to select from a given set of elements a subset of total cost bounded by a given budget, so that the sum of pairwise utilities of the pairs of selected elements and singleton utilities is maximized. We introduce here the Breakpoints algorithm for QKP, QKBP, that generates the concave piecewise linear envelope of the solutions to the relaxation of the problem for all values of the budget. The breakpoints in the concave envelopes are provably optimal solutions for the respective budgets, and for consecutive breakpoints the respective solutions are nested. For a given budget that falls between breakpoints we apply a simple greedy procedure that generates fast and high quality solutions. The breakpoints algorithm is highly scalable since the breakpoints and the concave envelope are attained using a parametric cut procedure that is very efficient. The performance of the parametric cut is further enhanced by a compact formulation of the problem. An extensive computational study presented here demonstrates that QKBP delivers consistently high quality solutions on known collections of benchmark instances, with much faster run times than state-of-the-art techniques. For newly introduced collections and large scale benchmark instances, the breakpoints algorithm delivers solutions that other state-of-the-art methods are either incapable of solving, or deliver poor quality even when provided with high time limits. All the benchmarks, algorithms used and results are publicly available on Github.

2 - Automatic Algorithm Selection for Pseudo-Boolean Optimization with Given Computational TIME Limits

Catalina Pezo Vergara, University of California, Berkeley, Berkeley, CA, United States, Dorit Hochbaum, Julio Godoy, Roberto Asín-Achá

Machine learning techniques have been proposed to automatically select the best solver from a portfolio of solvers, for a given problem. These techniques are used to implement meta-solvers that receive, as input, the instance of a problem, predict the best-performing solver in the portfolio, and execute it to deliver a solution. Typically, the quality of the solution improves with a longer computational time. This has led to the development of anytime meta-solvers, which consider both the instance and a user-prescribed computational time limit. Anytime meta-solvers predict the best-performing solver within the specified time limit.

This presentation will focus on the design of anytime meta-solvers for the NP-hard optimization problem of Pseudo-Boolean Optimization (PBO), which generalizes Satisfiability and Maximum Satisfiability problems. We demonstrate via extensive empirical study that our anytime meta-solver, named PBO_MS, improves dramatically on the performance of Mixed Integer Programming solver Gurobi, which is the best-performing single solver in the portfolio. We then generalize the anytime meta-solver by predicting a given number $p \geq 1$ of best solvers in the portfolio and run these sequentially, each with equal share of the specified time limit. The outcome is the best (minimum) objective function value obtained by any of the predicted solvers. This anytime p-meta-solver is shown here to outperform both the anytime 1-meta-solver as well as a fixed selection of solvers by a wide margin.

3 - Positive-Unlabaled Learning with Pairwise Similarity and Parametric Minimum Cut

Torpong Nitayanont, UC Berkeley, Berkeley, CA, United States, Dorit Hochbaum

Positive-unlabeled (PU) learning is a binary classification problem in which the labeled set only consists of samples from the positive class. The unlabeled set is a mixture of samples from positive and negative classes. In this work, we solve the PU learning problem using a network flow-based method called Hochbaum's Normalized Cut (HNC). HNC partitions samples, both labeled and unlabeled, into two groups to achieve high intra-similarity within groups and low inter-similarity between the two, with a tradeoff parameter that balances the two objectives. The problem is solved as a parametric minimum cut on an associated graph representation, producing different optimal partitions for different tradeoff parameters. Among all the generated cuts, we select one of them based on the prior information on the positive percentage, which is provided to most PU learning methods. Our proposed method works even when we have access to a limited number of labeled samples, and when the labeled set comes from only one class. When needed, reliable negative samples can be extracted from the unlabeled set. Our experimental study shows that HNC achieves competitive results compared to other state-of-the-art PU learning methods.

4 - The Max-Cut Decision Tree: Improving on The Accuracy and Running TIME of Decision Trees and Random Forests

Jonathan Bodine, UC Berkeley, Berkeley, CA, United States, Dorit Hochbaum

The Max-Cut decision tree involves novel modifications to a standard decision tree implementation, which is a widely used method of classification. It is implemented with the novel Maximum Cut splitting metric, maximally separating observations of different classes along locally meaningful representations of the input features. Experiments show these modifications can dramatically improve classification accuracy, while significantly decreasing computational time. The Max-Cut decision tree is expected to dramatically advance decision trees, with experimental extensions to random forests.

Machine Learning for Optimization - II

Invited Session

OPT: Machine Learning

Chair: Gonzalo Constante Flores, Purdue University, West Lafayette, IN, United States

1 - From Inverse Optimization to Feasibility to Erm

Sharan Vaswani, Simon Fraser University, Vancouver, BC, Canada, Saurabh Mishra, Anant Raj

Inverse optimization involves inferring unknown parameters of an optimization problem from known solutions and is widely used in fields such as transportation, power systems, and healthcare. We study the contextual inverse optimization setting that utilizes additional contextual information to better predict the unknown problem parameters. We focus on contextual inverse linear programming (CILP), addressing the challenges posed by the non-differentiable nature of LPs. For a linear prediction model, we reduce CILP to a convex feasibility problem allowing the use of standard algorithms such as alternating projections. The resulting algorithm for CILP is equipped with a linear convergence guarantee without additional assumptions such as degeneracy or interpolation. Next, we reduce CILP to empirical risk minimization (ERM) on a smooth, convex loss that satisfies the Polyak-Lojasiewicz condition. This reduction enables the use of scalable first-order optimization methods to solve large non-convex problems while maintaining theoretical guarantees in the convex setting. Finally, we experimentally validate our approach on both synthetic and real-world problems and demonstrate improved performance compared to existing methods.

2 - Towards Practical Physics-Informed ML Design and Evaluation for Power Grid

Amritanshu Pandey, University of Vermont, Burlington, VT, United States, Shimiao Li, Larry Pileggi

When applied to a real-world safety critical system like the power grid, general machine learning methods suffer from expensive training, non-physical solutions, and limited interpretability. To address these challenges for power grids, many recent works have explored the inclusion of grid physics (i.e., domain expertise) into their method design, primarily through including system constraints and technical limits, reducing search space and defining meaningful features in latent space. Yet, there is no general methodology to evaluate the practicality of these approaches in power grid tasks, and limitations exist regarding scalability, generalization, interpretability, etc. This work formalizes a new concept of physical interpretability which assesses how a ML model makes predictions in a physically meaningful way and introduces an evaluation methodology that identifies a set of attributes that a practical method should satisfy. Inspired by the evaluation attributes, the paper further develops a novel contingency analysis warm starter for MadIoT cyberattack, based on a conditional Gaussian random field. This method serves as an instance of an ML model that can incorporate diverse domain knowledge and improve on these identified attributes. Experiments validate that the warm starter significantly boosts the efficiency of contingency analysis for MadIoT attack even with shallow NN architectures.

3 - Self-Supervised Learning for Constrained Optimization with Hard Linear Constraints

Hao Chen, Purdue University, West Lafayette, IN, United States, Gonzalo Constante Flores, Can Li

Over recent years, the success of machine learning has sparked a growing interest in leveraging neural networks to efficiently predict near-optimality yet feasible (or close-to-feasible) solutions. However, it is challenging to generate datasets of large optimization instances and strictly guarantee the feasibility of model inference. In this talk, we present a novel self-supervised and hard-constrained learning method by incorporating the proximal gradient descent algorithm into the deep learning framework. This approach ensures hard constraints by alternating two types of projection layers in the neural network, which always converges to a feasible point. This eliminates the need for optimal solutions of large optimization instances in the loss function and allows for self-supervised learning. The proposed model is demonstrated in some benchmarks, such as DC optimal power flow (DCOPF), exhibiting excellent performance in terms of optimality gap and solution feasibility. Model inferences on any incoming instance strictly satisfy linear constraints through projections with controllable violations and can be provided instantly through GPUs. Our numerical experiments indicate that these approximations are remarkably close to the optimal solutions, suggesting that the approach offers a reliable and efficient way to address large but time-sensitive linearly constrained optimization problems.

4 - Fully First-Order Methods for Constrained Bilevel Optimization

Kai Wang, Georgia Institute of Technology, Atlanta, GA, United States, Guy Kornowski, Swati Padmanabhan, Zhe Zhang, Suvrit Sra

Algorithms for bilevel optimization often encounter Hessian computations, which are prohibitive in high dimensions. While recent works offer first-order methods for unconstrained bilevel problems, constrained bilevel optimization remains relatively underexplored. We present the first fully first-order constrained optimization methods with finite-time hypergradient stationarity guarantees. For linear equality constraints, our algorithm converges to an ε-stationary point in $\widetilde{O}(ε-2)$ gradient oracle calls, which is nearly-optimal. For general convex inequality constraints, we attain (δ,ε)-Goldstein stationarity in either $\widetilde{O}(δ-1ε-4)$ or $\widetilde{O}(d{δ-1ε-3)$ gradient oracle calls, where d is the upper-level dimension. Along the way, we develop novel nonsmooth nonconvex optimization methods with inexact oracles. Our preliminary numerical experiments verify these theoretical convergence guarantees.

Recent Advances in Data-driven Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Siva Ramani, Rice University, Houston, TX, United States

1 - Robustness Versus Statistical Efficiency: Superiority of Naive Optimization via Worst-Case Stochastic Dominance

Arindam Roy Chowdhury, Columbia University, New York City, NY, United States, Henry Lam

Many decision-making tasks give rise to optimization problems with uncertainty in the underlying parameter or probability distribution. This uncertainty can arise from statistical noises due to limited data, or non-stationary parameter shifts that are not predictable from the past. In the literature, various approaches ranging from (distributionally) robust optimization to regularization have been proposed, as attempts to obtain solutions that perform well statistically or robustly against model shifts. Contrary to common belief, we show that, in terms of the behavior of regret or optimality gap, a naive optimization formulation based on empirical or simple point estimate of the uncertain parameter is in a sense optimal, regardless of whether the uncertainty comes from statistical noises, unpredictable shifts, or both. Our superiority assertion for naive optimization is based on a new notion of worst-case stochastic dominance for the asymptotic regret, and is argued via what we call the "symmetry" of uncertainty that applies universally over statistical errors, adversarial errors, and their interactions. We show how our results apply to the comparisons among a wide range of existing data-driven and robust optimization formulations.

2 - Approximation Algorithms for Distributionally-Robust Combinatorial Optimization

Chaitanya Swamy, University of Waterloo, Bangalore, ON, Canada, Andre Linhares

In two-stage stochastic optimization, we have a probability distribution over possible realizations of the data, and we seek to take decisions both before and after a scenario is realized to typically minimize the total expected cost. We consider the popular distributionally-robust paradigm: we are now given a collection \C of distributions, and the goal is to minimize the maximum expected total cost with respect to a distribution in \C. There has been almost no prior work on developing approximation algorithms for distributionally-robust combinatorial-optimization problems, wherein the scenario-set is discrete and the underlying deterministic problem is often NP-hard. We provide a framework for designing approximation algorithms in such settings when the collection \C is a ball around a central distribution accessible only via a sampling black box. We devise

algorithms that draw polynomially many samples and return solutions with provable worst-case quality guarantees. We show that an LP-relaxation of the problem can be reduced to a standard 2-stage problem, which can then be (approximately) solved given an (approximation) algorithm for a certain max-min problem akin to the problem of finding the worst-case scenario in robust optimization. Complementing this with LP-rounding ideas, we obtain the first approximation algorithms for various distributionally-robust combinatorial-optimization problems including set cover, facility location, Steiner tree. Our guarantees are often within O(1)-factors of the guarantees known even for the deterministic version of the problem.

3 - A Unified Framework to Obtain Data-Driven Performance Guarantees for Robust Markov Decision Processes

Siva Ramani, University of Washington, Seattle, WA, United States

We introduce a family of distance-based s-rectangular robust MDPs (s-RMDPs), where in each state, the ambiguity set equals a sublevel set of the norm of a vector of distances from reference pmfs. The construction ensures that the distance-based (s,a)-rectangular robust MDP ((s,a)-RMDP) is contained within this family. In the first part, we rigorously analyze the relative conservativeness between (s,a)- and s-RMDPs in the non data-driven context. Next, we study the data-driven versions of our s-RMDPs. Under a unifying framework, we prove that our s-RMDPs satisfy all the data-driven performance guarantees that are deemed essential for any data-driven optimization framework. Moreover, this framework enables us to make sharp comparisons between (s,a)- and s-RMDP in the data-driven setup. An artifact of the analyses behind these guarantees is the surprising conclusion that (s,a)-RMDPs might be the least conservative among all s-RMDPs within our family. Finally, we compare our data-driven robust framework with other data-driven approaches for MDPs.

4 - Multistage Chance-Constrained Programming

Soumya Ranjan Pathy, Clemson University, Clemson, SC, United States, Hamed Rahimian

In this talk, we study multistage chance-constrained programming, a critical area in optimizing decision-making under uncertainty. Our analysis considers two possibilities for enforcing chance constraints in the model: (i) constraints that are statically enforced only at the end of the planning horizon and (ii) constraints that are dynamically enforced throughout the planning horizon. We introduce novel decomposition-based computational approaches for solving such complex problems. Using a stylized inventory management problem, we demonstrate preliminary computational results that highlight the efficacy and potential of our proposed methods. Furthermore, we provide a comparative analysis of the outcomes derived from a multistage policy against those obtained from a conventional two-stage multiperiod model. This discussion emphasizes the added value and strategic advantage of implementing a multistage approach in real-world applications.

5 - Light Pareto Robust Optimization for Radiotherapy Treatment Planning

Houra Mahmoudzadeh, University of Waterloo, Waterloo, ON, Canada, Fahimeh Rahimi, Danielle Ripsman, Hossein Abouee Mehrizi

Robust optimization (RO) is well-known for immunizing operators against worst-case uncertainty realizations. The RO methodology, however, neglects non-worst-case scenarios, potentially leading to overly-conservative solutions. Pareto robust optimization (PRO) further optimizes for non-worst-case scenarios, generating robust solutions that may be less conservative for non-worst-case uncertainty realizations. In this paper, we extend the theory of PRO to practical settings where expert knowledge on likely scenarios exists. We define and characterize superior PRO solutions and develop algorithms that can partition the set of RO solutions to determine the Pareto robust frontier of superior PRO solutions. To further reduce the level of conservatism of the PRO solutions, we also introduce the concept of light PRO solutions, which sacrifice some worst-case performance to improve non-worst-case behavior while maintaining robustness guarantees. We quantify the gain in non-worst-case performance as a function of worst-case loss, discuss the theoretical properties of this gain function, and analyze the trade-off between worst-case optimality and non-worst-case performance.
We apply these methods to a radiation therapy planning problem for breast cancer patients. The proposed approach is shown to significantly improve the quality of treatment plans in non-worst-case scenarios while maintaining robustness and limiting the optimality sacrificed in the worst-case outcomes.

Advances in Stochastic Programming: Theory and Applications

Invited Session

OPT: Optimization Under Uncertainty

Chair: Hanbin Yang, Chinese Universtiy of Hong Kong, Shenzhen, Shenzhen, N/A

1 - Enhanced Lagrangian Cuts for Multi-Stage Stochastic Mixed-Integer Programs

Hanbin Yang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Haoxiang Yang

This work addresses multi-stage stochastic mixed-integer linear programming (MS-MILP) with general mixed-integer state variables. We demonstrate that while vanilla Lagrangian cuts can approximate the convex envelope of value functions, they can be steep and fail to define a facet of this envelope. To overcome this limitation, we introduce enhanced Lagrangian cuts and an innovative iterative lifting/branching procedure. These enhanced cuts are obtained through a geometric approach linking the epigraph of value functions to cutting-plane methods, enabling the generation of tight Pareto-optimal cuts. Consequently, our method provides a superior lower approximation with fewer cuts. Moreover, we propose a convergent decomposition algorithm incorporating these enhanced cuts, making feasible the challenging task of solving general MS-MILP. Our computational results reveal the efficacy of the enhancement techniques: the proposed algorithm consistently achieves a small optimality gap within an acceptable time frame, marking a significant advancement in tackling MS-MILP problems.

2 - Equilibrium Existence and Algorithm of Discounted Non-Zero-Sum Stochastic Game Between Risk-Averse Players

Yufeng Gao, the University of Hong Kong, Hong Kong, Hong Kong

This paper presents a model for n-risk-averse-player finite state/action stochastic games. We consider non-zero-sum discounted stochastic games with uncertainty from both supply and demand, where players have risk-averse attitudes towards uncertainty. The measure of risk is conditional value-at-risk (CVaR). We prove the existence of equilibrium without complexity assumptions, and propose an algorithm to calculate equilibrium points. The algorithm is compared with traditional best response algorithm over multi-dimension performance.

3 - Dynamic Closed-Loop Supply Chain Network Design and Operations for Electric Vehicle Battery

Wentao Zhao, University of Southern California, Los Angeles, CA, United States, Maged Dessouky, Randolph Hall

Large-scale adoption of electric vehicles (EVs) can reduce greenhouse gas emissions and improve air quality. Nonetheless, a significant amount of EV batteries are expected to retire within five years, posing environmental and economic challenges regarding management and disposal. Implementing a closed-loop supply chain (CLSC) network is a promising strategy. The core idea is to enhance battery utilization and reuse valuable resources. In this work, we develop a bi-level computational framework for the dynamic CLSC network design and operations problem where two levels of decisions in different time resolutions are periodically optimized. At the upper level, we formulate a stochastic dynamic programming model to design a capacity expansion and facility-building policy for the CLSC to cope with the uncertainties from markets and politics. At the lower level, we formulate a stochastic multi-stage stochastic programming model to optimize the daily operations of the CLSC and maximize the overall revenue under demand and supply uncertainties. A heuristic approach is proposed to solve large-scale problems. The proposed heuristic is a local search algorithm embedded with sample average approximation. Lastly, we use real-world datasets to validate the model and demonstrate the solution approach.

4 - Multiscale Stochastic Programming with Applications on Power Systems

Yihang Zhang, University of Southern California, Los Angeles, CA, United States, Suvrajeet Sen

We introduce a multiscale stochastic programming framework tailored for power systems with high renewable penetration. This framework addresses the multiscale uncertainties inherent in renewable energy sources. Our approach employs multiscale modeling techniques to capture the dynamics of conventional and renewable generators as well as demand patterns across various scales. This enables us to form detailed operational strategies for short-term periods while maintaining a broader perspective for long-term planning. To coordinate decisions across different timescales in a manageable way, we introduce a context mechanism similar to the state concept in dynamic programming. Additionally, we propose a practical scenario-based decomposition method for efficient computational implementation.

Recent Advances in Min-Max Optimization

Invited Session

OPT: Nonlinear Optimization

Chair: Mert Gurbuzbalaban, Rutgers University, Piscataway, NJ, United States

Co-Chair: Necdet Aybat, Penn State University, University Park, PA, United States

1 - AGDA+: Proximal Alternating Gradient Descent Ascent Method with Backtracking for Double-regularized Nonconvex-Strongly Concave Minimax Problems

N. Serhat Aybat, Penn State University, University Park, PA, United States

We consider double-regularized weakly convex-strongly concave (WCSC) minimax problems of the form (P) : min_x max_y g(x) + f (x, y) − h(y), where g, h are closed convex, f is L-smooth in (x, y) and (strongly) concave in y. We propose a proximal alternating gradient descent ascent method AGDA+ that can adaptively choose primal-dual stepsizes to compute an approximate stationary point for (P) without requiring the knowledge of the global Lipschitz constant L. This algorithm stands out by its ability to exploit the local Lipschitz structure and eliminates the need for precise tuning of hyper-parameters. AGDA+ achieves the optimal iteration complexity of O(eps^−2) with the best O(1) constant among the existing methods agnostic to L. The numerical experiments demonstrate its robustness and efficiency in both deterministic and stochastic scenarios. To the best of our knowledge, this is the first single-loop backtracking method for solving WCSC minimax problems.

2 - High probability and risk-averse guarantees for stochastic saddle point problems

Mert Gurbuzbalaban, Rutgers University, Piscataway, NJ, United States

We first consider stochastic strongly-convex-strongly-concave (SCSC) saddle point (SP) problems which frequently arise in applications ranging from distributionally robust learning to game theory and fairness in machine learning. We focus on the recently developed stochastic accelerated primal-dual algorithm (SAPD), which admits optimal complexity in several settings as an accelerated algorithm. We provide high probability guarantees for convergence to a neighborhood of the saddle point that reflects accelerated convergence behavior. We also provide an analytical formula for the limiting covariance matrix of the iterates for a class of stochastic SCSC quadratic problems where the gradient noise is additive and Gaussian. This allows us to develop lower bounds for this class of quadratic problems which show that our analysis is tight in terms of the high probability bound dependency to the parameters. We also provide a risk-averse convergence analysis characterizing the ``Conditional Value at Risk", the ``Entropic Value at Risk", and the χ2-divergence of the distance to the saddle point, highlighting the trade-offs between the bias and the risk associated with an approximate solution obtained by terminating the algorithm at any iteration.

3 - A Stochastic GDA Method With Backtracking For Solving Nonconvex (Strongly) Concave Minimax Problems

Qiushui Xu, Penn State University, State College, PA, United States

We propose a stochastic GDA method with backtracking (SGDA-B) to solve nonconvex-strongly-concave minimax problems $\min_x \max_y \sum_{i=1}^N g_i(x_i)+f(x,y)-h(y)$, where $\{g_i\}_{i=1}^N$, h are closed convex, and f is L-smooth and μ-strongly concave in y. We assume that one only has an access to an unbiased stochastic oracle of ∇f with a finite variance. Without requiring to know L, SGDA-B using random block-coordinate updates can compute an ϵ-stationary point within $\mathcal{O}(L\kappa^3 \epsilon^{−4} log(1/p))$ stochastic oracle calls, with probability at least 1−p, where $kappa=L/\mu$. We provide numerical results for SGDA-B on a distributionally robust learning problem.

4 - High probability bounds for stochastic non-convex mini-max optimization

Yasa Syed, Rutgers University, Piscataway, NJ, United States

Stochastic min-max optimization is prevalent across various disciplines, from engineering to game theory and machine learning. Despite recent progress, satisfactory high-probability guarantees for non-convex mini-max problems still do not exist to our knowledge. We will provide first-time high-probability guarantees for NC-PL mini-max problems (where the objective is non-convex with respect to the primal variable and satisfies a Polyak-Łojasiewicz (PL) inequality in the dual variable) and illustrate the results on several numerical examples including distributionally robust learning.

Learning in Transportation Network Modeling

Invited Session

TSL: Intelligent Transportation Systems

Chair: Zhichen Liu, University of Michigan, Ann Arbor, United States

Co-Chair: Minghui Wu, University of Michigan, Ann Arbor, MI, United States

1 - An Unsupervised Learning-Based Branch-and-Price With Neural-Cuts Framework to Solve Dial-A-Ride Problem

Xinwu Qian, Rice University, Houston, TX, United States

The study presents the Neural Branch-Price-and-Cut (NeuralBPC) method, an ML-based approach that optimizes the Column Generation (CG) method by introducing Neural Cuts. Utilizing a Graph Neural Network (GNN) with an unsupervised learning model and a probabilistic loss function, this method overcomes traditional sample collection bottlenecks in ML solutions for optimization problems, which requires to completely solve the NP-hard problems as labels. The NeuralBPC uses previously generated columns and passenger-conflicting graphs to forecast effective cutting planes for the Restricted Master Problem (RMP), effectively reducing the search space of the Pricing Sub-Problem (SP), generating high-quality solutions with fewer CG iterations. By exploiting the iterative nature of CG for sample collection, the algorithm dynamically produces the most effective Neural Cuts, demonstrated through case studies on variants of Dial-a-Ride Problems (DARPs), enhancing solution quality and minimizing computational times.

2 - Learning from Global Satellite Imagery and Local Sensor Data for Enhanced Dynamic Origin-Destination Demand Estimation

Jiachao Liu, Carnegie Mellon University, Pittsburgh, PA, United States

The utilization of high-resolution satellite imagery is an increasingly prominent trend in transportation science, offering the potential to enhance existing dynamic network models and address the limitations of traditional data sources. Satellite images provide comprehensive coverage and detailed insights into road networks, traffic patterns, and infrastructure at a global scale that was previously unachievable with data collected from local sensors. A primary challenge lies in developing a robust calibration framework (i.e., dynamic origin-destination demand estimation, DODE) for large networks that effectively integrates traffic state information (i.e., traffic density) obtained from satellite imagery with other data sources (i.e., traffic count, speed). This study proposes a computational-graph-based DODE framework leveraging multi-source data including traffic densities derived from satellite images and explores the benefits of incorporating satellite imagery into model calibration through numerical experiments using both synthetic and real-world data.

3 - Linear Complementarity Systems for the Morning Commute Problem with Ridesharing and Dynamic Pricing

Wei Gu, University of Southern California, Los Angeles, CA, United States

Since Vickrey (1969), the morning commute problem has been studied for more than fifty years. The emerging ridesharing services and relevant infrastructures, such as High-Occupancy Toll (HOT) lanes, provide more flexibility for travelers, more opportunities for sustainable transportation systems, and at the same time, more challenges for this classical problem. To capture traffic dynamics, we propose a modified bottleneck model that avoids time-delayed terms in computing travel times and maintains desired mathematical properties. Then we develop a general mathematical modeling framework for the morning commute problem with ridesharing, including travel modes, infrastructures, and businesses. Formulated as Linear Complementary Systems (LCS), the proposed model simultaneously captures travelers' departure time choice, lane choice between HOT lane and general purpose lane, as well as mode choice between ridesharing and solo driving. We provide rigorous analysis of solution existence for the LCS-based general modeling framework. To approximate the proposed continuous-time model, discrete-time model is generated using an implicit time discretization scheme, with the theoretical guarantee to converge back to the original continuous-time form. Analytical solutions for dynamic prices, including drivers' incomes, passengers' payments, and HOT lane toll charges, are derived to balance the various demands of travelers, company, and society. The proposed models and dynamic pricing strategies are validated in numerical examples. Results show that our proposed methodology simultaneously benefits travelers, company, and society toward urban sustainability through ridesharing: smaller travel costs, positive cash flow for ridesharing businesses, and better system performance.

4 - Designing Robust Transportation Networks with Imperfect User Equilibrium Predictions

Zhichen Liu, University of Michigan, ANN ARBOR, MI, United States, Yafeng Yin

Forecasting current user equilibria accurately is challenging, and predictions based on current data often fail to align with actual future user equilibria, which are benchmarks for long-term transportation network design. This study proposes a robust network design framework that accommodates potential deviations between predicted and actual future equilibria. The optimized design from this framework ensures performance on the actual user equilibria despite the nonconvexity of the design problem. Moreover, to adapt this framework for real-world-sized road networks, we propose a novel computational-graph-based solution algorithm. This algorithm enables the efficient parallel computation of uncertain user equilibrium constraints and facilitates scalability.

Human-centric Warehouse and Order Fulfillment Operations

Invited Session

TSL: Facility Logistics

Chair: Junsu Kim, Inha University, Incheon, Korea, Republic of

Co-Chair: Junsu Kim, Inha University, Incheon, Korea, Republic of

1 - Can Collaborative Robotic Solutions Make Store Fulfillment Economically Viable?

Joyjit Bhowmick, Rensselaer Polytechnic Institute, Troy, NY, United States, Jennifer Pazour, Iman Dayarian, Sebastian Köhler, Gideon Arndt, Kai Furmans

Omnichannel services, such as buy-online-pickup-in-store, curbside pickup, and ship-from-store, have shifted the order-picking tasks previously completed by in-store customers doing their own shopping to the retailer's responsibility. To fulfill these orders, many retailers have deployed a store fulfillment strategy, where online orders are picked from brick-and-mortar retail store shelves. However, low profit margins, labor shortages, and increasing labor costs make it difficult for stores to cost effectively to fulfill online orders through store fulfillment. Motivated by this challenge, we explore two order-picking system designs where collaborative robotic solutions augment the picking process of dedicated employees. The first deploys autonomous mobile robots (AMRs) synchronizing with in-store customers to pick online items, where the availability of in-store customers is stochastic and in-store customers are compensated for their picking effort. In the second, a modular and moveable robotic platform with a picking arm is deployed in the store having the ability to perform order picking and replenishment. We create operational and economic models that are fed with empirical data for shopping behavior and actual online orders to illustrate that order-picking policies with such automated solutions are operationally and economically viable, whether the store purchases the robots upfront or follows a subscription based approach taking wages, benefits, automated solution investments, maintenance, customer compensation, and customer hassle into consideration.

2 - An experimental study of large language model for human interactive robots in a warehouse management

HanByul Ryu, Inha University, Incheon, Korea, Republic of, Daisik Nam

To address the increasing demand in logistics and ensure efficient logistics operations, warehouses are being automated. While logistics robots are being utilized as one of the strategies for automation, they lack flexibility compared to human workers, making efficient operations challenging. Consequently, human intervention is frequently required even within automated systems. This study proposes the utilization of Large Language Models (LLMs) as an intermediate solution to address collaboration between robots and workers and introduces its framework. LLMs like GPT utilize advanced artificial intelligence techniques to effectively interpret human instructions, offering the opportunity for flexible adaptation of robots within warehouse environments. Simultaneously, LLMs hold the potential to offer solutions for better warehouse operations such as save labors to control robots. This study discusses whether relying solely on LLMs for warehouse operations is feasible, or if a hybrid approach, integrating existing human control alongside tailored inputs for LLMs, would be more appropriate. The paper explores the potential benefits and challenges of each approach, aiming to provide insights into the most effective utilization of LLMs in warehouse management. This study can contribute to exploring collaborative approaches between humans and technology in warehouse operations before complete automation is achieved.

3 - The process of tailoring work schedules in warehouses considering the perceived physical fatigue levels

Junsu Kim, Inha University, Incheon, Korea, Republic of, Hosang Jung, SEUNGSIK OH

This study focuses on the process of tailoring work schedules for warehouse workers by incorporating their perceived physical fatigue levels. In light of the importance of understanding and mitigating workplace fatigue, we present a practical and systematic methodological framework for this process. This approach integrates survey-based fatigue measurements, regression analysis, and mathematical optimization modelling. A survey of order pickers in a South Korean order fulfillment center and the results of a corresponding regression analysis provide valuable insights regarding the process of tailoring work schedules to manage fatigue. Moreover, the optimization model, which takes into account realistic operational constraints, determines the duration of work cycles and the timing of work and break cycles. By using this regression model to inform the optimization model, we generate four distinct schedules that navigate between the goals of minimizing the average fatigue levels of workers and minimizing their final fatigue levels. The model's focus can be adjusted to suit practitioners' needs. After consulting with the center manager, we approved a schedule that focused on reducing workers' mean final fatigue levels. As compared to the current schedule, the selected new schedule reduced workers' final fatigue level by 11.5% when the same number of total hours were worked, thus highlighting the method's potential to enhance worker well-being.

4 - Optimization of Two-tier Robotized Sorting Systems for Parcel Delivery

Reem Khir, Purdue University, West Lafayette, IN, United States, Junsu Kim

This study addresses an operational planning challenge aimed at improving the parcel sortation process in two-tier robotized sorting systems, a forefront technology in e-commerce warehouse automation. The system's upper tier transports parcels from loading to drop-off points using autonomous mobile robots, while the lower tier organizes parcels into roll containers by their final destinations for loading onto outbound trucks. These processes are interconnected assignment problems, requiring holistic decision-making to maximize automation benefits and maintain productivity. We introduce a mixed-integer linear programming model to optimize operational coordination across the interdependent tiers, considering the incomplete information about parcel arrival sequences. By employing a tailored multiple-scenario approach, we develop the solution procedure to devise sortation plans that effectively manage the uncertainty of arrival sequences. The computational effectiveness of our approach remains robust even in larger-sized problem instances. Furthermore, our comprehensive analysis explores the value of information on incoming arrival sequences and the adaptability of assignment decisions, providing essential insights for managers at companies using or considering two-tier robotized sorting systems.

Summit - 429

Data-driven and Optimization Foundations for Emerging Mobility Systems

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Devansh Jalota, Stanford University, Stanford, CA, United States

Co-Chair: Matthew Tsao, Lyft, San Francisco, CA, United States

Co-Chair: Gioele Zardini, Stanford University, Stanford, United States

1 - Sustainability in Online Freight Marketplaces

Saurabh Amin, MIT, Cambridge, MA, United States, Maxime Bouscary, Mazen Danaf

Road freight transport moves about 26.8 trillion tonne-kilometers annually, mainly in trucks and delivery vehicles, emitting around 2.2 billion tonnes of CO_2. The trucking sector faces the dual challenges of increasing demand from e-commerce and on-time delivery services and supply-side constraints due to rising fuel costs and fledgling infrastructure to support electric trucks. We investigate the potential role of digital brokerage platforms in reducing both operational costs and empty miles by strategic bundling of loads and dynamic pricing over a finite horizon. Our approach accounts for the heterogeneities in carriers' arrival locations and preferences over quality and price of load bundles. We provide new asymptotically optimal bounds on the maximal expected revenue in this general setting and leverage these bounds to tractably select load bundles. We identify operational regimes under which optimally priced load bundles lead to simultaneous improvement in both platform revenue and carrier satisfaction, while reducing empty miles.

2 - Learning and Control for Safety, Efficiency, and Resiliency of Embodied AI

Fei Miao, University of Connecticut, Storrs, CT, United States

With rapid evolution of sensing, communication, and computation, integrating learning and control presents significant Embodied AI opportunities. However, current decision-making frameworks lack comprehensive understanding of the tridirectional relationship among communication, learning and control, posing challenges for multi-agent systems in complex environments. In the first part of the talk, we focus on learning and control with communication capabilities. We design an uncertainty quantification method for collaborative perception in connected autonomous vehicles (CAVs). Our findings demonstrate that communication among multiple agents can enhance object detection accuracy and reduce uncertainty. Building upon this, we develop a safe and scalable deep multi-agent reinforcement learning (MARL) framework that leverages shared information among agents to improve system safety and efficiency. We validate the benefits of communication in MARL, particularly in the context of CAVs in challenging mixed traffic scenarios. We incentivize agents to communicate and coordinate with a novel reward reallocation scheme based on Shapley value for MARL. Additionally, we present our theoretical analysis of robust MARL methods under state uncertainties, such as uncertainty quantification in the perception modules or worst-case adversarial state perturbations. In the second part of the talk, we briefly outline our research contributions on robust MARL and data-driven robust optimization for sustainable mobility. We also highlight our research results concerning CPS security. Through our findings, we aim to advance Embodied AI and CPS for safety, efficiency, and resiliency in dynamic environments.

3 - Combinatorial Optimization Augmented Machine Learning for Contextual Multi-Stage Problems

Maximilian Schiffer, Technical University of Munich, Munich, Germany

Combinatorial optimization augmented machine learning (COAML) is a novel field that combines methods from machine learning and operations research to tackle contextual data-driven problems that involve both uncertainty and combinatorics. These problems arise frequently in industrial processes, where firms seek to leverage large and noisy data sets to optimize their operations. COAML typically involves embedding combinatorial optimization layers into neural networks and training them with decision-aware learning techniques. This talk provides an overview of the underlying paradigm, algorithmic pipelines, and foundations based on selected application cases. Particularly, I will demonstrate the effectiveness of COAML on contextual and dynamic stochastic optimization problems, as evidenced by its winning performance on the 2022 EUROMeetsNeurIPS dynamic vehicle routing challenge.

4 - Markov Potential Games in on-Demand Mobility Services

Kenan Zhang, EPFL, Lausanne, Switzerland

Markov game is a game theoretical framework to describe the multi-agent interaction in a Markovian dynamic system. As a special case of Markov game, Markov potential game (MPG) features special properties on the agent utility such that finding the stationary Nash equilibrium can be reduced to solving a global optimization problem. In this talk, I will present our recent work on MPG in the context of on-demand mobility services and discuss how this framework facilitates the analysis of service design and operations, including market equilibrium, dynamic pricing, relocation incentives, etc.

Reliable and Scalable Urban Air Mobility

Invited Session

Aviation Applications

Co-Chair: Minghao Chen, Columbia University, 514 W 114 St, New York, 10025, United States

Co-Chair: Shulu Chen, George Washington University, Washington, DC, United States

1 - V-Hatt: An Integrated UAM Scheduling and Vertiport Management System

Shulu Chen, George Washington University, Washington, DC, United States

This paper presents the Vertiport Human Automation Teaming Toolbox (V-HATT), a novel framework for managing Urban Air Mobility (UAM) within terminal airspace and vertiports. V-HATT is designed to integrate the efforts of human vertiport operators with an automated system, enhancing scheduling and real-time operational control to establish a unified traffic management system. Utilizing the Helo Holdings, Inc. (HHI) Heliport as a case study, we demonstrate V-HATT's capability to effectively manage arrival and departure in densely populated urban airspaces such as New York City. The framework addresses all three critical phases of UAM operations: the planning phase focuses on the design of terminal airspace and vertiport layouts and on measuring airspace capacity; the scheduling phase employs mixed-integer linear programming (MILP) algorithms to optimize arrival and departure sequences and to efficiently manage vertiport ground resources on a rolling horizon, aiming to minimize delays and enhance the utilization of ground resources while considering specific constraints of vertiports and aircraft; the tactical operation phase supports the simulation of UAM operations in real-time and provides interfaces for human operators to issue maneuver advisories and adjust schedules to address unforeseen events. This integrative approach promises significant improvements in UAM efficiency, safety, and reliability, thereby contributing to the sustainable expansion of urban air transportation systems.

2 - A Hybrid Approach for in-Flight Li-Ion Battery Soc Prediction

Abenezer Taye, George Washington University, Washington DC, DC, United States

Lithium-ion (Li-ion) batteries are increasingly used to power unmanned aerial vehicles (UAVs) due to their high energy capacity and long lifespan. Accurately predicting the State of Charge (SoC) of these batteries, which estimates their remaining capacity as a percentage of total capacity, is essential for ensuring flight safety and effective planning of UAV operations. Traditional SoC prediction methods fall into two categories: model-based, which relies on physical models of the aircraft and battery but is computationally intensive and slow for in-flight use, and data-driven, which is faster but less accurate over longer prediction horizons. Our research introduces a hybrid method that combines the accuracy of model-based approaches with the efficiency of data-driven methods. By integrating a multi-rotor power consumption model with a Long Short-Term Memory (LSTM) based prediction scheme, our method uses projected power requirements and current battery state to predict SoC, allowing for dynamic flight mission planning. This approach was tested in simulated flight scenarios, demonstrating both high accuracy and computational efficiency compared to model-based methods, offering significant improvements in UAV safety and energy management.

3 - Flight Planning and Strategic Deconfliction Under Wind Hazards

Amin Tabrizian, The George Washington University, Washington, DC, United States

Winds pose challenges for small Unmanned Aircraft Systems (UAS) and electric vertical take-off and landing (eVTOL) aircraft, especially due to their lighter weight and lower altitude operations. Wind conditions can rapidly change in the lower atmosphere, affecting trajectories and increasing energy consumption. To address this, we develop flight planning algorithms to adjust routes and departure times, avoiding wind hazard areas.

We utilize Version 4.2 of the Weather Research and Forecasting model to predict wind conditions at a high resolution. These forecasts are processed using Kernel Density Estimation to identify regions where wind speeds exceed safety thresholds. Density-based clustering techniques help delineate unsafe airspace areas.

Our routing algorithm minimizes flight time while avoiding wind hazard polygons and operational volumes of other aircraft. Using the A* optimal cost path algorithm and fast marching tree algorithm, we generate efficient routes while ensuring deconfliction with other airspace users.

We apply our approach in the Dallas Fort Worth area, demonstrating its effectiveness for small UAS delivery and urban air mobility. Our findings highlight the algorithm's ability to suggest optimal ground delays and alternative routes, respect operational volumes, and mitigate system-wide delays and traffic pattern changes caused by diverse wind hazards.

4 - Energy-constrained, Risk-averse Drone Routing under Spatiotemporally Varying Urban Winds

Minghao Chen, Columbia University, New York, NY, United States, Max Li, Marco Giometto, Andrew Smyth

Urban areas present unique challenges for drone-based deliveries due to the spatially and temporally variable nature of the wind field at low altitudes. In this paper, we propose a novel approach to address these challenges and ensure safe and reliable drone delivery routings in windy urban environments. Our approach incorporates the stochastic and spatially heterogeneous urban wind field using scenario-based stochastic programming and probabilistic modeling techniques. We develop stochastic mixed integer linear programs (SMILPs) that integrate realistic wind scenarios generated via large-eddy simulations (LESs) with the stochastic drone routing problem (SDRP). We employ the parallel large neighborhood search algorithm, which effectively explores the solution space and handles hundreds of customers' requests in a short time. We compare the performance of heuristics implementation with SMILPs implementation on small cases and show its superiority in terms of solution quality. Through simulations and performance evaluations on large-scale instances, we demonstrate the effectiveness of our approach under different wind conditions and number of customers. We also conduct a sensitivity analysis to investigate the influence of operational altitude (i.e., the height of the wind field) on the performance of our method. Our results provide valuable insights for optimizing drone routing decisions in windy urban environments.

2 - Combining Mixed Integer Programming with Row Generation for Railway Network Capacity Assessment

Christopher Szymula, Technische Universität Dresden, Dresden, Germany, Nikola Besinovic, Karl Nachtigall

Railway network capacity assessment for large-scale networks with explicit regard of the intended operations proves crucial for strategic network planning and development. We present the MIP-based railway network utilization model (MIP-RNUM), which assesses the network's practical capacity with respect to given service characteristics. It is based on Petri Nets (PN) and combines the benefits of mixed-integer linear programming and PN-modelling. Based on the structures of critical process cycles,the presented MIP-RNUM is then used to assess the network's capacity. For better scalability on real-life instances, we extend it to the MIP-RNUM-RG, arow generation solution approach which considers the decisive set of critical process cycles only.The feasibility of every solution during the row-generation procedure is monitored by a newly introduced max-plus based lower bound. Our model computes the specific network'scapacity,regarding for the corresponding operational scenario. The results show the applicability of the MIP-RNUM-RG for network capacity assessment of real-life instances. As such, the model provides a comprehensive, applicable, and extendable solution to the capacity assessment of large and complex railway networks.It thus contributes to the recent efforts to strengthen the railway mode's share on the modal split of European transportation.

3 - Joint Rolling Stock and Crew Scheduling in Urban Rail Networks

Entai Wang, Beijing Jiaotong University, Beijing, China, People's Republic of, Lixing Yang, Yossiri Adulyasak, Jean-François Cordeau, Ziyou Gao

Rolling stock and crew scheduling are two critical and fundamental problems in the field of urban rail operations, especially under some flexible operation schemes and large-scale urban rail networks. These problems are often solved separately and sequentially from the perspectives of different planning stages, resulting in limited planning adjustment ranges of crew schedules and multiple feedback of two problems. To further make these two decision-making processes consistent, this paper investigates a joint rolling stock and crew scheduling problem in urban rail networks. A novel optimization model is formulated with the aim of reducing the operational cost of rolling stock units and crew members simultaneously, in which the multiple-train composition mode is also taken into consideration to adequately match dfferent frequency requirements and rolling stock transport capacities. To solve the proposed model, a customized branch-and-price-and-cut approach is designed to find the optimal operation schemes, in which Benders decomposition is used to solve the linear programming relaxation of the path-based reformulation. Two customized column generation methods with label correcting are embedded to solve the master problem and sub-problem for generating promising paths (columns) associated with each rolling stock unit and crew group, respectively. Finally, a branch-and-bound procedure is used to find integral solutions with several acceleration techniques. To demonstrate the performance and the robustness of the proposed approaches, a series of numerical experiments are conducted both on small-scale and real-life cases of the Beijing MTR urban rail network with different variations in the problem instance settings.

4 - Integrated Optimization of Train Makeup Problem and Resource Scheduling in Railway Shunting Yards: A Hybrid MILP-CP Approach with Logic-Based Benders Decomposition

Peiran Han, Beijing Jiaotong University, Beijing, China, People's Republic of, Lingyun Meng, Nikola Besinovic, Xiaojie Luan

In the shunting yard, various complex operations occur, leading to inefficiencies in railcar connections. Therefore, designing an effective operational research methodology is essential for the shunting yard, and even for the local rail freight network. At the planning level, this paper addresses the integrated train makeup problem and resource scheduling problem (TMRS). The train makeup is treated as an assignment problem, guiding all operations while a series of hybrid flow shop scheduling tasks are established to coordinate the operations of trains, blocks, and railcars. Due to the complexity of TMRS, the integrated problem is reformulated as a hybrid mixed-integer linear programming (MILP) and constraint programming (CP) model. Logic-based benders decomposition (LBBD) is used to partition the TMRS problem, with lower bounds designed and integrated into the solving procedure to accelerate the convergence. We propose feasibility cuts, optimality cuts, and symmetry cuts based on the structure of the subproblem, which are dynamically added to the master problem. Two numerical examples are designed to demonstrate the effectiveness of the proposed hybrid method and symmetry cuts. Finally, the proposed approach and algorithm are examined on a series of artificial instances and real-scale examples, demonstrating their practical effectiveness and ability to achieve high-quality solutions.

New Topics in BOM

Invited Session

Behavioral Operations Management

Chair: Ruth Beer, Baruch College, CUNY, New York, NY, United States

1 - Hasty Expectations: Judgment Bias in Process Analysis from Misappreciation of Jensen's Inequality

Jordan Tong, University of Wisconsin Madison, Madison, WI, United States, Daniel Feiler

How many weeks, on average, will it take your company to complete 30 client cases? When there is variability in a process capacity metric (e.g., some cases are easier than others), we argue that people tend to first average over that variability before performing other calculations required to answer such a question (e.g., division). Such "hasty expectations" sometimes works but often leads to predictable bias due to Jensen's inequality. In particular, because 1/x is a convex function, hasty expectations biases estimates when the units of the observed data and the estimate are inverses, i.e., one is a capacity rate (units per time) and the other is a cycle time (time per unit). Across five pre-registered experiments (including samples of managers and MBA students), we test the extent to which this mechanism drives predictable bias in managerial judgment tasks commonly assigned in core MBA classes, including bottleneck analysis, breakeven analysis, and project completion estimates. We show how the bias can be avoided by first converting the data’s units to be congruent with the requested managerial judgment, ensuring that hasty expectations does not introduce bias.

2 - Driving with Algorithms: The Role of Precision on Improving Human Decision-Making

Park Sinchaisri, University of California Berkeley, Berkeley, CA, United States, Philippe Blaettchen

Many everyday tasks require sequential, interlinked decisions that make it difficult for workers to identify the best strategy. As a result, Artificial Intelligence (AI)-based recommendation systems are applied increasingly to reduce complexity. However, due to human biases, there remains a gap between what is technically possible and what is utilized. This work seeks to understand how recommendation systems can help induce efficient behavior in sequential decision-making. We develop a sequential decision-making task in the form of a virtual electric vehicle driving game. Participants, equipped with algorithm-generated recommendations, need to make sequential charging decisions while facing uncertain traffic. Our experimental results offer key insights into how humans make sequential decisions and respond to different types of recommendations, both immediately and in terms of long-term learning. Based on these insights, we develop a recommendation system that takes into consideration possible deviations by drivers, with the objective of improving their long-term performance.

3 - A Behavioral Study of Self-Other Adoption Discrepancies in XAI

Zezhen He, Simon Business School, University of Rochester, Rochester, NY, United States, Fernanda Bravo, Yaron Shaposhnik, Leon Valdes

Despite major recent developments in machine learning (ML), there is ample empirical evidence that users do not always follow ML recommendations. However, the question of whether the subject that is affected by the prediction impacts adherence is not well understood. This question is relevant as many ML applications, from medicine to the judicial system to lending decisions, are made by a user but affect a third party. In this work, we conduct behavioral experiments to study whether the party that is affected by a user’s decision (the user, or another participant) impacts the adoption of ML recommendations. In addition, we explore whether the presence vs. absence of ML explanations moderates our results. We find no difference in adoption without explanations. In the presence of explanations, however, users are more willing to use ML when they are the affected party.

4 - Algorithm Reliance and Preferences for Information

Ruth Beer, Baruch College, CUNY, New York, NY, United States, Daniela Saban

We study individuals’ preferences for delegating managerial decisions to a matching algorithm, after a large set of alternatives has been screened and the best candidates have been identified. Two behavioral considerations are central to our setting: algorithm reliance (i.e., individuals' willingness to delegate decision rights) and preferences for information (i.e., individuals' preferences for making a more informed decision and learning).

Queueing Theory and Applications

Invited Session

Applied Probability Society

Chair: Daniela Hurtado Lange, Northwestern University, Evanston, IL, United States

1 - Multi-Dimensional State Space Collapse in Non-Complete Resource Pooling Scenarios

Ellen Cardinaels, Eindhoven University of Technology, Eindhoven, Netherlands, Sem Borst, Johan S. H. van Leeuwaarden

The this talk we focus on an explicit multi-dimensional state space collapse (SSC) for parallel-processing systems with arbitrary compatibility constraints between servers and job types. This breaks major new ground beyond the SSC results and queue length asymptotics in the literature which are largely restricted to complete resource pooling (CRP) scenarios where the steady-state queue length vector concentrates around a line in heavy traffic. The multi-dimensional SSC that we establish reveals heavy-traffic behavior which is also far more tractable than the pre-limit queue length distribution, yet exhibits a fundamentally more intricate structure than in the one-dimensional case, providing useful insight into the system dynamics. In particular, we prove that the limiting queue length vector lives in a K-dimensional cone of which the set of spanning vectors is random in general, capturing the delicate interplay between the various job types and servers. For a broad class of systems we provide a further simplification which shows that the collection of random cones constitutes a fixed K-dimensional cone, resulting in a K-dimensional SSC. The dimension K represents the number of critically loaded subsystems, or equivalently, capacity bottlenecks in heavy-traffic, with K=1 corresponding to conventional CRP scenarios. Our approach leverages probability generating function (PGF) expressions for Markovian systems operating under redundancy policies.

2 - Finite-TIME Convergence to Stationarity of $M/M/N$ Queues: A Lyapunov-Poincar\'E Approach

Hoang Nguyen, Georgia Institute of Technology, Atlanta, GA, United States, Sushil Mahavir Varma, Siva Theja Maguluri

Service systems like data centers and ride-hailing are popularly modeled as queueing systems in the literature. Such systems are primarily studied in the steady state due to its analytical traceability. However, almost all applications in real life do not operate in a steady state, and so, there is a clear discrepancy in translating theoretical queueing results to practical applications. To this end, we provide a finite time convergence for a simple $M/M/n$ queue, providing a stepping stone toward understanding the transient behavior of more general queueing systems. $M/M/n$ queue exhibits a phase-transition at the so-called Halfin-Whitt regime. We obtain a tight characterization of the finite time queue length distribution in the super-Halfin-Whitt regime, all the way until the phase transition at Halfin-Whitt. We also obtain a finite-time bound for the distance to stationarity for the sub-Halfin-Whitt regime as well, along with other finite-time statistics such as mean queue length and tail bound.

To prove such a result, we employ the Lyapunov-Poincar\'e approach, where we first carefully design a Lyapunov function to obtain a negative drift outside a bounded set. Within the bounded set, we get a handle on the behavior using a local version of the canonical path method to obtain a local Poincar\'e inequality. A key aspect of our methodological contribution is in obtaining tight guarantees in these two regions, which when combined give us tight mixing time bounds. Moreover, our approach has the potential to be generalized to other settings beyond $M/M/n$ systems.

3 - The Effect of Removing the Four-Hour Access Standard in The Ed: A Retrospective Observational Study

Tomas Momesso, UCL School of Management, London, United Kingdom, Bilal Gokpinar, Rouba Ibrahim, Adrian Boyle

Time-based targets are used to improve patient flow and quality of care within Emergency Departments. While previous research often highlighted the benefits of these targets, some studies found negative consequences of their implementation. We found that lifting the four-hour standard was associated with a drop in short-stay admission and an increase in the average length of stay in the ED.

4 - Online Learning for Reward-Driven and Congestion-Aware Service Rate Control

Wenqian Xing, Stanford University, Palo Alto, CA, United States, Vahid Sarhangian, Yue Hu, Anand Kalvit

We study service systems with heterogeneous customer and server types, where different types of servers can cooperate to serve a single customer. This collaborative service mode generates higher rewards, but faces the tradeoff of potentially taking capacity away from customers waiting in the queue. For such systems with flexible collaboration structures, our goal is to find a scheduling and collaboration policy that effectively minimizes revenue loss and waiting costs. We analyze this problem by considering both the long-run average and transient cost criteria. Our results provide insights into optimal strategies for initiating collaboration among servers.

Generative Diffusion Models: Theories and Applications

Invited Session

Applied Probability Society

Chair: Renyuan Xu, University of Southern California, Los Angeles, CA, United States

Co-Chair: Wenpin Tang, Columbia University, New York, NY, United States

1 - Robust Fine-Tuning of Diffusion Models as Stochastic Control

Yinbin Han, University of Southern California, Los Angeles, CA, United States, Meisam Razaviyayn, Renyuan Xu

Fine-tuning generative models can be computationally intensive, particularly when accounting for uncertainty in human evaluations. To address this challenge, we investigate the robustness of fine-tuning diffusion models in the presence of a corrupted reward model. We frame the fine-tuning of diffusion models as an entropy-regularized control problem with linear dynamics, incorporating an uncertainty set over the reward. By leveraging recent advancements in reinforcement learning for linear-quadratic regulators and the mathematical structure of diffusion models, we develop efficient (robust) policy gradient algorithms and provide a convergence analysis. Additionally, we conduct numerical experiments to validate our theoretical results.

2 - Score Approximation, Estimation and Distribution Recovery of Diffusion Models on Low-Dimensional Manifolds

Zixuan Zhang, Georgia Institute of Technology, Atlanta, GA, United States, Kaixuan Huang, Minshuo Chen, Mengdi Wang, Tuo Zhao

Diffusion models have achieved state-of-the-art performance in various generation tasks. However, their theoretical foundations are not well understood. We study score approximation, estimation, and distribution recovery of diffusion models, when data are supported on an unknown low-dimensional manifold. Our results show that with a properly chosen neural network architecture, the score function can be both accurately approximated and efficiently estimated. Furthermore, the generated distribution based on the estimated score function captures the data geometric structures and converges to the data distribution with minimax optimal rate, which depends on the intrinsic dimension of the manifold, indicating that diffusion models can circumvent the curse of data ambient dimensionality. More importantly, our analysis makes steps towards understanding score functions in diffusion models: (1) we study the non-asymptotic behavior of score functions when time goes to zero; (2) we show that the geometry of manifolds impacts the learning of score functions, that is, distributions supported on manifolds with larger reach are easier to be learned by diffusion models.

3 - Accelerating Convergence of Score-Based Diffusion Models

Yuxin Chen, University of Pennsylvania, Philadelphia, PA, United States, Gen Li, Yu Huang, Timofey Efimov, Yuting Wei, Yuejie Chi

Score-based diffusion models, while achieving remarkable empirical performance, often suffer from low sampling speed, due to extensive function evaluations needed during the sampling phase. Despite a flurry of recent activities towards speeding up diffusion generative modeling in practice, theoretical underpinnings for acceleration techniques remain severely limited. In this paper, we design novel training-free algorithms to accelerate popular deterministic (i.e., DDIM) and stochastic (i.e., DDPM) samplers. Our accelerated deterministic sampler converges at a rate O(1/T^2) with T the number of steps, improving upon the O(1/T) rate for the DDIM sampler; and our accelerated stochastic sampler converges at a rate O(1/T), outperforming the rate O(1/sqrt{T}) for the DDPM sampler. The design of our algorithms leverages insights from higher-order approximation, and shares similar intuitions as popular high-order ODE solvers like the DPM-Solver-2. Our theory accommodates ℓ2-accurate score estimates, and does not require log-concavity or smoothness on the target distribution.

4 - Convergence Analysis for General Probability Flow Odes of Diffusion Models in Wasserstein Distances

Xuefeng Gao, The Chinese University of Hong Kong, Hong Kong SAR, Hong Kong

Score-based generative modeling with probability flow ordinary differential equations (ODEs) has achieved remarkable success in a variety of applications. While various fast ODE-based samplers have been proposed in the literature and employed in practice, the theoretical understandings about convergence properties of the probability flow ODE are still quite limited. In this paper, we provide the first non-asymptotic convergence analysis for a general class of probability flow ODE samplers in 2-Wasserstein distance, assuming accurate score estimates. We then consider various examples and establish results on the iteration complexity of the corresponding ODE-based samplers. This is a joint work with Lingjiong Zhu.

Design of Experiments: From A/B Testing to Adaptive Experimentation

Invited Session

Applied Probability Society

Chair: Chao Qin, Columbia University, Palo Alto, CA, United States

1 - Estimating Distributional Treatment Effects in Randomized Experiments

Shota Yasui, Cyberagent, Tokyo, Japan, Undral Byambadalai, Tatsushi Oka

When analyzing data from randomized experiments, one commonly used measure is the Average Treatment Effect (ATE). However, understanding the distributional treatment effects can often provide a richer perspective than solely focusing on overall average effects. Estimating the Distributional Treatment Effect (DTE) allows researchers to investigate how the treatment impacts different points in the distribution of the outcome variable, revealing the heterogeneity in treatment effects.

In this session, we introduce methods to estimate DTE, including a novel regression-adjusted approach to estimate a wide range of distributional parameters in the context of randomized controlled trials (RCTs). We estimate DTE in data from an RCT on an online platform. Our results deepen our understanding of user behavior in response to treatments.

2 - Adaptive Experimentation Methods at Amazon

Tanner Fiez, Amazon, Seattle, WA, United States, Lalit Jain, houssam nassif

This talk explores the challenges and solutions associated with applying adaptive experimental design (AED) methods in complex real-world scenarios. While AED techniques have shown promise in simpler, idealized settings, their behavior and guarantees are not well-understood in environments characterized by non-stationarity or with complex (e.g., heteroskedastic, endogenous) noise structures. We discuss such problems that arise in industrial settings, and present solutions based on sequential linear experimental designs.

3 - Dual-Directed Algorithm Design for Efficient Pure Exploration

Wei You, The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Chao Qin

We consider pure-exploration problems in the context of stochastic sequential adaptive experiments with a finite set of alternative options. The goal of the decision-maker is to accurately answer a query question regarding the alternatives with high confidence with minimal measurement efforts. A typical query question is to identify the alternative with the best performance, leading to ranking and selection problems, or best-arm identification in the machine learning literature. We focus on the fixed-precision setting and derive a sufficient condition for optimality in terms of a notion of strong convergence to the optimal allocation of samples. By including the dual variables directly, we characterize the necessary and sufficient conditions for an allocation to be optimal. The use of dual variables allow us to bypass the combinatorial structure of the optimality conditions that relies solely on primal variables. Remarkably, these optimality conditions enable an extension of top-two algorithm design principle, initially proposed for best-arm identification. Furthermore, our optimality conditions give rise to a straightforward yet efficient selection rule, termed information-directed selection, which adaptively picks from a candidate set based on information gain of the candidates. We outline the broad contexts where our algorithmic approach can be implemented. We establish that, paired with information-directed selection, top-two Thompson sampling is (asymptotically) optimal for Gaussian best-arm identification, solving a glaring open problem in the pure exploration literature. Numerical experiments highlight the exceptional efficiency of our proposed algorithms relative to existing ones.

4 - Optimal Exploration is no harder than Thompson Sampling

Zhaoqi Li, University of Washington, Seattle, WA, United States, Kevin Jamieson, Lalit Jain

Given a set of arms and an unknown parameter vector, the pure exploration linear bandit problem aims to return the arm with the highest reward, with high probability through noisy measurements of the rewards. Existing (asymptotically) optimal methods require either a) potentially costly projections for each arm or b) explicitly maintaining a subset of the arms under consideration at each time. This complexity is at odds with the popular and simple Thompson Sampling algorithm for regret minimization, which just requires access to a posterior sampling and argmax oracle, and does not need to enumerate the set of arms at any point. Unfortunately, Thompson sampling is known to be sub-optimal for pure exploration. In this work, we pose a natural question: is there an algorithm that can explore optimally and only needs the same computational primitives as Thompson Sampling? We answer the question in the affirmative. We provide an algorithm that leverages only sampling and argmax oracles and achieves an exponential convergence rate, with the exponent being the optimal among all possible allocations asymptotically. In addition, we show that our algorithm can be easily implemented and performs as well empirically as existing asymptotically optimal methods.

5 - Closing the Computational-Statistical Gap in BAI for Combinatorial Semi-bandits

Po-An Wang, KTH Royal Institute of Technology, Stockholm, Sweden, Ruo-Chun Tzeng, Alexandre Proutiere, Chi-Jen Lu

We study the best arm identification problem in combinatorial semi-bandits in the fixed confidence setting. We present Perturbed Frank-Wolfe Sampling (P-FWS), an algorithm that (i) runs in polynomial time, (ii) achieves the instance-specific minimal sample complexity in the high confidence regime, and (iii) enjoys polynomial sample complexity guarantees in the moderate confidence regime. To the best of our knowledge, even for the vanilla bandit problems, no algorithm was able to achieve (ii) and (iii) simultaneously. With P-FWS, we close the computational-statistical gap in best arm identification in combinatorial semi-bandits. The design of P-FWS starts from the optimization problem that defines the information-theoretical and instance-specific sample complexity lower bound. P-FWS solves this problem in an online manner using, in each round, a single iteration of the Frank-Wolfe algorithm. Structural properties of the problem are leveraged to make the P-FWS successive updates computationally efficient. In turn, P-FWS only relies on a simple linear maximization oracle.

Simulation Models for Intermodal Transportation and Future Mobility

Invited Session

Simulation Society

Chair: Xueping Li, University of Tennessee, Knoxville, Knoxville, TN, United States

1 - Empowering Simulation Modeling: An Automated Ontology Framework Enhanced by Large Language Models

Jose Tupayachi, UTK, Knoxville, TN, United States, Haowen Xu, Xueping Li

We present an automated ontology framework designed to generate simulation models, with support from large language models. This framework uses ontological techniques to represent concepts, relationships, and attributes. We showcase its effectiveness through a simulation case study.

2 - A Simulation-Enabled Optimization Framework for Intermodal Freight Transportation

Zeyu Liu, West Virginia University, Morgantown, WV, United States

With the rise of E-commerce, freight transportation has been playing an increasingly important role in the U.S. economy. However, unimodal transportation, which uses solely heavy-duty vehicles or locomotives, typically leads to higher costs, less flexibility, and excessive greenhouse gas (GHG) emissions. Although the benefit of multimodal transportation has been pointed out by many, it still remains challenging to jointly optimize service routes and container flows for intermodal transportation problems, especially in large-scale networks. In this study, we develop a novel simulation-infused optimization framework to address the computational complexity in intermodal transportation problems involving heavy-duty vehicles, locomotives, and container ships. Our method seeks to minimize the total operating cost associated with large volumes of freight, as well as the life-cycle GHG emissions from all modes of transportation. We design novel linear approximation techniques to hierarchically combine agent-based simulation with mixed-integer programming models, optimized by a decomposition-accelerated branch-and-cut algorithm. We collect data from nationwide intermodal transportation facilities to validate framework performances through comprehensive experiments. Sensitivity analyses are conducted under what-if scenarios to provide insights to practitioners.

3 - Drone Pickup and Delivery System for Smart Cities

Aliza Sharmin, University of Tennessee Knoxville, Knoxville, TN, United States, Xueping Li

In drone pickup and delivery systems, identifying the optimal service design is a major challenge. The existing models of implementing drone pickup and delivery services either consider another mode of transportation to be in parallel operation with drones or require a depot or distribution center as a fixed start or end point of drones. This study envisions an integrated framework that utilizes solely drones to pick up and deliver packages from any origin to any destination within a region enhancing autonomy and economics in logistics. Instead of a drone delivery network that operates for a specific facility resulting in more non-delivery flight time due to fixed start and end points, this research proposes an extensive drone network being utilized by multiple facilities which can be prevalent in a city. The proposed system takes several factors, such as drone range, drone fleet size, charging time, charging strategies into account determining the optimal service design. The simulation specifically evaluates the performance of different charging strategies. Additionally, the study analyzes the impact of charging time variation, demand scenarios, drone fleet size and range, providing a more comprehensive understanding of the system and the factors that affect its performance.

4 - Energy Transaction Optimization of Hydrogen-Fueled Charging Station with Local Building Prosumers

Yang Chen, Oak Ridge National Laboratory, Oak Ridge, TN, United States, Olufemi Omitaomu, Haowen Xu, Xueping Li

Advancements in two-way communication smart grid technologies and distributed renewable energy have spurred growing interest in energy trading among neighborhood prosumers. This trend has led to the development of local energy transaction markets. This study focuses on the dynamics of energy transactions within a charging station-centric local energy market. Here, the charging station operates as the leader, while community building prosumers act as followers. The charging station is equipped with solar energy and a comprehensive hydrogen storage system, including a hydrogen tank, electrolyzer, and fuel cell. To delve into the pricing strategy within this local energy market, we propose a leader-follower optimization model. The model's upper level aims to maximize the operation profit for the charging station, whereas the lower level focuses on minimizing bill payments for the building prosumers. These prosumers possess solar energy and battery storage systems and can adjust their demand in response to pricing signals. Different groups of experiments have been designed to explore the effects of diverse building loads, electric vehicle drivers' behaviors, and levels of uncertainty on local energy pricing and transaction behaviors. Our experimental findings indicate that greater cost savings and energy-sharing levels are achievable within more heterogeneous building clusters.

5 - Simulation-Based Decision Support for Intermodal Transport Optimization with Container Consolidation under Demand Uncertainty and Limited Carbon Emission

Xudong Wang, The University of Tennessee, Knoxville, Knoxville, TN, United States

As global concerns over warming intensify, logistics stakeholders face pressures to reduce greenhouse gas emissions and energy consumption. Intermodal transportation, involving multiple transfer points and transport modes, which is a strategic response to these environmental challenges. However, balancing logistics costs with emissions reduction becomes complex amid unpredictable shipment demands and the prerequisite to pre-schedule diverse transportation methods. This study addresses these challenges by developing a decision-support system for intermodal logistics, optimizing the use of containers and transportation modes. Our goal is to develop a decision-support system that not only accommodates the initial transportation schedule but also flexibly adapts to upcoming demands that could share routes or resources, to enhance container and transportation mode utilization. To achieve this, we apply simulation-based methods that model various scenarios of containers and transportation modes availability. This approach allows us to test and refine strategies that dynamically adjust routing and scheduling decisions based on new information, reducing redundant resource usage and optimizing operational efficiency. Our simulation framework considers factors such as transportation and container booking costs, delivery time constraints, carbon emission limitation, and the logistic company's capability to synchronize resources effectively. This solution provides logistics companies with a strategic tool that fosters more informed and flexible decision-making in an uncertain market. This tool aims to boost logistical efficiency and sustainability by maximizing resource use and minimizing environmental impact, benefiting logistics service providers focused on enhancing adaptability and strategic planning.

Emerging Technologies in Healthcare

Invited Session

Health Applications Society

Chair: Vedat Verter, Smith School of Business, Queen's University, Kingston, ON, Canada

1 - Large Language Models for Patient Flow Predictions

Kimberly Villalobos Carballo, Massachusetts Institute of Technology, Cambridge, MA, United States, Liangyuan Na, Yu Ma, Leonard Boussioux, Cynthia Zeng, Luis Soenksen, Dimitris Bertsimas

Accurate predictions of patient outcomes can facilitate resource allocation and enhance personalized care. In collaboration with a large hospital network, we developed machine learning models that predict short-term and long-term outcomes for all inpatients using electronic medical records. We implemented an automated pipeline displaying our daily predictions with user-friendly software. Over 200 medical staff currently use our tool, resulting in a significant reduction in length of stay and projected annual benefits of millions of dollars for the healthcare system.

Given this successful implementation, the question arises: how could we extend these tools for the benefit of hospitals with limited resources, small patient populations, and/or non-standardized healthcare records? Even though electronic medical records are widely available for most digitized systems, tabular data in healthcare is generally disorganized, not standardized across institutions and scarce in small hospitals. We then identified two significant limitations in the existing approaches to handling tabular data: they require labor-intensive data processing, and they ignore contextual information which could be used for data augmentation.

To address these limitations, we present TabText, a systematic framework that leverages Large Language Models to extract contextual information from tabular structures, resulting in more complete and flexible data representations. These representations can then be used to train any standard machine learning model for downstream prediction tasks. We demonstrated the flexibility of our approach compared to traditional labor-consuming processing techniques, and we showed that TabText can significantly improve performance across all patient outcome classification tasks considered, especially those with small data sizes.

2 - Nurse Workload Balancing via Real-TIME Location Data

Vedat Verter, Queen's University, Kingston, ON, Canada, Pooya Hoseinpour, Beste Kucukyazici

Sustained inequities in the workload distribution can lead to increased stress and reduced job satisfaction, high turnover and shortages in the nursing team. We utilize an extensive data set collected by a real-time location system installed in the surgical services department of a large tertiary hospital. The nurse workload is modeled as a multi-attribute, multilinear function, where the significance of each attribute (for the nurse manager) is elicited using an inverse optimization procedure integrated into a clustering method. This involves inverse optimization with a nonlinear integer original problem, which has not been well studied in the literature. We also robustify the model to incorpo- rate the uncertainties in the attribute weights. Through a real-life case-study we show that the proposed approach would have reduced the maximum travel distance by 50% - 77%. In addition, the average ranges for total direct care, maximum travel distance, and number of assigned patients decrease by 65%, 45%, and 31%, respectively.

3 - Patient Scheduling Under No-Shows: An Application to Diagnostic Services

Elaheh Fata, Queen's University, Kingston, ON, Canada, Mina Dalirrooyfard, Yuriy Nevmyvaka, Vedat Verter

One of the challenges that medical facilities face is the no-show behavior of already booked clients. To reduce the doctor's idle time cost, schedulers overbook clients, while keeping in mind the waiting cost exerted on clients. The goal of the medical facility is to minimize the expected sum of clients' waiting cost, the doctor's idle and overtime costs. We first study the static problem, where the scheduler knows the set of clients and their characteristics in advance. Next, we study the online setting and propose algorithmic solutions for scheduling clients as they come in over time.

4 - Quantifying the Cost-Effectiveness of Whole Genome Sequencing Strategies

Sripad Devalkar, Indian School of Business, Hyderabad, India, Sarang Deo, Mayank Jha, Pankaj Jindal, Abhishek Reddy

We develop an integrated operational and disease transmission model that captures the operational characteristics of a whole genomic sequencing (WGS) based surveillance program to detect novel variants of concern of a pathogen. The operational model estimates (i) the time to detect a novel variant circulating in the population and implement a public health measure in response and (ii) the cost of implementing a WGS-based surveillance program. The transmission model estimates the cost of public health intervention and its effectiveness in population-level health outcomes, such as the number of infections and deaths averted and life-years saved. Using this model, we assess the incremental cost-effectiveness for a combination of different operational configurations of the surveillance network (proportion of positively tested samples sequenced, the capacity of the network, centralized vs. decentralized structure) and epidemiological characteristics (severity, immune escape properties, and the time of emergence of the novel variant).

Across the simulated scenarios, we find that increasing sequencing capacity is cost-effective when a large proportion of positive samples are sent for genomic sequencing. Increasing capacity is not advantageous at a lower sampling proportion of positive cases. Centralized configurations do not significantly differ in turnaround time of variant detection (TAT) from decentralized configurations except when the novel variant emerges very late and a large proportion of positive samples are sequenced Optimal cost-effective operational configuration varies based on variant characteristics and its emergence time.

Drone Use in Healthcare

Invited Session

Health Applications Society

Chair: Shakiba Enayati, University of Missouri - Saint Louis, St Louis, MO, United States

1 - Shortening Emergency Medical Response TIME with Unmanned Aerial Vehicle-Ambulance Joint Operations

Nan Kong, Purdue University, West Lafayette, IN, United States, Xiaoquan Gao, Paul Griffin

Unmanned aerial vehicles (UAVs) can improve emergency medical service (EMS) logistics by quickly delivering medical interventions with the help of bystanders. We formulate a large-scale MDP model to jointly optimize the dispatching and redeployment of UAVs and ambulances in real time. To tackle the curse of dimensionality, we adopt an approximate dynamic programming approach with neural network-based value function approximations. We construct a set of basis functions based on queueing and geographic properties of the UAV-augmented EMS system to design the approximation. Our approach outperforms existing benchmarks and provides guidance for effectively incorporating UAVs into EMS operations. By highlighting the potential advantages of using UAVs, we hope to encourage their wider adoption in the EMS field.

2 - Integrated Planning and Control of Drone Networks for Emergency Medical Response

Jamal Chu, University of Toronto, Toronto, ON, Canada, Sheng Liu, Wei Qi, Timothy Chan

Drones have been proposed as a supplemental response to medical emergencies such as cardiac arrest and anaphylactic shock through the delivery of time-critical supplies. Recent work has focused on separate drone base placement and heuristic dispatch policies via two-stage models, which may lead to performance loss compared to an integrated model. We first propose a new dispatch policy and prove that it is optimal under the assumption that drones have non-overlapping coverage zones. We then propose a novel stochastic integer program to jointly optimize base placements and dispatch policies and compare our integrated placement-dispatch model to a two-stage model. We efficiently solve large scale instances of this model using L-Shaped decomposition and a separation subroutine based on linear Irreducible Inconsistent Subsystems.

3 - Optimization of Drone and Truck Operations for Disaster Relief

Ricardo Modrego, Georgia Institute of Technology, Atlanta, GA, United States, Sofia Perez-Guzman

In post-disaster scenarios, the distribution of relief supplies is a very complex process due to lacking the relief supplies and transportation means to completely and promptly satisfy survivors' needs. The recent technological development of unmanned aerial technologies positions drones as potentially advantageous technology to support disaster relief distribution processes. Despite their limited capacity to carry goods, drones can access remote areas and attain faster speeds than road vehicles typically used to deliver relief supplies. The study develops a mixed-integer non-linear model comprising the routing, location, and allocation decisions for the distribution of relief supplies to survivors. The mathematical formulation minimizes a social cost function comprising logistic and suffering costs. The former costs are associated with trucks and drones transporting relief supplies and setting up PODs. The latter costs are associated with survivors' mobility and deprivation. Supplies can be transported via multiple deliveries from distribution centers to points of distribution (PODs). Survivors have heterogeneous needs based on their vulnerability. Individuals who cannot walk to their preferred POD stay at their initial location and have the supplies delivered. Trucks can also carry drones to PODs, and drones can independently fly to the staying survivors. The formulation integrates multiple complex parts, such as the hybrid vehicle fleet, deprivation costs, and survivor mobility. This research contributes to disaster relief distribution operations by introducing a drone fleet to complement the traditional truck network and modeling mobile survivors' mobility trajectories, further prioritizing vulnerable survivors and reducing social costs.

4 - Resilient Delivery Logistics: Integrating Truck and Drone Planning with Disruption Response

Mehmet Kurt, Auburn University, Auburn, AL, United States, Alice Smith, Daniel Silva Izquierdo

This study investigates the potential impacts of disruption, including adverse weather and unforeseen events like component failures or electromagnetic interference, on the well-known Flying Sidekick Traveling Salesman Problem (FSTSP). It introduces the first FSTSP extension with a recourse for disruptions, examining total disruption, affecting the entire planning area for a fixed period, and rolling disruption, progressing sequentially.

A two-stage model is introduced. The first stage plans routes for both the drone and the truck at the start of the day, while the second stage devises routes for remaining nodes during drone disruptions. This is a reactive strategy that reroutes as needed in response to a disruption. Solutions are obtained through Mixed Integer Linear Programming (MILP-exact) and heuristic methods for small instances, and solely heuristic for larger ones, adapted from Murray & Chu (2015).

Small-scale tests revealed a 3.1% gap between the exact and heuristic methods, indicating heuristic efficacy. On average, truck-and-drone scenarios performed 11.5% and 9.1% better than truck-only cases for the 12-customer exact and heuristic methods, respectively. In the 100-customer scenarios, the improvement was 5.7%. The recourse action for the rolling disruption proved 6.2% more effective on average than for total disruption, while the effect of the total disruption (with recourse action) was 16.7% relative to no disruption. Furthermore, experiments with perfect information demonstrated significant enhancements over reactive planning, all as expected.

This study offers key insights for truck and drone delivery planning, emphasizing the importance of considering disruptions during drone usage for efficient last-mile operations.

Co-Chair: Miao Bai, University of Connecticut, Storrs, CT, United States

1 - Cost-Effective Surveillance Strategies for Early Detection of Cancer Recurrence: Optimal Integration of Imaging and ctDNA Testing

Reza Skandari, Imperial College London, London, United Kingdom, Narges Mohammadi, Niloofar Zamani, Alexander Pearson

Recurrent cancer poses significant challenges, with fatalities often occurring within a year of detection. While standard practice relies on post-treatment radiological surveillance, emerging evidence suggests ctDNA, a novel blood test, may offer earlier detection. We aim to develop cost-effective strategies to identify the optimal choice and timing of testing modalities (imaging and ctDNA), minimizing recurrence detection time to improve survival while controlling screening costs. We utilize a partially observable Markov decision process to formulate optimal post-surveillance strategies. Recognizing the importance of the cost-effectiveness threshold, we aim to provide policymakers with a menu of optimal policies and their performances. We apply our developed modeling framework to head and neck cancer and utilize a data-driven model to assess alternative policies. We finally evaluate policy guidelines and recommendations against the optimal policy.

2 - Cost-effectiveness of a network of lethal ovitraps for the prevention and control and dengue fever

Yvonne Huijun Zhu, National University of Singapore, Singapore, Singapore, Joel Aik, Shuzhen Sim, Joel Goh

An estimated 390 million people around the world are infected with dengue fever each year, and this number is trending upwards. One of the interventions that the World Health Organization has recommended to control the spread of dengue fever is the use of a network of lethal ovitraps to capture dengue vectors: female Aedes mosquitoes that carry the dengue virus. Existing evidence supporting the use of this intervention has largely focused on the efficacy of these traps, but has ignored the substantial operational costs entailed in servicing the network of traps.

We introduces methodology to perform a system-level cost-effectiveness analysis of such an intervention. A novel feature of the method is that it incorporates elements of the operational processes required to maintain the ovitrap network and accounts for the labor costs in doing so. Effectiveness was measured as disability-adjusted life years (DALYs) averted from the reduced mosquito population due to the network of lethal ovitraps, modeled using a vector-host dynamic compartmental model. Labor costs were estimated by modeling the lethal ovitraps as nodes of an undirected graph, constructing approximately-balanced routes for service personnel that accounted both for the travel time between locations and the time taken to maintain each trap, and accounting for the costs of employing sufficient numbers of service workers to maintain all traps at a given service interval.

3 - Helping the Captive Audience: Advance Notice of Diagnostic Service for Hospital Inpatients

Zheng Zhang, Zhejiang University, Hangzhou, China, People's Republic of, Miao Bai, Nan Liu

Inpatients are often treated as the “captive audience” on-demand for hospital diagnostic service, and they are notified only when service capacity is available. This management approach, commonly employed by hospitals in both China and the United States, can cause significant chaos and inefficiencies. We propose an innovative scheduling approach called “advance notice” to manage hospital diagnostic practice. Advance notice is a brand-new scheduling paradigm in between the classic allocation scheduling and advance scheduling. Patients are placed in a common queue waiting to be called for service, and they will be provided both a fixed preparation time and a guaranteed service time window in advance (neither a last-minute notice nor an exact service time in the future). The advance notice policy enjoys the benefit of allocation scheduling and that of advance scheduling. It calls for two decisions: who to serve now and who to send advance notices to. We formulate a Markov Decision Process model to optimize these decisions dynamically. Via a novel variable transformation, we reveal the hidden antimultimodular structure of the problem and show how optimal decisions should be adjusted in response to changes in the system load. Beyond solving the MDP model for daily operations, we further investigate how the service time window and preparation time window, as system-level controls, can be used to manage system performance. Our numerical study demonstrates significant improvement in operational efficiency by switching from the current practice to adopting our proposed advance notice policy.

4 - Are No-Shows All That Bad? Strategic Double-Booking and When to Intervene

Arseniy Gorbushin, Rotman School of Management, Toronto, ON, Canada, Opher Baron, Olga Bountali, Binyamin Oz

No-shows constitute a long-standing challenge in various service sectors, particularly in healthcare, where they jeopardize resource utilization and patient care quality. Traditional approaches to reduce no-show rates, such as reminders, cancellation fees, and flexible scheduling have limited effectiveness, overlooking the strategic nature of double-booking—a phenomenon where individuals deliberately secure multiple appointments to expedite service.

We model strategic double-booking, investigate its impact on system dynamics, and explore strategies to tame it. In particular, we use a stylized queueing model and a game-theoretic framework to incorporate the notion of strategic double-booking. The system that we study consists of identical queues (e.g., hospitals), where customers have the option to double-book (or multi-book) upon arrival. We show that the model exhibits interdependencies among queues, that are intrinsic in the system dynamics. We analytically account for both them and the resulting capacity waste, providing insights into customer decision-making and system performance.

Our analysis reveals that double-booking has dual effects: Facilitating load distribution while increasing system traffic.
We show that increasing the perceived value of service (i.e., reward) does not always lead to a higher number of served customers, which is the typical result in the strategic queue literature. In addition, we prove that banning double-booking may not always improve system performance, especially under low traffic conditions. We also demonstrate how the presence of double-booking impact traditional remedies, such as no-show penalties and overbooking. Finally, we propose alternative solutions, such as a flexible admission control policy, to allow load distribution without excessively congesting the system.

Revenue Management in Supply Chain

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Bin Hu, University of Texas at Dallas, Richardson, TX, United States

Co-Chair: Haokun Du, The University of Texas at Dallas, Richardson, TX

1 - Competitive Markovian Pricing

Haokun Du, The University of Texas at Dallas, Richardson, TX, United States, Bin Hu, Elena Katok

Problem definition: Dynamic pricing is a popular price-discrimination strategy in retail; however, it is often undermined by customers' strategic waiting behavior. One tactic utilized by retailers to deter strategic waiting is to offer price discounts at random intervals. This phenomenon has been studied in the recent Markovian-pricing literature in single-retailer settings. In this paper, we extend the study to a competitive setting where two retailers offer random price discounts for incoming customers, and also investigate the impact of customer loyalty in this setting. Methodology/results: We perform an equilibrium analysis of a competitive Markovian-pricing model with loyal and opportunistic customers and recover a key insight from the single-retailer Markovian-pricing literature that the retailers should offer flash discounts that last only for an instant. Surprisingly, we also find that a larger proportion of opportunistic customers at both or each of the retailers may increase both retailers' profits when they engage in competitive Markovian pricing. Managerial implications: Our study extends the support for the use of flash discounts to competitive retail settings. The surprising finding that more opportunistic customers in the market or at each retailer may benefit both competing retailers highlights the unique properties of the competitive Markovian-pricing setting where common wisdom may not apply, and suggests that retailers engaging in competitive Markovian pricing should reconsider their policies regarding price-monitoring and comparison services as well as their efforts to foster customer loyalty.

2 - Familiarity-Based Dynamic Pricing with Hierarchical Bayes Estimation of Consumer Choice

Binghan Kou, Arizona State University, Tempe, AZ, United States, Hongmin Li, Yuqi Yang

Past consumption affects customers' familiarity with a product and influences their preference for future consumption of the product. This effect is heterogeneous among individuals. More generally, individuals' preferences may be nonmonotonic with respect to familiarity and exhibit various patterns. Meanwhile, the prevalence of customer management programs has made consumer transactional data readily accessible. This creates opportunities for the firm to tailor pricing decisions to each customer's specific familiarity-based utility pattern. A major hurdle, however, is the complexity of deciphering the diverse familiarity-based utility patterns embedded in the transactional data and integrating this information with the price optimization model. In this paper, we present a value-passing dynamic pricing strategy that is optimal under a familiarity-based multinomial logit (MNL) choice model. In this context, we develop several flexible variants of the familiarity-based pricing model that dramatically reduce the complexity of integrating diverse utility patterns into optimal pricing decisions. Employing a hierarchical Bayes estimation approach, we demonstrate how this data-driven dynamic pricing strategy improves a firm's bottom line.

3 - On the Value of Coalition Loyalty Programs

Jingmai Wang, The Hong Kong Polytechnic University, Hung Hom, Hong Kong, Yan Liu, Yulan Wang, Dan Zhang

A growing number of firms join forces with other firms in their loyalty program effort by participating in coalition loyalty programs (CLPs). Despite their increasing popularity and importance, CLPs remain significantly understudied, especially compared to proprietary loyalty programs (PLPs) offered by individual firms. This paper studies CLPs and compares them to PLPs using an analytical framework. We model a CLP consisting of n firms, each of which sells a nondurable product to infinitesimal, heterogeneous customers over an infinite time horizon. Our research reveals the critical role of market composition and customer discounting on the effectiveness of CLPs. We show that larger-sized CLPs are only preferred in markets where customer heterogeneity in valuation is more prominent than their heterogeneity in shopping intensity. Furthermore, when customers discount the future, smaller-sized CLPs can be more effective. Importantly, we show that firms have incentives to join CLPs even when PLPs are ineffective, corroborating the increasing popularity of CLPs in recent years. Our results offer useful guidelines for the design and operation of CLPs to firms and coalition managers. For example, we offer one explanation for the struggles of some CLPs in their expansion. We check the robustness of our results with model extensions and discuss the limitations of our study.

4 - Yielding to the Weather: How Climate Change Impacts Planting Decisions and Consumers

Yaniv Ravid, University of Toronto, Toronto, ON, Canada, Hongqiao Chen, Ming Hu, Wenbin Wang

Climate change is affecting crop yields worldwide and presenting threats to the global food supply chain. In this paper, we characterize the impact of climate change on crops' yields and analyze the downstream ramifications these changes have on consumers and agricultural firms' planting decisions. We assume that firms can influence prices by deciding on planting quantities in or across several growing regions, which will result in random crop yields depending on environmental conditions. As weather and climate trends vary across growing seasons, we analyze how changes to the yield distribution affect consumer surplus and the greater agricultural supply chain. We analyze both the cases of a monopolistic firm and competing firms and show that when the correlation in yield between agricultural regions decreases, consumer surplus under a monopoly always increases but may decrease in the case of competition. In addition, we show that competing firms may benefit from an increase in yield volatility, while a monopolistic firm's profit will always decrease after such changes to the yield distribution. We also show that an increase in average yield hurts competing firms in some instances, while a monopolistic firm always benefits from an increased average yield. These results show that a lack of coordination between competing firms could therefore be hurting consumers and firms alike. We illustrate our results and their implications on how firms should alter their planting decisions using practical examples of crops and regions. Our results provide guidance for agricultural operations on how to adapt to climate change.

Manufacturing and Service Operations Management (MSOM)

Chair: Yanhan (Savannah) Tang, SMU Cox School of Business, Dallas, TX, United States

1 - Human-Artificial Intelligence Teaming and the Effects of Workload on Child Welfare Screening

Alan Scheller-Wolf, Tepper School of Business, Pittsburgh, PA, United States, Yanhan Tang, Zhaohui Jiang, Justine Galbraith, Lindsey Lacey

Child welfare organizations regularly receive a significant number of calls alleging child neglect or abuse. Due to limited resources available for investigations and services, it is crucial to accurately assess and screen these allegations before further investigation or intervention to ensure service quality and efficiency. Furthermore, investigations initiated based on unsubstantiated allegations can lead to harmful consequences for the family involved. To aid these essential screening decisions and enhance overall efficiency, a Predictive Risk Model (PRM), essentially an artificial intelligence (AI) tool, has been deployed by our research partner. We empirically investigate this human-AI collaboration in call screening, particularly examining the influence of workload on this collaboration. We find that human agents are more likely to deviate from the AI recommendations when the workload is either high or low. While the AI tool does not adjust for varying workloads, human agents seem to factor in the workload when making screening decisions. Specifically, they lean toward admitting more low-risk referrals when the system load is low and lean toward rejecting more high-risk cases when the load is high, resulting in a U-shape relationship between deviation and workload. These findings indicate that human workers can complement the AI's recommendations by taking into account vital operational factors, such as system load. We provide evidence supporting that a sustainable investigation load is likely desirable for downstream operations, as increased investigation load is correlated with delayed investigation completion.

2 - Incentive Design for Sustainable Practices In Smallholder Supply Chains

Yuan Shi, Massachusetts Institute of Technology, Cambridge, MA, United States, Joann de Zegher, Yanchong Zheng

Promoting sustainable practices by smallholder farmers face significant challenges of resource constraints and uncertain crop prices. In practice, sustainability incentives are provided via two main mechanisms: (i) an offsetting scheme in which third-party nonprofits or project developers provide financial rewards for adoption; (ii) an insetting scheme in which downstream buyers directly incentivize farmers within their value chain. It is an open debate as to when either scheme may be more effective and economical than the other to promote long-term adoption of sustainable practices among smallholder farmers. In this paper, we examine optimal incentive design and economic viability for these two schemes when farmers are resource constrained and face price variability for their products. We develop a principal-agent model in which the principal aims to ensure continued compliance with sustainable practices at minimal cost, while farmers repeatedly make joint decisions on production effort and sustainability compliance over multiple periods. Our analysis suggests that insetting contracts with incentive payments depending on both compliance and production volume can significantly outperform offsetting contracts which focus exclusively on sustainability compliance. This is because insetting contracts help to prevent farmers from engaging in undesirable tradeoffs between production intensification and sustainable actions. We further examine and demonstrate the near-optimal performance of affine insetting contracts which are more implementable in practice. Using field data of oil palm farmers in Indonesia, we quantify that well-designed insetting contracts can achieve over 35% cost savings than offsetting contracts, while achieving the same level of sustainability.

3 - Child Welfare Platform Design to Improve Outcomes for Children with Disabilities

Ludwig Dierks, University of Illinois at Chicago, Chicago, IL, United States, Vincent Slaugh, Utku Unver

Children with disabilities age out of the U.S. child welfare system without a family resource at disproportionately high rates, resulting in worse life outcomes. Child welfare platforms seek to serve these children but struggle to identify high-capability families and direct them to children with high needs. Moreover, families without the necessary skills and resources for children with disabilities might express an eagerness to adopt any child, failing to recognize their own limitations. This costs agencies valuable screening resources and undermines the platform's usefulness for caseworkers.

We model the foster care or adoption placement process for a platform serving low-needs and high-needs children and low-capability and high-capability families. The platform elicits each family's type, which is unobservable. We derive closed-form expressions to characterize three placement mechanisms: a naive maxima mechanism that aims to maximize the number of placements but neglects families' incentives, a maximal envy-free mechanism that maximizes the number of placements while accounting for families' incentives, and a max-min envy-free mechanism that puts extra importance on helping high-needs children. The superior performance of the envy-free mechanisms demonstrates the importance of accounting for incentives.

Finally, we discuss managerial insights. We show that the ability to place high-needs children with high-capability families depends on the ratio of low-needs children to families unable to care for high-needs children. This ratio affects three strategic decisions: recruiting more families of different care capabilities, including more low-needs children on the platform, and coaching different types of families to better understand their care capability.

Co-Chair: Harriet Jeon, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States

1 - Redesigning Volunteermatch's Recommendation Algorithm: Toward More Equitable Access to Volunteers

Scott Rodilitz, UCLA Anderson School of Management, Los Angeles, CA, United States, Vahideh Manshadi, Daniela Saban, Akshaya Suresh

In collaboration with VolunteerMatch (VM)---the world's largest online platform for connecting volunteers with volunteering opportunities---we designed and implemented a new display ranking algorithm. VM's original ranking algorithm intended to maximize efficiency (i.e., the total number of connections), but as a consequence it repeatedly displayed the same few opportunities atop its ranking, effectively limiting access to volunteers for the other opportunities. To incorporate VM's desire for equity (defined as the weekly number of opportunities with at least one connection) along with efficiency, we propose a modeling framework for online display ranking in settings where it is important to manage the trade-off between the total number of connections and the equitable allocation of these connections. Taking an adversarial approach in evaluating the performance of online algorithms, we show that a class of algorithms that applies a *penalty* to opportunities after each connection provides a strong (and, in certain regimes, optimal) performance guarantee. Based on our theoretical development, we propose *SmartSort*, a simple online display ranking algorithm with a penalty term that we calibrated using VM's data and simulation. We implemented SmartSort in experiments covering Dallas-Fort Worth and all of Southern California. Using a difference-in-differences analysis, we find that the implementation of SmartSort led to an estimated 8% increase in equity (consistent across both experiments) without any significant decrease in efficiency.

2 - Stopping the Revolving Door: An Empirical and Textual Study of Crowdfunding and Teacher Turnover

Samantha Keppler, University of Michigan, Ann Arbor, MI, United States, Jun Li, Andrew Wu

Though the effectiveness and efficiency of education systems depends in part on a committed teacher workforce, high rates of teacher leaving have plagued the US public schools. A primary reason is that teacher workloads are high and involve many non-teaching tasks, such as procuring much of their own supplies and materials. This has recently become more salient with the emergence of teacher crowdfunding platforms. With the understanding that securing resources through crowdfunding may impact teacher work(loads), this paper investigates whether and how teacher crowdfunding affects teacher retention. We find that teachers funded on the largest teacher crowdfunding platform, DonorsChoose, are 1.6 percentage points (pp) less likely to leave their schools and 1.9 pp less likely to leave the teaching profession---a 14% and 41% reduction, respectively. The effect is larger for classroom environment (i.e., furniture) projects (4.2 and 2.8 pp) and for more unique projects (2.1 and 1.9 pp), evidencing that teachers are most impacted when they leverage the platform for resources particularly hard to get otherwise. This suggest that the effects are driven not only by the secured resources, but also by the efficient and autonomous platform procurement process. Improved US educational supply operations are needed to remedy the persistent gap between what resources teachers want and what they have. While that gap persists, teacher crowdfunding platforms appear to be a critical tool for stemming teacher turnover and attrition.

3 - To Each Their Own (Shifts): Incorporating Heterogeneous Worker Preferences into Shift Work Schedules

Hummy Song, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States, Harriet Jeon, Song-Hee Kim, Kyeongsug Kim, Sangwoon Cho, JeongHee Hong

While shifts are the dominant and often unavoidable way to schedule work in many contexts requiring around-the-clock staffing, their adverse effects, both at the individual and organization levels, are well-documented. We explore a potential organizational lever—incorporating heterogeneous preferences over shift design—to mitigate ramifications of shift work in the context of acute care bedside nurses. Using a novel combination of survey, administrative, and shift data, we examine whether, to what extent, and for whom individual choice over dimensions of their shifts mitigates the impact of shift work on work (dis)satisfaction and turnover of nurses.

4 - Policing Staffing and Fairness: Evidence from Atlanta Police

Jonathan Zhou, Georgia Institute of Technology, Atlanta, GA, United States, Qiuping Yu, Zheng Dong, Yao Xie

We study how scheduling and dispatching policies impact policing effectiveness and fairness using event-level police patrol and 911-call data collected across a five-year period from the Atlanta Police Department. We first empirically identify two major factors --- police's scheduling policy and the geographic division of the police patrolling units --- that lead to significant disparities in police response time to 911 calls across different neighborhoods. We then propose strategies to mitigate disparities while also improving overall policing outcomes using a framework that combines optimization and causal inference.

Empirical Studies in OM and Finance Interface

Invited Session

MSOM: iForm

Chair: Qi Wu, Case Western Reserve University, Cleveland, OH, United States

Co-Chair: Sridhar Seshadri, University of Illinois, Champaign, IL, United States

1 - Effects of Financial Constraints on Supply Chain Financing Choices and Operational Decisions

Anqi Wu, Florida International University, Miami, FL, United States, Qi Wu, Sridhar Seshadri

Bank credit access represents the opportunity to borrow funds from banks and other financial institutions. Although theories have been developed on how bank financing affects firms' operational decisions, limited operations management literature empirically investigates this impact and the mechanisms through which it manifests. This study focuses on firms' inventory decision and employs the adoption of interstate bank branching laws that introduced a staggered shock on operational firms' accessibility to bank credit. We collate a panel dataset for 1990--2005 by merging several datasets with credit line information obtained by data mining 10-K filings. We examine the effect of bank credit on inventory decisions using a difference-in-differences identification strategy. Our study reveals that enhanced access to bank credit results in quicker inventory turnover rather than a rise in firms' inventory investments. This effect is more pronounced among small firms. We observe that in the short term, small firms focused more on capacity expansion, which may crowd out inventory investment. In the long term, their fast inventory turns can be attributed to improved infrastructure and higher capital intensity. For bigger firms, the benefits of relaxed bank credit constraints become evident through their influence on the supply chain network. We observe that when customer firms have more bank credit, larger suppliers are willing to provide additional trade credit, and this is associated with higher trade with the new customer and therefore faster inventory turns. This research contributes to a better understanding of the comprehensive effect of bank credit on firms' management of their operations.

2 - Impact of Supply Chain Transparency: Evidence from Conflict Minerals Disclosures

Christopher Chen, Indiana University Kelley School of Business, Bloomington, IN, United States, Paola Martin

Supply chain transparency has become crucial due to societal expectations, environmental concerns, and regulatory requirements, emphasizing both ethical sourcing and operational challenges. This study investigates how mandated transparency regarding conflict minerals impacts buyer-supplier relationships, specifically examining supplier base concentration and supplier financing. Using a game theoretic model, we capture strategic interactions between buyers and suppliers, highlighting that suppliers may consolidate to be labeled as conformant and to drive out competition. To empirically analyze transparency's impact, we leverage the Dodd-Frank Act's Section 1502, which mandates firms to disclose the origins of their raw materials, focusing on tin, tungsten, tantalum, and gold (3TG) from conflict regions. We compare firms subject to these requirements with those that are not, using hand-collected conflict mineral disclosures from SEC filings and Compustat data (2007-2021). Our generalized difference-in-differences model reveals that mandated transparency leads to a significant increase in trade credit granted to disclosing firms, suggesting improved financing terms. Additionally, there is a trend of supplier base consolidation among disclosing firms, impacting non-conformant suppliers. This consolidation results in more buyers per supplier, indicating a shift towards fewer, more compliant suppliers. These findings suggest that transparency fosters compliance and ethical sourcing while influencing supply chain strategy and financial relationships. Firms can leverage transparency to enhance their brand and gain competitive advantages through better supplier terms and efficient supply chain management. However, achieving transparency requires balancing the benefits of disclosure with operational and financial burdens, and it may reshape market dynamics, potentially squeezing out smaller suppliers.

3 - Stock Market Reaction to New Technology Announcements: An Empirical Investigation into the Role of Continencies

Ujjal Mukherjee, University of Illinois, Urbana-Champaign, Champaign, IL, United States, Alok Raj, Samit Paul, Atanu Chaudhuri

In this paper, we analyze the reaction of stock markets in the context of new technology adoption in supply chains. The specific technology context we use is blockchain technology. We demonstrate empirically that while stock markets generally react positively to new technology adoption announcements, several contingencies are important considerations. The signals that investors perceive from new technology adoption announcements depend significantly on the context and contingencies of announcements. Our paper is positioned at the intersection of supply chain management and finance.

4 - Customer Portfolio Approach to Managing Cash Flow Variability

Nikolay Osadchiy, Emory University, Atlanta, GA, United States, William Schmidt, Jing Wu

Cash flow variability is driven by operational decisions, and it influences operating performance and valuation. Despite this, and the early role that operations management scholarship had on cash flow management theory, the prevailing approaches for managing cash flow variability focus on financial remedies such as accessing external capital and engaging in financial hedging, and to a lesser extent, operational remedies such as sourcing goods in currencies that align with revenues and implementing product or production flexibility. Our research extends this set of remedies by proposing customer portfolio management and selective trade credit as operational hedges for reducing cash flow variability. We empirically validate our proposal by studying new customer acquisition events using a large database of customer-supplier relationships that we join with quarterly firm financial reports. Our analysis shows that firms reduce their cash variability by (i) pursuing customers with desirable order patterns that offset the cash flow variability from serving legacy customers and (ii) selectively offering customers trade credit that harmonizes payment terms in the customer portfolio. We strengthen the inferences from this analysis by assembling random samples of customers for each firm in our study, and show that the firms' actual customer portfolios yield lower cash variability compared to the counterfactual sets of randomly sampled customers.

5 - The Role of Firm Risk in Supply Chain Network Adaptation

M. Hakan Hekimoglu, Rensselaer Polytechnic Institute, Troy, NY, United States, Shailesh Divey, T Ravichandran

The paper addresses how firm risk affects its centrality within a supply chain network. Using supplier-customer relationship data collected from FactSet pertaining to the US manufacturing industry, we examine the effects of a firm's risk on its centrality. We measure a firm's centrality using two alternative constructs: Degree centrality and eigenvector centrality. We measure firm risk with the idiosyncratic volatility from the Fama-French three-factor model with industry effects. Our paper presents three important findings. First, we show that a firm's risk has a negative impact on its centrality in the supply network. A higher risk firm has fewer supplier/customer links (i.e., lower degree centrality) in addition to those suppliers/customers being less-central firms (i.e., lower eigenvector centrality). Second, we show how a firm's centrality adapts to a change in its risk exposure. Using a first-difference estimator, we find that an increase in firm risk leads to a decrease in the firm's eigenvector centrality, but it does not affect its degree centrality. We interpret this interesting supply chain network adaptation as follows: Customers and suppliers of firms experiencing higher risk cut their ties with the focal firm, so the focal firm has to replace those customers and suppliers with less central ones. Third, we present that a firm's centrality changes more dramatically in response to an increase in risk than it does to a decrease in risk.

Summit - 444

Technology and Future of Work

Invited Session

MSOM: Service Operations

Chair: Qiuping Yu, Georgetown University, Washington, DC

1 - The Effect of Income Composition on Consumption Behavior

Paige Tsai, Harvard Business School, Boston, MA, United States, Ryan Buell

In this work, we study whether the scheduling flexibility afforded by part-time working arrangements hinder the financial flexibility of employees by altering the composition of their income. To the extent that the composition of an employee's income wields influence over how they spend it, different working arrangements with the same total level of compensation may be differentially sustainable – with meaningful implications for employee wellbeing and operational performance.

Our preliminary evidence suggests that income composition influences consumption behavior, such that individuals whose income is more concentrated around their primary income source report spending more of their total income overall – an effect driven by purchases denoted as relative necessities. We believe this research will lay the foundation for interventions that could improve the design of operations to bolster employee financial wellbeing by understanding the role a job plays in the overall composition of an individual's income.

2 - On Worker Scheduling Fairness: Evidence from An American Restaurant Chain

Qiuping Yu, Georgetown University, Washington, DC, DC, United States, Xiaoxuan Hou

Utilizing real-world shift data from an American casual dining chain, we examine racial and gender disparities in scheduling quality conceptualized along three dimensions: sufficiency (whether workers are allocated enough hours as they desire), predictability (the frequency of short-notice and real-time changes to the schedule), and hourly earning potential (whether workers' scheduled hours translate into equitable hourly earnings). We investigate two main questions: (1) are there racial and gender disparities in the schedule quality among workers? (2) what are the mechanisms that drive the disparities and what are the mitigation strategies? Our findings indicate that compared to white male colleagues, female and minority workers are scheduled for hours with lower income potential and are more likely to receive real-time additions to their schedules. They also experience a higher proportion of hours added on short notice rather than pre-scheduled. Further, female workers are scheduled for fewer hours than male workers. By ruling out worker preferences and skill differences, our analysis points to management bias as one of the primary drivers of these inequalities.

3 - The Impact of AI Technology on The Productivity of Gig Economy Workers

Serguei Netessine, The Wharton School, Philadelphia, PA, United States, Dmitry Mitrofanov

We conducted field experiments on a grocery shopping platform that uses an AI-enabled guidance system to help shoppers find products on store shelves. We find that, as one would expect, such technology helps by reducing the number of refunds (due to the item being hard-to-find, e.g. located at a pop-up display, etc.) and that less experienced shoppers tend to use this guidance the most. However, counter-intuitively, we also find that the usage of more complex routing algorithms is not free: it takes a longer time to consult AI guidance and picking times increase as a result. Overall, we find that AI improves the effectiveness of gig workers by helping less experienced workers achieve order outcomes that are more comparable to those of more experienced workers, thus increasing both customer satisfaction and revenue per order. However, there are boundary conditions for technology adoption and overuse of technology can even lead to lower productivity.

4 - Measuring Strategic Behavior by Gig Economy Workers: Multihoming and Repositioning

Gad Allon, University of Pennsylvania, Philadelphia, PA, United States, Daniel Chen, Kenneth Moon

Gig economy workers make strategic decisions about where and when to work. We empirically measure two types of strategic behavior: multihoming, an online change between platforms, and repositioning, a physical change between locations. Using a structural model, we show that workers are highly heterogeneous in their preferences and find multihoming especially costly, both in absolute terms and relative to the cost of repositioning. Through counterfactual simulations, we show the significance of enabling free multihoming and efficient repositioning for improved worker earnings and platform service levels, providing policy insights for platform operators and regulators.

Supply Transparency, Food Waste, and Carbon Emissions

Invited Session

MSOM: Supply Chain

Chair: Jing-Sheng Song, Duke University, Durham, NC, United States

Co-Chair: Chenghuai Li, Duke University, Durham, NC, United States

1 - An Empirical Study of Blockchain-Driven Transparency in A Consumer Marketplace

Wedad Elmaghraby, UMD, College Park, MD, United States, Ken Moon , Jane Jiang

Marketplaces have long been shaped by technological advancements from railroads to the mobile Internet and search. Now, with the potential to transform marketplace transparency, blockchain technology lets firms credibly trace the flow of products through their supply chains. It has been claimed that blockchain will soon enable consumers to track their food consumption from farm to table, uncover counterfeits and contamination, and better identify socially responsible products and firms. However, implementing a blockchain-based solution for supply chain transparency can be costly and complex, and no prior research has empirically examined blockchain technology's impact on consumer marketplaces. In collaboration with a leading Chinese technology company that operates the country's top online consumer grocery marketplace, we analyze the effects of its sellers' recent adoptions of blockchain tracing. We find that consumers respond to supply chain transparency by readily purchasing traced products, especially those that are handling-sensitive or sold by third-party sellers. For third-party sellers, information provided through blockchain tracing is fundamentally different than the sellers' own quality claims, leading to an up to 23.4% increase in average revenue for these sellers. By using structural estimation to analyze how consumers assess products, we highlight that consumers' prior experience with the product category shapes the sophistication and magnitude of their responses to tracing and the resulting welfare effects. Additionally, we show evidence that consumers deem blockchain-backed information to be markedly more reliable than sellers' own claims.

2 - The Environmental and Social Implications of Pay-What-You-Want Food Waste Supermarket

Luyi Gui, The Paul Merage School of Business, UC Irvine, Irvine, CA, United States, Xi Lin, Luyi Yang

Donating edible surplus food and making it available to food insecure communities is a preferred food recovery approach. An emerging type of donation outlet is pay-what-you-want food waste supermarkets where consumers can purchase edible salvaged food at a price that they are willing to pay as opposed to according to a posted price tag. In this paper, we analyze the impact of pay-what-you-want pricing for salvaged food on strategic consumer choices, and in turn, regular retailers' replenishment and donation decisions. Accordingly, we evaluate how pricing scheme choices of donation outlet could influence food waste generation and food insecurity reduction.

3 - Scope 3 Emission Disclosure in Supply Chains: Equity and Efficiency

Bin Hu, University of Texas at Dallas, Richardson, TX, United States, Ruize Ma, Yunke Mai

The United Nations has advocated the disclosure of Scope 3 (supply chain) carbon emissions. Two Scope 3 carbon emission assessments are commonly adopted: Cradle-to-Gate which includes emissions of all upstream firms, and Life-Cycle (or Cradle-to-Grave) which includes emissions of all upstream and downstream firms; in addition, one can conceptualize a Gate-to-Grave assessment which includes emissions of all downstream firms. We consider a serial supply chain where each firm discloses its carbon emissions subject to societal pressure, and study their emission-reduction and product-pricing decisions and the supply chain outcome under different carbon emission disclosure regulations in terms of carbon-reduction equity and efficiency. We find that Gate-to-Grave is consistently the most equitable assessment in terms of both carbon and profit reductions along the supply chain, whereas all assessments are virtually indistinguishable in carbon-reduction efficiency in terms of both consumer welfare and supply chain profit for the same total supply chain emission. These findings strongly advocate for the Gate-to-Grave Scope 3 emission assessment's formal definition, recognition and implementation.

4 - Innovator's Advantage In Competitive Technology Adoption: Enhancing Profit and Combating Food Waste via Supply Transparency

Chenghuai Li, Duke University, Durham, NC, United States, Bora Keskin, Jing-Sheng Song

Emerging digital technologies enable fresh produce retailers to trace and track the freshness conditions of their supplies in real time and communicate additional information, such as sustainable practice certifications, to consumers. These technologies offer retailers great opportunities to increase supply chain efficiency and reduce food waste. In a competitive retail market, we study whether an innovator of supply transparency technology has advantages over a follower. In a duopoly facing freshness-dependent demand, the adoption of transparency technology allows a retailer to observe the freshness state when placing orders and enhance consumer utility when selling fresh produce. We find that the innovator can benefit from capturing the demand spillover from competitor's stock-outs, thereby achieving greater profit growth compared to the follower. This spillover-capture effect is pronounced in the case of low retail margin as the non-adoper tends to under-order. Additionally, when technology creates consumer value through transparency, it can spur market growth, further amplifying the innovator's advantage through the market-expansion effect. Under certain conditions, the innovator can achieve a greater food waste reduction or more significant improvement in consumer welfare. We also find that the retail market with fewer competitors can have a higher propensity for industry-wide adoption, considering both the fixed and proportional costs of adoption. This finding suggests that mergers can reduce a grocery retail market's food waste and improve consumer demand fulfillment. We generalize our findings to the cases of freshness-based discounts and sequential technology adoption.

Co-Chair: Aditya Vedantam, State University of New York at Buffalo, Williamsville, NY, United States

1 - Renewable Energy Investments Under An Evolving Social Cost of Carbon

Thomas Palley, Indiana University, Bloomington, IN, United States, Owen Wu

The social cost of carbon (SCC) is an established measure for informing policymakers in making energy planning decisions. Uncertain and evolving SCC estimates present a challenge for the transition towards more renewable grids. We develop a model to examine how uncertainty and learning about SCC affects renewable energy investments, utilizing the relationship between atmospheric carbon levels and environmental and societal impacts. We consider a rational expectation equilibrium (REE) model in which individual firms make investment decisions based on their belief about the evolution of SCC, while the aggregate investment of all firms directly affects the atmospheric carbon accumulation and SCC. We analyze REE under various information structures to better understand how the speed of learning about components of SCC estimates can affect investments and emissions. We offer insights into how policymakers might improve decision making under uncertainty about the societal impact of carbon emissions.

2 - Renewable Energy Servicizing for Residential Homes in Developing Countries

Jaachinma Okafor, University of Tennessee, Knoxville, TN, United States, Russel Barton, Paolo Letizia, Gil Souza

Energy access remains a critical challenge in developing countries, characterized by the unavailability and unreliability of power supply systems. This paper explores the potential of adopting a servicizing approach to deliver renewable energy solutions to residential consumers in these regions. This proposed model involves a firm installing and maintaining a solar array-battery system in households in exchange for usage-based payments. By shifting ownership and maintenance responsibilities to service providers, households can gain access to clean and reliable solar energy without incurring upfront costs. The economic viability of this servicizing solution is examined by developing a stylized analytical model, considering factors such as investment costs, supply-demand variability, and consumer adoption. Our analysis derives the optimal charge per unit consumption of energy, the optimal solar generation capacity, and the optimal battery capacity, offering insights for firms aiming to provide sustainable energy solutions in developing nations. Notably, our results highlight the profitability of the servicizing model, especially in areas heavily reliant on gasoline generators for backup power. To further validate our findings, we conduct a trace simulation using actual solar irradiation and demand data from households in Nigeria. This simulation enhances the robustness of our results in a more realistic setting, showcasing the value of a shared system that efficiently serves multiple households.

3 - Empowering Supply Chain Energy Efficiency: Merits and Pitfalls of Buyer Collaboration

Jason Nguyen, Ivey Business School, Western University, London, ON, Canada

Environmental agencies in developing countries are increasingly partnering with large corporate buyers to enhance energy efficiency at local manufacturing facilities. We examine when such collaboration can improve social welfare and energy efficiency investments. We show buyer collaboration enhances energy efficiency investments, but it can harm the overall social welfare.

4 - Resale-as-a-Service: The Impact of Second-Hand Platforms on Fashion Goods Retailer

Robert Swinney, Duke University, Durham, NC, United States, Fernando Bernstein, Yuan Guo

We examine how a retailer selling fashion apparel should account for a second-hand market amid changing fashion trends and diverging customer tastes. We propose a customer decision model that incorporates both customer purchase decisions (i.e., purchasing a new product, a used product, or no product) as well as their selling decisions (i.e., selling a used product) over time. Customers have heterogeneous tastes for product design and each product released by the retailer has random popularity in the market. We discuss how uncertainty in customer taste over time can affect the retailer’s design and production decisions when the resale platform operates independently from the brand or retailer. Furthermore, we investigate the implications of collaborating with such a platform and embracing Resale-as-a-Service (RaaS) for different types of retailer’s design and production decisions. We examine the potential benefit of RaaS for both parties involved and discuss its role in the supply chain.

5 - Survival Analysis for Managing Animal Rescue

Elena Katok, The University of Texas at Dallas, Richardson, TX, United States, Qiuxia Chen, Ernan Haruvy

Municipal shelters must euthanize numerous animals (primarily dogs) every day due to a shortage of space. The choice of which dogs to euthanize is based on two policy decisions: the length of time the dog is given at the shelter, and the degree to which the shelter capacity can be expanded. The more the shelter is over capacity, the more stressful it is for the dogs who are there, due to noise, overcrowding, and a lower quality of care, therefore, shelter managers have to consider the trade-off between the higher probability of a dog being adopted when it stays longer, and the lower probability of a dog being adopted due to over-crowded conditions. Using data from a large municipal shelter in Dallas, we derive a method for determining the optimal policies using dual-objective survival analysis. This analysis allows us to qualitatively estimate the number of lives saved compared to the current practice. Our work can be generalized to the problem of when to liquidate excess inventory.

Summit - 447

Humanitarian and Disaster Operations Management II

Invited Session

Public Sector OR

Chair: Andrew Arnette, Virginia Tech, Blacksburg, VA, United States

Co-Chair: Christopher Zobel, Virginia Tech, Blacksburg, VA, United States

1 - Media Coverage of Disasters and Its Implications for Precautionary Purchases

Trilce Encarnacion, University of Missouri- St. Louis, Saint Louis, MO, United States, Johanna Amaya

In preparation for disasters, households purchase large quantities of supplies to ensure they have enough resources during emergencies. This phenomenon is commonly referred to as "Panic Buying." These purchases can severely disrupt supply chains by creating sudden, extreme demand spikes that lead to stock shortages, logistical bottlenecks, and price inflation, making it difficult for retailers to maintain steady supply and for consumers to access essential goods. Understanding the influencers of these precautionary purchases is crucial for developing strategies to mitigate its impact on supply chains and ensure equitable access to essential supplies during emergencies. To explore the dynamics of this behavior, we analyze the relationship between media influence and consumer purchasing patterns by integrating two key data sources. First, we use news reports about hurricanes that have impacted the United States, which provide a timeline and intensity of media coverage before and during these events. Second, we utilize retail scanner data that records sales of emergency supplies such as bottled water, batteries, and non-perishable foods. Leveraging Theory of Planned Behavior and Media Influence Theory as theoretical basis, we develop econometric models to quantify how media coverage triggers precautionary buying behaviors among consumers.

2 - A Resource Allocation Model to Mitigate the Risk of Disruptive Events in Homeland Security

Parastoo Akbari, Iowa State University, Ames, IA, United States, Cameron MacKenzie

A disruptive event in homeland security, whether it is a natural, technological, or human-caused event, that impacts the homeland can have severe consequences. The Department of Homeland Security and state governments in homeland security and emergency management are responsible for allocating resources and funding projects that reduce the risk of these disruptive events. This research proposes a resource allocation model that enables a decision maker to choose among a set of projects that mitigate the risk of disruptive events in a geographic area while satisfying a budget constraint. The risk of a disruptive event is measured as the product of the probability of the event and the multidimensional consequences if the event occurs. We apply the resource allocation model to the state of Iowa and identify 16 different hazards that threaten the state including floods, tornadoes, winter storms, bridge failure, a cyberattack, and an improvised explosive device. Based on a variety of information sources, we assess an annual occurrence probability for each event and 6 consequences (injuries, fatalities, property damage, crop damage, number of customers without power, and number of businesses closed). We estimate the costs and effectiveness of 52 projects described in the State of Iowa’s homeland security planning documents. We solve the resulting optimization problem to select the projects that best mitigate the risk of these 16 different hazards. This resource allocation model can improve the selection of projects and assign homeland security resources more effectively based on risk.

3 - Optimizing Humanitarian Aid Delivery in Disaster Zones: a Mathematical Model for Collaborative Truck and Drone Logistics

Ramin Talebi Khameneh, Stevens Institute of Technology, Hoboken, NJ, United States, Nafiseh Ghorbani-Renani, Jose Emmanuel Ramirez-Marquez

In post-disaster urban areas, humanitarian aid operations are not only essential but also complex because of dense populations and damaged infrastructure. Despite the common logistics, humanitarian logistics must manage a variety of critical objectives beyond minimization of cost, ensuring quick and equitable distribution of aid to affected populations. These challenges highlight the importance of strategies that optimize the use of diverse technologies and modalities. In spite of significant advances in transportation technologies, there is still a considerable gap in coordinating multiple transport modes to optimize aid delivery time and efficiency in urban areas affected by disasters, such as trucks and drones. In this study, we propose a mathematical model for solving the cooperative trucks and drones humanitarian relief delivery problem where each drone is associated with a particular truck, and both are dispatched from a central depot simultaneously to serve aid recipients. The implementation of this model aims to significantly reduce total delivery time, enhancing the speed and precision of aid deployment with key innovations, including optimizing route paths for both trucks and drones within operational constraints like battery life and payload capacities. From a practical perspective, the case study of urban flooding illustrated the potential to dramatically increase disaster preparedness and response strategies, thereby increasing the resilience of urban environments.

4 - Optimizing Spatial Prepositioning of Food Supplies: A Covering Model for Disaster Resilience in Germany

Sonja Rosenberg, Karlsruhe Institute of Technology, Karlsruhe, Germany, Katharina Eberhardt, Frank Schultmann

Public food stockholding is critical in facilitating recovery from disruptions like natural or human-made disasters, enhancing a nation's resilience. However, many challenges exist in planning food stockpiling, including adequate pre-positioning of supplies. This challenge is even more significant if it is conducted for disasters with a low probability of occurrence but a high degree of vulnerability for a nation. Disasters, such as pandemics or severe power blackouts, may be long-lasting and nationwide. Some nations, like Germany, prepare for these circumstances by stockpiling durable goods, e.g., wheat, in defined warehouses over long periods. Because only limited aid can be expected from surrounding regions in case of large-spatial disasters, the pre-positioning of durable goods must ensure an adequate covering of the complete area. Therefore, we propose a covering model that maximizes the demand coverage of a population during a food crisis by optimizing the warehouse locations, their capacities, and the individual covering zones under a limited public budget. Trade-offs exist between economies of scale for warehouse sizing and efficient use of transport infrastructure when distributing the supplies. The model is applied to Germany as a case study, investigating the degree to which spatial vulnerability indicators of the population affect the model results.

5 - Does Gender Shape Organizers' Charitable Crowdfunding Success?

Margaret Traeger, University of Notre Dame, Notre Dame, IN, United States

Do donors on a charitable crowdfunding platform give more money to women or men campaign organizers? Examining the role of organizers' gender in this context allows us to address underexplored theoretical questions about how gender shapes interactions in a context with clear feminine and masculine elements. Social psychological theories of gender predict that men's presumed higher status will advantage them in most situations, except communal contexts in which women are expected to excel. Because the charitable crowdfunding context combines elements of both caring-oriented and achievement-oriented contexts, it is possible that either women or men could perform better. Despite the strong communal content of charitable crowdfunding, we find men organizers raise substantially more money than women. Gender differences in campaign design do not explain the disparity. There are additional inequities in how donors respond to the type of language women and men use in their campaigns. Agentic words increase donations for women and men, but agentic language is associated with larger donations to men than women. Strikingly, communal language increases donations to men, but decreases donations to women's campaigns. Our results suggest donors hold unconscious gender biases about men's greater status that drive donors to lend more money to men's campaigns than women's campaigns.

Innovative Applications of Optimization Techniques in Healthcare

Invited Session

Health Applications Society

Chair: Nasrin Yousefi, Queen's University, Toronto, ON, Canada

1 - Patient-to-Bed Placement Optimization: Improving Coordination for a Hospital Command Center

Arlen Dean, University of Michigan, Ann Arbor, MI, United States, Mark Van Oyen, Mohammad Zhalechian

We present our work with a large hospital to improve coordination among bed managers for patient-to-bed placements. Hospital bed managers are responsible for managing patient flow, a critical aspect of hospital operations and patient care. Allocating beds can be complex and time-consuming due to the shared resource nature of beds and the varying care needs of patients. To address these challenges, we developed and implemented an algorithm based on an optimization model that uses operational practices and real-time patient and system information. We examine the effects of our algorithm on our partner hospital's operations post-implementation using an empirical analysis based on several key outcome metrics related to care quality.

2 - Screening Process Information Matters More than Clinical Information: a Randomized Controlled Trial of Information Sharing on Cancer Screening Decision

Sarah Yini Gao, Singapore Management University, Singapore, Singapore, Xiaodong Wang, Zhichao Zheng, Yongjian Zhu

Policymakers often rely on information sharing for decision-making, especially in healthcare. The effectiveness of sharing the right information is pivotal for influencing patient behavior, particularly in encouraging cancer screening uptake, yet the literature lacks consensus regarding the most effective elements of information to share. This study investigates the specific types of information that should be disseminated to encourage cancer screening uptake.

By analyzing data from a randomized controlled trial focused on colorectal cancer screening, our findings reveal that sharing relevant information significantly improves participants' intention to take up screening, independent of their initial level of knowledge before the intervention. Specifically, sharing information on the screening process improves the screening intention significantly, whereas the effect of sharing clinical information about cancer is insignificant. Furthermore, sharing information that is already familiar to participants proves to be just as effective as introducing new information to enhance the screening intention. We also identify heterogeneous responses from different subpopulations to different types of information content.

Our findings suggest that identifying knowledge gaps before sharing information might be less crucial than previously thought, as reinforcing known information also proves beneficial. For public health campaigns, emphasizing the screening process and tailoring information to diverse subpopulation reactions are recommended to optimize effectiveness.

3 - Quantifying the Benefits of Customized Vaccination Strategies: a Network-Based Optimization Approach

Su Li, Texas A&M University, College Station, TX, United States, Hrayer Aprahamian

We study the problem of designing vaccine distribution strategies that maximally mitigate the negative impact of an infectious disease outbreak. This is achieved through a multiperiod optimization-based framework that embeds important subject-specific risk and contact information into the decision-making process. By analyzing the structure of the resulting optimization problem, we identify key structural properties which we use to construct a globally convergent solution scheme (suitable for smaller problem instances) and two, more scalable, heuristic schemes. We demonstrate the benefits of the considered framework through a case study on COVID-19 in Texas. Our results highlight the importance of considering risk and contact information as doing so substantially reduces the total expected number of fatalities over conventional compartmental-based approaches. These findings indicate that customization can have a significant benefit, particularly for community-scale planning.

4 - Uncertainty Quantification in Inverse Optimization

Nasrin Yousefi, Queen's University, Toronto, ON, Canada, Timothy Chan, Nathan Sandholtz

Decisions often exhibit "noise" around theoretical optimums in applied optimization tasks. Noise may arise from measurement, model, or human decision-making errors. The presence of noise adds significant complexity when considering the inverse optimization problem, which is the problem of inferring unknown parameters of an optimization model such that a collection of observed decisions is rendered optimal for the inferred model. While several works have proposed solutions for the noisy inverse optimization problem in terms of point estimation, they have not directly addressed the uncertainty in their estimates. Although uncertainty is inherent in the context of noisy inverse optimization, the quantification of this uncertainty has been treated very little in the literature. Our work is the first to address this topic directly. We study optimization problems with linear objective functions and convex feasible regions where the objective coefficient vectors are unknown. We propose a parametric approach to estimate the unknown coefficient vectors and construct credible regions around the estimates.

5 - Feasibility and Optimization of Prehospital Critical Care Team Response to Major Trauma in the Greater Toronto Area

Rachel Stephenson, University of Toronto, Toronto, ON, Canada

In the United Kingdom and Europe, it is common for physician-led prehospital critical care teams (PHCCTs) to respond to major traumas at the scene of the incident. PHCCTs provide interventions outside of the competencies of standard paramedics which, while required infrequently relative to other standard paramedic-administered interventions, can be lifesaving for major trauma patients. We aim to assess the feasibility of PHCCT response to major trauma in the Greater Toronto Area (GTA). We use geospatial modeling and maximal covering location models to determine the optimal base locations for PHCCT teams in the GTA to respond to major traumas under different expert-informed emergency medical services response configurations. We evaluate our proposed solutions using discrete event simulation considering both total coverage as well as the equity and fairness implications of allocating a scarce health resource.

Chair: Yuming Sun, Georgia Institute of Technology, ATLANTA, GA, United States

1 - Online Learning with Survival Data

Arielle Anderer, Cornell University, Johnson School, Ithaca, NY, United States, Hamsa Bastani, John Silberholz

This project adapts online learning techniques to scenarios with time-to-event data, where there is a delay between choosing an arm and observing feedback that is endogenous to the quality of the arm. We posit a multi-armed bandit algorithm that uses a cox-proportional hazards estimator. We theoretically analyze and prove guarantees on the regret under this algorithm. Lastly, we examine its performance on a dataset of metastatic breast cancer clinical trials, and compare it to that of other adaptive allocation schemes.

2 - Diabetes Treatment Planning Using Nonstationary Combinatorial Multi-Armed Bandits

Katherine Adams, University of Wisconsin-Madison, Madison, WI, United States, Justin Boutilier, Sarang Deo, Yonatan Mintz

Unhealthy diets and sedentary lifestyles are key drivers of the global diabetes pandemic. Research shows office workers are particularly at risk of developing diabetes. The chronic nature of diabetes burdens firms with increased labor costs due to reduced productivity, absenteeism, and turnover. Partnering with Community Health Worker (CHW) organizations provides cost-effective solutions for early detection and management of diabetes symptoms, driving a healthier, more productive workforce. Building efficient CHW visit plans require modeling tradeoffs between screenings, provision of care to the enrolled, and visits to gather information on each patients' disease status. To address this problem, we propose a nonstationary combinatorial multi-armed bandit framework that allows providers to build personalized CHW visit plans to screen and manage patients with diabetes under uncertainty.

3 - Quantifying the Impact of Vaccinating Under-Immunized Groups in Polio Outbreak Responses: a Model-Based Study

Yuming Sun, Georgia Tech ISyE, Atlanta, GA, United States, Hongyu Xue, Pinar Keskinocak, Lauren Steimle

Polio, an infectious disease that causes paralysis, remains a global health concern, especially with the emergence of circulating vaccine-derived poliovirus (cVDPV) and recurring outbreaks in areas with cohorts of under-immunized individuals. This study systematically assessed how the allocation of vaccines during a polio outbreak response might impact outcomes. Adapting a compartmental simulation model, we projected poliovirus transmission from 2024 to 2026 under different levels of vaccination campaign coverage (i.e., the proportion of the target population planned to be vaccinated), vaccine allocation schemes (e.g., across different immunity groups), and vaccination campaign delays. Results highlighted that compared to other allocation schemes, priority allocation of vaccines to under-immunized immunity groups (i) significantly reduced the case burden, even with lower coverage and longer delay; (ii) achieved die-out of transmission with two rounds of vaccination if the delay was short (<= 3 weeks) and coverage was high (>= 70%).

4 - Interpretable and Equitable Population Guidelines

Sun Ju Lee, Georgia Institute of Technology, Atlanta, GA, United States, Gian Garcia

Evidence-based guidelines play an important role in informing how chronic diseases should be managed, as these recommendations are widely disseminated and widely implemented. However, they are one-size-fits-most, failing to account for patient-to-patient differences. Personalized medicine has shown significant potential to improve health outcomes over clinical practice guidelines. However, the implementation of personalized medicine may be challenging, resulting in unwanted practice variation and suboptimal patient care. To find the right balance between personalized medicine and clinical guidelines, we propose the treatment guideline design problem. We develop a framework to design optimal treatment guidelines for a population of patients which are each modeled according to their own Markov Decision Process parameters. We propose several exact and heuristic methods to solve the problem, including a mixed-integer linear program formulation and a branch-and-bound clustering algorithm. Our results on a hypertension treatment planning case study demonstrate that with only a small number of subgroups, we can develop clinical practice guidelines which perform almost as well as personalized treatment policies.

Order Fulfillment Optimization within 4 walls of Amazon Warehouses

Invited Session

The Practice Section of INFORMS

Chair: Ignacio Erazo, Amazon, Bellevue, WA, 98004, United States

1 - Optimizing Storage Across Bin Types in Traditional Fulfillment Centers

Kevin Bunn, Amazon, Bellevue, WA, United States

In this presentation, we look at a traditional fulfillment centers (FCs), where items are stowed in different types of bins based on the shapes and sizes of those items. In many cases, items can be stowed in multiple bin types. The goal of this research is to propose a strategy that considers the current fullness levels of different bin types, and makes a recommendation for which bin type to stow items in order to optimize the FC's overall stow and pick rates. In order to do so, we model how stow and pick rates are impacted by fullness levels for each bin type. We then estimate how many items we plan to stow and pick per day, and the distribution of bin types where items can be stowed. From there we can set an optimal fullness level across each bin type which minimizes the amount of time it would take to stow and pick. We also plan consolidation, which is the process of moving inventory between bins, to identify situations where a consolidation plan can improve fullness levels.

2 - Manual Pick Scheduling Optimization in Traditional Fulfillment Centers

venkatachalam avadiappan, Amazon, Bellevue, WA, United States, Kay Zheng

In the Amazon traditional fulfillment centers (FC), the pickers move to the inventory stored in bins and manually pick the assigned demands, place them in carts and send them downstream for consolidation and packaging. The picking services play a key role in the order fulfillment process in a FC and significantly impacts the FC speed and throughput. They determine which inventory to use to fulfill a demand, at what time, and by which picker so that it can be shipped out on time to meet the customer promise. Currently, the demand to inventory binding decisions are pre-determined (i.e., early binding), while picker assignment and picker path routing are based on greedy heuristics, resulting in long picker travel distances and low pick throughput. We propose a novel manual pick scheduling (MaPS) optimization model which improves the demand to inventory binding (i.e., late binding) and picker path routing and solves within reasonable times, thereby reducing distance traveled by pickers and enhancing pick throughput. MaPS is decomposed into a two-stage sequential optimization to address scalability challenges, wherein, in the first stage, selection of demand from backlog, demand to inventory binding, picker assignments are determined, while in the second stage, the picker routing decisions are made. Preliminary results suggest that MaPS significantly improves the average expected travel time between picks compared to the heuristic.

3 - Reinventing Robotic-Assisted Picking Algorithms in Amazon

Kay Zheng, Amazon, Bellevue, WA, United States, Ignacio Erazo

Fulfilling orders at the scale and speed that Amazon does is a challenging task that requires optimized processes throughout an order's life cycle. Amazon Robotics (AR) Fulfillment Centers (FC) have proved to be more efficient and ergonomics-friendly than its traditional counterparts, empowered by the robotic technology that enables stationary and continuous picking from inventory pods that are brought to pickers by robotic drives. AR FCs face different challenges than traditional FCs and requires innovative ways to solve for a pick execution plan quickly while accounting for associate safety. Today’s pick planning in AR FCs is driven by a heuristic that can quickly create short-term pick execution plans to meet upstream targets; however, its greedy nature has shown to be very limited in leveraging all the data and optimizing for multiple objectives. In this talk, we present a new optimization-based, scalable and flexible framework for AR pick planning and execution that coherently optimizes for upstream targets adherence, pick productivity and associate safety.

4 - Prioritizing Demand Picking with Multiple Objectives

Elcin Cetinkaya, Amazon.com, Seattle, WA, United States, Prem Viswanathan, Kevin Bunn

A specific service at Amazon Order Fulfillment Systems prioritizes shipments within a Fulfillment Center driven by a multi-objective optimization model. The service is based on a model predictive control framework whose output is in the form of a multi-hour plan for picking that's refreshed multiple times during the day. The plan is then used to construct a set of nested shipment groups from which the picking service has the flexibility to select a subset of work. In this talk, we will present the multi-objective optimization model and nested shipment grouping framework.

5 - Scaling Up Pick Planning in Amazon

Ignacio Erazo, Amazon, Bellevue, WA, United States, Kay Zheng

Order picking is a vital component in an order's fulfillment journey, and the creation of picking plans is subject to multiple business requirements and operational targets that are updated every 2.5 minutes by upstream systems. Pick planning algorithms for Amazon Robotics (AR) Fulfillment Centers (FC) must be able to react to these moving operational targets as soon as possible, hence the need to create new pick execution plans within 2.5 minutes. Because of this challenge, Amazon created a fast heuristic that creates feasible plans in a somewhat greedy manner. While the heuristic has proven to be reliable, we have observed degradation of pick productivity since this algorithm's gradual network roll-out. Moreover, the current methods have difficulty creating solutions of high quality when considering the new use cases in AR FCs. We propose an optimization-based algorithm that decomposes the original pick planning problem with multiple millions of integer variables into at least two phases, allowing to generate picking plans that meet the business constraints and improve picking efficiency all while scaling to the new use cases and solving within the time constraints. Experiments show that our new methodology improves significantly the quality of the picking plans, and we also demonstrate that it is not needed to solve the new models to optimality to obtain such improvement. Furthermore, by using our methodology offline to train a machine learning model, we are able to reduce by 18% the size of our problem, without loss of optimality.

Humanitarian Operations and Earmarked Funding

Invited Session

TutORial

Chair: Harish Krishnan, University of British Columbia, Vancouver, BC, Canada

1 - Humanitarian Operations and Earmarked Funding

Alfonso Pedraza-Martinez, University of Notre Dame, Notre Dame, IN, United States

Earmarked funding, also referred to as restricted funding, is one of the main characteristics of humanitarian operations. Earmarked funding can be defined as the donors' contributions to humanitarian organizations to be used for a specific purpose. This is in contrast to flexible funding, which can be used for any purpose. This tutorial introduces the trade-off between total donations and operational performance due to humanitarian earmarking. The tutorial explains why allowing donors to earmark their contributions helps organizations increase fundraising effectiveness. It also explains why earmarking hurts organizations' per-dollar performance. Because humanitarian organizations' utility increases in total donations and per-dollar (or any other currency) performance, the best fundraising strategy for the organizations, collecting earmarked or flexible funds, is not apparent. Moreover, this tutorial argues that ear marked funding is here to stay and discusses models that reduce the negative effect of earmarked funding. Then, it proposes that a thoughtful mix of earmarked and flexible donations may be the best way for humanitarian organizations to fund their operations. The balance between earmarked and flexible funds depends on reducing the negative operational consequences of earmarked funds. The tutorial concludes by identifying areas for future research on humanitarian operations and earmarked funding.

Economics of Information Systems

Invited Session

Information Systems

Chair: Stephanie Lee, University of Washington, Seattle, WA, United States

1 - Pseudonymity, Anonymity and Online Discussion Community

Jiaying Deng, Fordham University, New York, NY, United States, Lin Hao, Yingda Lu, Ali Tafti

Users' active engagement is strongly correlated with the success of online discussion community and identity plays an important role in shifting individuals' participation. Previous literature often entails the comparison between anonymity and offline identity in individual engagement on social media platforms. However, the effects of pseudonymity on users' content-generation behaviors are nonetheless under-studied. While both pseudonymity and anonymity involve concealing one's offline identity, pseudonymity involves the use of fictitious online identity (such as usernames) whereas anonymity entails the complete absence of personally identifiable information. In this study, we examine the impact of pseudonyms on users' engagement within online discussion forums through a unique natural experiment where our treatment forum removed all usernames. Our findings reveal distinct user responses to pseudonymous settings compared with previous literature on anonymity. Notably, individuals are less likely to ask questions or provide answers after concealing their pseudonyms. In addition, the negative impact is more significant for users who are more centrally embedded in a network. Nevertheless, contrary to previous research suggesting that anonymity contributes to Internet trolling, we find no evidence of an increase in trolling behavior when pseudonyms become anonymous. Our study contributes to the literature on user content generation and the development of identity policies in online discussion community.

2 - News in the Dark: Effects of Facebook's Australian News Ban on News Consumption

Ying Gu, Univesity of Washington, Seattle, WA, United States, Stephanie Lee, Yong Tan

In the contemporary news consumption landscape, social media platforms have emerged as key sources of news consumption, and there have been ongoing discussions on the relationship between social media platforms and news publishers. In 2021, the Australian News Media Bargaining Code was proposed to mandate platforms to pay news publishers for their content. In response, Facebook removed news content from the platform in Australia from February 18th to 26th, 2021. This study examines how Facebook's decision to restrict news sharing in Australia affected news consumption in Australia. Using a difference-in-differences approach, along with the propensity score matching, we find a decline in news page views in Australia post-ban, indicating significant changes in news engagement patterns, particularly among casual readers who predominantly relied on Facebook for news dissemination. The paper extends beyond merely documenting this decline, looking into the broader implications of such platform policies on digital news consumption landscapes. It uncovers shifts in device usage, with a notable transition from mobile to desktop engagement, and finds resilience in user behavior, evidenced by increased traffic from search engines post-ban. These findings offer a valuable empirical perspective on the dynamics shaping digital news engagement, providing key takeaways for policymakers, news organizations, and digital platforms navigating the complex landscape of news dissemination in the digital age.

3 - Netflix and Chilling Effect? the Impact of Streaming Video Licenses on Paid Digital Downloads

Shahryar Doosti, Chapman University, Orange, CA, United States, Brett Danaher

Digital distribution of entertainment products has led to new opportunities for firms to extract revenues through a variety of different channels but also new challenges in determining how to best manage those channels, given the potential for complementarities and cannibalization. In particular, television networks and movie studios are faced with the challenge of negotiating fixed-fee licensing deals for their content on streaming services such as Netflix without knowing what effect such deals will have on the demand through other channels. In this research, we exploit the natural experiment of Netflix's launch in Australia to determine the causal effect of licensing a title to this service on paid digital downloads of that content. We find that licensing TV shows to Netflix caused digital sales of those shows to decrease by an average of 31% relative to shows that were not licensed, while licensing films caused a 52% decrease. We also find evidence that films continue to experience a depressive effect on digital downloads even after they are removed from Netflix. Our results shed light on the effect that consumption through a subscription bundle has on a la carte purchases, and they also have practical implications for content owners negotiating deals for their content with streaming video services.

4 - From Bytes to Bites: Enhancing Personalized Nutrition Interventions for Diabetes Management Through Causal Inference with Double ML and Large Language Models

Rebekah Baik, University of Washington, SEATTLE, WA, United States, Leonard Boussioux

Personalized nutrition plays a crucial role in the prevention and management of diabetes. However, understanding the causal relationships between dietary factors and blood glucose levels remains a complex challenge. This research proposes a novel causal inference framework that leverages the power of large language models (LLMs) and double machine learning (DML) to integrate multimodal data and uncover complex patterns in the diet-diabetes relationship. By generating rich embeddings from both structured and unstructured data, the proposed approach enhances the input features for the DML model, which employs tree-based models for treatment and outcome estimation. This integration allows for the identification of the causal impact of specific dietary interventions while controlling for confounding variables. A key focus of this framework is to improve the interpretability of treatment effects, facilitating the development of targeted dietary recommendations and optimizing healthcare resource allocation for diabetes prevention and management. This research aims to bridge the gap between complex causal inference techniques and their practical application in healthcare decision-making by providing a more understandable and explainable model. The insights gained from this framework can lead to more efficient and cost-effective personalized prescriptive nutrition strategies, ultimately benefiting individual health outcomes and healthcare systems.

Social Media Analytics Student Paper Contest

Award Session

Social Media Analytics

Chair: Lingshu Hu, Washington and Lee University, Lexington, VA, United States

1 - Measuring the Impact of Unobserved Social Networks on Group-buying Decisions under Privacy Concerns

Jingwen Zhang, University of Washington, Seattle, WA, United States, Jin Liu, Yongjun Li, Yong Tan

Leveraging the viral power of social networks, group buying has rapidly emerged as a promising e-commerce model with substantial market potential. Companies have been increasingly integrating group-buying campaigns into social media platforms to further accelerate demand growth. However, tapping into these expansive social networks heightens users' privacy concerns - not just around corporate data practices but also regarding the uncontrolled exposure risks as personal information propagates across widening social circles. The inability to observe the underlying peer connections in most group-buying datasets has posed significant challenges for researchers seeking to identify social network effects on group-buying behaviors, especially social network effects of privacy preferences. We address this obstacle through applying an econometric technique tailored for social network effects with unobserved networks into the group buying context. Leveraging a novel group-buying dataset on a Chinese social media platform, we measure the impacts of social networks on consumers' sign up behaviors in group buying while the social network is unobserved. We find that (1) An individual consumer is more likely to participate in group buying when close friends have signed up, indicating a positive peer effect. (2) A privacy-sensitive individual consumer is less likely to participate in group buying themselves. Yet when close friends with high privacy sensitivity sign up, the individual consumer would be more likely to participate in group buying, indicating a surprisingly positive contextual effect of privacy preference. Our findings provide important implications for platforms to design group-buying mechanisms.

2 - Content-Centered or Creator-Centered? An Economic Analysis of Fan Loyalty on User-Generated Content Platforms

Meilin Gu, Tsinghua University, Beijing, China, People's Republic of, Zizheng Liu, Dengpan Liu

The loyalty of fan communities to content creators significantly impacts stakeholders on user-generated content (UGC) platforms. Notably, major UGC platforms exhibit varying stances on creators' cultivation of fan loyalty. For instance, Douyin (the Chinese version of TikTok) hinders creators from building robust fan followings, while Kuaishou (another major UGC platform in China) takes active measures to encourage and support creators in cultivating fan loyalty on its platform. This stark contrast has sparked an ongoing debate about the role of UGC platforms in the cultivation of fan loyalty. In this paper, using a game-theoretic model, we explore the optimal strategies embraced by platforms in managing creators' cultivation of fan loyalty and their implications for key stakeholders. Our findings challenge the conventional wisdom that suggests UGC platforms should always facilitate creators in cultivating fan loyalty, as such assistance may sometimes hurt the platforms. Furthermore, our study generates meaningful implications by providing guidelines for UGC platforms to strategically manage creators' cultivation of fan loyalty and for creators to balance their efforts between cultivating fan loyalty and enhancing content quality.

3 - Shaping Opinions in Social Networks with Shadow Banning

Yen-Shao Chen, Yale University, New Haven, CT, United States, Tauhid Zaman

The proliferation of harmful content and misinformation on social networks necessitates content moderation policies to maintain platform health. One such policy is shadow banning, which limits content visibility. The danger of shadow banning is that it can be misused by social media platforms to manipulate opinions. Here we present an optimization based approach to shadow banning that can shape opinions into a desired distribution and scale to large networks. Simulations on real network topologies show that our shadow banning policies can shift opinions and increase or decrease opinion polarization. We find that if one shadow bans with the aim of shifting opinions in a certain direction, the resulting shadow banning policy can appear neutral. This shows the potential for social media platforms to misuse shadow banning without being detected. Our results demonstrate the power and danger of shadow banning for opinion manipulation in social networks.

4 - The Interplay of Opinions and Behavior in Social Trading: Early Cryptocurrency Adoption Dynamics

Ye Liu, University of Washington, Seattle, WA, United States, Mingwen Yang, Matthias Pelster, Yong Tan

Social trading platforms allow individual investors to access peer opinions to make their investment decisions while transparently observing their peers' trading behaviors. We exploit a unique dataset from a large social trading platform and study how the interplay of opinions and behaviors within social networks influences an individual's decision to adopt cryptocurrency. We focus on cryptocurrency adoption, as cryptocurrencies have gained increasing attention over the last few years. Due to the lack of standardized information, social media has become a main information channel for individuals to decide whether to trade cryptocurrencies. This reliance on social media presents a unique challenge: The vast and unregulated nature of social media can often lead to disseminating information of questionable credibility. Using investment opinions and actual trading behaviors, we find a pronounced social learning effect in cryptocurrency adoption. Individuals are more inclined to adopt Bitcoin when their network peers do, especially when these peers' trading actions are consistent with their expressed opinions. In times of high uncertainty, investors tend to rely more on positive opinions, regardless of others' actual trading actions. In addition, high-income and older investors are more susceptible to opinions from their neighbors. Textual analysis indicates that Bitcoin posts are longer and more forward-looking compared to non-Bitcoin posts. We rule out alternative mechanisms such as awareness or "Keeping up with the Joneses."

Pedagogical Design and Innovations for Analytics Education

Invited Session

INFORMS Committee on Teaching and Learning

Chair: Tiffany Bayley, Ivey Business School, London, ON, Canada

1 - Enhancing Systems Thinking Skills in Healthcare Management Through Experiential Learning with &Ldquo;Friday Night in the Er&Rdquo;

Natallia Gray, Iowa State University, Ames, IA, United States

Healthcare professionals today are encouraged to build their skills in teamwork, systems thinking, and interprofessional collaboration to enhance patient safety and the quality of care. However, the avenues for effectively learning and practicing these skills are often scarce. Additionally, health educators face the challenge of finding effective methods to teach systems thinking.

To address this need, we integrated "Friday Night in the ER," an experiential learning tabletop game, into an existing healthcare management course. This game provides a hands-on approach to teaching systems thinking by immersing participants in the role of a hospital department manager during a condensed 24-hour simulation. Through this activity, participants learn to apply core principles of systems thinking to optimize system-wide performance, and receive scores based on quality of care, cost, and efficiency.

Additionally, we facilitate an industry workshop where healthcare administrative professionals engage in the same game. By comparing performance metrics between healthcare management students and seasoned professionals, we uncover valuable insights into potential gaps in systems thinking skills across the two groups.

To measure the effectiveness of the game in teaching systems thinking, both groups of participants are asked to complete a Likert scale survey. This survey evaluates the extent to which the activity contributes to achieving the game's learning objectives.

2 - The Feature-Based Newsvendor Model: The Fusion of Predictive and Prescriptive Approaches

Vahid Roshanaei, Rotman School of Management, University of Toronto, Toronto, ON, Canada, AKRAM KHALEGHEI

In this talk, we will present the newly designed and implemented Python-based lecture on the feature-based newsvendor problem (F-NVP), which has been integrated into the curriculum of the "Management Analytics" course at the Rotman School of Management, University of Toronto. Unlike the traditional newsvendor model, which concentrates solely on individual products, F-NVP integrates features from analogous products to provide a more nuanced comprehension of demand dynamics, a particularly beneficial approach for new product launches where historical data may be scarce or absent. By quantifying the average contribution of each feature in generating demands for similar products, F-NVP helps decision-makers better predict the expected demand for the product about to be released, based on its features. Our talk covers aspects such as the (i) non-linear formulation of the F-NVP, (ii) techniques for its linearization, and (iii) the application of the traditional two-step predict-then-optimize approach and the new single-step machine-learning approaches to address "big data" challenges. We will illustrate the superiority of this single-step approach over the traditional two-step predict-then-optimize method using a women's jeans product from Zara as an example. This lecture provides students with insights into inventory optimization strategies. By bridging theory with hands-on Python coding, students gain a deeper understanding of inventory management principles and their applications in today's data-driven business landscape.

3 - Strategic Course Sequencing in Business Education: a Mixed-Method Inquiry

Tiffany Bayley, Ivey Business School, London, ON, Canada, Kyle Maclean, Mazi Raz

Business school curricula traditionally encompass courses on analytics, strategy, marketing, organization behaviour, operations management, finance, accounting, and more. These topics are covered over the duration of 3- or 4-year program. However, the order in which these courses are introduced varies across institutions. Motivated by discussions during our institution's recent quality assurance process, we explore 'designed' or curated approaches to course sequencing, specifically examining how foundational knowledge can set the stage for higher-order understanding. We use a mixed-method approach, combining quantitative data analysis with qualitative insights from faculty and industry experts, to investigate the "Critical Paths of Business Education," and when the right time to introduce analytics could be.

4 - Analytically Astute: Training our Students to Understand Real World Phenomena

Srinivas Krishnamoorthy, Beedie School of Business, Simon Fraser University, Vancouver, BC, Canada

Students typically view analytics knowledge as a means to boost their career prospects rather than a way to understand real world phenomena. We can motivate our students to adopt a holistic analytics perspective by discussing examples from the happenings around us. We will explore such examples in the talk and offer tips for training our students to become analytically astute.

Multitask and Federated Learning: Challenges of Optimization Under Heterogeneity

Invited Session

Artificial Intelligence

Chair: Hongyang Zhang, Northeastern University, Boston, MA, United States

Co-Chair: Yang Tianbao, Texas A&M University, College Station, TX, United States

1 - On the Effect of Defections in Federated Learning and How to Prevent Them

Han Shao, Toyota Technological Institute at Chicago, Chicago, IL, United States, Minbiao Han, Kumar Kshitij Patel, Lingxiao Wang

Federated learning is a machine learning protocol that enables a large population of agents to collaborate over multiple rounds to produce a single consensus model. There are several federated learning applications where agents may choose to defect permanently--essentially withdrawing from the collaboration--if they are content with their instantaneous model in that round. This work demonstrates the detrimental impact of such defections on the final model's robustness and ability to generalize. We also show that current federated optimization algorithms fail to disincentivize these harmful defections. We introduce a novel optimization algorithm with theoretical guarantees to prevent defections while ensuring asymptotic convergence to an effective solution for all participating agents. We also provide numerical experiments to corroborate our findings and demonstrate the effectiveness of our algorithm.

2 - Boosting Multitask Learning Through Higher-Order Task Affinities

Hongyang Zhang, Northeastern University, Boston, MA, United States

Multitask learning is a widely used paradigm for training models on diverse tasks, with applications ranging from graph neural networks to language model fine-tuning. Since tasks may interfere with each other, a key notion for modeling their relationships is {\em task affinity}. This includes pairwise task affinity, computed among pairs of tasks, and higher-order affinity, computed among subsets of tasks. Naively computing either of them requires repeatedly training on data pooled from various task combinations, which is computationally intensive. We present a new algorithm that can estimate task affinities without this repeated training.

The key idea is to train a ``base'' model for all tasks and then use a linearization technique to estimate the loss of any other model with a specific task combination. The linearization works by computing a gradient-based first-order approximation of the loss, using low-dimensional projections of gradients as features in a logistic regression trained to predict labels for the specific task combination. We show theoretically that the linearized model can provably approximate the loss when the gradient-based approximation is accurate, and empirically verify that on several large models. Then, given the estimated task affinity matrix, we design a semi-definite program for clustering to group similar tasks that maximize the average density of clusters.

We evaluate the performance across seven datasets, including multi-label classification on graphs, and instruction fine-tuning of language models. We show that our task affinity estimates are within 2.7% distance of the true affinities while needing only 3% of FLOPs compared to full training.

3 - A Multi-Objective Neural Architecture Search Framework for Optimizing Spiking Neural Networks Using NSGA-II

Esmat Ghasemi Saghand, university of south florida, Tampa, FL, United States, Susana Lai-Yuen

Spiking Neural Networks (SNNs) are emerging as an energy-efficient and biologically plausible alternative to traditional Artificial Neural Networks (ANNs). Unlike ANNs, SNNs process asynchronous and sparse spike information, reducing the need for expensive computations and lowering energy consumption. However, finding suitable SNN architectures is challenging and time-consuming due to their non-differentiable spiking dynamics. While Neural Architecture Search (NAS) techniques have been developed for ANNs, only a few studies have applied NAS to SNNs. In this study, we introduce MONAS-ESNN, a multi-objective NAS framework based on the NSGA-II algorithm, to automate the design of SNN architectures. MONAS-ESNN identifies the best architectures in terms of both accuracy and the number of generated spikes. During the search, we evaluate micro-level neural blocks that include relevant components for SNNs, such as connectivity patterns and feed-forward and backward connections. We introduce a new scoring function within MONAS-ESNN to predict the performance of candidate architectures without training, reducing the search time. The performance prediction is based on the diversity of spike activation patterns across different data samples and considers the binary activation pattern of parametric leaky integrate-and-fire (PLIF) neurons. MONAS-ESNN is evaluated across three image classification benchmarks. Our results demonstrate the effectiveness of the proposed framework in identifying SNN architectures that achieve higher accuracy with a lower number of spikes compared to existing methods. This work provides insights for improving the discovery of more effective and energy-efficient SNN architectures.

Daniel H. Wagner Competition I

Award Session

Daniel H Wagner

Chair: James Cochran, The University of Alabama, Tuscaloosa, AL, United States

1 - JD.com Improves Fulfillment Efficiency with Data-driven Integrated Assortment Planning and Inventory Allocation

Shuo Sun, University of California,Berkeley, Berkeley, CA, United States, Zuo-Jun Shen, Yongzhi Qi, Hao Hu, ningxuan kang, Jianshen zhang, Xin Wang, Xiaoming lin

JD.com, a leading e-commerce company in China, has significantly improved its fulfillment efficiency to enhance customer satisfaction. JD.com uses a two-level inventory network with Regional Distribution Centers (RDCs) and Front Distribution Centers (FDCs). JD.com develops a decision support system that integrates optimization techniques and machine learning algorithms to decide the assortment at FDCs and daily inventory allocation from RDCs to FDCs. Implemented across JD.com’s network in China, it significantly enhances order fulfillment efficiency and reduces inventory and transfer costs.

2 - Optimizing Music Station Playlists on Broadcast Radio

J. Antonio Carbajal, iHeartMedia, Atlanta, GA, United States, Juan Ma, Nannan Chen, Mario Aboytes-Ojeda

iHeartMedia has pioneered the use of mathematical optimization in music playlist creation, developing an engine that generates 24/7 playlists for radio stations, subject to strategic scheduling goals and key business rules. Utilizing song meta data, the latest research and predictive analytics around song performance, and radio listenership data, the engine produces music playlists simultaneously optimizing strength and diversity. The engine has been successfully deployed to production and has proven effective in boosting the operational efficiency and quality of music scheduling processes.

Undergradutate Operations Research Prize I

Award Session

Undergraduate Operations Research Prize

Chair: Rachel Cummings, Columbia University, New York, NY, United States

1 - Online Newsvendor Problem with Blackbox Predictions

Rohan Kulkarni, Columbia University, New York, NY, United States

We explore the application of algorithms with blackbox predictions to the online newsvendor problem, an established problem in inventory management. We introduce a no-regret algorithm, TEST, which leverages predictions to achieve exponential improvement in best-case regret bound compared to existing algorithms that do not use predictions. We also formulate novel regret-based consistency and robustness metrics to evaluate algorithm competitiveness in the online setting. TEST achieves a best-case consistency regret bound of O(T^(1/2)e^-T) while remaining sublinear in regret in the worst-case.

2 - Practical Bayesian Algorithm Execution via Posterior Sampling

Chu Xin (Cloris) Cheng, California Institute of Technology, Pasadena, CA, United States

We consider Bayesian algorithm execution, where the goal is to select points for evaluating an expensive function to best infer a property of interest. Observing that the property of interest for many tasks is a target set of points defined by the function, we derive PS-BAX, a simple and effective posterior sampling algorithm. Experiments show PS-BAX achieves competitive performance against baselines while being much faster to compute. Additionally, we show that PS-BAX is consistent under mild conditions. Our work thus provides new insights into posterior sampling and its application scope.

3 - Statistical Properties of Robust Satisficing

Zhiyi Li, Peking University, Beijing, China, People's Republic of

Robust Satisficing is an emerging robust optimization method. However, it lacks the statistical guarantees of its widely-studied counterpart, DRO. This paper addresses this gap by deriving two-sided confidence intervals for optimal loss and finite-sample generalization error bounds under Wasserstein distance, extending also to distribution shifts. For f-divergence, we establish an asymptotic upper bound on generalization error. Numerical experiments show that RS outperforms ERM in small-sample regimes and under distribution shifts, and shows less sensitivity to hyperparameter tuning than DRO.

4 - On Partial Optimal Transport: Revising the Infeasibility of Sinkhorn and Efficient Gradient Methods

Anh Duc Nguyen, National University of Singapore, Singapore, Singapore

We study the Partial Optimal Transport (POT) problem. We first investigate the infeasibility of the SOTA Sinkhorn algorithm for POT, degradeing its performance in applications. To this end, we propose a novel rounding algorithm for POT, and then provide a feasible Sinkhorn procedure. Our rounding algorithm also permits the development of two novel POT methods: Adaptive Primal-Dual Accelerated Gradient Descent and Dual Extrapolation which has the best complexity in the literature. We show the practicality of our algorithms on applications such as point-cloud registration and domain adaptation.

Generative AI, Algorithmic Bias, and Dynamics in Digital Disruptions

Invited Session

eBusiness

Chair: Yi Gao, Texas Tech University, Lubbock, TX, United States

1 - Generative AI and Human Knowledge Sharing: Evidence from a Natural Experiment

Qili Wang, University of Florida, Gainesville, FL, United States, Yi Su, Kaiyu Zhang, Liangfei Qiu

Generative AI, known for its content creation capabilities, possesses great potential to reshape knowledge-sharing activities. By leveraging a unique policy of a leading online Q&A platform that introduces generative AI answers, we explore the effects of generative AI answers on human knowledge contribution efforts in knowledge-sharing platforms. Our findings demonstrate the positive effects of the generative AI answers on human knowledge contribution efforts, both in terms of quantity and length of the subsequent answers to a question. Notably, a more nuanced investigation into human-AI answer similarity indicates that generative AI answers prompt users to provide answers more aligned with the AI-generated answers, underscoring the AI-conformity effect rather than the AI-differentiation effect as the underlying mechanism. Moreover, we observe an increase in human experts' contribution following the introduction of generative AI answers, suggesting generative AI answers encourage rather than crowd out human experts' contribution to the platform. In a follow-up randomized experiment, we offer corroborative evidence for the results of empirical analysis. Furthermore, it provides preliminary evidence that labeling generative AI as the knowledge provider, rather than the content of generative AI answers, primarily drives the observed effects of introducing generative AI answers. Our research highlights the potential of generative AI to motivate human participation in knowledge generation and dissemination, adding to the burgeoning body of work on how generative AI influences human knowledge sharing.

2 - Wrong Model OR Wrong Practices? Mis-Specified Demand Model and Algorithmic Bias in Personalized Pricing

Qiaochu Wang, Carnegie Mellon University, Pittsburgh, PA, United States, Yan Huang, Param Singh, Kannan Srinivasan

The societal significance of fair machine learning (ML) cannot be overstated, yet quantifying algorithmic bias and ensuring fair ML remains a challenging task. One popular fair ML objective, equality of opportunity, requires equal treatment for individuals who are equally deserving, regardless of their group affiliation. However, determining who should be considered ``equally deserving" is a complex and critical aspect that directly affects the estimation of algorithmic bias. This paper emphasizes the importance of accurately measuring equal deservingness in order to accurately estimate algorithmic bias. To illustrate this, the paper examines the case of personalized pricing and shows that assuming a mis-specified model for equal deservingness can result in incorrect bias estimates. Using a detailed consumer data set from a large e-commerce platform, the paper demonstrates that when the correct consumer demand model is a non-sequential search model where consumers differ in their search costs based on gender, assuming a standard choice demand model or a traditional ML (e.g. Support Vector Machine) can lead to incorrect bias estimates. This research highlights the critical role that a proper model specification plays in achieving fair ML practices.

3 - Decoding Signal Discrepancies: Uncertainty and Exploration in Digital Music Consumption

Xinyu Fu, Georgia State University, Atlanta, GA, United States, Narayan Ramasubbu, Shadi Janansefat

Digital platforms deploy various signals to direct and shape user behaviors. Challenging the prevailing view that signal designs are crafted to reduce uncertainty, we leverage information gap theory to hypothesize that exposure to misaligned signals could, paradoxically, amplify content discovery behaviors. In particular, we focus on inconsistencies across signals from different sources, such as the disparity between users' social network preferences and overall platform trends. In a field experiment on a music streaming platform, participants were randomly assigned to one of four design scenarios that varied by the signal source and uncertainty level. Results indicate that users who received misaligned signals not only listened to more new music content, but also viewed a greater number of other users' profiles, relative to the other designs. We discuss the implications of information foraging behaviors of users for digital platforms and for further research on content discovery and user engagement.

4 - Balancing Biased Prices in Art: The Impact of Decentralized Nft Marketplace on Minority Artists

Agnes Yang, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States, YoungJin Kwon

Web3 has ushered in a decentralized online ecosystem underpinned by blockchain technology, consequently reducing the influence of traditional gatekeepers and intermediaries. This development prompts our research inquiry: \textit{How does this emergent environment impact prevailing gender and racial biases?} To address this question, we collect artist-, NFT-, and transaction-level data from Superrare, a leading NFT art market, and revisit the concept introduced by Goldin and Rouse (2000), demonstrating how "blinding" musicians' identities affects audition results for female musician. We present a nuanced perspective on NFT markets: (i) White males continue to dominate the NFT art market in terms of supply volume; (ii) Female, Black, and Hispanic NFT artists experience discounts compared to their White and male counterparts; (iii) NFT artists who conceal their identity do not experience gendered and racialized valuations, supporting the notion of blind audition effect; (iv) Female and Black NFT artists who disclose their identity derive greater benefits from providing textual self-description compared to their White and male counterparts. The paper discusses theoretical contributions and managerial implications.

5 - Decoding Coding Advice: Generative AI is Thinking Outside the Box in Problem Solving

ZIYI ZHAO, Temple University, Philadelphia, PA, United States, Kanghyun Cho, Aleksi Aaltonen, Detmar Straub

Generative AI (GenAI) surpasses traditional search technologies by generating novel solutions that do not exist in the search space. As such, traditional understandings of problem-solving, attitudes toward algorithmic solutions, and related mechanisms do not necessarily apply in the context of GenAI. Using the Elaboration Likelihood Model (ELM) and Cognitive Load Theory (CLT), we investigate how programmers search, evaluate, and adopt GenAI- versus human-generated programming solutions in a sequential mixed-methods study. The first part of the study based on behavioral modeling reveals contradictory results whereby GenAI-generated solutions are perceived as higher quality, despite human sources being considered more credible. The apparent paradox is resolved in the second part of the study based on qualitative analysis of problem-solving sessions showing that improved quality can be attributed to reduced cognitive load when using GenAI. GenAI supports various problem-solving approaches, such as backward and iterative search, which foster human-in-the-loop to efficiently prompt GenAI for high-quality solutions. However, the cognitive ease of GenAI raises concerns about users uncritically accepting potentially flawed solutions, and that an effective human-in-the-loop approach necessitates appropriate prompt representation, by which we refer to the iterative structuring of queries to guide GenAI toward more accurate and relevant solutions. This paper contributes to the understanding of human-GenAI collaboration in problem-solving.

Data-driven Analytics for Applications in Water and Food Supply

Invited Session

Energy: Natural Resources

Chair: Victoria Chen, The University of Texas at Arlington, Arlington, TX, United States

1 - A Design and Analysis of Computer Experiments Approach to Water Distribution Network Rehabilitation Optimization

Uthman Kareem, University of Texas at Arlington, Arlington, TX, United States, Jay Rosenberger, Victoria Chen, Mohsen Shahandashti, Raghavendra Kumar Punugu

Determining seismic vulnerabilities of water network modeling is critically important to ensure access to water in the face of an earthquake. In this research, we apply design of experiments from a number theoretic method (NTM) and a seismic modeling approach to create several post-disaster scenarios of a network. The variables in the design are the pipes while their levels are different states such as leaks, breaks or unaffected after network disruption. The same sample points from NTM are used to generate different rehabilitation policies through a ranking algorithm. These rehabilitation policies are applied on each scenarios and evaluated using computer simulation. The simulation results present opportunity for analysis as a way of generating better alternative improvement policies.

2 - A Cvar-Var-Standard Deviation Multi-Objective Risk Optimization for Enhancing Seismic Resilience in Water Pipe Network Rehabilitation

Raghavendra Kumar Punugu, The University of Texas at Arlington, Arlington, TX, United States, Jay Rosenberger, Victoria Chen, Uthman Kareem, Mohsen Shahandashti

Risk measures such as value-at-risk (VaR), conditional value-at-risk (CVaR), and standard deviation are among the popular risk measures widely used in financial risk management with applications in portfolio management, risk capital management, performance attributions and many more. Although these are predominantly used in quantitative finance, in this talk they are employed for enhancing water pipe network resilience to seismic events, which involves high uncertainty. VaR and CVaR at a given confidence level for a random variable X, representing the network's System Serviceability Index (SSI), are defined as the lower α-tail percentile and the conditional expectation below VaR, respectively. In this study, we propose using VaR, CVaR, and standard deviation as performance metrics to evaluate rehabilitation policies as a function of SSI for decision-making under seismic uncertainty. Using VaR-CVaR-Standard Deviation, we develop a multi-objective risk optimization model to increase the value realization from VaR-CVaR and minimize the value realization from standard deviation, generating a set of nondominated policies

3 - Machine Learning for Predicting Crop Yield Based on Soil Properties

Darya Abbasi, University of Texas at Arlington, Arlington, TX, United States, Amanda Ashworth, Phillip Owens, Edwin Winzeler, Kharel Tulsi, Yuan Zhou

Soil, as the primary agricultural medium, holds a crucial position in farming practices, and understanding the intricate relationship between soil properties and crop yield stability is vital for effective agricultural management. This study aims to use machine learning (ML) to predict crop yield stability based on comprehensive soil data analyses. The research was carried out across four sites in Ottawa County, Oklahoma, USA, encompassing a comprehensive dataset featuring yield data for corn, soybean, canola, and wheat, alongside soil nutrient properties across varying depths.
This abstract covers two main topics. First, we define the measurement of yield stability and discuss the process for merging multi-source data at a high spatial resolution within precision agriculture. Then, we discuss the ML techniques used to predict crop yield stability and explore their correlations with soil properties. The findings highlight the most effective approaches for linking soil characteristics to crop yield stability, emphasizing the importance of consistent and reliable crop production for long-term agricultural sustainability and food security.

4 - Designing a Crowd Logistics Network of a Regional Food System by Analyzing An Agent-Based Model Using Sequential Sampling

Victoria Chen, The University of Texas at Arlington, Arlington, TX, United States, Preetam Kulkarni, Caroline Krejci

Regional food systems involve farmers selling locally produced food to customers and it would benefit farmers if they can expand their market reach. It also gives customers access to fresh produce and promotes better health. Small scale farmers tend to be involved in transporting their produce to the destination as they can not afford hiring a third party logistics service as it is expensive. Moreover, farmers are also concerned about the safety of the produce while it is being transported. Crowd logistics is a potential solution to this problem as it could help farmers by providing an affordable and safe means of transportation given that the participants on the crowd logistics network are vetted and credible. This research aims to develop methods to evaluate a crowd logistics network using agent based modeling as these models tend to be computationally intensive. We propose the use of sequential sampling as a means to reduce the number of simulation runs and still be able to evaluate the factors influencing the performance of a crowd logistics network as it's success is important to ensure continued service to farmers.

Online Learning and Data-driven Decision Making: Recent Advances and Applications

Invited Session

Data Mining

Chair: Tanapol Kosolwattana, University of Houston, Houston, TX, United States

Co-Chair: Ying Lin, University of Houston, Houston, TX

1 - A Tensor-Based Approach for Monitoring Partially Observed High-Dimensional Data Stream

Junghee Pyeon, Georgia Institute of Technology, Atlanta, GA, United States, Kamran Paynabar

Many types of high-dimensional (HD) data stream have become available to engineers in a number of fields thanks to the development of measuring equipment as well as communication technology. In practice, however, a variety of reasons such as insufficient transmission bandwidth, time constraints, and surging costs, forces practitioners to deal with partially observed information in order to examine whether their processes are currently working without any anomalies. To address these challenges, we propose a novel framework capable of effectively monitoring incomplete streaming HD data by capturing the inherent auto-/cross-correlation. To be specific, our approach involves two key components: (i) delay-embedding transformation along with the time axis, which has been widely used for missing value imputation, to generate the high-dimensional but low-rank tensor and (ii) Tucker decomposition to fragment the tensor into invariant factorizing matrices and time-dependent core tensors, which are then monitored by statistical process control methodologies. Through intensive simulation experiments and a case study, we evaluate the performance of our procedure and compare it with existing methods.

2 - Fcom: a Federated Collaborative Online Monitoring Framework via Representation Learning

Ying Lin, University of Houston, Houston, TX, United States, Tanapol Kosolwattana, Huazheng Wang, Raed Kontar

Monitoring a large population of dynamic processes with limited monitoring resources poses a significant challenge across various industrial sectors due to 1) the inherent disparity between the limited monitoring resources available and the large population of processes to be monitored and 2) the unpredictable and heterogeneous dynamics inherent in the progression of these processes. Online learning approaches, commonly referred to as bandit methods, have demonstrated notable potential to solve this problem by dynamically allocating limited resources, effectively balancing the exploitation of processes yielding high rewards, and the exploration of uncertain processes. However, most online learning algorithms are designed under 1) a centralized setting that requires data sharing across processes to obtain an accurate prediction or 2) a homogeneity assumption that estimates a single global model from the decentralized data. To overcome these limitations and facilitate online learning in a heterogeneous population under a decentralized setting, we propose a federated collaborative online monitoring method. Our approach captures the latent representative models inherent in the population through representation learning and designs a novel federated collaborative UCB algorithm to estimate the representative models from sequentially observed decentralized data. This allows an informed strategy for monitoring resource allocation. The efficiency of our method is illustrated through theoretical analysis, simulation studies, and decentralized cognitive degradation monitoring in Alzheimer's disease.

3 - MT-RAM: Multi Task-Recurrent Attention Model for Partially Observable Image Anomaly Classification and Localization

Jie Guo, Tsinghua University, Beijing, China, People's Republic of, Chen Zhang

With the rapid development of the digital manufacturing industry, the nature of quality data has transformed from simple univariate or multivariate characteristics to big data comprising multimedia elements such as images and videos. The utilization of image data for automated monitoring and anomaly detection has gained significant attention in recent years, which also poses new and complex challenges. A critical challenge is the substantial demand for sensing and computation resources. When these resources are limited, only a fraction of the image data can be observed and analyzed. Hence, adaptive sampling becomes imperative to select the most informative pixels that effectively capture anomaly information. In this paper, we propose a novel recurrent neural network framework named Multi Task-Recurrent Attention Model (MT-RAM) which incorporates adaptive sampling for anomaly classification and localization in partially observable image data. MT-RAM emulates human-like perception by generating a sequence of glimpses to comprehend the image, with the location of each glimpse depending on the information gleaned from previous glimpses. Thorough numerical studies and case studies are conducted to evaluate the performance of MT-RAM in comparison to state-of-the-art adaptive-sampling-based anomaly detection methods.

4 - Fourier Learning with Cyclical Data

Zhihan Xiong, University of Washington, Seattle, WA, United States, Yingxiang Yang, Tianyi Liu, Taiqing Wang, Chong Wang

Many machine learning models for online applications, such as recommender systems, are often trained on data with cyclical properties. These data sequentially arrive from a time-varying distribution that is periodic in time. Existing algorithms either use streaming learning to track a time-varying set of optimal model parameters, yielding a dynamic regret that scales linearly in time; or partition the data of each cycle into multiple segments and train a separate model for each---a pluralistic approach that is computationally and storage-wise expensive. In this paper, we have designed a novel approach to overcome the aforementioned shortcomings. Our method, named ``Fourier learning", encodes the periodicity into the model representation using a partial Fourier sequence, and trains the coefficient functions modeled by neural networks. Particularly, we design a Fourier multi-layer perceptron (F-MLP) that can be trained on streaming data with stochastic gradient descent (streaming-SGD), and we derive its convergence guarantees. We demonstrate Fourier learning's better performance with extensive experiments on synthetic and public datasets, as well as on a large-scale recommender system that is updated in real-time, and trained with tens of millions of samples per day.

5 - Bandit Optimisation under Fused Gaussian Processes

Muyun Lu, University of Houston, Houston, TX, United States, Huazheng Wang, Ying Lin

In many situations across computational science and engineering, there are tasks to maximize an expensive to estimate black box function of a system (target function). To save the cost, in many cases, cheap approximations to the target function can be available to gain partial information which helps us identify the optimum at the target function, which are known as multi-fidelity bandit optimisation. However, existing multi-fidelity bandit optimisation models ignore the latent structure among fidelities in reality, where the observations in target fidelity and its approximations can be correlated by a fusion model. To solve this problem, we develop a novel Fused Gaussian Process-based Upper Confidence Bound (FGP-UCB) method which leverages the low fidelities to gain partial information for uncertainty reduction through the fusion model and facilitates the target fidelity to identify the optimum quickly. Comparing to the state-of-art multi-fidelity GP-UCB approach, our model does not constrain the functions in different fidelities via a uniform bound, which is more flexible to fit the real data. Effectiveness of the proposed method is demonstrated via both theoretical analysis and empirical studies.

Regency - 703

Machine Learning Aided Causal Inference

Invited Session

Data Mining

Chair: Srikar Katta, Duke University, Durham, NC, United States

1 - Assessing Robustness to Unobserved Confounding by Combining Experimental and Observational Data

Quinn Lanners, Duke University, Durham, NC, United States

Combining data from a randomized experiment with observational study data can offer considerable improvements in efficiency and generalizability; however, this comes at a great cost, as it typically sacrifices the robustness to confounding which is the hallmark of randomization. To avoid biased estimates when using observational data, we rely on a different assumption, referred to as study exchangeability. While this assumption may be more valid in certain scenarios, it is a difficult assumption to validate and violations in study exchangeability can have equally as detrimental effects as unobserved confounding. In this talk, we discuss how we handle the assumptions of conditional ignorability and study exchangeability more carefully. Particularly, we present a partial identification approach to heterogenous treatment effect estimation when combining randomized experiment and observational study data under potential violations to both conditional confounding and study exchangeability.

2 - Bayesian Causal Synthesis for Meta-Inference on Heterogeneous Treatment Effects

Kenichiro McAlinn, Temple University, Philadelphia, PA, United States, Shonosuke Sugasawa, Kosaku Takanashi, Edoardo Airoldi

The estimation of heterogeneous treatment effects in the potential outcome setting is biased when there exists model misspecification or unobserved confounding. As these biases are unobservable, what model to use when remains a critical open question. In this paper, we propose a novel Bayesian methodology to mitigate misspecification and improve estimation via a synthesis of multiple causal estimates, which we call Bayesian causal synthesis. Our development is built upon identifying a synthesis function that correctly specifies the heterogeneous treatment effect under no unobserved confounding, and achieves the irreducible bias under unobserved confounding. We show that our proposed method results in consistent estimates of the heterogeneous treatment effect; either with no bias or with irreducible bias. We provide a computational algorithm for fast posterior sampling. Several benchmark simulations and an empirical study highlight the efficacy of the proposed approach compared to existing methodologies, providing improved point and density estimation of the heterogeneous treatment effect, even under unobserved confounding.

3 - Auditing Fairness under Unobserved Confounding

Michael Oberst, Johns Hopkins University, Baltimore, MD, United States, Yewon Byun, Dylan Sam, Zachary Lipton, Bryan Wilder

Inequity in resource allocation has been well-documented in many domains, such as healthcare. Causal measures of equity / fairness seek to isolate biases in allocation that are not explained by other factors, such as underlying need. However, these fairness measures require the (strong) assumption that we observe all relevant indicators of need, an assumption that rarely holds in practice. For instance, if resources are allocated based on indicators of need that are not recorded in our data ("unobserved confounders"), we may understate (or overstate) the amount of inequity.

In this talk, I will present work demonstrating that we can still give informative bounds on certain causal measures of fairness, even while relaxing (or even eliminating) the assumption that all relevant indicators of need are observed. We use the fact that in many real-world settings (e.g., the release of a new treatment) we have data from prior to any allocation, which can be used to derive unbiased estimates of need. This result is of immediate practical interest: we can audit unfair outcomes of existing decision-making systems in a principled manner. For instance, in a real-world study of Paxlovid allocation, we show that observed racial inequity cannot be explained by unobserved confounders of the same strength as important observed covariates.

4 - Covariate-Assisted Inference on Partially Identified Causal Effects

Asher Spector, Stanford University, Stanford, CA, United States, Wenlong Ji, Lihua Lei

Many causal estimands are only partially identifiable since they depend on the unobservable joint distribution between potential outcomes. Stratification on pretreatment covariates can yield sharper partial identification bounds; however, unless the covariates are discrete with relatively small support, this approach typically requires consistent estimation of the conditional distributions of the potential outcomes given the covariates. Thus, existing approaches may fail under model misspecification or if consistency assumptions are violated. In this study, we propose a unified and model-agnostic inferential approach for a wide class of partially identified estimands, based on duality theory for optimal transport problems. In randomized experiments, our approach can wrap around any estimates of the conditional distributions and provide uniformly valid inference, even if the initial estimates are arbitrarily inaccurate. Also, our approach is doubly robust in observational studies. Notably, this property allows analysts to use the multiplier bootstrap to select covariates and models without sacrificing validity even if the true model is not included. Furthermore, if the conditional distributions are estimated at semiparametric rates, our approach matches the performance of an oracle with perfect knowledge of the outcome model. Finally, we propose an efficient computational framework, enabling implementation on many practical problems in causal inference.

Data Mining Best Paper Competition (Student Track)

Award Session

Data Mining

Chair: Hadis Anahideh, University of Illinois Chicago, Chicago, IL, United States

Co-Chair: Andi Wang, University of Wisconsin-Madison, Madison, WI, United States

1 - Distributionally and Adversarially Robust Logistic Regression via Intersecting Wasserstein Balls

2 - MOSS: Multi-Objective Optimization for Stable Rule Sets

3 - Statistical and Computational Guarantees of Kernel Max-Sliced Wasserstein Distances

4 - A Bayesian Jump Model-based Pathwise Sampling Approach for Online Anomaly Detection

Dongmin Li, Georgia Institute of Technology, Atlanta, GA, United States, Miao Bai, Di Wang, Xiaochen Xian

Moving vehicle-based sensors (MVSs) have received growing attention for real-time anomaly detection in various applications such as wildfire and oil spill detection. To tackle challenges due to the spatial covariance structure among observations, uncertainties under partial observations, as well as the physical MVS movements, we propose a Bayesian jump model-based pathwise sampling approach to detect abrupt changes in an area of interest in real time using MVSs. Specifically, we integrate a jump-model based Bayesian scheme, the upper confidence bound algorithm, and mathematical optimization in a unified manner to exploit spatial correlation and real-time partial observations, to handle uncertainties of noisy observations, limited observability, and anomaly occurrences, and to adaptively coordinate the routes of multiple MVSs for quick anomaly detection. We perform theoretical investigations and conduct simulations to confirm the exceptional effectiveness of the method we propose. A case study for early wildfire detection demonstrates that our proposed method outperforms benchmark methods, which contributes to the reduction of the area of affected land and wildfire-related costs.

Issues in Energy Market Modeling

Invited Session

ENRE: Electricity

Chair: Joseph Duggan, University of Dayton, Dayton, OH, United States

Co-Chair: Ramteen Sioshansi, Carnegie Mellon University, Pittsburgh, PA, United States

1 - Stochastic Capacity Expansion Modeling Considering Interconnection Queue Risk

Yiwen Wang, University of Massachussets, Amherst, Amherst, MA, United States

Interconnection queue is a list of projects awaiting impact studies before getting approved for grid connections. Long delays and high withdrawal rates have been observed in the interconnection queues in many regions of the US. The delays and withdraws predominantly affect renewable and battery-hybrid projects, potentially impeding the energy transition. Few studies have examined how risks associated with interconnection queues influence investment decisions of the energy system. This study employs a multi-year stochastic capacity expansion model that accounts for the uncertainty in lead times and withdrawal rates of new projects. We utilize the Expected Value of Perfect Information (EVPI) and the Value of Stochastic Solution (VSS) to assess the impacts of the interconnection queue congestion on deep decarbonization efforts. The results aim to inform how interconnection policy could affect deep decarbonization.

2 - Uniqueness of Nash-Cournot Equilibria in an Oligopolistic Energy Market with Demand Uncertainty and Uncertain Renewable Generation

Benjamin Chaiken, Parametric Portfolio Associates, Seattle, WA, United States, Joseph Duggan

This work explores the uniqueness of Nash-Cournot equilibria in wholesale electricity markets with both thermal and renewable generation in the presence of both uncertain demand uncertainty and uncertain renewable generation. In a previous work, the authors expand upon the uniqueness results proven by Lagerl ̈of (2006) to incorporate the presence of renewable generation into the market in the manner of Acemoglu et al. (2017). The model of Acemoglu et al. (2017) incorporates a constant amount of renewable generation, with zero marginal cost, distributed among all firms. The present work extends this model to include uncertainty over the amount of renewable generation available in any given period, and extends the prior uniqueness results to study the effects of uncertain renewable supply on the multiplicity of equilibiria.

3 - Designing Carbon Policy with Profit-Maximising Energy Storage

Afzal Siddiqui, Stockholm University, Kista, Sweden, Ramteen Sioshansi

In a storage-enabled renewable-thermal power system, carbon emissions still require mitigation based on their social cost of damage. A central-planning solution internalises the environmental externality by curbing thermal production in proportion to the marginal cost of damage. Consequently, in a two-period setup, the price in the peak (second) period increases by more than that in the off-peak (first) period. In particular, the rates at which the prices increase differ by the inverse of the storage device’s efficiency. Thus, an infinitesimal increase in the slope of the marginal cost of damage curbs thermal generation in both periods without affecting storage-enabled renewable operations. Moreover, a degradation in storage efficiency has a monotonic impact on the marginal cost of damage. By contrast, in a decentralised electricity industry, a bi-level approach is necessary in which a welfare-maximising policymaker at the upper level sets a carbon tax to impose on industry at the lower level. For a completely efficient storage device, the carbon tax in this bi-level setting renders the first-best outcome. However, in the presence of an inefficient storage device, an infinitesimal increase in the carbon tax induces prices in both periods to increase at the same rate. As a result, the storage-enabled renewable operator shifts energy to the off-peak period in order to offset the loss in the value of stored energy. Hence, relative to a centralised industry’s marginal cost of damage from emissions, the carbon tax in a decentralised industry is lower and may be nonmonotonic in the storage device’s inefficiency.

4 - The implications of storage degeneracy on power system optimization models

Thomas Klatzer, Graz University of Technology, Graz, Austria, Sonja Wogrin, Ramteen Sioshansi

With the ongoing transition towards decarbonized power systems, storage technologies are becoming increasingly important to mitigate the variability of renewable generation, i.e. solar and wind, and to achieve modest total system cost. In the context of power system optimization models (PSOMs), storage technologies can contribute to degeneracy in the decision variables, i.e. when a storage unit is charged and its corresponding state of charge, which implies that the determined values of the decision variables are not unique. Against this background, we formulate a PSOM with a highly flexible temporal structure to study degeneracy of both short-term and long-term storage technologies using a full chronological representation of time and representative periods. As a unique model feature, the representative periods framework enables modeling of long-term storage behavior without sacrificing the computational benefits of such a framework. In our talk, we will discuss the impact of degeneracy of short-term and long-term storage technologies on decision variables, computational performance and local marginal prices and showcase approaches to reduce storage degeneracy.

5 - Routing India's thermal generation towards Net Zero with CCS: optimal planning and development policy implications

Olivier Massol, CentraleSupélec & City, University of London, Gif sur Yvette, France, Adrien Nicolle, Stephanie Monjon

India’s CO2 emissions are among the highest globally, largely due to its extensive coal-fired power plant fleet. Despite the commitment to achieving net-zero emissions, India has not planned a coal phase-out and continues to expand its coal power capacity to meet the nation's rapidly growing consumption of electricity. Carbon Capture and Storage (CCS) technologies offer a viable solution to mitigate these emissions while preserving the country's ambition to monetize its domestic coal resources. However, CCS deployment in India is still embryonic as no Indian coal-fired power plant currently employs CCS. The puprose of this study is to: (i) examine the optimal deployment of CCS in India's power sector, (ii) analyze its economics to evaluate the associated investment gap, and (iii) evaluate policy options aimed at accelerating CCS adoption. We use a network optimization approach to design a cost-effective pipeline network for transporting CO2 from coal power plants to storage sites across India. Our analysis shows that a significant portion of the transport infrastructure is consistent across various scenarios, highlighting strategic priorities for infrastructure investments. This insight is crucial as Indian authorities and development agencies consider subsidizing CCS infrastructure, providing clear guidance on which pipelines should receive priority investment. Our research offers valuable insights into the economic and policy frameworks necessary for the efficient and accelerated deployment of CCS technology, supporting India's transition towards a sustainable energy future.

Planning the Electric Grid for Climate Change

Invited Session

ENRE: Energy-Climate

Chair: Sofia Taylor, University of Wisconsin-Madison, Madison

Co-Chair: Line Roald, University of Wisconsin - Madison, Madison, WI, United States

1 - Winter vulnerabilities to weather and climate in future power systems

Ana Dyreson, Michigan Technological University, Houghton, MI, United States, Shelbie Wickett

Changes in weather and climate impact electric power system vulnerabilities in myriad ways that depend also depend on technology changes in supply and demand. This talk focuses on planning electric power systems for winter weather. In northern climates, where winter heating loads are significant, adoption of electric heat pumps will change the seasonal electricity demand at the same time that solar photovoltaics (PV) become a critical part of resource supply in those regions. We use high resolution daily snow depth data to estimate how snow will affect the availability of future solar PV resource supply. Using metrics including capacity credit, we overlay these supply changes with winter and spring peak demand for electricity for heating to determine how cold and snowy weather will overlay to affect future resource adequacy. These analyses highlight key springtime periods for resource adequacy and reliability assessments and underscore the need to continue to understand how snow affects solar PV systems and how snow shedding from solar PV can be better mitigated and forecast for operational planning.

2 - Computational pipeline predicts solar and wind energy availability under various climate change projections

Matthew Signorotti, Lawrence Livermore National Laboratory, Livermore, CA, United States

Background/objectives

Renewable and low-carbon energy sources should power the grid to minimize future climate change. This project seeks to predict climate dependent generation availability, such as from solar and wind farms, under various future climate projections.

Approach/activities

I create a computational pipeline for working with large numeric objects such as scientific array data. Features include streamlining reading inconsistent netCDF files while performing various validation checks, lazy evaluation, eager garbage collection, and automatic unit conversion. The pipeline is used to run renewable power simulations with the System Advisor Model (SAM) from the National Renewable Energy Laboratory (NREL) for different netCDF climate datasets, from past to future data, with various gridding schemes, spatial and temporal resolutions, variables, units, climate projection scenarios, and data sources. The pipeline builds upon numerous climate simulations, which themselves include just climatological information. It generates future power simulation data that can inform sustainable energy policy investment decisions.

Results/lessons learned

I present empirical results on real climate datasets and implications for future renewable power availability.

3 - Optimizing Power Line Undergrounding Decisions under Wildfire Risk and Varying Weather Scenarios

Sofia Taylor, University of Wisconsin - Madison, Madison, WI, United States, Amelia Musselman, Line Roald, Jean-Paul Watson

The threat of wildfire ignitions from electric power equipment has led utilities to increasingly turn to preemptive power shutoffs, which, while effective in reducing grid-induced wildfire risk, can cause significant load loss. Undergrounding power lines is an alternative strategy for preventing grid-induced wildfires. However, undergrounding lines is costly, so an effective undergrounding plan must balance the cost of load loss with the cost of undergrounding lines. We propose a robust optimization model to identify power lines to underground to maximize load served while limiting wildfire risk across a range of wildfire risk and weather scenarios. Since solving this problem may be computationally heavy for large power systems and many operating scenarios, we present a delayed constraint generation algorithm to iteratively add scenarios until an optimal solution is found. We evaluate the performance of this robust optimization framework on the RTS-GMLC system with scenarios representing a year of operating conditions.

4 - Resilient Capacity Planning with EPRI’s Climate READi Initiative

Jesse Bukenberger, Electric Power Research Institute, Pittsburgh, PA, United States

Electric grids have always been exposed to extreme events with hazards such as extreme heat, cold, and storm-force winds, but the nature of these hazards is shifting with the climate. Planners need more rigorous ways to plan a resilient system. This work gives utilities a systematic approach to integrate resilience goals into established long-term capacity planning practices.

One path to resilience is through hardening. Individual assets can often be hardened with outfits that protect against some, but usually not all, hazard impacts. In the system more broadly, resilience can also be improved through more traditional capacity planning decisions that include changing the size, location, and timing of new generation and transmission investments. These investments can bring benefits beyond resilience, such as reduced operating costs and emissions. The plan that best meets all the planning requirements will likely include a balance of these options, and finding such a plan requires an integrated planning model.

The presented model optimizes investments in generation, transmission, and hardening options. Extreme events with many different hazards are considered alongside normal operating conditions. Specific resilience targets are included as planning criteria. The resulting solution is the least-cost expansion plan that meets the planner's specified resilience and other planning targets. We demonstrate the approach and highlight some resulting insights on a 4,894-node synthetic Texas power system with extreme heat, cold, and hurricane events.

Multi-Objective Decision Support Systems for Coping with Deep Uncertainties

Invited Session

ENRE: Environment and Sustainability

Chair: Chao Wang, Beijing University of Technology, 100 PING LE YUAN, Beijing, 100124

1 - Resilience strategies in an intertwined supply network: Mitigating the vulnerability under disruption ripple effects

Chao Wang, Beijing University of Technology, Beijing, China, People's Republic of

Intertwined supply network (ISN) is a complex system consisting of multiple interconnected supply chains orchestrated by different focal firms. The inherent interconnectedness of an ISN makes it vulnerable to localized disruptions, which can propagate through intricate supplier-buyer relationships, causing unpredictable disruption ripple effects that exacerbate vulnerabilities. While existing literature provides valuable insights into the vulnerability of supply networks with a single focal firm, less attention has been given to ISN comprising multiple competing focal firms. This study proposes an agent-based model to simulate the diffusion of disruption ripple effects in a realistic ISN. The model is used to assess the relative effects of firms' structural and operational attributes on vulnerability and to compare the effectiveness of three mainstream resilience strategies—resistance, adaptation, and recovery—in mitigating the overall vulnerability of ISN. Furthermore, the interaction of resilience strategies initiated by different focal firms in the ISN is explored. The results suggest that focal firms should prioritize their own structural attributes and those of their neighboring firms to address vulnerabilities effectively. Moreover, focal firms can identify partners with higher reciprocity and engage in cooperation for resilience investment. This study contributes to the understanding of ISN vulnerability and provides practical insights for developing effective resilience strategies in complex supply networks.

2 - A Decision Support System for Improving Drought Resilience under Climate Change

Abdullah Konak, Penn State Berks, Reading, PA, United States, Michael Jacobson, Daniel Winstead

Environmental risk modeling involves using indicators to measure extreme climate events and their impact, as well as coping mechanisms to reduce their effects. Index-based approaches make quantifying, comparing, and monitoring risks associated with natural hazards easier because a large set of indicators can be summarized into a few key performance indicators. This work will present a decision-support system (DSS) developed from a Belmont international collaborative research project to help policymakers devise and evaluate drought response and adaptation strategies based on a composite index-based approach. As drought events are becoming more frequent and unpredictable due to climate change, there is a need for decision support systems that incorporate risk assessment tools to help policymakers make decisions under uncertainty with incomplete data. We have developed a decision-support system framework that can integrate diverse climatic, biophysical, technological, and socioeconomic indicators to evaluate the drought resilience of at-risk communities. The framework considers complex relationships among these various indicators, combined with expert opinions from these diverse fields, to provide a what-if analysis for holistic policy recommendations.

3 - Should we stay or should we leave? Multi-objective tradeoffs driven by choices between beach nourishment and managed retreat under deep uncertainty.

Prabhat Hegde, Dartmouth College, Hanover, NH, United States, Adam Pollack, Vikrant Vaze, Klaus Keller

In some low-lying coastal areas around the world, decision-makers are beginning to consider "managed retreat" of human populations to adapt to sea-level rise. One of the main challenges in designing a managed retreat strategy is determining when to trigger retreat. Decision-makers lack tools and scientific understanding to evaluate whether the benefits of interim response strategies, like beach nourishment, outweigh the costs of waiting longer to trigger retreat. The current academic state of the art identifies the optimal timing of retreat for maximizing net present value with an assumption of perfect knowledge about climate and economic parameters. However, when evaluating strategies that look at timing sequences of beach nourishment and managed retreat, this approach remains silent on certain key considerations: First, there are trade-offs between key planning objectives such as benefits, investment costs, damage costs, and reliability. Second, this approach does not address how deep uncertainties surrounding climate and economic parameters influence these trade-offs and decision-making. Third, from a practical standpoint, the approach overlooks the viability of a strategy being financed by ignoring government benefit-cost ratio tests. Here, we introduce and operationalize an open-source, many-objective robust decision-making quantitative framework that fills these gaps. We identify the planning horizon and uncertainty ensemble required to achieve numerical convergence on the timing of retreat. We demonstrate that accounting for multiple objectives and uncertainty helps us identify robust strategies that also pass the government cost-benefit ratio tests more often.

4 - Mapping crop residue cover by integrating satellite time-series imagery and machine learning

Leticia Santos, North Carolina State University, Raleigh, NC, United States, Daniela Jones, Brian Lamb, Dean Hively, Jyoti Jennewein, Alison Thieme, Chris Reberg-Horton

Conservation tillage is a pivotal sustainable agricultural practice that enhances soil health and biodiversity by leaving crop residue on the field. This residue acts as a protective layer, preventing erosion, conserving soil moisture, and suppressing weeds, while also aiding in soil carbon sequestration to mitigate climate change. However, assessing its adoption accurately on a large scale poses significant challenges due to the time-consuming and labor-intensive nature of traditional ground-level surveys, which also lack scalability. To address these challenges, this study utilizes aerial and space-borne sensors, including shortwave infrared (SWIR) satellite imagery combined with machine learning algorithms, to efficiently collect high-resolution data. Specifically, the research maps and quantifies crop residue in croplands across the Delmarva Peninsula. By scaling ground-truthed high-resolution (4m pixels, 144 km2 footprint) crop residue cover maps derived from WorldView-3 SWIR imagery to more widely available, medium resolution Landsat images (30m pixels, 33,300 km2 footprint), we apply advanced machine learning techniques such as random forest, gradient boosting, and neural networks. The study incorporates inventories of conservation tillage on agricultural lands using imagery from satellite sensors and a novel, low-cost, scale-neutral tractor-mounted camera system developed by the PSA team. This approach not only quantifies soil cover residue, which may include cover crops, but also empowers government agencies and agricultural stakeholders with high-throughput techniques to measure, monitor, report, and verify tillage intensity practices on large-scale agricultural lands. This research are expected to enhance decision-making processes for stakeholders, policymakers, and farmers, and incentivize climate-smart agricultural practices that reduce greenhouse gas emissions.

5 - The Development of Machine Learning Models for Assessing In-season Sweetpotato Root Growth and Crop Yield Estimates

Shana McDowell, North Carolina State University, Raleigh, NC, United States, Daniela Jones, Michael Kudenov, Shelly Hunt

Sweetpotatoes vary widely in shape and size, and consumers prefer particular characteristics over others. Optimizing the yield to match consumer preferences would increase growers' profits and reduce waste. We used machine learning algorithms to highlight the environmental factors, harvesting, planting, and application decisions that contribute to sweetpotato shape and size throughout the growing season. In this process, we also gained a better understanding of the sweetpotato developmental stages through root images of sweetpotatoes as input into computer vision algorithms. We collaborated with a large sweetpotato grower, packer, and distributor in North Carolina, managing nearly fifteen thousand acres. Data was collected from several on-farm locations scattered over 2,500 square miles across three growing seasons. Sweetpotato weight and length-to-width ratio were predicted using Linear Regression, Support Vector Machine, Random Forest, and XG Boost models. Data splitting included random split, split between fields, and split between seasons. Results show that important predictors of sweetpotato weight are days after planting, average relative humidity, and average temperature. Predictors for length-to-width ratio include days after planting, the time between planting and liquid fertilizer application, and maximum wind speed. XG Boost performed best for predicting weight (MSE = 0.24, R^2 = 0.99), and Random Forest performed best for predicting length-to-width ratio (MSE = 0.01, R^2 = 0.98). As part of our translational research, we created a dashboard displaying in-field data to support stakeholder decision-making. This analysis aids in developing farm-to-market decision models, optimizing crop yield and crop quality, and better utilizing growers' resources.

Network Models in Optimization and Their Applications

Invited Session

Computing Society

Chair: Yajun Lu, Jacksonville State University, Jacksonville, AL, United States

1 - The Longest Path Problem in Perturbed Directed Acyclic Graph and Its Application in Manufacturing Scheduling

Golshan Madraki, Clarkson University, Potsdam, NY, United States, Seyedamirabbas Mousavian

We proposed *an algorithm* to accelerate the calculation of the length of the longest path in a directed acyclic graph where there are multiple added and deleted edges. Our algorithm updates the affected nodes instead of calculating the length of the longest path from scratch. Our algorithm has an application in Manufacturing system scheduling problems. It can be used to accelerate the scheduling heuristics (such as Genetic Algorithm, Simulated Annealing, etc.) in manufacturing systems) because these heuristics use a graph to model the system and calculate the makespan, i.e., longest path in the graph, during each iteration after scheduling perturbations. These algorithms iteratively perturb the graph and recalculate the makespan in each iteration until a satisfactory schedule is determined. These scheduling perturbations can be modeled by added and deleted edges in the corresponding graph of the manufacturing systems.

2 - Robust Supply Chain Network Design: Maximizing Matching Size with Adversarial Node Deletion

Eugene Ang, National University of Singapore, Singapore, Singapore, Yifan Feng

Supply chain disruptions, such as natural disasters and geopolitical events, pose significant challenges to businesses and economies worldwide. In this paper, we extend the existing work from Feng et al., 2023 by considering adversarial node deletion and investigate how appropriate graph design can enhance the robustness of supply chain networks, by maximizing its matching size in the residual graph upon adversarial node deletion. In brevity, this is a (n,m,k) problem, where n and m are the order and the size of the designed graph G, respectively, and k is the number of adversarially deleted nodes. When n and k are of the same parity, we show that the optimal graphs G^* have certain graph properties such as connectedness and minimum degree of k + 1. When n and k are of different parity, we obtain bounds on the size of G^* by analyzing optimal disconnected and connected graph designs. To quantify the loss in matching due to constraints on the size, we construct corresponding loss curves for fixed n and k. We conduct a performance analysis between K-chains and K-clusters, which act as proxies for connected and disconnected graph classes respectively. Through these curves, we illustrate a transition in the graph designs from

K-clusters to K-chains as m increases. Our work aims to provide a framework for stakeholders to enhance their supply chain networks' adaptability in an increasingly volatile world.

3 - Environmental impacts of pickup point networks in last mile logistics

Ilkka Leppänen, Aalto University, Espoo, Finland, Lauri Kuula, Juuso Leskinen, Linus Antell

Pickup point networks (PPNs) are being increasingly used by logistics companies in e-commerce. Because PPNs reduce the need for last mile home deliveries, they are often viewed as an environmentally sustainable alternative. However, previous research has not comprehensively taken into account the environmental impacts that incur when customers travel to pickup points. Moreover, the problem is complicated by customers' preferences to chain their parcel pickup trips with other daily commute. Building on the vehicle routing problem, we use operational data and behavioural survey data from a large national postal logistics operator and compare the total environmental impacts that different PPN configurations have, including a configuration with trip chaining. Our results show the importance of accounting for customer habits and preferences in network models that are used to study last mile parcel deliveries.

4 - Correspondent Banking Networks Optimization

NIMA SAFAEI, Scotiabank, Toronto, ON, Canada

Correspondent Banking (CB) Network refers to a network of financial institutions providing cross-border payment services for customers through different channels such as SWIFT, Fedwire, etc. We employ the mathematical programming approach in conjunction with the graph theory to optimize a CB network. Optimizing the network requires decisions to be made to onboard, terminate or restrict the bank relationships to optimize the size and overall risk of the network. This study provides theoretical foundation to detect the components, the removal of which does not affect some key properties of the network such as connectivity and diameter. We find that the correspondent banking networks have a feature we call k-accessibility, which helps to drastically reduce the computational burden required for finding the above mentioned components.

Optimization Modeling Software II

Invited Session

Computing Society

Chair: Susanne Heipcke, FICO, Xpress Optimization, Birmingham, United Kingdom

Co-Chair: Bob Fourer, AMPL Optimization Inc., Evanston, IL, 60201, United States

1 - Building and Solving Optimization Problems with the Augmented Api for Fico Xpress Solver

Alexander Biele, FICO, Darmstadt, Germany

The new FICO Xpress Solver API for Java, C# and C++ is designed as an object-oriented layer achieving an optimized interaction between Xpress Solver and model. This leads to a dramatically reduced overall model building time and increased memory efficiency. With the new API all Xpress Solver features are accessible, including full access to the recently added Global Solver. Among the key features of the new Xpress Solver API are the ability to use modern programming concepts such as Collections, Streams, Lambdas, and operator overloading to build expressions and constraints. In the presentation we show that the interface guarantees a consistent user experience across different programming languages. Furthermore, we will provide guidelines on how to efficiently implement optimization models in the new object-oriented API and discuss selected examples.

2 - A modeling language-based approach to automatically recommend first-order optimization methods

Sofiane Tanji, UCLouvain, Louvain-la-Neuve, Belgium, Francois Glineur

Since the advent of modern computational mathematics, the literature on optimization algorithms has been ever-growing, and a wide range of methods are now available. Usually, published algorithms are shown to be applicable to given templates of optimization problems, and are often accompanied by proofs characterizing their convergence rates.

There exist many variations of such templates. Indeed, a template may describe the objective as a single function or a sum of functions with different characteristics (say, smoothness, convexity, existence of a computable proximal operator, etc.), accompanied by constraints that can also be described in various ways (e.g. linear constraints, feasible set with a computable projection operator, functional constraints, etc.).

Hence, for a given instance of an optimization problem, it is not always easy to identify which templates it can match, especially if one wants to consider equivalent reformulations of the problem. This makes the task of choosing an optimization method tedious for the practitioner.

In this talk, we present a modeling language that aims at describing oracle-based optimization problem formulations. Using this language, we propose a framework that automatically checks whether a user-provided optimization problem fits a known template. The framework, implemented as a Python package, relies on an extensive library of optimization methods, described using the above-mentioned language, with their associated known convergence rate for one or several templates, with the goal of automatically ranking applicable optimization methods according to their worst-case theoretical guarantees. The framework also handles some reformulation techniques, allowing more corresponding templates to be potentially identified.

3 - Challenges in Automated Conversion of Optimization Problems

Bob Fourer, AMPL Optimization Inc., Evanston, IL, United States

The range of expressions recognized by modeling languages and solvers has been steadily extended, in ways that make optimization models easier to describe, validate, and maintain — but that make conversion possibilities ever more numerous and complex. Following an introductory survey, this presentation describes a variety of challenges that have been faced in detecting formulations that solvers can handle, and in implementing conversions to forms that solvers require. Issues include distinguishing easy from hard cases, recognizing alternatives preferred by solvers, accounting for side-effects of tolerance settings, and verifying results. Examples are taken from a new solver interface library designed for the AMPL modeling language.

4 - User Friendly Modeling from LINDO Systems

Linus Schrage, LINDO Systems, Inc., Chicago, IL, United States

We describe the latest enhancements to 1) LINDO API, the solver engine, and 2) LINGO, the algebraic modeling language. 3) What'sBest!, the Excel add-in optimizer, Some of the new features are: LINDO API: smarter handling of polynomial functions, and more generally, exotic functions for which derivatives are not available. Substantial improvements to the Global solver, especially linearization, improved reproducibility when using concurrent solver(simplex vs barrier). LINGO: Enhanced editor including model-smart text auto-completion so spelling errors are a thing of the past, and improved performance on large files/models.. What'sBest!: Smart support for more Excel functions, especially in large spreadsheets, plus improved Black Box solver supporting all Excel functions. To help users get started, we also describe our expanded Models Library with smart lookup of various application types: financial models, supply chain, scheduling, production line design, cutting stock, and more.

Summit - 320

New Models for Project Management and Scheduling Under Uncertainty

Invited Session

Scheduling and Project Management

Chair: Caihua Chen, Santiago, N/A, United States

Co-Chair: Houcai SHEN, Nanjing University, Nanjing, 210008

1 - An approach for robust resource constrained project scheduling problem

Qian Hu, Nanjing University, Nanjing, China, People's Republic of

Uncertain activity durations and resource disruptions are often found in project scheduling. We study a robust version of the resource constrained project scheduling problem. A robust optimization model, reformulation and a new algorithm are studied. With a computational study, we provide insights about the robustness and analyze the performance of the approach.

2 - Distributed Robust Optimisation Approaches for Resilience and Low Carbon Enhancement of Distributed Power Systems

Caihua Chen, Nanjing University, Nanjing, China, People's Republic of, Houcai SHEN

Resilience and Low Carbon are two trend to quantity the ability of distribution power system. In this work, we discuss the approach which accesses to microgrids in the main grid, which can handle significant power-disrupting incidents due to their islanding capabilities and the potential to support renewable energy penetration. In terms of the definition of resilience, we propose a multi-stage distributionally robust optimization model which capture the preparation, resoinse, and restoration three states. We further add the consideration of the cost of carbon emissions in our objection. The proposed framework stipulates that the chance constraints hold under the worst-case distribution within a novel ambiguity set, which incorporates the Wasserstein distance and the first-order moment. To solve the issue, the model is reduced to a mixed-integer linear programming problem that can readily be implemented. Numerical experiments are carried out on the IEEE 34-bus test systems to show the significantly enhancement of the addtion of microgrids.

3 - R&D Project Investment with Delay Option and Information Spillover Effect

Houcai SHEN, Nanjing University, Nanjing, China, People's Republic of, Yu Ge

This study explores how two competing companies make investment decisions in R&D markets, considering positive policy uncertainty and negative technology uncertainty. Additionally, this paper demonstrates that the delay option may bring profits for the investors from information spillover of the pioneer firm and from the waiting value of the market. Since different firms may have different information spillover effect on the followers, the optimal investment decisions of firms are also considered under asymmetric information spillover effects in this paper. Game theory is also employed to obtain the Nash equilibrium investment policies for these two competing firms.

4 - Dynamic Assortment with Online Learning under Threshold Multinomial Logit Model

Wenxiang Chen, Nanjing University, Nanjing, China, People's Republic of, Caihua Chen, Houcai SHEN, Ruxian Wang, Weili Xue

Consumers often find themselves overwhelmed by extensive assortments offered by online retailers and show bounded rationality behavior. However, existing literature on assortment optimization didn’t consider consumers' such bounded rationality behavior. This motivates us to employ a simple and effective two-stage consider-then-choose model, namely the Threshold Multinomial Logit (TMNL) model to investigate the online assortment optimization problem. The TMNL model characterizes consumers' endogenous consideration sets formation by the threshold effect. This endogenous dependency can capture more flexible substitution patterns than the classical MNL choice model, but it also creates great difficulties for online learning. In the offline assortment setting, we analyze the properties of optimal assortment and propose an efficient assortment optimization algorithm outperforms the benchmark. In the online setting with unknown customer preferences and consideration set formation, we propose online learning algorithms that achieve nearly optimal regret bounds under both instance-independent and instance-dependent conditions. To the best of our knowledge, we are the first work to consider online assortment problem with consumers' endogenous consider-then-choose behavior. Moreover, our algorithm is extended to the contextual learning setting, effectively mitigating the impact of the number of products on its performance. Extensive numerical experiments validate the efficacy of our proposed algorithms.

Summit - 321

Journal of Quality Technology Invited Session

Award Session

Quality, Statistics and Reliability

Chair: Rong Pan, Arizona State University, Tempe, AZ, United States

1 - Directional fault classification for correlated high-dimensional data streams using hidden Markov models

Modern manufacturing systems are often installed with sensor networks which generate high-dimensional data at high velocity. These data streams offer valuable information about the industrial system's real-time performance. If a shift occurs in the manufacturing process, fault diagnosis based on the data streams becomes a fundamental task as it identifies the affected data streams and provides insights into the root cause. Existing fault diagnostic methods either ignore the correlation between different streams or fail to determine the shift directions. In this paper, we propose a directional fault classification procedure that incorporates the between-stream correlations. We suggest a three-state hidden Markov model that captures the correlation structure and enables inference about the shift direction. We show that our procedure is optimal in the sense that it minimizes the expected number of false discoveries while controlling the proportion of missed signals at a desired level. We also propose a deconvolution-expectation-maximization (DEM) algorithm for estimating the model parameters and establish the asymptotic optimality for the data-driven version of our procedure. Numerical comparisons with an existing approach and an application to a semiconductor production study show that the proposed procedure works well in practice.

2 - Spatio-temporal process monitoring using exponentially weighted spatial LASSO

Peihua Qiu, University of Florida - Department of Biostatistics, Gainesville, FL, United States, Kai Yang

Spatio-temporal process monitoring (STPM) has received a considerable attention recently due to its broad applications in environment monitoring, disease surveillance, streaming image processing, and more. Because spatio-temporal data often have complicated structure, including latent spatio-temporal data correlation, complex spatio-temporal mean structure, and nonparametric data distribution, STPM is a challenging research problem. In practice, if a spatio-temporal process has a distributional shift (e.g., mean shift) started at a specific time point, then the spatial locations with the shift are usually clustered in small regions. This kind of spatial feature of the shift has not been considered in the existing STPM literature yet. In this paper, we develop a new STPM method that takes into account the spatial feature of the shift in its construction. The new method combines the ideas of exponentially weighted moving average in the temporal domain for online process monitoring and spatial LASSO in the spatial domain for accommodating the spatial feature of a future shift. It can also accommodate the complicated spatio-temporal data structure well. Both simulation studies and a real-data application show that it can provide a reliable and effective tool for different STPM applications.

3 - Quality prediction using functional linear regression with in-situ image and functional sensor data

Jionghua Jin, University of Michigan, Ann Arbor, MI, United States, Wenbo Sun

This article studies a general regression model for a scalar quality response with mixed types of process predictors including process images, functional sensing signals, and scalar process setup attributes. To represent a set of time-dependent process images, a third-order tensor is employed for preserving not only the spatial correlation of pixels within one image but also the temporal dependency among a sequence of images. Although there exist some papers dealing with either tensorial or functional regression, there is little research to thoroughly study a regression model consisting of both tensorial and functional predictors. For simplicity, the presented regression model is called functional linear regression with tensorial and functional predictor (FLR-TFP). The advantage of the presented FLR-TFP model, which is compared to the classical stack-up strategy, is that FLR-TFP can handle both tensorial and functional predictors without destroying the data correlation structure. To estimate an FLR-TFP model, this article presents a new alternating Elastic Net (AEN) estimation algorithm, in which the problem is reformed as three sub-problems by iteratively estimating each group of tensorial, functional, and scalar parameters. To execute the proposed AEN algorithm, a systematic approach is developed to effectively determine the initial running sequence among three sub-problems. The performance of the FLR-TFP model is evaluated using simulations and a real-world case study of friction stir blind riveting process.

4 - Directional fault classification for correlated high-dimensional data streams using hidden Markov models

Yan He, East China Normal University, Shanghai, China, People's Republic of

Modern manufacturing systems are often installed with sensor networks which generate high-dimensional data at high velocity. These data streams offer valuable information about the industrial system's real-time performance. If a shift occurs in the manufacturing process, fault diagnosis based on the data streams becomes a fundamental task as it identifies the affected data streams and provides insights into the root cause. Existing fault diagnostic methods either ignore the correlation between different streams or fail to determine the shift directions. In this paper, we propose a directional fault classification procedure that incorporates the between-stream correlations. We suggest a three-state hidden Markov model that captures the correlation structure and enables inference about the shift direction. We show that our procedure is optimal in the sense that it minimizes the expected number of false discoveries while controlling the proportion of missed signals at a desired level. We also propose a deconvolution-expectation-maximization (DEM) algorithm for estimating the model parameters and establish the asymptotic optimality for the data-driven version of our procedure. Numerical comparisons with an existing approach and an application to a semiconductor production study show that the proposed procedure works well in practice.

Summit - 322

From Data to Decisions: Advancing Smart Healthcare through Machine Learning

Invited Session

Quality, Statistics and Reliability

Chair: Jianxin Xie, University of Virginia, Charlottesville, VA, United States

Co-Chair: Zekai Wang, Fairfield University, Fairfield, CT, United States

1 - Generating Counterfactual Explanations in Breast Cancer Prediction

Siqiong Zhou, Arizona State University, Tempe, AZ, United States, Ashif Iquebal

Imaging phenotypes extracted via radiomics of magnetic resonance imaging have shown great potential in predicting the treatment response in breast cancer patients after administering neoadjuvant systemic therapy (NST). Understanding the causal relationships between the treatment response and Imaging phenotypes, Clinical information, and Molecular (ICM) features are critical in guiding treatment strategies and management plans. Counterfactual explanations provide an interpretable approach to generating causal inference. However, existing approaches are either computationally prohibitive for high dimensional problems, generate unrealistic counterfactuals, or confound the effects of causal features by changing multiple features simultaneously. In previous work, we proposed Sparse Counterfactual Generative Adversarial Networks (SCGAN) for generating counterfactual instances to reveal causal relationships between ICM features and the treatment response after NST. SCGAN generates sparse and diverse counterfactual instances that also achieve plausibility and feasibility. In this work, we improve SCGAN on coefficient tuning and enhance model efficiency, making it a valuable tool for understanding the causal relationships between ICM features and treatment response.

2 - Generative Model and Incremental Learning for Longitudinal Electric Health Record Data

Ziyang Zhang, Oklahoma State University, Stillwater, OK, United States, Chenang Liu

The combination of generative models and incremental learning offers a powerful approach for handling continuously evolving data while generating realistic synthetic Electronic Health Records (EHR) samples for training and research. This work explores the integration of these techniques to improve predictive models and patient outcomes, focusing on challenges such as longitudinal data handling, data incompleteness, and model adaptability for dynamic non-equally spaced longitudinal data.

3 - Dual-Output Deep Learning for Reducing Unnecessary Lab Tests in ICU

Nasim sadat Mousavi, University Of Arkansas, fayetteville, AR, United States, Shengfan Zhang

Unnecessary laboratory testing in Intensive Care Units (ICUs) imposes excessive costs with minimal clinical benefits for patients, particularly for those undergoing Gabapentin therapy. The primary goal of this research is to develop a dual-output Long Short-Term Memory (LSTM) neural network model capable of predicting laboratory test results for ICU patients on Gabapentin, using the MIMIC-IV data. Encompassing demographic information, vital signs, and historical lab results for critical biomarkers, the LSTM model can help reduce unnecessary testing and optimize healthcare resource utilization. The primary output of this model accurately forecasts the quantitative values of future laboratory tests. Simultaneously, the secondary output evaluates the probability of the need for each test based on a novel loss function that balances the accuracy of prediction and the efficiency of test reduction. This loss function can enhance the decision-making process by minimizing the number of performed tests and prediction errors, aiming for a reduced number of lab tests without compromising diagnostic accuracy. Decision thresholds derived from these probabilities determine whether tests should be performed, minimizing redundant testing, and aligning with clinical needs. This approach introduces a systematic shift towards precision medicine by tailoring lab testing to patients' needs. It promises to enhance the efficiency of lab testing in ICU settings by reducing unnecessary procedures, optimizing the use of medical resources, and enhancing patient care.

Keywords: LSTM, laboratory test reduction, Gabapentin, Dynamic decision-making

Computation Service and Data Quality in Manufacturing Industrial Internet

Invited Session

Quality, Statistics and Reliability

Chair: Yingyan Zeng, University of Cincinnati, Blacksburg, VA, United States

Co-Chair: Ran Jin, Virginia Tech, Blacksburg, VA, United States

1 - Ontology-guided Data Sharing with Differential Privacy in Interconnected Additive Manufacturing

Hui Wang, Florida A&M University-Florida State University College of Engineering, Tallahassee, FL, United States

The scarcity of measured data crucial for defect identification often presents a challenge to additive manufacturing process development and certification. Knowledge sharing has become an emerging solution to the problem. However, manufacturers are concerned about privacy loss during knowledge sharing. This study integrates a differential privacy model with federated learning to improve knowledge sharing with privacy protection, thereby using the knowledge sharing to improve defect identification given limited data. The framework addresses the following issues, which existing federated learning fails to deal with (1) How to represent information in the knowledge to be shared; (2) How to select and mask the shared knowledge while balancing the trade-off between privacy protection and defect identification; and (3) How to quantitatively control privacy loss.

2 - A fast nonparametric process monitoring scheme in fully decentralized systems

Jiahui Zhang, University of Wisconsin-Madison, Madison, WI, United States

Along with the development of big-data technologies, multi-sensor systems have become more and more prevalent in manufacturing industries. To ensure the production process is in normal condition, process monitoring algorithms have been applied to multi-sensor systems, in which a central server aggregates information from all sensors and make decisions about the process condition. This kind of centralized systems, however, highly relies on the central server and cannot protect the privacy of the sensor data. This leads to the need of decentralized

systems, in which each edge device can communicate with each other and individually raise the system alarm. The goal of this paper is to develop a fully decentralized process monitoring scheme for fast online change detection. Our monitoring framework includes the design of a nonparametric device-level statistic, a smart strategy for inter-device communication, and an alarm-raising mechanism which responds quickly to mean shifts and is resilient to partial function failures of the devices. The proposed method enjoys good theoretical properties which enables its effectiveness and efficiency. The outperformance of the proposed method is shown in numerical experiments and a case study.

3 - Memory Span Reinforcement Learning: Bridging Short-Term Actions and Long-Term Goals in Dual-Agent Systems

Zehua Dong, University at Buffalo , Buffalo , NY, United States, Xiaoyu Chen, Xiaomei Wang

Recent advancements in multi-agent reinforcement learning (MARL) systems have made significant contributions to a variety of fields, including autonomous vehicle coordination, financial trading, and grid management. These systems require the cooperation among multiple agents, enabling dynamic interactions in real-world applications. However, the lack of clearly defined roles in current multi-agent reinforcement learning (MARL) systems prevents agents from effectively fulfilling their own goals, necessitating methodologies like Centralized Training with Decentralized Execution (CTDE) and fully decentralized training. These approaches are essential for coordinated learning and independent execution, but they limit the transferability from a well-perceived environment to similar-but-not-identical environments.

Motivated by underdefined cooperation, we propose a novel cooperative dual-agent reinforcement learning framework that mimics human cognitive processes. It enables inter-agent coordination by assigning different agents with different but cooperative goals. Inspired by human information processing (HIP) model, we created a hierarchical structure featuring two agents: a long-term agent and a short-term agent. This architecture mirrors the HIP model where short-term actions are driven by immediate stimuli (bottom-up processes), represented by immediate rewards; while long-term strategies are guided by overarching goals and knowledge (top-down processes), represented by historical trajectories. The long-term agent strategically oversees the learning process and directly controls the action space of the short-term agent, thus enhancing learning efficiency and transferability across similar-but-not-identical environments. Our framework is particularly suitable for applications requiring domain adaptation.

4 - On High-quality Data Trade

Ran Jin, Virginia Tech, Blacksburg, VA, United States

The advancement of artificial intelligence (AI) models heavily relies on the availability of large, informative, and high-quality datasets. However, in critical applications such as manufacturing and transportation, it takes a long time and intensive effort for high-quality data collection and preparation for AI training and deployment. In this paper, we will introduce a few methodologies to define dataset quality, high-quality data generation, and performance-oriented data trade with privacy preserving consideration. A representation learning framework in Directed Acyclic Graph Neural Network is introduced. The effectiveness of the work is validated by two case studies: a semiconducting manufacturing network and design and manufacturing network of Microbial Fuel Cells.

Summit - 324

DEI Ambassador Program

Flash Session

Diversity, Equity, and Inclusion

Chair: Daniel Reich, Naval Postgraduate School, Monterey, CA, United States

Co-Chair: Banafsheh Behzad, California State University, Long Beach, Long Beach, CA, United States

Co-Chair: David Czerwinski, San Jose State University, San Jose, CA, United States

1 - Informs K-12 Education Outreach and Networking Program

Neil Desnoyers, Saint Joseph's University, Philadelphia, PA, United States, Zihan Zhang, Fenglian Pan

The primary goals of the K-12 Education Outreach and Networking Program 2024 DEI Ambassador Project are to extend the footprint of and strengthen INFORMS' K-12 outreach program. The major components of our work this year are:

1. Organize an in-person focus group for secondary math teachers in the Philadelphia region, thereby extending the footprint of INFORMS' K-12 outreach program.
2. Strengthen INFORMS' K-12 outreach program by holding a series of webinars introducing K-12 outreach to the INFORMS membership and others.
3. Facilitate communication and collaboration among the K-12 community within INFORMS by organizing the second K-12 panel at the 2024 INFORMS Annual Meeting.

An update on the project will be provided.

2 - Uncovering Racial Bias in Automated Traffic Law Enforcement: Extensions

Chrysafis Vogiatzis, University of Illinois Urbana-Champaign, Urbana, IL, United States, Chris Raymond-Bertrand, Eleftheria Kontou

In 2023, two of the classes at the University of Illinois Urbana-Champaign adopted a novel culturally relevant case study that focused on a contemporary societal issue: injustice in automated traffic law enforcement. The case study, which received the INFORMS Best Case Runner-up recognition in the INFORMS Annual Meeting in 2023, had two main components. The first one focused on proper statistical hypothesis testing using real-life demographic and traffic data. The second one introduced a new network optimization problem in the form of a side-constrained shortest path. Students that were introduced to this case study found it very interesting, specifically due to the connection and implications that operations research and the management sciences have for policy. In this extension, we study different origin-destination pairs in the city of Chicago. That way, we can establish how automated traffic law enforcement disproportionately hurts travelers and commuters from different parts of the city (with different socioeconomic characteristics) when trying to reach specific points of economic and cultural activity.

3 - Data Analysis&Mdash;Perspectives of DEI Initiatives in Academia & Industry

Mubarak Iddrisu, University of Massachusetts Boston, Boston, MA, United States, Ogechi Vivian Nwadiaru, Hamid Arzani, Andrea Hupman, Allison Reilly, Jun Zhuang, Gul Kremer

This study examines the alignment between organizational Diversity, Equity, and Inclusion (DEI) commitments at the management level and individual employee perceptions in practice. Organizational commitment to DEI initiatives is pivotal for fostering inclusive workplace cultures. However, a gap could exist between aspirational ideals and actual behaviors, raising questions about the practical implementation of DEI values within organizations. Drawing from existing literature and frameworks, including McKinsey & Company's "Diversity Wins: How Inclusion Matters," we address this gap by investigating the specific barriers and challenges hindering the translation of DEI commitments into action. Our research questions include; How do DEI commitments at the management level align with individuals' perceptions in practice? How do organizations manifest their DEI value statements into actions? How to design metrics to measure DEI initiatives?

Together these questions explore how DEI commitments at the management level align with employees' day-to-day experiences, shedding light on the effectiveness of DEI initiatives within organizations. Through survey-based methodology, we analyze perceptions from both managerial and non-managerial roles, focusing on aspects such as inclusion efforts, alignment with institutional DEI statements, and perceptions of equity. By probing into these dimensions, our study provides evidence-based insights to support organizations, especially in the operations research and management sciences striving to create genuinely inclusive cultures.

4 - Unite: Uplifting Networks for Inclusive Transformation and Equity

Fatemeh Nosrat, Rice University, Houston, TX, United States, Aysenur Karagoz

We intend to implement tailored mentorship programs, workshops, and resources to address the unique challenges faced by to address the unique challenges faced by women, African Americans, Asians, Middle Eastern individuals, Hispanic and Latino Americans, Native Americans, individuals with disabilities, and members of the LGBT+ community within the INFORMS community. Through collaboration with existing minority communities, such as WORMS and Pride Forum, we aim to foster partnerships and amplify diverse voices. Our initiatives focus on creating a more inclusive environment, attracting a broader range of students, and celebrating diversity through events and success stories. By incorporating feedback mechanisms and regular assessments, we are committed to continuous improvement and ensuring the success of our DEI efforts.

5 - Active Engagement with DEI Students from Data-Related Undergraduate Programs in the INFORMS Data Mining Society and Beyond

Ying Lin, University of Houston, Houston, TX, United States, Andi Wang, Chun-An Chou, Nathan Gaw

Data science (DS) has drawn increasing attention in academia and every conceivable industry. As a result, there is ever-increasing motivation for students of diverse backgrounds to learn data mining and decision analytics (DMDA) skillsets for their future career. However, it brings apparent difficulties and barriers to train and foster students who were not in DS-related majors. This project is a continuation of the project last year titled, Active Engagement with DEI Students from Data-Related Master's Programs in the INFORMS Data Mining Society and Beyond. Due to the massive success in this project from last year, we chose to continue the direction of these efforts by (1) engaging with DEI students in undergraduate programs, (2) gaining insights on how we can better engage with minority K-12 populations in STEM topics, and (3) initiating with universities that have underserved Hispanic demographic. To achieve the goals, we initiate the first data mining undergraduate poster session, host a data competition with K-12 focus, organize a DEI-oriented DMDA workshop and evaluate the impact on DEI students post the DMDA workshop.

6 - Operations Research in Women's Health and Healthcare: a Scoping-Inspired Narrative Review and Roadmap for the Future

Rachel Stephenson, University of Toronto, Toronto, ON, Canada, Rachel Wong

Operations Research (OR) approaches have been applied to derive meaningful policy insights and effective solutions to a broad range of healthcare problems, but we believe that there is a gap in OR literature addressing issues that differently or disproportionately impact women's health and healthcare (hereafter referred to as "issues in women's health and healthcare" for brevity). As such, we are undertaking a project to identify this gap and promote a research agenda to close it. The project consists of three phases:

Phase 1: Perform a scoping-inspired review of literature on significant issues in women's health and healthcare studied and published in top OR journals over the past 10 years.

Phase 2: Distribute a survey to experts in women's health and healthcare with the research gaps identified in Phase 1. Experts will be asked to prioritize research areas, identify specific subproblems within broad areas that may be solved using OR approaches, and identify any emerging issues that were excluded from the list provided.

Phase 3: The results from Phases 1 and 2 will be synthesized and disseminated in a survey to the OR community. Experts will be asked to describe how OR could be applied to solve these problems.

The primary outcome of this work will be the identification of opportunities for novel applications of OR in women's health and healthcare. The goal of this project is to promote applications of OR to women's health and healthcare issues, and therefore, to ultimately improve women's health outcomes.

7 - Innovation In Operations Research: Fostering Equity and Justice In Problem Formulation

Sadan Kulturel-Konak, Penn State Berks, Reading, PA, United States, Abdullah Konak, Sara Abu Aridah

The fields of Operations Research (OR) and Management Science (MS) have traditionally prioritized cost, benefit, and efficiency in problem-solving. While these considerations are undoubtedly vital, our proposed project seeks to push the boundaries of traditional thinking by introducing new dimensions – justice and equity- in problem-solving. By integrating case studies that highlight social justice and equity aspects, we aim to broaden the scope of discussions within introductory-level OR and MS courses. Our emphasis extends beyond merely solving problems efficiently by only focusing on conventional cost/profit optimization; we aspire to actively contribute to the cultivation of a framework that also prioritizes and fosters principles of equity and justice; by doing so, we hope to provide practices for students to nurture an 'equity mindset.' Integrating social justice and equity perspectives into OR and MS with a multi-objective approach is essential for several reasons. Firstly, it aligns with the dynamic evolution of societal values, where ethical considerations are increasingly taking center stage. Secondly, by instilling these concepts at the foundational level, we are not only equipping future professionals to tackle real-world challenges but also fostering a more inclusive and diverse community within the fields of OR and MS. Our approach involves the development of problems and case studies that illustrate the intersection of OR with equity and social justice principles. We plan to focus on the basic and introductory level problems that are typically used in the first OR and MS courses.We will also create instructor companions summarizing pedagogical strategies to support instructors.

8 - Techfest Dayton: Large-Scale K-12 Stem Outreach Targeting DEI-Focused Organizations, Presenters, & Communities

Kara Combs, Air Force Research Laboratory, Wright-Patterson AFB, OH, United States, Nathan Gaw, Trevor Bihl

TechFest Dayton is the premiere K-12 Science, Technology, Engineering, and Mathematics (STEM) Outreach event held over two days in Dayton, OH. Dayton faces several socio-economic challenges that affect the city's poverty, substance abuse, and education levels. Hosted by its namesake 501(c)3 foundation, TechFest Dayton aims to improve the statistics of these areas by exciting local kids about STEM and higher education through accessible hands-on activities and demonstrations. In 2024, over 1,100 kids and an estimated 2,500+ attendees came to TechFest Dayton. With 2023 attendee feedback focused on greater consideration for DEI-related issues, the 2024 committee was happy to triple the number of DEI-focused exhibitors, schedule presenters such that 20% were female, and add a sensory-friendly hour. This is in addition to ensuring the event remains free for all participants – attendees, exhibitors, and presenters. Of the children in attendance 42.5% of them belonged to female- and minority-identifying populations and over half were first-time attendees at the event. The local Cincinnati-Dayton INFORMS chapter co-exhibited with the Institute of Industrial and Systems Engineers Dayton-Cincinnati professional chapter and provided an introduction to operations research and engineering for the kids in attendance. Their joint booth had multiple activities including a getting ready for school activity (management/planning) and two computerized games aimed to teach the kids about statistics and programming. In conclusion, the DEI Ambassador grant program provided crucial financial support for TechFest Dayton and also played a pivotal role in diversifying and raising awareness about operations research within the Dayton community.

9 - Diverse Voices in Operations Research and Management Sciences: a Storytelling Platform

Will Cong, Cornell University, Ithaca, NY, United States, Jihye Jang, Yutong Meng, Luyao Zhang

<div overflow-hidden"=""><div h-full"="">

<div text-token-text-primary"="" dir="auto" data-testid="conversation-turn-3" data-scroll-anchor="true">

This project aims to create an inclusive online platform showcasing the diversity within the INFORMS community, fostering interdisciplinary collaboration, and amplifying underrepresented voices. Through a series of activities and deliverables, including email Q&A interviews, eCornell webinars, and interview article publications, the project highlights contributions from academia, industry, and policy circles. These efforts are designed to enhance engagement and promote diversity and inclusion across various spheres. Interview questions tailored for scholars, practitioners, and policymakers delve into research impact, practical applications, policy implications, challenges, and future directions, emphasizing the importance of interdisciplinary collaboration in addressing contemporary challenges in operations research and management sciences.

Summit - 325

Facility/Hub Location 2

Invited Session

Location Analysis

Chair: Gita Taherkhani, Loyola University Chicago, Chicago, IL, United States

1 - Towards Classifying Instances for the Capacitated Facility Location Problem

Stefan Nickel, Karlsruhe Institute of Technology, Karlsruhe, Germany, Hannah Bakker

The Capacitated Facility Location Problem (CFLP) is a core problem of location. As such, it attracted much research presenting novel solution methods that are typically evaluated with an empirical assessment of a chosen set of benchmark instances. An algorithm is considered successful if it outperforms other algorithms on average. Such an average-case analysis comes with limitations as it fails to incentivize a thorough discussion of an algorithm's strengths and weaknesses, and bears a risk of inherent bias in the selected instances. The latter risk is particularly prevalent for the CFLP for which only very few real-world-based test instances exist, and a significant proportion of the available instances are based on the same generation procedure. We perform a systematic analysis of the features that make a CFLP instance hard or easy for a particular algorithm using Instance Space Analysis (ISA), a recent framework that supports objective testing and assessing the diversity of test instances. While several works exist that propose a variety of characterizing features for different combinatorial optimization problems, the CFLP differs from these problems in that it contains a more diverse set of parameters that are even measured on different scales (costs and volume) and have partially overlaying effects on the solution structure. We identify hardness revealing features and link them to the performance of a greedy heuristic, Kernel Search, and a commercial MIP solver with different parameter settings.

2 - Strategic Expansion of Freight Transportation Hub Networks Under Uncertainty

Gita Taherkhani, Loyola University, Chicago, IL, United States, Hao Li, Sibel Alumur Alev, Mike Hewitt

We focus on freight transportation carriers that transport shipments that are small relative to vehicle capacity and incur transportation costs that exhibit economies of scale. To achieve profitability, such carriers route shipments through a network of hubs. The locations of a carrier's hubs dictate the customer markets it can profitably serve. We consider a carrier that seeks to increase its profitability by growing its customer base. To do so, it seeks to expand its network into new regions by merging with carriers that already operate in those regions. We focus on how, and by how much, the network that results from such a merger should be redesigned to maximize profitability. To study this issue we present deterministic and stochastic profit-maximizing hub location models that capture the interaction between economies of scale and profitability. The models differ in whether and how they model the recognition of uncertainty in shipment sizes in the decision-making process. We perform a case study based on operations from a multi-regional less-than-truckload freight transportation carrier to derive insights into the profitability of different redesign strategies. We analyze the networks prescribed by solutions to these optimization models to derive insights into how a network that results from a merger should be redesigned. We also study how uncertainty impacts the structure of the redesigned networks.

3 - Periodic Vehicle Location Routing and Scheduling in Humanitarian Logistics

Bahar Yetis Kara, Ihsan Dogramaci Bilkent University, Ankara, Turkey, Cagla Dursunoglu, Okan Arslan

In the recovery phase of a humanitarian crisis, periodic demand service is an important aspect of mobile services, referring to the requirement for a service that occurs at regular intervals. Mobile barbers, mobile laundry, and mobile showers are examples of mobile services that are in demand on a regular basis. The demand occurs at certain periods since the impacted population may frequently need such services. In order to service this demand type, the customer locations need to be visited at certain intervals. This creates a regular pattern of demand that the mobile service provider must satisfy by providing flexible scheduling and efficient service delivery. Each service type has its own set of mobile service units and each demand point should be served at least a certain number of times by the various mobile services within the specified planning horizon. The initial and terminal locations for vehicles and their routes should be determined, which collectively induces the order of demand visits. Furthermore, the duration of mobile service visits at a demand location is also a decision. There may be incompatible services that are forbidden to visit a location simultaneously. Additionally, the visits by mobile service centers offering the same services should be spaced apart by at least a certain duration of time.

1 - Craftsmanship versus Investment: Exploring Factors Affecting the Nonfungible Token (NFT) Projects Performance

Yanxin Wang, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Jingzhao An, Xiaoni Lu, Xi Zhao

The nonfungible token (NFT) market has experienced tremendous volatility in recent years, prompting a need for deeper investigation into the effective design of NFT projects amid this period of uncertainty. This study therefore investigates how NFT design-related features influence the performance of NFT projects in the short- and long-term. From the perspective of consumption, this study distinguishes NFT consumption into competency-based and investment-based consumption, according to the dual attributes of information goods and tokens associated with NFTs. Correspondingly, we identify two types of design features of NFT collections, namely, competency-related features (i.e., NFT image complexity and consistency), as well as investment-related features (i.e., initial prices and royalties). Using transaction data of 3,037 NFT projects on Ethereum blockchain, we find that NFT image complexity has a significant inverted U-shaped effect on long-term performance due to the possible information overload. Image consistency within NFT projects has positive impacts on both short-term and long-term performance due to the formulation of brand symbolism. Royalty as the resale cost negatively affects the short-term performance. Additionally, royalty and initial price exhibit inverted U-shaped impacts on long-term performance, owing to their mixed roles as both costs and signals. As for the moderating effect of market uncertainty, time pressure brought by uncertainty enhances the impact of image complexity and royalty, while weakening the role of initial price as a quality signal. Our findings provide both theoretical and practical implications for NFT project design, enhancing the understanding of consumer behavior in the Web3 context.

2 - The Impact of Social Effect on Funding Success

Sanghyun Park, Baruch College, City University of New York, New York, NY, United States, Qiang Gao

The exponential growth of online donation-based crowdfunding for education has raised questions about the influence of social effects on funding success and the justification behind backers' decisions. This pioneering study extends beyond conventional crowdfunding research by examining the unique dynamics of donation-based crowdfunding. Utilizing a comprehensive dataset from DonorsChoose.org and the U.S.

Department of Education, the analysis reveals an inverted U-shaped relationship between predicted social effects and funding success, indicating that projects with moderate social effects are more likely to succeed compared to those with low or high appeals. The study also investigates post-donation interactions between fundraisers and backers, providing insights into the reasoning behind backers' decisions. The results demonstrate that social effects reflected by fundraisers's unobservable attribute, such as dedication, have a curvilinear relationship with funding impact. Robustness tests and checks for endogeneity confirm the consistency of the findings. This research highlights the critical need for strategically balanced social effects in educational crowdfunding narratives to optimize funding success. It significantly contributes to the broader crowdfunding literature by elucidating the distinct behaviors of donors in the non-return, charitable context of educational fundraising.

3 - Using Simulation to Enhance Customer Experience and Reduce Congestion Within a Non-Profit Food Bank

Meredith DePuy, Virginia Polytechnic Institute and State University, Blacksburg, VA, United States, Kara Gossard, Madison Harmon, Kimberly Ellis

A non-profit food bank, sponsored by more than 25 local churches, provides service to 300 families (approximately 900 people) monthly in southwest Virginia. The food bank operates four days a week (for 1.5 hours each day) and is fully staffed by volunteers, with no paid employees. With increasing demand and rotating volunteers, the pantry needs to improve and standardize processes to enhance customer experience. For this project, we evaluate multiple layout, process, and flow alternatives using discrete event simulation. The results are used to streamline processes and justify capital investments to improve customer flow and overall experience. In addition, the results also provide valuable insights for similar food banks.

4 - Managing cross-departmental knowledge flows to accelerate learning in a high-tech firm

Alex Alblas, Eindhoven University of Technology , Eindhoven, Netherlands, Massimo Manca, Fred Langerak

This study evaluates the differential effect of cross-departmental knowledge flows on organizational learning and operational performance in a firm operating in the semiconductor industry. Knowledge transfers across departments via several mechanisms, which have different returns and require different resources. Previous research examined knowledge transfer mechanisms between departments (R&D, production, service) separately. Our study integrally estimates knowledge flows' differential effect on learning and performance simultaneously. Using a rich panel dataset concerning knowledge flows between departments and service performance, we analyze how the service department learns to improve machine availability via each knowledge flow. Knowledge flows are quantified with the cumulative number of knowledge transfer tasks spanning departmental boundaries, such as problem-solving tasks, work instructions, and design changes. Our study contributes by shedding light on the most effective cross-departmental knowledge flows to accelerate the learning curve in the context of a knowledge-intensive firm.

5 - Traditional vs. Generative Design: Student Artifacts and Decisions

Molly Goldstein, University of Illinois, Urbana-Champaign, Urbana, IL, United States

The rise of generative tools powered by AI has created an urgent desire in many industries to capitalize on the powerful capabilities of these tools, but an understanding of how these tools are utilized and perceived by students is lacking. Generative Design is an AI tool in the computer-aided design software Fusion 360 that can be used to accelerate the design-to-make process. Generative Design achieves this by taking user-defined constraints, existing assembly geometry, and obstacle geometry to generate numerous potential design solutions that have been iterated upon one another. The designer can then select which model to continue developing based on several calculated metrics. However, since generative design produces a range of possible solutions, students need to be able to articulate why those chose a particular solution.

Research Questions: How do generative design tools affect the quality of engineering student's design artifacts and their design decisions?

An observational study was conducted with engineering student participants of varying levels of standing (undergraduate and graduate) and CAD experience. Students were tasked with completing two separate challenges in which they had to design and model a structural component for an existing assembly with traditional parametric CAD techniques and with generative design tools. The collected design artifacts were assessed for quality using the Trade-off Value Protocol and the Informed Design Teaching and Learning Matrix. We compared student rationale for their design process in both the traditional and generative design environments. Preliminary results indicate that students differ on their design rationale in the two environments.

6 - Investigating the impact of behavior representation on targeted ads effectiveness: An empirical study

Wei Xiong, Mercer University, Atlanta, GA, United States

The success of behavioral targeting (BT) hinges largely on how effectively online users are classified, as advertisers prioritize reaching the most relevant audience for their ads. This study considers BT as a user classification problem and describes a machine learning-based solution. We introduce three user behavior representation methods and compare them empirically using the area under the receiver operating characteristic curve (AUC). The experimental results confirm the effectiveness of BT on user classification and provide a validation of BT for online advertising. Notably, combining user search queries, clicked URLs, and clicked ads yields the most significant performance improvement compared to a baseline of user location. Furthermore, this study also investigates the temporal dimension of user behavior by analyzing how historical data length influences targeting performance.

Summit - 328

Optimization Applications in Defense

Invited Session

Military and Security

Chair: Robert Curry, University of Arkansas, Fayetteville, AR, United States

1 - Mixed-integer Programming Models for solving Network Flow Optimization Problems in Contested Settings

Robert Curry, University of Arkansas, Fayetteville, AR, United States

Various applications require dynamic flow solutions characterized by a schedule of network flows consecutively transmitted over a sequence of successive periods. For these schedules, we assume flows transmit via arcs *during* periods while flows *reside* at nodes from one period to the next. Within this context, we introduce the Maximum Value Dynamic Network Flow Problem (MVDFP) in which we seek to maximize the cumulative *value* of a non-simultaneous network flow schedule that accumulates node *value* whenever some minimum amount of flow resides at a node between periods. For solving the MVDFP, we first introduce a large mixed-integer program (MIP). As this MIP can become computationally-expensive for large networks, we also present a computationally-effective heuristic that sequentially solves a series of smaller, more manageable MIPs. This heuristic approach determines a high-quality solution significantly faster than the MIP obtains an optimal solution by dividing the full network flow schedule into a sequence of consecutive shorter network flow subschedules. In many cases this approach produces an optimal solution in a fraction of the MIP's computational time. We present extensive computational results to highlight our heuristic's efficacy and discuss future research avenues.

2 - Approximate Linear Model for Optimal Surveillance Deployment

Daphne Skipper, United States Naval Academy, Annapolis, MD, United States, Sebastian Martin, Anna Svirsko, Esra Toy

We consider the problem of optimally selecting and locating surveillance devices to detect stealth traffic transiting an operational theater. These surveillance decisions are based on historical traffic data, as well as sensor ranges and detection capabilities. Accounting for overlapping sensor coverage leads to a mixed-integer non-convex optimization model. A log transformation converts the model’s nonlinearity into convex univariate constraints. By careful selection of linearization points, we develop an approximate linear model that is within a specified error tolerance. We solve this problem in the context of detecting illegal fishing off the coast of Thailand to demonstrate the viability of the approximate linear model.

3 - Optimal Multi-Searcher Maneuver with Uptime / Downtime Constraints

Anna Svirsko, United States Naval Academy, Annapolis, MD, United States, Sebastian Martin, Miles Dixon, Daphne Skipper, Esra Buyuktahtakin Toy

When surveillance devices detect a stealth target that is transiting through an operational theater, an area of uncertainty (where the target may be located) is generated and continues to grow until the target is precisely located. We consider the problem of optimally routing search assets to find and apprehend targets following the generation of one or more areas of uncertainty by surveillance devices. The integer programming model allows for searchers with varying initial positions, search speeds, transit speeds, search endurance, and downtime requirements. To demonstrate its effectiveness, we solve the model to determine an optimal scheme of maneuver for a team of searchers of three different types seeking targets in two areas of uncertainty.

4 - Prioritizing High Schools for Marine Corps Recruiting

Gary Lazzaro, United States Naval Academy, Annapolis, MD, United States

Marine Corps Recruiting Command needs an improved quantitative method to classify high schools for optimizing recruiting efforts. Marine recruiters currently use a qualitative model to classify high schools as priority “1” or “2” or “3” or “N” that is based on school population, number of past recruits, and recruiter opinion. Our analysis shows the current classification process produces inconsistent priority codes for high schools with similar statistics across the nation and even in the same recruiting areas. We use a variety of analytical techniques to assist with the determination of high school priority codes. We use linear regression, machine learning methods, and data wrangling techniques to show how the high school classification process can be improved. Specifically, we demonstrate a data visualization for California high schools overlaid with additional data fields. We merge publicly available United States census tract data for population, income, education levels and veteran population with past Marine Corps Recruiting Command data for each high school into one interactive chart.

1 - Competing for Limited Attention Online

James Siderius, Tuck School of Business at Dartmouth College, Hanover, NH, United States, Daron Acemoglu, Asuman Ozdaglar

We consider a model of endogenous content creation where articles can consist of two attributes, catchiness and informativeness, one of which is an easily observed characteristic and the other which is hidden and may only be learned through careful reading. A representative platform user with limited attention receives utility from both entertainment and from absorbing information, and strategically chooses how to allocate her time reading based on the headlines she observes. We fully characterize the set of equilibria when M articles can be produced by K creators, which in general will not be unique, admitting a most information rich and least information rich equilibrium. As the number of articles M grows holding K fixed, we find that while the most information rich equilibrium supplies more information, the least information rich equilibrium also supplies less information. As we increase competition (increasing K holding M fixed), information provision deteriorates further across all equilibria because creators cannibalize each other through catchy content to steal user attention, substituting away from more informative content. We show that carefully designed ranking algorithms by the platform can mitigate the quality loss associated with information overload, but that if these algorithms are solely designed to maximize engagement, they tend to exacerbate the problem.

2 - Design of Resale Platforms

Ilan Morgenstern, Stanford University, Palo Alto, CA, United States

We study resale platforms, an emerging type of online marketplaces in developing countries. These platforms are designed for individuals (resellers) to sell products to others as opposed to buying for themselves, enabling them to supplement their income by earning a margin on the transactions they generate. One challenge these platforms face is that competition among resellers may emerge as more of them join the platform, as their social circles increasingly overlap. We investigate the mechanisms by which competition affects resellers and the role of the platform's design in shaping this relationship. We combine analytical modeling with empirical analysis. Our model captures the resellers' interactions with the platform (in searching for products to sell) and with consumers (in offering these products for purchase). We find that as competition intensifies, resellers not only lower their margins but also reduce the effort they exert in searching for products to sell. We empirically validate these equilibrium predictions using data from a major platform: as competition increases, resellers earn lower margins and reduce the number of products they view while browsing on the app, which we interpret as lower search effort. We explore two interventions that aim to benefit resellers: centralizing margin decisions (a practice adopted by several platforms) and optimizing its product ranking algorithm, offering insights to guide key design choices for resale platforms, aiming to foster sustainable online entrepreneurship in developing economies.

3 - Homomorphic Encrypted Revenue Management

Mojtaba Abdolmaleki, University of Michigan, Ann Arbor, MI, United States, Ruslan Momot

We develop a novel homomorphic encryption-based approach to privacy preservation in a dynamic personalized pricing setting. In each period, the firm offers a personalized price to an incoming customer based on (i) this customer's observable characteristics and (ii) the firm's estimate of the demand function (obtained using the data of the historical customers with whom the firm interacted in the past). Our method enables the firm to use homomorphic encryption to encrypt the data of incoming and historical customers, then estimate the demand function and personalize prices directly based on these encrypted data without the need to decrypt them. In contrast to the previous literature, which only preserves the privacy of historical customers via adding statistical noise to their data (so-called statistics-based approach), our approach allows the firm to protect the privacy of all customers -- both incoming and historical. Our theoretical analysis further reveals that our approach i) provides perfect privacy protection (achieving 0-differential privacy) and ii) does so at no cost to the firm's expected revenue, thus achieving better revenue performance than statistics-based algorithms, but (iii) it is computationally expensive. We thus develop a hybrid approach to privacy preservation that leverages the strengths of both statistics- and encryption-based methods, achieving the required privacy protection at a comparatively lower computational cost without significant compromise on the expected revenue. We confirm our theoretical findings through a numerical example based on synthetically generated data.

4 - Measuring Strategization in Recommendation: Users Adapt Their Behavior to Shape Future Content

Jennifer Allen, MIT, Cambridge, MA, United States, Sarah Cen, Andrew Ilyas, Hannah Li, Aleksander Madry

Most modern recommendation algorithms are data-driven: they generate personalized recommendations by observing users' past behaviors. A common assumption in recommendation is that how a user interacts with a piece of content (e.g., whether they choose to "like" it) is a reflection of the content, but not of the algorithm that generated it. Although this assumption is convenient, it fails to capture user strategization: that users may attempt to shape their future recommendations by adapting their behavior to the recommendation algorithm. In this work, we test for user strategization by conducting a lab experiment and survey. To capture strategization, we adopt a model in which strategic users select their engagement behavior based not only on the content, but also on how their behavior affects downstream recommendations. Using a custom music player, we study how users respond to different information about their recommendation algorithm as well as to different incentives about how their actions affect downstream outcomes. We find strong evidence of strategization across outcome metrics, including participants' dwell time and use of "likes." A close analysis of participant behavior rules out experimenter demand as the main driver of these trends. Further, in our post-experiment survey, nearly half of participants self-report strategizing "in the wild," with some stating that they ignore content they actually like to avoid over-recommendation of that content in the future. Together, our findings suggest that user strategization is common and that platforms cannot ignore the effect of their algorithms on user behavior.

5 - When Big Data Enables Behavioral Manipulation

Azarakhsh Malekian, University of Toronto Joseph L Rotman School of Management, Toronto, ON, Canada

We build a model of online behavioral manipulation driven by AI advances. A platform dynami-
cally offers one of n products to a user who slowly learns product quality. User learning depends on a product’s “glossiness,’ which captures attributes that make products appear more attractive than they are. AI tools enable platforms to learn glossiness and engage in behavioral manipulation. We establish that AI benefits consumers when glossiness is short-lived. In contrast, when glossiness is long-lived, behavioral manipulation reduces user welfare. Finally, as the number of products increases, the platform can intensify behavioral manipulation by presenting more low-quality, glossy products.

1 - Dynamic Pricing and Learning with Long-term Reference Effects

Shipra Agrawal, Columbia University, New York, New York, NY, United States, Wei Tang

We consider a dynamic pricing problem where customer response to the current price is impacted by the customer price expectation, aka reference price. We study a simple and novel reference price mechanism where reference price is the average of the past prices offered by the seller. As opposed to the more commonly studied exponential smoothing mechanism, in our reference price mechanism the prices offered by seller have a longer term effect on the future customer expectations. We show that under this mechanism, a markdown policy is near-optimal irrespective of the parameters of the model. This matches the common intuition that a seller may be better off by starting with a higher price and then decreasing it, as the customers feel like they are getting bargains on items that are ordinarily more expensive. For linear demand models, we also provide a detailed characterization of the near-optimal markdown policy along with an efficient way of computing it. We then consider a more challenging dynamic pricing and learning problem, where the demand model parameters are apriori unknown, and the seller needs to learn them online from the customers' responses to the offered prices while simultaneously optimizing revenue. The objective is to minimize regret, i.e., the T -round revenue loss compared to a clairvoyant optimal policy. This task essentially amounts to learning a non-stationary optimal policy in a timevariant Markov Decision Process (MDP). For linear demand models, we provide an efficient learning algorithm with an optimal square-root-T regret upper bound.

2 - Incentivized Exploration via Filtered Posterior Sampling

Anand Kalvit, Stanford University, Stanford, CA, United States, Aleksandrs Slivkins, Yonatan Gur

We study "incentivized exploration" (IE) in social learning problems where the principal (a recommendation algorithm) can leverage information asymmetry to incentivize sequentially-arriving agents to take exploratory actions. We identify posterior sampling, an algorithmic approach that is well known in the multi-armed bandits literature, as a general-purpose solution for IE. In particular, we expand the existing scope of IE in several practically-relevant dimensions, from private agent types to informative recommendations to correlated Bayesian priors. We obtain a general analysis of posterior sampling in IE which allows us to subsume these extended settings as corollaries, while also recovering existing results as special cases.

3 - Barriers to Collusion-resistant Transaction Fee Mechanisms

Aviv Yaish, Yale University, New Haven, CT, United States

To allocate transactions to blocks, cryptocurrencies use an auction-like transaction fee mechanism (TFM). A conjecture of Roughgarden [44] asks whether there is a TFM that is incentive compatible for both the users and the miner, and is also resistant to off-chain agreements (OCAs) between these parties, a collusion notion that captures the ability of users and the miner to jointly deviate for profit. The work of Chung and Shi [12] tackles the problem using the different collusion resistance notion of side-channel proofness (SCP), and shows an impossibility given this notion. We show that OCA-proofness and SCP are different, with SCP being strictly stronger. We then fully characterize the intersection of deterministic dominant strategy incentive-compatible (DSIC) and OCA-proof mechanisms, as well as deterministic MMIC and OCA-proof ones, and use this characterization to show that only the trivial mechanism is DSIC, myopic miner incentive-compatible (MMIC) and OCA-proof. We also show that a randomized mechanism can be at most 0.842-efficient in the worst case, and that the impossibility of a non-trivial DSIC, MMIC and OCA-proof extends to a couple of natural classes of randomized mechanisms

4 - Complexity, Communication and Misrepresentation

Junya Zhou, University of Texas at Dallas, Richardson, TX, United States

We investigate how increasing the complexity of the message space, in the presence of limited memory, can reduce misrepresentation in strategic communication. We enrich a standard cheap talk game so that senders must communicate not just a payoff-relevant state, but also payoff-irrelevant attributes correlated with the state. We show that: (i) increasing the set of attributes that may need to be reported (i.e., the complexity of the game) improves the amount of information transmitted in equilibrium, (ii) too much of an increase in complexity leads to a reversal of those gains, (iii) limited memory on the part of players, as well as the relative complexity faced by senders and receivers, drives these changes, and {iv} individuals experience cognitive costs when dealing with complex environments that they are willing to pay to avoid. Our findings demonstrate that the reporting of redundant information may induce equilibria that feature improved outcomes compared to simpler, more direct reporting systems, and point out the importance of complexity when trying to induce truthful information revelation.

Network Analysis and Graph Neural Networks I

Invited Session

Telecommunications and Network Analytics

Chair: Wenting Li, Los Alamos National Laboratory, Los Alamos, NM, United States

1 - Complex-Valued Graph Convolutional Neural Networks and Their Applications in Energy Systems

Tong Wu, Cornell University, New York, NY, United States

The effective representation, processing, analysis, and visualization of large-scale structured data over graphs, especially power grids, are gaining a lot of attention. So far most of the literature considered exclusively real-valued graph signals. However, graph signals are often sparse in the Fourier domain, and more informative and compact representations for them can be obtained using the complex envelope of their spectral components, as opposed to the original real-valued signals. This is the case for the AC carrier, and motivates its complex phasor representation. Focusing on applications in power systems, in this paper we generalize graph convolutional neural networks (GCN) to the complex domain, incorporating a complex-valued graph shift operators (GSO) based on the admittance matrix of power grids in the definition of graph filters (GF) and process complex-valued voltage phasor graph signals (GS). The theory developed is generalized to handle spatio-temporal complex network processes. We prove that complex-valued GCNs can be stable with respect to perturbations of the underlying graph support, by bounding of the error propagation through multiple NN layers. The paper showcases the benefits of complex GCN relative to several benchmarks, in power grid state forecasting and cyber-attack detection and localization.

2 - Demystifying and Mitigating Unfairness for Learning over Graphs

Yanning Shen, The University of California, Irvine, Irvine, CA, United States

We live in an era of big data and ``small world'', where a large amount of data resides on inter-connected graphs representing a wide range of physical and social interdependencies, e.g., smart grids and social networks. Hence, machine learning (ML) over graphs has attracted significant attention and has shown promising success in various applications. Despite this success, the large-scale deployment of graph-based ML algorithms in real-world systems relies heavily on how socially responsible they are. While graph-based ML models nicely integrate the nodal data with the connectivity, they also inherit potential unfairness. Using such ML models may therefore result in inevitable unfair results in various decision- and policy-making in the related applications. To this end, this talk will introduce novel fairness-aware graph neural network (GNN) designs to address unfairness issues in learning over graphs. Furthermore, theoretical understandings are provided to explain the potential source of unfairness in GNNs and prove the efficacy of the proposed schemes. Experimental results on real networks are presented to demonstrate that the proposed framework can enhance fairness while providing comparable accuracy to state-of-the-art alternative approaches for node classification and link prediction tasks.

3 - Provable Efficient Graph Neural Network Learning via Joint Edge-Model Sparsification

shuai zhang, NJIT, Newark, NJ, United States

Due to substantial computational challenges associated with training large-scale graph neural networks (GNNs), various sparse learning techniques have been developed to minimize memory and storage demands. These methods include graph sparsification, which involves sampling a subgraph to reduce data aggregation, and model sparsification, which entails pruning the neural network to decrease the number of trainable weights. While these strategies have demonstrated empirical success in reducing training costs while preserving test accuracy, a comprehensive theoretical generalization analysis for sparse learning in GNNs remains underdeveloped. This presentation will concentrate on the theoretical characterization of joint edge-model sparse learning, exploring its impact on sample complexity and convergence rates towards bounded generalization error. We will also provide analytical justifications for the strategies of selectively sampling critical nodes and pruning low-magnitude neurons, showing how these approaches can reduce sample complexity and improve convergence without compromising test accuracy. Finally, we will discuss our latest progress in the generalization analysis of graph transformers, which examines the optimization and generalization of a one-layer Graph Transformer for semi-supervised node classification. This analysis shows that the training mechanism of Graph Transformers, through self-attention and positional encoding, enhances generalization by making the attention map sparse and promoting the core neighborhood during training.

1 - Equity and Demand Tradeoffs in Level 2 EV Chargers Siting Optimization

Carlos Mateo Samudi Lezcano, Carnegie Mellon University, Pittsburgh, PA, United States

Electric vehicles are a plausible way to decarbonize the US private vehicle fleet. One of the main obstacles to hinder this transition is the availability of public charging infrastructure. This is particularly true for households that do not possess off-street parking, or low income households where owners cannot afford to install their own chargers. In deciding where to place these equipment, there is a tension between serving those locations that are expected to have high demand in the short term, and placing chargers in locations that lack this infrastructure to be able to adopt electric vehicles. Our work provides a framework to investigate this tension, through a bi-objective mixed integer linear program, and a series of metrics we develop to quantify the tradeoffs between different demographic groups in an ex post analysis. Our results indicate that including equity in charger siting and sizing decisions can lead to a more spread out spatial coverage and a higher number of total households with access to chargers. However, this does not come without drawbacks, since our equity objective prioritizes disadvantaged populations. Hence, as we increase our preference for this objective, we leave other demographics relatively worse off. The method was implemented in the cities of Pittsburgh, PA, and Seattle, WA, and can serve as a tool for energy public policy and urban planning inquiries.

2 - An Electric Vehicle Routing Problem applied for a Chain of Swiss Supermarkets

Reinaldo Garcia, University of Brasilia (UnB) - Director ORLaB (www.orlab.com.br), Brasília, Brazil, Bruno Souza, Ian Amaral

The use of electric vehicles by citizens and companies is already a reality in the world. Moreover, the replacement of vehicles powered by fossil fuels has been motivated by the most of the governments aiming to mitigate carbon dioxide emissions. In this work, a route optimization model that includes the electric vehicles distance travel and their load capacity besides the vehicles battery life is implemented to a chain of supermarkets located in Zurich, Switzerland. The implemented model considered crucial points for the solution such as the labor working hours, vehicle load capacity, battery life and demand stores in order to minimize the total distance traveled by the delivery trucks.

3 - Integrated electric vehicle routing with time window and mobile charging problem for logistics delivery system

Senyan Yang, Beijing University of Posts and Telecommunications, Beijing, China, People's Republic of, Ruiyan Zhang

Electric vehicles have gradually emerged as a green transportation mode for urban logistics, considering the increase in global warming and environmental pollution. However, their limited driving range and short battery life limit their widespread deployment. This study proposes an integrated electric vehicle routing with time window and mobile charging problem for logistics delivery system. In this system, mobile charging vehicles, serving as the moving charging stations, can charge the electric vehicles flexibly at customer locations, which can reduce the energy consumption generated by detour visits. The effect of charging on battery degradation is considered to optimize the charging strategies for extending the battery life. A hybrid heuristic algorithm is developed in the adaptive large neighborhood search framework, embedding a dynamic programming algorithm. Mobile charging strategies are designed to optimize the charging scheme based on the synchronization of the electric vehicles and mobile charging vehicles. The numerical experiments are conducted to explore the impact of battery degradation and mobile charging on the electric vehicle routing and charging solutions. The proposed algorithm performs well in solving large-scale problems, demonstrating its efficiency and accuracy.

4 - Coordinated Scheduling and Adaptive Control in a Shared Charging System with On-demand Mobility and Individually Owned Electric Vehicles

Zihao Zhu, Southeast University, Nanjing,China, China, People's Republic of, Xinlian Yu, Xiaofeng Li

Electric vehicles (EVs) have been widely adopted among both individual users and mobility On-demand (MoD) operators, privately due to their environmental and economic benefits. However, the full potential of EVs has not yet been realized, due to the spatial and temporal mismatches between uncertain charging demands and the availability of charging stations. In contrast to existing studies, which focus on charging of MoD fleet or private EVs separately, we aim to optimize the real-time charging scheduling and fleet management for EMoD considering charging admission of private EVs. A bi-level framework is designed to maximize the revenue of shared charging stations and EMoD fleet, combing deep reinforcement learning (DRL), queuing, and combinatory optimization. At the upper level, the number of EVs for charging, serving, and relocating in the fleet are determined via reinforcement learning, incorporating the expected charging revenue from private EVs which are obtained by a queuing model. In particular, the arrival process of private EVs at each charging station is exogenous, while that of fleet EVs is scheduled based on the passenger trip requests and charging accessibility. At the lower level, an adaptive admission strategy of private EVs as well as real-time dispatching for EMoD fleet are optimized based on the upper-level outcomes.

Numerical studies conducted using Manhattan's dataset in New York, USA demonstrate that the proposed framework effectively enhances both the utilization of charging stations and the fulfillment ratio of passenger trip orders.

5 - Improved Parameterization Schemes for WRF Wind Speeds

Siddhant Srivastava, Carleton University, Gatineau, QC, Canada, Kristen Schell

Wind power forecasting plays a critical role in enhancing the reliability of renewable energy sources; however, significant errors remain in current forecasting methods. The most detailed computational representation of local wind speeds is delivered by the Weather Research Forecasting (WRF) model. Despite the widespread use of the WRF model, its performance in diverse terrains remains suboptimal, which is crucial for grid integration and operational planning. Our study proposes a novel WRF model configuration that improves wind speed prediction accuracy across these varied terrains. The refined model significantly reduces wind speed prediction errors, thereby improving the reliability and viability of wind energy as a major power source.

6 - Optimization of Ship-deployed AUVs Synergistic Scheduling for Offshore Wind Turbines Underwater Foundations Inspection

Xu Han, Harbin Engineering University, Harbin, China, People's Republic of, Yuzhen Hu

Guided by the IMO's GHG reduction strategy and the "dual-carbon" goal, offshore wind power has become vital in renewable energy, and more attention has been paid to the regular inspection of offshore wind turbines (OWTs). The Autonomous Underwater Vehicle (AUV) has significantly improved inspection, but the current technology limits it to independently perform long-distance and complex tasks. We propose a ship-deployed AUVs synergistic mode to cover larger areas inspections in a shorter period. A mixed-integer programming model is developed to optimize the vessels' routes and schedule AUVs' drop and pick-up time. An adaptive large neighborhood search heuristic based on constraint programming called ALNSCP is developed for large-scale instances to help update the current solution during the repair operation. The simulation instances-based computational experiments verify the superiority of the synergistic mode and solution method in improving inspection efficiency. Sensitivity analysis further reveals how AUV debugging time and allowed float time affect inspection efficiency and cost. The experimental results can realize the cost reduction and efficiency of OWTs underwater foundations inspection and provide decision support for relevant practitioners to develop safety inspection plans.

7 - Condition Monitoring and Fault Detection of Gearbox Subsystem in Mid-sized Onshore Wind Turbines using SCADA Sensor Data

Jacob Shusko, University of Texas at Austin, Austin, TX, United States

Intelligent operation and maintenance optimization for wind turbines is a crucial area of research, driven by the growing prevalence of wind energy for electricity generation. The gearbox systems within wind turbines are particularly prone to failures within a five-year timeframe due to strenuous operating conditions. Effective monitoring of these critical systems can facilitate predictive maintenance strategies, mitigating the impact of potential total failures which necessitate expensive repairs and prolonged downtime. In this study, we develop condition monitoring models for key subsystems of mid-sized onshore wind turbines, employing both conventional time series modeling techniques and machine learning-based approaches. To demonstrate the efficacy of these models, we conduct a case study utilizing an open-source dataset comprising three years of sensor data from five mid-sized onshore wind turbines, encompassing a range of fault scenarios.

8 - Approximate Maintenance Policies for Large-Scale Offshore Wind Farms

Morteza Soltani, Clemson University, Clemson, SC, United States, Amin Khademi, Jeffrey Kharoufeh

We consider maintenance strategies for a large-scale, offshore wind farm in which wind turbines progressively degrade over time due to normal usage and exposure to a randomly varying environment. The turbines exhibit both economic and stochastic dependence due to shared setup costs and their common environment. The objective is to minimize the expected total discounted setup, replacement and lost power production costs over an infinite horizon. The problem is formulated using a Markov decision process (MDP) model; however, due to the curse of dimensionality, we examine an approximate formulation that is amenable to solution via column generation. Provided are upper and lower bounds to assess the quality of the approximation, as well as conditions under which the optimal policy is obtained via the approximate value function. The sensitivity of the maintenance policy to environment condition, setup cost and farm size is also discussed.

1 - Whose pie is bigger? CEO pay, blockholder earnings, and firm acquisitions: Distributive justice approach

Junghoon Kim, Sogang University, Seoul, Korea, Republic of, Jeongil Seo, Gyeonghwan Lee

In this study, we examined the impact of CEO relative pay to blockholder earnings on CEO's pay justice perception and subsequent decisions. Prior corporate governance research has demonstrated that blockholders with ownership exceeding 5% of total shareholdings can compel their CEOs to produce a bigger pie (i.e., higher corporate earnings) while receiving a small slice (i.e., less CEO pay). However, we propose that blockholders' monitoring of CEO pay may exert a negative second-order effect on CEO's strategic decision-making.

Drawing on organization justice theory and resource-based view, we posit that CEO pay results from a zero-sum distribution of corporate earnings between a CEO and shareholders. Thus, when evaluating justice in their pay, CEO will consider blockholder earnings as essential reference points. Because CEOs generally expect to appropriate a larger share of corporate earnings than any other resource provides, they will perceive distributive injustice when their pay is less than blockholder earnings. Relatively underpaid CEOs will attempt to restore pay justice by pursuing acquisitions that have been identified as an effective strategy for augmenting CEO pay. By analyzing a longitudinal sample of S&P 1500 firms spanning from 2001 to 2019, we discovered a positive association between CEO underpayment relative to blockholder earnings and acquisition activities. Moreover, this association is stronger when an underpaid CEO is powerful. Our study significantly contributes to the literatures on CEO pay and organization justice.

2 - Common Ownership Networks and the Expansion of Female Board Representation

Calvin Chiou, National Chengchi University, Taipei City, Taiwan

This study investigates the potential of common ownership to expand the pool of female director candidates and alleviate the underrepresentation of women on corporate boards. Using the California Senate Bill No. 826 and peer female director appointments as quasi-experimental settings, our findings demonstrate that firms under common ownership exhibit greater female board representation and a higher propensity to appoint new female directors. Furthermore, these firms show an increased likelihood of women attaining leadership positions on board committees. Our results remain robust to accounting for the activeness of the Big Three, underscore the network effect of common ownership on the supply side of the labor market for female directors.

3 - ESG Investment Strategy based on ESG Sustainable Growth Using ESG Thematic Revenue Exposure Data

Rei Yamamoto, Keio University, Kohoku-ku, Japan, Akifumi Isogai, Masatoshi Nozaki

This study proposes the use of the degree of diversification of ESG activities as a measure of the sustainability of ESG activities and tests the effectiveness of investment strategies based on it. Specifically, we use ESG-related sales data provided by FactSet to calculate entropy as the degree of diversification of ESG activities. We conduct empirical analysis on the U.S. stock market, and confirm that the proposed strategy yields significant excess returns.

4 - Leave My Case to Harry: The Double Response to Examiner Rejection

Qianqian Liu, Tianjin University, Tianjin, China, People's Republic of, Baofeng Huo

Gendered processes and outcomes are pervasive in the labor market. However, while most studies focus on the impact of applicant gender on their performance evaluations and application outcomes, few of these studies pay attention to the potential impact of evaluator gender characteristics. This leads to our research question: Does the gender of evaluators affect how their decisions are perceived by applicants? If so, how and what factors can moderate this relationship? We examine this research question in the context of patent examination, where applicants can challenge an examiner's final rejection decision by filing an appeal. Our empirical analysis reveals a notable gender disparity: following a rejection-decision sending, female examiners are 6.83% more likely to have their decisions appealed against than their male counterparts. This suggests that applicants may trust the decisions of female examiners less, opting to pass their cases to more advanced reviewers for further examination. Conversely, when male examiners issue the same rejection decisions, applicants prefer to request continued examination with the same examiner rather than filing an appeal. This indicates that applicants are more likely to attribute the rejection to their own application reasons and choose to revise their submissions accordingly when interacting with male evaluators.

5 - Eroding restrictive gender norms through schools: An 8-year follow-up study

Tarun Jain, Indian Institute of Management Ahmedabad, Ahmedabad, India, Diva Dhar, Seema Jayachandran

Abstract

Women and girls continue to lag behind men and boys in many domains, partly due to regressive attitudes about gender roles and the importance of equal opportunities. Evidence suggests that even culturally entrenched gender attitudes are amenable to change, and reshaping attitudes among young people may be a particularly effective strategy to change behaviors and outcomes to become more equitable. We report the impacts of a school-based gender attitude change program in India, evaluated using an RCT methodology, 6 years after the program ended. The evaluation is required since long run effects of the program are uncertain. Gender attitudes could erode over time, or translating the improved attitudes to equitable behavior might be challenging. The hypothesized transmission of attitude change to family members might not occur - because treated individuals might not spend time with their younger siblings discussing attitude change, or because attitudes of adult parents might not be malleable.

In the 6 year follow up, we do not find significant impacts on girls' educational completion, participation in productive activity (enrollment in college or a vocational course, or paid employment), or age of first marriage. The program increased girls' personal autonomy, as female students in treatment schools reported a 0.097 higher standard deviation personal autonomy index than their counterparts in control schools. Younger siblings of treated individuals reported 0.12 standard deviation more progressive gender attitudes overall. Fathers of boys also reported improved gender attitudes, pointing to spillovers from school-based programs to the wider family.

1 - Personal Experience Effects across Markets: Evidence from NFT and Cryptocurrency Investing

Chuyi Sun, University of North Carolina, Chapel Hill, NC, United States

I examine how personal experiences causally impact investor behaviors and market boom-bust episodes by exploiting a unique experimental setting in the non-fungible token (NFT) market. Using blockchain transaction-level data for about 1 million wallets, I find that NFT investors who randomly receive more valuable NFTs in the primary market are more likely to participate in subsequent primary market sales and trade more NFTs in the secondary market. These experience effects spill over to the cryptocurrency market as investors who randomly receive more valuable NFTs purchase more lottery-like cryptocurrencies. I also find that personal experiences and new investor inflows have contributed to the formation of bubbles in the NFT market. A model-free reinforcement learning framework best explains the empirical results.

2 - The Economics of Decentralized Autonomous Organizations

Valerie Laturnus, Durham University Business School, Durham, United Kingdom

The advent of blockchain, smart contracts, and Web3 has empowered new concepts for equity partnerships with autonomous operating systems and democratic corporate governance. This paper explores 2,377 of such new partnerships and uses detailed transaction data (from 2017 through 2022) to examine the performance of so-called decentralized autonomous organizations (DAOs) on Ethereum. As a result, I find that DAOs with greater participation rates in voting are associated with superior performance. Small members are a prevalent and important class of investors, while the degree of decentralization in DAOs (ownership concentration) plays only a minor role in firm valuation. Overall, DAOs are an effective organizational structure, when members take an active interest in the venture.

3 - Does Vote Trading Improve Voting Outcome?

Konstantin Sokolov, University of Memphis, Memphis, TN, United States, Nirmol Das, Sailendra Mishra

Decentralized autonomous organization design implies that stakeholders vote to express their individual opinions. Nonetheless, this design is disrupted by vote trading. We take advantage of the blockchain data transparency and explore how vote trading affects voting outcome. Our findings indicate that vote trading facilitates the decision-making by better informed stakeholders. Specifically, informed stakeholders use purchased votes to signal the quality of their contributions to the platform and thereby attract the non-purchased votes of uninformed stakeholders. Vote buying typically attracts 51% more non-purchased votes, and the reputation of vote buying stakeholders improves over time. Therefore, it is unlikely that vote trading leads to overselling the platform contributions. We conduct an experiment to confirm the robustness of our findings. Finally, an event study reveals that a demand shock in the market for votes encourages voting by those stakeholders who used to abstain from voting before the shock. Our findings lend support to theoretical and experimental research showing the benefits of vote trading in the absence of the majority rule.

4 - Centralization vs. Decentralization: First Evidence from the Laboratory

Nir Chemaya, UC Santa Barbara, GOLETA, CA, United States, Gabriele Camera, Gary Charness

We study trading networks where governance of payments flows—or, *validation*—relies on a digital registry. Strategic manipulation of the registry causes validation failure and inefficiency. We contrast two architectures: centralized, where validation authority is concentrated in a single participant (e.g., a Central Bank in a traditional monetary network), and decentralized, with a consensus-based validation mechanism (e.g., blockchain networks such as Bitcoin). Both architectures admit multiple Pareto-ranked equilibria. Pre-play communication, a natural feature of a trading environment, may facilitate coordination on efficient play. In our experimental data, decentralization reduced the incidence of validation failures and boosted trading activity. This governance advantage shows that there is scope for decentralization in innovating monetary and payments systems.

1 - Store Network Design for Omnichannel Retailing

Mert Cetin, Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands, Victor Martínez-de-Albéniz, Laura Wagner

We investigate the impact of physical store networks on purchase decisions in omnichannel retailing. Using geolocated consumer-level data, we explore how factors like store proximity, store density, assortment breadth, and inventory availability affect consumer behavior across online, offline, and hybrid channels, where orders are placed in-store but fulfilled online. Our analysis distinguishes between the effects of accessibility, such as the number of nearby stores and distance to the closest store, and service quality, including the variety of products available and stock levels. Our findings indicate that while better physical access to stores generally increases overall sales across all channels, the service quality provided by physical stores has a more nuanced effect: it boosts offline sales but decreases online and hybrid sales. This suggests that consumers who have access to well-stocked and varied physical stores may prefer to complete their purchases in person rather than online. To support retailers in optimizing their strategies, we conduct a counterfactual analysis showing that omnichannel retailers should consider maintaining dense store networks to sustain high sales levels. This contrasts with the recent trend of store closures, indicating that a well-distributed physical presence remains crucial for success in omnichannel retailing.

2 - OMGPT: A Sequence Modeling Framework for Data-driven Operational Decision Making

Hanzhao Wang, Imperial College Business School, London, United Kingdom, Kalyan Talluri, Xiaocheng Li

We build a Generative Pre-trained Transformer (GPT) model from scratch to solve sequential decision-making tasks arising in contexts of operations research and management science which we call OMGPT. We first propose a general sequence modeling framework to cover several operational decision-making tasks as special cases, such as dynamic pricing, inventory management, resource allocation, and queueing control. Under the framework, all these tasks can be viewed as a sequential prediction problem where the goal is to predict the optimal future action given all the historical information. Then we train a transformer-based neural network model (OMGPT) as a natural and powerful architecture for sequential modeling. This marks a paradigm shift compared to the existing methods for these OR/OM tasks in that (i) the OMGPT model can take advantage of the huge amount of pre-trained data; (ii) when tackling these problems, OMGPT does not assume any analytical model structure and enables a direct and rich mapping from the history to the future actions. Either of these two aspects, to the best of our knowledge, is not achieved by any existing method. We establish a Bayesian perspective to theoretically understand the working mechanism of the OMGPT on these tasks, which relates its performance with the pre-training task diversity and the divergence between the testing task and pre-training tasks. Numerically, we observe a surprising performance of the proposed model across all the above tasks.

3 - Sequential Choice Model with Representative Products: Behavior, Modeling and Optimization

Yu Sun, Chinese University of Hong Kong, Hong Kong, Hong Kong, Daniel Zhuoyu Long, Ruxian Wang

Modeling decision behavior among multiple choice options has been an active research area for several decades. Typically, classic discrete choice models consider that customers observe all available products simultaneously and select the one with the highest utility (e.g., the widely used MNL and NL models). In this paper, we propose a novel sequential choice model with representative products to describe customers' purchase behaviors, in which the products are grouped in multiple nests, and each nest has a representative product that is viewed in the first stage and other products that are viewed in the second stage. Customers make their purchase decision sequentially following the product information disclosure process in two stages: in the first stage, customers only observe incomplete information about the product set (i.e., limited information of all representative products) and choose a nest with the most attractive representative; in the second stage, customers unlock full information about all products in the selected nest and purchase the product in this nest with the highest utility, where the no-purchase option may exist in both stages and all nests. We employ the widely used MNL choice model in each stage to formulate the sequential choice process. Under this sequential choice model, we first investigate the problem on the selection of representative products. We then investigate the assortment and nest planning problem and establish the optimality of the adjusted revenue-ordered assortments. Finally, we study the pricing problem and show the optimality of adjusted same-markup pricing policies.

4 - Placement Optimization of Substitutable Products

Omar El Housni, Cornell University, New York, NY, United States, Rajan Udwani

Strategic product placement can have a strong influence on customer purchase behavior in physical stores as well as online platforms. Motivated by this, we consider the problem of optimizing the placement of substitutable products in designated display locations to maximize the expected revenue of the seller. We model the customer behavior as a two-stage process: first, the customer visits a subset of display locations according to a browsing distribution; second, the customer chooses at most one product from the displayed products at those locations according to a choice model. Our goal is to design a general algorithm that can select and place the products optimally for any browsing distribution and choice model, and we call this the Placement problem. We give a randomized algorithm that utilizes an α-approximate algorithm for cardinality constrained assortment optimization and outputs a $\Theta(\alpha)/\log(m)$-approximate solution (in expectation) for Placement with m display locations, i.e., our algorithm outputs a solution with value at least $\Omega(\alpha)/\log(m)$ factor of the optimal and this is tight in the worst case. We also give algorithms with stronger guarantees in some special cases. In particular, we give a deterministic $\Omega(1)/\log(m)$-approximation algorithm for the Markov choice model, and a tight $(1-1/e)$-approximation algorithm for the problem when products have identical prices.

[tent] Emerging Topics in Pricing and Revenue Management in Retail Industry

Invited Session

Revenue Management and Pricing

Chair: Mehmet Altug, George Mason University, Fairfax, VA, United States

Co-Chair: Aditya Jain, Baruch College, Zicklin School of Business, New York, NY, United States

1 - Buyout Price Optimization for the Rent-to-Own Business

Metin Cakanyildirim, The University of Texas at Dallas, Richardson, TX, United States, Milad Armaghan, Andrew Frazelle, Divakar Rajamani

We study the multidimensional price optimization problem faced by a rent-to-own (RTO) firm, which rents a product and during the rental offers it for sale repeatedly at a sequence of prices forming the buyout price path. We first employ calculus of variations to obtain optimal buyout prices in closed form for a special case. Next, to overcome the nonconcavity of the profit in the general problem, we formulate an equivalent bilevel optimization over the resource utilization and price path. We then transform the inner pricing problem into an efficient deterministic dynamic program (DP). Standard practice in the RTO business is to steeply decrease buyout prices early in the agreement and gradually later. However, we prove for the special case that the optimal prices should optimally decrease gradually early in the agreement and steeply later. Applying our methodology to jointly optimize buyout prices and inventory, our results reveal that higher inventory levels tend to entail higher optimal prices. Last, in a calibrated case study, we again find that prices should optimally decrease gradually early in the agreement and steeply later, validating our insights from the special case. Moreover, our methodology yields approximately a 22% increase in profit relative to industry prices.

2 - If the Blockchain Could Block: Strategic Blockchain Adoption by Manufacturer as Deterrence to the Selling of Counterfeits by Retailer

Jingjing Weng, Fox School of Business, Temple University, Philadelphia, PA, United States, Abhishek Roy, Subodha Kumar

Counterfeiting is a significant concern for many industries, especially in the online channel. We first investigate an online retailer's motivation to sell counterfeits along with the genuine product. We then explore the strategic adoption of blockchain technology by the manufacturer to combat deceptive counterfeit sold by the retailer. Our results show that the retailer is incentivized to sell counterfeits when the production cost is relatively high. However, a higher production cost does not necessarily imply a higher counterfeit rate. Additionally, we demonstrate that the introduction of deceptive counterfeits can sometimes benefits the manufacturer while hurting the retailer. That is, the sales of deceptive counterfeits may lead to win-win, win-lose, lose-win, and lose-lose outcomes for the manufacturer and the retailer. Moreover, we establish the conditions under which the manufacturer adopts blockchain technology. Furthermore, we identify that blockchain technology can serve as a commitment device and thus benefit the retailer by eliminating the prisoner's dilemma region. We extend the base model by relaxing several assumptions, our analysis reveals that our qualitative findings remain consistent with those derived from the base model. Our research provides novel insights for managers and policymakers in combating counterfeits.

3 - Impact of Price Strategy on Returns: A Price Transparency and Valuation Uncertainty Story

Jane Jiang, The Ohio State University, Columbus, OH, United States, Wedad Elmaghraby, Ozge Sahin

We study how discount strategies affect net sales -- sales after accounting for returns. We evaluate two prevalent discount strategies: bundle discounts, which apply discounted prices exclusively to product bundles, and single-item discounts, where the discount extends to all products. Two primary factors are considered in analyzing the discount strategies' performance in enhancing net sales: the leverage effect of bundles at the return stage, and customers' attentiveness to the discount pricing structure. The latter is particularly relevant under bundle discounts, where customers retaining any items must pay full price, a detail that could be overlooked by those inattentive to pricing, leading to an overestimation of bundle values. We adopt a forward-looking approach to customer behavior by modeling the interconnected purchase and return decisions, incorporating post-purchase valuation changes and potential pricing inattentiveness. Partnering with one of Turkey's largest fashion retailers, we apply structural estimation to ascertain how customers reassess product valuations post-purchase and their attentiveness to pricing details. Furthermore, we simulate generic retail scenarios to discern the optimal discount strategy for retailers. Our findings reveal that factoring in returns shifts the retailer's preference in discount strategies. By tailoring bundles to maximize the leverage effect post-purchase, the retailer's net sales can be enhanced by 15.6%. We also find that customers tend to overlook pricing structures, leading to increased returns. Enhancing customer attentiveness to pricing can decrease the retailer's return rates by 20.9%. Moreover, improving customer attentiveness benefits retailers by enabling them to create more versatile bundle offers, further optimizing their sales strategy.

4 - Sales Versus Subscription Business Models in Retail: Price and Assortment Competition

Mehmet Altug, George Mason University, Fairfax, VA, United States, Aditya Jain, Tolga Aydinliyim, Oben Ceryan

Motivated by retailers' introduction of subscription services, we study consumers' self-selection between "buying from seller firms" versus subscribing to renter firms. Modeling price and assortment competition among sellers and renters, we characterize a solution wherein the renter's large assortment at premium prices and the seller's limited assortment split equilibrium demand.

Emerging Techniques in Revenue Management and Logistics Planning

Invited Session

Revenue Management and Pricing

Chair: Zhenzhen Yan, Nanyang Technological University, Singapore, Singapore

1 - Privacy-Preserving Inventory Control

Guangyan Gan, NTU, Singapore, Singapore, Hanzhang Qin, Zhenzhen Yan

Data-driven inventory policies can inadvertently expose sensitive information of retailers in the training data (i.e.demand samples), thus susceptible to privacy risks. In this paper, we focus on the privacy issue in the multistage inventory control problem and design data-driven

inventory policies with differential privacy guarantees which provably prevent such risks. We propose the first differential private inventory control algorithms for the multistage inventory control problem in both the backlog setting and lost sales setting, leveraging offline reinforcement learning algorithms with privacy guarantees. Furthermore, we prove that our algorithm preserves privacy and establish the sample complexity (i.e., the number of demand samples needed) bound of two private inventory policies which match a known lower bound for non-private inventory control models. Theoretical results suggest that collecting more data can offer privacy benefits at no additional cost when the sample size is sufficiently large. Experiments further demonstrate the effectiveness of our proposed privacy-preserving inventory policies in achieving satisfactory performance.

2 - Pricing with Adversarial Inventory Constraints

Jianyu Xu, UC Santa Barbara, Santa Barbara, CA, United States, Yining Wang, Xi Chen, Yu-Xiang Wang

We study a dynamic pricing problem under the online framework, where the potential demand is dependent on the price proposed by the seller (we) at each time period t=1,2, ..., T. However, a perishable inventory is imposed at every time t, *censoring* the potential demand if it exceeds the inventory level. To make it more challenging, the inventory quantity γ_t varies over time and is given by *adversary*. To address this problem, we develop a novel and efficient algorithm that achieves $O(\sqrt{T})$ regret for linear noisy demands. This result matches the information-theoretic lower bound, indicating the optimality of our algorithm. Our findings advance the state-of-the-art in online decision-making problems with censored feedback, offering a theoretically optimal solution that can be broadly applied.

3 - Enhancing Avocado Shelf-life Prediction with Machine Learning and Spectral Analysis

Xiaoyue Zhang, National University of Singapore, Singapore, Singapore, Jingyang Li, Xueming Yuan, Mabel C. Chou

Managing the shelf-life of fresh fruits, like avocados, is crucial to minimize spoilage and waste in supply chains. This study collected daily spectral data from 150 avocados until spoilage and applied machine learning techniques—specifically Quadratic Discriminant Analysis (QDA), XGBoost, and LightGBM—to improve avocado shelf-life prediction. Furthermore, we emphasize the significance of applying Moving Average Smoothing (MAS) Transformation to enhance prediction accuracy. Our results highlight the effectiveness of combining spectral data with advanced data processing and analytics methods in accurately forecasting perishable fruit shelf-life, providing important information for optimizing inventory management strategies.

Empirical Research in Revenue Management

Invited Session

Revenue Management and Pricing

Chair: Abhishek Deshmane, Georgia Institute of Technology, Atlanta, GA, United States

1 - Operations and Analytics to Improve Welfare in Artisanal Supply Chains

Somya Singhvi, USC Marshall School of Business, Los Angeles, CA, United States, Divya Singhvi, Xinyu Zhang

This research investigates strategies to enhance welfare and productivity in artisanal supply chains, focusing on two critical directions: supervising geographically distributed weavers and using information transparency to increase productivity. First, because weavers work from geographically remote areas and a limited number of supervisors are expected to visit weavers physically, optimizing supervision operations is a key challenge. Using supply chain data, we provide robust empirical evidence that frequent supervisor visits can play a crucial role in improving artisans' productivity. Our results indicate that a one-day decrease in the average number of days between supervisor visits to remote weavers can increase weaving rates and monthly income by 8.6%-11.3%. We also find that (i) visits to looms with difficult-to-weave rugs and (ii) visits that are consistently scheduled have a more substantial positive impact on weavers' productivity. To capitalize on these insights, we propose an optimization framework for scheduling supervisor visits in the supply chain using a Mixed Integer Linear Program (MILP) and show its impact in practice. Second, we investigate the role of information transparency in improving productivity within artisanal supply chains. By providing weavers with transparent access to information regarding work completion and potential increase in income, we hypothesize that productivity will increase. This transparency could also mitigate severe financial stress that weavers often face during the course of the month. These insights offer practical implications for policymakers and supply chain managers aiming to improve welfare and efficiency in artisanal supply chains.

2 - Choice Models and Permutation Invariance: Demand Estimation in Differentiated Products Markets

Amandeep Singh, University of Washington, Seattle, WA, United States, Ye Liu, Hema YOGANARASIMHAN

Choice modeling is at the core of understanding how changes to the competitive landscape affect consumer choices and reshape market equilibria. In this paper, we propose a fundamental characterization of choice functions that encompasses a wide variety of extant choice models. We demonstrate how non-parametric estimators like neural nets can easily approximate such functionals and overcome the curse of dimensionality that is inherent in the non-parametric estimation of choice functions. We demonstrate through extensive simulations that our proposed functionals can flexibly capture underlying consumer behavior in a completely data-driven fashion and outperform traditional parametric models. As demand settings often exhibit endogenous features, we extend our framework to incorporate estimation under endogenous features. Further, we also describe a formal inference procedure to construct valid confidence intervals on objects of interest like price elasticity. Finally, to assess the practical applicability of our estimator, we utilize a real-world dataset from S. Berry, Levinsohn, and Pakes (1995). Our empirical analysis confirms that the estimator generates realistic and comparable own- and cross-price elasticities that are consistent with the observations reported in the existing literature.

3 - Data-Driven Real-TIME Coupon Allocation in Online Platform: Theory and Experiment

Weiming Zhu, The University of Hong Kong, Hong Kong, Hong Kong, Hanwei Li, Jinglong Dai, Jianfeng Lin, Binqiang Huang

Recent advancements in machine learning and the availability of abundant customer data enable platforms to provide customized coupons to individuals. In this study, we partner with Meituan, a leading shopping platform, to develop a real-time, end-to-end coupon allocation system that is fast and effective in stimulating demand while adhering to marketing budgets when faced with uncertain traffic from a diverse customer base. Leveraging comprehensive customer and product features, we estimate CVR under various coupon values and employ isotonic regression to ensure the monotonicity of predicted CVRs with respect to coupon value. Using calibrated CVR predictions as input, we propose a Lagrangian Dual-based algorithm that efficiently determines optimal coupon values for each arriving customer within 50 milliseconds. We theoretically and numerically investigate the model performance under parameter misspecifications and apply a control loop to adapt to customer features in real-time to better adhere to the marketing budget. Finally, we demonstrate through large-scale field experiments and observational data that our proposed coupon allocation algorithm outperforms traditional approaches in terms of both higher conversion rates and increased revenue. To date, our framework has been implemented by Meituan's bike-sharing division and has distributed coupons to over 100 million users across more than 110 major cities in China. This implementation has resulted in a 0.7% increase in revenue, which is equivalent to an additional 8 million RMB in annual profit.

4 - Unlocking the Power of Exchangeable Tickets: a Study of Consumer Behavior in spORts Events

Ovunc Yilmaz, University of Colorado Boulder, Boulder, CO, United States, Hayri Alper Arslan, Yao Cui

Using transactional data from a US professional sports company that owns a baseball and a soccer team, we investigate the impact of selling exchangeable tickets that provide fans flexibility to change the game they attend for a small additional fee. We find that the use of exchangeable tickets leads to significant changes in customers' purchase time and total spending.

5 - Managing Cart Abandonment: Evidence from an Online Delivery Platform

Can Kucukgul, Rutgers University - Camden, Philadelphia, PA, United States, Gad Allon, Dmitry Mitrofanov

In the era of e-commerce, the phenomenon of cart abandonment has become a significant challenge for online retailers. Reduction in abandonment rates allows retailers not only to recover lost revenue but also to improve customer satisfaction. Utilizing a large-size consumer click data from a prestigious market-leader delivery platform, in this paper, we first aim to uncover both store and cart-level characteristics impacting abandonment. Further, employing a hazard-logit model, we investigate the intricate interplay between cart abandonment and customer shopping behavior. Our first set of results indicate that sticker shocks fail to fully explain why customers are deterring from checking their carts. In addition, we provide valuable insights for online delivery platforms on how to tailor their data-driven promotion strategies to different customer segments.

1 - Price restraining policies and search cost: economic analysis and implications

Roman Kapuscinski, Ross School of Business, Ann Arbor, MI, United States, Ozge Sahin, Mojtaba Abdolmaleki

During the last twenty years, many traditional retailers have been facing an increasing competition from online retailers and local discounters. Customers are able to experience products in a brick-and-mortar store but purchase online for lower prices. As a result, traditional retailers' sales decrease and some of them stop promoting or carrying such products. For manufacturers, however, traditional retailers play a crucial role by showcasing and advertising products to customers. Manufacturers use price restraining policies to protect retailers' margins. Resale Price Maintenance (RPM) and Minimum Advertised Price (MAP) are two most commonly-used policies intended to protect retailers' margin. Under RPM policy, the manufacturer sets a minimum price for each product and requires all retailers not to price below it. Under MAP policy, manufacturers set a "suggested" retail price. While retailers can sell at lower prices, they are not allowed to advertise a price lower-than-suggested retail price. In this paper, we build a stylized model to study RPM and MAP under various market situations. In particular, we explore which policy is more beneficial for the manufacturer, retailers, and consumers. We find that MAP policy is beneficial for the manufacturer when the search cost is high and consumers are highly heterogeneous in their valuation of the product. Otherwise RPM policy is preferred. Traditional retailers and consumers may prefer MAP to be used, and prefer a market with a higher search cost and higher heterogeneity in consumer valuations, compared to the manufacturer. Online retailers always prefer MAP policy.

2 - A Revenue Management Approach to Fair Hospital Diagnostic Service Scheduling

Joyce Luo, Massachusetts Institute of Technology, Cambridge, MA, United States, Maureen Canellas, Dessislava Pachamanova, Georgia Perakis

The management of diagnostic imaging services is a challenging and important task for hospital systems. Suboptimal scheduling of diagnostic services increases patient wait times and prevents the availability of overnight beds that could otherwise be utilized by incoming patients. Patients are served by a limited number of radiology technicians, who have been experiencing higher rates of exhaustion and burnout. Current diagnostic scheduling systems overlook the importance of distributing scans fairly among technicians, which could help alleviate these problems. In collaboration with a large Level I Trauma hospital in Central Massachusetts, we develop a real-time optimization algorithm that manages daily radiology technician schedules more fairly and efficiently than current practice. Our algorithm balances the need to maximize the number of patients receiving scans, with fairness considerations for technicians in terms of scan load and difficulty. We also consider that patients have different urgency levels and characteristics, so certain more urgent patients need to be seen sooner. We provide analytical guarantees in comparison to a full-knowledge formulation and analyze our algorithm's performance using echocardiogram order data from our hospital partner. Simulation results show that in higher demand scenarios, our algorithm's policy shortens patient wait time and improves throughput for certain patient types compared to current hospital policy. In addition, our algorithm's recommended allocations are more fair for technicians compared to current hospital allocations in terms of total scan time, total number of scans performed, difficult scan time, and number of difficult scans performed.

3 - Bayesian Demand Learning and Revenue Management under Limited Capacity

Mihalis Markakis, IESE Business School, Barcelona, Spain, Victor Martínez de Albéniz, Marcos Serrano

In Revenue Management (RM) problems with limited capacity, the optimal price or quantity decision is mainly driven by the ratio of supply over total demand during the sales season. Under ex ante uncertainty about certain demand statistics, primarily its rate, the seller not only adjusts pricing or capacity allocation to optimize revenues but also to learn the demand. We thus consider a stylized quantity-based RM problem whereby a fixed amount of capacity needs to be sold within a given horizon, into either a high margin, low volume channel, or a low margin, high volume one. The demand rate in either channel is uncertain, but a prior distribution over it is available. We formulate the dynamic optimization problem with Bayesian demand learning. We provide a clean and intuitive structural characterization for the general case of the problem; a closed-form solution for the special case where there is one unit of capacity to sell (precisely the regime of limited capacity); and an efficient heuristic policy for the multi-unit case, which provides near-optimal performance in various regimes in our numerical experiments. We find that higher uncertainty regarding the demand rate may push the seller to opt for a high margin, low volume position for longer, rather than look for higher volumes to accelerate learning, as intuition may suggest. Finally, we show that the monetary value of Bayesian demand learning is comparable to the value of allocating capacity in an optimal way, suggesting that demand learning could be a first-order consideration in RM.

4 - Robust One-Shot Price Experimentation

Ali Daei Naby, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Setareh Farajollahzadeh, Ming Hu

We assess the benefit of one-shot price experimentation for a seller in setting a price with limited information about the customer valuation distribution. Specifically, we consider a seller who knows the exact sales probability associated with a single historical price and aims to maximize the worst-case revenue ratio compared to an oracle with complete knowledge of the valuation distribution, referred to as the competitive ratio. For the class of regular distributions, we assess the benefit of one-shot price experimentation for the seller, who can first choose an experimental price and then set a final price based on the realized sales probability. We quantify the value of experimentation, defined as the difference between the optimal competitive ratio with and without experimentation. More specifically, first, we fully characterize the optimal distributionally robust experimental price point and its guaranteed performance. Second, we quantify the value of experimentation. For example, when the market share of the historical price is 0.05 (resp., 0.75), the performance of the optimal robust price without experimentation is 0.37 (resp., 0.25), while with one-shot price experimentation, the performance is 0.63 (resp., 0.5), where the value of experimentation is 0.26 (resp. 0.25). Third, we provide insights into experimenting with higher or lower prices compared to the historical price. For instance, we show that when the historical sales probability exceeds a threshold at around 0.3, the firm should opt for experimenting with a higher price; otherwise, it should opt for a lower experimental price.

5 - A Robust Optimization Approach to Assortment Planning with Cross-Item Effects

Georgia Perakis, Massachusetts Institute of Technology, Cambridge, MA, United States, Manuel Moran-Pelaez

Assortment planning in retail involves the strategic selection of products to offer customers and their inventory levels, with the goal of maximizing profit. While cannibalization or more generally substitution effects are widely studied in the assortment planning literature, complementarity effects remain relatively unexplored. Cannibalization occurs when a product is bought instead of a similar one, and complementarity occurs when two products are bought together because they will be used together. This paper introduces a novel demand model that captures cannibalization and complementarity effects. We also introduce a fixed point method to compute solutions for the assortment planning problem under the aforementioned demand model. Additionally, we introduce a novel robust method to deal with cross-item effects and their uncertainty while using much less computation power than the fixed point method. Through experiments on synthetic and real-world retail datasets, we demonstrate the effectiveness of our proposed approaches in improving assortment planning outcomes, particularly in scenarios with complex interdependencies between items. Our findings underscore the importance of considering both cannibalization and complementarity effects in assortment planning and provide practical insights for retailers.

Predictive Analytics for High-Stakes Decision Making

Invited Session

Decision Analysis Society

Chair: Shixiang Woody Zhu, Carnegie Mellon University, Pittsburgh, PA, United States

Co-Chair: Wenbin Zhou, Carnegie Mellon University, Pittsburgh, PA, 15213, United States

1 - Point Processes with Event TIME Uncertainty

Tingnan Gong, Georgia Institute of Technology, Atlanta, GA, United States, Xiuyuan Cheng, Yao Xie

Point processes are popular instruments in statistics that uncover the temporal pattern of dependent event data. In many applications, the event data cannot be observed exactly. Hence, we need to take the time uncertainty into account. Most existing works yet propose point process models with temporally stationary kernels, including the classical Hawkes process. However, modern data demands more general point process models, which can characterize non-stationary temporal influences. To settle the mentioned challenges, we construct a novel point process model that can handle the time uncertainty in data and capture non-stationary temporal influences. We also extend the model to a network setting, which can unveil the temporal causal relationship between nodes. We derive two effective vector fields to learn the kernel and provide theoretical performance guarantees. The statistical performance of the proposed model is demonstrated on simulated and real data, compared with classical and up-to-date baselines.

2 - Sequential Conformal Prediction with Spatial Temporal Point Processes

Wenbin Zhou, Carnegie Mellon University, Pittsburgh, PA, United States

Spatial-temporal forecasting is crucial for various real-world applications, including energy planning, traffic modeling, and epidemic modeling. However, uncertainty quantification methods specifically tailored for spatial-temporal forecasting are limited, primarily due to challenges such as temporal covariate shift and spatial multimodal heterogeneity. In this work, we present a novel conformal prediction framework designed to quantify spatial temporal uncertainty in a distribution-free manner. We assess our proposed framework using both synthetic and real-world datasets, demonstrating that our method achieves a lower coverage gap with high probability and better computational efficiency, compared to state-of-the-art methods.

3 - Towards a Network-Scale Causal Understanding and Forecasting of Traffic Crash Risks with Large Language Models

Frank Yang, Johns Hopkins University, Baltimore, MD, United States, Zhiwen Fan, Pu Wang, Yang Zhao, Yibo Zhao

Current research in traffic accident analysis has predominantly approached the problem as classification tasks, focusing mainly on learning-based classification or ensemble learning methods. These approaches often overlook the intricate relationships among the complex human and contextual factors related to traffic crashes and risky situations. In contrast, we initially formulate a large-scale traffic accident dataset consisting of abundant textual and visual information. We then present a novel application of large language models (LLMs) to enhance causal understanding and improve forecasting of traffic crash specifics, such as accident types and injury severity. Utilizing this rich dataset, we calibrate and fine-tune various LLM configurations to predict detailed accident outcomes based on contextual and environmental inputs. Our AccidentLLM diverges from traditional ensemble machine learning models by leveraging the inherent capabilities of LLMs to parse and learn from complex, unstructured data, thereby enabling a more nuanced analysis of contributing factors. Preliminary results indicate that our LLM-based approach not only predicts the severity of accidents but also classifies different types of accidents and predicts injury outcomes, all with an accuracy above 92%.

4 - Quantifying Uncertainty in Deep Spatiotemporal Forecasting

Dongxia Wu, University of California San Diego, La Jolla, CA, United States, Liyao Gao, Xinyue Xiong, Matteo Chinazzi, Alessandro Vespignani, Yi-An Ma, Rose Yu

Deep learning is gaining increasing popularity for spatiotemporal forecasting. However, prior works have mostly focused on point estimates without quantifying the uncertainty of the predictions. In high stakes domains, being able to generate probabilistic forecasts with confidence intervals is critical to risk assessment and decision making. Hence, a systematic study of uncertainty quantification (UQ) methods for spatiotemporal forecasting is missing in the community. In this paper, we describe two types of spatiotemporal forecasting problems: regular grid-based and graph-based. Then we analyze UQ methods from both the Bayesian and the frequentist point of view, casting in a unified framework via statistical decision theory. Through extensive experiments on real-world road network traffic, epidemics, and air quality forecasting tasks, we reveal the statistical and computational trade-offs for different UQ methods: Bayesian methods are typically more robust in mean prediction, while confidence levels obtained from frequentist methods provide more extensive coverage over data variations. Computationally, quantile regression type methods are cheaper for a single confidence interval but require re-training for different intervals. Sampling based methods generate samples that can form multiple confidence intervals, albeit at a higher computational cost.

1 - Behavioral Analysis and User Motivation in Crowdfunding Campaigns: Effect of HCI driven design

Saunak Basu, University of Nevada Las Vegas, Las Vegas, NV, United States

This study investigates the impact of Human-Computer Interaction (HCI) design on user motivation within crowdfunding campaigns. By analyzing data from diverse crowdfunding platforms, we explore how interface design influences donor engagement and contribution behavior. Our research reveals the significance of HCI-driven elements such as interface usability, persuasive design, and social proof in shaping donation decisions.

Through advanced data analytics and behavioral modeling techniques, we examine nuanced patterns in user interactions and funding outcomes. Additionally, we examine the role of psychological factors like reciprocity and perceived efficacy in driving donor engagement. The synthesis of quantitative analysis and qualitative user feedback provides actionable insights for platform designers and crowdfunding practitioners.

This presentation contributes to the understanding of crowdfunding dynamics by elucidating the complex interplay between HCI design principles and user behavior. By leveraging these insights, practitioners can optimize campaign interfaces to enhance user motivation and maximize fundraising success on digital platforms.

2 - The Impact of Supply Chain Cyberattacks on the Performance of Downstream Firms

Shreya Gokhale, University of Illinois Urbana-Champaign, Champaign, IL, United States, Abhijeet Ghoshal, Gopesh Anand, Yang Gao

Supply chain cyberattack incidents have been increasing in number and severity over the last few years. These cyberattacks occur when malicious actors exploit the buyer-supplier relationships between firms to compromise downstream buyer companies through their suppliers' weaknesses. These attacks have the ability to simultaneously compromise multiple organizations in a supply chain and are difficult to curb since they can be caused by a single security vulnerability of an upstream supplier. Despite the increasing gravity of supply chain cyberattack incidents, there is a scarcity of empirical literature investigating how cyberattacks on an upstream supplier firm impact the performance of the downstream buyer firms associated with the supplier. In this paper, we examine the impact of supply chain cyberattack events on the stock market performance of these downstream buyer firms. Using event study and stacked difference-in-difference methods we analyze supply chain cyberattack incidents that occurred from 2020 to 2023. We find that the publicly known downstream buyer firms associated with such compromised suppliers experience a drop in their stock market performance and the impact lasts for around five trading days after the first public revelation about the event. We further hypothesize that this impact could be moderated by the bargaining power of the buyer firm over the supplier firm and find that the downstream buyer firms having higher bargaining power over their suppliers face a more intense stock market reaction.

3 - Machine Learning, Professional Expertise, and Entry-level Jobs

Yuanyang Liu, University of Tennessee, knoxville, TN, United States, Chuanren Liu, Tingliang Huang

How machine learning (ML) technologies change the job requirements for workers? Using over 51 million job postings of S&P 500 companies from 2011 to 2023, we find that firms utilizing ML also increase the requirements for their workers in prior work experience and decision-making related skills. We provide a causal link with a Shift-Share IV estimation strategy based on the text of occupation description and AI patents. Further, such effects exist for not only knowledge workers (e.g., Managers), but also the lower skill occupations that may not require a college degree (e.g., Retail Salespersons and Customer Service Representatives). Our results indicate that, with the ability to handle straightforward cases and processes, ML technologies may shift the ``mass'' of work for people to handle novel scenarios which necessitate greater domain expertise and decision-making. Consequently, the proliferation of ML could lead to a reduction in entry-level job opportunities. With the ever-growing adoption of ML and related technologies, these consequences require proactive career development strategies for individuals and institutions.

4 - Share-the-Road: Exploring the Relationship between Bicycle-sharing and Ridesharing Platforms

Ayush Sengupta, Alfred University, Alfred, NY, United States

In this paper, we explore the relationship between bicycle-sharing platforms such as Citi Bike and ridesharing platforms such as Lyft. The two groups of platforms are both relatively new business models in the transportation service industry and are driven by innovative online technologies. It is debated in academic research and in industry whether the two types of platforms have a complementary or substitution effect on each other. Some argue that the bicycle-sharing platforms may help alleviate the last-mile barrier in urban transportation and benefit ridesharing platforms by providing additional customers from their untapped market and by improving their financial situation. Others suggest that an adverse impact of bicycle-sharing platforms on ridesharing platforms may arise through a reduction in the ridership of the latter, especially over short trips, due to a substitution effect. We focus on answering this question empirically by examining the impact of the entry of Citi Bike on the ridership of all ridesharing platforms, in the context of New York City. We analyze data on ridesharing-platform ridership, measured by the number of their pick-ups. Through our analyses, we examine how Citi Bike’s entry influences ridesharing’s popularity in a large metropolis and how the impact varies across trips with different travel distances. We also analyze how Citi Bike’s entry influences pooled ridesharing trips and ridesharing trips during rush hours. Our findings offer insights for bicycle-sharing and ridesharing-platform companies to make business decisions and for policymakers to devise policies to improve traffic congestion and reduce vehicular emissions.

5 - Predicting Firm Alliances: Leveraging Relational Pluralism in Innovation with Graph Neural Networks

Junho Yoon, The University of Iowa, Iowa City, IA, United States, Gautam Pant

Interfirm alliances in high-tech industries are a synergistic resource-sharing mechanism that can lead to efficient innovation. As an initial critical step in forming alliances, firms conduct partner search, which involves finding other firms that possess complementary technological resources and capabilities. This study proposes an automated alliance prediction framework that can simplify partner search as well as provide valuable intelligence to third parties such as analysts and investors. Our graph neural network-based framework utilizes a key alliance theory on relational pluralism, which refers to multitudes of relationships that exist between firms that can provide an understanding of how firms interact and collaborate. To operationalize our prediction framework, we compile a rigorous firm-level network data set derived from 8,739 alliances between 11,499 firms in 11 high-tech industries through the period of 1990 - 2018. Our theory-driven predictive models incorporate multiple innovation-based relations—interfirm collaborations, human capital flow, and knowledge spillovers—into graph neural networks (GNNs). Our prediction results show that the plurality of interfirm relations collectively contributes to superior predictive performance across varying evaluation metrics, highlighting the practical utility of our predictive models as a partner search instrument. We also discuss the stakeholders who can benefit from our prediction framework in practice, as well as several contributions to the alliance literature.

Strategic Mechanisms in Contemporary Markets

Invited Session

Decision Analysis Society

Chair: Linsheng Zhuang, NUS Institute of Operations Research and Analytics, Singapore, Singapore

1 - Joint Bidding and Information Frictions

Shanglyu Deng, University of Macau, Macao, China, People's Republic of, Qiang Fu, Zenan Wu

In public procurement where some firms must cooperate to finish the project, allowing joint bidding by complementary firms is a natural way to promote competition. This paper compares the performance of the joint bidding approach with that of the VCG auction, which allows complementary firms to submit independent bids without forming consortia. Absent information frictions, joint bidding outperforms the VCG auction, achieving full allocative efficiency at lower procurement prices. However, information frictions can hinder joint bidding due to non-assortative matching of firms or strategic behavior within consortia, making it perform worse than the VCG auction in terms of allocative efficiency and procurement price.

2 - Spillovers on Crowdsourcing Platforms

Sanjiv Erat, University of California-San Diego, La Jolla, CA, United States, Xiaofeng Liu

Crowdsourcing platforms, such as Kaggle, facilitate innovation and problem-solving contests, with diverse deadlines, that run over time and compete for the same set of solvers. The current article offers a tractable model of multiple solvers competing in multiple contests over time, and characterizes the equilibrium solver efforts and the resultant quantity and quality of submitted solutions. The model reveals a negative externality between contests arising from solvers splitting their efforts, and a positive externality arising from the possibility of solver's learning from similar contests. Much more interestingly, the model also predicts a nuanced relationship between when the competing contest ends and the strength of these externalities. Building on these predictions, we conduct an empirical analysis of Kaggle contests. Results confirm a negative correlation between the number of competing contests and both submission quantity and quality, a relationship that is particularly pronounced when competing contests end before focal contests. Analysis of contest similarity shows positive externalities from competing contests to the focal contest, and its interaction with the contest deadlines. Specifically, when the competing contests that ends after the focal contest is more similar, we observe higher submission quantity in the focal contest, while when the competing contest that ends before before the focal contest exhibit greater similarity, the focal contest attracts higher submission quality. Beyond the theoretical contribution, our research provides actionable insights for contest organizers and crowdsourcing platforms, offering the first empirical assessment of how differing deadlines and contest similarity relate to the quality and quantity of solver-submitted solutions.

3 - Sourcing Innovation and Production: the Value Of Commitment

Ersin Korpeoglu, University College London, London, United Kingdom, Xiaoshuai Fan, Cuihong Li, Jun Liang

We consider a buyer firm that sources the design and production of an innovative product from two suppliers. The value of a supplier's design depends on the supplier's effort, while the production cost is the supplier's private information. A supplier can potentially produce the design of another supplier, albeit at a switching cost added to the production cost. Hence, a sourcing mechanism for an innovative product should motivate suppliers' innovation efforts to improve the design value and identify low-cost production solutions. We first investigate the ex-post optimal sourcing mechanism: the *no-commitment* mechanism in which the buyer specifies the rules to select suppliers for design and production after receiving the designs submitted by suppliers. After that, we consider two sourcing mechanisms commonly observed in practice, under which the buyer commits to sourcing the design and the production *jointly* or *separately*. We then compare the no-commitment mechanism with these two mechanisms. We also consider an *enhanced-commitment* mechanism in which the buyer commits to using the supplier who provides the best design for production. Our findings provide valuable managerial insights for buyers to manage suppliers' innovation effort and production costs in sourcing mechanism design.

4 - Aggregating OR Interacting?: the Role of Individual Overconfidence

Wenjie Tang, University of Vienna, Vienna, Austria, Yanwei Jia

We compare two approaches of combining individual judgments about an unknown value into a collective estimate when individuals are overconfident: statistically aggregating individual estimates or asking individuals to interact and reach consensus. We are interested in which approach, aggregating or interacting, is better able to alleviate individual overconfidence and achieve a higher accuracy of the collective estimate.

Consistent with existing findings from laboratory experiments, our model shows that, in the absence of individual overconfidence, the value of group interactions, compared to a statistical aggregation of individual estimates, is always positive. However, we find that this is no longer the case when the individuals are overconfident; in particular, the value of group interactions can become negative when individuals' level of overconfidence is high. Moreover, we show that whereas the accuracy of the aggregating approach always increases in the group size, it is not always optimal to have as many interacting group members as possible when these group members are overconfident. Finally, we provide the optimal solutions for the joint decision of how to form collective estimates, aggregating versus interacting, and how to determine group size.

5 - Orchestrating Organizational Politics: Baron and Ferejohn Meet Tullock

Zenan Wu, Peking University, Beijing, China, People's Republic of, Qiang Fu, Yuxuan Zhu

This paper examines the optimal design of the rules that govern the process of dividing a fixed surplus and recognizing a proposer inside an organization. The process is modeled as a multiplayer sequential bargaining game with costly recognition. The designer is endowed with instruments: first, she sets the voting rule, i.e., the minimum number of favourable votes required to approve a proposal; second, she can manipulate the mechanism of proposer recognition, which is modeled as a contest. That is, she can bias the contest for recognition in favor of certain players by imposing multiplicative weights and additive headstart on their outputs. The design objective accommodates diverse preferences. We show that when the designer can flexibly alter both voting rule and recognition mechanism, the optimum can be achieved by a dictator voting rule and a biased recognition mechanism without headstarts, which reduces to a standard biased rent-seeking model. When the recognition mechanism is kept fixed, the optimum may involve headstarts. When the recognition mechanism is kept fixed, a k-majority-rule with k>1 can be optimal.

Theory, Algorithms, and Applications of Multi-objective Optimization

Invited Session

Multi Criteria Decision Making

Chair: Margaret Wiecek, Clemson University, Clemson, SC, United States

Co-Chair: Nathan Adelgren, United States Naval Academy, Annapolis, MD, United States

1 - A Benders' Decomposition Algorithm for Multiobjective Linear Optimization

Benjamin Hamlin, Clemson University, Clemson, SC, United States, Margaret Wiecek

We consider a multiobjective linear program (MOLP) suitable for Benders' decomposition. Applying the weighted-sum method to the MOLP yields a parametric linear program which can be solved with a newly developed parametric Benders' decomposition algorithm. We demonstrate the application of the algorithm to a problem in economics.

2 - Line Decomposition for Multiobjective Programs

Emma Soriano, Clemson University, Clemson, SC, United States, Margaret Wiecek, Mishko Mitkovski

We present a modification of a decomposition theorem for computing the efficient set of multiobjective programs we have earlier established. The decision space, formerly decomposed into subsets, is now decomposed into lines. The efficient sets on these lines can be obtained in a closed form by solving multiple single-objective programs. The new theorem shows that the entire efficient set can be computed as the intersection of the efficient sets on lines. While in general this intersection is infinite, we identify the special cases in which it is finite. Convergence results allowing for a decomposition implementation and examples are included.

3 - On Subproblem Tradeoffs in Multiobjective Optimization

Philip de Castro, Clemson University, Clemson, SC, United States, Margaret Wiecek

We are interested in obtaining efficient solutions for multiobjective optimization problems (MOPs) with many criteria by decomposing an MOP into a set of multiobjective subproblems (MOSPs). Notably, we show that (weakly) efficient solutions of the subproblems can be used to construct (weakly) efficient solutions for the original problem. However, in order to gain a deeper understanding of the interaction between subproblems, we introduce the concept of subproblem tradeoffs which measures the performance of a feasible decision with respect to each MOSP. To compute these tradeoffs, we present extensions to the theory of achievement scalarizing functions. Our new theory leads to an interactive coordination procedure to compute a preferred MOP-efficient solution, and if necessary, achieve an acceptable compromise among the MOSPs. Finally, we demonstrate the utility of our proposed procedure on an assignment problem inspired by humanitarian aid management.

4 - Optimization- and Wargaming-Based Approaches to Improve Medevac Mission Planning and Decision Making

Armin Fugenschuh, Brandenburg University of Technology, Cottbus, Germany

In the highly dynamic environment of military operations, efficient medical evacuation (MEDEVAC) of casualties is a critical strategic challenge. This talk presents a method for planning MEDEVAC missions using mathematical optimization and gamification. By applying Mixed-Integer Programming (MIP), a mathematical optimization technique, to solve a MEDEVAC dispatching problem, a structured approach to decision making in emergency situations is presented. Our MIP model enables the detailed consideration of operational conditions and the mission support with combat helicopters as escorts, and thus improves the strategic planning and efficiency of MEDEVAC operations. We also discuss ethical considerations in prioritizing evacuation decisions and emphasize the need to integrate ethical principles into the development. When it comes to prioritize mission safety versus execution speed, we will enter the realm of multicriteria optimization models. Moreover, we discuss the potential impact of technologies such as wearable monitoring devices on future triage and MEDEVAC planning that could further improve the precision and effectiveness of medical evacuation.

As a further aspect, the role of gamification is emphasized by developing a board game that simulates the planning task and thus promotes understanding of the planning software. This approach allows planners to compare the quality of their manual planning with the computer-generated solution, improve their own planning skills and realize the benefits of software support for automated, AI-assisted planning.

5 - A Multiobjective Exploration of Compact Ecological Reserve System Design

Nathan Adelgren, United States Naval Academy, Annapolis, MD, United States, Lakmali Weerasena

In this work we consider the design of compact ecological reserve systems. Various metrics that have been used in the past to measure the compactness of such a system are analyzed, and new alternatives are proposed. We then discuss modeling techniques that can be used to incorporate a number of the most suitable of these metrics into multiobjective optimization models containing binary variables. We note that many of these metrics require the use of nonlinear objectives and/or constraints. As such, during computational testing we consider both the original forms of these models as well as linearized alternatives. In order to solve these models, we make slight modifications to an existing technique for solving multiobjective integer programs and develop a parallel implementation. Details of the implementation are provided along with computational results.

Innovative Approaches in Stochastic and Explanatory Modeling

Contributed Session

Contributed

Chair: Libo Li, University of Southampton, Southampton, United Kingdom

1 - Robust SHAP Computation for Problem-Level Explanatory Modeling

David Collins, Edward Jones, St Louis, MO, United States, Laura Kang

SHAP values are frequently used to understand the order, direction, and relative magnitude of the influence of the underlying features in a model, however trained models of similar quality can have significant differences in SHAP values, which limits the ability to treat them as explanatory of the underlying problem rather than just the model. This paper develops a technique for including SHAP values in the hyperparameter optimization process, which results in a process that is more robust to perturbations in the training data and closer approximations of the true values of an underlying generative process. This algorithm is broadly applicable to a wide range of models, and can be computed efficiently using existing optimization techniques, without a significant decrease in the quality of the model.

2 - Optimal solutions with bounded inequality

John Hooker, Carnegie Mellon University, Pittsburgh, PA, United States, Ozgun Elci, Peter Zhang

When multiple stakeholders are affected by the solution of an optimization model, fairness may be a concern. We investigate the utility distributions across stakeholders that result from maximizing total utility subject to a resource constraint and a bound on inequality, the latter measured by the utility range or the Gini coefficient. We find that in both cases, the optimal solution consists of only two or three utility levels, and if there are three, those on the lowest level receive nothing. We provide closed form solutions that depend on the resource costs of generating utility for individual stakeholders. These results suggest that the occurrence of two or three major socioeconomic classes in many societies may be partially rooted in the mathematics of optimal distributions.

3 - Managing Distributional Ambiguity in Stochastic Optimization through a Statistical Upper Bound Framework

Jian Hu, University of Michigan - Dearborn, Dearborn, MI, United States

Stochastic optimization is often hampered by distributional ambiguity, where critical probability distributions are poorly characterized or unknown. Addressing this challenge, we introduce a new framework that targets the minimization of a statistical upper bound for the expected value of uncertain objectives, facilitating more statistically robust decision-making. Central to our approach is the Average Percentile Upper Bound (APUB), a novel construct that simultaneously delivers a statistically rigorous upper bound for the population mean and a meaningful risk metric for the sample mean. The integration of APUB into stochastic optimization not only fortifies the process against distributional ambiguity but also reinforces key data-driven decision-making attributes, such as reliability, consistency, and comprehensibility. Notably, APUB-enriched optimization problems feature tractability, with particular advantages in two-stage stochastic optimization with random recourse. Empirical demonstrations on two-stage product mix and multi-product newsvendor benchmark problems reveal the benefit of the APUB optimization framework, in comparison with conventional techniques such as sample average approximation and distributionally robust optimization.

4 - A Framework for Stochastic Fairness in Dominant Resource Allocation with Cloud Computing Applications

Jiaqi Lei, Northwestern University, Evanston, IL, United States, Sanjay Mehrotra

Allocation of limited resources often requires fairness considerations. Such situations arise in application areas such as computer systems, health systems, and humanitarian logistics. This paper introduces a fairness framework in multi-resource allocation when the anticipated needs are stochastic. We apply the distributionally robust optimization (DRO) model to the proposed stochastic fairness model when the distribution of the required resources is uncertain. We show that it satisfies key properties of Stochastic Pareto-efficiency, Stochastic sharing incentive, and Stochastic envy-freeness under suitable conditions. Empirically we find that the variance in the requested resources has implications on resource allocation. Convergence and differences in solutions are illustrated using data from two cloud computing applications.

5 - Explainable Artificial Intelligence via generative agent feedback

Libo Li, University of Southampton, Southampton, United Kingdom

Explainable Artificial Intelligence (XAI) empowers modern AI systems by enhancing their ability to provide clear and understandable explanations of system outputs. Interactive machine learning, as a design option for producing XAI, shows promising progress in enriching the machine learning paradigm and offering interfaces and contexts for developing machine learning use cases. Among various research paradigms developing adaptive and incremental learning algorithms, we propose a novel large language model (LLM)-based generative adaptive learning approach. Using LLMs as agents to respond to specific modelling tasks, we evaluate machine learning outputs based on given metrics and embed the evaluation process to refine model building. We explore LLMs' role as generative agents and extensions such as Supervised Fine-Tuning (SFT) and Retrieval-Augmented Generation (RAG) to assess whether extended architectures improve model usability compared to general-purpose LLMs. We also assess the impact of auxiliary data sources on our use cases. The rich information generated during the interactive process benefits system designers and business analysts in gaining insights into model performance. We discuss the implications of our work through case studies in healthcare risk management, product diffusion, and knowledge management. Stakeholders such as system developers, administrators, and end-users stand to benefit from the generative adaptive learning approach in XAI development and deployment.

1 - Reducing Food Waste in Production: A Field Experiment in Ghana

Mahyar Eftekhar, Arizona State University, Tempe, AZ, United States, Xinming Liu, Karen Zheng, Richard Boso

Research indicates that food waste is a global issue affecting countries across various income levels, with about 931 million tonnes—or 17% of consumer-available food—being discarded in 2019. Meanwhile, nearly 3 billion people worldwide cannot afford a nutritious diet. This study showcases a straightforward, practical method aimed at reducing food waste by focusing on the food preparation processes in restaurants, which contribute to approximately 26% of the total waste.

2 - Technology Enabled Agent-choice and Uptake of Social Assistance Programs

Rakesh Allu, Cornell University, Ithaca, NY, United States, Maya Ganesh, Sarang Deo, Sripad Devalkar

Beneficiaries of social assistance programs with transfers of undifferentiated commodities often have a designated agent to collect their entitlements from. This gives monopoly power to agents over beneficiaries. When coupled with weak government monitoring, agents do not have incentives to adhere to stipulated operating guidelines, leading to reduced uptake by beneficiaries. Governments are attempting to break the monopoly by allowing beneficiaries to choose agents. However, the impact of choice on uptake may be limited by lack of alternate agents in beneficiaries' vicinities, restricted ability of agents to compete with undifferentiated commodities, and collusion among agents. Using a reverse difference-in-differences framework on data from a food security program in two neighboring states in India, we find that providing agent choice results in a 6.6% increase in the quantity of entitlements collected by the beneficiary households. The increase in uptake is about four times higher in regions with high agent density compared with those with low agent density. Nearly all of the increase is attributable to new beneficiaries collecting entitlements from their preassigned agent. This is suggestive of agents improving adherence to operating guidelines in response to choice. We find associative evidence for this response in the number of days agents keep their shops open. Governments executing in-kind transfers of undifferentiated commodities are considering replacement of in-kind transfers with cash. Our results indicate that alternate designs of providing choice even in a limited form can present a viable alternative.

3 - Workload Management and Human-Algorithm Collaboration in Child Welfare Screening

Yanhan (Savannah) Tang, SMU Cox School of Business, Dallas, TX, United States, Zhaohui Jiang, Alan Scheller-Wolf

This video provides an overview of the child welfare system in the U.S. and the reporting process. It highlights the challenges within the current system, particularly caseworker stress and high turnover rates, and discusses a potential solution to effectively reduce stress and manage workloads through improved report screening decisions facilitated by enhanced human-AI collaboration.

Co-Chair: Gaoyu Xie, George Washington University, Arlington, VA, United States

1 - Open Innovation for Smes

Gaoyu Xie, George Washington University, Washington, DC, United States, Pascale Crama, Janne Kettunen

We develop a game theoretic model to explore the innovation strategies of small and medium-sized enterprises (SMEs), focusing on two critical factors differentiating SMEs from large firms: risk aversion and cost of capital. These frictions cause launch and effort inefficiencies which reduce the innovativeness of SMEs. Our model studies whether building an open innovation ecosystem and encouraging SMEs to collaborate with institutes of higher learning (IHLs) or large partner firms can improve innovation outcomes. By incorporating IHL into the ecosystem, we find that the SME's innovation efforts increase, though launch inefficiency persists. In comparison, cooperating with partner firm reduces launch inefficiency and decreases innovation efforts. We determine whether the SME chooses to engage in open innovation with the IHL or the partner firm based on the innovation characteristics.

2 - Incentivizing Project Managers Competing for R&D Funds

Niyazi Taneri, Cambridge Judge Business School, Cambridge, United Kingdom, Ozge Tuncel, Nektarios Oraiopoulos, Jochen Schlapp

Theory suggests combining shared and individual incentives can align the incentives of managers competing for R&D funds. We characterize the optimal contract that incentivizes project managers to evaluate their projects and truthfully report evaluation outcomes, which determines the firm's resource allocation decision. Through a series of treatments, we then explore the contract's interaction with different business environments. Our experimental results indicate that the optimal contract alone doesn't sufficiently motivate project managers, suggesting that the business environment, paired with the optimal contract, plays a crucial role in moving towards theoretical outcomes.

3 - Composing New Product Development Portfolios with Internal and External Projects

Jochen Schlapp, Frankfurt School of Finance & Management gGmbH, Frankfurt Am Main, Germany, Hossein Nikpayam, Moritz Fleischmann

The process of building portfolios with competing internal and external new product development projects comprises two daunting challenges: (i) the collection of relevant information about the projects under consideration and (ii) the selection of the most promising projects under uncertainty. In order to create optimal NPD portfolios, firms must implement project selection policies that carefully control the tensions that arise between these two challenges. Most notably, installing a higher level of selection flexibility allows firms to better select projects based on the information they obtain; however, greater selection flexibility also induces fiercer competition for resources among the projects, which undermines the reliability of a firm's information acquisition efforts and thus harms the quality of its selection decisions. Hence, we ask the following question: Which project selection policies can best align a firm's (ex ante) information acquisition efforts with its (ex post) project selection decisions when the firm contemplates investing in competing internal and external NPD projects? We study this question by developing a principal-multiagent model, and we identify different contingencies
that strongly impact a firm's optimal project selection policy, including the projects' market potential and riskiness, the quality of acquired information, and the severity of agency issues.

4 - Three Years, Two Papers, One Course Off: Optimal Non-Monetary Reward Policies

Shivam Gupta, University of Nebraska Lincoln, Lincoln, NE, United States, Wei Chen, Milind Dawande, Ganesh Janakiraman

Motivated by practical examples from academia (a reduced teaching-load for achieving a certain research productivity threshold) and industry (Supplier-of-the-Year awards in recognition of excellent performance), we consider a principal whose goal is to design a policy for giving non-monetary rewards to an agent. The following limited-term reward policy has been quite popular in practice: The principal evaluates each agent periodically; if an agent's performance over a certain (limited) number of periods in the immediate past exceeds a pre-defined threshold, then the principal rewards him for a certain (limited) number of periods in the immediate future. We identify a limited-term policy that is arbitrarily near-optimal. We also introduce and analyze the class of score-based policies and show that it always contains an optimal policy.

New Product Development

Chair: Yi Xu, University of Maryland, College Park, MD, United States

1 - R&D Project Portfolio Collaboration: How to Structure the Strategic Alliance?

Guiyun Feng, Singapore Management University, singapore, Singapore, Pascale Crama, Wenqi Lian

Incumbent companies target innovative firms with promising research and development (R&D) projects to rejuvenate their product portfolio. Such strategic alliances create value by combining the innovator's research expertise with the partner firm's superior marketing capability. The partner firm chooses the timing and payment terms of the strategic alliance, accounting for the innovator's budget and marketing capability, and the project portfolio's market interaction and revenue variability. The partner firm may prefer delayed alliances post R&D completion for innovator firms with high marketing capability when the innovator has sufficient budget or when market interaction is weak. Upfront alliances—prior to the R&D stage—are always preferred when the innovator's marketing capability is low to cement the partner's commitment to payments that incentivize innovator R&D. The partner also contracts upfront when projects exhibit strong market interaction yet the innovator is budget-constrained, as the upfront payment augments the innovator's R&D budget. Finally, a strategic alliance may fail to form when the project portfolio has high revenue variability and low market interaction, and the innovator has low marketing capability. Interestingly, the partner's profit does not always decrease in the innovator's marketing capability—her outside option—and the partner may prefer an innovator with intermediate marketing capability when revenue variability is high. Furthermore, the partner's profit weakly increases in the innovator's R&D budget up to a threshold, yet may exhibit a discontinuous jump/drop at that threshold.

2 - Consumer Privacy and Personalized Recommendation on Online Platforms

Farzad Fathi, University of Maryland, College Park, MD, United States, Yi Xu, Bo Zhou

This paper examines the privacy-personalization paradox within online platforms, focusing on the trade-offs between consumer privacy and personalized recommendations and pricing. Our research incorporates a model that characterizes consumers by their maximum willingness to pay and their product preferences, treating privacy levels as a crucial factor influencing platform decisions on product offerings and pricing strategies.

We emphasize privacy's dual impact on consumer utility and platform profits. The study identifies conditions under which consumers might surrender their privacy to maximize expected utility, particularly when the benefits of increased product consumption outweigh the costs of privacy loss. Through this comprehensive analysis, the paper sheds light on the complex dynamics between privacy, personalization, and consumer behavior in the digital marketplace.

3 - Designing Data Science Contests: the Role of Training vs. Testing Split

Ping-Chieh Huang, University of California, San Diego, La Jolla, CA, United States, Zhe Zhang, Sanjiv Erat

Companies organize data science contests to source innovative solutions that provide long-term competitive advantage. Using contests hosted on Kaggle as a motivating example, we formulate a model of data science contests where the final evaluation is performed with a statistical holdout sample. Our theoretical results illustrate that the split ratio of training vs. testing samples influences the contestants' incentives, and their likelihood of submitting a statistically efficient solution. Specifically, our investigation of 30 most recent contests shows contestants' tendency of pursuing a risk-seeking approach and a potential agency problem between innovation seekers and problem solvers. Our prescriptive analysis of the optimal split ratio manages these agency issues and provides actionable insights for firms hosting data science contests.

4 - Product Line Design and Planning for Startups

Sreekumar Bhaskaran, SMU-Cox School of Business, Dallas, TX, United States, Karthik Ramachandran, Zeya Wang

How should a startup design its product line? Startups face several unique challenges including limited resources, market uncertainty, and diverse customer preferences. Through a model-based investigation, we explore strategies for optimizing market coverage while mitigating the risks of cannibalization in the pursuit of startup success.

1 - Is Climate (Adversity) the Mother of Innovation? Evaluating the Impact of U.S. Billion-Dollar Weather and Climate Disasters on Firm-Level Innovation

Max Ji, The Pennsylvania State University, University Park, PA, United States, Suvrat Dhanorkar, Suresh Muthulingam

The escalating frequency and intensity of climate-related extreme events, such as hurricanes, floods, droughts, tornadoes, and wildfires, pose substantial global challenges. The United States, in particular, has experienced an increase in major weather-related disasters and billion-dollar weather-related damages over the past five decades. This underscores the pressing need to understand the impact of these events. This paper focuses on exploring how extreme weather events affect firm-level innovation. We use data from the National Oceanic and Atmospheric Administration (NOAA) and the US Patent and Trademark Office (USPTO) to study the relationship between extreme weather events and innovation within impacted firms. Our results indicate that while climate events generally impede overall innovation, they also stimulate the advancement of green innovation within affected companies.

2 - Pride or Guilt? Impacts of Consumers' Socially Influenced Recycling Behaviors on Closed-Loop Supply Chains

wenlin chen, University of Electronic Science and Technology of China, Chengdu, China, People's Republic of, Wenjie Huang, Jason Nguyen, Chung-Li Tseng, Sam Kirshner

Social influenced pride and guilt are found to impact recycling behavior, but are overlooked in closed-loop supply chain research. In contrast, Environmental Psychology literature ignores firms' operational decisions. We analyze how social influence affects consumers' recycling behaviors and their resulting impacts on a manufacturer's strategy in a closed-loop supply chain.

3 - Sustainable and Affordable? The Effects of CSR Performance and Price on Consumer Purchase Decisions

Tim Kraft, NC State - Poole College of Management, Raleigh, NC, United States, Junhao Yu, Robert Handfield, Rejaul Hasan, Marguerite Moore

We use controlled experiments in an online purchase context to examine how consumers' willingness to buy is influenced by a retailer's disclosure of a manufacturer's CSR performance. We show that disclosing CSR performance is more challenging (and potentially riskier) with consumers who typically pay a higher price, but consumers who typically pay a lower price are willing to reward positive CSR performance.

1 - Uniqueness of DRS as the 2 Operator Resolvent-splitting and Impossibility of 3 Operator Resolvent-splitting

Ernest Ryu, UCLA, Los Angeles, CA, United States

Given the success of Douglas–Rachford splitting (DRS), it is natural to ask whether DRS can be generalized. Are there other 2 operator resolvent-splittings sharing the favorable properties of DRS? Can DRS be generalized to 3 operators? This talk presents the answers: no and no. In a certain sense, DRS is the unique 2 operator resolvent-splitting, and generalizing DRS to 3 operators is impossible without lifting, where lifting roughly corresponds to enlarging the problem size. Finally, we conclude by overviewing the recent line of research in optimization focused on characterizing and classifying first-order optimization algorithms.

2 - On the Column Number and Forbidden Submatrices for Delta-modular Matrices

Luze Xu, University of California, Davis, Davis, CA, United States, Joseph Paat, Ingo Stallknecht, Zach Walsh

Totally unimodular (TU) matrices have been used for decades to solve various integer programs (IPs) in polynomial time using linear programming. Given the importance of TU matrices, one may ask about generalizations. One such generalization is the family of Delta-modular matrices, whose full rank subdeterminants are bounded by Delta. An open conjecture is whether IPs with Delta-modular constraint matrices can be solved in polynomial time if Delta is fixed. A natural approach to tackle this conjecture is to understand structural properties of Delta-modular matrices. In this talk, we explore one such structural property: how many distinct columns can a rank-r Delta-modular matrix have? We give an overview of this question and discuss some implications for Delta-modular IPs. By identifying excluded submatrices and combining these with results from matroid theory, we derive a new bound on this column number that is best possible up to a polynomial in Delta.

3 - The Magic of Monotone Integer Programs: Polynomial Time Solvability with Min-cut Procedure and Fast High Quality Solutions for Related Hard Problems

Dorit Hochbaum, UC Berkeley, Berkeley, CA, United States

Monotone Integer problems (IPM) are those formulated as integer programming with constraints that have at most two variables, x-variables, appearing with opposite sign coefficients, and a third variable, z-variable, that can appear in one constraint only. All IPMs are solved as a minimum s,t-cut on a respective graph.

Any NP-hard minimization problem formulated with two variables per inequality, has a 2-approximation algorithm, attained with one min-cut procedure, resulting from
a transformation to IPM.

Many NP-hard problems are IPM plus a budget constraint, e.g. the quadratic knapsack problem and facility dispersion problem. For these, the breakpoints algorithm that relaxes the budget constraint, delivers high quality solutions in very fast run times. This presentation focuses on recent results for IPM ratio problems, that include the maximum density subgraph problem. We introduce the Incremental Parametric Cut algorithm, that solves monotone ratio problems in the complexity of a single min-cut procedure. This algorithm is efficient not only in theory but in practice as well. For large scale instances of the maximum density problems, it is orders of magnitude faster than recent leading methods that are all based on heuristics, and also significantly faster than the theoretically-efficient parametric cut algorithm.

Large-Scale Methods for Linear and Nonlinear Optimization

Invited Session

OPT: Linear and Conic Optimization

Chair: Zikai Xiong, MIT OR Center, Cambridge, 02139, United States

Co-Chair: Robert Freund, MIT Sloan School of Management, Cambridge, MA, 02139, United States

1 - The radius of statistical efficiency

Mateo Diaz, Johns Hopkins University, Baltimore, MD, United States, Joshua Cutler, Dmitriy Drusvyatskiy

Classical results in asymptotic statistics show that the Fisher information matrix controls the difficulty of estimating a statistical model from observed data. In this work, we introduce a companion measure of robustness of an estimation problem: the radius of statistical efficiency (RSE) is the size of the smallest perturbation to the problem data that renders the Fisher information matrix singular. We compute the RSE up to numerical constants for a variety of test bed problems, including principal component analysis, generalized linear models, phase retrieval, bilinear sensing, and matrix completion. In all cases, the RSE quantifies the compatibility between the covariance of the population data and the latent model parameter. Interestingly, we observe a precise reciprocal relationship between the RSE and the intrinsic complexity/sensitivity of the problem instance, paralleling the classical Eckart–Young theorem in numerical analysis.

2 - Level-Set Geometry and Improving the Performance of PDHG for Linear Optimization

Zikai Xiong, MIT OR Center, Cambridge, MA, United States, Robert Freund

It is now the case that many linear programming (LP) problem instances are at a scale where matrix-factorization-free methods are attractive or necessary. The restarted primal-dual hybrid gradient method (rPDHG)—with heuristic enhancements and GPU implementation—has been very successful in solving these huge-scale LP problems; however, its performance can be highly variable and lacks intuitive understanding. We analyze the theoretical foundation and practical performance of rPDHG and generalize it to general conic linear optimization. Our analysis reveals that the geometry of the primal-dual (sub-)level sets plays a crucial role in the performance of rPDHG. Specifically, unfavorable geometry of some instances leads to the poor performance of rPDHG, both in theory and practice. To address this issue, we show how central-path-based linear transformations - including conic rescaling - can markedly enhance the convergence of rPDHG. Furthermore, we present computational results that demonstrate how such rescalings accelerate convergence to high-accuracy solutions, and lead to more efficient methods for huge-scale linear optimization problems.

3 - Optimization on a Finer Scale: Bounded Local Subgradient Variation Perspective

Jelena Diakonikolas, University of Wisconsin-Madison, Madison, WI, United States, Cristobal Guzman

Nonsmooth optimization problems are ubiquitous in industrial and machine learning applications, arising from the need to address tasks such as resource allocation, threat detection, and model training. Within the realm of mathematical optimization, nonsmooth problems stand as some of the most challenging; yet they often offer the possibility of developing efficient algorithms with provable guarantees. The complexity of these problems, encompassing both lower and upper bounds, has historically typically been examined under generic assumptions, bounding the growth of the objective functions by assuming Lipschitz continuity of either the objective itself or its gradient. In this talk, I will argue that these traditional assumptions defining classes of nonsmooth optimization problems inadequately capture local properties of problems that may make them amenable to more efficient algorithms. I will introduce a notion of bounded local variation of the (sub)gradient and discuss how, under this notion, we can obtain a more fine-grained characterization of the complexity of nonsmooth problems. One consequence of these results is that, contrary to prior belief, the complexity of nonsmooth optimization problems, such as those with piecewise linear objectives with polynomially many pieces, can be improved using parallelization even in high dimensions, either if the problem is unconstrained or if the function is allowed to be queried outside the feasible set.

4 - Solving Saddle Point Formulations of Linear Programs with Frank-Wolfe

Matthew Hough, University of Waterloo, Waterloo, ON, Canada, Stephen Vavasis

We discuss the author's recent efforts toward applying the Frank-Wolfe algorithm to solving linear programs. The talk will introduce two first-order primal-dual algorithms for solving saddle point formulations of linear programs, namely FWLP and FWLP-P. The former iteratively applies the Frank-Wolfe algorithm to both the primal and dual of the saddle point formulation of a standard-form LP. The latter is a modification of FWLP in which regularizing perturbations are used in computing the iterates. We will outline our convergence analysis of FWLP-P, noting that FWLP convergence guarantees have not yet been established, and finally describe the advantages of using FWLP and FWLP-P for solving very large LPs.

Methods for Large-Scale Nonlinear and Stochastic Optimization I

Invited Session

OPT: Nonlinear Optimization

Chair: Jiahao Shi, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Shagun Gupta, UT Austin, Austin

Co-Chair: Albert Berahas, University of Michigan, Ann Arbor, MI, United States

1 - Retrospective Approximation for Stochastic Constrained Problems Using Sequential Quadratic Programming

Shagun Gupta, UT Austin, Austin, TX, United States, Raghu Bollapragada, Albert Berahas

Sequential Quadratic Programming (SQP) is one of the state of the art algorithms to solve deterministic constrained problems. In recent years the framework has been extended to solve equality constrained problems with stochastic objective functions. To adapt the step size in stochastic settings, new schemes like stochastic line search, Lipschitz constant estimation, hessian averaging have been introduced in SQP. We use SQP algorithms in a Retrospective approximation framework that allows us to solve a series of subsampled deterministic subproblems to solve the the stochastic constrained problem. This framework decouples the stochasticity from the SQP algorithm allowing us to use legacy deterministic solvers (other than SQP as well) to solve constrained stochastic programs.

2 - High Efficiency in Stochastic Trust Regions

Sara Shashaani, North Carolina State University, Raleigh, NC, United States, Yunsoo Ha

Trust Region (TR) methods are celebrated for their flexibility in finding stationary points of non-convex problems and their automated step size adjustments. In noisy settings, stochastic and deterministic sources of error are linked via the TR radius, governing the samples needed to estimate the objective function value at each point. But this comes at the cost of significant added complexity. Recent developments such as variance reduction mechanisms and regularization steps have shown promise for making TR competitive with typical worst case complexity lower bounds of non-convex stochastic optimization algorithms. We discuss the features and risks within a TR framework that can guarantee better complexity rates in this literature.

3 - A Double Stepsize Stochastic SQP Method with Complexity Guarantees

Michael ONeill, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Stochastic gradient algorithms play a key role in the training of large-scale machine learning models. These algorithms can be readily extended to problems with simple constraints, such as when projections onto the feasible region can be computed efficiently. Recently, there has been a surge of interest in stochastic gradient-like algorithms for stochastic optimization problems with nonlinear and nonconvex constraints due to modern machine learning applications such as fair machine learning and physics informed neural networks. In this talk, we present a new stochastic Sequential Quadratic Programming (SQP) for deterministically constrained stochastic optimization. Unlike previous work, this algorithm utilizes a different step size for each component of the orthogonal decomposition of the SQP step, which enables faster convergence with respect to the constraint violation and an improved worst-case complexity result. In addition to improving the worst-case complexity, this algorithmic approach also enables significant flexibility with respect to computing step sizes, such as employing a (safeguarded) line search on the constraint violation. Some preliminary numerical experiments will also be presented.

4 - A Quasi-Newton Method for Nonsmooth, Nonconvex, Stochastic Optimization

We consider the minimization of a Lipschitz continuous and expectation-valued function over a closed and convex set. Our focus lies on obtaining both asymptotics as well as rate and complexity guarantees for computing an approximate stationary point (in a Clarke sense) via zeroth-order schemes. We adopt a randomized-smoothing-based approach reliant on minimizing a smooth approximation of our objective function. In such a setting, we develop a zeroth-order stochastic quasi-Newton scheme reliant on a combination of randomized and Moreau smoothing is proposed and analyzed, for which iteration and sample complexities are derived.

Recent Advances in Mixed-Integer Nonlinear Programming

Invited Session

OPT: Global Optimization

Chair: Linchuan Wei, Northwestern University, Evanston, IL, 60201, United States

1 - An Outer Approximation Method for Solving Mixed-Integer Convex Quadratic Programs with Indicators

Linchuan Wei, Northwestern University, Evanston, IL, United States, Simge Kucukyavuz

Mixed-integer convex quadratic programs with indicator variables (MIQP) encompass a wide range of applications, from statistical learning to energy, finance, and logistics. The outer approximation (OA) algorithm has been proven efficient in solving MIQP, and the key to the success of an OA algorithm is the strength of the cutting planes employed. In this paper, we propose a new technique for deriving cutting planes for MIQP from various convex relaxations, and, as a result, we develop new OA algorithms for solving MIQP at scale. The contributions of our work are two-fold: (1) we bridge the work on the convexification of MIQP and the algorithm design to solve large-scale problems, and (2) we demonstrate through a computational study on the sparse portfolio selection problem that our algorithms give rise to significant speedups compared with the state-of-the-art methods in the literature.

2 - Mixed Integer Approach for Fair Regression

Anna Deza, University of California-Berkeley, Berkeley, CA, United States, Alper Atamturk, Andres Gomez

TBD

3 - The Treewidth-Convex Hull Theorem and DP for Cut Generation in MINLP

Sourabh Kumar Choudhary, Georgia Tech, Atlanta, GA, United States, Santanu Dey, Nick Sahinidis

We revisit unconstrained nonlinear binary programming problems with a limited treewidth of the associated hypergraph. We provide an alternate proof of exactness of a reformulated LP with $O(d^2n)$ variables, n being the number of variables and d being the treewidth. Our proof links the solution of this exact LP with the well-known dynamic programming algorithm which is known to run in $O(d^2n)$ time. In the second part, we introduce column generation method for solving CGLP to add cuts to non-convex problems with multilinear intermediates. We use the DP algorithm to solve pricing problem. The benefit over the currently practiced algorithm employing graycodes for navigating and pricing columns is experimentally shown.

4 - Disjunctive Sum of Squares

Yixuan Hua, Princeton University, Princeton, NJ, United States, Amir Ali Ahmadi, Sanjeeb Dash, Bartolomeo Stellato

We present the disjunctive sum of squares (DiSOS) approach for certifying nonnegativity of polynomials. Our method strategically partitions the certification problem into tractable subproblems, providing certificates with low polynomial degrees. We introduce the concept of DiSOS cone, and show that it can approximate the set of positive definite forms arbitrarily well. Using the DiSOS cone, we construct a converging hierarchy of optimization problems to solve general polynomial optimization problems. Furthermore, we provide a constructive approach to iteratively partition the certification problem in order to develop efficient solution algorithms. Numerical experiments show that our method is very versatile, as it is able to certify nonnegativity of non-sum-of-squares polynomials, prove copositivity of matrices, and compute the clique number of graphs.

5 - What's new for the global solver in FICO Xpress

Tristan Gally, FICO, Birmingham, United Kingdom

This talk discusses the latest updates and improvements to the global optimization capability within FICO Xpress Solver, which allows to solve general mixed-integer nonlinear problems to global optimality. We will discuss the internal workings of the solver, its features, and recent performance improvements.

OPT: Optimization Under Uncertainty

Chair: Haitao Li, University of Missouri - St. Louis, Saint Louis, MO, United States

1 - Multi-Facility Location Models Incorporating Multipurpose Shopping Trips

Pawel Kalczynski, California State University-Fullerton, Fullerton, CA, United States, Zvi Drezner, Morton O'Kelly

This work continues to develop and explore the impact of multipurpose trips on retail location. We develop the model of locating multiple competing facilities of a chain where several competing facilities exist in the area. There may be some existing facilities of the same chain as well. The addition of multiple new outlets can cause cannibalization of existing sales, but this effect is mitigated by selecting good locations, and the total market share captured by the chain increases. The introduction of multipurpose trips enhances the total market share of the location decision maker. Since in reality many customers combine a visit to more than one facility in one shopping trip, the model predicts the expected market share captured more accurately. Therefore, the selected locations for new facilities are more accurate as well.

2 - Efficient Drone Integration for Last-Mile Rural Healthcare Delivery

Shakiba Enayati, University of Missouri - Saint Louis, St Louis, MO, United States, Sina Ansari, Ziteng Wang, Srikanth Gururajan

Rural areas encounter challenges such as limited infrastructure, vast distances, rugged terrains, and harsh weather conditions. These factors impede the timely and efficient delivery of medical supplies, putting the health and well-being of residents at risk. Existing literature recognizes the potential of drones in healthcare logistics, yet a critical research gap exists in optimizing drone selections in the health supply networks considering realistic energy consumption. We develop a decision-support tool to pragmatically integrate drones into existing last-mile distribution networks, considering uncertain environmental conditions such as wind, air quality, precipitation, and terrain impacting drone flight range and payload requirements. We apply our model to a case study from Shield Illinois, an organization that enabled the rapid and widespread distribution of medical supplies, including test kits and samples, during the COVID-19 pandemic, and present our findings.

3 - On the Optimal Flexibility of Stochastic Service Systems with Multi-Class Customers

Zhe Zhang, Simon Fraser University/Western Washington University, Bellingham, WA 98229, USA, WA, United States

In this talk, by developing some stylized queueing models, we will discuss the issue of determining the optimal level of the service flexibility for a stochastic service system with multiple class of customers. Both theoretical results and numerical illustrations are presented to the insights for practitioners for these service systems.

Advances in Nonlinear, Stochastic, and Constrained Optimization

Invited Session

OPT: Nonlinear Optimization

Chair: Baoyu Zhou, Arizona State University, Tempe, AZ, United States

1 - Universal First-Order Methods for Convex Optimization Problems

Jiaming Liang, University of Rochester, Rochester, NY, United States, Vincent Guigues, Renato Monteiro

We present a generic algorithmic framework for convex optimization without knowing the levels of convexity and smoothness of the problem. In particular, the framework includes an adaptive subgradient method and an adaptive proximal bundle method. One advantage of the framework is that it does not perform any line search on the strong convexity parameter. To the best of our knowledge, this is the first universal method that does not use a backtracking procedure on the strong convexity parameter. We present complexity results in terms of both the optimality gap and the stationarity. Their complexity bounds are as good as those obtained with known convexity and smoothness parameters.

2 - Stochastic Nonlinear Constrained Optimization

Qi Wang, Lehigh University, Bethlehem, PA, United States, Frank E. Curtis

This presentation covers two recently proposed classes of stochastic algorithms for constrained optimization that I have explored in my research: stochastic interior-point methods (sIPM) and stochastic sequential quadratic programming (sSQP). These methods are designed to solve problems where information about the objective can only be accessed through stochastic gradient estimates wheras constraint function and derivative values can be computed explicitly. I will discuss the challenges for ensuring the convergence of these algorithms and how our methods overcome these challenges. Applications in fair machine learning and physics-informed learning are examined, demonstrating the performance of our proposed algorithms compared to alternative unconstrained and constrained optimization techniques.

3 - A Quasi-Newton Method for Nonsmooth, Nonconvex, Stochastic Optimization

Luke Marrinan, Pennsylvania State University, State College, PA, United States, Uday Shanbhag, Farzad Yousefian

We consider the minimization of a Lipschitz continuous and expectation-valued function over a closed and convex set. Our focus lies on obtaining both asymptotics as well as rate and complexity guarantees for computing an approximate stationary point (in a Clarke sense) via zeroth-order schemes. We adopt a randomized-smoothing-based approach reliant on minimizing a smooth approximation of our objective function. In such a setting, we develop a zeroth-order stochastic quasi-Newton scheme reliant on a combination of randomized and Moreau smoothing is proposed and analyzed, for which iteration and sample complexities are derived.

4 - A First-Order Augmented Lagrangian Method for Constrained Minimax Optimization

Sanyou Mei, University of Minnesota, Minneapolis, MN, United States, Zhaosong Lu

Minimax optimization with coupled constraints has received tremendous amount of attention in the recent years, finding widespread applications in many areas such as adversarial training, reinforcement learning and distributed computing. In this talk, we will introduce a first-order augmented Lagrangian method for solving a class of constrained minimax optimization with coupled constraints. Under some suitable assumptions, we will establish an operation complexity, measured by its fundamental operations, for the first-order augmented Lagrangian method for finding an approximate KKT solution of the constrained minimax problem.

Learning in Transportation Network Modeling (Part 2)

Invited Session

TSL: Intelligent Transportation Systems

Chair: Minghui Wu, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Zhichen Liu, University of Michigan, Ann Arbor, United States

1 - Online Routing for Connected Vehicles Against Stealthy Cyberattacks

Minghui Wu, University of Michigan, Ann Arbor, MI, United States, Yafeng Yin, Jerome Lynch

This talk introduces a novel online routing algorithm, wherein a connected and automated vehicle recursively leverages real-time traffic predictions to make informed decisions. The algorithm is designed to be robust to cyberattacks on prediction services, which not only withstands adverse conditions but also maintains high efficiency in normal operational conditions. The proposed algorithm achieves this by decomposing decision-making across various nodes, with each node executing an individual sub-algorithm that considers both immediate and long-term effects on the routing process. We theoretically establish a sub-linear regret bound for the algorithm, offering a worst-case performance guarantee. When implemented in a practical routing scenario using real-world data, the algorithm demonstrates its effectiveness beyond merely adversarial contexts. Unlike traditional defense approaches that are designed against particular attack models, our approach requires no knowledge of underlying prediction mechanisms and attack strategies, paving the way for a more reliable and safe transportation system.

2 - Providing Real-TIME En-Route Suggestions to Cavs for Congestion Mitigation: a Two-Way Deep Reinforcement Learning Approach

Xiaoyu Ma, Rensselaer Polytechnic Institute, Troy, NY, United States, Xiaozheng He

This research investigates the effectiveness of information provision for congestion reduction in Connected Autonomous Vehicle (CAV) systems. The inherent advantages of CAVs, such as vehicle-to-everything communication, advanced vehicle autonomy, and reduced human involvement, make them conducive to achieving Correlated Equilibrium (CE). Leveraging these advantages, this research proposes a reinforcement learning framework involving CAVs and an information provider, where CAVs conduct real-time learning to minimize their individual travel time, while the information provider offers real-time route suggestions aiming to minimize the system's total travel time. The en-route routing problem of the CAVs is formulated as a Markov game and the information provision problem is formulated as a single-agent Markov decision process. Then, this research develops a customized two-way deep reinforcement learning approach to solve the interrelated problems, accounting for their unique characteristics. Moreover, CE has been formulated within the proposed framework. Theoretical analysis rigorously proves the realization of CE and that the proposed framework can effectively mitigate congestion without compromising individual user optimality. Numerical results demonstrate the effectiveness of this approach. Our research contributes to the advancement of congestion reduction strategies in CAV systems with the mitigation of the conflict between system-level and individual-level goals using CE as a theoretical foundation. The results highlight the potential of information provision in fostering coordination and correlation among CAVs, thereby enhancing traffic efficiency and achieving system-level goals in smart transportation.

3 - Online Relocating and Matching of Ride-Hailing Services: a Model-Based Modular Approach

Chang Gao, Department of Industrial Engineering, Tsinghua University, Beijing, China, People's Republic of, Xi Lin, Fang He, Xindi Tang

This study proposes an innovative model-based modular approach (MMA) to dynamically optimize order matching and vehicle relocation in a ride-hailing platform. MMA utilizes a two-layer and modular modeling structure. The upper layer determines the spatial transfer patterns of vehicle flow within the system to maximize the total revenue of the current and future stages. With the guidance provided by the upper layer, the lower layer performs rapid vehicle-to-order matching and vehicle relocation. MMA is interpretable, and equipped with the customized and polynomial-time algorithm, which, as an online order-matching and vehicle-relocation algorithm, can scale past thousands of vehicles. We theoretically prove that the proposed algorithm can achieve the global optimum in stylized networks, while the numerical experiments based on both the toy network and realistic dataset demonstrate that MMA is capable of achieving superior systematic performance compared to batch matching and reinforcement-learning based methods. Moreover, its modular and lightweight modeling structure further enables it to achieve a high level of robustness against demand variation while maintaining a relatively low computational cost.

4 - Discovering Traffic Dynamics from Trajectory Data Through Deep Learning

Ohay Angah, University of Washington, Seattle, WA, United States, Xuegang Ban

This study aims to discover traffic dynamics from vehicle trajectories through automatic learning techniques considering expression parsimony and interoperability. We propose an expression exploration framework based on deep symbolic regression (DSR) while encouraging parsimonious mathematical expressions to include potential variable interactions performed from data. In the expression exploration process, two penalty terms are added to the reward function to train recurrent neural networks (RNNs): (i) a complexity penalty to regulate the complexity of explored expressions and (ii) a variable interaction penalty to encourage the exploration to explore expressions consisting of potential feature combinations. Instead of limiting the expression complexities in exploration aggressively, the complexity penalty strategy is embedded in the reward function to encourage the RNNs to explore expressions with reasonable complexities. The strategy is found to be able to better regulate the complexities of expression candidates than the existing DSR framework. In the experiments, we further investigate the robustness of the proposed framework. Results demonstrate that our framework is efficient and robust for discovering mathematical representations of car-following dynamics. The proposed reward function performs well in regulating the complexity range of expression search.

New Applications of Routing Problems

Invited Session

TSL: Freight Transportation

Chair: Rui Zhang, University of Colorado Boulder, Boulder, CO, 80309, United States

Co-Chair: Mengting Chao, University of Maryland-College Park, College Park, MD, United States

1 - On-Demand Routing for B2b Retailers

Mengting Chao, University of Maryland-College Park, College Park, MD, United States

COVID-19 significantly changed the last-mile delivery network for B2B retailers. Due to work-from-home, delivery locations were more spread out in the suburbs with 1-2 boxes per stop compared to a larger number of boxes in more centralized office locations. This exposed a general underlying problem in last-mile delivery when demand (total route time) exceeds delivery capacity (temporal). The challenge is to deliver to all customers on the promised delivery day with the retailer driver (RD) staying within the regular shift hours. Evolving industry practices include outsourcing some deliveries to on-demand drivers (ODDs). We aim to determine the route of the RD, the locations that the ODDs will deliver, and the drop-off locations where the RD will hand over packages to the ODDs.

2 - Disaster Response on a Network with Stochastic Demand and Uncertain Edge Accessibility

Jessa Rhea, University of Iowa - Applied Mathematical and Computational Sciences, Iowa City, IA, United States, Jeffrey Ohlmann

We present a mobile facility routing problem to provide safe and immediate disaster response for a network in which there is uncertain edge traversability and stochastic beneficiary demand. Our problem is formulated as a Markov decision process, and the objective is to maximize the amount of beneficiary demand served by the capacitated fleet over the problem horizon. We note that a mobile facility can contribute to this objective even if it does not serve demand at an epoch (e.g., when its capacity is entirely depleted) by determining accessibility of edges and observing beneficiary demand at locations along its route. Our solution approach is a reinforcement learning algorithm benchmarked by the vehicle routing problem with stochastic demand.

3 - The Truck-and-Robot Routing Problem with Pickups and Deliveries

Manuel Ostermeier, University of Augsburg, Augsburg, Germany, Tobias Huf

The increasing number of home deliveries paired with various delivery modes and channels require retailers to establish efficient last-mile solutions. The innovative truck-and-robot concept poses a promising approach in this regard. The concept relies on Sidewalk Autonomous Delivery Robots (SADRs) carried and released by trucks to serve customers in predefined time windows. We extend existing concepts by integrating store locations and corresponding customer requests for direct deliveries from stores. This setup combines the first and the last mile, giving rise to a novel concept where different delivery modes are established that provide robots as a service to pick up and deliver goods to customers.

The described problem is formalized as the Truck-and-Robot Pickup-and-Delivery Problem (TnR-PDP) and solved using a tailored approach, the Adaptive Genetic Algorithm (AGA). The AGA is based on a recombination-based search framework but tailored to the problem-specifics (e.g., no or multiple visits per location) using specialized recombination operators and an adaptive search strategy for location and operator selection.

The numerical experiments show that our approach outperforms existing benchmark approaches concerning runtime by up to 79 % while also improving the solution quality. The AGA solves relevant instances in a reasonable amount of time and generates robust solutions. Further analyses highlight the value of store integration into the truck-and-robot concept and show the benefits of the TnR-PDP compared with commonly applied approaches in the industry.

4 - Estimating Optimal Solution Values in TSP, VRP, and SDVRP

Shuhan Kou, University of Maryland, College Park, College Park, MD, United States, Bruce Golden, Luca Bertazzi

Motivated by Basel and Willemain's (2001) work on estimating optimal tour lengths in the Traveling Salesman Problem (TSP), we identify an intrinsic relationship between the distribution of the feasible solution space and the optimal solution value in combinatorial optimization problems. We begin with a linear regression model that uses standard deviation as a predictor to predict the optimal TSP tour length. Building on this, we improve our model by incorporating the mean and minimum predictors, significantly enhancing predictive accuracy. We also extend this method to over 10,000 vehicle routing problem (VRP) instances. To tackle the more complex split delivery vehicle routing problem (SDVRP), we integrate mean, standard deviation, and two other topological features into our model. Evaluating our approach across 95 diverse benchmark instances, our regression model provides an average margin of 3%. Moreover, our recent experiments reveal that employing these predictors in random forest and neural network models further enhances the predictive accuracy beyond that of linear regression for the TSP and the VRP.

5 - An empirical study of a compact formulation of the capacitated fixed-charge network flow problem

Eli Olinick, Southern Methodist University, Dallas, TX, United States

The triples formulation is a compact formulation of multicommodity network flow that provides an alternative to the traditional and widely used node-arc and arc-path representations. When applied in mixed integer programming formulations of the capacitated fixed charge network flow problem (CFCNFP), the triples formulation significantly reduces the number of constraints and continuous variables compared to the standard node-arc formulations. In an empirical study, we find that CFCNFP instances that can be solved to provable optimality are solved an average of 2.75 times faster with the triples formulation than with the node-arc formulation. For instances that cannot be solved to provable optimality in our computing environment, we find that given a 30-minute time limit the triples formulation produces solutions with lower costs and optimality gaps.

Transportation and Optimization for Strategic Decisions and Policymaking

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Arthur Delarue, Georgia Institute of Technology, Atlanta, GA, United States

1 - School District Design Under Uncertainty

Aysu Ozel, Northwestern University, Evanston, IL, United States, Karen Smilowitz

Many decisions in school district design aim to provide continuity in educational experiences, particularly long-term district design decisions that include opening/closing schools, drawing attendance boundaries, and placing programs within schools. Given the need for continuity, it is important to consider the robustness of district design options with respect to uncertain changes. We explore school district design under uncertainty in the larger context of decision making under uncertainty, considering the unique features of school settings. We examine multiple sources of uncertainty in school enrollment, including exogenous demographic changes and endogenous changes stemming from community response to district design updates. Further, we consider modeling of decisions given different levers to address uncertain enrollment and current practices in school districts.

2 - On-trip matching in shared rides

Julia Yan, University of British Columbia, Vancouver, BC, Canada, Yifan Shen, Chiwei Yan

We will discuss issues related to on-trip matching in shared rides.

3 - A Scalable Algorithm for Large-Scale Network Design with Service Time Guarantees

Myungeun Eom, Georgia Institute of Technology, Atlanta, GA, United States, Alejandro Toriello, Alan Erera

We propose a scalable algorithm for a large-scale network design problem with service time guarantees, motivated by small package delivery systems. Our model captures an important constraint that commodities must be delivered within specified service time periods. We aim to determine paths for commodities to minimize transportation and hold costs while ensuring the service time guarantees. We solve this problem on the entire United States network, which includes approximately 250 hub buildings and 40,000 commodities. The main challenges of this problem arise from the large network size and the high volume of commodities. To address the scalability issue from the network size, we partition the network into smaller sub-networks considering geographic features. We solve each sub-network independently for commodities whose origins and destinations are within the same sub-network. For commodities with origins and destinations in different sub-networks, we identify networks containing potential transfer terminals and solve the problem within these chosen networks. To handle a large number of commodities, we develop a batching method that prioritizes commodities with less flexibility. We iteratively solve the problem for each batch, building on the previous solutions for consolidation. We demonstrate the effectiveness of our approach through a computational study conducted on networks of various sizes.

4 - Two-stage stochastic optimization formulation for the police staffing problem

Lynn Xu, Georgia Institute of Technology, Atlanta, GA, United States

We present a two-stage stochastic optimization formulation of the police staffing problem, where staffing decisions are made in the first stage and dispatch decisions in the second stage. Noticing the special structure of our problem, we provide a customized integer L-shaped method for our second-stage problem and show its computational advantage compared to the existing methods using 911 call data from the Atlanta Police Department. We also develop a new formulation for the second-stage problem, which adopts ideas from interval scheduling theory.

5 - Novel Regret Bounds based on Information Relaxations

Lavanya Marla, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Tharunkumar Amirthalingam

We present a novel approach to evaluating policies for large-scale resource allocation problems on networks. Strategic and tactical policies are often evaluated based on regret bounds, which may be too loose. Our approach is based on the idea of penalized information-relaxation bounds, proposed earlier by Brown, Smith and Sun (2010). We identify and solve methodological gaps in the existing approach and demonstrate how these can be successfully operationalized for large-scale decision-making problems on networks. We demonstrate our methodology on applications involving airline recovery, emergency medical service policies and training autonomous vehicles.

1 - Airline competitive Hub-and-Spoke network design by reweighted norm-1

Fernando Real Rojas, King Juan Carlos University, Mostoles, Spain, Luis Cadarso, Antonio Marques

The widespread adoption of hub-and-spoke networks in the airline sector has sparked interest in hub location problems. Our research introduces a profit-maximizing, flow-based mathematical model tailored for designing airlines' capacitated networks. Unlike traditional methods assuming a predefined hub-and-spoke structure, we allow hubs to emerge based on cost-effectiveness, passenger preferences, and airline competition.

Given the competitive nature of the airline industry, we focus on optimizing network design while considering passenger behavior. Discrete choice models capture factors influencing passenger decisions, such as route price and travel time, integrating supply and demand interactions. These models, like the logit model, are nonlinear and nonconvex, posing solver development challenges. We address this with a reverse engineering approach, adding convex negative entropy passenger flow regularizers, leading to logit-based solutions.

Our formulation jointly considers key decision variables like airport base locations, route offerings, and associated capacities. This complicates the optimization but integrates network infrastructure design with passenger choices and market shares. To solve this, we propose a novel approach using convex relaxation and reweighted norm-1 minimization, combining decision and dimensioning network infrastructure variables, and considering operating costs and passenger decisions.

A strategic element of our approach is tailored flow conservation constraints that only allow transfers at hubs, crucial for yielding hub-and-spoke topologies and modeling passenger choices. Our method optimizes hub-and-spoke network design considering profitability, demand forecasts, passenger choices, and competitor presence. We demonstrate effectiveness with a case study of a new domestic airline across 25 U.S. airports, validating the methodology and offering insights into the hub-and-spoke design.

Railway Timetabling and Demand Forecasting

Invited Session

Railway Applications

Chair: Pengli Mo, N/A, United States

Co-Chair: Marcella Samà, Roma Tre University, Roma, Italy

1 - Delay risk evaluation in real-time train rescheduling under uncertain dwell times

Marcella Samà, Roma Tre University, Roma, Italy, Marco Pranzo, Carlo Meloni

Given a train timetable made infeasible by unexpected disturbances, the real-time Railway Traffic Management Problem (rtRTMP) returns a new feasible plan of operations in which corrective decisions have been taken to minimize delay propagation. The rtRTMP is a very well-studied problem in the literature. Usually, given the necessity to quickly return a good quality solution, the problem is solved considering deterministic passengers dwell time, disregarding how uncertainty may affect the new constructed plans. Such simplification of the problem may lead to unexpected worsening of the performance promised by an rtRTMP solver, which in turn may negatively impact the confidence of dispatchers on such tools. A clearer picture of the actual rtRTMP solution quality, especially in case of worst-case scenarios realizations, would be preferable, to better allow dispatchers to take more informed decisions. In this talk we present an approach to assess the risk of worsening delays associated to an rtRTMP solution when dwell times are uncertain. We explore the evaluation of the Conditional-Value-at-Risk of the maximum train delay as risk index. We model an rtRTMP solution as a temporal activity network and apply an innovative numerical method to obtain a real-time risk evaluation for rtRTMP solutions. We test the proposed approach on a real case study analyzing the effects of uncertainties of different severity. Different computational schemes are presented, testing and analyzing their suitability for practical contexts requiring risk-averse or risk-aware scheduling processes. The methodology appears to be promising to deal with the different risk attitudes of the decision-makers.

2 - A Fragility-based Approach to Timetable Design

Marta Leonina Tessitore, Roma Tre University, Rome, Italy, Marcella Samà, Giorgio Sartor, CARLO MANNINO, Dario Pacciarelli

In a typical tactical timetabling process, route planners are usually tasked to produce a timetable for the next months or year. They start from an existing timetable and follow a time-consuming trial-and-error process to obtain a new timetable. Given the increase in traffic demand, public service companies require the implementation of effective decision support systems that can guide practitioners throughout their decision-making process, regardless of their experience level. In this work, we present a fragility-based approach to timetable design. Specifically, we show how the concept of fragility can be easily exploited by route planners to design new and more robust timetables, i.e., to suggest where to add new time supplements or redistribute the available ones. We propose a timetabling model that aims at building a more robust timetable, modifying the existing timetable, and reducing the fragility of its most critical sections, that is a single large model capable of simultaneously doing timetabling and dispatching. We solve this model using a delayed row generation algorithm similar to the one first described in Lamorgese and Mannino (2015). Each iteration of the algorithm produces a new timetable that may contain different fragile sections. The process can be iterated until the desired level of robustness is achieved. Considering real-life scenarios from a Norwegian railway line, we show that we can significantly improve the fragility of a timetable, even when considering conservative strategies for possible improvements.

3 - Collaborative Optimization of Rolling Stock Allocation and Timetable Coordination in a Multi-Modal Rail Network: MILP Formulation and Decomposition-Based Algorithm

Jiateng Yin, Beijing Jiaotong University, Beijing, China, People's Republic of

The transportation system is shifting towards a shared mobility ecosystem, emphasizing resource aggregation and coordination among different transport modes to enhance service quality and encourage passengers to shift from private cars to public transit. This study focuses on the coordination between metro and rail networks in a city, to alleviate congestion at transfer hubs and to decrease the travel time of passengers. Given the "tide-like" transfer passengers between rail and metro hubs, we investigate the potential of reserving a number of rolling stocks, strategically allocated to the metro trains with the highest demand to avoid over-congestion. We present a mixed integer linear programming (MILP) model to formulate this problem, with decision variables including rolling stock allocation and coordinated schedules for both metro and rail networks, by considering the time-varying demand of passengers. The objectives aim to minimize the passenger travel/transfer time and operational costs for managers. Then, we analyze the mathematical properties and propose an exact decomposition-based solution algorithm. Our algorithm reformulates the original problem into a relaxed master problem (corresponding to rolling stock allocation and timetabling) and a series of independent subproblems (corresponding to passenger flows). We provide optimality conditions and prove that the subproblems can be solved by an analytical procedure. According to these properties, we further propose a set of feasibility cuts and we prove that the new cuts provide tighter bounds in comparison with traditional Benders cuts. We test our integrated approach and solution algorithms on real-world instances from the Beijing railway network.

4 - Passenger-oriented rolling stock scheduling in the metro system with multiple depots: Network flow based approaches

Entai Wang, HEC Montreal, Montreal, QC, Canada, Lixing Yang, Jiateng Yin

This study investigates a rolling stock scheduling problem on a metro line with multiple depots. Two novel optimization models, i.e., an arc-based and a path-based network-flow models, are formulated with the aim of improving the service level and reducing the operation cost simultaneously, in which the flexible train composition mode is also taken into consideration to well match the transport capacity and time-varying passenger demand. To solve the proposed models, a branch-and-price (B&P) approach is designed to find the near optimal operation schemes, in which the column generation is used to solve the relaxed problem at each node of the searching tree, where a dynamic programming approach is embedded to solve the pricing sub-problem associated with each depot to generate promising paths (columns) for each rolling stock unit, and then the branch-and-bound (B&B) procedure is incorporated to find integral solutions. To test the performance of the proposed approaches, a series of numerical experiments are conducted both on small-scale and real-life cases of the Beijing metro Batong line with historically recorded passenger data. The computation results have verified the improved operational efficiency and a better service level of the solutions found by our proposed approaches.

Human-in-the-loop in Forecast and Inventory Systems

Invited Session

Behavioral Operations Management

Chair: Enno Siemsen, University of Wisconsin-Madison, Madison, WI, United States

1 - Inventory and Forecast Adjustments

Eirini Spiliotopoulou, Tilburg University, Tilburg, Netherlands, Enno Siemsen

We examine whether planners should be allowed to adjust forecasts or the resulting inventory orders (or both). We use experiments to establish that order adjustments work better due to less noise in the decisions. Several experiments examine the behavioral cause for this phenomenon, and compare students and professional forecasters as participants in the experiment.

2 - Reluctant to Decrease: Human-Algorithm Collaboration in Tactical Inventory Decisions

Joan Stip, Eindhoven University of Technology, Eindhoven, Netherlands, Jan Fransoo, Geert-Jan van Houtum

We study augmented decision-making when setting base stock levels in high-stakes spare parts inventory management. Such spare parts inventory management is characterized by many 0-1 decisions: the base stock level is either 0 or 1. We partner with an OEM where state-of-the-art inventory control algorithms have been deployed and observe that human decision-makers deviate from the optimal solution by adjusting 24% of the base stock levels. We deploy a structural estimation model estimating the humans' psychological cost for overage and underage and find that in particular, the psychological cost for underage are substantially higher than parameterized in the algorithms. Interestingly, we can show that such psychological costs for underage are particularly high in case the algorithm proposes to reduce the inventory from 1 to 0, similar to the well-known endowment effect. Leveraging our structural estimation, we run a counterfactual analysis and show that a Pareto-optimal alternative solution can be obtained that is more aligned with the humans' perceptions of underage costs.

3 - Navigating Forecast Dynamics: the Decision Dilemma of Multi-Ordering Newsvendors

Michael Becker-Peth, Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands, Anne Dohmen, Stephanie Eckherd, Lance Saunders

In supply chain management, orders are typically placed well in advance based on forecasts. However, these forecasts may evolve over time, leading to potential inaccuracies in the original orders. This study investigates the decision-making process of human operators facing the option to update order quantities in a multi-ordering newsvendor system. Through controlled laboratory experiments, we examine how variations in mean demand, demand uncertainty, and change fees influence the propensity to adjust initial orders. Our findings reveal that changes in mean demand consistently trigger order updates, regardless of the potential benefits, while adjustments in demand uncertainty result in fewer updates. This dynamic introduces the risk of both false positives—updating unnecessarily—and false negatives—failing to update when beneficial—impacting overall system performance. Thus, understanding the underlying decision mechanisms is crucial for determining the impact of providing the option to update orders. Our research sheds light on the complexities of navigating forecast dynamics in multi-ordering newsvendor systems, highlighting the balance between the potential gains from order adjustments and the associated risks.

4 - Profit Implications of Judgmental Adjustments to Forecast Inputs: Evidence from a Large-Scale Field Experiment

Dayton Steele, University of Minnesota, Carlson School of Management, Minneapolis, MN, United States, Saravanan Kesavan, Tarun Kushwaha

In this paper, we report the results from a large-scale field experiment at a spare parts retail chain that considers whether allowing merchants to override forecast inputs to an inventory algorithm improves profits. While the judgmental forecasting literature has studied extensively whether judgmental adjustments improve forecast performance, causal empirical evidence is missing in regards to whether judgmental adjustments improve bottom-line profits. Our results show that judgmental adjustments to the forecast input increase profitability by 3.98% on average compared to relying on automation without human intervention. We find that the well-established motivation-opportunity-ability framework provides clear insight into when judgmental adjustments improve profits, by examining heterogeneity in our data regarding SKU margin, lifecycle, and size of supplier. Our dataset also allows for examining both forecast accuracy and profits. We empirically support the wisdom from the judgmental forecasting literature that forecast improvements need not translate to profit improvements, calling attention to the need to consider operational performance beyond forecast accuracy as an end in itself.

Causal Inference & ML

Invited Session

Applied Probability Society

Chair: Kelly Zhang, Columbia Business School (DRO), New York, NY, United States

1 - On Experiment Design Under Network Interference

Mohsen Bayati, Stanford University, Standford, CA, United States, Yuwei Luo, William Overman, Sadegh Shirani, Ruoxuan Xiong

Randomized experiments are a powerful methodology for data-driven evaluation of decisions or interventions. Yet, their validity may be undermined by network interference. This occurs when the treatment of one unit impacts not only its outcome but also that of connected units, biasing traditional treatment effect estimations. This talk discusses a new framework to accommodate complex and unknown network interference and produce practical estimators.

2 - Minimax Optimal Estimates of Individual Causal Effects in Panel Data under General Intervention Patterns

Christina Yu, Cornell University, Ithaca, NY, United States, Yudong Chen, Xumei Xu

Consider estimating individual causal effects of a treatment on an individual i at time t from panel data, where we observe the outcomes of multiple units across a period of time. Each unit may be exposed to the treatment at different time points across the horizon. Assuming the two-way linear fixed effects model, for any general intervention pattern, we present tight conditions for identification of individual causal effects along with a simple unbiased estimator. The estimator is both minimax optimal and is a uniform minimum variance unbiased estimator when the observation noise is independent from the treatment variables. In particular, the minimax achievable squared error for recovery of the causal effect associated to the (i,t) unit-time pair is proportional to the effective resistance of (i,t) in the bipartite graph associated to the intervention pattern, and the estimator is derived from the unit (i,t) electrical flow on that graph. We show that our estimator can be viewed as a generalization of the difference in differences estimator, and our results provide insights for understanding two-way fixed effects regression estimators.

3 - Adaptive Experimentation at Scale: A Mathematical Programming Approach

Hongseok Namkoong, Columbia University, New York, NY, United States, Ethan Che

Adaptive experimentation can improve statistical power significantly, but typical algorithms overlook important issues that arise in practice: multiple objectives, non-stationarity, batched/delayed feedback, constraints, and personalization. Moving away from developing bespoke algorithms for each setting, we present a mathematical programming view of adaptive experimentation that can flexibly incorporate a wide range of objectives, constraints, and statistical procedures. By formulating a dynamic program in the batched limit, our modeling framework enables the use of scalable optimization methods (e.g., SGD and auto-differentiation) to solve for treatment allocations. To spur algorithmic progress, we build a suite of benchmark problems based on hundreds of real A/B tests at ASOS that model key practical issues such as non-stationarity, personalization, multi-objectives, and constraints. Our empirical results show standard Thompson sampling-based policies fail to reliably improve upon static designs, and demonstrate the effectiveness of a simple planning approach.

4 - Orthogonal Estimation of the Difference-of-Q-Functions

Angela Zhou, USC Marshall School of Business Data Sciences and Operations, Los Angeles, CA, United States

Offline reinforcement learning is important in many settings with available observational data but the inability to deploy new policies online due to safety, cost, and other concerns. Many recent advances in causal inference and machine learning target estimation of heterogeneous treatment effects, and more broadly causal contrast functions. Estimating causal contrasts is sufficient for making optimal decisions and can adapt to potentially smoother structure. We develop a dynamic generalization of the R-learner for estimating the difference of Q-functions, Q(s,1)-Q(s,0) (and for multiple actions, fixing a choice of a_0, Q(s,a)-Q(s,a_0). The method wraps around standard estimation procedures in offline reinforcement learning via a sequence of sequential loss minimization problems, which makes it appealingly practical. But, the residualized learning step allows for targeting the more structured smoothness of the Q-function contrast itself. We illustrate with relevant examples, including "decision-theoretic sparsity" of the difference-of-Q function that arises due to joint structure of reward and transitions.

Topics in Data-driven Stochastic Optimal Control

Invited Session

Applied Probability Society

Chair: Andrew Lim, National University of Singapore, Singapore, Singapore

Co-Chair: Wang Chi Cheung, National University of Singapore, Singapore, Singapore

1 - Q-Learning in Continuous TIME

Xunyu Zhou, Columbia University, New York, NY, United States, Yanwei Jia

We study the continuous-time counterpart of Q-learning for reinforcement learning (RL) under the entropy-regularized, exploratory diffusion process formulation introduced by Wang et al. (2020). As the conventional (big) Q-function collapses in continuous time, we consider its first-order approximation and coin the term “(little) q-function”. This function is related to the instantaneous advantage rate function as well as the Hamiltonian. We develop a “q-learning” theory around the q-function that is independent of time discretization. Given a stochastic policy, we jointly characterize the associated q-function and value function by martingale conditions of certain stochastic processes, in both on-policy and off-policy settings. We then apply the theory to devise different actor–critic algorithms for solving underlying RL problems, depending on whether or not the density function of the Gibbs measure generated from the q-function can be computed explicitly. One of our algorithms interprets the well-known Q-learning algorithm SARSA, and another recovers a policy gradient (PG) based continuous-time algorithm proposed in Jia and Zhou (2022b). Finally, we conduct simulation experiments to compare the performance of our algorithms with those of PG-based algorithms in Jia and Zhou (2022b) and time-discretized conventional Q-learning algorithms.

2 - Optimal Trade Execution with Learning

Andrew Lim, National University of Singapore, Singapore, Singapore, Galvin Ng

We consider the problem of optimal trade execution with a linear price impact function when both the drift (intercept) and permanent price impact (slope) parameters are uncertain. Since the trading rate affects the returns data that is used to learn the uncertain parameters, this problem is intrinsically a tradeoff between exploration and exploitation, and it is of particular interest to understand how the trader goes about "exploring" under the optimal policy. To sidestep the well-known challenges of solving the dynamic programming equation, which is infinite dimensional in general and has no explicit solution even when the prior on both parameters is Gaussian, we consider the asymptotic regime where the learning rate vanishes and use a Taylor Series expansion extract the exploration component of the optimal policy. This exploration term can be easily characterized and computed, and provides surprising but ultimately intuitive insights into the nature of exploration, its dependence on the time horizon, the inventory level and the value of learning the drift and market impact parameters.

3 - Leveraging (Biased) Information: Multi-armed Bandits with Offline Data

Lixing Lyu, National University of Singapore, Singapore, Singapore, Wang Chi Cheung

We leverage offline data to facilitate online learning in stochastic multi-armed bandits. The probability distributions that govern the offline data and the online rewards can be different. Without any non-trivial upper bound on their difference, we show that no non-anticipatory policy can out-perform the UCB policy by (Auer et al. 2002), even in the presence of offline data. In complement, we propose an online policy MIN-UCB, which outperforms UCB when a non-trivial upper bound is given. MIN-UCB adaptively chooses to utilize the offline data when they are deemed informative, and to ignore them otherwise. MIN-UCB is shown to be tight in terms of both instance independent and dependent regret bounds. Finally, we corroborate the theoretical results with numerical experiments.

4 - Continuous Time Reinforcement Learning using Rough Paths

Prakash Chakraborty, The Pennsylvania State University, University park, PA, United States, Harsha Honnappa, Samy Tindel

This study delves into an optimal control formulation for continuous time reinforcement learning in rough environments. To model uncertainty and facilitate effective exploration of the environment, our approach incorporates relaxed controls into the controller's actions. We carefully study the properties of the corresponding relaxed and rough Hamilton-Jacobi-Bellman (HJB) equation and discuss how our rough control framework can enhance reinforcement learning strategies.

Learning in Changing Environments

Invited Session

Applied Probability Society

Chair: Gal Mendelson, Technion, Haifa, Israel

1 - Roping in Uncertainty: Robustness and Regularization in Markov Games

Qiaomin Xie, University of Wisconsin-Madison, Madison, WI, United States, Jeremy McMahan, Giovanni Artiglio

We study robust Markov games (RMG) with s-rectangular uncertainty. We show a general equivalence between computing a robust Nash equilibrium (RNE) of a s-rectangular RMG and computing a NE of an appropriately constructed regularized MG. The equivalence result yields both a planning algorithm for solving s-rectangular RMGs and provable robustness guarantees for policies computed using regularized methods. However, we show that even for just reward-uncertain two-player zero-sum matrix games, computing an RNE is PPAD-hard. Consequently, we derive a special uncertainty structure called efficient player-decomposability, and show that RNE for two-player zero-sum RMG in this class can be provably solved in polynomial time. This class includes commonly used uncertainty sets such as L_1 and L_\infty ball uncertainty sets.

2 - A Definition of Non-Stationary Bandits

Yueyang Liu, Stanford University, Stanford, CA, United States, Benjamin Van Roy, Kuang Xu

Despite the subject of non-stationary bandit learning having attracted much recent attention, we have yet to identify a formal definition of non-stationarity that can consistently distinguish non-stationary bandits from stationary ones. Prior work has characterized non-stationary bandits as bandits for which the reward distribution changes over time. We demonstrate that this definition can ambiguously classify the same bandit as both stationary and non-stationary; this ambiguity arises in the existing definition's dependence on the latent sequence of reward distributions. Moreover, the definition has given rise to two widely used notions of regret: the dynamic regret and the weak regret. These notions are not indicative of qualitative agent performance in some bandits. Additionally, this definition of non-stationary bandits has led to the design of agents that explore excessively. We introduce a formal definition of non-stationary bandits that resolves these issues. Our new definition provides a unified approach, applicable seamlessly to both Bayesian and frequentist formulations of bandits. Furthermore, our definition ensures consistent classification of two bandits offering agents indistinguishable experiences, categorizing them as either both stationary or both non-stationary. This advancement provides a more robust framework for agent design and analysis in non-stationary bandit learning.

3 - Average Reward Restless Bandits: Unichain and Aperiodicity are Sufficient for Asymptotic Optimality

Yige Hong, Carnegie Mellon University, Pittsburgh, PA, United States, Qiaomin Xie, Yudong Chen, Weina Wang

We consider the infinite-horizon, average-reward restless bandit problem in discrete time. We propose a new class of policies that are designed to drive a progressively larger subset of arms toward the optimal distribution. We show that our policies are asymptotically optimal with an $O(1/\sqrt{N})$ optimality gap for an N-armed problem, provided that the single-armed relaxed problem is unichain and aperiodic.

Our approach departs from most existing work that focuses on index or priority policies, which rely on the Uniform Global Attractor Property (UGAP) to guarantee convergence to the optimum, or a recently developed simulation-based policy, which requires a Synchronization Assumption (SA).

4 - An Information-Theoretic Analysis of Nonstationary Bandit Learning

Seungki Min, KAIST, Daejeon, Korea, Republic of, Daniel Russo

In nonstationary bandit learning problems, the decision-maker must continually gather information and adapt their action selection as the latent state of the environment evolves. In each time period, some latent optimal action maximizes expected reward under the environment state. We view the optimal action sequence as a stochastic process, and take an information-theoretic approach to analyze attainable performance. We bound per-period regret in terms of the entropy rate of the optimal action process. The bound applies to a wide array of problems studied in the literature and reflects the problem's information structure through its information-ratio.

Summit - 436

Active Learning for Optimization

Invited Session

Simulation Society

Chair: Giulia Pedrielli, Arizona State University, Tempe, AZ, United States

1 - Recent Advances in Grey-Box Bayesian Optimization

Raul Astudillo, California Institute of Technology, Pasadena, CA, United States

Bayesian optimization (BO) is a framework for global optimization of expensive-to-evaluate objective functions. Classical BO methods assume the objective function is a "black box". However, information about the objective function is often available. Recently, "grey-box" BO methods leveraging such information have been shown to provide dramatic performance improvements in a broad range of problems. In this talk, I will discuss new advances in grey-box BO and the applications these methods have unlocked.

2 - Fast and Effective Gaussian Process Based Bayesian Optimization Without Maximum Likelihood Estimation

Antonio Candelieri, University of Milano-Bicocca, Milano, Italy

A novel Gaussian Process based Bayesian Optimization framework is presented, in which the modelling of the objective function and the selection of the new incumbent solution are simultaneously addressed by predicting the most suitable value of the Gaussian Process's kernel kyperparameter(s), avoding expensive computation of the Maximum Likelihood Estimation. Indeed, the Gaussian Process model is fitted at a constant time, independently on the number of function evaluations performed so far. At the same time, the prediction of the most suitable value of the kernel's hyperparameter(s) also avoids instability in the kernel matrix. As a result, the approach can be applied to globally optimize noise-free functions, without the need to add artificial noise (also known as nugget effect) to avoid ill-conditioning.

Results on a set of diversified test problems empirically show the benefits of the proposed approach, in terms of effectiveness and efficiency, against the well known *no-regret* Gaussian Process Lower Confidence Bound. Specifically, the proposed approach provides a lower cumulative regret until the best observed value can be improved. Otherwise, the regret increases because exploration is intrinsically triggered by the impossibility to further improve, close to the current best solution, without incurring into ill-conditioning. This leads to a completely new way to learn the Gaussian Process by simultaneously considering risk for ill-conditioning and exploration-exploitation balance provided by the next incumbent solution.

3 - Stochastic Linear Bandits with Partial Observability

Gautam Dasarathy, Arizona State University, Tempe, AZ, United States, Vineet Gattani, Lalit Jain

We consider the problem of stochastic linear bandits where the decision vectors available to the agent may only be partially observed. This models several modern sequential decision-making applications, such as recommendation systems, where it is impossible, impractical, or even imprudent to fully observe these decision vectors. As one example, the recent migration from third-party cookies means that advertisers only get limited observability into the user context. In this work, we propose Partially Observed Linear Bandit (POLB), an algorithm for tackling this problem. Our method sequentially builds an estimate of the (possibly low-dimensional) subspace the decision vectors lie in, and then leveraging this estimate in a sequential decision making framework. Our theory elucidates the effect of the amount of observability and the presence of low-dimensional structure underlying the decision vectors on the regret performance of POLB. We complement this with empirical results that highlight the advantages of the proposed framework.

4 - Respecting the limit: Bayesian optimization with a known bound on the optimal value

Matthias Poloczek, Amazon, San Francisco, CA, United States

Bayesian optimization (BO) has become a powerful method for the sample-efficient optimization of expensive black-box functions that arise in materials discovery, hardware design, AutoML, or portfolio optimization, for example. These functions do not have a closed-form and are evaluated by running a complex simulation or an experiment. In many real-world optimization problems, we have prior information about what values are achievable under the objective function. We study the scenario that we have either exact knowledge of the value of the global minimum or a, possibly inexact, lower bound on its value. We propose Bound-Aware Bayesian Optimization (BABO) that uses a tailored surrogate model called SlogGP and a new acquisition criterion based on Expected Improvement to leverage the bound information. Empirical results on a variety of benchmarks demonstrate the benefit of taking prior information about the optimal value into account. Interestingly, we notice that even in the absence of such prior information, the new SlogGP surrogate model outperforms the standard GP model in many cases.

Joint work of Hanyang Wang, Juergen Branke (both Warwick Business School, UK), and Matthias Poloczek (Amazon, USA).

5 - Simulation-based digital twins: Identifying optimal alternatives using real-time data

Moones Keshvarinia, Iowa State University, Ames, IA, United States, Cameron MacKenzie

Digital twins have the potential to support decision making in real time in a manufacturing facility. The digital twin should run in parallel with the manufacturing facility so that the digital twin represents the current state of the manufacturing system. Simulation within the digital twin can be used to explore different scenarios and forecast potential outcomes in the manufacturing system. When problems arise in the manufacturing system, the manufacturer can use the digital twin simulation to identify alternatives to resolve these problems while incorporating real-time data from the manufacturing facility. This study investigates the use of a digital twin to resolve a severe supply shortage in a manufacturing facility. We use a discrete-event simulation to determine if a digital twin relying on real-time data from the manufacturing facility generates a different set of optimal alternatives that mitigate the effects of the supply shortage compared to the optimal alternatives generated from a static simulation without access to real-time data. The simulation models different operational alternatives such as adding more forklifts, employing condition-based maintenance, hiring more workers, and moving workers from one station to another station. Machine learning algorithms identify the combination of alternatives that maximizes the manufacturer's expected profit using data generated by the simulation. The findings from this research quantify the potential benefit of digital twins in manufacturing for the purpose of managing disruptions.

Co-Chair: Zhaowei She, Singapore Management University, Singapore, Singapore

1 - Urban-Rural Differences in Emergency Medical Services TIME Intervals for Traumatic Injury in the United States

Maria Mayorga, North Carolina State University, Raleigh, NC, United States

Purpose: This study aims to evaluate urban-rural differences in emergency medical services (EMS) time intervals for traumatic injury patients in the United States. We also explored the intersectionality of rurality and minority race/ethnicity on EMS time intervals.

Methods: We conducted a retrospective cohort study of EMS incidents for traumatic injury in the 2021 National EMS Information System (NEMSIS) Public Release Research Dataset. Prehospital time intervals, including EMS response, scene, and transport times, were analyzed by urban, suburban, and rural areas for the entire study population and within race/ethnicity subgroups. Multivariable quantile regression was used to estimate adjusted differences in median and 90th percentile times.

Findings: We analyzed 3,952,030 eligible EMS incidents for traumatic injury. Median EMS response, scene, and transport times were 7.1, 14.7, and 12.0 minutes, respectively. In adjusted quantile regression analyses, urban areas had the shortest median and 90th percentile response and scene times while suburban areas had the shortest transport times. Statistically significant differences in EMS time intervals were observed between race/ethnicity groups within each urbanicity level.

Conclusions: In a national database of EMS encounters, EMS response and transport times for traumatic injuries occurring in rural areas were substantially longer compared to urban areas, adjusting for patient demographics and other incident-level factors. Further research on the impact of prehospital emergency care on injury-related disparities in rural and other underserved populations is needed.

2 - Optimizing HPV Intervention Strategies: A Reinforcement Learning Approach

Shalome Hanisha Tatapudi, Merck, Tampa, FL, United States

The decision-making process in healthcare, especially in the field of infectious diseases, is complex and challenging due to various factors such as disease transmission mechanisms, demographic variables, population behaviors, and available interventions. Disease modeling has proven to be an effective tool for evaluating the implications of policymakers' choices and quantifying the effects of decision-making.

However, there is still a need to navigate the trade-offs between cost-effective and efficient intervention strategies, dynamically. The evolving nature of disease and population further complicates the situation, as strategies that are effective today may become less effective in the future. Therefore, it is essential to examine how present intervention decisions will impact future outcomes and the health of the population at large. In this study, we propose the development of a reinforcement learning model to determine optimal intervention strategies, focusing on a case study of the human papilloma virus (HPV). By developing an intelligible learning model, we can evaluate comprehensive interventions, such as cervical cancer screening and vaccination strategies, at different time intervals and aim to create an optimal policy that spans an extended period. This research will help validate current decisions and provide insights into long-term impact of our choices on population's health. Designing effective intervention strategies is crucial for reducing the prevalence of HPV-related diseases and improving overall health outcomes. By leveraging accordingly, we can identify the most efficient and cost-effective approaches to HPV intervention and prevention.

3 - Analyzing BMI Dynamics During Pregnancy Using Growth Mixture Modeling and Machine Learning Techniques

Ashaar Rasheed, Binghamton University, Binghamton, NY, United States, Sreenath Chalil Madathil

Pregnancy induces various physiological changes, including Body Mass Index (BMI) fluctuations. Understanding these changes is crucial for monitoring maternal health. This study reveals different BMI trajectories across pregnancy using a growth mixture model (GMM), incorporating covariates such as age, race, and ethnicity to enhance interpretability. We analyzed BMI values at three time points—from the first to the third trimester—in a cohort of 234 pregnant women, employing 16 GMMs to identify distinct trajectories. Model selection included the use of the Akaike Information Criterion (AIC), Bayesian Information Criterion (BIC), and Integrated Completed Likelihood (ICL).

Our analysis identified three unique BMI trajectories, each characterized by average and variance parameters. The direct inclusion of age, race, and ethnicity in the GMM provided deeper insights into the variations in BMI trajectories. In addition to GMM, tree-based algorithms and regression analyses were used to explore the impact of additional covariates, including CDC morbidity indicators, diabetes, behavioral risk assessments, and delivery outcomes. This further enhanced our understanding of the factors influencing BMI changes.

The combined use of GMM and machine learning methods helped classify pregnancies into normal and abnormal categories, offering a nuanced view of body fat changes during pregnancy. This can inform health policies and practices aimed at improving maternal outcomes. The research emphasizes the importance of personalized health monitoring, which can lead to targeted interventions to optimize pregnancy outcomes.

Keywords: Pregnancy, BMI Dynamics, Growth Mixture Modeling, Covariate Analysis, Maternal Health

4 - A Theory-Based Framework for Understanding the Effectiveness of Generative Artificial Intelligence for Mental Support

Xunyu Chen, Virginia Commonwealth University, Richmond, VA, United States, Lingyu Li, Xiaojin Liu, Victoria Yoon

With its remarkable capabilities for language understanding and generation, Generative Artificial Intelligence (GAI), exemplified by ChatGPT, shows a high potential to address the global shortage of mental health support. However, little is known about how help-seekers perceive mental support provided by GAI, and consequently, how GAI can be improved to offer high-quality mental support. To address these questions, we propose an analytical framework grounded in communication and social support theories. Utilizing this framework, we develop multiple hypotheses regarding GAI's effectiveness in providing mental support and identify various moderators of its effectiveness, based on a comprehensive analysis of GAI's training and inference processes. The proposed hypotheses are tested using user-generated textual and evaluation data collected from a leading online mental healthcare community. Our findings not only reveal the unique attributes of GAI's mental support but, more importantly, provide systematic and actionable pathways to enhance GAI's effectiveness in delivering automated mental health support.

5 - Small Area Estimation of Case Growths for Timely Covid-19 Outbreak Detection

Zhaowei She, Singapore Management University, Singapore, Singapore, Zilong Wang, Jagpreet Chhatwal, Turgay Ayer

 Rapid and accurate detection of local outbreaks is critical to tackle resurgent waves of COVID-19. A fundamental challenge in case growth rate estimation, a key epidemiological parameter, is balancing the accuracy vs. speed tradeoff for small sample sizes of counties. We develop an algorithm, Transfer Learning Generalized Random Forest (TLGRF), that balances this tradeoff. Through transfer learning, TLGRF can accurately estimate case growth rates for counties with small sample sizes based on relevant day and county-level features affecting the disease spread. TLGRF outperforms established growth rate estimation methods and demonstrated that it can greatly improve the timely detection of outbreaks. We thus developed a open source tool for timely detection of COVID-19 outbreaks in each U.S. county, which received substantial attention by policymakers.

1 - A Transfer Reinforcement Learning Approach for Precision Follow-up Colonoscopy Recommendation for Colorectal Cancer Screening

Mu Du, School of Economics and Management, Dalian University of Technology, Dalian, China, People's Republic of, hongtao yu, Nan Kong

In precision public health (PPH), making well-informed intervention decisions tailored to sub-populations' disease progressions is challenging because of the scarcity of relevant data on target sub-populations. This study addresses precision follow-up colonoscopy recommendations for colorectal cancer prevention in multiple cohorts, whose medical data can only be obtained progressively during their follow-up visits. Specifically, each sub-population's disease progression is modeled as a Markov decision process (MDP) with unknown transition parameters and rewards based on a well-established microsimulation colon model. To solve the MDPs, we propose a learning-while-optimization framework with a transfer reinforcement learning (RL) approach facilitated by a general upper confidence bound value iteration scheme. We design this transfer RL approach by integrating a model-based RL with a joint estimator, which can combine huge proxy data historically collected from the entire population and scarce true data progressively obtained from target sub-populations. In addition, we accelerate the proposed transfer RL approach by modifying its algorithmic procedure to employ short-term planning for value iteration instead of full planning. We establish a theoretical performance guarantee by proving the regret bound of the proposed transfer RL approach. We also prove the accelerated transfer RL can significantly decrease the computational complexity without suffering performance degradation in regret. To the best of our knowledge, there is no regret guarantee for such transfer RL approaches, even in the tabular MDP settings. By integrating the RL techniques and operations research, our study pioneers an actionable plan for precision follow-up screening.

2 - Optimizing HIV Point-of-care Testing Systems in Kenya Under a Conditional Value at Risk Objective

Yinsheng Wang, University of Washington, Seattle, WA, United States, Shan Liu, Chaoyue Zhao

Minimizing the turnaround time for HIV testing by allocating point-of-care testing machines in a hub-and-spoke network of clinics has been proven effective in enhancing HIV care. Our previous work has successfully developed practical decision-support tools using queuing theory for HIV viral load and drug resistance testing in Kisumu County, Kenya. The data from Kisumu County between 2019 and 2023 reveal a distinct seasonal trend in viral load testing demand, with notable surges each spring. In light of the demand variations, this study extends a deterministic mixed integer programming model to a two-stage stochastic model. In this framework, the allocation of testing machines is determined in the first stage, while the referral network from clinics to hubs hosting these machines is optimized in the second stage. We have developed and solved a queueing-location-allocation model that incorporates a Conditional Value at Risk objective to manage uncertainties and risks associated with fluctuating testing demands. To ensure computational efficiency, the solution process employs Benders decomposition and heuristic cuts to expedite convergence. Computational results based on a HIV viral load testing network in Kisumu County are presented to compare the robust model to its deterministic counterpart and to demonstrate the robustness of the model.

3 - Early-Stage Clinical Trials with Patient Choice

Connor Van Ryn, Clemson University, Clemson, SC, United States, Amin Khademi, Qi Luo

Early-stage clinical trials (CTs) seek to identify safe dosages for new drugs for later trial phases. Clinical investigators (CIs) often face difficulty in the recruitment and retention of patients during these early stages, which can cause substantial expense and delay to the trial. The prevailing methods used in CTs are dose-escalation methods, where consecutive groups of patients receive increasing doses until significant toxicities are seen. Patient dosing is entirely structured and scheduled by the CI, with the patient having no input. This form of trial is highly conservative in its efficacy and toxicity and gives no agency to patients. This research involves the creation of a new CT design method which balances CT participant satisfaction and CI information gain by increasing the control patients have while still ensuring that adequate information about the drug is learned. The model being developed is a psuedo-market mechanism in which patients are attempting to maximize their expected health gain from different dosages, and CIs are attempting to maximize the information gained about efficiency and toxicity of the drug across different dosages.

4 - Personalized screening policy based on individual women's breast cancer risk

Yifan Lu, University of Wisconsin-Madison, Madison, WI, United States, Oguzhan Alagoz, Eugenio Quessep, Rick Groeneweg, John Hampton, Karla Kerlikowske, Harry Koning, Kathryn Lowry, Diana Miglioretti, Jeanne Mandelblatt , Clyde Schechter, Nicolien Ravesteyn, Brian Sprague, Natasha Stout, Anna Tosteson, Amy Trentham-Dietz

Most existing breast cancer screening guidelines focus only on average-risk women, which may lead to over-screening of low-risk women and under-screening of high-risk women. Several successful risk assessment models exist, which provide an individual woman's risk of developing breast cancer in the next several years (E.g. 5-year risk), however, their impact on long-term breast cancer outcomes is unknown. We utilized University of Wisconsin Breast Cancer Simulation Model, a member of National Cancer Institute-funded Cancer Intervention and Surveillance Modeling Network (CISNET) breast cancer working group, to incorporate risk-based screening based on risk assessment models. CISNET models have been used by policy makers in 2009, 2016 and 2024 to set the breast cancer screening guidelines in the US. We developed and evaluated several personalized screening strategies based on an individual's breast cancer risk to improve the balance of benefits and harms as well as better allocate the clinical screening resources more efficiently.

Machine Learning Applications on Inventory Models

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Jingkai Huang, Zhejiang University, Hangzhou, N/A

Co-Chair: Kevin Shang, Duke University, Durham, NC, United States

1 - Data-Driven Optimal and Myopic Policies for Inventory Systems with Demand Covariates

Jingkai Huang, Zhejiang University, Hangzhou, China, People's Republic of, Kevin Shang, Yi Yang, Weihua Zhou

We study a multi-period backorder inventory system in which the random demand depends on exogenous covariates. The main goal is to develop a data-driven inventory policy that minimizes the total expected inventory cost. Based on the optimal policy structure under full distribution information, we first propose the Data-Driven Optimal (DDO) policy which utilizes a ``first predict, then optimize the residual-based empirical dynamic programming" framework, and provide its finite-sample performance bound. However, the DDO policy may suffer the curse of dimensionality, especially when the sample size is large. We then propose the simple myopic policy with covariates. With known distribution information, we characterize its optimality conditions and optimality ratio. With unknown demand distribution, we introduce the Data-Driven Myopic (DDM) policy and provide its finite-sample performance bound. Interestingly, we can show that the DDM policy performs the same as the DDO policy under a small sample size. We further propose another simple policy, called semi-myopic policy which takes the future costs into account, while maintaining a simple structure. The idea is to approximate cost-to-go functions by those from the classic multi-period inventory system without covariates which can be easily solved. We prove that the optimality condition of semi-myopic policy is looser than that of myopic policy. Accordingly, we also propose Data-Driven Semi-Myopic (DDSM) policy for the unknown demand case. Finally, we extend the main results to the scenario with correlated demand covariates. Numerical studies demonstrate that both heuristic policies perform well, while the semi-myopic policy performs better.

2 - Online Learning for Dual Index Policies in Dual Sourcing Systems

Jingwen Tang, University of Miami, Coral Gables, FL, United States, Boxiao Chen, Cong Shi

We consider a periodic-review dual-sourcing inventory system with a regular source (lower unit cost but longer lead time) and an expedited source (shorter lead time but higher unit cost), under carried-over supply and backlogged demand. Unlike existing literature, we assume that the firm does not have access to the demand distribution a priori and relies solely on past demand realizations. Even with complete information on the demand distribution, it is well-known in the literature that the optimal inventory replenishment policy is complex and state-dependent. Therefore, we focus our attention on a class of popular, easy-to-implement, and near-optimal heuristic policies called the dual-index policy. The performance measure is the regret, defined as the cost difference of any feasible learning algorithm against the full-information optimal dual-index policy. We develop a nonparametric online learning algorithm that admits a regret upper bound of O(\sqrt{T log T}), which matches the regret lower bound for any feasible learning algorithms up to a logarithmic factor. Our algorithm integrates stochastic bandits and sample average approximation techniques in an innovative way. As part of our regret analysis, we explicitly prove that the underlying Markov chain is ergodic and converges to its steady state exponentially fast via coupling arguments, which could be of independent interest. Our work provides practitioners with an easy-to-implement, robust, and provably-good online decision support system for managing a dual-sourcing inventory system.

3 - Dynamic Pricing with Infrequent Inventory Replenishments

Boxiao Chen, University of Illinois Chicago, Chicago, IL, United States, Menglong Li, David Simchi-Levi

We consider a joint pricing and inventory control problem where pricing can be adjusted more frequently than inventory ordering decisions. We consider the situation where the demand-price function and the distribution of random demand noise are both unknown to the retailer. We propose an online learning algorithm that achieves the optimal convergence rate to the true optimal solution.

4 - Multi-Period Newsvendor Optimization for Capacity Planning

Gah-Yi Ban, Imperial College Business School, London, United Kingdom, Abhilasha Katariya, Chinmoy Mohapatra, Liron Yedidsion

Capacity planning in Amazon Logistics is inherently a multi-period decision problem, whereby decisions are made and adjusted weeks in advance of deliveries. We formulate and solve a multi-period newsvendor optimization model for Amazon Logistics capacity planning. Since the general multi-period problem is computationally intractable, we propose four computationally efficient heuristic solutions: (i) a solution equivalent to the single-period newsvendor solution (NV), which is reflective of the current state-of-the-art, (ii) an extension of the newsvendor solution that takes ramp-up and down costs into account (NV+), (iii) a linear decision rule-based solution (LDR) and (iv) a hybrid of NV+ and LDR solution to solve the problem numerically. Our numerical results show that the multi-period solutions (LDR and Hybrid) outperform the single-stage solutions (NV and NV+) when the demand model exhibits non-stationarity and dependence over time, which can translate to substantial cost savings.

5 - Two-Sided Pricing and Learning with Inventory Constraints

Meichun Lin, Singapore Management University, Singapore, Singapore, Tim Huh

Motivated by online used-car platforms, we study pricing decisions for purchasing and selling a product in a two-sided market. With uncertainty from both supply and demand, a platform sequentially adjusts purchase and selling prices to maximize profit while satisfying inventory constraints. Moreover, the platform does not know in advance how supply and demand depend on the prices. Our work investigates how the platform can manage demand and supply in the presence of the two sides of uncertainty and inventory constraints. When the demand and supply functions are known, we show that simple fixed-price policies can be implemented with a small performance loss. Given limited information on supply and demand, we propose pricing algorithms that achieve the best possible regret when the planning horizon is large, which sheds light on how to balance the trade-off between two sides of learning and profit maximization (earning).

New Advancements in Partially Observable Markov Decision Processes (POMDPs)

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Hao Zhang, University of British Columbia, Vancouver, BC, V6S 0H1, Canada

1 - Exact Solution to a Machine-Maintenance Problem with Multiple Unobservable States

Cong Yang, University of British Columbia, Vancouver, BC, Canada, Hao Zhang

We study a classic machine maintenance problem with multiple unobservable machine states. The state of the machine deteriorates according to a Markov process. The decision maker can choose from three actions---production, inspection, and replacement. Assuming perfect inspection, perfect replacement, and production without monitoring, the model is simplified to its essence while still encompassing a comprehensive and intricate optimal solution. We identify several possible structures of the optimal solution, which can be conveniently represented by graphs with multiple absorbing cycles. These cycles describe the steady-state phase of the optimal policy, which is endowed with desired features such as 'condition-based maintenance', 'dynamically scheduled inspections', and 'postponed replacement after an inspection'. Based on the analysis of these structures, we develop a policy iteration algorithm capable of finding the exact optimal solution in finite time. We also obtain a full characterization of the optimal solution in the three-state special case. This study fills a visible gap in our quest for optimal solutions for machine maintenance problems.

2 - Structural Estimation of Partially Observable Markov Decision Processes and Their Psychology Applications

Yanling Chang, Southern Methodist University, Dallas, TX, United States

Partially Observable Markov Decision Processes (POMDPs) is a well-developed framework for sequential decision making under uncertainty and partial information. This paper considers the (inverse) structural estimation of the primitives of a POMDP based upon data in the form of sequences of observables and implemented actions. We analyze the structural properties of an entropy regularized POMDP, specify conditions under which the model is identifiable without knowledge of the state dynamics, and develop a soft policy gradient algorithm to compute a maximum likelihood estimator. We apply the method to learn (i) mental fatigue dynamics which cannot be accurately observed in workplaces, and (ii) the net subjective task value for exerting cognitive control under different fatigue levels. Tested via a standard cognitively demanding n-back task, the method accurately inferred hidden fatigue dynamics and the agent's reward function. More importantly, the simulations and predictions of the fitted model are consistent with classic findings from existing empirical studies.

3 - Efficient Discovery of Cost-Effective Policies for Sequential Medical Decision-Making Problems

Narges Mohammadi, Imperial College London, London, United Kingdom, Reza Skandari, Anand Shah

Cost-effectiveness analysis (CEA) is extensively employed by healthcare policymakers to guide funding decisions and inform optimal design of medical interventions. In the CEA literature, willingness to pay (WTP) serves as a common metric for converting health benefits into monetary value and defining the net monetary benefit of an intervention. However, there is no universally accepted value for WTP. To address this issue, we propose presenting policymakers with a comprehensive menu of strategies that are proven cost-effective across a reasonable range of WTP values. In our approach, we consider a setting where the medical decision-making process can be formulated as a parametric linear programming model. We have developed a novel algorithm aimed at efficiently constructing the menu of cost-effective policies. Our algorithm is particularly suited for Constrained Markov Decision Process (CMDP) and Constrained Partially Observable Markov Decision Process (CPOMDP) models, which are commonly utilized modeling frameworks for addressing sequential medical decision-making problems. We have applied our modeling framework to design hearing loss screening strategies for cystic fibrosis patients. Informed by a validated, data-driven model, we have developed several heuristic and approximate policies, allowing policymakers to balance between performance and ease of implementation.

4 - Optimal Learning and Management of Threatened Species

Jue Wang, Smith School of Business, Queen's University, Kingston, ON, Canada, Xueze Song, Roozbeh Yousefi, Zhigang Jiang

Amid an unprecedented loss of biodiversity, a pressing issue is how to improve the efficiency of conservation with limited resources and information. Collecting data on species with a small population is costly and time-consuming, and many high-stake decisions need to be made based on limited data. We develop a partially observable Markov decision processes (POMDP) model with unknown parameters to jointly optimize the information collection and protection efforts for threatened species. The model takes into account uncertainties about the state, detectability, and dynamics of the species, and adaptively adjusts the efforts of surveying and protection in real time. Although the standard formulation is intractable, we exploit the structure of ecological problems to identify a hybrid belief state in low dimension, and reformulate the stochastic dynamic program as a piecewise deterministic optimal control problem. We also conduct a case study on the conservation of Hainan Gibbon, the rarest primate species, in which we extend the model to optimize the spatiotemporal allocation of limited resources.

Retail Analytics

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Zumbul Atan, Eindhoven University of Technology-Industrial Engineering &Innovation Sciences, Eindhoven, Netherlands

Co-Chair: Alexander Huebner, TU Munich, Straubing, Germany

1 - Perishable Inventory Management under Freshness Dependent Stochastic Demand and Backroom Operations

Ilgin Efe Senyuva, Eindhoven University of Technology, Eindhoven, Netherlands, Melvin Drent, Zumbul Atan

We study a discrete-time perishable inventory management problem in which a retailer sells a single product whose lifetime decays linearly with time. Consumers value products with a higher remaining lifetime more than they value ones with lower remaining lifetimes. We assume that there is only a single batch of products with the same lifetime on the shelves. Periodically, the retailer can replace the old batch of products that are not yet sold with a new batch of fresh products. This induces a higher demand, but comes at a discarding cost. We formulate this problem as a Markov decision process and find the optimal policy through value iteration. Through simulations, we compare the optimal policy with myopic, near-myopic, base-stock and base-lifetime heuristic policies. The numerical experiments provide insights into the practical settings in which each heuristic performs well. Finally, we study multiple extensions to our problem. We include backroom operations in which products can be stored that decay at a lower rate. Here, we assume a non-fixed remaining lifetime when the replenishment is made, and make the replenishment batch size dependent on the displayed lifetime to account for products being mishandled at the backroom. We use the heuristics and optimal policies for our original problem as heuristic policies in these extensions and we show numerically how well they perform.

2 - Dynamic Cart Recommendation with Demand Learning

SHIWEI CHAI, University of Florida, Gainesville, FL, United States, Yining Wang, Lucy Zhang, Xiajun Pan

We consider an assortment recommendation problem in the context of an online shopping platform. Each customer, after arriving at the platform, picks up a primary product and adds it to the shopping cart. Based on the choice of the primary product, the platform then recommends at most K auxiliary products to the customer to maximize its revenue. We characterize customers' decision to buy an auxiliary product by a multinomial logit choice model, but the valuation of each product is unknown to the platform. This problem is closely related to the so-called MNL-bandit problem (Agrawal et al. 2019), but since the auxiliary product is recommended after observing the choice of the primary product, providing the same assortment repeatedly is not possible in our setting (which however is the key component in the algorithm design to derive unbiased estimators in Agrawal et al. (2019)). To overcome this challenge, we propose a new algorithm (MLE-UCB) based on the maximum likelihood estimation. Finally, a case study using the calibrated real-world data from a large online shopping platform in north America shows the proposed algorithm performs well empirically.

3 - Optimizing Assortment and Inventory on Shelves When Products Perish

Alexander Huebner, TU Munich, Straubing, Germany

Optimizing retail assortments is essential to maximize revenues, but also can have an impact on inventory ages and therefore product expiration. The limiting condition for assortment decisions is the shelf space of retailers. Assuming a constant available, but in size restricted shelf space, the assortment size also defines how much shelf space each product gets, and therefore how much items of each product can be stored on the shelf. That is why assortment planning is also important in terms of inventory management. Especially for perishable products, the inventory level on the shelf has to be carefully chosen in order to prevent deteriorating overstocks. Current literature considers single-period assortment and shelf space models, despite products can be stored and replenished over multiple sales periods, leading to different expiration dates on the shelf. We contribute with an assortment and shelf space model that considers replenishment and customer withdrawal over several periods, taking into account stochastic demand, space elasticity, substitution effects and customer's freshness preferences. To solve the model, we use an iterative heuristic approach with a recurring update of demand to account for substitution effects and their impacts on the assortment and shelf space decisions.

4 - Multi-product pricing: A customer choice model and a dynamic pricing approximation

Zumbul Atan, Eindhoven University of Technology-Industrial Engineering &Innovation Sciences, Eindhoven, Netherlands, Laura Sprenkels, Ivo Adan

We study a retailer's pricing problem of substitutable products. Demand is influenced by selling prices and availability of inventory. Assuming stationary demand process, we aim to find the optimal selling prices of the products. We study two practical variants of the problem. In the first one, we consider an infinite time horizon. Our model includes both customers' willingness to pay and substitution behavior explicitly, and can handle any type of correlation between products. For this problem, we present a new customer choice model. In the second variant, we consider a finite time horizon and finite amount of inventory, and we develop a dynamic pricing approximation for the selling prices.

Sustainability and Technology

Invited Session

MSOM: iForm

Chair: Rowena Gan, Cox School of Business, Southern Methodist University, Dallas, TX, United States

Co-Chair: Rong Li, Syracuse University, Syracuse, NY, United States

1 - Contract Tokenization in the Renewable Energy Market

Rowena Gan, Southern Methodist University, Dallas, TX, United States

Endorsed by the blockchain technology, supply chain contracts can be digitally recorded and stored in crypto tokens, which is referred to as being tokenized. Tokenized contracts offer new ways of financing, trading and owning an asset. Using the renewable energy market as a backdrop, we study the impact of contract tokenization on different parties in the supply chain based on their respective incentives.

2 - Delivery Terms for Voluntary Carbon Offsets

Safak Yucel, Georgetown University, Washington, DC, United States, Vishal Agrawal, Gokce Esenduran

In addition to abating emissions, corporations purchase carbon offsets for voluntary decarbonization targets, such as reaching net-zero emissions. A carbon offset represents emissions reduction achieved by a developer through investments in projects, such as forestry and renewable energy. Corporations purchase offsets under two delivery terms. The first is forward delivery, where the buyer orders a certain quantity before the seller undertakes the investment and yield uncertainty realizes. The second is prompt delivery, where the seller invests and uncertainty realizes, before the buyer orders offsets. Motivated by the importance of choosing the right delivery term for buyers and sellers, in this paper, we investigate economic and environmental implications of these delivery terms. Our results offer several managerial insights: First, a seller should prefer forward delivery if investment cost is low, but prompt delivery otherwise. Although one would expect that the delivery term that enables the seller to make a higher investment results in a higher profit, we find that prompt delivery may lead to a higher profit despite lower investment. Second, a buyer should prefer forward delivery only for a project with either a low or high investment cost.

Interestingly, the delivery term that leads to a lower cost for the buyer may actually require higher abatement. Finally, environmental groups should promote forward delivery only for a project with a low investment cost. Moreover, when the buyer and seller prefer different delivery terms, the one preferred by the seller leads to greater emissions reduction, and should be promoted by environmental groups.

3 - Integrated Planning of Power System and Hydrogen Supply Chain

Siqiang Guo, University of Missouri-St. Louis, St. Louis, MO, United States, Erhan Kutanoglu, Shadi Goodarzi

Hydrogen is important as it can serve as a carrier of clean energy, providing decarbonization solutions to sectors that are highly carbon-intensive and hard to electrify (e.g., steelmaking). As the proportion of renewable energy in the power system continues to grow, hydrogen's role in mitigating the energy supply and demand discrepancies (both temporally and spatially) will become even more crucial. However, the hydrogen economy currently faces many challenges, such as the high cost of green hydrogen and the lack of adequate infrastructure. The diversity of the power system and hydrogen supply chain (in terms of energy/hydrogen production, transportation, and storage) and the close correlation between them complicate the expansion of both systems. This complexity is intensified by the potential influence of various environmental policies such as carbon allowance, carbon tax, and clean hydrogen subsidy. We provide a model for the joint optimization of the power system and hydrogen supply chain, and we delve into the aforementioned environmental policies, examining their impact on the entire system. Our detailed analysis reveals the rationales of different policies and yields several efficient policy combinations that can achieve significant carbon reduction (50 - 80%), maintain corporations' decision-making flexibility, ensure a low decarbonization cost for both corporations and society (< $65/ton of CO_2), while not adding significant burdens to corporations (< 3% cost increase).

4 - Collective Power Purchase Agreement Negotiation and Risk Sharing

Xiaoxuan Hou, University of Washington, Seattle, WA, United States, Shi Chen

Over 400 companies spanning more than 175 markets worldwide have committed to 100% renewable electricity. But achieving these goals can be challenging. In the past decade, long-term power purchase agreement (PPA) has gained popularity among large corporations like Google and Amazon (buyers) as the main vehicle to source supply from renewable energy developers (the seller). Under a PPA, the buyer commits to purchasing the renewable energy from the seller at a fixed price for a predetermined length of time (usually 10 to 15 years). Yet signing a PPA remains difficult for small-to-medium-sized corporate buyers, who may be too small to sponsor a full project, not have the expertise, or lack sufficient negotiation power on their own. As a result, collective PPAs emerged as a potential solution. We build Nash bargaining-based economic models to compare the performance of three negotiation mechanisms for these small-to-medium buyers to sign PPA contracts collectively: separate negotiation, agent-based negotiation, and joint negotiation. Our analysis reveals the impact of different mechanisms on the renewable project size in equilibrium and different players' preference. Assuming risk neutrality, our findings indicate that the three negotiation mechanisms lead to identical equilibrium project sizes, thus contributing equally to adding renewable capacity to the grid. Yet conflicts of preference for different negotiation mechanisms exists among parties, and rising number of buyers simplifies the consensus-building process for adopting joint negotiations. Further, buyers' perception of risks due to the uncertainty of the future market prices can harm the achievement of the sustainable goals.

Enhancing Service Operations in Digital Platforms and Healthcare

Invited Session

MSOM: Service Operations

Chair: Chloe Glaeser, UNC Kenan-Flagler Business School, Chapel Hill, NC, United States

1 - Can Employees&Rsquo; past Helping Behavior be Used to Improve Shift Scheduling? Evidence from ICU Nurses

Yixin Iris Wang, University of Illinois at Urbana-Champaign, Champaign, IL, United States, Zhaohui Jiang, John Silberholz, Deena Costa, Michael Sjoding

Employees routinely make valuable contributions at work that are not part of their formal job description, such as helping a struggling coworker. However, the degree to which the past helping behavior of employees scheduled to a shift impacts that shift’s operational outcomes remains an under-explored question. Our empirical results indicate that shift-level past helping measures are predictive of patient length of stay (LOS), more so than the broadly studied notion of team familiarity. Counterfactual analysis shows that relatively small changes in shift composition can yield a significant reduction in total LOS. Overall, our study suggests the potential value of shift scheduling using data on past helping behaviors, which may have promise far beyond the selected application to ICU nursing.

2 - Predictive Modeling of Relapse Rates and Simulation for Improved Early Intervention in Opioid Treatment Centers

Umit Celik, UNC Kenan-Flagler Business School, Chapel Hill, NC, United States, Bradley Staats

This study employs machine learning to predict relapse rates among opioid treatment patients, aiming to enhance early intervention strategies. Utilizing a dataset from over 200 U.S. opioid treatment facilities, we develop a predictive model using ensemble machine learning techniques, including random forests and logistic regression. This model identifies patients at high risk of relapse, facilitating the creation of personalized intervention strategies.

We apply simulation techniques to evaluate the causal effect of these targeted interventions in real-world scenarios, focusing on improving treatment outcomes and resource allocation. Preliminary results indicate that our predictive approach significantly improves the accuracy of risk assessments, enabling healthcare providers to implement more effective and efficient interventions.

This research demonstrates the potential of machine learning in transforming opioid treatment strategies, ultimately contributing to better patient care and enhanced operational efficiency in healthcare settings.

3 - Multihoming on on-Demand Ride-Hailing Platforms

Jaelynn Oh, The University of Utah, Salt Lake City, UT, United States, Kaitlin Daniels

We study the informational value of single homing on on-demand ride-hailing platforms.

4 - The Impact of Entry Fee Increase on Emergency Department Demand: a Territory-Wide Study in a Universal Healthcare System

Hyun Seok (Huck) Lee, Korea University Business School, Seoul, Korea, Republic of, Eric Park, Timothy Rainer

Emergency department (ED) overcrowding is a global health problem as it disrupts EDs' role as a public safety net. Several countries have increased the financial burden on access to ED care by increasing the ED entry fee in hopes of reducing patient traffic to mitigate ED overcrowding. We perform a territory-wide study of the universal public health system of Hong Kong SAR and empirically investigate the impact of the increase in the entry fee for the ED in June 2017 from HK$100 (US$13) to HK$180 (US$23) on the behavior of the visit of patients in the ED. In addition, we examine the heterogeneous effect between different types of patients.

1 - Lower Price OR Entry Barrier? Technical Service Design for Customers of Varying Expertise: An Application to 3D Printing Rental Business

Yue Zhang, Pennsylvania State University, University Park, PA, United States, Brian Tomlin

Customers with short-term, low-volume 3D printing (3DP) needs can rent a printer from a manufacturer or distributor (hereafter, OEM), or use a third-party printing service provider (hereafter, print farm). The customers vary in their 3DP expertise and will therefore differ in their cost of attaining any quality if using a rented printer, whereas print-farm technicians are experts in 3DP. Customers can choose to rent a printer and conduct 3DP on their own to attain qualities that maximize their payoff, or to delegate their needs to print-farm technicians who attain the desired qualities for them. To compete with print farms, OEMs can choose to offer technical service that augments the expertise of customers who rent printers. Technical service can be provided along with printer rentals in different formats - some OEMs bundle service with rentals whereas others offer optional service. Moreover, OEMs can adopt a standard approach to offer technical service in an identical way to all customers, or alternatively adopt a customized approach that caters the technical service offering to each customer's expertise. In this paper, we explore both approaches to study how (in terms of magnitude, format and price) should technical service be offered, and how customer expertise distribution influences the optimal offering and the OEM profit.

2 - Delegated Customization Using Retail 3D Printing

Ali Parlakturk, University of North Carolina Kenan-Flagler Business School, Chapel Hill, NC, United States

Retail customization with partially 3D printed products with traditionally manufactured cores has gained significant interest in recent years as a means of offering customized products. we propose a modeling framework that allows for partial customization using 3D printing while also capturing the impact of customer waiting time, quality issues, and inventory management.

3 - Minimizing the Number of Late Parts in Additive Manufacturing

Michael Stott, Texas A&M University, College Station, TX, United States, Jon Stauffer, Chelliah Sriskandarajah

Additive Manufacturing is a process by which three-dimensional components and products are made via the addition of material in a layer-by-layer fashion. This manufacturing technique has begun to see serious commercial usage given its advantages in creating very dense or complex geometries as well as highly customizable components. This paper studies the Nesting and Scheduling problem within the Additive Manufacturing context and shows the problem of minimizing the Number of Late Parts is strongly NP-hard even if the nesting of jobs is given. We also study and evaluate the performance of efficient heuristic algorithms to minimize this measure for given nesting of jobs, Heuristic algorithms are extended to study the problem with job nesting as well. An extensive computational study is contacted to evaluate the performance of these algorithms. These results are not currently shown in the literature. Moreover, all complexity results with nesting are obtained using minimal problem instances in the sense that parts are identical and differ only in their length but width and height of the parts are same. Consequently, these problem instances do not require any complex 2D or 3D packing algorithms for finding the nesting of jobs. In this way, the complexity results obtained here are unique and provide insights in to the complexity of nesting problems with minimal problem instances. We also study related scheduling problems under generalized due date problems context.

4 - Predictive Spare Parts Printing Using Sensor Information

Ipek Tanil, Eindhoven University of Technology, Eindhoven, Netherlands, Rob Basten, Collin Drent

We present our research on predictive spare parts printing on-site with sensor information to benefit from the additive manufacturing (AM) capability on time. AM enables the production of spare parts with an extremely short lead time, thereby enabling a faster supply solution than regular replenishments from the original equipment manufacturer. The former is however more expensive than the latter, which leads to a trade-off. We investigate this trade-off in the context of spare parts provisioning for a partially observable degrading system. Specifically, we consider a system with embedded sensors that relay classification data of critical components. We then propose a Bayesian procedure to infer from this data and the confusion matrices of the classifiers whether these critical components are nearing failure. Using this Bayesian procedure, a decision maker responsible for the uptime of the system needs to sequentially decide whether to predictively print spare parts or replenish spare parts from the regular supplier. To analyze this sequential decision problem, we formulate a partially observable Markov decision process. In an extensive numerical study, we investigate the trade-off between predictive printing and replenishing parts from the supplier. Notably, our numerical analysis gives answer to when it is optimal to print or order a part, and how this decision is impacted by various input parameters. The findings of this study allow us to quantify the benefit of using AM for printing spare parts with sensor information.

1 - Generative AI Can Harm Educational Outcomes

Alp Sungu, The Wharton School of the University of Pennsylvania, Philadelphia, PA, United States, Hamsa Bastani, Osbert Bastani, Haosen Ge, Rachel Mariman, Ozge Kabakci

Generative artificial intelligence (AI) is poised to revolutionize how humans work and has already shown promise in significantly improving productivity. However, a key question remains: how does generative AI affect learning, specifically how humans acquire new skills while performing tasks? This skill learning is critical for long-term productivity gains, especially in areas where generative AI is fallible and human experts must check its outputs. We studied the impact of generative AI, specifically OpenAI's GPT-4, on human learning in high school math classes. In a field experiment involving nearly a thousand students, we deployed and evaluated two GPT-based tutors: one mimicking a standard ChatGPT interface (GPT Base) and one with prompts designed to safeguard learning (GPT Tutor). These tutors comprised about 15% of the curriculum in three grades. Consistent with prior work, our results show that access to GPT-4 significantly improves performance (46% improvement for GPT Base and 131% for GPT Tutor). However, when access was subsequently removed, students performed worse than those who never had access (17% reduction for GPT Base). This indicates that GPT-4 can harm educational outcomes. These negative effects were largely mitigated by the safeguards in GPT Tutor. Our findings suggest that students use GPT-4 as a "crutch" during practice, leading to poorer performance on their own. To maintain long-term productivity, we must deploy generative AI cautiously to ensure humans continue to learn critical skills.

2 - Ai Inventory Co-Pilots for Data-Driven Perishable Inventory Management

Yu Nu, Cornell University, New York City, NY, United States, Meng Qi, Elena Belavina, Karan Girotra

This study explores using AI tools for reducing food waste in commercial food service establishments. We first examine the impact of building computer vision based systems to accurately measure and classify food waste, which provides high-fidelity transaction-level data on how food is wasted in a food service establishment. We quantify the value of deploying such systems, with early pilot trials indicating 30%~40% waste reduction. Moreover, we develop AI co-pilots that assist kitchen managers in managing inventory with a food waste reduction objective. These co-pilots could be prescriptive in providing directions on how to order, or simply watch out and detect when managers may be subject to biases and make mistakes in food production.

3 - Food Safety Risk Propagation Within Agricultural Supply Chains

Jane Wang, Massachusetts Institute of Technology, Cambridge, MA, United States, Retsef Levi, El Ghali Ahmed Zerhouni, Yanchong Zheng

Before reaching consumers, food products flow through multiple supply chain locations, including production, processing, and distribution points. At each location, these products can be exposed to adulterants such as environmental contaminants, pesticides, and food additives which can increase their food safety risk. Thus, understanding how food safety risk "spread" within the supply chain can inform the design of timely and resource-efficient regulatory strategies to protect consumers. Leveraging a comprehensive self-constructed database of 11.3 million food safety test records in China, this study builds a unique panel data set to evaluate food safety risks propagation within the supply chain. Specifically, it develops a causal inference assessment of the product-level and adulterant-specific propagation effect of food safety risks from upstream wholesale markets and wet markets (WSMs/WMs) to more downstream supply chain locations such as retailers and restaurants. The key findings of this study highlight several regulatory insights. Notably, effective food safety risk management for perishable products can benefit from more frequent testing in WSMs/WMs. In particular, frequent testing for pesticides and veterinary drugs in WSMs/WMs can effectively prevent risk associated with these adulterants from propagating downstream. On the other hand, food additives/illegal non-food substances and environmental/microbial contaminants require additional inspection at the manufacturer and retail level.

4 - Financial Access or Price Premiums? A Nuanced View into Improving Farmer Welfare and Reducing Child Labor in Commodity Supply Chains

Andreas Kilian Gernert, KLU, Hamburg, Germany, Andre Calmon, Dan Iancu, Luk Van Wassenhove

Millions of smallholder farming households engaged in the production of agricultural commodities grapple with poverty and resort to their children's labor to boost production and enhance their living conditions. In response, governments, commodity-buying firms, micro-finance institutions, and non-profits have initiated various interventions to improve household welfare and mitigate child labor, but the effectiveness of these interventions remains uncertain. Drawing inspiration from cocoa supply chains, we propose a model that captures a farming household's need to secure basic subsistence, alongside its decisions on borrowing, saving, consumption, and the reliance on child labor for farm production. With this model, we evaluate the effects of common financial interventions, including improved access to credit and savings and the implementation of price premiums, examining their impacts on household welfare, immediate consumption, and child labor usage. Our analysis reveals a complex landscape: improved access to credit can either decrease or inadvertently increase child labor, depending on whether households borrow for subsistence or discretionary expenses.

Conversely, enhancing access to savings invariably curtails child labor but might simultaneously depress household consumption. Furthermore, price premiums can effectively diminish child labor usage only when they are significantly large; otherwise, they may inadvertently incentivize increased child labor. These results highlight the dual-edged nature of financial interventions and underscore the critical need for tailoring strategies to the specific operational dynamics of farming households, ensuring interventions do not inadvertently exacerbate the issues they aim to resolve.

1 - Community Engaged Learning as a Tool for Learning Community Systems

EunSu Lee, New Jersey City University, Jersey City, NJ, United States

This research explains the practices of civic engagement and discusses directions to improve them in the classroom. During the students' activities, the concept of Public Operations Research was introduced, and students identified community issues and provided data-based decision making.

2 - "Exploring Digital Logistics Living Lab: Implementing Vehicle-to-Vehicle Transshipment for Small Business Expedited Delivery

HanByul Ryu, Inha University, Michuhol-gu, Korea, Republic of, Daisik Nam

With the growth of the e-commerce and logistics markets, the demand for expedited delivery services, such as same-day delivery, has been increasing. Consumers now expect same-day or next-day delivery as a standard, raising the expectations for logistics services, in turn, small businesses lose their competency with massive ecommerce platforms such as Amazon and Coupang. While previous studies have focused on the increased utility for consumers and the efficiency of carriers for same-day delivery, there is a lack of research on the utility of same-day delivery for small businesses. Small businesses, characterized by lower volumes and minimal inventory, require logistics services beyond traditional solutions like Fulfillment Centers, which are often designed with higher demand in mind. This study presents the planning and implementation of a digital logistics living lab project in collaboration with local governments in South Korea, driven by governmental initiatives and public-private partnerships. We demonstrate the viability of a logistics network utilizing vehicle-to-vehicle transshipment to achieve same-day delivery goals. We also analyze the impact of expedited delivery goals for small businesses and the community. Results indicate an increase in sales and social utility for small businesses. This research is expected to provide critical insights for the formulation of policies and strategies to support small businesses.

3 - Retirement decision-making: When is the right time?

Ilbin Lee, University of Alberta, Edmonton, AB, Canada, Mehrnaz Behrooz, Ivor Cribben

Retirement is a crucial stage in life and a significant life transition that requires careful planning and decision-making. Commencing retirement planning at younger ages enables individuals to make smarter decisions and provides them with a broader spectrum of choices as they age. In this research, we developed a Markov Decision Process (MDP) model to optimize retirement decisions while refining its parameters through data analytics of longitudinal datasets. Initially, we discerned which and how different factors, such as health, marital status, gender, income, etc., affect retirement determinants, including retirement age and type (voluntary/involuntary). Subsequently, we devised a personalized MDP model to delineate the optimal retirement age and savings strategy. Our model determined the optimal age for retirement based on factors such as health status, risk tolerance, income, and savings levels. Furthermore, the empirical results of our model suggest that retirement can be expedited by beginning to save at younger ages. These insights hold significance for policymakers aiming to refine pension programs and individuals striving to enhance their retirement prospects through informed planning.

4 - Conjoint Analysis and IPA of OTT service

Junho Lee, Korea University Business School, Seoul, Korea, Republic of, Hosun Rhim

We conduct text mining to extract attributes reflecting user opinions by collecting reviews of OTT users through web crawling. Conjoint analysis is performed to obtain part-worth for all attributes. IPA is used to identify attributes to prioritize sequence of the development.

5 - Conjoint Analysis of M-Commerce

Jaejun Hwang, Korea University Business School, Seoul, Korea, Republic of, Hosun Rhim

We develop a service strategy of M-commerce firms based on conjoint analysis. Attributes are identified by text mining. We used 7,820 Amazon, Alibaba review data.

1 - A Stochastic Programming Approach for Patient Acceptance Decision-Making in Prenatal Care

Leena Ghrayeb, University of Michigan, Ann Arbor, MI, United States, Amy Cohn, Ruiwei Jiang, Alex Peahl

In current practice, depending on physician and clinic-related capacity constraints, prenatal care clinics define the number of patients they can accept by the number of patients that each physician can care for at any point in time. Once a patient is accepted to the clinic, they are considered under the provider's care for the entirety of their pregnancy. While this method is simple and provides clear guidelines, it does not account for the stochastic nature of patients' health states – patients may require additional appointments beyond their defined pathways due to complications during pregnancy. This can result in unexpected overutilization, overbooking, and poor scheduling practices, which are burdensome for clinics and can hinder access to care for patients. We propose a multi-stage stochastic programming approach to aid clinics in deciding how many patients to accept on a weekly basis, given patient-related randomness inherent in pregnancy. We derive upper and lower bounds for this model and draw insights about patient acceptance policies.

2 - Identify Medically Unnecessary Cesarean Deliveries

Emily Fainman, Texas State University, San Marcos, TX, United States, Beste Kucukyazici, TING WU

We first use semi-supervised learning methods to classify pregnancy women into low- and high- risk groups based on approximately 18 million individual birth records in the U.S. from 2016 to 2021.
We develop an innovative semi-supervising fuzzy clustering (S-FCMd) algorithm by introducing a distance measure for mixed data consisting of numerical and categorical variables. We develop an innovative semi-supervising fuzzy clustering (S-FCMd) algorithm by introducing a distance measure for mixed data consisting of numerical and categorical variables. The labelled observations incorporate prior medical knowledge and effectively speed up the convergence. The method of updating cluster medoid ensures a computational complexity proportional to the sample size. Our experiments on real-life and synthetic data demonstrate the efficiency of our algorithm for large datasets. Then, we validate the optimal delivery methods for two risk groups through post-delivery variables in the dataset. We perform statistical inferences to compare actual post-delivery complications resulting from natural births and C-Sections in each cluster, and thus figure out the optimal delivery mode for each patient group.

3 - The Role of Hospital Occupancy on Maternal Health Disparities

Rachna Shah, University of Minnesota, Minneapolis, MN, United States, Alison Murphy

Racial disparities in maternal health are well documented, with Black women 2.5 times more likely than non-Hispanic white women to experience a major complication or death. Unfortunately, both the overall rate of negative outcomes and the racial disparities are increasing. Social determinants of health (e.g., income, housing, and access to medical care) and structural racism are significant contributors to racial disparities. For example, perceived racism among Black women is associated with pre-term birth and racial disparities in infant health are higher in counties with higher implicit or explicit racial bias. In this study, we (1) Determine if the effects of provider workload are moderated by patient race. We ask if Black women are more impacted by workload than white women in the context of maternal health; (2) Determine if the above relationship is stronger in areas which higher level of implicit or explicit bias compared to areas with lower bias, and (3) Demonstrate the mechanism that we theorize to link workload with racial health disparities.

4 - Preventing Rural Obstetric Hospital Closures: a Multi-Level Optimization Approach

Meghan Meredith, Georgia Institute of Technology, Atlanta, GA, United States

Rural residents experience high rates of maternal mortality and travel far distances for obstetric care as rural obstetric hospitals are closing at an increasing rate. Rural hospital administrators are faced with challenging decisions to close their hospitals as they confront patient safety and financial viability concerns. In response to these closures, the US government has initiated many programs to prevent rural hospital closures and maintain access to high-quality obstetric care. We propose a multi-level optimization modeling approach to determine the optimal allocation of rural hospital closure prevention resources to maximize access to obstetric care. We incorporate multiple aspects of access, including quality and risk-appropriateness. A case study of the state of Georgia is presented to illustrate geographic access to obstetric care and the impact of optimally allocating resources.

Chair: Xiaoquan Gao, Purdue University, West Lafayette, IN, United States

1 - Achieving Rawlsian Justice in Food Rescue

Gerdus Benade, Boston University, Boston, MA, United States, Aydin Alptekinoglu

We explore a practical idea to achieve more fair outcomes in food rescue platforms that operate on a first-come-first-serve basis: Give priority to a select set of recipients – first dibs in claiming a food item – for a limited time window. We develop a general model of priority lists and show several structural results that characterize the optimal priority list for a given donation. The objective is to maximize the benefit (defined as pounds of food received) gained by the worst-off recipient on the platform, which is a Rawlsian notion of fairness. The model captures priority lists in their most general form: For each donation, it sets a release time for each potential recipient after which they will be notified of the donation. It can also accommodate perishability of food donations. Intuitively, our structural results show that it's optimal (in a max-min sense) to give higher priority to recipients that have received less than others in the past (so, they are currently among the worst-off) and to recipients that are slower than others in responding to posted donations. A simple index combines these two characteristics of recipients and provides the optimal priority ordering. We then construct an efficient algorithm to compute the optimal priority list for a given donation, which (in its most general form) boils down to setting notification times for each recipient. Finally, we present counterfactuals that quantify the potential impact of implementing this algorithm in practice by using historical data from our partner platform's Florida operations.

2 - Volunteer Management

Xinyuan Zhang, UNIVERSITY OF NOTRE DAME, South Bend, IN, United States, Eunae Yoo, Alfonso Pedraza-Martinez

Online volunteering platforms allow individuals to contribute to humanitarian projects remotely. This paper investigates user behavior in online volunteering platforms integrated within larger online communities with broader purposes. We study volunteers shifting between humanitarian and non-humanitarian projects, and its implications on volunteer retention.

3 - Enhancing Support for Survivors of Abuse Through Intelligent Volunteer Management

Rachel Wong, University of Toronto, Toronto, ON, Canada, Sheng Liu, Timothy Chan

In Canada, at least 1 in 5 women experience some form of abuse from a spousal partner with the economic repercussions of intimate partner violence (IPV) reaching an annual sum of $7.2 billion. Survivors risk losing everything they own when leaving an abusive relationship since moving and storing one's belongings is challenging due to financial, legal, and logistical barriers While shelters provide a temporary refuge, they seldom can assist with retrieval and/or storage of survivor's belongings. Shelter Movers stands out as the sole organization in Canada addressing this vital need. The organization uniquely offers free, survivor-focused moving and storage services, bridging a crucial service gap for those in need. Like many other non-profit organizations, they call on volunteers to provide essential services. As the demand surges, Shelter Movers face growing challenges in engaging and retaining volunteers to ensure a fast turnaround time for urgent service requests. Notably, fewer than five percent of the active volunteers in the pool regularly participate in move requests. The high volatility of service demand and volunteer availability further complicates the retention challenge. This work proposes an optimal model to match volunteers to 'move teams' considering underlying volunteer behavior based on past experiences. We utilize this matching and behavioral model in a multiclass queuing model to better understand system dynamics and make managerial recommendations for how Shelter Movers can better engage volunteers and improve volunteer retention.

4 - Keep Water Flowing: The Hidden Crisis of Rural Water Management

Chengcheng Zhai, University of Notre Dame, Notre Dame, IN, United States, Rodney Parker, Kurt Bretthauer, Alfonso Pedraza-Martinez, Jorge Mejia

In rural areas of sub-Saharan Africa (SSA), people rely on communal handpumps for clean drinking water. But these handpumps break down frequently. Thus, it is crucial to proactively maintain and reactively repair these handpumps to ensure continuous access to water. In this research, we study the optimal design of a water point maintenance program implemented by NGOs. We first conducted field research in Ethiopia and Malawi to better understand the context of water point maintenance. We then collected 56,344 water point functionality observations from NGOs implementing water point maintenance programs in the Central African Republic, Ethiopia, and Malawi. Lastly, we develop a Markov decision process that determines the optimal schedule for NGO mechanics to visit water points. We apply the optimization model to data from the three countries to identify the gap between practice and optimality, while exercising two heuristic policies (cyclic and responsive) observed in practice.

Advanced Modeling Techniques in Infectious Disease Management

Invited Session

Health Applications Society

Chair: Pinar Keskinocak, ISyE Georgia Tech, Atlanta, GA, United States

Co-Chair: Daniel Kim, Harvard Medical School & Massachusetts General Hospital, Boston, MA, United States

1 - The Benefits of Using Geospatially Detailed Agent-Based Models for Modeling Mitigation Strategies for Infectious Disease

Mark Roberts, University of Pittsburgh, Pittsburgh, PA, United States

The Public Health Dynamics Laboratory (PHDL) at the University of Pittsburgh has developed flexible, open-source agent-based modeling platforms to represent infectious diseases and evaluate prevention, mitigation, and treatment strategies across a wide variety of diseases, including influenza, Covid-19, measles, and others. By combining synthetic populations that are statistically equivalent to the real population in given areas, the models can incorporate characteristics of location and individual in their representation of the disease. This talk will describe successful representations of measles, influenza, and COVID-19.

We developed a national tool to example county-specific vaccination rates against measles after the Disneyland measles outbreak in 2014. Using location-specific data on schools, households, neighborhoods and workplaces, we could provide visual representations of the effect of decreasing vaccination for any county in the US. Similarly, using a modified SEIR model of influenza that operates within each individual in a simulation, we have investigated multiple vaccination and treatment strategies for both annual epidemic and pandemic influenza. Finally, by modifying the influenza model to represent the infectious and disease characteristics of COVID-19, we were able to estimate the impact of prevention and mitigation strategies in Pennsylvania prior to the widespread introduction of the COVID vaccine for the PA department of Health.

Agent-based models are particularly well suited to represent infectious diseases through their ability to alter the contact rates and infectivity of different people in different geographic locations.

2 - The Burden of Tuberculosis Among Foreign-Born Canadians: Estimates with Dynamic Models

Jeremy Chiu, Simon Fraser University, Burnaby, BC, Canada, Alexander Rutherford

Tuberculosis (TB) disease caused 1.6 million deaths worldwide in 2021. Foreign-born Canadians bear 80% of the burden of tuberculosis disease despite only comprising 23% of the total population in Canada. In this talk, we describe the pathology of TB and its unique characteristics that make it different from other infectious agents. We then illustrate how we investigate the impact immigration has on TB incidence.

We estimate the prevalence of latent TB infection (LTBI) among new immigrants by synthesizing census data with WHO reported tuberculin skin tests and smear positive tests. We also extend an SEIR (susceptible-exposed-infected-recovered) compartment model. The solution to the system of ordinary differential equations gives the distribution of actively infected, latently infected, and uninfected individuals among the foreign-born population. We then use Matlab's optimizer *fmincon*, a non-linear constrained optimizer, to infer unknown parameters by minimizing the least-squares differences between our model's computed incidence and prevalence vs Canadian reports.

We estimate that in 2014, 21.8% of new immigrants had latent TB infection, and that 0.73% were recently infected (2 years). Including this data in our model gives estimates that are consistent with Canadian reports of incidence and prevalence of active TB, a case study's findings on recurrent TB cases, and other estimates of LTBI-prevalence among foreign-born Canadians. This model can help inform policy to reach the Public Health Agency of Canada's goal to reduce incidence to <1 per 100,000 by 2035.

3 - A Multi-Agent Reinforcement Learning Framework for Evaluating the U.S. 'Ending the Hiv Epidemic' Plan

Dinesh Sharma, University of South Florida, Tampa, FL, United States, Ankit Shah, Chaitra Gopalappa

HIV remains a pressing public health issue in the United States, affecting approximately 1.2 million individuals, with 35,000 new infections annually. Disparities in HIV prevalence and access to care persist across different regions of the country. The 'Ending the HIV Epidemic (EHE)' initiative, launched in 2019, seeks to reduce new infections by 90% by 2030 by enhancing diagnoses, treatment, and prevention efforts, particularly in high-prevalence areas. However, existing decision models often focus solely on specific cities or the national population, failing to account for jurisdictional nuances and interactions. To address this gap, we propose a novel approach using multi-agent reinforcement learning (MARL) to analyze jurisdiction-specific interventions while considering cross-jurisdictional epidemiological dynamics. Our experimental analyses, conducted in California and Florida, reveal significant disparities between optimal policies derived from MARL versus single-agent reinforcement learning (SARL), underscoring the importance of accounting for jurisdictional variations and interactions. By leveraging comprehensive HIV modeling and tailored formulation of state space, action space, and reward functions, our study showcases the effectiveness of MARL in guiding public health policies and provides a scalable framework for informing the EHE at the national level.

4 - A Predictor-Corrector Algorithm for Estimating Time-Dependent Parameters of COVID-19 Models

Susan Rogowski, North Carolina State University, Raleigh, NC, United States

Stable parameter estimation is an ongoing challenge within biomathematics, especially in epidemiology. Oftentimes epidemiological models are composed of large numbers of equations and parameters. Due to high dimensionality, classic parameter estimation approaches, such as least square fitting, are computationally expensive. Additionally, the presence of observational noise and reporting errors that accompany real-time data can make these parameter estimation problems ill-posed and unstable. The recent COVID-19 pandemic highlighted the need for efficient parameter estimation tools. In this talk, we present a modified version of a regularized predictor–corrector algorithm aimed at stable low-cost reconstruction of infectious disease parameters. This method is applied to a novel compartmental disease model describing COVID-19 dynamics, which accounts for vaccination and immunity loss (from vaccinated and recovered populations). Numerical simulations are carried out with synthetic and real data for COVID-19 pandemic. We apply the predictor-corrector algorithm to reconstruct the time-dependent transmission rate and the effective reproduction number. This model and algorithm can easily be adjusted to be applied to other seasonal outbreaks.

Transportation and Network Optimization at Amazon

Invited Session

The Practice Section of INFORMS

Chair: Nicholas Kullman, Amazon, Bellevue, WA, United States

Co-Chair: Meltem Ozmadenci, Amazon, Seattle, WA, United States

1 - Optimizing Amazon's Network Flow Plan: A Decomposition Approach in Balancing Truck Fill Rates and Labor Utilization

Hyemin Jeon, Amazon.com, Bellevue, WA, United States, Theodoros Pantelidis, Martin Bagaram

Amazon's transportation network consists of different components whose operational plan rely on multiple layers of analytical tools to forecast, simulate, and optimize. As obtaining a solution that satisfies all business objectives concurrently is unrealistic over a large complex system such as Amazon's, many decisions are made isolated without the full awareness of other components. In this work, we introduce a coherent volume plan in order to maximize utilization of outbound truck capacity and labor supply on downstream processing sites concurrently. However, developing a mathematical formulation that captures all necessary dynamics between origin-destination pairs, i.e. fulfillment centers, sort centers and delivery stations has proven to be computationally intractable. Thus, we seek to decompose this complex problem into two components, one which contains the fulfillment center outbound network subgraph and aims to maximize truck fill rate and the other one that maximizes sort centers and delivery stations labor utilization. In this manner, each problem solves for a subgraph of the network and objective while remaining in parity via the propagation of minimum volume targets on fulfillment center outbound trucks generated by the second optimization problem that restrict the first problem solution. Hence, we approximate the global optimization solution for the entire network.

2 - COPPER: Contract Price Optimization Using Willingness-to-Pay Models for Amazon Freight

Yebin Tao, Amazon, San Mateo, CA, United States, Juan Xu, Roger Lederman

We develop COPPER, contract price optimization using execution and award models for willingness-to-pay (WTP), to replace the current manual and rule-based pricing mechanism for Amazon Freight (AF) contract. To capture shippers' WTP, we first build an award model to predict the probability of awarding a contract at a certain price, and then build an execution model to predict the number of executed loads given a contract awarded at a certain price. To estimate the optimal prices, we first consider each lane separately using simple grid search over a list of candidate prices, denoted as single-lane COPPER. As an enhancement, we further explore portfolio optimization by jointly considering lanes within the same portfolio (e.g., same pickup location), denoted as portfolio COPPER. We utilize coordinate descent to solve the high-dimensional portfolio price optimization efficiently. We conduct comprehensive model comparisons to build the WTP models and test the price optimization using the AF contracts that we bid on in 2023. From the test, single-lane COPPER shows significant improvements over the historical manual pricing with an estimated revenue increase of 13%, while portfolio COPPER would further increase revenue by another 10%.

3 - Air Cargo Revenue Management: A Two-Stage Stochastic Program with Learning-based Recourse

Yan Zhang, Amazon, Seattle, WA, United States, Nilay Noyan, Roger Lederman

In a logistics system, the space in trucks or airplanes unfilled by existing loads is considered as opportunity loss. To mitigate such loss, it is beneficial to find additional shippers who are willing to pay to use these space. However, finding such shippers could incur risk of displacing existing loads, due to the uncertain knowledge of the amount of unfilled space in the network. When displacement happens, existing loads are re-routed by a subsequent system at different displacement costs. To optimize the total revenue realized by the logistic system, it is critical to predict such displacement cost rendered by the subsequent routing system so that we can price shippers properly. To solve this problem, in this talk, we present a model-based machine learning approach to learn the routing decisions of the black-box system. Then, we incorporate the learned module into a two-stage stochastic programming problem, and solve the formulated problem using decomposition framework. The model estimates the value of the unfilled space in the logistic network, which will be used to set the price for shippers and to guardrail the revenue of the network.

4 - Accelerating Deliveries: Decomposition-based Approaches for Large-Scale Air Network Optimization

Tulio Toffolo, Amazon, Bellevue, WA, United States, Haroldo Santos, Valentina Vaca, Ruilin Ouyang, Wendian Wan, Na An

The Amazon Air Network Design (A2ND) tool is a patented model that optimizes flight schedule and package flow problems for Amazon Air. In recent years, features have been added to the model to incorporate optimization for package delivery speed, while maximizing aircraft utilization and minimizing operating cost. Over 70 types of operational constraints and a configurable objective function are used to explore network designs and perform trade-off analyses. As Amazon Air grew so did the size and complexity of the optimization model and computational performance became a bottleneck. This talk discusses the decomposition-based approaches developed to improve the scalability of the solver and the quality of the network solutions, including model generation and dynamic flight-set population. Computational experiments show a runtime reduction of more than 50%.

Nonconvex, Nonsmooth, and Nonregular Optimization: A Computational Framework

Invited Session

TutORial

Chair: Jamol Pender, Cornell University, Ithaca, NY, United States

1 - Nonconvex, Nonsmooth, and Nonregular Optimization: A Computational Framework

Michael Ferris, University of Wisconsin, Madison, WI, United States, Olivier Huber, Johannes Royset

Algebraic modeling languages presently lack the ability to effectively support the formulation and solution of nonconvex and nonsmooth optimization problems. Since an arbitrary problem of this kind is intractable, any hope to achieve practically useful solutions would rely on means to convey specific problem structure to an algorithm. In this tutorial, we present a framework for specifying nonconvex, nonsmooth, and nonregular problems within an algebraic modeling language that makes available the key structural properties to an algorithm. It also facilitates experimentation with different model formulations and algorithmic approaches. The framework entails a change of mindset away from the traditional formulation of objective and constraint functions, and instead asks the analyst to specify a basic feasible set, a basic objective function, one or more monitoring functions, and several performance functions. Eleven examples ranging from goal programming to variational inequalities and engineering risk analysis illustrate the practical implications of the framework.

Innovative Application of AI in Information Systems Research

Invited Session

Information Systems

Chair: Ali Tosyali, Rochester Institute of Technology, Rochester, NY, United States

Co-Chair: Jeongsub Choi, West Virginia University, Morgantown, WV, United States

1 - An Explainable Ai Framework for Identifying Deceptive Reviewers in E-Commerce Platforms

Ali Tosyali, Rochester Institute of Technology, Rochester, NY, United States

This study addresses the pressing issue of fake reviews on e-commerce platforms, which significantly impact consumer choices and threaten the credibility of online marketplaces. Recognizing the limitations of current methods focused on detecting individual fraudulent reviews, our research introduces a novel approach by examining the broader network of review activities. Leveraging insights from recent findings, we aim to identify and analyze the behavior of reviewers involved in fake review schemes. By using an advanced AI framework that integrates textual analysis, metadata, and network structure, we explore the characteristics that distinguish genuine reviewers from fraudulent ones. This comprehensive methodology not only enhances our ability to detect deceptive practices but also sheds light on the underlying mechanisms of online review manipulation, offering new avenues for improving the transparency and trustworthiness of online review ecosystems.

2 - Xscanner An Explainable Ai Approach for Comprehensive Screening and Pattern Analysis

Salih Tutun, Washington University in St Louis, St Louis, MO, United States, Ali Tosyali, Kazim Topuz, Anol Bhattacherjee

In this research, we introduce XScanner, an innovative explainable AI (XAI) approach designed for comprehensive screening and pattern analysis across various problems. XScanner leverages clinical data and protocols to ensure reliability, employing an XAI framework to predict outcomes and provide clear explanations of the underlying features influencing each prediction. This transparency is critical for building trust and acceptance of AI applications. XScanner distinguishes itself by generating full-color diagnostic images that visualize patterns in the data, akin to radiological images, offering a novel way for experts to interpret AI-driven insights. Unlike traditional black-box AI models, XScanner's explainability enhances its utility by making the decision-making process accessible and understandable to experts, thereby improving outcomes through informed decision-making. Our approach has been rigorously evaluated through various studies, demonstrating high classification accuracy with average F1 scores. These results underscore XScanner's potential as a powerful tool for early screening and analysis, capable of addressing the critical gaps in different business problems. XScanner represents a significant advancement in the screening and analysis. This research highlights the importance of transparency and explainability in AI, paving the way for future innovations that can enhance the accessibility and effectiveness of mental health care.

3 - Adaptive Sparse Pca: Enhancing Interpretability and Robustness in High-Dimensional Data

Yifan Xie, Rutgers University, Piscataway, NJ, United States

The surge in high-dimensional datasets has highlighted the limitations of traditional Principal Component Analysis (PCA), particularly the curse of dimensionality and the need for interpretable, sparse representations. Sparse PCA has emerged as a valuable tool to address these issues, but existing methods often rely on fixed thresholds, which can be suboptimal and inflexible. We introduce Adaptive Sparse PCA (AS-PCA), an innovative method that dynamically adjusts the sparsity threshold based on the data's intrinsic characteristics at each iteration. This approach ensures better adaptability, robustness to noise, and computational efficiency. By focusing on sparse principal components, AS-PCA enhances interpretability and generalization, making it especially suited for diverse datasets where fixed thresholds may fall short. Our theoretical analysis and empirical results demonstrate AS-PCA's superiority in balancing variance explanation and sparsity, offering a powerful tool for modern high-dimensional data analysis.

4 - Robust Wafer Defect Pattern Classification and New Defect Pattern Detection in Imbalanced Data Using Few-Shot Learning

Byunghoon Kim, Hanyang University, Ansan, Korea, Republic of

In the semiconductor industry, Wafer Bin Maps (WBMs) generated through Electrical Die Sorting (EDS) inspection are crucial for identifying defect patterns on a wafer. The WBMs facilitate the classification of defect patterns based on the specific locations and distributions of faulty chips. Defect patterns often stem from specific manufacturing processes. Using machine learning models to quickly classify Wafer Bin Maps (WBMs) during production can greatly enhance process yield and product quality. Additionally, detecting new defect patterns is also crucial to improve model reliability.

In this study, we utilize the Prototypical Network, a few-shot learning technique, to classify existing defective patterns and detect new ones. This method effectively handles imbalanced data and requires minimal data for each class, making it particularly well-suited for scenarios with limited data availability. To reflect real manufacturing conditions, we adapted the existing model and incorporated class prototypes into the validation process without relying on labeled data. We developed a method for generating prototypes that excludes improperly labeled data from the dataset. By establishing class prototypes and calculating the distances between validation data and these prototypes, we effectively classified existing defect patterns and detected new ones. Compared to previous research, our approach demonstrated superior classification accuracy, particularly in significantly enhancing the accuracy for minority classes.

5 - Machine learning based business competitor identification

Nathaniel Smith, West Virginia University, Morgantown, WV, United States, Jeongsub Choi

Competitor identification (CI) is an essential step for successful business strategy development by strategically navigating the business environment and making informed decisions. Due to the complexity, various approaches to identifying competitors have been studied in the literature to shed light on the blind spots of managerial radars. Recently, modeling with machine learning has been actively adopted for efficient CI with vast amounts of data. In this talk, we present experimental results from predictive models for CI based on business organizational profiles.

1 - What to Sell and When to Sell in Live Streaming? An Online Decision-Making Approach

Jingwen Zhang, University of Washington, Seattle, WA, United States, Shaohui Wu, Yong Tan

Livestream selling has emerged as a popular and influential e-commerce format, yet little is known about how hosts effectively sell products in this dynamic environment. This study investigates the decision-making processes of hosts in livestream selling, focusing on their product assortment and presentation timing strategies. We propose a novel approach that combines the online learning framework of Thompson Sampling and the COX proportional hazards model to capture hosts' learning and decision-making behaviors. Specifically, we employ Thompson Sampling to model how hosts learn consumer preferences, predict demand, and decide on the product assortment to present during their livestreams. Concurrently, we utilize the COX proportional hazards model to examine the factors influencing hosts' decisions on the timing of each product set presentation. By applying these models to a dataset from one of the largest livestreaming platforms in China, we demonstrate how our approach effectively captures hosts' product assortment and presentation timing decisions in real practice. Our findings provide valuable insights into the learning and decision-making processes of hosts in livestream selling and offer managerial implications for enhancing the effectiveness of this increasingly important e-commerce format.

2 - Using Noisy Interval Data in Information System Research: Theory and Applications

Wendao Xue, University of Texas at Austin, Austin, TX, United States, Huidi Ma, Yifan Yu

This paper examines inference in regression models where one latent variable is known to belong to an interval with a certain probability, while other variables are measured accurately. We demonstrate that, under certain assumptions, the parameters of interest constitute an identified set. We propose an estimator for this identified set and show that it can be consistently estimated. Two applications are presented: (1) regression using variables generated by large language models, and (2) protecting information privacy when sharing data. For each application, we outline specific tailored assumptions, discuss the identification results, and detail the estimation process. The efficacy of our proposed method is demonstrated through simulations in each application. Additionally, we employ semi-simulated data to further validate the effectiveness of our method in these applications. This research illustrates that utilizing noisy interval data can enhance current methodologies, facilitating more accurate results under less stringent assumptions and reducing potential biases.

3 - Emotion AI in Disguise Spurs Strategic Behavior in Customer Care

Yu Kan, University of Washington- Michael G. Foster School of Business, Seattle, WA, United States

As organizations increasingly turn to AI for addressing customer complaints, understanding the dynamics of user interactions with AI and human agents becomes imperative. In this study, we investigate customers' strategic behavior when interacting with agents of different identity cues on a food delivery platform. We employ two AI-human interactive experiments, where participants are randomly assigned to AI agents (including a general AI and a GPT-based AI agent), a human agent, or a non-disclosure agent group. We observe significant strategic behavior and decreased satisfaction only in the non-disclosure group. The participants in the non-disclosure group present a unique paradox. Even though they report experiencing less negative emotions, their expressions are more negative, and they have the lowest satisfaction ratings among all groups. Our findings contribute to the growing research on AI-human interactions and emotion regulation, suggesting intriguing dynamics when the agent's identity is non-disclosed. This work provides valuable insights for organizations considering AI adoption for customer service, highlighting the potential challenges and implications for user experience, customer satisfaction, and solution acceptance.

Frontiers in Causal Inference

Invited Session

Artificial Intelligence

Chair: Fei Fang, Yale University, New Haven, CT, United States

Co-Chair: Ruoxuan Xiong, Emory University, Atlanta, GA, United States

1 - Long-Term Causal Inference Under Persistent Confounding via Data Combination

Yuhao Wang, Tsinghua University, Beijing, China, People's Republic of, guido Imbens, Nathan Kallus, Xiaojie Mao

<blockquote mathjax"="">We study the identification and estimation of long-term treatment effects when both experimental and observational data are available. Since the long-term outcome is observed only after a long delay, it is not measured in the experimental data, but only recorded in the observational data. However, both types of data include observations of some short-term outcomes. In this paper, we uniquely tackle the challenge of persistent unmeasured confounders, i.e., some unmeasured confounders that can simultaneously affect the treatment, short-term outcomes and the long-term outcome, noting that they invalidate identification strategies in previous literature. To address this challenge, we exploit the sequential structure of multiple short-term outcomes, and develop three novel identification strategies for the average long-term treatment effect. We further propose three corresponding estimators and prove their asymptotic consistency and asymptotic normality. We finally apply our methods to estimate the effect of a job training program on long-term employment using semi-synthetic data. We numerically show that our proposals outperform existing methods that fail to handle persistent confounders.

2 - Regression Analysis for Conditional Spillover Effects Under Design-Based Uncertainty

Fei Fang, Yale University, New Haven, CT, United States, Laura Forastiere , Edoardo Airoldi

When interference exists, estimating spillover effects to correct bias for direct effects or the effects themselves is of interest. While regression analysis is commonly utilized for this task, e.g., regressing the outcome on the neighboring treatments, the analysis often relies on strong assumptions about the outcome model, such as homogeneity and additivity of the spillover effects. Alternatively, the weighted least squares (WLS) estimator from regression, with appropriately designed weights and covariate matrix, can be equivalent to the Hajek estimator for average spillover effects, which is model-free.

In this study, we focus on regression analysis for conditional spillover effects which are useful for understanding the heterogeneity of such effects across different groups. We propose integrated weights for the WLS estimator, demonstrating its equivalence to the Hajek estimator when the conditional covariate is categorical, without imposing assumptions on potential outcomes. For conditioning on continuous covariates, we assume linear outcome models but with heterogeneous coefficients. Under this assumption and design-based randomness, we define interpretable estimands and obtain consistent WLS estimators. We establish central limit theorem and derive a cluster-robust variance estimator under partial interference assumption. If homogeneous spillover effects can be further assumed, then the spillover effects can be decomposed and obtained from the dyadic regression between one's outcome and others' treatments separately. We examine the relationship between these estimators and the Hajek estimator and provide a variance estimator accommodating repeated dyads. Finally, we apply these methods to Honduras datasets to evaluate the spillover effects of educational programs on villagers' adoption behaviors.

3 - When the Bartik instrument meets topic models: a principled approach to text-based causal inferences

Tong Guo, Duke University, Durham, NC, United States

We propose the Bartik instrument as a principled source of IV for text-based causal inferences. The proposed procedure uses the estimated topic distribution from topic models to construct the Bartik instrument, and provides a useful alternative when the traditional BLP or Waldfogel IV does not work. We illustrate our approach in a study of the impact of social media news on Impossible Meats adoption by local restaurants and stores. Understanding this connection is challenging because of the lack of empirical measurement of local entrepreneur decisions at scale and, more importantly, the endogeneity of marketing communication to unobserved local demand shocks. We devise a unique location-specific adoption metric based on social media announcements, tracking local business decisions from 2015 to 2019. This metric is linked to comprehensive marketing communication extracted from social media using Natural Language Processing. We leverage the quasi-random variations of county-quarter-level news production for different topics to causally identify the linkage between social media publicity and adoption. We find that local coverage of social media news on the innovation increases the adoption of impossible meat products by local entrepreneurs. Interestingly, news content about producer financials was as important as content about sustainability and taste in driving local adoption of impossible meat products, potentially due to the signaling role of financial news for the trustworthiness of the technology (thus lowering uncertainty) and the trendiness of the technology (thus providing free marketing to small businesses who adopted the innovation).

4 - Data Integration for Efficient Causal Inference

Harsh Parikh, Johns Hopkins University, Durham, NC, United States, Elizabeth Stuart, Kara Rudolph

Recent works in the literature have focused on data integration from various studies for efficient causal effect estimation. These works typically assume that the intervention and outcome measures are same across all studies. In our work, we explore scenarios where the outcome measures are disparate across studies. We theoretically and empirically investigate when and how integrating data with disparate outcome measures can yield performance enhancement. Our findings indicate that performance enhancement is possible either under strong assumptions relating various outcome measures or on the existence of a calibration data where various outcome measures are simultaneously observed. We apply our data integration approach to study the effect of medication for treating opioid use disorder on the strength of withdrawal symptoms.

1 - Redesigning Zoning Systems for Equitable and Efficient Last-Mile Delivery at Ninja Van

Stanley Lim, Michigan State University, East Lansing, MI, United States, John Carlsson, Sheng Liu, Han Yu, Witsanu Arntong, Ee Hsin Tan

Last-mile logistics poses many challenges and high costs for firms. We develop a zoning system for Ninja Van to enhance last-mile delivery efficiency and boost customer satisfaction. By incorporating Voronoi Diagrams, stochastic and robust optimization techniques, we introduce a novel zoning optimization procedure and tested the model's efficacy in a major Southeast Asian city. The results showed substantial reduction in delivery work spans and the time drivers spend on deliveries. We project yearly savings exceeding $400,000 just by redefining zones and their boundaries in one country.

2 - Transportation marketplace rate forecast using signature transform

Haotian Gu, UC Berkeley, Albany, CA, United States, Xin Guo, Timothy Jacobs, Philip Kaminsky, Xinyu Li

This work develops a novel statistical method leveraging signature transforms to predict freight transportation marketplace rates. Our approach utilizes the universal nonlinearity property of signature transform to linearize the feature space and hence translates the forecasting problem into linear regression, and uses signature kernels for efficient comparison of time series data. This enables precise feature generation and identification of regime switching. Deployed by Amazon trucking operations, our algorithm surpasses industry models by improving prediction accuracy by over fivefold.

1 - Planning Adaptive Experiments: A Mathematical Programming Approach

Jimmy Wang, Columbia University, New York, NY, United States, Ethan Che

Standard adaptive experimentation algorithms overlook important practical issues including multiple objectives, non-stationarity, batched feedback, constraints, and personalization. Moving away from developing bespoke algorithms for each setting, we present a mathematical programming framework that flexibly incorporates a wide range of objectives, constraints, and statistical procedures. By formulating a dynamic program in the batched limit, our modeling framework enables the use of scalable optimization methods (e.g., SGD and auto-differentiation) to solve for treatment allocations.

2 - The maximum length car sequencing problem

Lara Pontes, Universidade Federal da Paraíba, João Pessoa, Brazil, Carlos Neves

The maximum length car sequencing problem aims to support the assembly operations arising in multinational automotive companies. We propose an integer programming formulation to schedule the maximum number of cars without violating spacing constraints associated with car options (sunroof, radio), a valid combinatorial upper bound, and iterative algorithms to solve the problem when good primal bounds are not available. An ILS-based heuristic enhances the performance of the exact methods. Computational results achieve low gaps for benchmark instances and optimally solve the company's demands.

3 - A Projection-Free Method for Solving Convex Bilevel Optimization Problems

Khanh-Hung Giang-Tran, University of Sydney, Sydney, Australia

We consider a class of convex bilevel optimization problems, where we minimize a convex smooth objective function over the optimal solution set of another convex smooth constrained optimization problem. We propose a new projection-free method for convex bilevel optimization requiring only a linear optimization oracle over the domain. We establish $O(t^{−1/2})$ convergence rate guarantees in terms of both inner- and outer-level objectives and demonstrate how additional assumptions result in accelerated rates of up to $O(t^{−1})$ and $O(t^{−2/3})$ for inner- and outer-levels respectively.

4 - Allocation of Surveillance Assets in Undersea Warfare

Sebastian Martin, United States Naval Academy, Annapolis, MD, United States

Recent advances in submarine technology require an effective national strategy for detecting undersea threats. We formulate an optimization model to effectively deploy sensors, maximizing the expected number of detected targets based on historical threat data and sensor resources. The model accommodates sensor overlap, introducing nonlinearity, which we handle by linearizing with a logarithmic transformation and tangent line approximations. We solve the model with notional sensor and maritime shipping traffic data.

1 - Navigating Product Diversification in Live Streaming E-Commerce: Evidence from Douyin

Jingyun Hu, Clemson University, Pendleton, SC, United States, Yi Gao, Keran Zhao

The past decade has witnessed the growing prevalence of live streaming selling (LSS). As streamers serve as a proxy between manufacturers and consumers, product assortment management has been a critical strategic factor for their success. Relying on data collected from Douyin, a prominent Chinese LSS platform, this study aims to investigate the impact of diversification on LSS performance through the lens of adding new categories in live streaming sessions. The results in this study show that product category diversification, in general, has a significant positive effect on sales during live streaming events. However, this effect is alleviated by the semantic similarity between the newly introduced and existing categories. In addition, we find that product diversification has a negative impact on the sales of incumbent categories. This study contributes to the literature on product assortment by providing insights into the role of product diversification in the context of real-time selling. We also discuss the managerial implications for the platform and streamers.

2 - How Does Popularity Information Affect Product Design?

Guangrui Li, York University, Toronto, ON, Canada, Zheng Gong, Zhepeng Li

Popularity information serves as quality signal for consumers to learn about products. Past literature has shown that the revealing popularity information may herd consumers to the popular products and leads to a superstar phenomenon, and narrow-appeal products benefit more from the same popularity. Up to our knowledge, the previous literature takes the product design as given, but the firms could change their product design in response to the popularity information revealing. In this paper, we examine the impact of popularity information revealing on firms' product design strategy by using a policy change on Wechat Official Account platform that reveals articles' popularity to subscribers. More specifically, we are interested in understanding the following aspects: (1) The quality and amount of advertisement in the content; (2) The topic choice of the contents. Our results show that the official accounts tend to increase their topic diversity as a strategic response to the demand shock induced by the reveal of popularity information.

3 - How Generative AI Shapes Video Sharing Platform: a Tale of Two Forces

Luying (Iris) Qiu, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Oliver Wei, Jiali Zhou, Weiyin Hong, Kai-lung Hui

We study the impact of generative AI on participants of video-sharing platforms using a natural experiment setting: the introduction of AI summary feature on one of the largest video-sharing platforms in China in November 2023. By leveraging a regression discontinuity strategy, we find that AI summaries significantly reduced creators’ contribution, viewers’ in-video engagement, and the number of reviews. We also find that the reduction in creators’ contribution is more severe for inexperienced creators. We draw related research and managerial implications.

4 - Logistics Service Sharing in Cross-Border E-Commerce

Nevin Mutlu, Eindhoven University of Technology, Eindhoven, Netherlands, Faranak Khooban, Ton de Kok

As demand for cross-border e-commerce has grown rapidly, challenges have emerged for both retailers and consumers participating in this global market. Retailers have been struggling with high logistics costs to fulfill cross-border demand, while they also suffer from consumers' lack of trust in foreign retailers. In this paper, we study a cross-border collaboration scheme between a domestic and a foreign retailer to mitigate these challenges. This entails a co-opetition framework where the domestic retailer is responsible for the last-mile delivery of the foreign retailer's orders in exchange for a logistics service fee. We model demand via an MNL choice model incorporating trust- and price-sensitive consumers. We compare the market outcomes of the two retailers in "pre-collaboration" and "post-collaboration" settings. We find that there exist win-win outcomes where both retailers benefit from collaboration under realistic settings. We also show that a cooperative mechanism can lead to higher profits for both retailers compared to the non-cooperative mechanism for setting the logistics service fee, if the contract terms are decided carefully.

1 - Optimal Sampling Strategy for Probability Estimation: An Application to the Agricultural Quarantine Inspection Monitoring Program

Huidi Ma, The University of Texas at Austin, Austin, TX, United States, Benjamin Leibowicz, John Hasenbein

Imported agricultural pests can cause substantial damage to agriculture, food security, and ecosystems. In the United States, the Agricultural Quarantine Inspection Monitoring (AQIM) program conducts random sampling to estimate the probabilities that cargo and passengers arriving at ports of entry carry pests. Assessing these risks accurately is critical to enable ef- fective policies and operational procedures. In this paper, we formulate an optimization model that minimizes the mean squared error of the probability estimates that AQIM obtains. The central decision-making tradeoff that the model explores is whether it is preferable to sample more arriving containers (and fewer boxes per container) or more boxes per container (and fewer containers), given limited resources. We first derive an analytical solution for the optimal sam- pling strategy by leveraging several approximations. Then, we apply our model to a numerical case study of maritime cargo sampling at the Port of Long Beach. We find that, across a wide range of parameter settings, the optimal strategy samples more containers (but fewer boxes per container) than the current AQIM protocol. The difference between the two strategies and the accuracy improvement with the optimal approach are larger if the pest statuses of boxes in the same container are more strongly correlated.

2 - Managing Large-Scale Invasions: Simulation-Optimization with Gaussian Dispersal Kernels and Stochastic Seed Establishment

Sevilay Onal, University of Illinois Springfield, Springfield, IL, United States

Biological invaders cause substantial economic losses exceeding $21 billion annually for the US government by damaging crops, agricultural lands, habitats, and sustainability. Aggressive invaders recognized under the Federal Noxious Weed Act of 2000, such as Sericea lespedeza, drive continuous federal efforts to prevent, eliminate, and manage invasive species. This highlights the critical need for optimal control methods to minimize their detrimental effects on biodiversity and the economy. To our knowledge, this paper is the first to integrate completely random occurrences of an invader that are not explainable by biophysical impacts within an integrated simulation- optimization model to control Sericea. The simulation model estimates the natural behavior of seed dispersal using Gaussian cell-to-cell transition probabilities and an algorithm developed to estimate the random or unexpected behavior of the invader. The case study data and parameter calibration are based on large-scale field data collected in Kansas and Oklahoma. We simulate Sericea growth over a 2500-acre landscape for 25 years and optimize search and treatment locations while minimizing its economic damage to forage production under a restricted budget. The results of the simulation-optimization framework provide information on the optimal treatment location and frequency, the optimal search speed, and the cost-benefit analysis of treatment in various invasion and seed dispersal scenarios. The computational results suggest that more budget is allocated to search in lower-density areas than treatment. If the weed is detected in a cell, the entire area is searched for a possible stochastic establishment. In higherdensity scenarios, treatment is preferred, and a search

3 -

An Integer Programming Approach for Designing Wildlife Conservation Corridors with Geometry Requirements

Chao Wang, Arizona State University, Tempe, AZ, United States, Jorge Sefair

Conservation corridors have been widely used to prevent biodiversity loss by linking fragmented habitats. One of the key design challenges involves identifying corridors that meet ecological requirements, including considerations of connectedness, width, and length. In this study, we propose a MIP model to enforce geometry requirements into the corridor design problem, aiming to maximize the corridor’s utility within a grid landscape. To enhance solution performance, we develop a Branch-and-Cut algorithm, paired with a bound-improving heuristic and a variable reduction preprocessing algorithm. A byproduct of our work is a polynomial-time algorithm for the solution of the minimization variant of this problem, focusing on finding a least-cost corridor with a specified width. Our algorithm is tested on a real instance for the protection of the Florida panther and a set of computer-generated landscapes. Test results demonstrate the algorithm’s ability to find near-optimal solutions for landscapes comprising up to 3000 patches within a two-hour timeframe.

4 - An Adaptive Simulation-Optimization Framework to Survey and Control Invasive Species

Sabah Bushaj, SUNY, Plattsburgh, NY, United States

Invasive species are a serious threat to ecosystems worldwide, calling for innovative methods to survey and control them effectively. This research presents a new approach—an adaptive simulation-optimization framework—specifically designed to tackle the complexities of managing invasive species. This framework is highly adaptable, providing standardized features for different species and offering various simulation options to match different environments and species dynamics. Researchers and practitioners can use this framework to tailor simulations for accurate surveys and strategic control efforts. By incorporating advanced solvers and allowing for problem-specific adjustments, it ensures reliable optimization customized to the specific challenges of invasive species scenarios.

Chair: Yongchun Li, Georgia Institute of Technology, Atlanta, GA, United States

1 - Convergence of Gradient Descent with Small Initialization for Unregularized Matrix Completion

Salar Fattahi, University of Michigan, Ann Arbor, MI, United States, Jianhao Ma

We study the problem of symmetric matrix completion, where the goal is to reconstruct a positive semidefinite matrix of low rank from only a subset of its observed entries. For the first time, we prove that vanilla gradient descent (GD) with small initialization converges to the ground truth, without requiring any explicit regularization or projection. This convergence result holds true even in the over-parameterized scenario, where the true rank is unknown and conservatively over-estimated. It also achieves a near-optimal sample complexity. The existing results for this problem either require explicit regularization, a sufficiently accurate initial point, or exact knowledge of the true rank. At the crux of our method lies a novel weakly-coupled leave-one-out analysis, which allows us to establish the global convergence of GD, extending beyond what was previously possible using the classical leave-one-out analysis.

2 - Derivation and Generation of Path-Based Valid Inequalities for Transmission Expansion Planning with New Bus Integration

Behnam Jabbari Marand, North Carolina State University, Raleigh, NC, United States, Adolfo Escobedo

This research tackles an extension of the DC OPF-based transmission expansion planning problem where both new lines and buses can be added to the existing network. To handle the general intractability of this problem, the primary computational strategy involves deriving valid inequalities (VIs) that leverage the problem's structure. Effective VIs are generated by considering different paths within the existing and expanded network both a priori and during the solution of the dispatch problem. While in the associated theorems identifying the longest paths is necessary to ensure validity in the general case, the proposed approach circumvents such an inefficient procedure for the majority of bus pairs. It is shown that the path-based VIs derived through this method dominate those obtained from solving the longest path problem, leading to a stronger problem formulation. This work also proposes a methodological framework for constructing an effective cut pool and identifying strong VIs to generate cutting planes. Two classes of VIs result from these insights, and their efficacy and computational advantages are demonstrated through application to a modified Polish 2383-bus system.

3 - Statistically Optimal K-Means Clustering via Nonnegative Low-Rank Semidefinite Programming

Richard Zhang, University of Illinois, Urbana, IL, United States, Yubo Zhuang, Xiaohui Chen, Yun Yang

K-means clustering is a widely used machine learning method for identifying patterns in large datasets. Semidefinite programming (SDP) relaxations have recently been proposed for solving the K-means optimization problem that enjoy strong statistical optimality guarantees, but the prohibitive cost of implementing an SDP solver renders these guarantees inaccessible to practical datasets. By contrast, nonnegative matrix factorization (NMF) is a simple clustering algorithm that is widely used by machine learning practitioners, but without a solid statistical underpinning nor rigorous guarantees. In this paper, we describe an NMF-like algorithm that works by solving a nonnegative low-rank restriction of the SDP relaxed K-means formulation using a nonconvex Burer--Monteiro factorization approach. The resulting algorithm is just as simple and scalable as state-of-the-art NMF algorithms, while also enjoying the same strong statistical optimality guarantees as the SDP. In our experiments, we observe that our algorithm achieves substantially smaller mis-clustering errors compared to the existing state-of-the-art.

4 - Integer Programming for Learning Directed Acyclic Graphs from Non-Identifiable Gaussian Models

Tong Xu, Northwestern University, Evanston, IL, United States, Armeen Taeb, Simge Kucukyavuz, Ali Shojaie

We study the problem of learning directed acyclic graphs from continuous observational data, generated according to a linear Gaussian structural equation model. State-of-the-art structure learning methods for this setting have at least one of the following shortcomings: i) they cannot provide optimality guarantees and can suffer from learning sub-optimal models; ii) they rely on the stringent assumption that the noise is homoscedastic, and hence the underlying model is fully identifiable. We overcome these shortcomings and develop a computationally efficient mixed-integer programming framework for learning medium-sized problems that accounts for arbitrary heteroscedastic noise. We present an early stopping criterion under which we can terminate the branch-and-bound procedure to achieve an asymptotically optimal solution and establish the consistency of this approximate solution. In addition, we show via numerical experiments that our method outperforms three state-of-the-art algorithms and is robust to noise heteroscedasticity, whereas the performance of the competing methods deteriorates under strong violations of the identifiability assumption. The software implementation of our method is available as the Python package micodag.

MSOM: Sustainable Operations

Chair: Vibhuti Dhingra, Schulich School of Business, York University, Toronto, ON, Canada

Co-Chair: Ali Kaan Tuna, Tilburg University, Tilburg, N/A, Netherlands

1 - Managing Carbon-Neutral Delivery in Online Retailing

Huseyn Abdulla, University of Tennessee, Knoxville, TN, United States, Seulchan Lee, Han Oh

Order-delivery related emissions constitute the vast majority of the environmental footprint of online retailers. A growing segment of consumers has become concerned with these emissions, discouraging them from shopping online. To alleviate these concerns, many online retailers consider committing to carbon-neutrality in the order delivery domain. These retailers partner with Sustainability as a Service (SaaS) providers to offer a voluntary, carbon offset-based green shipping option to eco-conscious consumers to reduce the cost burden of offsetting the emissions. Using a game theoretical approach, we examine the conditions under which it is optimal for a profit-maximizing online retailer to become carbon-neutral in the order delivery domain and to offer a consumer-paid green shipping option by partnering with a SaaS provider. We compare two common offset payment models that back the green shipping option, namely, preset and calculated offset payment models, and explore the implications of a hybrid approach that combine the advantages of both models.

2 - An Operational Perspective on the Role of Liability in Microfinancing

Elaheh Rashidinejad, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Opher Baron, Gonzalo Romero

We study the effects of different liability structures on the microfinancing performance in low- and middle- income countries through an operational lens. We investigate this problem using a Newsvendor with financing and effort framework. The Base of the Pyramid entrepreneur's outcome depends on her production quantity, effort level and business characteristics. The entrepreneur's effort directly impacts the success of her business in a multiplicative way. Furthermore, she starts with zero initial budget and borrows a loan to operate her business.One extreme of the liability structure we consider is a social bank that operates as an external lending institution and cannot collect the entire debt in the presence of business losses. The other extreme is a community bank that consists of peers in a community gathering their savings to form a bank and using their social ties to collect the debt eventually. We study these banks under profit-maximizing or zero-profit objectives, where the banks may face bankruptcy costs. Our study reveals that under any of these microfinancing setups, the effort exerted by the entrepreneur is the main driver of her equilibrium utility. Further, the effectiveness of microfinancing depends on two main factors: the bankruptcy cost and the product's critical fractile. Surprisingly, we show that the peer pressure mechanism may not always benefit both the entrepreneur and the bank. We establish conditions under which the zero-profit (profit-maximizing) community bank generates higher social welfare than the zero-profit (profit-maximizing) low-liability banks. A numerical study provides additional insights on the performance of moderate-liability banks.

3 - Responsible Operations in the Mining Sector: Do Penalties Improve Safety?

Vibhuti Dhingra, Schulich School of Business, York University, Toronto, ON, Canada, Anna Saez de Tejada Cuenca

Mining is one of the most hazardous industries in the world. Workplace injury rates in mining are 14.2 for every 100,000 workers—273% higher than other sectors, and the industry had more than 500 fatalities between 2017-2022. With the expected growth in mineral extraction necessary to power a green economy, the sector is only poised to expand further.

Given their massive footprint, mines are regularly inspected for compliance with workplace safety and health standards. The Mine Safety and Health Administration (MSHA) in the U.S., for example, conducts over 12,000 inspections every year. If a violation is detected, the inspectors enforce corrective measures and levy financial penalties on the responsible entities. In 2010, for instance, the MSHA imposed 160 million dollars in fines for mine safety violations.

Penalties can act as a deterrent against future violations by prompting mine operators to make process improvements such as enhancing ventilation and ensuring proper machine maintenance. However, penalties can also be ineffective if mine operators do not pay the finesand instead continue business as usual.

What is the causal effect of penalties on mine safety? In this paper, we answer this research question using data on mine safety inspections, violations, and penalties from the MSHA—spanning over one million inspections conducted on more than 4,000 coal and 18,000 metal/non-metal mines in the U.S. involving over 14,000 mine operators. Our identification strategy leverages the passage of the MINER Act in 2006 that significantly increased the penalties imposed for safety violations.

4 - Outsourcing, Reshoring, and Carbon Emissions in Supply Chains

Ali Kaan Tuna, Tilburg University, Tilburg, Netherlands, Robert Swinney

Nearshoring has garnered significant attention from firms, governments, and policymakers in recent years, and has emerged as one of the most prominent supply chain strategies to build more sustainable (and resilient) supply chains. In decentralized supply chains, an agent's reshoring decision might have an important impact on the whole supply chain. Motivated by the potential economic and environmental consequences of nearshoring in decentralized supply chains, we study a two-tier decentralized supply chain, where a buyer needs to source a critical component from a supplier to manufacture a single end-product.

Well before the buyer makes any procurement or production decisions, the firms first decide on their locations to form a supply chain to manufacture, with the buyer acting as a leader in this phase. They can form a fully offshore supply chain, a hybrid supply chain with the buyer onshore and the supplier offshore, or a fully nearshore supply chain. Firms' reshoring decisions change their fixed and variable costs, the per-unit environmental impact of their production and distribution processes, and when the buyer has to choose a procurement quantity for the component or a production quantity for the end-product. Our chief goal is to understand when the firms form each type of supply chain configuration in equilibrium, and the environmental implications of the equilibrium outcome. We also seek to understand how the relative power of the firms in the supply chain has an impact on their reshoring decisions and the subsequent environmental impact.

MSOM Student Paper Competition Finalists

Award Session

Manufacturing and Service Operations Management (MSOM)

Co-Chair: Vasiliki Kostami, HEC Paris, Jouy-En-Josas, France

1 - Optimizing Health Supply Chains with Decision-Aware Machine Learning

Tsai-Hsuan (Angel) Chung, The Wharton School, UPenn, Philadelphia, PA, United States

We address the problem of allocating limited medical resources in a developing country by combining ML (to predict demand) with optimization (to optimize allocations). A key challenge is aligning the ML model's loss function with the decision loss in optimization. We propose a scalable decision-aware learning framework and successfully deployed in collaboration with the Sierra Leone government across 1,123 healthcare facilities nationwide, leading to a 15-29% increase in medicine consumption and improved real-world patient access to care.

2 - Signaling Competition in Two-Sided Markets

Yuri Fonseca, Stanford University, Stanford, CA, United States

We consider decentralized platforms facilitating many-to-many matches between two sides of a marketplace. In the absence of direct matching, inefficiency in market outcomes can easily arise. For instance, popular supply agents may garner many units from the demand side, while other supply units may not receive any match. A central question for the platform is how to manage congestion and improve market outcomes. We study the impact of a detail-free lever: the disclosure of information to agents on current competition levels. Disclosing competition reduces the perceived value of popular units, but, at the same time, it can help agents on the other side better elect across options. How large are such effects, and how do they affect overall market outcomes? We answer this question empirically. We partner with the largest service marketplace in Latin America, which sells non-exclusive labor market leads to workers. We propose a structural model which allows workers to internalize competition at the lead level and captures the equilibrium effect of such reaction to competition at the platform level. We estimate the model by leveraging agents' exogenous arrival times and a change in the platform's pricing policy. Using the estimated model, we conduct counterfactual analyses to study the impact of signaling competition on workers' lead purchasing decisions, the platform's revenue, and the expected number of matches. We find that signaling competition is a powerful lever for the platform to reduce congestion, redirecting demand, and ultimately improving the expected number of matches for the markets we analyze.

3 - Dynamic Matching with Post-allocation Service and its Application to Refugee Resettlement

Soonbong Lee, Yale university, New Haven, CT, United States

Motivated by our collaboration with a major refugee resettlement agency in the U.S., we study a dynamic matching problem where each new arrival (a refugee case) must be matched immediately and irrevocably to one of the static resources (a location with a fixed annual quota). In addition to consuming the static resource, each case requires post-allocation services from a server, such as a translator. Given the uncertainty in service time, a server may not be available at a given time, thus referred to as a dynamic resource. Upon matching, the case waits to avail service in a first-come-first-serve manner. Bursty matching may result in undesirable congestion of the servers. Consequently, the planner (the agency) faces a dynamic matching problem with an objective combining the matching reward (pair-specific employment outcomes) with the cost for congestion for dynamic resources and over-allocation for the static ones. Motivated by the observed fluctuations in the refugee pools across the years, we aim to design algorithms with no distributional knowledge. We develop learning-based algorithms that are asymptotically optimal in certain regimes, easy to interpret, and computationally fast. Our design is based on learning the dual variables of the underlying optimization problem; however, the main challenge is the time-varying nature of the dual variables associated with dynamic resources. Our theoretical development integrates techniques from Lyapunov analysis, adversarial online learning, and stochastic optimization. When tested on our partner agency's data, our method outperforms existing ones making it a viable candidate for replacing the current practice upon experimentation.

4 - Causal Message Passing: A Method for Experiments with Unknown and General Network Interference

Sadegh Shirani, Stanford University, Stanford, CA, United States

Randomized experiments are a powerful methodology for data-driven evaluation of decisions. Yet, their validity may be undermined by network interference. This study introduces a new framework to accommodate complex and unknown network interference. Our framework, termed causal message-passing, is grounded in approximate message passing methodology. Utilizing causal message-passing, we introduce a practical algorithm to estimate the total treatment effect. We demonstrate the effectiveness of this approach across five numerical scenarios, each characterized by a distinct interference structure.

ENRE: Risk Analysis for Electricity Markets

Invited Session

ENRE: Electricity

Chair: Ryan Ent, University of Massachusetts-Amherst, Ringoes, NJ, 08551, United States

Co-Chair: Golbon Zakeri, University of Massachusetts - Amherst, Amherst, MA, United States

1 - Analysis of ISO New England's Energy Imbalance Reserve Product with Risk Averse Agents

Ryan Ent, University of Massachusetts-Amherst, Amherst, MA, United States, Golbon Zakeri

In wholesale electricity markets, operating reserves are contracts for generation capacity sold by electricity providers to provide the power system with flexibility in the case of N-1-1 contingencies. In 2025, the independent system operator of New England(ISO-NE) will introduce a co-optimized day ahead energy and reserve market that contains four reserve products with a call option settlement based on the difference between the real time price of energy and a strike price set by ISO-NE. Part of this market is a new product, the energy imbalance reserve, which will make up the difference between energy cleared on the day ahead market and the system operator's real time load forecast. ISO-NE's goals for this market are to incentivize the generators in their fleet, mainly reliant on natural gas, to invest in advanced fuel and increase energy purchased on the day ahead to a level equal to the expected real time load. To analyze how this market may or may not achieve these goals, we model the simultaneous equilibrium of multiple risk-averse generators participating in day ahead and real time markets for energy with and without the presence of energy imbalance reserve.

2 - ISO New England Regional Energy Shortfall Threshold Project

Jinye Zhao, ISO New England, Holyoke, MA, United States

ISO New England is pioneering the development of a Regional Energy Shortfall Threshold (REST), establishing an acceptable level of regional energy shortfall risk during extreme weather conditions. The development of REST will utilize the Probabilistic Energy Adequacy Tool, which is capable of identifying weather events that could cause energy deficits as well as assessing the likelihood and severity of such events. REST will serve as an energy adequacy standard for extreme weather events, complementing the widely used 1-day-in-10-year resource adequacy criterion. This presentation focuses on ISO's current thinking regarding the selection criteria for extreme weather events, the metrics used to quantify energy adequacy risk and the frequency of REST evaluations.

3 - Towards Completion of Risk Markets

Iman Khajepourtadvani, University of Massachusetts Amherst, Amherst, MA, United States, Golbon Zakeri

The seminal paper of Ralph and Smeers (2011) demonstrates that when risk markets are complete, the competitive risk-averse equilibrium of a game, where agents are endowed with coherent risk measures is equivalent to a system optimization problem. This finding is of interest to policymakers in many markets, including energy markets. In this presentation, we will lay out some foundational steps for completing risk markets.

4 - The Impact of Capacity Accreditation on Long-term Resource Adequacy

KE XIN ZUO, Cornell University , Ithaca, NY, United States, Jacob Mays

The rapidly evolving global energy landscape reveals critical flaws in current resource adequacy (RA) mechanisms. Weak non-performance penalties in capacity markets incentivize suppliers to over-promise and under-deliver, leaving the grid vulnerable during extreme events. Central to this issue is capacity accreditation - the process by which ISOs assess each resource's contribution to system reliability during stress periods. A popular approach to assigning capacity credits is measuring generators' effective load carrying capability (ELCC) over designated performance assessment hours (PAHs). However, the misalignment of these PAHs with actual shortage events, along with inconsistencies in measuring shortfall risk, often lead to systemic over-accreditation. This paper first addresses the need for a standardized characterization of resource adequacy in wholesale electricity markets. Building on this foundation, we introduce an economically aligned ELCC and corresponding capacity accreditation framework that incentivizes optimal levels of capacity investment while meeting specified reliability standards. Using a stochastic optimization framework, we then compute the market equilibria arising under various approaches to accreditation for a numerical example, demonstrating the sub-optimality of standard practices. This study contributes to understanding how capacity accreditation affects long-term resource adequacy and informs the design of efficient market mechanisms and policies to ensure a resilient grid.

Regency - 706

Modeling the Impact of Climate Change on the Electric Power Sector: Inputs, Assumptions, and Use Cases

Invited Session

ENRE: Energy-Climate

Chair: Ana Dyreson, Michigan Technological University, Houghton

1 - Enhancing Climate Resilience in Power System Planning: An Integrated Framework

Maren Ihlemann, EPRI International, Golden, BC, Canada

Climate change has been manifesting in more frequent and extreme weather conditions which expose power systems to escalating challenges. These challenges are projected to intensify over the next decades. Concurrently, there's a growing dependency of electricity as main energy carrier for multiple sectors, increasing the need for a robust infrastructure.

Traditionally, power system planning was based on extrapolating historically observed conditions, with limited representation of weather data and visibility of climate-related hazards. However, modeling advances allow for more complex representations of hazards and their impacts in power system planning. The robustness of the design will depend on the resiliency considerations and metrics adopted, as well as the tolerance enforced by the planner to withstand stressful periods.

A holistic planning to operations solution requires an integrated planning framework that leverages climate data and asset vulnerabilities against adverse conditions. By connecting various power systems planning functions, key climate hazards are identified, adapted to, and ultimately mitigated. As a first step to this framework, an initial buildout is screened over a large set of climate-projected weather data identifying potential periods at risk using the Risk Screening tool (*RiSc*). Key potential risks are then passed to the capacity expansions tool, extended to explicitly incorporate climate hazards and adaptations. To assess expected system reliability, resource adequacy is assessed over a large set of operating conditions considering system weather dependencies.

The framework is applied to a synthetic Texas case study and results demonstrate that resilient planning significantly enhances system reliability and effectively mitigates extreme weather impacts.

2 - Generative Super Resolution for Estimating Climate Change Impacts on Power Systems and Communities

Brandon Benton, National Renewable Energy Laboratory, Golden, CO, United States, Grant Buster, Jordan Cox, Andrew Glaws, Ryan King

As climate change progresses, high-resolution climate-change-impacted weather data is crucial for assessing the impacts on power systems and communities. We introduce methods using generative adversarial networks (GANs) to downscale global climate model (GCM) data, achieving enhanced spatiotemporal resolutions suitable for power system and community analysis. We have effectively downscaled key power system modeling inputs, including wind, solar, temperature, and humidity, to 4km hourly resolutions. This advancement facilitates more nuanced power system analysis and better adaptation planning. Similar methods combine satellite imagery and human settlement layers to generate 1-km hourly urban heat island estimates. These estimates are crucial for evaluating heat risk and resilience in urban areas, including the impact of climate change on energy cost and burden, especially during future extreme events. By leveraging GANs, our approach significantly improves climate data resolution at low computational cost, offering new insights into the impacts of climate change on power infrastructure and urban communities, thus aiding in the development of more informed and resilient adaptation strategies.

3 - Navigating Climate Uncertainty: A Collaborative Approach for Grid Planning in California

Liyang Wang, University of California, Berkeley, Berkeley, CA, United States, Owen Doherty, Kripa Jagannathan, Nancy Freitas, Julia Szinai, Andrew Jones

The escalating frequency and intensity of climate change-driven extreme weather events expose critical vulnerabilities in our energy infrastructure. Concurrently, the rapid shift towards electrification and renewable energy introduces deep uncertainties into long-term grid planning. These interconnected stressors are challenging to address using traditional planning and modeling approaches. Planners are seeking actionable and computationally tractable approaches that explore how climate change impacts grid design and that examine the tradeoffs among the competing priorities among stakeholders. We describe a co-production effort between electricity sector practitioners, climate scientists, and power system modelers to translate climate projections into grid model inputs.

Using California as a case study, we define extreme events and establish appropriate thresholds using cluster analysis and extreme value theory, translating climate projections into demand scenario inputs for a capacity expansion model. We then introduce the application of Decision-Making under Deep Uncertainty (DMDU) framework to capacity expansion planning. We discuss how DMDU allows for multi-objective evaluation of different grid designs across a wide range of climate scenarios in a computationally tractable manner, enables planners to explore different definitions of robustness and grid resilience, and incorporates different risk tolerance from different stakeholders. This case study provides insight into the actionability of climate science and DMDU, illustrates the challenges in applying DMDU and coproduction, and bridges the gap between climate science projections and the needs of grid planners.

4 - What is the Contribution of Transmission to U.S. Resource Adequacy?

Charalampos Avraam, National Renewable Energy Laboratory, Golden, CO, United States, Jessica Kuna, Brian Sergi

Resource adequacy encompasses the availability of resources to cover future electricity demand. In a fuel-dominated electricity mix, resource adequacy metrics aimed to ensure sufficient future nameplate capacity. Fuel-fired generators can be sited in proximity to demand, and generation capacity offers predictable electricity delivery under normal operating conditions. Traditional resource adequacy frameworks either focus on ensuring generation capacity availability, or assess whether a system is resource adequate for some given generation capacity. However, nameplate capacity availability of fuel-fired generators does not always translate into electricity delivery. Fuel delivery to natural gas-fired plants failed during the 2021 Texas Power Crisis, rendering existing capacity inoperable. Moreover, the rapid deployment of energy-limited resources, including renewables and batteries, challenges existing resource adequacy frameworks and couples regional electricity demand and renewables potential via transmission. While ongoing research illuminates the contribution of transmission to resource adequacy, long-term planning fails to quantify transmission contributions, which are eventually disregarded in real-life decision-making. Our contribution is twofold. First, we go beyond the existing generation capacity-centered approaches to design metrics for the assessment of transmission contributions to resource adequacy. Second, we leverage a large-scale capacity expansion model within a multi-objective optimization framework to quantify the merits of transmission expansion under alternative decarbonization and policy pathways. We enhance the Regional Energy Deployment System (ReEDS) and generate Pareto Frontiers across engineering and economic resource adequacy metrics. This work aims to inform policy-makers and regional stakeholders engaged in long-term transmission planning under heavy penetration of energy-limited resources in highly decarbonized futures.

5 - A Universal Synthetic Weather Data Generator for Use in Power System Resource Adequacy, Short-term Optimization, and Control

Duc-Huy Pham, Edward P. Fitts Department of Industrial and Systems Engineering, North Carolina State University, Raleigh, NC, United States, Jordan Kern

Both long-term capacity expansion and short-term operational models of power systems require some characterization of weather-based uncertainties in electricity supply and demand. Resource adequacy, defined as the ability of the electric grid to satisfy end-user power demand at any time, is typically measured by subjecting models to past observations (weather reanalysis), outputs from forward-looking global climate models (GCMs), or a combination of both. To ensure more robust outcomes, system operators should evaluate planning and operational strategies using very large samples. However, when using weather reanalysis or global climate datasets, increasing the sample size pulls data from a wider temporal range, potentially obscuring meaningful shifts in the underlying system state (e.g., due to climate change). Here, we present a fairly universal approach for creating synthetic meteorological ensembles (including short-term forecasts) of unlimited size that replicate the statistical and time series characteristics of any user-defined "base" dataset (e.g., a 20-year window of GCM outputs or a 10-year window of historical observations). We demonstrate how this approach can be used in multiple modeling applications (resource adequacy, short-term optimization, and control) and how it can be easily transferred to any U.S. balancing authority.

Critical Mineral and Lithium Supply Chains for Clean Energy Technologies

Invited Session

ENRE: Other Energy

Chair: Erick Jones, University of Texas at Arlington, Arlington, TX, United States

1 - Lithium Supply Chain Optimization

Sarasadat Alavi, University of Texas at Arlington, Arlington, TX, United States

The surging demand for lithium in the United States necessitates the development of efficient and sustainable supply chain strategies. This research introduces a novel lithium closed-loop supply chain model that optimizes planning for different regions in the USA while considering uncertainty. The model employs stochastic programming to address inherent uncertainties such as demand fluctuations and resource availability. Capacity acquisition decisions are incorporated to ensure the supply chain can meet the growing demand for lithium. The model emphasizes sustainability, seeking to minimize the ecological footprint of the lithium supply chain. Social fairness is also addressed, ensuring the equitable distribution of benefits and burdens among different communities and stakeholders. This research contributes to the development of a more resilient, sustainable, and socially responsible lithium industry in the United States by integrating critical aspects into a comprehensive closed-loop supply chain model. The findings provide valuable insights for policymakers, industry practitioners, and researchers, facilitating effective management of the lithium supply chain in the face of uncertainty and multiple objectives. The proposed model is distinct in its holistic approach, balancing economic, environmental, and social considerations. It offers a framework for evaluating and optimizing lithium supply chains, taking into account the unique challenges and opportunities presented by the U.S. market. By incorporating stochastic programming and considering regional differences, this research provides a robust tool for decision-makers to navigate the complexities of the lithium industry and drive sustainable growth.

2 - Lithium Recycling: An Experimental Approach

Oluwatosin Atitebi, University of Texas at Arlington, Arlington, TX, United States

As the need for critical minerals like lithium increases for clean energy technologies, new sources will have to be discovered and quickly. However, unlike the fossil fuel energy system the minerals needed for the clean energy system can be recycled. Nonetheless, the science behind recycling lithium is nascent. This work presents our lab scale attempts to efficiently develop experiments to recycle lithium using industrial engineering and operations research techniques.

3 - A Reverse Logistics Supply Chain Network for Sustainable Value Recovery from Li-Ion Batteries in the United States

Apurba Kumar, University of Arizona, Tuscon, AZ, United States

Li-ion batteries (LIB) are increasingly used in renewable energy storage (e.g., solar and wind) and (hybrid) electric vehicles, contributing to the UN sustainable development goals and net zero emissions goal. However, proper management of hazardous wastes after their end of life (EOL) is a great concern. Value recovery from spent LIBs could facilitate sustainable EOL management and recover valuable materials to create a resilient supply of critical raw materials such as lithium, cobalt, and nickel. This study focuses on the design of an optimal reverse logistic supply chain network for sustainable collection and recycling of spent LIBs. An optimization model has been developed to (1) quantify the impact of a governmental policy on promoting the large-scale adoption of LIB recycling technologies and (2) maximize the economic benefits from LIB recycling in the next ten years. The model was applied to the case of United States and suggested the optimal facility locations, processing capacities, recycling technology, and material flows for LIB recyclers. According to our analysis, up to 57% of total available feedstock could be collected over a planning horizon of ten years without any government intervention. However, the government must come forward with properly planned policies to improve the collection rate further. Depending on the budget available to the government, mandating 90% collection of total available spent LIBs and matching 30% of recycling revenue can boost the feedstock collection rate up to 94%.

4 - Critical Minerals for the Clean Energy Transition: An Evaluation

Erick Jones, University of Texas at Arlington, Arlington, TX, United States

Critical minerals, named because of their importance to the economy, are essential for the clean energy economy. The clean energy system is much more mineral intensive than our current fossil fuel based economy. However, like the current economy these minerals are concentrated in locations where securing a supply chain may make it more difficult. This work evaluates modeling strategies to assess this supply chain and shore up the minerals needed for the clean energy transition.

Towards a Sustainable Resilient Future - Part B

Invited Session

Computing Society

Chair: Himadri Sen Gupta, University of Oklahoma, 202 W Boyd St, Norman, OK, 73019, United States

Co-Chair: Andrés González, University of Oklahoma, Norman, OK, 73019, United States

1 - A Community Resilience Planning Framework for Maximizing Post-Disaster Healthcare Accessibility

Tasnim Faiz, University of Maryland, College Park, MD, United States, William Hughes, Kenneth Harrison

Accessibility to healthcare services following a disaster is a crucial metric of community resilience. Damages to hospital structures and transportation networks caused by disaster events significantly impact a community's accessibility to these services. Moreover, the increased number of visits to the emergency departments resulting from injured occupants of damaged residential buildings further challenges a community's healthcare system capacity. By adopting suitable mitigation actions, a community can avert the reduction in healthcare accessibility following a disaster, thereby improving resilience. However, identifying suitable mitigation actions for critical infrastructure and buildings, i.e., a community's built environment, to achieve that goal is challenging due to the uncertainty in hazard impact, budgetary limitations, and other restrictions. This work presents a decision-making framework to develop alternative mitigation decision sets for improved healthcare accessibility as a community resilience goal under varied hazard scenarios. The framework adopts a two-stage robust optimization approach, which includes a first-stage model to identify optimal mitigation decisions for maximizing accessibility under a set of hazard impact scenarios and a second-stage model to generate the worst-case scenarios for the current set of actions and evaluate their consequences on a community's built environment and social element. A case study with a community in Shelby County, Tennessee, subjected to earthquake hazards is presented to showcase the applicability of the proposed framework in developing alternative mitigation strategies.

2 - Text Mining of Practical Disaster Reports: Case Study on Cascadia Earthquake Preparedness

Julia Lensing, University of Washington, Lacey, WA, United States

Many practical disaster reports are published every day across the globe in various forms (e.g., after-action reports, response plans, impact assessments, and resiliency plans). These reports enable the next generations to learn from past events to best mitigate and prepare for future disasters. However, the extensive practical literature has limited impacts on research and practice because of the challenge in synthesizing and analyzing the reports. In this study, we 1) present a corpus of practical reports for text mining and 2) an approach to extract insights from the corpus using select text mining tools. We validate the approach through a case study that examines practical reports about the preparedness of the U.S. Pacific Northwest for a magnitude 9 Cascadia Subduction Zone earthquake, which can disrupt lifeline infrastructures for months. The case study illustrated the types of insights that the approach can extract from a corpus. For example, it identified potential differences in priorities between Washington and Oregon state-level emergency management, highlighted latent sentiments expressed in the corpus, and recognized the inconsistent vocabulary across the field. Based on a brief survey of potential user groups, we also discuss opportunities and challenges with text mining of practical disaster reports. For example, simple tools can provide insights potentially only interpretable by those experienced in the field, whereas more complex tools using large language models such as ChatGPT can provide more readily accessible insights, if with known risks of current artificial intelligence. For reproducibility, supporting data and code are made publicly available (DOI: 10.17603/ds2-9s7w-9694).

3 - Machine Learning and Cge Models: A Synergistic Approach to Enhanced Resilience Optimization

Nushra Zannat, The University of Oklahoma, Norman, OK, United States, Charles Nicholson, Harvey Cutler, Himadri Sen Gupta, Andres Gonzalez

This research presents an innovative framework that integrates machine learning (ML) with optimization techniques to analyze and mitigate the impacts of disasters on community infrastructure and the economy. We used penalized regression models to interpret computable general equilibrium (CGE) model outputs and extract predictive insights that quantify the effects of various disaster scenarios as coefficients. The study focuses on utilizing these ML-derived coefficients to refine the objective of an optimization model for enhancing strategic planning in disaster response.

Overall, this research highlights the potential of using advanced analytics in enhancing community resilience -- by transforming data into actionable insights that improve preparedness, response, and mitigation strategies, thereby contributing significantly to sustainable disaster risk management.

4 - Analyzing the Ability of AI Chatbots to Extract Data and Information About Natural Disasters

Ritvik Karthik, Iowa State University, Ames, IA, United States, Cameron MacKenzie, Wilson Diep, Ule Mewanu

Two major trends in the world right now are the increasing capabilities of artificial intelligence (AI) and climate change. One provides great opportunities to advance the world, and the other represents one of the great challenges facing humanity. The risk of natural disasters is increasing due to climate change. Operations researchers frequently sift through a variety of text documents in order to find information and data that can inform a mathematical model for natural disasters. This research examines whether AI chatbots can be used to find accurate data and statistics about natural disasters. The first phase compares the accuracy of ChatGPT 3.5 and Google Bard to answer different questions about natural disasters. The second phase analyzes the ability of ChatGPT 4 to accurately answer questions about a specific natural disaster based on receiving dozens of news articles as an input. In the first phase, Google Bard was more accurate than ChatGPT 3.5 for all the different categories of questions. In the second phase, ChatGPT 4 correctly answered most questions. Our results show there is potential in using AI chatbots to find and reveal information about natural disasters that can be incorporated into operations research models. The ability of AI chatbots to provide input for modelers will likely increase in the future as AI continues to become more capable and accurate.

Discrete Optimization and Machine Learning

Invited Session

Computing Society

Chair: Connor Lawless, Cornell University, Ithaca, NY, United States

1 - Physician Rostering with Downstream Capacity Constraints

Yaron Shaposhnik, University of Rochester, Rochester, NY, United States, Yashi Huang, Arik Senderovich

We collaborate with a large hospital that specializes in cancer treatment and develop an interactive interface that optimizes the physicians' roster (i.e., sessions) to improve patient flow and the utilization of resources. We conduct numerical experiments using historical data to assess the accuracy of the infusion load predictions and the potential improvement in different service quality metrics that can be obtained by optimizing the roster.

2 - A Scalable Linear Programming Based Algorithm for Fair K-Means Clustering

Yakun Wang, Lehigh University, Bethlehem, PA, United States, Aida Khajavirad

In [De Rosa and Khajavirad, 2022], the authors introduce a new linear programming (LP) relaxation for K-means clustering, and in [De Rosa and Khajavirad, 2024], they examine its theoretical properties, finding it nearly always tight on various data sets. However, this LP includes $\Omega(n^3)$ inequality constraints, making it impractical for large data sets.

In this work, we propose an efficient algorithm for solving this LP relaxation. The main components of our algorithm are: a separation algorithm to select a proper subset of inequalities, the LP solver *cuPDLP*, which is an efficient GPU-based implementation of the Restarted Primal-Dual Hybrid Gradient method, and warm starting using the effective heuristic *kmeans++*.

We conduct a comprehensive numerical study on real-world data sets from the UCI library.

We are able to solve all instances with up to 2000 data points to global optimality within one hour, hence, significantly outperforming an SDP-based exact solver for K-means clustering.

Subsequently, we consider a variant of fair K-means clustering first proposed by Chierichetti et al. In this framework, each data point is characterized by a sensitive attribute, and a clustering of data is considered fair if the proportion of sensitive attributes in each cluster closely matches their overall proportion in the dataset. We then propose a fair LP relaxation for this problem by showing that clustering fairness can be obtained by adding linear inequalities to the K-means clustering problem.

Our numerical experiments demonstrate the effectiveness of the fair LP relaxation for both synthetic and real-world data sets.

3 - Okridge: Scalable Optimal K-Sparse Ridge Regression

Jiachang Liu, Duke University, Durham, NC, United States, Sam Rosen, Chudi Zhong, Cynthia Rudin

We consider an important problem in scientific discovery, namely identifying sparse governing equations for nonlinear dynamical systems. This involves solving sparse ridge regression problems to provable optimality in order to determine which terms drive the underlying dynamics. We propose a fast algorithm, OKRidge, for sparse ridge regression, using a novel lower bound calculation involving, first, a saddle point formulation, and from there, either solving (i) a linear system or (ii) using an ADMM-based approach, where the proximal operators can be efficiently evaluated by solving another linear system and an isotonic regression problem. We also propose a method to warm-start our solver, which leverages a beam search. Experimentally, our methods attain provable optimality with run times that are orders of magnitude faster than those of the existing MIP formulations solved by the commercial solver Gurobi.

1 - Optimizing Vehicle Fleet Composition in Underground Mines

John Ayaburi, Colorado School of Mines, Golden, CO, United States, Aaron Swift, Jason Porter, Andrea Brickey, Alexandra Newman

The mining industry relies heavily on the use of diesel-powered equipment, which accounts for heat accumulation and exhaust emissions that can create unsafe working conditions. We present a large-scale production scheduling model that (i) prescribes activity start times at daily fidelity, taking into account ventilation and refrigeration; and, (ii) determines a fleet composition, relative to a diesel-only fleet, that improves productivity. We find that the need for refrigeration is delayed and exhaust emission is reduced as more battery-powered equipment is introduced, showcasing the utility of battery vehicles in maintaining productivity and improving the safety of underground work environments.

Amaya McNealey, Georgia Institute of Technology, Atlanta, GA, United States

VBAC-1.0, the vaginal birth after cesarean calculator, incorporated race/ethnicity and faced criticism, leading to the race-neutral VBAC-2.0. Our decision-analytic framework compared both calculators' recommendations, with results showing higher cesarean rates for Black patients under VBAC-2.0 compared to VBAC-1.0.

6 - Distributionally Fair Stochastic Optimization using Wasserstein Distance

Qing Ye, Georgia Institute of Technology, Atlanta, GA, United States

This paper introduces Distributionally Fair Stochastic Optimization (DFSO) based on the Wasserstein fairness measure. DFSO seeks to minimize distributional disparities among groups defined by sensitive attributes, such as gender and race, measured by the Wasserstein distance. We present exact mixed-integer convex programming formulations and propose two lower bounds for the Wasserstein fairness measure. Additionally, we develop efficient algorithms to solve DFSO problems. Numerical studies demonstrate the practical applicability of DFSO in various societally relevant real-world scenarios.

7 - Exploring Nutritional Equity in Foodbank Supply Chains

Nowshin Sharmile, North Carolina A&T State University, Greensboro, NC, United States, Lauren Davis

This research targets enhancing nutritional equity in food distribution by the Foodbank of Central and Eastern North Carolina. It introduces a linear programming model based on the Healthy Eating Research Nutrition Guideline to minimize disparities in access to nutritious food, advancing responses to food insecurity within non-profit operations.

11 - Federated Multiple Tensor-on-Tensor Regression (FedMTOT) for Multimodal Data Under Data-Sharing Constraints

Zihan Zhang, ISyE Georgia Tech, Atlanta, GA, United States, Shancong Mou, Mostafa Reisi, Massimo Pacella, Jianjun Shi

In recent years, diversified measurements reflect the system dynamics from a more comprehensive perspective in system modeling and analysis, such as scalars, waveform signals, images, and structured point clouds. To handle such multimodal structured high-dimensional (SHD) data, combining a large amount of data from multiple sites is necessary (i) to reduce the inherent population bias from a single site and (ii) to increase the model accuracy. However, impeded by data management policies and storage costs, data could not be easily shared or directly exchanged among different sites. Instead of simplifying or facilitating the data query process, we propose a federated multiple tensor-on-tensor regression (FedMTOT) framework to train the individual system model locally using (i) its own data and (ii) data features (not data itself) from other sites. Specifically, federated computation is executed based on alternating direction method of multipliers (ADMM) to satisfy data-sharing requirements, while the individual model at each site can still benefit from feature knowledge from other sites to improve its own model accuracy. Finally, two simulations and two case studies validate the superiority of the proposed FedMTOT framework.

21 - Comparative Performance of Battery- and Diesel-Powered Haulage Fleets in Underground Mines

Aaron Swift, Colorado School of Mines, Golden, CO, United States

Battery-electric vehicles can improve ambient conditions in underground mines by reducing the amount of heat and diesel exhaust in working areas. This study uses simulation techniques to determine the effect of electrifying a haulage fleet on the heat load, emissions, and energy usage of an underground mine versus current diesel equipment. This information is important as mine operators assess vehicle electrification as a means to achieve greenhouse gas emissions reduction targets.

1 - Scheduling Polices of a Flexible Worker in Two-Station Production Systems

Jingchuan Chen, The University of Hong Kong, Hong Kong, Hong Kong, Shaochong Lin, Zuo-Jun Max Shen

This work is motivated by practical observations in a truck manufacturing line, where some workers are arranged to produce parts for two stations by switching regularly due to the unbalanced productivity of stations. Indeed, the introduction of flexible workers can improve the performance of manufacturing and service systems. Therefore, we study single-cycle scheduling policies for two-stage production systems with one dedicated worker in each station and a flexible worker that can serve both stations. We find that a dedicated allocation policy, i.e., assigning the flexible worker to the station of lower efficiency, is optimal when switches are costly. Besides, our analysis shows that a dynamic scheduling policy is optimal when switch costs are medium, and we provided some instructions for scheduling the flexible worker dynamically. For the system with low-cost switches, we identify the optimal conditions for switching the flexible worker. Finally, we tentatively extend our results for single-cycle scheduling to the policies for multiple cycles.

2 - Minimizing the Stay Time of Open Shop Scheduling Problems with the Unit Processing Time

Gwanhee Lee, POSTECH, Pohang, Korea, Republic of, Kyungduk Moon, Dongyun Kim, Yeonjun Choi, Insoo Park, Juntaek Hong, Kangbok Lee

The open shop scheduling problem involves determining the starting times and routes of jobs across multiple machines. In this study, we introduce a novel service quality metric called "stay time," defined as the duration between a job's starting time and its completion time within a schedule. We examine two objectives related to stay time: the maximum stay time and the total stay time. Our investigation focuses on the computational complexity of scenarios where each job must visit every machine exactly once, with each operation requiring unit processing time, under the condition of an optimal makespan. Additionally, we propose algorithms to address cases that are solvable in polynomial time.

3 - Metric selection and weighted scoring method for determining technology novelty

SungChan Jun, Korea University, Seoul, Korea, Republic of, Chulung Lee

Assessing the characteristics of target technology and determining the value and originality of the technology is crucial for enabling efficient decision-making and creating technology roadmap for countries and companies. While various studies are being conducted to find the value and originality of technology in specific fields using various indicators and classical statistical methodologies, research on a methodology that can analyze the entire industry as a whole is currently insufficient. To address this need, this study developed the following framework: (1) collection of patents related to technologies similar to the target technology, (2) establishment and analysis of technological indicators, (3) determination of weights for each indicator, and (4) evaluation of technology through the derivation of originality scores. The developed framework derives indicators and originality grades based on natural language processing algorithms, ARM algorithms, and network analysis results. Furthermore, this study enhances its credibility by conducting empirical analysis using South Korea's fundamental technology research projects and patents that have been rejected for application. By using the metheodology suggested in this study, the value and originality of the target technology can be converted into objective figures, which will bring great advantages in establishing intellectual property strategies and technology roadmaps.

4 - Predicting promising technologies using a multi-layered network of country, company, and technology

Leehee Kim, Seoul National University, Seoul, Korea, Republic of, Sungjoo Lee

Identifying promising technology is crucial for companies and countries to establish effective technology strategies. and accordingly, much effort has been made to develop an approach to predict such technologies. Despite such effort, however, few studies considered the intertwined effect of various factors on technology growth. To fill the research gap, this study aims to propose a patent-based approach to predict promising technologies using a multi-layered network consisting of three layers – country, company, and technology. To achieve this aim, firstly, similar patents are clustered to define technologies, with each cluster named according to the technology area of the patent. A heterogeneous multilayer network is then constructed to illustrate the relationships between, countries, companies, and technologies, with each entity serving as a node. Promising technology clusters are predicted using indicators from three perspectives: country, company, and technology . Following this prediction, the research findings are expected to provide valuable insights for technology strategies, identifying the country-company-technology community through multilayer overlapping community detection and analyzing the impact of each country and company on the emergence of specific technology as promising fields. Ultimately, this study seeks to elucidate how countries and companies influence the development of specific technology into promising fields. The results are expected to assist companies and countries in formulating technology strategies by identifying promising technology clusters within their areas of interest.

5 - An Integrative Framework for The Sustainable Supply Chains; From Operational to ESG-Based Performance Metrics

Leili Soltanisehat, University of Massachusetts Dartmouth, Boston, MA, United States

Aligned with the Sustainable Development Goals (SDGs), companies are increasingly integrating Environmental, Social, and Governance (ESG) considerations into their investment strategies and operations management. Supply chain risk management is one of the most important targets of SDGs, as a sustainable supply chain surpasses the conventional emphasis on cost-cutting and efficiency. Through the adoption of sustainable supply chain practices, organizations can not only improve their environmental footprint but also attain sustainable financial and operational viability. However traditional supply chain risk assessment tools often fall short of comprehensively addressing the multifaceted challenges that modern supply chains face. Traditional tools often focus on narrow aspects of risk, such as operational disruptions or supplier reliability, neglecting broader environmental, social, and governance (ESG) factors. In addition, traditional tools may not facilitate collaboration and information sharing across supply chain partners (e.g., echelons), limiting their ability to identify and mitigate the propagated and accumulated risks. Therefore, to cover this gap, this research aims to design a universal supply chain risk assessment tool, that utilizes a mathematical modeling approach to integrate supply chain network dynamics, the material flows, and the risk propagation within the supply chain network. The proposed framework incorporates various aspects of the risks affecting the performance of the supply chain including, ESG risks, operational risks, and material risks. In addition, the risk assessment tool provides multiple scales of the risk measurements such as financial (profit and cost), time (delivery time), and social (affected community) scales.

1 - Dynamic exploration–exploitation trade-off in active learning regression with Bayesian hierarchical modeling

Ashif Iquebal, Arizona State University, Tempe, AZ, United States

Active learning provides a framework to adaptively query the most informative experiments towards learning an unknown black-box function. Various approaches of active learning have been proposed in the literature, however, they either focus on exploration or exploitation in the design space. Methods that do consider exploration–exploitation simultaneously employ fixed or ad-hoc measures to control the trade-off that may not be optimal. In this article, we develop a Bayesian hierarchical approach, referred to as BHEEM, to dynamically balance the exploration-exploitation trade-off as more data points are queried. To sample from the posterior distribution of the trade-off parameter, we subsequently formulate an approximate Bayesian computation approach based on the linear dependence of queried data in the feature space. Simulated and real-world examples show the proposed approach achieves at least 21% and 11% average improvement when compared to pure exploration and exploitation strategies, respectively. More importantly, we note that by optimally balancing the trade-off between exploration and exploitation, BHEEM performs better or at least as well as either pure exploration or pure exploitation.

2 - Simultaneous optimal control of directional missed discovery rates in data stream diagnosis

High-dimensional data streams are ubiquitous in modern manufacturing, due to their ability to provide valuable information about the industrial system's performance on a real-time basis. If a shift occurs in a production process, fault diagnosis based on the data streams is of critical importance for identifying the root cause. Existing methods have largely focused on controlling the total missed discovery rate without distinguishing missed signals for positive versus negative components of the shift vector. In practice, however, losses incurred from the two directional shifts can differ substantially, so it is desirable to constrain the proportions of missed signals for positive and negative components at two distinctive levels. In this article, we propose a fault classification procedure that controls the two proportions separately. By formulating the problem as Lagrangian multiplier optimization, we show that the proposed procedure is optimal in the sense that it minimizes the expected number of false discoveries. We also suggest an iterative adjustment algorithm that converges to the optimal Lagrangian parameters. The asymptotic optimality for the data-driven version of our procedure is also established. Theoretical justification and numerical comparison with state-of-the-art methods show that the proposed procedure works well in applications.

3 - 0 CrossRef citations to date 0 Altmetric Data Science, Quality & Reliability Inspection policy optimization for hierarchical multistate systems under uncertain mission scenarios: A risk-averse perspective

Most engineered systems intend to perform missions with a pre-specified target success probability to reduce undesirable failure risks. Before executing the next mission, inspection activities are conducted across various physical levels for assessing the probability of mission success. However, due to the randomness of a system's degradation behavior and the presence of measurement errors, inspection results inevitably contain uncertainty. Meanwhile, mission durations and acceptable system states may also be uncertain, due to uncontrollable factors, such as random operating environments and mission demands. In such a circumstance, it is of great significance to identify the optimal multilevel inspection policy to answer, as great confident as possible, the question that the system can complete the next mission with a target mission success probability. This paper develops a novel metric to gauge the effectiveness of a multilevel inspection policy to assess if the system can complete the next mission with a pre-specified target success probability from a risk-averse perspective, based on which an optimization method is proposed to seek an inspection policy under uncertain scenarios with the aim of minimizing the maximum regret of the proposed metric. A stochastic fractal search algorithm, along with two tailored local search rules, is designed to efficiently resolve the resulting optimization problem. Two cases, including a three-component system and a rocket fueling mechanism's control system, are used to illustrate the efficacy of the proposed approach, which is capable of effectively identifying the risk of mission failures by inspection policies.

1 - A Deep-Learning-Based Solution for Interpretable in-Situ Monitoring in Additive Manufacturing

Xiaoyang Song, University of Michigan, Ann Arbor, MI, United States, Wenbo Sun, Metin Kayitmazbatir, Judy Jin

In situ quality inspection is a key challenge in additive manufacturing. In this work, we developed a deep-learning-based model to monitor the product porosity using purely optical emission spectra, which has been proven useful in detecting microscopic pores. Although recurrent neural networks and transformers exhibit decent performance in sequential data processing, feature extraction from high-dimensional noisy spectra is still a challenging task. To overcome the challenges, we also collect layer-wise CT scan data after the manufacturing process and use them to guide the learning of spectra features. Specifically, we build connections between the spectra and CT scans using deep canonical correlation analysis to ensure that the learned features are good representatives with those defects, which are presented in the CT scans. We experiment with the proposed method on both simulation data and data that are collected during the real manufacturing process. In addition, as the structure of the proposed multimodal model is akin to that of the real data generation process, it also exhibits decent interpretability compared to other deep-learning-based methods.

2 - Active Multi-Modal Data Fusion for Physiological Signals

Yue Zhao, Rensselaer Polytechnic Institute, Tory, NY, United States, Yinan Wang

Exploring human cognitive states through multi-modal physiological signals from multiple sources by using machine learning method is increasingly significant and has attracted considerable attention in recent research. Machine learning methods often require large datasets, but extensive data collection may be limited due to the significant costs and time investment. Multi-modal data fusion integrates data from multiple sources and is supposed to provide a more comprehensive understanding. However, fusing multi-modal data can usually include misleading information due to noise and data quality issues. Additionally, multi-modality datasets often contain redundant information, so it is essential to identify a subset of modalities with complementary information along with high-quality and informative data samples to improve the performance of the ML method. There are two main challenges: (1) which combination of modalities will benefit the downstream task the most and (2) how to evaluate the informativeness and quality of data samples. We proposed the active multi-modal data fusion framework by integrating Active Learning and Bayesian Optimization. Our proposed framework is validated on collected multi-modal physiological data from the pilots who were tested by the simulated Instrumented Landing System (ILS). The objective is to classify the level of difficulty of flight conditions using the multi-modal physiological data. The result indicates that our framework can select the combination of modalities with complementary information and high-quality data samples to improve performance while has a better sample efficiency.

3 - Transformer-Empowered Incremental Learning for Preventive Defect Monitoring in Additive Manufacturing

Boris Oskolkov, Oklahoma State University, Stillwater, OK, United States, Zhangyue Shi, Chenang Liu

Additive Manufacturing (AM) enables unparalleled design freedom and customization capabilities in modern manufacturing. However, the occurrence of defects during the AM process remains a significant challenge, hindering wider adoption and limiting the reliability of AM-produced parts. However, traditional methods relying on computationally expensive simulations or time-consuming post-build inspections are often inadequate for the dynamic nature of AM processes. Our work introduces an improved approach for preventive defect monitoring in AM that leverages the power of transformers and incremental learning. Transformers, renowned for their ability to capture complex temporal short-term and long-term relationships in sequential data, are employed to learn intricate patterns from in-situ sensor data collected during the AM process. This enables the model to predict defects before they manifest, facilitating proactive intervention and mitigation strategies. The transformer is accompanying our previously introduced incremental learning framework which empowers the model to continuously evolve and refine its predictive capabilities as the process environment evolves. We will showcase experimental results demonstrating the effectiveness of our approach in real-world AM scenarios. Specifically, we will highlight the model's ability to accurately predict defects in real-time, its adaptability to evolving AM environments, and its potential to significantly enhance the quality and efficiency of AM production within cost-related manufacturing constraints.

4 - Detecting Geometric Defects in Gears Using Deep Learning of 3D Point Clouds

Alice Mei, University of Michigan Ann Arbor, Ann Arbor, MI, United States

Geometric integrity is vital in manufacturing as it affects a product’s functionality, reliability, and safety, making accurate geometric assessments critical for quality control. The recent advancement of three-dimensional (3D) metrology has greatly improved the precision of examining geometric integrity, focusing on dimensional accuracy, surface quality, and shape conformity. However, the high dimensionality, unstructured data, and sparseness in defective regions present significant challenges in utilizing high-resolution 3D metrology for advanced manufacturing processes.

To address these issues, our study proposes the "MFGNet-gear" dataset, a scalable and specialized manufacturing dataset featuring twelve part designs, each offered in four quality levels. We have adapted the PointNet++ framework to develop a deep learning model that efficiently performs end-to-end analysis of 3D point clouds. This model is designed to carry out various analytical tasks, which include the classification of part designs and detection of a range of geometric defects. Applied to the "MFGNet-gear" dataset, the model achieved up to 100% accuracy in gear design classification and 85% in discerning different quality levels. Through a series of experiments, we’ve assessed how changes in measurement resolution and precision influence model performance. Results obtained also highlight the potential of deep learning in automating 3D point cloud analysis for quality control applications beyond gear manufacturing. Lastly, our work suggests potential future research directions, including the development of new deep learning architectures specifically designed for manufacturing 3D point clouds and strategies for adaptive measurement planning.

1 - Long term prediction of dynamic intermittency with application for telecardiology based monitoring and prognosis

Zimo Wang, SUNY Binghamton, Binghamton, NY, United States, Qiyang Ma

The performance of long-term prediction models is currently impeded due to the mismatch between the nonstationary representations of statistical learning models and the underlying dynamics from real-world systems, which results in low long-term prediction accuracies for many real-world applications. We present a Recurrent Gated Unit-based Mixture Kriging Machine Bayesian Filtering (ReGU-MKMBF) approach for characterizing nonstationary and nonlinear behaviors of one ubiquitous real-world process—dynamic intermittency. It models the transient dynamics in the state space as recurrent transitions between localized stationary segments/attractors. Then, a case study on predicting the onset of pathological symptoms associated with Electrocardiogram signals is presented. The results suggest that ReGU-MKMBF improves forecasting performance by extending the prediction time horizon by an order of magnitude while maintaining high accuracies for the foreseen estimates. Implementing the presented approach can subsequently change the current scheme of online monitoring and aftermath mitigation into a prediction and timely prevention for telecardiology.

3 - Counterfactual explanations to generate clinical inference into genetic mutation prediction from black-box models

Ishraq Rahman, Arizona State University, Tempe, AZ, United States, Ashif Iquebal

We investigate the problem of predicting and explaining genetic mutation in breast cancer patients derived from high-dimensional magnetic resonance imaging (MRI) without any tumor segmentations. We propose a sparse counterGAN that leverages a generative adversarial model to generate counterfactual MRI instances by learning the true data distribution. During the training process, the generator network generates residuals that are added to the original MRI instance to produce a counterfactual instance. The discriminator network tries to distinguish the counterfactual instance from the original instance. A pre-trained classifier network then classifies the original and counterfactual examples into different categories, such as “mutation” and “non-mutation”. We regularize the loss function to include a p-norm regularization. With p-norm regularization, we can set the value of p to control the sparsity of the solution, where a larger value of p corresponds to a sparser solution with fewer changed features. Finally, we present our results obtained from clinical MRI data as well as inference from domain experts in explaining the genetic prediction results.

1 - Designing Size Inclusive Fashion Assortments

Alireza Alavi, McGill University, Montreal, QC, Canada, Mehmet Gumus, Javad Nasiry

In fashion retailing, size unavailability occurs when displayed items are unavailable in some sizes, leading to lost sales. Plus-size customers encounter size unavailability far more frequently than others, contributing to a "subtle form of social discrimination" that frustrates customers and harms brand perception. This raises a critical question: How should an online fashion retailer design its assortment to be both size inclusive and profitable? In this work, we answer this question by developing a choice model that incorporates customers' reactions to size unavailability, framing the problem as a zero-sum game between the retailer and an adversary (nature), and designing (slow) exact and (fast) approximation algorithms to find the equilibrium of this game. We calibrate our model using data from a large European-based fashion retailer. Our simulations show that our approximation algorithm can reduce unfairness by 30% with only a 1.5% reduction in revenue.

2 - Pay Transparency in Heterogeneous Teams: Could Some Fairness Concerns Hurt Productivity?

Guillaume Roels, INSEAD, Fontainebleau, France, Lin Chen

In homogeneous teams, pay transparency, which induces agents to compare themselves to others, leads to a higher output, results in no inequalities in equilibrium, and is inclusive (i.e., all agents are engaged). This is true irrespective of the basis of social comparisons: income, utility, or reward. How about heterogeneous teams? Could pay transparency backfire under some types of fairness concerns? We consider a model of a principal and two agents of different abilities who are averse to inequalities between each other under pay transparency. We study all three bases of comparison. For each type of fairness concern, we characterize when pay transparency leads to a higher or lower payoff for the principal, results or not in inequalities between agents, and involves only one or both agents in production. We find that income fairness never benefits the principal and might be perceived as unfair and non-inclusive, in contrast to reward fairness, which is always beneficial on all three fronts. Utility fairness lies somewhere in between, offering benefits on all three fronts when agents are not so heterogeneous, but hurting fairness and inclusivity without changing the principal's payoff otherwise. Although pay transparency can help close the gender pay gap, anchoring agents to income fairness by disclosing only their incomes can hurt their productivity while creating feelings of unfairness and lack of inclusivity. In contrast, anchoring them to reward or utility fairness by contextualizing their incomes with their individual contributions or costs may be beneficial on all three fronts.

3 - From Black to Grey: Improving Access to Antimalarial Drugs in the Presence of Deceptive Counterfeits

Jiatao Ding, Nanyang Technological University, Singapore, Singapore, Michael Freeman, Sasa Zorc

In malaria-endemic countries, limited access to affordable antimalarial drugs has fueled the proliferation of counterfeit medications. This paper examines such markets to determine how philanthropic donors can optimize fund allocation to subsidize antimalarial drug distribution through private-sector channels. We develop a game-theoretic model where retailers can source drugs from certified suppliers, uncertified (potential counterfeit) suppliers, or both. Unlike previous studies, we show that relying solely on purchase subsidies may not be optimal when counterfeits are present. Under donor budget constraints, sales subsidies that account for both legitimate and counterfeit drugs may be more effective, or it may be better to avoid subsidies altogether. We also analyze five non-subsidy strategies — improving consumer awareness, penalizing counterfeit sourcing, adopting traceability technology, cracking down on counterfeit supplies, and enforcing price controls — to determine when these can enhance or hinder outcomes. A numerical analysis, calibrated to Mozambique’s malaria data, provides further practical insights. Our findings emphasize the importance of tailoring subsidy schemes and policy choices to market conditions, such as retailer pricing power and demand uncertainty, to improve access to life-saving medicines. These insights could be applied to other endemic diseases, offering a broader framework for enhancing public health in resource-constrained settings.

Emerging Topics in Location Analysis

Invited Session

Location Analysis

Chair: Gina Galindo, Universidad del Norte, Puerto Colombia, Colombia

1 - *Developing a Statewide Active Transportation Planning Dashboard with Mobility Data*

Rebecca Bian, Louisiana Transportation Research Center; Louisiana State University, Baton Rouge, LA, United States

Existing walking/biking data are often insufficient to support active transportation planning activities. This study used an emerging large-scale human mobility dataset to identify places where there are a higher number of short-distance trips to public places (expressed by a mobility index). Demographic variables were integrated into the mobility index to prioritize access for more people and address equity concerns. In addition, a safety index (reflecting crash injuries/fatalities involving pedestrians/bicyclists) and a connectivity index (reflecting the density of existing active transportation infrastructure) were also considered together with the mobility index in generating an investment potential score. All the indices/scores were mapped at hexagon and segment level on an online dashboard. The developed dashboard is expected to support statewide active transportation planning and project selection/prioritization decision-makings. The proposed methodology is replicable for any places that have few active transportation facilities and where pedestrian/bicyclist count data are not sufficient to model demand directly.

2 - Powering routes: Strategically locating chargers for electric trucks' viability

Carlos Otero, Universidad Del Norte, Barranquilla, Colombia

Besides their high procurement prices, battery electric heavy-duty trucks are also limited in range, which is one of the biggest barriers to their adoption. It is particularly difficult to deal with this in the for-hire trucking market, where demand is highly dynamic and geographically dispersed. Despite the lower operative cost of electric trucks compared to diesel trucks, the limited income due to serving a smaller number of loads does not offset profit. An alternative solution is to strategically install electric chargers along freight corridors. According to recent research, locating charging stations at different distances may improve the profitability of these trucks. Here, it is presented the results of a study based on real-life data, which combines the simulation of cargo generation and the routing of fleets of electric and diesel trucks. Results indicate that optimizing fleet composition, charging station locations, and routing decisions may lead to profitable trucking operations in favor of the adoption of cleaner vehicles.

3 - Strategic Evacuation Planning: Integrating Road Network Performance Risk for Natural Hazard Preparedness

Daniel Rivera, University of California Davis, Davis, CA, United States, Miguel Jaller

In this paper, the authors devise a method to design an evacuation plan for preparing for natural hazards such as wildfires, flash floods, and other hazards that require evacuations. The authors examine the critical aspects of the road network infrastructure and their influence on estimating the evacuation performance (EP). They use the Road Network Performance (RNP) Risk to prioritize the evacuation process for the most vulnerable individuals in a case study in California. The purpose of this paper is to determine the minimum evacuation time in a staggered evacuation, where the evacuation will be conducted using the minimum set of evacuation paths at the minimum risk cost. The authors will combine a set of mathematical programming optimization models with RNP risk based on historical data of natural hazards, socio-economic characteristics of the population, and topological characteristics of the road network. This methodology will provide the evacuation scheduling (traffic generation and distribution) and the routes (traffic assignment) that optimize the time, risk, and utilization of resources (paths). The authors demonstrate how the evacuation time and total risk perceived by evacuees correspond to the socio-economic characteristics of the population. Additionally, a set of scenarios are conducted to determine the sensitivity of the evacuation plans in terms of the evacuation time and the overall perceived risk in a set of cities in California. Finally, the authors provide policy insights for the development of evacuation plans.

1 - The Limits of Transfer Reinforcement Learning with Latent Low-rank Structure

Tyler Sam, Cornell University, Ithaca, NY, United States, Yudong Chen, Christina Yu

While reinforcement learning algorithms are increasing in popularity, many algorithms are too costly due to the size of the problem's state space S or action space A. To resolve this issue, we study transfer reinforcement learning with latent low rank structure, where the learner interacts with M source MDPs and attempts to learn a latent representation of the action, states, or both to use in the target MDP to greatly improve performance. Specifically, we study the settings in which the source and target MDPs have transition kernels with Tucker rank $(|S|, d, |A|)$, $(|S|, |S|, d), (d, |S|, |A|)$, or $(|S|, d, d)$. In these settings, our algorithm first learns a near-optimal Q function or estimate of transition kernel for each of the source MDPs and constructs a latent feature representation with the singular vectors of the estimate Q function. Then, our algorithm employs a modification of LSVI-UCB, a common linear MDP algorithm \cite{Jin2020ProvablyER}, to remove the dependence on $|S|, |A|, $ or both in the regret bound in the target MDP. Furthermore, we introduce the transfer-ability coefficient that quantifies the difficulty in performing transfer learning on a specific problem. We then prove lower bounds that show our algorithms are optimal with to the transfer-ability coefficient.

2 - ChatGPT and Firms Performance

Aida Sanatizadeh, Northern Illinois University, Dekalb, IL, United States, Hamid Vakilzadeh, David Wood

This abstract investigates the impact of Large Language Models (LLMs) like ChatGPT on the quality of corporate earnings announcements (EAs). Utilizing AI tools enhances the precision and clarity of financial disclosures, potentially influencing investor decisions and market efficiency. Our study uses data from S&P500 non-English companies, employing event study and difference-in-differences methodologies to assess changes in EA characteristics post-ChatGPT. This research contributes to understanding how generative AI reshapes financial communication and market dynamics.

3 - Pandemic Effect on Online Reviews: The Role of Restrictive Policies, Elite Users, and Political Leanings

Xilu Zhai, Antai College of Economics and Management, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Jifeng Luo

This study investigates the impacts of government-imposed restrictive policies on consumer behavior and online sentiment within the restaurant industry during the COVID-19 pandemic. Utilizing Yelp review data and the Oxford COVID-19 Government Response Tracker, the research employs a continuous difference-in-differences methodology to analyze how early review sentiments and the strictness of government policies influence online review sentiments and ratings. Key findings suggest that positive emotions in early reviews amplify the negative impact of the pandemic on subsequent user ratings. Moreover, stringent government policies, while necessary for public health, significantly exacerbate public unrest and negatively affect online review sentiments. Political orientations also play a crucial role, with consumers in liberal and swing states showing heightened sensitivity to policies compared to those in conservative states. These insights are vital for policymakers and businesses in crafting strategies that balance public health priorities with minimizing adverse psychological impacts during health crises.

4 - Self-Interest and Systemic Benefits: Emergence of Collective Rationality in Mixed Autonomy Traffic Through Deep Reinforcement Learning

Di Chen, University of California, Davis, Davis, CA, United States, Jia Li, Michael Zhang

Autonomous vehicles (AVs) are expected to be commercially available in the near future, leading to mixed traffic with human-driven vehicles (HVs). Although studies have shown that AVs can be deployed to benefit the overall traffic system performance by incorporating system-level goals into their decision making, it is not clear whether they remain beneficial when acting out of self-interest—a trait common to all driving agents, both human and autonomous. This study aims to explore the potential of leveraging self-interested AVs to bring benefits to all driving agents in mixed autonomy traffic systems. We introduce the concept of collective rationality (CR) in mixed traffic and examine its properties in micro-simulation. This concept, originating from game theory and behavioral economics, means that driving agents may form cooperation at collective level even when pursuing individual interests. Our recent research has proven the existence of CR in an analytical game-theoretical model and empirically in mixed human-driven traffic. In this paper, we demonstrate CR can be attained among driving agents trained with deep-reinforcement learning and a simple reward design. We examine the extent to which self-interested traffic agents can achieve CR without directly incorporating system-level objectives. Results show the consistent emergence of CR, which indicates the robustness of these properties. We also postulated and analyzed the underlying mechanism to explain the emergence of CR in the microscopic, dynamic environment. These findings paved the way for the adoption of advanced learning methods, such as federated learning, to achieve cooperation spontaneously among self-interested driving agents in mixed-autonomy systems.

5 - The Individual&Rsquo;S Perception of AI and Its Effects on The Organization&Rsquo;S Ai Initiatives

Catherine Petersen, Johnson & Wales University, Mont Vernon, NH, United States

Investment in Artificial Intelligence (AI) does not result in returns for business despite improving technology. This study investigated one potential reason for the failure of AI when implemented within an organization with the intent to drive success with this technology. AI is unique amongst technologies due to its ability to inspire emotions from potential users and these emotions can affect the individual’s willingness to adopt the technology.

Using an explanatory sequential research design, this study examined the relationship between how an individual perceives AI and their willingness to accept the technology in their role within an organization. It also considered the role of experience and an individual’s perception of AI.

The results found that including AI in the description of the initiative decreased support from 81.5% to 54.8%. There was also a significant relationship between an individual’s perception of AI and their support of an initiative that specifically names AI ($p < .05$). In interviews, nine out of ten respondents discussed job replacement and showed a tension between hopes and fears with regard to the technology. No statistically significant relationship was found between an individual’s experience with AI and their perception of AI but there was a relationship between experience and their expectations for effort and performance. Interviews showed that an individual’s perception of job replacement or challenges with the technology were not affected or increased with experience using AI. Based on these findings, managers can better determine if their organizations are ready to implement AI successfully.

Summit - 328

OR in Security & Defense III (Mission Support)

Invited Session

Military and Security

Chair: Kyle Swan Hovey, Department of Defense, Columbia, MD, United States

1 - Modeling Attrition for More Accurate Hiring Goals

Beth Goodman, DoD, Laurel, MD, United States, Alex Schulte, Sarah Charlton

A challenging problem for any large organization is ensuring that the workforce is adequate to meet the requirements of that entity. Understanding who and how many people are leaving (attrition) can assist with planning for replacements, and therefore inform hiring goals. We have used a variety of forecasting techniques and historical data to select models that can leverage trends to suggest a more robust estimate of overall (and a selection of subcategories) attrition.

2 - UAS Swarms and Swarm Intelligence: The Current State and Future Concepts

Cameron Carter, USAF, Baltimore, MD, United States

The adoption of unmanned systems in the US military has been a disruptive shift in the realm of modern warfare. Unmanned Aircraft Systems (UAS) Swarms are the next iteration in the shift to drone technology, particularly as the development of Swarm Intelligence and better autonomous systems accelerates. Our efforts aim to examine the current literature and body of research on Swarm Intelligence and the types of AI models and algorithms fueling it. We will identify the current levels of autonomy and human involvement in relation to drone swarms, the current technological limitations, and where we believe the capabilities will be in the future.

This research will also examine the current efforts from USG agencies as well as military research laboratories in order to capture the current state of UAS swarm testing and development and their vision for the future of swarm technology. We will explore the defense applications and benefits of these low-equity, unmanned systems highlighting the effectiveness and adaptability that comes with their dynamic approach. Our efforts will take a look at the legal and ethical considerations surrounding the use of intelligent UAS swarms for both offensive and defensive applications. We aim to provide a comprehensive analysis of the current and potential future capabilities of UAS swarms in the context of a military application.

3 - Enhancing Textual Data Classification with Advanced Language Models: An Evaluation of GPT, BARD, and LLAMA

andrew gelbard, Department of Defense, Annapolis Junction, MD, United States

The accurate classification of textual data is critical for many organizations, but it can be a challenging and time-consuming task that depends on contextual interpretations. Our research aims to explore the potential of advanced language models, such as GPT, BARD, and LLAMA, to automate and refine the task of text classification. We will fine-tune these foundation models to assess their efficacy in distinguishing between different types of textual data. This approach could dramatically enhance decision-making speeds, reduce human workload, and ensure consistent information security across various organizations. We will use a dataset of textual data to test the adaptability and accuracy of these AI models, and we expect that our results will have a broader applications in automatic data handling and security protocols in various sectors.

4 - Internship Opportunities within the DoD

Kyle Hovey, Department of Defense, Columbia, MD, United States

The U.S. Department of Defense has a long history of employing Operations Researchers to tackle some of its most complex problems. To ensure the DoD continues to bring in exceptional operations researchers, there are a number of well-established internship opportunities within the DoD targeting those pursuing degrees in Operations Research and related fields. In this talk, we will discuss several of these opportunities and provide additional information on how to apply. Note: while this talk is open to any interested participants, most DoD internships are restricted to U.S. citizens only.

Prompt Engineering, Fine Tuning, Alignment and Market Applications of Large Language Models

Invited Session

Auctions and Market Design

Chair: Wanning Chen, University of Washington, Seattle, WA, United States

1 - Risk Control for Large Language Models

Catherine Chen, Stanford University, Stanford, CA, United States, Lihua Lei

Recent developments in large language models (LLMs) have led to their widespread usage for various tasks. The prevalence of LLMs in society implores the assurance on the reliability of their performance. In particular, risk-sensitive applications demand meticulous attention to unexpectedly poor outcomes, e.g., toxic answers, humiliating language, and offensive outputs. In this work, we present an approach that is guaranteed to control any distortion risk measure, characterized by a weighted average of quantiles of the loss incurred by the LLM, without making any assumptions on the statistical properties of the LLM. Our method exploits the connection between conformal risk control and L-statistics, a type of estimator that dates back to the 40s, and leverages asymptotic properties of L-statistics.

2 - Rlhf and Independence of Irrelevant Alternatives: Perverse Incentives

Wanqiao Xu, Stanford University, Stanford, CA, United States, Shi Dong, Xiuyuan Lu, Grace Lam, Zheng Wen, Benjamin Van Roy

Existing algorithms for reinforcement learning from human feedback (RLHF) can incentivize responses at odds with preferences because they are based on models that assume independence of irrelevant alternatives (IIA).
The perverse incentives induced by IIA hinder innovations on query formats and learning algorithms.

3 - A Probabilistic Approach for Model Alignment with Human Comparisons

Junyu Cao, The University of Texas at Austin, Austin, TX, United States, Mohsen Bayati

A growing trend involves integrating human knowledge into learning frameworks, leveraging subtle human feedback to refine AI models. Despite these advances, no comprehensive theoretical framework describing the specific conditions under which human comparisons improve the traditional supervised fine-tuning process has been developed. To bridge this gap, this paper studies the effective use of human comparisons to address limitations arising from noisy data and high-dimensional models. We propose a two-stage "Supervised Fine Tuning+Human Comparison" (SFT+HC) framework connecting machine learning with human feedback through a probabilistic bisection approach. The two-stage framework first learns low-dimensional representations from noisy-labeled data via an SFT procedure, and then uses human comparisons to improve the model alignment. To examine the efficacy of the alignment phase, we introduce a novel concept termed the "label-noise-to-comparison-accuracy" (LNCA) ratio. This paper theoretically identifies the conditions under which the "SFT+HC" framework outperforms pure SFT approach, leveraging this ratio to highlight the advantage of incorporating human evaluators in reducing sample complexity. We validate that the proposed conditions for the LNCA ratio are met in a case study conducted via an Amazon Mechanical Turk experiment.

4 - Orchestrating Language Models for Supply Chain Optimization

Beibin Li, Microsoft Research, Redmond, WA, United States, Konstantina Mellou, Luke Marshall, Ishai Menache

Supply chain operations traditionally involve a variety of complex decision making problems. Over the last few decades, supply chains greatly benefited from advances in computation, which allowed the transition from manual processing to automation and cost-effective optimization. Nonetheless, business operators still need to spend substantial efforts in explaining and interpreting the optimization outcomes to stakeholders. Motivated by the recent advances in Large Language Models (LLMs), we study how this disruptive technology can help bridge the gap between supply chain automation and human comprehension and trust thereof. We design OptiGuide -- a framework that accepts as input queries in plain text, and outputs insights about the underlying optimization outcomes. Our framework does not forgo the state-of-the-art combinatorial optimization technology, but rather leverages it to quantitatively answer what-if scenarios (e.g., how would the cost change if we used supplier B instead of supplier A for a given demand?). Importantly, our design does not require sending proprietary data over to LLMs, which can be a privacy concern in some circumstances. We demonstrate the effectiveness of our framework on a real server placement scenario within Microsoft's cloud supply chain. Along the way, we develop a general evaluation benchmark, which can be used to evaluate the accuracy of the LLM output in other scenarios.

Summit - 331

Network Analysis and Graph Neural Networks II

Invited Session

Telecommunications and Network Analytics

Chair: Wenting Li, Los Alamos National Laboratory, Los Alamos, NM, United States

Co-Chair: Lili Zhang, Hewlett Packard Enterprise, Suwanee, GA, United States

1 - Empower Graph Machine Learning for Trustworthy Decision Making

Jundong Li, University of Virginia, Charlottesville , VA, United States

Graph machine learning (GML) models, such as graph neural networks, have proven to be highly effective in modeling graph-structured data and achieving remarkable predictive performance in various high-stake applications, including credit risk scoring, crime prediction, and medical diagnosis. However, concerns have been raised regarding the trustworthiness of GML models in decision making scenarios when fairness, transparency, and accountability are lacking.

To address these concerns, I will present our recent work on empowering GML for trustworthy decision making by focusing on three key aspects: fairness, explanation, and causality. First, I will discuss how to improve the fairness of GML from a data debiasing perspective. In particular, I will show how to measure data biases regarding different modalities of graph data and how to mitigate the data biases in a model-agnostic manner that can benefit different GML models. Second, I will show that explanation, as an effective debugging tool, not only can help us understand how the decisions are made but also could serve as a useful tool to diagnose how biases and discrimination are introduced in GML. Toward this goal, I will present a post-hoc structural explanation framework that can understand the unfairness issues of GML.

Third, I will argue the emerging need to introduce causality for trustworthy decision making on graphs, as traditional GML could heavily rely on spurious correlations for making decisions. To bridge the gap, I will present a GML-based causal inference framework that aims to unleash the power of graph information for causal effect estimation.

2 - Signal Processing over Multilayer Graphs: Theoretical Foundations and Practical Applications

Songyang Zhang, University of Louisiana at Lafayette, Lafayette, LA, United States, Qinwen Deng, Zhi Ding

Signal processing over single-layer graphs has become a mainstream tool owing to its power in revealing obscure underlying structures within data signals. However, many real-life data sets and systems are characterized by more complex interactions among distinct entities, which may represent multilevel interactions that are harder to be captured with a single-layer graph, and can be better characterized by multilayer graph connections. Such multilayer or multilevel data structures can be more naturally modeled by high-dimensional multilayer graphs (MLGs). To generalize traditional graph signal processing (GSP) over MLGs for analyzing multilevel signal features and their interactions, this presentation will introduce a tensor-based framework of MLG signal processing (M-GSP). Specifically, we will first introduce core concepts of M-GSP and study the properties of MLG spectral space, followed by fundamentals of MLG-based filter design. To illustrate novel aspects of M-GSP, we will further provide the example applications to demonstrate the efficacy and benefits of applying MLGs and M-GSP in practical scenarios. Finally, we will discuss its correlations to graph neural networks and its potential for tensor-based MLG neural networks (MGNN).

3 - Combining Knowledge Graph and Large Language Model: use Cases and Challenges

Lili Zhang, Hewlett Packard Enterprise, Alpharetta, GA, United States

Both Knowledge Graph and Large Language Model have generated significant values across industries and daily life. Knowledge Graph is efficient in identifying the patterns from the relationships. Large Language Model mimics human language understanding and response behaviors. In this session, we explore the use cases (e.g., webpage phishing detection) and challenges of combining Knowledge Graph and Large Language Model.

Digital Innovation and Social Media

Flash Session

Flash

Chair: Somak Paul, California State University, Alameda, CA, United States

1 - Effects of digital orientation on innovation performance: a mediating role of digital capabilities

Xian Zhang, School of Management, Huazhong University of Science and Technology, Wuhan, China, People's Republic of, Wenyi Luo, Feifei Guo, Peng Wang

In the era of the digital economy, digital orientation is considered a crucial development strategy for firms. Despite the predominant focus on the effect of digital orientation on innovation performance, there is a lack of research exploring the mechanisms through which digital orientation enables innovation performance. Drawing on dynamic capability theory as the core theoretical foundation, this study investigates the Interrelationships of digital orientation, digital capabilities, and innovation performance from a dynamic evolutionary perspective and examines the mediating effect of digital capabilities and the moderating effect of environmental uncertainty. We collected survey data from 368 Chinese firms and used hierarchical linear regression to test our hypotheses. The empirical results show that digital orientation and the three sub-dimensions of digital capabilities (digital sensing capabilities, digital integrative capabilities, and digital network capabilities) all promote innovation performance; digital capabilities have a positive mediating effect on the relationship between digital orientation and innovation performance; environmental uncertainty moderates the relationship between digital capabilities and innovation performance, but does not moderate the relationship between digital orientation and innovation performance or between digital orientation and digital capabilities. This study reveals the micro-mechanism between digital orientation and innovation performance and constructs a theoretical framework of "digital orientation-digital capabilities-innovation performance", which is a beneficial extension of dynamic capability theory in the context of digitalization. Furthermore, the research findings encourage firms to enhance their digital capabilities by adopting digitally-oriented strategies to cope with changing environments and improve their innovation performance.

2 - Understanding the Role of Developers' Social Interaction within Open Source Software Platforms on Strategic Directions for Digital Innovation

Sidi Zhao, Auburn University, Auburn, AL, United States, Pei Xu, Uzma Raja

Firms proactively invest in digital innovation to strategically allocate IT resources and boost business performance. Upper Echelons Theory suggests that top managers' characteristics influence strategic directions, but many lack the technical expertise for effective decision-making. Digital innovations require new organizational forms to manage complex relationships and interactions among actors at various knowledge and learning levels. Many firms leverage open innovation platforms like open-source software (OSS) communities to access external knowledge and resources. While the benefits of open innovation are well-documented, the impact of social interactions among OSS developers on firms' digital innovation efforts is underexplored. We posit that social dynamics within OSS communities significantly shape knowledge diffusion across firms. Utilizing a heterogeneous diffusion model, we develop a framework to understand how social context impacts innovation adoption through social proximity, infectiousness, and susceptibility factors. We construct the social network among firms' developers on GitHub and the patent network of artificial intelligence (AI) and Blockchain-related patents from the US Patent and Trademark Office (USPTO). Blockchain and AI, as typical forms of digital innovation, have substantial potential to impact business activities. Based on link prediction and panel fixed effect estimation on longitudinal datasets from 2010 to 2023, our empirical investigation contributes to social network analysis by addressing the complexities of predicting firm network ties through individual social interactions.

The findings offer actionable insights into how developers influence firm strategy from the bottom up, helping firms maintain strategic flexibility and stay attuned to innovation trends among market peers.

3 - Analyzing the effects of knowledge management on organizational performance through knowledge utilization and sustainability

Faezeh Mohaghegh, Alfred University, Alfred, NY, United States, Halil Zaim, Vladimir Dzenopoljac, Aleksandra Dzenopoljac, Nick Bontis

In today's turbulent business environment, gaining sustainable competitive advantage requires organizations to manage knowledge capabilities effectively and use resources efficiently. The primary objective of this study is to explore the relationship among knowledge management (KM) processes, including knowledge generation, knowledge codification, and knowledge sharing, with knowledge utilization, sustainability, and organizational performance. The research mainly examines both the direct effect of KM on organizational performance and its indirect effect through sustainability and knowledge utilization. A theoretical framework is introduced and tested using data gathered from companies within the services sector in Kuwait. The results indicate that knowledge utilization and sustainability fully mediate the relationship between KM and organizational performance. Both knowledge utilization and sustainability exert direct and positive effects on organizational performance while being directly influenced by KM. Accordingly, it is suggested that the firms enhance their performance by effectively managing knowledge capabilities appropriately, utilizing knowledge, and investing in sustainability and organizational resources.

4 - Decentralized Decision-Making Framework for Managing Product Rollovers in the Semiconductor Industry Under Uncertainty.

Carlos Leca, North Carolina State University, Raleigh, NC, United States, Karl Kempf, Reha Uzsoy

In competitive industries, firms seek to gain competitive advantage through new product introductions and the retirement of existing products, a process termed *'product rollover.'* Navigating an effective rollover strategy is a complex task, that can jeopardize a firm's financial stability if not managed adeptly. Firms face the challenge of *resource allocation* across diverse divisions, each serving distinct market niches, possessing proprietary information, and *competing* for the firm's resources.

In prior research, we developed a *decentralized resource allocation mechanism* that coordinates agents involved in product rollover strategy execution within a reasonable computational time. However, this mechanism was only tested under deterministic conditions. To address this limitation, our current study integrates the decentralized model into a rolling horizon framework capable of accommodating *parameter uncertainty*. Furthermore, we propose an adapted framework fostering *strategic conduct* among agents, allowing them to hedge against uncertainty by signaling oversized estimated allocation requirements. This perturbation from the estimated requirements leads to increased resource scarcity impacting the resource cost in future periods and hence affecting the performance of other agents.

Finally, we applied a *reinforcement learning* technique to determine the agent's optimal buffering level given the current state of the rollover campaign. The resulting policy matrices shed light on situations where an agent's optimal decision, driven by self-interested objectives, may not align with the firm's overall objectives.

5 - Adapting to Adversity: The Impact of Data Breaches on the Disclosure of Digital Strategic Initiatives

HILAL PATACI, University of Texas at San Antonio, San Antonio, TX, United States, T Ravichandran, Nishtha Langer

Digital transformation is fundamentally reshaping how organizations operate and deliver value to their stakeholders. Central to this transformation are digital strategic initiatives, which encompass specific projects and programs undertaken to leverage digital technologies and achieve strategic objectives. These initiatives often entail implementing advanced security measures to safeguard sensitive data and prevent unauthorized access. Understanding how these initiatives are influenced by factors such as data breaches is crucial for organizations navigating the complex challenges of digital transformation and cybersecurity. Drawing on disclosure and institutional theories, we explore mechanisms driving organizations' voluntary disclosure decisions post-data breaches, considering their access to privileged information about breaches in their competitors and upstream suppliers. Institutional theory suggests that organizations face mimetic pressures, compelling them to emulate successful, non-breached peers. Disclosure theory emphasizes meeting shareholders' information needs, prompting organizations to disclose more nonproprietary information under mandatory disclosure requirements. Organizations acting as customers of breached upstream suppliers often access privileged information on breach specifics, prompting them to refine their disclosure strategies to assuage stakeholder concerns and minimize uncertainty by disclosing less proprietary information. Conversely, organizations associated with breached competitors, with limited access to privileged information, face heightened pressure to conform to industry standards. They enhance their disclosure efforts to maintain shareholder trust, even without precise breach information, by disclosing more proprietary information. Our findings highlight that access to privileged information leads to more conservative voluntary disclosure behavior. Further, organizations with prior breach experience possess deeper insights into breach impacts, shaping their disclosure strategies accordingly.

6 - Partial Persuasive Marketing on Service Operations Platforms

Yang XIA, City University of Hong Kong, Hong Kong, China, People's Republic of, Pengfei Guo, Qiaochu He, Yulan Wang

This study investigates the strategic use of partial persuasive marketing on an online service platform under uncertain service quality. We model the partial persuasive marketing with “targeting technology”, assuming that the platform strategically communicates service quality to a subset of customers from the perspective of Bayesian persuasion. A queuing game model is developed to determine the platform’s optimal information strategy, aiming to tune the online service recommendation algorithm’s accuracy. The algorithm commits to binary signal strategies based on service quality, influencing informed customers’ beliefs. All customers then decide whether to join the platform. Interestingly, at a moderate market size, we discover that adjusting the beliefs of partial customers with targeting technology can achieve the same effective arrival rate as adjusting the beliefs of all customers. We show that the platform can maximize throughput by fine-tuning positive signal accuracy or to enhance social welfare by obfuscating negative signals. We demonstrate that a unique targeting strategy that maximizes platform throughput can be identified, and partial persuasive marketing is better in a large market size since it is more difficult to adjust the beliefs of all customers than to adjust the beliefs of a subset of customers. To maximize social welfare, we demonstrate that the optimal targeting strategy and information disclosure level can significantly enhance collective payoffs, particularly when market sizes are unconstrained. This insight challenges the intuition that strategically communicating with all potential customers is invariably the preferred strategy, highlighting the benefits of well-designed and targeted information campaigns.

7 - Operational Inefficiencies and Misinformation

Jingyi Sun, Stevens Institute of Technology, Hoboken, NJ, United States, Feng Mai, Muer Yang

This study examines the relationship between operational factors such as waiting time in queues and online misinformation spread using a unique dataset combining granular measures from geospatial data, social media content, and demographic information. Employing mixed research methods, the findings suggest that operational variables are associated with increased sharing of misinformation, with significant heterogeneity based on demographics. The research introduces a novel operational factor into the study of information dynamics on social media.

8 - Fairness as a Heuristic in Socially Responsible Decision-Making: An Experimental Study

Somak Paul, California State University, Hayward, CA, United States

The fairness heuristic is an effective lever as it allows people to free up their cognitive capacity in situations that could otherwise overwhelm their cognitive and attentive resources. The perception of fair treatment leads people to respond cooperatively to the demands and requests of others. On the other hand, if they perceive to have been treated unfairly, individuals reciprocate by rejecting cooperation and embrace self-interested orientation. In this research we study how the decision-maker in a supplier firm faces a complicated situation where they not only need to focus on their profit motif but also need to make investment decisions for workplace safety compliance. Through a controlled experiment we observe that the perception of procedural and distributional fairness in a buyer's ordering characteristics impact how the supplier firm wants to orient itself in fulfilling its social responsibility. Additionally, we note that the financial reliability of the buyer in upholding the contract also impacts the supplier's investment in building a safe workplace. Our research illuminates that buyers should use their fairness lever carefully to help establish socially responsible operations in their supplier's workplace.

Healthcare Resource Management

Flash Session

Contributed

Chair: Jens Brunner, Technical University of Denmark, Akademivej, Kgs. Lyngby, 2800, Denmark

1 - Optimizing Ambulance Allocation to On-Campus and Free-Standing Emergency Departments Using a Multistage Stochastic Programming Approach

Jorge Acuña, Universidad Adolfo Ibáñez, Viña del Mar, Chile, Daniela Cantarino, Jose Zayas-Castro, Michael Lozano Jr.

Emergency department (ED) overcrowding is a significant issue in the US healthcare system, leading to adverse patient outcomes. ED visits have surged by over 60% since 1997, surpassing 130 million annually, prompting the construction of free-standing EDs across the country. However, patient transfers between on-campus and free-standing EDs exacerbate issues like ambulance diversion and prolonged EMS wait times. The literature has shown that overcrowding stems from systemic dysfunction rather than individual inefficiencies. We propose a stochastic mixed-integer programming model for allocating ambulances to on-campus and free-standing EDs over a finite planning horizon to address this. Our model considers patient conditions, priorities, real-time routing, and ED capacities to minimize travel and wait times. We developed an enhanced progressive hedging algorithm (EPHA) to analyze a real-size scenario in a county in Florida. While commercial solvers may find optimal solutions faster for small instances, they struggle with larger scenarios. In contrast, the EPHA delivers near-optimal solutions within 15 minutes for real scenarios. The preliminary results show that ignoring current and future utilization levels can turn free-standing EDs into bottlenecks. Therefore, a centralized decision system for allocation policies can reduce average patient wait times by up to 45% (27 minutes), improve EMS and ED efficiency, and provide robust alternatives during demand surges. Proper utilization of the combined capacities of free-standing and on-campus EDs ensures prompt patient care, even during high demand. Sensitivity analysis on primal and dual multipliers highlights the significance of the penalty update method in enhancing EPHA's accuracy and computation time.

2 - Aggregate surgery capacity planning with consideration of self-cancellation

Xue Yang, Simon Fraser University, Burnaby, BC, Canada, Zhe Zhang, Yang Wang, Abraham Punnen

Patient self-cancellation in day surgery centers (DSCs), as common as the cancellation because of insufficient surgery resources or emergency patients, leads to waste of surgery resources and increase of the hospital costs. However, current healthcare capacity planning methods usually only consider the latter. To address such a shortcoming, we examine a long-term sequential surgery capacity planning problem in which the DSC allocates operating room hours and surgical intensive unit care (SICU) bed days to different specialties with consideration of the time-dependent self-cancellation-related waiting risk. We formulate this problem as a Markov decision process, explicitly taking into account patient length-of-stay in SICU beds, self-cancellation chances and elective patient census. We solve the model by approximate dynamic programming: variable aggregation-based Lagrangian relaxation and constraint-generation-based heuristics. We also propose a heuristic policy in which patients in different specialties are viewed as single-type patients. To illustrate the efficiency of our approaches and draw managerial insights, we apply our solutions to a two-year data set from the day surgery center in a large public hospital in Sichuan, China. We examine the quality of our approaches and compare their solutions with the proposed heuristic policy. We also show good performances of our approaches in the complex environment through the extensive numerical analysis.

3 - Operating Room Scheduling under Human Resource

Xiajie Yi, IÉSEG School of Management, Lille, France, Christine DI MARTINELLY

Effective Operating Room (OR) scheduling holds significant financial implications for hospitals, particularly when dealing with inpatient procedures at the operational level. However, the duration of a surgery is often uncertain and it is rather challenging to accurately predict. Estimates can vary significantly across different departments, leading to various extents of underestimations. As a result, it exacerbates nurse shortage issue in hospitals. To address this, we propose an approach to build robust surgery schedules in an OR theatre made of several rooms with different specialties and sharing nurses. Our method utilizes a two-stage stochastic optimization model. In the first stage, we determine the number of nurses working each day, while the second stage focuses on creating the detailed schedule. Additionally, we adopt the sampling average approximation (SAA) technique to address uncertainties in surgery duration. Based on the samples generated from real-life data, the simulation results imply that i) the surgery schedule could be fully scheduled with fewer number of nurses; ii) the nurse shortage/absence issue can be potentially avoided as we can accommodate uncertain duration better.

4 - Planning surgeries and staff simultaneously subject to scheduling flexibility

Jens Brunner, Technical University of Denmark, Kgs. Lyngby, Denmark

Physicians and operating rooms are two of hospitals' most important, expensive, and scarce resources. Therefore, effective and efficient scheduling of these resources is among hospitals' most relevant planning tasks. The decisions to be made on the daily planning level regarding sequencing patients’ surgeries and assigning appropriate staff to surgeries. Since there are several interdependencies between surgery schedules and physician rosters, it is a meaningful approach to consider both planning problems within one integrated optimization problem. We provide mixed-integer programming models within a column generation algorithm that solves both scheduling problems. We create schedules for surgeries and operating room staff. We use test data based on a real-world dataset to provide meaningful insights. The algorithm leads to optimal solutions in more than 75% of all test cases and solves the problem efficiently within a desirable amount of time. We further evaluate our algorithm with respect to different aspects of flexibility in the context of surgery and staff scheduling and generate key insights about their interdependencies.

Summit - 334

Climate Financial Risk

Invited Session

Finance

Chair: Kay Giesecke, Stanford University, Stanford, CA, United States

1 - How Much Sustainability is Really in Stock Prices?

Enrica Archetti, Stanford University, Stanford, CA, United States, Eva Lütkebohmert, Markus Pelger, Marcus Rockel

We show that financial markets do not price environmental risk once we control for conventional sources of risk. In a comprehensive empirical study we use machine learning to predict stock returns with a large set of conventional firm characteristics and climate characteristics. Our battery of machine learning methods allows us to capture complex dependencies and control for a large number of variables. When using only climate variables, they predict stock returns. However, this predictability disappears when controlling for conventional sources of risk. These results are robust to the choice of machine learning method. Thus, sustainability characteristics do not represent a new source of financial risk but merely repackage existing risk factors.

2 - Physical Climate Risk and Small Business Defaults

Alec Madayan, Stanford University, Stanford, CA, United States

This study examines the causal impact of physical climate risk on small business loan defaults in the United States, a critical factor for insurance pricing. Initially focusing on Hurricane Harvey, we analyze its effect on small business defaults while controlling for various confounding variables. Our findings demonstrate a significant causal relationship between climate risk and loan defaults. Notably, the timing of defaults is influenced by specific loan characteristics and the severity of the climate impact on the region of the issuer. We employ both linear and nonlinear modeling approaches, along with clustering algorithms, to estimate these effects and conduct robustness checks to ensure the reliability of our results. Our methodology is then systematically applied across various climate events, offering a comprehensive understanding of the interplay between climate risk and small business financial stability. This research provides valuable insights for insurers and policymakers, aiding in the development of more accurate risk assessment models and pricing strategies.

3 - Physical Climate Risk for Mortgage Markets

Johannes Fuest, Stanford University, Stanford, CA, United States

We develop causal machine learning estimators for point processes tracking the timing of correlated events. We apply these estimators to evaluate the impact of physical climate risk on the behavior of individual mortgage borrowers and agency mortgage-backed securities (MBS). We find that natural disasters such as hurricanes have significant causal effects on mortgage borrower behavior including voluntary and involuntary prepayments. The effects are found to vary greatly with borrower characteristics including leverage, geography, and credit score, as well as macro-economic conditions including interest rates. However, the geographic diversity of agency MBS collateral loan pools greatly mitigates these causal effects, basically shielding MBS investors from physical climate risk. These findings have important implications for the disclosure of climate-related risks by financial institutions and the optimal structuring of MBS pools by agencies such as Fannie Mae.

4 - Transportation Marketplace Rate Forecast Using Signature Transform

Xinyu Li, UC Berkeley, Berkeley, CA, United States

Freight transportation marketplace rates are typically challenging to forecast accurately. In this work, we have developed a novel statistical technique based on signature transforms and have built a predictive and adaptive model to forecast these marketplace rates. Our technique is based on two key elements of the signature transform: one being its universal nonlinearity property, which linearizes the feature space and hence translates the forecasting problem into linear regression, and the other being the signature kernel, which allows for comparing computationally efficiently similarities between time series data. Combined, it allows for efficient feature generation and precise identification of seasonality and regime switching in the forecasting process. An algorithm based on our technique has been deployed by Amazon trucking operations, with far superior forecast accuracy and better interpretability versus commercially available industry models, even during the COVID-19 pandemic and the Ukraine conflict. Furthermore, our technique is able to capture the influence of business cycles and the heterogeneity of the marketplace, improving prediction accuracy by more than fivefold, with an estimated annualized saving of $50 million.

Innovations in Data-driven Marketplaces

Invited Session

Revenue Management and Pricing

Chair: Yiding Feng, University of Chicago Booth School of Business, Chicago, IL, N/A, United States

1 - Dynamic Pricing of Split Stays

Yi Zhuang, Baruch College, The City University of New York, New York City, NY, United States, Arash Asadpour, Yuan-Mao Kao

Traditionally, hotel bookings are listed based on the search for check-in and check-out dates for a room. Recently, Airbnb introduced an option to book split stays for two listings. However, this option can incur inconvenience when a traveler needs to relocate to a new lodging during their stay. Thus, pricing considerations for split stays are different from those for single reservations, and relocating discounts might be in order. We develop a dynamic pricing framework that provides the optimal pricing policy for split stays as an alternative to single reservations. We study how the discounts for split stays change over time and in different availability scenarios. We find that split stays play a role in balancing the inventory of the rooms when it is about to deviate. We also study the revenue gains resulting from offering these new products.

2 - Regulation of Algorithmic Collusion

Chenhao Zhang, Northwestern University, Evanston, IL, United States, Jason Hartline, Sheng Long

Consider sellers in a competitive market that use algorithms to adapt their prices from data that they collect. In such a context it is plausible that algorithms could arrive at prices that are higher than the competitive prices and this may benefit sellers at the expense of consumers (i.e., the buyers in the market). This paper gives a definition of plausible algorithmic non-collusion for pricing algorithms. The definition allows a regulator to empirically audit algorithms by applying a statistical test to the data that they collect. Algorithms that are good, i.e., approximately optimize prices to market conditions, can be augmented to collect the data sufficient to pass the audit. Algorithms that have colluded on, e.g., supra-competitive prices cannot pass the audit. The definition allows sellers to possess useful side information that may be correlated with supply and demand and could affect the prices used by good algorithms. The paper provides an analysis of the statistical complexity of such an audit, i.e., how much data is sufficient for the test of non-collusion to be accurate.

3 - Bayesian Persuasion with a Learning Agent

Tao Lin, Harvard University, Cambridge, MA, United States, Yiling Chen

We study a repeated Bayesian persuasion problem (and more generally, any generalized principal-agent problem with complete information) where the principal does not have commitment power and the agent uses algorithms to learn to respond to the principal's signals. We reduce this problem to a one-shot generalized principal-agent problem with an approximately-best-responding agent. This reduction allows us to show that: if the agent uses contextual no-regret learning algorithms, then the principal can guarantee a utility that is arbitrarily close to the principal's optimal utility in the classic non-learning model with commitment; if the agent uses contextual no-swap-regret learning algorithms, then the principal cannot obtain any utility significantly more than the optimal utility in the non-learning model with commitment. The difference between the principal's obtainable utility in the learning model and the non-learning model is bounded by the agent's regret (swap-regret). If the agent uses mean-based learning algorithms (which can be no-regret but not no-swap-regret), then the principal can do significantly better than the non-learning model. These conclusions hold not only for Bayesian persuasion, but also for any generalized principal-agent problem with complete information, including Stackelberg games and contract design.

4 - Are Bounded Contracts Learnable and Approximately Optimal?

YURONG CHEN, Peking University, Beijing, China, People's Republic of, Zhaohua Chen, Xiaotie Deng, Zhiyi Huang

This paper considers the hidden-action model of the principal-agent problem, in which a principal incentivizes an agent to work on a project using a contract. We investigate whether contracts with bounded payments are learnable and approximately optimal. Our main results are two learning algorithms that can find a nearly optimal bounded contract using a polynomial number of queries, under two standard assumptions in the literature: a costlier action for the agent leads to a better outcome distribution for the principal, and the agent's cost/effort has diminishing returns. Our polynomial query complexity upper bound shows that standard assumptions are sufficient for achieving an exponential improvement upon the known lower bound for general instances. Unlike the existing algorithms which relied on discretizing the contract space, our algorithms directly learn the underlying outcome distributions. As for the approximate optimality of bounded contracts, we find that they could be far from optimal in terms of multiplicative or additive approximation, but satisfy a notion of mixed approximation.

5 - Screening Signal-Manipulating Agents via Contests

Xiaoyun Qiu, Northwestern University, Evanston, IL, United States, Yingkai Li

We study the design of screening mechanisms subject to competition and manipulation. A social planner has limited resources to allocate to multiple agents using *only* signals manipulable through unproductive effort. We show that the welfare-maximizing mechanism takes the form of a contest and characterize the optimal contest. We apply our results to two settings: either the planner has one item or a number of items proportional to the number of agents. We show that in both settings, with sufficiently many agents, a winner-takes-all contest is never optimal. In particular, the planner always benefits from randomizing the allocation to some agents.

1 - Comparative Analysis of Parsimonious Discrete Choice Models for Prediction and Assortment Optimization

Guillermo Gallego, Chinese University of Hong Kong Shenzhen, Shenzhen, China, People's Republic of, Anran Li, Pengyu Zuo

The bias-variance tradeoff suggest the use of parsimonious discrete choice models for small to moderately-sized datasets. This study assesses five such models, focusing on predictive accuracy and assortment optimization, both with and without cardinality constraints. We compare the established Exponomial, BAM, GAM, and RCS models against a new variant, the G-RCS model – a generalization of RCS. The G-RCS model extends its functionality to include shadow attractions for unavailable products and offers a closed-form representation based on first-and-last choice probabilities. The talk will elaborate on the G-RCS model's attributes and conduct a numerical comparison of all five models, utilizing both synthetic and real-world industrial datasets.

2 - LP-Based Control for Network Revenue Management under Markovian Demands

Haixiang Lan, Columbia University, New York, NY, United States

We study the network revenue management (NRM) problem, where the seller irrevocably accepts or rejects customers' requests to maximize the total revenue over a finite time horizon subject to limited resources. We consider the setting where customer arrivals are dependent and follow the Markov chain choice model. We propose a deterministic linear program (DLP), a fluid approximation of the original problem, and provide an upper bound for the expected revenue of the optimal policy. We design a static probabilistic allocation (SPA) policy which accepts the request for each product with a certain probability and show that the randomized policy is asymptotically optimal. We show that the regret of the randomized policy, defined as the difference between our policy's expected revenue and the DLP's optimal value, scales in the square root of the time horizon.

When the parameters of our model, the initial arrival probabilities of each product and the transition probabilities between products, are unknown \textit{a priori}, the seller needs to simultaneously (i) learn customers' preferences based on the collected purchase and transition data, and (ii) maximize the cumulative revenue by making online acceptance or rejection decisions while satisfying the resource constraints. To achieve such an exploration-exploitation trade-off, we design an online probabilistic allocation (OPA) policy that achieves a near-optimal order of regret up to a logarithmic factor under some mild conditions. We also conduct numerical experiments to validate the performance of the proposed policies.

3 - Simple is Enough: A Cascade Approximation for Attention-Based Satisficing Choice Models

Chenhao Wang, The Chinese University of Hong Kong, ShenZhen, China, People's Republic of, Pin Gao, Yicheng Liu, Zizhuo Wang

Empirical evidence suggests that consumers commonly focus their attention on a subset of available products and evaluate them in batches to identify a satisfactory option. To capture this phenomenon, we introduce the attention-based satisficing choice rule, which encompasses special cases such as the sequential MNL (e.g., Gao et al. 2021), click-based MNL (e.g., Aouad et al. 2019), and random consideration set models (e.g., Gallego and Li 2017). Through an empirical investigation employing data sourced from Expedia, we provide evidence that special cases of the proposed model exhibit a notable advantage in terms of predictive accuracy when compared to the mixed MNL. Notwithstanding the NP-hardness of finding the revenuemaximizing assortment and estimating certain parameters for the proposed model, we demonstrate that it can be approximated by a simple cascade model (e.g., Kempe and Mahdian 2008) with substantially fewer parameters. Specifically, we establish that the overall likelihood of purchasing from any given assortment under the proposed model can be estimated within a certain range, multiplied by that in the cascade model; moreover, by utilizing the readily computable optimal assortment derived from the approximated model as a heuristic, we show that the worst-case revenue given partial information is at least 3/8 of that obtained from an optimized assortment under the best parameter configuration. Finally, based on the technique established in this study, we extend the analysis to the constrained assortment optimization problem, the joint assortment and pricing problem, and the categorized attention-based assortment optimization problem.

Co-Chair: Hongseok Namkoong, Columbia University, New York, NY, United States

1 - Can ChatGPT do it? Identifying product complements using pre-trained large language models.

Srikant Jagabathula, NYU, New York, NY, United States

With large pre-trained language models (LLMs), we appear to be closer than ever to achieving universal prediction engines. For every prediction problem we aim to solve, it is natural to wonder if the commercially available LLMs can already handle it. Many practitioners are leveraging these models' predictions for critical business applications. But is it appropriate to rely on these models for such essential tasks? Beyond hallucinations, what other concerns should we consider? In this work, we systematically address these and various other questions.

2 - Causal Inference for Human-Language Model Collaboration

Paramveer Dhillon, University of Michigan, Ann Arbor, MI, United States

We examine the collaborative dynamics between humans and language models (LMs), where the interactions typically involve LMs proposing text segments and humans editing or responding to these proposals. Productive engagement with LMs in such scenarios necessitates that humans discern effective text-based interaction strategies, such as editing and response styles, from historical human-LM interactions. This objective is inherently causal, driven by the counterfactual `what-if' question: how would the outcome of collaboration change if humans employed a different text editing/refinement strategy? A key challenge in answering this causal inference question is formulating an appropriate causal estimand: the conventional average treatment effect (ATE) estimand is inapplicable to text-based treatments due to their high dimensionality. To address this concern, we introduce a new causal estimand-- Incremental Stylistic Effect (ISE), which characterizes the average impact of infinitesimally shifting a text towards a specific style, such as increasing formality. We establish the conditions for the non-parametric identification of ISE. Building on this, we develop CausalCollab, an algorithm designed to estimate the ISE of various interaction strategies in dynamic human-LM collaborations. Our empirical investigations across three distinct human-LM collaboration scenarios reveal that CausalCollab effectively reduces confounding and significantly improves counterfactual estimation over a set of competitive baselines.

3 - Optimal Experimentation for Learning Personalized Policies Across Locations

Spyros Zoumpoulis, INSEAD, Fontainebleau, France, Georgina Hall, Stefanos Poulidis

Firms wish to learn personalized policies for customers in heterogeneous yet related locations to maximize their monetary gains. To do this, they conduct experiments at each location to estimate the parameters of a customer response function. A crucial decision is which action to assign to each participant in the experiment, especially when a participant can only be assigned one action or there are budget constraints. The existing experimentation methodology considers locations and experiments individually. In this work, we leverage the relationship between locations in the experimentation problem to learn more profitable policies by proposing novel estimators and a semidefinite programming approach.

4 - Planning Adaptive Experiments: A Math Programming Approach

Ethan Che, Columbia Business School, New York, NY, United States, Daniel Jiang, Hongseok Namkoong, Jimmy Wang

Adaptive experimentation can improve statistical power significantly, but typical algorithms overlook important issues that arise in practice: multiple objectives, non-stationarity, batched/delayed feedback, constraints, and personalization. Moving away from developing bespoke algorithms for each setting, we present a mathematical programming view of adaptive experimentation that can flexibly incorporate a wide range of objectives, constraints, and statistical procedures. By formulating a dynamic program in the batched limit, our modeling framework enables the use of scalable optimization methods (e.g., SGD and auto-differentiation) to solve for treatment allocations. To spur algorithmic progress, we build a suite of benchmark problems based on hundreds of real A/B tests at ASOS that model key practical issues such as non-stationarity, personalization, multi-objectives, and constraints. Our empirical results show standard Thompson sampling-based policies fail to reliably improve upon static designs, and demonstrate the effectiveness of a simple planning approach.

1 - Deep Learning for Policy Targeting with Continuous Treatment

Zhiqi Zhang, Washington University in St. Louis, St. Louis, MO, United States, Zhiyu Zeng, Ruohan Zhan, Dennis Zhang

Experimentation has become a cornerstone technique in product development and operations management for technology companies. While many experiments focus on binary treatments (hence the term A/B testing), these companies increasingly conduct experiments to determine the optimal level of continuous treatment variables. Platforms often approach this problem by discretizing the continuous variable, testing each level as one treatment, and selecting the best level. While discretizing a continuous treatment into different levels in an experiment is simple to implement, this approach has several shortcomings. First, it cannot provide any statistical guarantees on the treatment levels beyond the tested ones. Second, since the experiment cannot provide any statistical guarantees on the untested treatments, it cannot provide any performance guarantees on the derived policies. Third, this approach ignores the important dependencies of treatment effects on often high-dimensional and influential user features. We propose a double-machine-learning framework that leverages personal characteristics to determine the optimal treatment level for each customer. Unlike traditional discrete experiments, our approach provides theoretical guarantees on revenue and enables the identification of the optimal treatment level without relying on discrete levels. We rigorously validate our approach using a random field experiment on a large-scale video-sharing platform and conduct synthetic studies for further validation.

2 - Adaptive Experimentation when You Can&Rsquo;T Experiment: Efficient Encouragement Designs via Experimental Design

Lalit Jain, Foster School of Business, University of Washington, Seattle, WA, United States, Yao Zhao, Kwang-Sung Jun, Tanner Fiez

Often online services cannot directly assign users to specific control or treatment experiences either for business or practical reasons. In these settings, naively comparing treatment and control groups that may result from self-selection can lead to biased estimates of underlying treatment effects. Instead, online services can employ a properly randomized encouragement that incentivizes users toward a specific treatment. Our methodology provides online services with an adaptive experimental design approach for learning the best-performing treatment for such encouragement designs. We consider a more general underlying model captured by a linear structural equation and formulate pure exploration linear bandits in this setting. Though pure exploration has been extensively studied in standard adaptive experimental design settings, we believe this is the first work considering a setting where noise is confounded. Elimination-style algorithms using experimental design methods in combination with a novel finite-time confidence interval on an instrumental variable style estimator are presented with sample complexity upper bounds nearly matching a minimax lower bound. Finally, experiments are conducted that demonstrate the efficacy of our approach.

3 - Harnessing Large Language Models for Market Research: a De-Biasing Approach

Mengxin Wang, The University of Texas at Dallas, Richardson, TX, United States, Dennis Zhang, Heng Zhang

This study investigates the potential of large language models (LLMs) as data augmenters in market research, focusing on their ability to generate conjoint choice data traditionally collected through expensive and resource-intensive surveys. Conjoint analysis, a staple in market research, depends on surveys that elicit consumer preferences for products characterized by various attributes, facilitating the estimation of preference models and utility parameters critical for product development. Our research examines whether LLMs can replicate the intricate decision-making processes inherent in these analyses, offering a cost-effective alternative to human subject surveys.

Past research primarily focused on the empirical efficacy of LLM-generated data in enhancing data quality and alignment with human responses through prompt engineering. Our work diverges by developing a novel statistical de-biasing methodology, which aligns any LLM-generated data with human responses. This method leverages minimal human responses to detect correlations between LLM responses and human choices in specific contexts. The de-biasing performance strengthens when employing advanced prompt engineering techniques such as the Chain-of-Thought method.

Theoretical evaluations of our approach demonstrate significant statistical advantages over traditional methods, promising to reduce logistical barriers and democratize access to high-quality market research tools. These findings not only enhance the understanding of LLM capabilities and limitations but also pave the way for broader applications in market research, potentially revolutionizing the field.

4 - Deep Causal Inequalities: Demand Estimation in the Differentiated Products Markets

Jiding Zhang, Arizona State University, Tempe, AZ, United States, Edvard Bakhitov, Amandeep Singh

In this paper, we borrow from the literature on partial identification and propose the Deep Causal Inequalities (DeepCI) estimator that overcomes both these issues. Instead of relying on observed labels, we use inferred moment inequalities from the observed behavior of agents in the data, which allows us to factor out the endogenous component and nonparametrically model the underlying utility. We demonstrate that DeepCI is consistent under mild restrictions and derive the estimation bounds in the projected root mean squared error norm. The approach is flexible and can be applied to a large variety of hypothesis spaces.

1 - Harnessing the Continuous Structure: Improved Algorithms in Online Contract Design

Shiliang Zuo, UIUC, Savoy, IL, United States

This work studies online learning algorithms for repeated principal-agent problems, where the principal seeks to learn the optimal contract that maximizes utility through repeated interactions, without prior knowledge of the agent's type (i.e., cost and production functions). By leveraging economic structures, specifically the first-order approach, we show that learning the optimal contract can be reduced to a Lipschitz bandit problem. In the special case of learning an optimal linear contract, this reduction simplifies further to a 1-dimensional continuum-armed bandit problem, sharing the same structure as the dynamic pricing problem.

2 - A/B tests: non-stationarity and beyond

Yuhang Wu, University of California, Berkeley, Berkeley, CA, United States

A/B tests have been used at scale by data-driven enterprises to guide decisions. Meanwhile, non-stationarities can often arise in key business metrics. In this work, we discuss challenges of non-stationary A/B tests and discuss how to address them. We also discuss some extensions of other aspects in A/B tests with additional constraints or goals, This includes joint work with Zeyu Zheng and Amazon.

3 - Statistical Properties of Robust Satisficing

Zhiyi Li, Peking University, Beijing, China, People's Republic of, Yunbei Xu, Ruohan Zhan

The Robust Satisficing (RS) model is an emerging approach to robust optimization, offering streamlined procedures and robust generalization across various applications. However, the statistical theory of RS remains unexplored in the literature. Our work fills in the gap by comprehensively analyzing the theoretical properties of the RS model. Notably, the RS structure offers a more straightforward path to deriving statistical guarantees compared to the seminal Distributionally Robust Optimization (DRO), resulting in a richer set of results. In particular, we establish two-sided confidence intervals for the optimal loss without the need to solve the optimization problem explicitly. We further provide finite-sample generalization error bounds for the RS optimizer. Importantly, our results extend to scenarios involving distribution shifts, where discrepancies exist between the sampling and target distributions. Our numerical experiments show that the RS model consistently outperforms the baseline empirical risk minimization in small-sample regimes and under distribution shifts. Furthermore, compared to the DRO model, the RS model exhibits lower sensitivity to hyperparameter tuning, highlighting its practicability for robustness considerations.

4 - Can large language models explore in-context?

Akshay Krishnamurthy, Microsoft Research, New York, NY, United States

An emergent paradigm in machine learning is in-context learning, where one uses a pre-trained foundation model to solve a problem by specifying the problem description and data entirely within the model's context, with no updates to the model parameters. We study in-context reinforcement learning and decision making, specifically focusing on exploration---the ability to deliberately gather information in order to evaluate alternatives and reduce uncertainty. We ask: Do contemporary large language model possess the capability to explore in-context?

In this talk, I will summarize our experiments toward answering this question. We focused on simple multi-armed bandit problems, three modern large language models (LLMs), and a variety of prompt designs and configurations. We found that only one configuration resulted in satisfactory exploratory behavior: GPT-4 with chain-of-thought reasoning and an externally summarized interaction history. All other configurations did not result in robust exploratory behavior. Thus we conclude that non-trivial algorithmic interventions may be required to empower LLM-based decision making agents in complex settings.

Advancements in Online Sequential Decision-Making: Theory and Applications

Invited Session

Decision Analysis Society

Chair: Feng Zhu, MIT, Cambridge, MA, United States

1 - Actions as Instruments: An Online Strategic Decision-Making View

Rui Ai, MIT, Cambridge, MA, United States, David Simchi-Levi, Feng Zhu

It is common to observe only the equilibrium price and quantity in the market, while the entire demand curve remains inaccessible. This situation raises concerns about Ordinary Least Squares (OLS) leading to biased estimators due to confounding issues. We address this in a service fee pricing context by demonstrating a solution that utilizes proactive actions as instruments. Additionally, we illustrate that market randomness can be beneficial to some extent and identify the corresponding phase transition. Furthermore, considering agents with long-term perspectives, we develop a robust algorithm designed to counteract their strategic behaviors through low switching. Our novel algorithm achieves optimal regret upper bounds, which we compare to the associated lower bounds in various settings. Finally, we expand our approach to include generalized reinforcement learning, detailing the sample complexity involved in learning an ε-optimal policy.

2 - Generalization Analysis via Online Learning: New Bounds and Insights

Hao Liang, University of Illinois Urbana-Champaign, Champaign, IL, United States, Yunzong Xu

In this talk, we discuss an interesting framework for analyzing the generalization error of statistical learning algorithms via techniques from online learning theory. We present new upper and lower bounds and discuss their implications.

3 - Risk Detection and Inventory Coordination under Uncertain Time-To-Recover

PENGFENG SHU, Institute of Operations Research and Analytics, National University of Singapore, Singapore, Singapore, Feng Zhu, Chung Piaw Teo, David Simchi-Levi

Time-To-Recover (TTR) is the duration needed for a supplier to restore full functionality after a disruption, serving as a fundamental metric for assessing supply chain risk exposure. Although previous studies typically presume complete knowledge of TTR, companies often possess only limited distributional information about TTR. In this work, we introduce a new supply chain resiliency framework that accommodates uncertain TTR for risk detection and inventory coordination across general supply chains. We propose a new Risk Exposure Index (REI) for pre-disruption risk assessment, which evaluates the expected lost sales using a prioritization model that underscores the necessity of prioritizing production of some products over others under uncertain TTR. Notably, using the new REI, the ranking between two nodes can completely “flip” in contrast to the conventional approach. We then theoretically analyze the cost of TTR uncertainty for intra-disruption inventory coordination by comparing the optimal prioritization decisions with the scenario-wise optimal solutions (those obtained when TTR is fully known). Our main result is a tight competitive ratio. Additionally, we extend our framework to include post-disruption inventory recovery, offering a broader view of the trade-offs between inventory recovery time minimization and lost sales minimization under uncertain

TTR. Through an extensive numerical case study, we illustrate the benefits of our new framework. Our results highlight that uncertain TTR can significantly alter the risk exposure of suppliers, emphasizing the importance of coordinated inventory management during a supply chain disruption.

4 - Rl for Ride-Hailing

Shuze Chen, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Tianyi Peng

This is a work about how reinforcement learning can facilitate online decision-making of large-scale ride-hailing system.

5 - Offline Oracle-Efficient Learning for Contextual MDPs via Layerwise Exploration-Exploitation Tradeoff

Haichen Hu, MIT, Cambridge, MA, United States, Jian Qian, David Simchi-Levi

In this paper, we address the stochastic Contextual Markov Decision Process (CMDP) problem with horizon H. We introduce a reduction from CMDPs to offline density estimation under the realizability assumption. We develop an efficient, statistically near-optimal algorithm requiring only O(H log T) calls to an offline density estimation algorithm (or oracle) across all T rounds of interaction. This number can be further reduced to O(H log log T) if T is known in advance. Our results mark the first efficient and near-optimal reduction from CMDPs to offline density estimation without imposing any structural assumptions on the model class. A notable feature of our algorithm is the design of a layerwise exploration-exploitation tradeoff tailored to address the layerwise structure of CMDPs.

Control Applications in Finance

Invited Session

Decision Analysis Society

Chair: Ruijing Yang, Stevens Institute of Technology, Hoboken, NJ, United States

1 - Valuing Non-Myopic Views in Equity Premium Forecasting

Cheng Lu, Stevens Institute of Technology, Hoboken, NJ, United States, Majeed Simaan

There is mixed evidence on the relationship between macroeconomic variables and future stock returns. On the one hand, Welch and Goyal (2008) demonstrate that a naive moving average of stock returns outperforms individual macroeconomic variables in predicting the equity risk premium. On the other hand, a different stream of literature demonstrates that combining forecasts from macroeconomic variables enhances out-of-sample (OOS) predictions (Rapach et al., 2010). More recently, machine learning (ML) has shown a prominent ability to uncover hidden patterns in financial data. Given recent advances in artificial intelligence, ML stands as an appropriate candidate for predicting the equity premium. Nonetheless, one drawback of ML models is that they do not incorporate equilibrium characteristics and other forward-looking market mechanisms. In this regard, our paper fills the gap in the literature and proposes a non-myopic reinforcement learning (RL) approach that extracts equilibrium views about the equity risk premium, which we compare with 23 benchmarks used in the literature, including ML. While RL does not result in the highest OOS R^2, it provides the best performance in terms of Recall, i.e., identifying true market decline. This evidence is strongest during recession periods when hedging is needed the most. Our findings align with the nature of a risk-averse RL agent, underscoring the value of incorporating non-myopic views into forecasting models.

2 - A Global Discrete simulation Optimization Approach for Quantile Functions

Tianrui Zhao, Stony Brook University, Stony Brook, NY, United States

We propose a modification of the simulated annealing algorithm for solving discrete simulation optimization problems in which the objective function is the quantile function of a simulation output with noise. Unlike the original simulated annealing algorithm, our method uses a constant temperature, and it uses the number of visits made to different states to estimate the optimal solution. In contrast to performing multiple simulations at a candidate state to estimate its quantile performance, we propose an iterative framework that performs a single simulation for the candidate points encountered.

3 - Optimization in Energy Markets

Kai Chen, KPMG, New York City, NY, United States

Mathematical optimization techniques, such as linear programming and stochastic optimization, are commonly used to solve the complex optimization problems encountered in energy markets. This presentation delves into various facets of optimization within this dynamic domain, exploring its pivotal role in allocating resources and managing operations to maximize benefits or achieve specific objectives, such as valuation and risk management. First, we examine foundational market operations, focusing on power plant dispatching and the management of trading portfolios using Mixed Integer Linear Programming (MILP) algorithms. Subsequently, we illustrate the formulation for gas storage and pipeline systems with dynamic programming and a simplified version that uses only linear programming. Additionally, we explore the utilization of Battery Energy Storage Systems (BESS) in energy trading, outlining the requisite optimization techniques. Delving deeper, we navigate the intricacies of the Financial Transmission Right (FTR) market, recognized as one of the most complex arenas within energy markets, which often requires modeling the operations of the entire power grid. Finally, we present recent developments in the sector, offering insights into ongoing advancements.

4 - Optimal Portfolio Execution Strategies under Chance Constraints on Capital Adequacy Ratio Requirement

Ruijing Yang, Stevens Institute of Technology, Hoboken, NJ, United States, Zachary Feinstein, Somayeh Moazeni

We investigate optimal strategies to liquidate a portfolio of risky assets over a period of time under capital adequacy requirements subject to price impacts. Liquidating risky assets at every time step induces temporary impact on execution prices and permanent price impacts on the market prices. We study this problem with chance constraints on the regulatory requirements. Two versions of the chance constraints on the capital adequacy ratio requirements are provided: (i) require the capital adequacy requirement to be satisfied with a given probability at each individual time step or (ii) require the capital adequacy ratio time series to exceed the mandated level with a given probability. For the first problem, we develop a conservative approximation reformulation of the problem and establish sufficient conditions for its convexity. For the second problem, we use a stochastic approximation method to find the optimal liquidation strategy. Numerical studies are provided to study the optimal liquidation strategies in single-asset and multiple-illiquid asset cases. We show that in general the optimal portfolio execution strategy under the capital adequacy ratio requirement constraints differs from the optimal strategy in the absence of this requirement; in particular, when including these regulatory constraints, the liquidation strategy tends to postpone actions to the future. Computation costs of these two problems are also compared and we find that the conservative approximation method for the individual constraint problem is more computationally efficient compared to the stochastic approximation method for the joint constraint problem.

Utility, Sharing, and the Value of Information

Invited Session

Decision Analysis Society

Chair: Andrea Hupman, University of Missouri - St. Louis, Saint Louis, MO, United States

1 - Risk Sharing with a TIME Preference

Ali Abbas, University of Southern California, Los Angeles, CA, United States, Zhengwei Sun

We consider the case of a partnership where individuals face an uncertain deal whose pay-offs will be realized at some future time. The individuals have (i) different risk tolerances and (ii) different time preference discount rates. Within this context, we derive the optimal share of each individual within the partnership. We discuss deviations and interpretations of the optimal shares from classic risk-sharing formulations that do not incorporate time preference.

2 - Wealth, Preferences, and the Value of Information

Andrea Hupman, University of Missouri - St. Louis, Saint Louis, MO, United States

This talk examines how characteristics of the decision maker affect the value of information (VOI) and how these effects have real-world implications. In particular, we consider how wealth effects and preferences of a decision maker influence the calculation of VOI. We characterize how simplifications in the formulation of VOI can create risk for the decision maker. We use the case of organizations purchasing information from a data broker to illustrate the implications of these results.

3 - Maximum Entropy Utility and Evaluation of Uav Designs

Robert Bordley, University of Michigan, Troy, MI, United States

In design problem, individuals make decisions on behalf of stakeholders. Stakeholder preferences are formalized as design targets. But assigning appropriate design targets is challenging. A maximum entropy utility is used to ensure that design decisions only reflect requirements and not other extraneous preferences. This paper derives a Gaussian utility function defined over the logarithm of a concave function. Certainty equivalents are easily computed when uncertainty is conjugate to the utility. The multivariate extension of the utility is also Gaussian with correlations describing complementarity and substitutability across target dimensions.

This utility can score how well different design solutions address different design targets.

4 - The Shapley Value of Information

Emanuele Borgonovo, Bocconi University, Milan, Italy, Francesca Beccacece, Emanuele Borgonovo, Giovanni Rabitti, Andrei Savochkin

In this work, we present the notion of Shapley value of information. In a 1988 Risk Analysis paper, Howard proposes a decomposition of the information value across sources of uncertainty. The decomposition, however, depends on the order with which sources of information are considered. We propose a Shapley decomposition that uniquely apportion the total information value in a decision problem to each information source. We prove several properties of the decomposition and address computational issues.

5 - Discounted Incremental Utility

Manel Baucells, Darden School of Business, Charlottesville, VA, United States, Michał Lewandowski, Krzysztof Kontek

Most decisions involve multiple payoffs over time and under risk, as for instance the sequential play of a lottery. For an individual who cares not only about profit at the end, but also on how early these profits accrue, we apply a modified version of the axioms of subjective expected utility to obtain the Discounted Incremental Utility model. To this classical bedrock, we add the notion that preferences are affected by range effects. This modification results in the so-called Range-Discounted Incremental Utility, which can successfully predict a plethora of phenomena such as attitudes towards sequential play, the four-fold pattern, preference for temporal hedging, preference reversals for risk and time, and patterns of decreasing impatience. For comparison, we also introduce a rank-dependent modification and examine its shortcomings.

Multiple Objective Optimization and Decision Processes

Invited Session

Multi Criteria Decision Making

Chair: Honggang Wang, California State Poly Tech Pomona, 3801 West Temple Avenue, Pomona, 91768, United States

1 - Continuation Search in Manifold Surface for Multi-Objective Optimization

Honggang Wang, Cal Poly Pomona, Pomona, CA, United States

Imagine one day, your breathing became consistently labored and shallow. Months later you were finally diagnosed with pulmonary fibrosis, a disorder with no known cause and no known cure, created by scarring of the lungs. If that happened to you, you would want to know your prognosis. That’s where a troubling disease becomes frightening for the patient: outcomes can range from long-term stability to rapid deterioration, but doctors aren’t easily able to tell where an individual may fall on that spectrum. Machine learning analytics may be able to aid in this prediction, which would dramatically help both patients and clinicians. In this research, we will predict a patient’s severity of decline in lung function based on a CT scan of their lungs together with some other patient clinic data. The lung function is determined based on FVC output from a spirometer, which measures the volume of air inhaled and exhaled. One major challenge of this work is about accurately uncovering such multiple-dimensional temporal patterns unstructured 3D scan images and time series. Some preliminary results using real-life patient datasets will be presented and discussed.

2 - Integrating Simulation and Multiple-objective Optimization Using MGD-SPSA Algorithm

Haobin Li, National University of Singapore, Singapore, Singapore, Yan Li, Ying Huang , Ek Peng Chew

Constructing a Common Descent Vector (CDV) from a combination of gradients offers a practical method to address Multi-Objective Optimization (MOO) challenges by simultaneously minimizing multiple objectives. This approach, however, faces difficulties in environments where gradients are unavailable, such as in black-box simulations. To overcome this, our paper presents the Multiple Gradient Descent-Simultaneous Perturbation Stochastic Approximation (MGD-SPSA) algorithm. This advanced algorithm utilizes biased gradient estimations from the SPSA to construct an estimator for the CDV, aiming for Pareto optimality. Leveraging the characteristics of the SPSA, which perturbs all decision variables at once and approximates the gradient of the objective function using only two function evaluations per iteration, the MGD-SPSA achieves substantial computational efficiency in high-dimensional settings. We detail its algorithmic process for both bi-objective and many-objective scenarios and provide theoretical evidence of its strong convergence. The effectiveness of MGD-SPSA is demonstrated through ZDT test functions and diverse simulation-optimization frameworks, showing significant reductions in CPU time and enhancements in the quality of Pareto solutions compared to traditional evolutionary algorithms. These findings highlight the transformative impact of integrating advanced simulations with MOO strategies, facilitating optimal trade-offs across various objectives in different industrial systems.

3 - A new approach for Selection Green Supplier Problem: A Q-Rof MCDM Approach

Babek Erdebilli, AYBU, Ankara, Turkey, Sara Saberi

The selection of green suppliers (GSS) has emerged as a crucial aspect in sustainability initiatives, focusing on efficient natural resource utilization. In a case study pertaining and selection are conducted using the intuitionistic Q-Rof MCDM method, which accommodates both qualitative and quantitative criteria. Introducing a novel perspective on the GSS, this innovative approach offers a fresh methodology for selecting environmentally responsible suppliers. In response to the growing importance of sustainability in supply chain management, this approach addresses the need for efficient and effective green supplier selection processes. By integrating advanced decision-making techniques and environmental criteria, this method aims to optimize supplier selection while promoting eco-friendly practices throughout the supply chain. environmental applications, and recycling. Q-Rof MCDM is employed due to its suitability for evaluating decision-makers and criteria. The hybrid method combining Q-Rof and MCDM proves highly effective in selecting the most suitable supplier among alternatives, offering potential integration into similar decision-making scenarios.

4 - PRIORITIZING PATIENT SAFETY ISSUES: A MULTI-CRITERIA APPROACH USING MEREC-CoCoSo INTEGRATION

Fatma Pakdil, Eastern Connecticut State University, Willimantic, CT, United States, Pelin Toktas, Gulin Feryal Can

Patient safety is one of the highly prioritized performance areas in the healthcare systems. Despite healthcare facilities and practitioners put a substantial effort on implementing patient safety improvements, there is still an uncertainty about prioritizing patient safety needs. In this context, healthcare organizations are expected to follow a systematic prioritization strategy for potential patient safety projects to allocate their scarce resources more effectively in order to achieve zero harm to patients. Complex nature of patient safety issues necessitates a well-structured prioritization and selection process to allocate scarce resources more effectively and efficiently onto patient safety improvement efforts. Given the complexity and urgency of such decision-making processes, decision-makers need multi-criteria decision-making (MCDM) methods to prioritize and select potential patient safety issues in a given time. In light of this, this study aims to exemplify how MCDM methods can be employed in patient safety issue prioritization and selection processes in acute care hospitals. This study proposes a model that implements the Method based on the Removal Effects of Criteria (MEREC)-Combined Compromise Solution (CoCoSo) method to show the practicality and feasibility of MCDM methods for such needs. The proposed model employs MEREC to evaluate and weight the criteria and CoCoSo to prioritize the alternative patient safety issues. This is the first study that employs an MCDM approach to prioritize and select patient safety issues in the healthcare industry.

5 - Multi-objective cooperative game theory for improving coordination in humanitarian operations

Ayesha Farooq, Kansas State University, Manhattan, KS, United States, Jessica Heier Stamm

In humanitarian settings, coordination is pivotal for efficient and effective operations given the presence of diverse decision makers and challenging conditions. We integrate cooperative game theory and optimization to enhance multi-objective, multi-stakeholder coordination. Our approach fairly allocates system-wide costs and utilities among all participating organizations. The model addresses the inherent tension

between demand fulfillment and cost efficiency by applying Chebyshev goal programming. The model minimizes the maximum relative deviation from predefined goals, ensuring rationality at both individual and collective levels. We analyze player behavior under several policies for allocating the costs and benefits of coordination. When stakeholders' perspectives are considered, organizations can identify unified strategies that maximize their collective impact.

6 - Multi-Objective Optimization in Decision Spaces

Kalyanmoy Deb, Michigan State University, East Lansing, MI, United States

Evolutionary multi-objective optimization (EMO) algorithms are capable of finding multiple near Pareto-optimal (PO) solutions simultaneously in a single run for two to about 20-objective problems. These algorithms use a population of solutions in each iteration and update the population by selecting better solutions using domination and diversity-preserving techniques and then by mixing them to create new and hopefully better solutions. While the obtained PO solutions are expected to be well distributed in the objective space, they may not be well-distributed in a decision space which a decision-maker (DM) may prefer. For example, if a relative importance of objectives are known a priori, the DM may be interested in solutions well distributed in an importance metric space clearly indicating a hierarchy of PO solutions from highest to the lowest important objectives, rather than having a set of PO solutions with a good distribution in the objective space. In this talk, we introduce a number of decision spaces which a DM may prefer in finding a good distribution of solutions in that space and then present three different EMO approaches to find a preferred distribution of PO solutions using modified EMO approaches. The advantages and disadvantages of these approaches will be highlighted by applying them on a number of test and engineering design problems. This study makes the EMO approaches more generic and bring the importance of decision-making aspects within the task of multi-objective optimization.

1 - Targeting broadcasts to moderate opinion dynamics in social networks

Philip Solimine, University of British Columbia, Vancouver, BC, Canada, Wei Li

We discuss the solution to a restricted or coarse targeting problem in social networks. In this problem a benevolent social planner moderates opinion dynamics in a network of naive agents, by broadcasting a common signal to each node with varying intensity. For a class of natural quadratic planner objectives, the coarse targeting problem has a unique solution that is amenable to numerical optimization. Generally the vector of optimal broadcast strengths is a combination of network centrality with the final state of the autonomous network. We explore moderation and stability of opinions under various moderation objectives and find that the planner is frequently incentivized to broadcast polarizing signals, even when her goal is to synchronize opinions. We also characterize the optimal target weights in a number of special cases, in which symmetries in the network topology allow for the solution to the restricted targeting problem to be characterized in terms of a small set of moments of the distribution of broadcast weights through the network.

2 - An optimization framework to provide volunteers with task selection autonomy and group opportunities on nonprofit crowdsourcing platforms

Milan Kaur, Rensselaer Polytechnic Institute, Troy, NY, United States, Jennifer Pazour

Nonprofit Organizations (NPOs) rely on volunteers to support community needs but due to lack of available volunteer information, can seldom make strategic task assignments to achieve successful volunteer participation and NPO task completion. Making successful volunteer group-to-task assignments is challenging because (i) there are exponentially many ways a set of volunteers can be assigned in groups; and (ii) NPOs tend to have limited data concerning volunteers' personal preferences, availability, and skills. To address these challenges, we introduce a framework that integrates a set of static integer programs that enables nonprofits to offer volunteers a menu of tasks to choose from and creates ideal volunteer groups assigned to tasks. The menu creation (MC) IP offers volunteers with personalized task recommendations menus. The group creation (GC) IP creates homogenous volunteer groups with ideal learning potential and affinity among volunteers to encourage their motivations to participate through successful engagement, networking, skill learning and utilization. Our methodology is implemented with a case study representing a partner NPO with online tasks. Results indicate that the implementation of the MC methodology provides a statistically significant improvement to nonprofits and volunteers. Implementing the GC methodology helps obtain a statistically significant increase in ideal group creations but results in a tradeoff of decrease in other NPO KPIs. This static model is being extended to a dynamic integer linear program with a sequential decision-making framework. The aim of the dynamic model is to identify the impact of assignment decisions on task completion and volunteer retention in future periods.

3 - Mapping the past to Build the Future: a Visualization System for Enhancing Humanitarian Aid Effectiveness Through Project Topic Modeling Based on Final Evaluation Reports

Yeeun Choi, Seoul National University, Seoul, Korea, Republic of, Jinwoo Choi, Hyunwoo Park

This study aims to support the more effective planning and execution of new development cooperation projects by visualizing the relationships among completed projects based on specific criteria. As the number of aid organizations continues to increase and the overall number of projects expands, it has become challenging to identify which aid projects were carried out. This difficulty leads to overlapping projects and repeated mistakes, resulting in reduced aid effectiveness. To address these issues, we developed a system to support various actors in development cooperation by providing comprehensive visualizations of project networks. The system employs final evaluation reports of projects conducted by various organizations and visualizes the similarity network of completed projects based on these reports. To allow users to search for the desired type of project based on specific criteria, we used a predefined topic modeling method. First, we established criteria such as the Sustainable Development Goals (SDGs), regions, and cultural areas, and defined detailed classes to characterize projects within each criterion. Then, extracted keywords for each class were used for predefined topic modeling method to quantify the characteristics of each project based on these criteria. Through this, the system visualizes the project network, allowing users to intuitively identify similarities among previously implemented projects and offering links to download each project's final evaluation report. By facilitating the review of past project outcomes, limitations, and lessons learned, the system aims to enhance the planning and execution of more effective aid projects by leveraging empirical knowledge gained from similar past initiatives.

Chair: Robin Na

1 - Does Reading the Literature Improve the Ability to Predict the Effects of Interventions?

Robin Na, Massachusetts Institute of Technology, Cambridge, MA, United States, Abdullah Almaatouq

Making effective policy recommendations remains notoriously challenging due to the formidable heterogeneity and contingency we must navigate to predict the outcomes of interventions. While science is expected to generate cumulative knowledge that helps people understand such complexity, this raises an empirical question of which set of academic papers could shift human priors in a direction that enhances predictions. Motivated by the infeasibility of conducting controlled human-subject experiments of such a nature, we propose a novel method for investigating this fundamental question by using large language models (LLMs) and retrieval-augmented generation (RAG) as proxies for exploring the treatment effect of research papers. Each version of GPT-4, augmented with a specific set of behavioral research papers, is asked to predict intervention outcomes of cooperation under the high-dimensional, integrative experiment design space of a public goods game (PGG). The space consists of 211 unique experiment designs with 20 dimensions of varying conditions to map the rich heterogeneity of treatment effects. We demonstrate the LLM’s ability to retrieve academic papers and alter its distribution of predictions for experiment outcomes in directions that are expected based on the documents' contents. However, such shifts do not contribute to higher accuracy for the most time and our method explores the features of papers that improves such accuracy. The framework introduces a method for evaluating the potential contribution and informativeness of scientific literature in prediction tasks, while also showing how our integrative experiment can be used as a benchmark for LLM's ability to make predictions about human behavior.

2 - Strategies for the Global Alliance for Vaccines and Immunization in International Vaccine Pricing and Procurement

Banafsheh Behzad, California State University, Long Beach, Long Beach, CA, United States, Susan Martonosi, Ruben Proano, Zooey Meznarich

The Global Alliance for Vaccines and Immunization (Gavi) is an organization that works with manufacturers and governments to mediate the pricing and procurement of vaccine products and facilitates the transfer of technology to manufacturers. Their work with UNICEF supports low-income countries by improving access to pediatric vaccines. Multivalent vaccines, which inoculate against multiple diseases, improve efficiency of immunization. However, the production of multivalent vaccines is often limited, as is the case for the hexavalent (6-antigen) pediatric vaccine. Because Gavi negotiates large contracts on behalf of many countries, they can incentivize manufacturers to produce hexavalent. Existing models of vaccine markets with price negotiations between external organizations and private manufacturers are adapted and applied to the international vaccine market. Mathematical programming tools are used to examine optimal prices and quantities within the global vaccine market, while incentivizing the production of multivalent vaccines. As a result, relationships among manufacturer capacity, demand projections, and price provide insight into future policy recommendations and feasibility.

3 - A Stochastic Optimization Model for Scheduling Tenders for Pediatric Vaccines in Low- and Low-Middle-Income Countries

Nicholas Uhorchak, University of Arkansas, Fayetteville, AR, United States, Ruben Proano, Sandra Eksioglu, Fatih Cengil, Burak Eksioglu

Pediatric vaccine tender scheduling represents a strategic approach for countries to efficiently plan and procure essential vaccines over extended periods. This process, facilitated by organizations like UNICEF (United Nations Children’s Fund), PAHO (Pan American Health Organization), and GAVI (Gavi, the Vaccine Alliance), aims to ensure fairness and effectiveness in vaccine distribution. However, it's a multifaceted challenge, balancing the need to meet demand, maintain an ample supply, and navigate logistical hurdles. Complicating matters further are the unpredictable fluctuations in vaccine demand and manufacturing capacity. To tackle these complexities, we propose a stochastic optimization model. This approach dynamically generates vaccine tender schedules, taking into account uncertainties, thus enabling proactive planning over long timeframes. Our model addresses key research questions: How can we optimize the sequencing and timing of vaccine tenders to maximize affordability and profit? What is the ideal procurement schedule for single or multiple antigen scenarios? And how do uncertainties in demand and manufacturing capacity influence tender scheduling? Leveraging real-world data and forecasting techniques, we test our model's efficacy. Our analysis reveals that our approach yields robust first stage (i.e., here and now) decisions and adeptly adapts to stochastic factors in the second stage (i.e., wait and see) decisions. We demonstrate the feasibility of generating optimal procurement schedules for various scenarios, while effectively responding to fluctuations in stochastic inputs.

4 - Resilience strategies for epidemic testing capacity: pooling, scheduling, and flexible machine allocation

Erica Gralla, George Washington University, Washington, DC, United States, Nadia Lahrichi, Jad El Hage, Fannie Côté

The COVID-19 pandemic brought to light a critical problem in the global pandemic response infrastructure: insufficient testing capacity. Major epidemics stress existing systems with a surge in demand for testing, leading to very long turnaround times for results. This paper identifies and explores sources of fragility in testing laboratories and develops strategies for resilience, including pooling specimens, scheduling personnel, and flexibly allocating liquid handling machines. These resilience strategies are evaluating using processes and data from two diverse COVID-19 testing facilities: a Nepalese laboratory system relying heavily on manual operations, and a US university-based laboratory relying on automation. Discrete event simulations and a scheduling algorithm test the impact of the resilience strategies and identify when and why they are beneficial. The results show that pooling strategies are beneficial for meeting surges in demand, but require more liquid handling capacity. Flexibility in personnel scheduling and machine allocation also increases the laboratory capacity in centers that rely heavily on manual or automated tasks, respectively. With these strategies, testing facilities could increase their resilience to surges in testing demand by better leveraging their current resources without significant additional investment.

Chair: Mengfan Xu, Northwestern University, 2145 Sheridan Road, Evanston, IL, 60208, United States

1 - An efficient node selection and validation method for providing decentralization in a blockchain with multiple dynamic consensus groups

Jin Choi, Ajou University, Suwon, Korea, Republic of, Jon Hwi Lee, Jaeyoung Lee

In a blockchain network with multiple dynamic consensus groups, it is very important to provide decentralization by designing an efficient method for node selection and validation for each group. Especially, we consider decentralization from two points of views such as node point and stake point. Even for the stake point of view, it is not easy to attain decentralization because any node investing large stakes might have big impact on generating blocks by participating in the consensus process. In this work, we devise a good policy for providing decentralization for the considered cases by performing a numerical experiment, while considering some performance measures such as fairness, entropy, and gini coefficient.

2 - Competitiveness and Cross-Ownership of Startups in the Blockchain Industry: a Network-Based Empirical Analysis

Samaneh Samiee, University of Texas at Arlington, Arlington, TX, United States

This study investigates two key challenges of running an early stage blockchain based business in different markets. It examines whether the competitiveness of the field of activity of a blockchain startup affects its success. Moreover, it studies the (dis)advantages of accepting venture capital funding from investors who own other blockchain startups in their portfolios. Additionally, this study examines whether the competitiveness of the startup's field of activity and cross-ownership moderate the relationship between its entry to market and its success and survival. Utilizing a Bipartite network analysis approach, we develop an empirical model by analyzing network-based relations between startups founded between 2008 and 2023. We find empirical evidence for the moderating roles of competitiveness and cross-ownership. Thus, the results show that the advantages of choosing a competitive field of activity and being cross-owned with other blockchain startups outweigh the business stealing anti-competitive effects. The managerial and theoretical implications of this research brings the ongoing entrepreneurship debates on these scenarios to the technology entrepreneurship for the first time and establishes how business applications of blockchain moderates business success.

3 - The Influence of Blockchain Traceability on Consumer Purchase Intention in The Organic Food Industry

Jin-Jin Lyu, Kyungpook National University Business Administration, Daegu, Korea, Republic of, Chae-Bogk Kim

Embracing the transformative potential of blockchain traceability label enables enterprises to carve out new avenues for consumer engagement and brand differentiation, ultimately fostering sustainable growth in a fiercely competitive market environment. This study innovatively explores the impact of blockchain traceability label on consumer purchase intention within the organic food industry. A total of 975 valid questionnaires were collected online via a paid survey platform, and one-way ANOVA was employed to ascertain the significance of label variations on purchase intention. Additionally, we utilized two-way ANOVA to unveil the intricate interplay between brand maturity, income level, and the influence of label on purchase intention. The analysis demonstrates that consumers exposed to blockchain traceability label exhibit significantly higher purchase intention compared to those encountering standard or no label. Furthermore, it was observed that high-income consumers exhibit heightened purchase intention when presented with products featuring blockchain traceability label. Moreover, the presence of blockchain traceability label on product packaging disrupts traditional brand preference theories by amplifying purchase intention for new brand. These innovative findings offer valuable insights for enterprises seeking to navigate the evolving consumer landscape and stay ahead of the curve.

4 - The Impact of Blockchain Adoption on Vertically Differentiated Competition

Yuhan Yan, Renmin University of China, Beijing, China, People's Republic of, Xiaofang Wang

The rapid proliferation of blockchain technology has changed the management practice of firms in many aspects. This paper considers pricing competition between two firms offering vertically differentiated products, as well as the quality improvement decision of the low-quality firm. Our paper captures two roles blockchain can play in practice: transmitting reliable quality signals and expanding sales toward technology-sensitive customers. Our results highlight the interactive impacts of blockchain adoption on quality-differentiated firms under different decision sequences.

5 - Decentralized Blockchain-based Robust Multi-agent Multi-armed Bandit

Mengfan Xu, Northwestern University, Evanston, IL, United States, Diego Klabjan

We study a robust multi-agent multi-armed bandit problem where multiple clients or participants are distributed on a fully decentralized blockchain, with the possibility of some being malicious. The rewards of arms are homogeneous among the clients, following time-invariant stochastic distributions that are revealed to the participants only when the system is secure enough. The system's objective is to efficiently ensure the cumulative rewards gained by the honest participants. To this end and to the best of our knowledge, we are the first to incorporate advanced techniques from blockchains, as well as novel mechanisms, into the system to design optimal strategies for honest participants. This allows various malicious behaviors and the maintenance of participant privacy. More specifically, we randomly select a pool of validators who have access to all participants, design a brand-new consensus mechanism based on digital signatures for these validators, invent a UCB-based strategy that requires less information from participants through secure multi-party computation, and design the chain-participant interaction and an incentive mechanism to encourage participants' participation. Notably, we are the first to prove the theoretical guarantee of the proposed algorithms by regret analyses in the context of optimality in blockchains. Unlike existing work that integrates blockchains with learning problems such as federated learning which mainly focuses on numerical optimality, we demonstrate that the regret of honest participants is upper bounded by $\log{T}$. This is consistent with the multi-agent multi-armed bandit problem without malicious participants and the robust multi-agent multi-armed bandit problem with purely Byzantine attacks.

1 - Generative AI at School: How ChatGPT Changes Student Learning

Philipp Cornelius, Rotterdam School of Management, Rotterdam, Netherlands, Matthias Lehmann, Fabian Sting

Generative AI tools such as ChatGPT are transforming education. At any hour of the day, for any subject, students now have access to a personalised AI tutor, who can answer questions and explain difficult concepts. However, students may also be tempted to rely on AI for more than tutoring. Many educational programmes rely substantially on homework assignments for practice and assessment. If students use generative AI to reduce the amount of time spent on homework, they may engage less with educational material and in effect learn less. In this paper, we study how the use of generative AI during homework assignments affects students’ short-term performance in the assignments as well as their long-term learning.

2 - Artificial Intelligence, Ceo Turnover, and Exploration Orientation in Firm Innovation

Xinyu Ma, University of Pennsylvania, Philadelphia, PA, United States, Bowen Lou, Lynn Wu

This study examines the role of artificial intelligence (AI) in facilitating corporate innovation following a CEO turnover event. Using patent data for firms that have undergone a CEO turnover, we find that firms with greater AI investment are more successful in explorative innovation. Further analyses show that this effect is likely due to the firms with AI investment being better positioned to enable strategic change in innovation, cultivate a culture of exploring frontiers in innovation, and manage R&D. Importantly, AI mitigates myopic management of CEOs and overcomes the barrier of information overload that they often encounter. A new CEO can also direct more resources to acquiring employees with AI skills to facilitate explorative innovation. Overall, this study highlights the significant value of AI in promoting exploration in innovation during organizational transition periods. By shedding light on the role of AI in guiding innovation and fostering change, we provide insights for AI-driven transformation and creativity in organizations when navigating dynamic environments.

3 - Generative AI and Copyright: A Dynamic Perspective

Song Yang, London Business School, London, United Kingdom

The rapid advancement of generative AI is poised to disrupt the creative industry. Amidst the immense excitement for this new technology, its future development and applications in the creative industry hinge crucially upon two copyright issues: 1) the compensation to creators whose content has been used to train generative AI models (the fair use standard); and 2) the eligibility of AI-generated content for copyright protection (AI-copyrightability). In this paper, we aim to better understand the economic implications of these two regulatory issues and their interactions. By constructing a dynamic model with endogenous content creation and AI model development, we unravel the impacts of the fair use standard and AI-copyrightability on AI development, AI company profit, creators’ income, and consumer welfare, and how these impacts are influenced by various economic and operational factors. For example, while generous fair use (use data for AI training without compensating the creator) benefits all parties when abundant training data exists, it can hurt creators and consumers when such data is scarce. Similarly, stronger AI-copyrightability (AI content enjoys more copyright protection) could hinder AI development and reduce social welfare. Our analysis also highlights the complex interplay between these two copyright issues. For instance, when existing training data is scarce, generous fair use may be preferred only when AI-copyrightability is weak. Our findings underscore the need for policymakers to embrace a dynamic, context-specific approach in making regulatory decisions and provide insights for business leaders navigating the complexities of the global regulatory environment.

4 - Examining the Impact of Generative AI on Users’ Questioning Behavior: Evidence from a Natural Experiment of Pilot Usage of ChatGPT

xinzhi rao, University of Florida Warrington College of Business Administration, Gainesville, FL, United States, Guohou Shan, Liangfei Qiu

Our study examines the impact of the usage of generative AI on users’ questioning behavior on Stack Overflow, one of the largest Q&A platforms. Leveraging a natural experiment of piloting the usage of ChatGPT during its launch and ban on the platform, we employ the difference-in-differences (DID) estimation to investigate the effects of generative AI on the quantity and quality of users’ questioning behavior, measured by the number of questions generated per week, question length, novelty, and received upvotes. Our findings reveal that using generative AI increases the number of questions generated by users. Additionally, these questions tend to be longer in length, more novel in content, and receive more upvotes. This suggests that users treat generative AI as an assistant, helping them generate higher-quality questions at a faster speed. We also explore the moderating effects of the number of answers generated (proxy as an experience) and the users' received badge (proxy as the reputation or celebrity on the platform) on the impact of generative AI to test the mechanisms. The implications of this study are both theoretical and practical. Theoretically, we contribute to the Information Systems literature by examining the impact of generative AI on users' questioning behavior in the context of Q&A platforms. Practically, our findings provide knowledge platform owners and managers with a better understanding of how generative AI influences users' knowledge contribution behavior in terms of asking questions. This understanding can guide decision-making and strategy development regarding the integration of generative AI on their platforms.

Business and Climate Change

Invited Session

MSOM: Sustainable Operations

Chair: Safak Yucel, Georgetown University, Washington, DC, United States

Co-Chair: Soudipta Chakraborty, University of Kansas, Lawrence, 66213, United States

1 - How Does Flexibility Affect Emissions Performance?: Evidence from U.S. Power Generation

David Drake, Leeds School of Business, University of Colorado, Boulder, CO, United States, Suresh Muthulingam

Several CO2 abatement paths alter the flexibility burden placed on the conventional power generation grid. However, the environmental consequences of this flexibility are unexplored. In this study, we examine the environmental impact of flexibility in US power generation, distinguishing between the environmental effects of possessing flexibility and exercising flexibility.

2 - Additionality of Carbon Offsets: Project-Specific vs. Standardized Baselines

Soudipta Chakraborty, University of Kansas, Lawrence, KS, United States, Vishal Agrawal, Safak Yucel

A carbon offset represents reduction in emissions that can be used to compensate for emissions elsewhere. Developers generate offsets through emissions-reduction projects. A non-profit carbon registry issues offsets to developers while ensuring *additionality:* An offset needs to represent one unit of reduction from a developer's business-as-usual emissions, i.e., what the developer's emissions would have been in the absence of the market for offsets. Accordingly, environmental groups raise greenwashing concerns against non-additional offsets. Ensuring additionality is challenging because business-as-usual emissions is a developer's private information and an unobservable counterfactual for the registry. In practice, the registry assigns a baseline to represent business-as-usual emissions through one of the two methods: Under the *project-specific* method, a developer self-reports its business-as-usual emissions to the registry, which then inspects the report and assigns reported emissions as the baseline if it accepts the project. Under the *standardized* method, the registry assigns a common baseline to a group of developers. We compare economic and environmental implications of these two methods.

3 - The Implications of Minimum Recycled Content Requirements on Product Design and Recycling Channel Decisions

Donghyun Choi, Georgia Institute of Technology, Atlanta, GA, United States, Andre Calmon, Beril Toktay

Extended producer responsibility (EPR) is increasingly implemented across various industries through minimum recycled content requirements, presenting significant operational challenges for producers in securing recycled materials. Concurrently, producers are adopting materials with lower carbon footprints to adapt to a carbon-constrained business environment. In this context, we examine whether regulations promoting circularity synergize or conflict with carbon reduction targets. To address this question, we develop a stylized model to analyze a producer's product design and recycling channel decisions to comply with minimum recycled content requirements, where producers can either purchase recycled content (open-loop) or internally recycle end-of-use products (closed-loop). Our findings indicate that producers may face trade-offs between pursuing material circularity and carbon reduction under current regulations or voluntary carbon reduction targets, which mainly account for the firm's internal operations (i.e., scope 1 and 2). We suggest that incorporating supply chain emissions (scope 3) into regulations or carbon targets can promote both material circularity and carbon reduction. This study provides managerial insights on managing and identifying synergies among multiple environmental performance metrics and offers policy implications to further foster green innovation in product and supply chain management.

Co-Chair: Jian Li, Stony Brook University, Stony Brook, NY, United States

1 - Strategic DG Placement and Sizing for Microgrid Formation using Sample Average Approximation

Dhiraj Pokhrel, University of Tennessee, Knoxville, Knoxville, TN, United States, Hugh Medal

Severe blackout events due to extreme weather are increasing in the recent years. Therefore, highlighting the need of resilient power distribution networks. Microgrid formation through strategic distributed generation (DG) placement is one of the measures that can be done to increase distribution system resilience. In this research we have formulated the DG placement and sizing problem as the two-stage stochastic mixed-integer program. The first stage decisions are DG placement and sizing decisions while the second stage is the network restoration decisions, which include which switches to close and which existing lines to open. The objective is to minimize the cost associated with the load shed and power generation. We tested our model in IEEE 33 bus system. Because the formulated stochastic problem contains extremely large number of scenarios, we used a sampling method to solve it. We present a detail computational study of the problem using a sample average approximation (SAA) method. Computational results on IEEE test case network demonstrate the effectiveness of the SAA method.

2 - Optimizing Discretized Time Network Train Scheduling: Introducing Adaptive Valid Inequalities and Computational Insights

Masoud Barah, Northwestern University, Evanston, IL, United States

Time-discretized train scheduling problems suffer from the issue of near-identical sub-optimal solutions that significantly slow down exact solution algorithms, especially when the fidelity of time-discretization is higher. One efficient method to eliminate these solutions is by lifting the solution space to an aggregated space, wherein the set of near-identical solutions is mapped into new variables. To effectively utilize the aggregated space, this paper proposes a set of minimal cover inequalities that tighten the lifted polyhedron of the aggregated space. Additionally, we present a heuristic algorithm based on the concept of arbitrarily extending lengths of arcs while dynamically aggregating the original space. Computational experiments demonstrate a 44% speedup in solution times and a reduction in the optimality gap when employing our valid inequalities and the heuristic.

3 - Structured Learning and Optimization: Foundations and Practice

Jian Li, Stony Brook University, Stony Brook, NY, United States

Next-generation (NextG) networked systems enabling applications ranging from 5G/6G, transportation, smart cities to autonomous driving will be data-driven and large-scale. This poses enormous burdens on traditional systems such as wireless networks, and emerging architectures such as edge and cloud computing systems, in which classic algorithmic guarantees do not always hold and rigorous performance evaluation can be even difficult. Though data-driven techniques have been applied to a variety of networking and distributed systems, pure data-driven solutions face their own challenges on curse-of-dimensionality and generalization. In this talk, I will present a structured reinforcement learning framework for NextG networked systems, which overcomes these challenges. This framework exploits the inherent structure encoded in classical models, and enables the design of novel learning architectures with low-complexity and improved sample efficiency.

4 - Optimizing Transport of Valuables: A Multi-Objective Approach Under Uncertainty

Fatemeh Zandieh, Department of Architecture and Civil Engineering, Chalmers University of Technology, Gothenburg, Sweden, Alireza Fallahtafti, Armin Hamedizad

Transporting valuables and cash entails inherent risks, prompting the integration of security measures into routing strategies. This study presents a new approach, the multi-objective valuables/cash routing problem (MO-VCRP), to efficiently manage transportation. Our model aims to minimize both transportation risks and travel costs concurrently. To address inherent uncertainty, we propose utilizing an interval type-2 fuzzy controller to estimate risk, considering several factors. Additionally, we introduce a type-2 fuzzy multi-objective genetic algorithm (T2F-MOGA) to optimize MO-VCRP.

1 - A Practical and Optimal First-Order Method for Large-Scale Convex Quadratic Programming

Jinwen Yang, University of Chicago, Chicago, IL, United States, Haihao Lu

Convex quadratic programming (QP) is an important class of optimization problem with wide applications in practice. The classic QP solvers are based on either simplex or barrier method, both of which suffer from the scalability issue because their computational bottleneck is solving linear equations. In this paper, we design and analyze a first-order method for QP, called restarted accelerated primal-dual hybrid gradient (rAPDHG), whose computational bottleneck is matrix-vector multiplication. We show that rAPDHG has a linear convergence rate to an optimal solution when solving QP, and the obtained linear rate is optimal among a wide class of primal-dual methods. Furthermore, we connect the linear rate with a sharpness constant of the KKT system of QP, which is a standard quantity to measure the hardness of a continuous optimization problem. Numerical experiments demonstrate that both restarts and acceleration can significantly improve the performance of the algorithm. Lastly, we present PDQP.jl, an open-source solver based on rAPDHG that can be run on both GPU and CPU. With a numerical comparison with SCS and OSQP on standard QP benchmark sets and large-scale synthetic QP instances, we demonstrate the effectiveness of rAPDHG for solving QP.

2 - Breaking the Cycle: Deterministic Block-Iterative Analysis for the Frank-Wolfe Algorithm

Zev Woodstock, James Madison University, Harrisonburg, VA, United States, Gabor Braun, Sebastian Pokutta

Over the last decade, Block-Coordinate Frank-Wolfe (BCFW) algorithms have led to the advent of many efficient first-order algorithms with applications in ML and engineering. However, to-date, they are only proven to work under restrictive assumptions on how the block-coordinates are updated, namely, (A) single-coordinate updates (via stochastic and greedy selection), and (B) cyclic/full update schemes which require the evaluation of all LMOs in the Cartesian product for every outer iteration. These settings are particularly disadvantageous when the coordinate LMOs require significantly different amounts of time (e.g., when some LMOs are cheap, while others require an eigencomputation or a large LP solve). We prove that the BCFW algorithm converges with a much milder "block-iterative" assumption, allowing for (I) progress without activating the most-expensive LMO(s) at every iteration, and (II) more flexibility in parallelized updates. We prove that our results are valid for several stepsize strategies, and we demonstrate a concrete gain in speed using *FrankWolfe.jl*.

3 - DEFBAL Part I: A Connection Between the ADMM and Proximal Gradient Methods

Jonathan Eckstein, Rutgers University, Piscataway, NJ, United States, Chang Yu, Paulo J. S. Silva, Felipe Atenas

The two minimization steps of the ADMM can be interpreted as the proximal gradient method applied to a particular dual formulation of the augmented Lagrangian subproblem. This talk explains this connection and how it can be used to create new ADMM-like convex optimization methods by substituting similar algorithms for the standard proximal gradient procedure.

4 - DEFBAL, Part II: New Approximate Augmented Lagrangian Methods and their Application to ADMM-Like Algorithms

Chang Yu, Rutgers University, Piscataway, NJ, United States, Jonathan Eckstein

We describe a new approximate augmented Lagrangian method in which the length of the multiplier adjustment step is dynamically adapted to the accuracy of the subproblem solution. In the DEFBAL framework, we combine this outer loop with an inner loop applying the FISTA-like method of Chambolle and Dossal to obtain an ADMM-like algorithm for convex programming. We also present some basic computational results.

Discrete Optimization for Machine Learning

Invited Session

OPT: Machine Learning

Chair: Kayhan Behdin, LinkedIn, Sunnyvale

1 - Exact Algorithms for Regularized a-Optimal Experimental Design

Yongchun Li, Georgia Institute of Technology, Atlanta, GA, United States

We study the regularized A-optimal Experimental Design (AED) problem, which aims to select new data points, given an existing Fisher information matrix, to minimize the trace of the inverse of the overall Fisher information matrix. AED arises in various machine learning and statistics problems. We prove that the AED problem is NP-hard. To solve the AED problem effectively, we derive an equivalent mixed-integer second-order conic reformulation that can be directly solve by commercial solvers. Furthermore, we derive an equivalent mixed-integer convex reformulation that allows us to design a branch-and-cut algorithm. We provide theoretical comparisons of the continuous relaxations of the two exact formulations. Finally, we test our algorithms using real-world data to demonstrate their efficiency.

2 - Osscar: One-Shot Structured Pruning in Vision and Language Models with Combinatorial Optimization

Xiang Meng, MIT, Cambridge, MA, United States, Shibal Ibrahim, Kayhan Behdin, Rahul Mazumder

Structured pruning is a promising approach for reducing the inference costs of large vision and language models. By removing carefully chosen structures, e.g., neurons or attention heads, the improvements from this approach can be realized on standard deep learning hardware. In this work, we focus on structured pruning in the one-shot (post-training) setting, which does not require model retraining after pruning. We propose a novel combinatorial optimization framework for this problem, based on a layer-wise reconstruction objective and a careful reformulation that allows for scalable optimization. Moreover, we design a new local combinatorial optimization algorithm, which exploits low-rank updates for efficient local search. Our framework is time and memory-efficient and considerably improves upon state-of-the-art one-shot methods on vision models (e.g., ResNet50, MobileNet) and language models (e.g., OPT-1.3B -- OPT-30B). For language models, e.g., OPT-2.7B, OSSCAR can lead to 125x lower test perplexity on WikiText with 2x inference time speedup in comparison to the state-of-the-art ZipLM approach. Our framework is also 6x--8x faster. Notably, our work considers models with tens of billions of parameters, which is up to 100x larger than what has been previously considered in the structured pruning literature.

3 - Grand-Slamin&Rsquo; Interpretable Additive Modeling with Structural Constraints

Gabriel Afriat, Massachusetts Institute of Technology, Cambridge, MA, United States, Shibal Ibrahim, Kayhan Behdin, Rahul Mazumder

Generalized Additive Models (GAMs) are a family of flexible and interpretable models with old roots in statistics. GAMs are often used with pairwise interactions to improve model accuracy while still retaining flexibility and interpretability but lead to computational challenges as we are dealing with order of p^2 terms. It is desirable to restrict the number of components (i.e., encourage sparsity) for easier interpretability, and better computational and statistical properties. Earlier approaches, considering sparse pairwise interactions, have limited scalability, especially when imposing additional structural interpretability constraints. We propose a flexible GRAND-SLAMIN framework that can learn GAMs with interactions under sparsity and additional structural constraints in a differentiable end-to-end fashion. We customize first-order gradient-based optimization to perform sparse backpropagation to exploit sparsity in additive effects for any differentiable loss function in a GPU-compatible manner. Additionally, we establish novel non-asymptotic prediction bounds for our estimators with tree-based shape functions. Numerical experiments on real-world datasets show that our toolkit performs favorably in terms of performance, variable selection and scalability when compared with popular toolkits to fit GAMs with interactions. Our work expands the landscape of interpretable modeling while maintaining prediction accuracy competitive with non-interpretable black-box models. Our code is available at https://github.com/mazumder-lab/grandslamin.

4 - Modeling with Categorical Features via Exact Fusion and Sparsity Regularization

Kayhan Behdin, Massachusetts Institute of Technology, Cambridge, MA, United States

We study the high-dimensional linear regression problem with categorical predictors that have many levels. We propose a new estimation approach, which performs model compression via two mechanisms by simultaneously encouraging (a) clustering of the regression coefficients to collapse some of the categorical levels together; and (b) sparsity of the regression coefficients. We present novel mixed integer programming formulations for our estimator, and develop a custom row generation procedure to speed-up the exact off-the-shelf solvers. We also propose a fast approximate algorithm for our method that obtains high-quality feasible solutions via block coordinate descent. As the main building block of our algorithm, we develop an exact solver for the univariate case based on dynamic programming, which can be of independent interest. We establish new theoretical guarantees for both the prediction and the cluster recovery performance of our estimator. Our numerical experiments on synthetic and real datasets demonstrate that our proposed estimator tends to outperform the state-of-the-art.

5 - Mathematical Optimization Models for Multiple Support Vector Machine based classifiers

Harshit Kothari, University of Wisconsin-Madison, Madison, WI, United States, Victor Blanco, Jim Luedtke

We introduce a new approach based on Support Vector Machines (SVM) for building multiclass classifiers by arrangement of hyperplanes. We propose a mixed integer programming formulation for the problem. Additionally, we introduce symmetry breaking inequalities to strengthen the model. We also develop some dimensionality reduction methods which help us run the problem for larger datasets. Finally we present our results on an extensive set of computational experiments.

Exact Approaches for Multistage Optimization

Invited Session

OPT: Global Optimization

Chair: Leonardo Lozano, University of Cincinnati, Cincinnati, OH, United States

1 - Decision Diagram Based Approaches for Discrete Bilevel Programming

Leonardo Lozano, University of Cincinnati, Cincinnati, OH, United States, Andre Cire, David Bergman

Integer bilevel programming problems are known to be very challenging due to the lack of strong relaxations that can be efficiently computed. We propose single-level representations of integer bilevel programming problems that rely on network flow-based approximations of the follower's value function, using decision diagram. We then show how we can derive scalable relaxations from this representation by constructing a minorizer of the follower’s value function. We experimentally compare our approach with state-of-the-art bilevel programming solvers and show that we can obtain competitive results for certain problem classes.

2 - A Single-Level Reformulation of Integer Bilevel Programs using Decision Diagrams

Sebastian Vasquez, Carnegie Mellon University, Pittsburgh, PA, United States, Leonardo Lozano, Willem-Jan van Hoeve

Integer bilevel programming problems are known to be very challenging due to the lack of strong relaxations that can be efficiently computed. We propose a new single-level representation of integer bilevel programming problems that relies on a network flow-based formulation of the follower’s value function, using decision diagrams and primal-dual constraints. We then show how we can derive scalable relaxations from this representation by incorporating only a restricted set of the master problem solutions, yielding dual bounds. We experimentally compare our approach with state-of-the-art bilevel programming solvers and show that we can obtain competitive results for certain problem classes, especially when considering follower's problems with combinatorial structure.

3 - Aggregation of two bilinear bipartite equality constraints and application to FEM update problem

Dahye Han, Georgia Institute of Technology, Atlanta, GA, United States, Santanu Dey, Yang Wang

Aggregating constraints that describe a set gives a relaxation of the set. Some previous works on quadratic inequalities show that sometimes “nice” aggregations give a convex hull of the set. In this work, we wish to understand the aggregation of two bilinear bipartite equality constraints and whether we can find such nice aggregations. First, we show that for a special case where there are two variables involved, the convex hull can be represented as an intersection of at most three aggregations of constraints. Next, we show that when there are three variables involved, in general, an intersection of a finite number of aggregations cannot represent a convex hull. Furthermore, we provide a counterexample where an intersection of infinite aggregations still does not give a convex hull. Despite these results, aggregated equalities can provide a tight approximation of a convex hull. We experimentally show that adding a few aggregated equality constraints significantly reduces the size of the outer approximation of the convex hull of two bilinear bipartite equalities. Since adding many randomly aggregated constraints increases the complexity, we devise a simple heuristic to find aggregation weights based on a relaxed solution. We apply this heuristic to instances from finite element model updating problems in structural engineering. The experiment shows that the aggregated constraints can close almost 5% more gap in the root node and subsequently outperform the existing branch and bound method without aggregation and a commercial global solver.

Advances in Stochastic Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Yifan Hu, EPFL & ETH, Zurich, Switzerland

1 - Contextual Stochastic Bilevel Optimization and Three-Stage Stochastic Programming

Yifan Hu, EPFL, Lausanne, Switzerland, Daniel Kuhn, Andreas Krause, Jie Wang, Yao Xie

Multistage stochastic programming poses significant challenges due to the curse of dimensionality. In this talk, we study three-stage stochastic programming using contextual stochastic bilevel optimization. Note that three-stage problems are often perceived as more challenging than the classical stochastic optimization. We develop a randomized gradient-based algorithm that achieves the same complexity bound as classical stochastic optimization. This result challenges conventional wisdom regarding the difficulty of three-stage problems, suggesting that prevailing beliefs may not always hold true. The development of such a randomized gradient-based algorithm opens up exciting directions for advancing algorithmic design for three-stage stochastic programming.

2 - Dynamic Pricing of Unique Products: Approximations and Applications to Bundling

Maxime Bouscary, Massachusetts Institute of Technology, Cambridge, MA, United States, Mazen Danaf, Saurabh Amin

Digital brokerage platforms present significant potential for improved load recommendations through strategic bundling and pricing strategies. By devising effective strategies factoring in carriers' strategic decisions and spatial positioning, these platforms can better accommodate carriers' preferences and reduce operational costs while ensuring timely load delivery. We formulate the problem as one of expected revenue maximization, considering a monopolistic online seller offering a set of unique and non-replenishable products priced dynamically over a finite horizon.

Our approach develops tractable bounds on expected revenue that are tailored to unique products and compatible with customer choice models that satisfy mild properties. Unlike the bounds provided by the static and fluid approximations, our bounds are asymptotically optimal under the multinomial logit model as the season length grows, yielding a performance bound that is $O(1/T)$. Subsequently, we propose a bundling algorithm leveraging these bounds to efficiently select bundles in a column-generation fashion. We analyze the performance of the developed bounds and the bundling algorithm on both synthetic and real-world data, allowing us to benchmark our bounds against the static and fluid approximations, and gain insight into the added value of bundling.

Our general formulation allows our framework to be used for a variety of applications. We show in our real-world study that the freight transportation industry can benefit from improved load recommendations and pricing decisions: by reducing not only operating costs, but also empty miles, our methodology benefits digital brokerage platforms while contributing to the industry's sustainability efforts.

3 - A Unified Linear Programming Framework for Reward Learning with Offline Human Demonstration and Feedback Data

Kihyun Kim, Massachusetts Institute of Technology, Cambridge, MA, United States, Jiawei Zhang, Pablo Parrilo, Asuman Ozdaglar

Inverse Reinforcement Learning (IRL) and Reinforcement Learning from Human Feedback (RLHF) are pivotal methodologies in reward learning, which involve inferring and shaping the underlying reward function of sequential decision-making problems based on observed human demonstration and feedback. Most prior work in reward learning has relied on prior knowledge or assumptions about decision or preference models, potentially leading to robustness issues. We introduce a novel linear programming (LP) framework tailored for offline reward learning. This framework estimates a feasible reward set from the primal-dual optimality conditions of a suitably designed LP, utilizing pre-collected trajectories without online exploration, and offers an optimality guarantee with provable sample efficiency. Our LP framework also enables aligning the reward functions with human feedback, such as pairwise trajectory comparison data, while maintaining computational tractability and sample efficiency. We demonstrate that our framework potentially achieves better performance compared to the conventional maximum likelihood estimation (MLE) approach through analytical examples and numerical experiments.

4 - An MILP-Based Solution Scheme for Factored and Robust Factored Markov Decision Processes

Man-Chung Yue, The University of Hong Kong, Hong Kong, Hong Kong, Huikang Liu, Wolfram Wiesemann

Factored Markov decision processes (MDPs) are a prominent paradigm within the artificial intelligence community for modeling and solving large-scale MDPs whose rewards and dynamics decompose into smaller, loosely interacting components. Through the use of dynamic Bayesian networks and context-specific independence, factored MDPs can achieve an exponential reduction in the state space of an MDP and thus scale to problem sizes that are beyond the reach of classical MDP algorithms. However, factored MDPs are typically solved using custom-designed algorithms that can require meticulous implementations and considerable fine-tuning. In this paper, we propose a mathematical programming approach to solving factored MDPs. In contrast to existing solution schemes, our approach leverages off-the-shelf solvers, which allows for a streamlined implementation and maintenance; it effectively capitalizes on the factored structure present in both state and action spaces; and it readily extends to the largely unexplored class of robust factored MDPs, whose transition kernels are only known to reside in a pre-specified ambiguity set. Our numerical experiments demonstrate the potential of our approach.

Methods for Large-Scale Nonlinear and Stochastic Optimization II

Invited Session

OPT: Nonlinear Optimization

Chair: Jiahao Shi, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Shagun Gupta, UT Austin, Austin

Co-Chair: Albert Berahas, University of Michigan, Ann Arbor, MI, United States

1 - Newton-Cg Methods Under HÖLder Conditions

Chuan He, University of Minnesota, Minneapolis, MN, United States, Zhaosong Lu

Second-order methods have played an important role in the recent development of nonconvex optimization with numerous fruitful applications in science and engineering. In this talk, we introduce new Newton-CG methods for nonconvex unconstrained optimization with complexity guarantees under Hölder conditions. In particular, we propose the first parameter-free second-order method with iteration and operation complexity bounds that can seek an approximate first-order stationary point and second-order stationary point without requiring any prior knowledge of the Hölder parameters. Numerical results demonstrate the superior practical performance of our proposed method.

2 - Scalable Projection-Free Optimization Methods via Multiradial Duality Theory

Thabo Samakhoana, Johns Hopkins University, Baltimore, MD, United States, Benjamin Grimmer

Recent works have developed new projection-free first-order methods based on utilizing linesearches and normal vector computations to maintain feasibility. These oracles can be cheaper than orthogonal projection or linear optimization subroutines but have the drawback of requiring a known strictly feasible point to do these linesearches with respect to. In this work, we develop new theory and algorithms which can operate using these cheaper linesearches while only requiring knowledge of points strictly satisfying each constraint separately. Convergence theory for several resulting ``multiradial" gradient methods is established. We also provide preliminary numerics showing performance is essentially independent of how one selects the reference points for synthetic quadratically constrained quadratic programs

3 - A Simple, Reliable and Adaptive Trust-Region Method

Oliver Hinder, University of Pittsburgh, Pittsburgh, PA, United States, Fadi Hamad

We develop a simple trust-region method that obtains the best possible iteration bound for a second-order method on functions with Lipschitz continuous Hessian (up to additive logarithmic factors). Moreover, on the CUTEst test set our method is significantly faster and more reliable than the state of the art adaptive cubic regularization and trust-region methods implementations available in the GALHAD library.

4 - Fast regularized interior method for large scale separable convex quadratic programming

Ya-Chi Chu, Stanford University, Stanford, CA, United States

In this talk, we will present a new algorithm for convex separable quadratic programming (QP) called Nys-IP-PMM, a regularized interior-point solver that uses low-rank structure to accelerate solution of the Newton system. The algorithm combines the interior point proximal method of multipliers (IP-PMM) with the randomized Nyström preconditioned conjugate gradient method as the inner linear system solver. Our algorithm is matrix-free: it accesses the input matrices solely through matrix-vector products, as opposed to methods involving matrix factorization. It works particularly well for separable QP instances with dense constraint matrices. We establish convergence of Nys-IP-PMM. Numerical experiments demonstrate its superior performance in terms of wallclock time compared to previous matrix-free IPM-based approaches.

Data-driven Decision-making in Urban Mobility

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Julia Yan, University of British Columbia, Vancouver, Canada

1 - Microtransit Design: Fixed-Line Transit, on-Demand Mobility, OR Both?

Shriya Karam, Massachusetts Institute of Technology, Cambridge, MA, United States, Alexandre Jacquillat, Julia Yan, Arthur Delarue

Urban mobility providers are increasingly leveraging emerging operating models based on microtransit, which integrate fixed-line transit and on-demand services. This paper seeks to understand the benefits and tradeoffs behind transit and on-demand operations and the optimal design of integrated microtransit systems. Using continuous approximation techniques, we first consider stylized settings to provide theoretical insights on the optimal transit and on-demand allocation structure. To build on our theoretical findings, we develop optimization models and algorithms to design spatial and temporal operations for door-to-door ride-sharing and fixed-line transit to serve passenger demand. Computational results show the advantages of operating hybrid transit and on-demand systems and the trade-offs across modes on agency operating costs and passenger convenience.

2 - Optimizing Public Transit: A Data-Driven Approach

Boxuan Zhou, UIUC, Champaign, IL, United States, John Birge, Ozan Candogan

Our model proposes an enhancement for fixed-station public transportation systems by optimizing express station selection and vehicle allocation between express and regular routes. While applicable to both bus and subway systems, we focus on subways due to data availability. The problem of optimizing express routes is inherently complex and algorithmically challenging. To simplify it, we introduce an "admissibility" condition that narrows down the feasible express route set to a practically relevant class. Leveraging this condition, we develop a dynamic programming algorithm for a manageable solution to the planner's problem. Initially designed for a single straight train line, our algorithm extends successfully to various transportation network topologies, including circular routes and tree structures.

Our methodology requires knowledge of riders' origin-destination (O-D) demand, which is often absent in subway systems. What we have is turnstile data that captures station entrances and exits. To bridge this gap, we propose a choice model that accounts for riders' destination preferences, time, and distance values. Algorithms are provided to estimate this model and construct the O-D demand matrix.

We apply our approach to the NYC subway system using data from the Metropolitan Transportation Authority (MTA) and our estimation framework for O-D demand. Through dynamic programming, we determine optimal express station locations and frequencies. Focusing on the Red (Green) Line, our results indicate potential time savings for riders ranging from 5% to 15% (2% to 5%), and the optimal express station locations differ significantly from the current setup.

3 - Reweighted L1-Norm Minimization Approach to Transportation Network Design Under Demand Endogeneity

Pushpendra Singh, Dartmouth College, Hanover, NH, United States, Vikrant Vaze

Many transportation applications involve some form of network design. Network design problem has been well-studied in the literature but most prior studies assume passenger demand to be exogenously determined. In reality, demand depends on network design. But capturing such endogenous demand adds significantly to the model complexity. We define a new class of mixed-integer non-convex optimization problems for network design, which are important to practice across many fields and share some mathematical similarities that motivate this work. We provide a compact and general formulation for this class of problems and also define subproblems and map existing research to these subclasses. Next, we characterize the key existing solution approaches, as well as presenting new approaches, for solving these problems successfully. The approaches include: Reweighted L1 norm minimization, Exponential Conic Programming, and Adaptive Discretization Algorithm. While all the three approaches provide either optimal or very close to optimal solution, the reweighted L1-norm minimization which takes the advantage of the sparse nature of matrix of transportation network design problems, outperforms the other approaches when it comes to scalability while providing very close to optimal solutions (within 1.5% optimality gap). Our results from both real-life case studies and simulated networks uphold our claims while providing solutions in much faster runtimes than other proposed methods.

4 - Achieving Transit Accessibility Gains through Flexible Bus Routing and Advance Online Reservation for a Low-Demand Route

Md Hishamur Rahman, University of Utah, Salt Lake City, UT, United States, Ye Chen, Shijie Chen, Yanshuo Sun, Nikola Markovic

The objective of this paper is to enhance the accessibility of conventional bus routes by increasing the number of stops, particularly on routes where existing stops are underutilized. We propose a new type of semi-flexible transit system where buses can selectively skip stops lacking passenger demand and take shortcuts, thereby reducing the tour duration compared to that of conventional routes. This system requires passengers to provide advance notice for their desired stops, ensuring these stops are reliably serviced. We introduce analytical and simulation-based models to design and optimize this semi-flexible transit system. The optimization objective is to maximize the number of stops, subject to tour duration and arrival time constraints. Integral to our methodology is the development of an efficient online learning approach, which we use to sequentially evaluate the system's feasibility across different scenarios. In the Allegany County, Maryland case study, significant enhancements were observed in bus routes where route configurations allowed taking substantial shortcuts and the average probability of skipping a stop exceeded 45%. In these instances, the number of stops can be increased by up to 160%, with the actual improvement depending on route configuration, passenger demand, and advance notice requirements.

5 - Curbing Emissions: Enhancing Sustainability Through Collaborative Shipment in Horizontal Supply Chains

Tanvir Ibna Kaisar, University of Southern California, Los Angeles, CA, United States, Maged Dessouky, Randolph Hall

In recent years, the importance of sustainable and resilient supply chains has become increasingly important due to the growing concerns over energy crises, environmental pollution, and supply chain disruptions. Amidst these challenges, battery electric vehicles (BEVs) have emerged as a promising solution as they offer several key advantages that contribute to sustainable and resilient supply chains. BEVs have the potential to significantly reduce greenhouse gas (GHG) emissions in the logistics sector, thereby helping companies meet their sustainability goals and mitigate their environmental impact. Moreover, BEVs can enhance supply chain resiliency by reducing reliance on volatile fossil fuel markets and providing a more stable and predictable energy source for transportation. However, the BEV technology is still evolving, and the significant initial investment required for BEV adoption remains a deterrent, particularly among small companies. To address this challenge, we propose a cooperative mechanism for BEV adoption among multiple small companies in a horizontal supply chain. We specifically focus on the logistics sector, where a set of firms deliver their products to their customers through a shared distribution center using a BEV fleet. We formulate the routing problem as a mixed integer programming (MIP) problem and solve it exactly for small instances. For larger instances, we use a customized Adaptive Large Neighborhood Search (ALNS) heuristic. We also develop cost-sharing mechanisms to fairly distribute the cost of the collaboration among the participants under various scenarios.

Optimization and Decarbonization of Multi-modal Freight Transportation Systems

Invited Session

TSL: Freight Transportation

Chair: Adrian Hernandez, Northwestern University, Evanston, IL, United States

1 - Multimodal Freight Network Design and Facility Location Optimization to Support Freight Transportation Decarbonization

Adrian Hernandez, Northwestern University, Evanston, IL, United States, Pablo Durango-Cohen, Hani Mahmassani, Vasileios Volakakis, Cal Skiles, Dana Monzer

This paper proposes a multimodal freight network design and facility location model to optimize the integration of road, rail, and maritime transportation modes with respect to efficiency, costs, and emissions. We build on classical network models such as multi-commodity network flow problems and hub location-allocation problems to formulate a model for (i) locating transloading facilities and (ii) establishing links to connect two or more freight modes and networks. We present model variants with different objectives, including minimization of transportation costs, minimization of environmental impacts, and maximization of connectivity across modes. Furthermore, we capture alternative refueling facility location decisions within the model and allowing flows to be split among different modes and energy technologies between nodes on the network. We apply this model in the context of the US freight transportation network and market, with examples including the deployment of charging infrastructure to support battery-electric trucks and locomotives, as well as the location of transloading facilities to connect rail and domestic maritime modes. In addition to evaluating model results on cost, emissions, and travel time impacts, we evaluate network resilience through simulation of local and regional disruptions.

2 - Improving Multimodal Freight Transportation Operations: A Hybrid Multi-Objective Routing Optimization – Agent Based Modelling Logistics Framework

Vasileios Volakakis, Northwestern University, Evanston, IL, United States, Adrian Hernandez, Max Ng, Cal Skiles, Dana Monzer, Pablo Durango-Cohen, Hani Mahmassani

This work proposes a logistics optimization framework for multimodal freight operations, consisting of two methodological components, an optimization-based and a simulation-based model. Regarding the former component, a multi-objective routing optimization model with objectives of travel time, emissions, and risk (disruption and charging/refueling range sufficiency – related) minimization was developed, that provides a set of pareto optimal solutions, i.e. multiple routing options. For the solution of the optimization problem, the Adaptive Weighted Sum (AWS) method has been used, which initially uses the common weighted sum approach to swiftly approximate the Pareto surface and identify a grid of Pareto front segments. These segments are then refined through additional equality constraints that link specific reference points to anticipated optimal solutions on a segmented hypersurface in a multidimensional objective space. For the later methodological component, an agent-based model was developed, to simulate the transport operations and capture behavioral responses of transport agents, focusing on key variables in the mode choice process, such as price, transit time, reliability, and flexibility. Such agents are shipper, carrier, and container agents. The proposed methodological framework is to be applied at a national level set of networks and scenarios, with the ultimate objective of forging a tool that facilitates the comparison and evaluation of various routing options under different scenarios, accounting for the interrelations and interactions of different entities in such a network.

3 - A Decarbonized and Resilient Intermodal Freight Transportation (DRIFT) Modeling Platform for Intermodal Logistical Decisions under Uncertainty

Kuilin Zhang, Michigan Technological University, Houghton, MI, United States, Yun-Chu Hung, Yingtong Tan

This talk presents an intermodal logistical modeling platform - Decarbonized and Resilient Intermodal Freight Transportation (DRIFT) to support long-term planning decisions on mode, route, and charging for future charging/fueling strategies up to the year 2050, and also quasi-real-time dynamic decisions on scheduling and re-routing to respond to disruptions and real-time traffic conditions. The objective is to reduce overall energy usage per ton-mile of freight transported while minimizing the levelized cost of ton-kilometers (LCOTKM) with increased supply chain resiliency. Considering future scenarios of renewable energy sources, charging/fueling infrastructure rollout strategies, projected freight demand from ports to warehouses, and natural- and man-made extreme events for intermodal logistics, DRIFT provides optimized intermodal logistical decisions that could help identify the most cost-effective transition pathways to a net-zero GHG emissions intermodal transportation systems, including water, rail, and road.

4 - Identifying capacities in a multimodal maritime freight network

Kyle Bathgate, The University of Texas at Austin, Austin, TX, United States, Debojjal Bagchi, Stephen Boyles

We investigate how a "capacity" can meaningfully be defined in multimodal maritime freight systems, and how such a notion can be used to improve performance and resilience by identifying bottlenecks. Shipping channels and ports are each complex systems that interact deeply, and the bottlenecks in the individual facilities may not represent bottlenecks in the combined multimodal system. We first describe a data-driven discrete event simulation framework to describe operations of such a system. We then show how this simulation framework can provide a notion of "capacity" by identifying the most significant variables and parameters, and how this notion can be used in resource allocation problems involving maintenance or improvements in multimodal systems. We present a case study to demonstrate how the framework can be applied.

5 - Integrated multimodal network models for decarbonization of intermodal freight shipments

Yiduo Huang, University of California-Berkeley, Berkeley, CA, United States, Yanfeng Ouyang

The U.S. freight transportation industry is responsible for a significant portion of the nation’s greenhouse gas (GHG) emissions, and its under-capacitated infrastructure has exacerbated its vulnerability to disruptions. We present integrated data and computational models that enable modeling and decision making on the nation’s intermodal freight logistics systems across water, roadway, and railway modes. Logistics optimization models will be developed that could explain freight shippers’ choices (e.g., mode, origin/destination) and logistics service providers’ decisions (e.g., on routing and scheduling) across multiple integrated shipment modes.

Game Theory in Smart Mobility

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Xiaotong Sun, The Hong Kong University of Science and Technology (Guangzhou), Guangzhou, N/A

Co-Chair: Jiayang Li, Northwestern University, Evanston, IL, United States

1 - Can information design resolve EV charging chaos? Author: Qianni Wang, Jiayang Li, Xiaotong Sun, Yu (Marco) Nie

Qianni Wang, Northwestern University, Evanston, IL, United States

The rapid expansion of the electric vehicle (EV) market has heightened concern about the shortage of charging infrastructure, especially for long-distance travel. Range anxiety, combined with uncertain availability and delays at charging facilities, can lead to behaviors that undermine system efficiency, at times when efficiency matters the most. Here, we consider a designer who, equipped with exclusive real-time information on the uncertain state of charging, attempts to guide EV drivers toward a socially desirable outcome by designing an optimal information dissemination scheme. Building on information design theory, we develop Bayesian persuasion models for both public and private information designs. Whereas the public model provides the same information to all drivers, the private model offers personalized recommendations based on individual attributes (i.e. the remaining range of an EV at decision points in our model). Our analysis reveals that consistently disclosing the true state of charging is the most effective scheme for public information design. However, personalized information delivery often leads to better outcomes. We also find that information design works best when there is a high level of uncertainty in the drivers' perception of the charging state, and that benefits of information tend to increase as the cost associated with charging worsens relative to other choices.

2 - Sequential Information Design: Markov Persuasion Process and Its Efficient Reinforcement Learning

Jibang Wu, University of Chicago, Chicago, IL, United States

This paper proposes a novel model of sequential information design, namely the Markov persuasion processes (MPPs), in which a sender, with informational advantage, seeks to persuade a stream of myopic receivers to take actions that maximize the sender's cumulative utilities in a finite horizon multi-agent Markovian environment. Planning in MPPs thus faces the unique challenge in finding a signaling policy that is persuasive to the myopic receivers and simultaneously induces the optimal long-term cumulative utility for the sender. For such a problem, we design a provably efficient no-regret learning algorithm, which features a novel combination of both optimism and pessimism principles. In particular, we obtain optimistic estimates of the value functions to encourage exploration under the unknown environment, and additionally robustify the signaling policy with respect to the uncertainty of prior estimation to prevent receiver's detrimental equilibrium behavior. Our algorithm enjoys sample efficiency by achieving a sublinear $\sqrt{T}$-regret upper bound. Furthermore, both our algorithm and theory can be applied to MPPs with a large space of outcomes and states via function approximation, and we showcase such a success under the linear setting.

3 - Balancing mobility and power grid considerations with shared autonomous electric vehicles

Stephen Boyles, The University of Texas at Austin, Austin, TX, United States

Authors: Jake Robbennolt, Meiyi Li, Stephen D. Boyles, Javad Mohammadi Abstract: Shared autonomous electric vehicle systems can provide on-demand mobility, but also interact extensively with the power grid. To balance these needs, we describe a rolling-horizon model-predictive control approach to vehicle dispatch, accounting for both transportation network dynamics and power distribution constraints. We then present a distributed solution technique using the alternating direction method of multipliers to improve computational efficiency and support real-time implementation. The transportation and power flow subproblems are coupled by power transfer at charging stations, and the transportation subproblem is further decomposed across vehicles. In this cooperative game scenario, we investigate incentive compatibility of the integrated mobility-energy system, computational performance of our algorithms, and impacts on mobility and grid operation through numerical experiments on urban test cases.

4 - Safety, Liability, and Insurance in the Age of Automated Driving

Sina Bahrami, University of Michigan, Ann Arbor, MI, United States, Daniel Vignon

This paper investigates two questions related to safety and insurance in the age of automation. First, the question of safety and liability under infrastructure-assisted automated driving. In such an environment, automakers provide vehicle automation technology while infrastructure service providers (ISSPs) provide smart infrastructure services. Additionally, customers can receive coverage for accidents from either of these actors but also from legacy auto insurers. We investigate the effect of market structure on safety and accident coverage and show that an integrated monopoly provides full coverage and fully accounts for accident costs when choosing safety levels. However, in the Nash setting, even though full coverage obtains, lack of coordination leads to partial internalization of accident costs by the automaker. Moreover, multiple equilibria might exist, some of them undesirable. We show that, with and without legacy insurance, an appropriate liability rule can induce optimal safety levels under the Nash setting. Our second question concerns itself with the role of legacy auto insurance in the age of infrastructure-assisted automated driving. We show that the industry is not necessary for optimal coverage when the cost of accidents is known in advance and all possible accident scenarios are contractible. In fact, their presence can even harm safety, even though it ensures full coverage for accidents. However, when only insurance contracts with capped liability for automakers and ISSPs are available, we cannot rule out that customers benefit from legacy insurers. Thus, the disappearance of the industry in the age of automated driving is not a foregone conclusion.

5 - Error bounds for stochastic user equilibrium traffic assignment

Debojjal Bagchi, The University of Texas at Austin, Austin, TX, United States, Stephen Boyles

Author: Debojjal Bagchi, Stephen Boyles Abstract: In stochastic user equilibrium traffic assignment, we develop bounds on the distance between a given feasible solution and the equilibrium solution in terms of a gap function. The intent is to provide guidance on termination criteria to reduce run times, which is important because this assignment problem is often a subproblem to a more complex bilevel optimization. These mathematical bounds complement existing rules-of-thumb drawn empirically from numerical case studies. Our approach is based on Taylor's theorem, as applied to the fixed-point formulation of the stochastic user equilibrium assignment, and provides upper bounds on differences in both aggregate metrics (total travel time, distance traveled) and disaggregate metrics (link flows, path flows). We demonstrate that these bounds are tight and cannot be further improved without additional restrictions on the network topology or problem instance.

2 - Dynamic Discretization Discovery Algorithm for Airline Timetable Development and Fleet Assignment with Passenger Choice

Ritesh Ojha, Georgia Institute of Technology, Atlanta, GA, United States, Luke Marshall, Keji Wei

The airline timetable development and fleet assignment problem un- der endogenous passenger choice (ATFP), aims to create flight timetables based on passenger choice while optimizing fleet utilization for profitability [1]. Traditionally, airlines make incremental adjustments to their existing flight schedules. State-of-the-art methods for ATFP involve multiphase heuristic ideas. In this paper, we develop an exact dynamic discretization discovery (DDD) algorithm that iteratively solves relatively small mixed-integer programs (MIPs) formulated over partially time-expanded networks to generate optimal solutions [2]; the effectiveness of the algorithm relies on a sophisticated lower-bound MIP model and a novel upper-bound construction procedure. We prove that the DDD algorithm always converges to the optimal solution in a finite number of iterations. We also develop effective arc-based and flight itinerary-based network refinement strategies that enable the DDD algorithm to converge to the optimal solutions while generating only a small fraction of the complete time-expanded network.

The exact DDD algorithm finds the optimal solution and is 8× faster than directly using a commercial solver on small-scale instances obtained from real-life data of Alaska Airlines; the commercial solver cannot prove optimality for the small instances even in 15 minutes. The algorithm is computationally efficient because it solves small MIPs (LBM) in each iteration and finds the optimal solution while generating only 10−30% of the complete time-expanded network. Computational results suggest that our solution approach can result in significant profit improvements, as compared to the most advanced incremental and multi- phase heuristic approaches to flight timetabling.

Railway Scheduling and Management of Crews, Intermodal, Yards and Networks

Contributed Session

Railway Applications

Chair: Hangyu Ji, N/A

1 - Benders Decomposition for Robust Tactical Railway Crew Scheduling

Bart van Rossum, Erasmus University Rotterdam, Rotterdam, Netherlands, Twan Dollevoet, Dennis Huisman

We consider robust tactical crew scheduling for a large passenger railway operator, whose timetable is subject to minor but uncertain updates on a weekly basis. Before the start of the planning period we must select a number of templates, specifying the time windows in which crew is supposed to work. These templates must be cost-efficient whilst providing sufficient capacity for the realised updated timetables. Moreover, the templates must be compatible with the rostering process, i.e., we wish to limit the number of different templates used and ensure that there are not too many templates on early or late moments of the day. Throughout the planning period, the templates are fixed and the updated timetable is released on a weekly basis. All tasks in the timetable must be covered using the capacity provided by the templates, or, if necessary, costly reserve capacity. We model the template selection problem as a scenario-based robust optimisation model, for which we propose a Benders decomposition algorithm. We conduct computational experiments on real-life instances from Netherlands Railways and show that our algorithm is able to solve instances featuring up to three scenarios and up to 1,000 tasks per scenario to optimality. Including more scenarios, allowing for more flexibility in choosing templates, or enlarging the template length all lead to reductions in reserve crew costs without increasing template-based crew costs.

2 - An Open-Specification-Based Ecosystem for Optimizing intermodal Freight Transportation

Xuesong (Simon) Zhou, ASU, Tempe, AZ, United States

Our presentation introduces the GMNS-based Open-Specification-Based Planning approach, aiming to achieve Net-Zero Emissions through sustainable supply chains. We will highlight the Open Computational Ecosystem for Adaptive Networked National and Transportation Systems (OCEAN+), a crucial tool that employs dynamic, multi-level structures and scalable computing to tackle complex scheduling and routing challenges in intermodal freight operations. This initiative promises significant energy savings and aims to set new standards for sustainability and resilience in the freight sector.

3 - Railcar-to-train Optimization in a Freight Railyard

Ruonan Zhao, Texas A&M University, College Station, TX, United States, Joseph Geunes, Xiaofeng Nie

A typical freight railyard at a manufacturing facility contains multiple tracks designated for classification and departure purposes. After loading cars with outbound goods at the manufacturing facility, railcars with different destinations are stored on these classification tracks and must later be moved to departure tracks to create outbound trains with designated destinations, incurring associated repositioning costs. Car storage locations on classification tracks are often determined before knowledge of destination locations is revealed, leading to problems that require retrieving subset of cars located randomly throughout the yard to build outbound trains. To address this challenge, we propose a mixed-integer programming (MIP) model that allows simultaneous movement of multiple railcars at minimum repositioning cost. By constructing the associated conflict graph, we prove the problem's NP-hardness. Furthermore, we devise a Track-Adaptive Car Reassignment Heuristic (TACR-H) algorithm to solve the problem. Results of a set of numerical experiments are presented to demonstrate the ability of the TACR-H algorithm to obtain fast solutions while achieving acceptable solution quality.

4 - Joint Planning of Passenger and Freight Trains in High-Speed Railway Express System

Hangyu Ji, Beijing Jiaotong University, Beijing, China, People's Republic of, Jiateng Yin

High-speed railway (HSR) has experienced significant expansion and has become the primary choice for passengers traveling between intercities in recent years. In HSR, passenger demand varies during different time periods. Thus, the rail managers, suffering from financial pressures in low seasons, are actively exploring the potentials for using a part of vehicles in some trains to transport both passengers and fast-delivery goods, while these is few research along this line. Our study formally addresses this problem for the integrated planning of train schedule and set allocations for passengers and freight. We develop a mixed integer linear programming model to optimally determine the tactical train schedule, train stopping plan, and train compositions. The objective of our model is to minimize the total travel time and operation costs of trains while satisfying the demands of both passengers and freight. In addition, we carefully consider some new constraints in our formulation, involving the time window limitation of freight, the freight loading/unloading work time at platforms, which are practically significant while were not fully investigated in the existing literature. Then, we prove that the constructed model is an NP-hard problem, indicating its inherent difficulty in being solved. To tackle this challenge, we develop an decomposition-based approach to solve the model, where the passenger-freight allocation is formulated as the master problem, and the scheduling of each train is formulated as one subproblem. Real-world case studies on Wuhan-Guangzhou high-speed railway corridor are conducted to verify the effectiveness of our approach.

5 - Train Service Design Problem with Perceived Headway Consideration and Passenger Flow Allocation for Urban Rail Transit Lines

Max Ng, Northwestern University Transportation Center, Evanston, IL, United States, Hani Mahmassani, Omer Verbas, Taner Cokyasar, Draco Tong

This study addresses the train service design problem for urban rail transit lines, optimizing stop sequences and headways of each pattern simultaneously to minimize user costs (composed of riding, waiting, and transfer times) under operational constraints (e.g., number of trains). The formulation does not rely on pre-defined candidate pattern sets but allows for flexible pattern options. It incorporates various service strategies (e.g., express/local services, short-turning, and dead-heading) and considers bi-directional origin-destination (inelastic) demand and (continuous) operations. It evaluates perceived headways of joint patterns for passengers, assigns passenger flows to each pattern accordingly, and allows transfers across patterns in different directions. Multi-line optimization of patterns and headways considering fleet assignment is also considered. We develop a destination-labeled multi-commodity network flow (MCNF) formulation, leading to efficient mixed-integer linear programming (MILP) solutions. Binary variables assign stop sequences and headways to patterns, and perceived headways to origin-destination pairs. Continuous variables assist in evaluating flows and costs. The methodology is demonstrated with a case study of metro lines in Chicago, USA, with 42 stations and scenarios ranging from two to three patterns and three to seven headways. Results indicate that optimized patterns outperform a full-stop pattern, reducing average user costs by 2.4% and average riding time by 9.0%.

6 - Fast and Efficient Heuristic Algorithm for Selecting Highway-Rail Grade Crossings for Closure

Razieh Khayamim, FAMU-FSU College of Engineering, Tallahassee, FL, United States, Bokang Li, Payam Afkhami, Zeinab Elmi, Ren Moses, John Sobanjo, Eren Ozguven, Maxim Dulebenets

An intersection of railway and highway segments at the same elevation, known as a highway-rail grade crossing or level crossing, presents significant safety concerns and operational challenges. To mitigate these issues, different methods can be adopted, such as implementation of countermeasures (e.g., installation of flashing lights, gates, and median barriers), grade separations, and level crossing closures. The closure of selected level crossings, when done thoughtfully in consultation with relevant stakeholders and affected communities, can be a highly effective alternative. However, the majority of studies in this field primarily focuses on the implementation of countermeasures and mainly concentrates on safety-related aspects. Considering the drawbacks in the current research, a novel optimization model to identify level crossings for closure is presented in this study, which evaluates various benefits from closing specifically selected level crossings, including safety, economic, and environmental benefits, as well as reduction in traffic delays and maintenance and operational costs. A specialized heuristic algorithm inspired by sorting principles is developed to solve the decision problem addressed in this study. A set of comprehensive computational experiments are performed focusing on level crossings situated in the State of Florida (United States). The findings show clear superiority of the developed heuristic algorithm against the exact method, as it was able to solve the generated problem instances ≈20 times faster with the average optimality gap of only 0.14%. Additionally, various sensitivity analyses are performed to illustrate managerial implications from the implementation of the proposed optimization approach to administer closures of level crossings.

1 - Time Accommodation for Call Center Agents with Disabilities: A Mediation Analysis

Yingru Han, University of South Carolina, Columbia, SC, United States, Luv Sharma, Sriram Narayanan

While labor shortage remains persistent in the global economy, a subsegment of the population - people with disabilities (PWDs), has been continuously marginalized by the labor market. Positions exist where disabilities do not directly prevent individuals from performing the job, such as a call center agent. However, the high-stress nature of the job requires appropriate accommodations for PWDs to sustain and prosper, which are not often formally implemented especially in less developed economies. Such a phenomenon requires employers and PWDs to create informal accommodations. In this study we examine the role of spontaneous idleness, defined as the naturally occurring idleness between two calls, as a new source of accommodation for PWDs working in call centers. We first study how spontaneous idleness affects PWDs' productivity and how this relationship changes for PWDs of different levels of disability severity. We also study how spontaneous idleness affects agents' behaviors in taking flexible breaks, defined as the flexibility given by employers to take breaks as an agent sees needed. Using panel data at an agent-day level and a mediation analysis, we uncover the positive relationship between spontaneous idleness and productivity and identify flexible breaks as a partial mediator and the severity level of disability as a moderator. Our findings can assist organizations in similar contexts to better accommodate PWDs and improve their productivity by configuring spontaneous idleness.

2 - Assigning Volunteers to Beneficiaries in A Non-Profit Organization

Shikha Safaya, Scheller College of Business, Georgia Tech, Atlanta, GA, United States, Basak Kalkanci, Ravi Subramanian

Non-Profit Organizations (NPOs) play an important socioeconomic role by providing services to people in need, often with volunteers from the community acting as service providers. However, absent monetary incentives, volunteer scheduling and retention are key challenges faced by many NPOs. Motivated by the context of Meals on Wheels Atlanta (MOWA), an NPO providing meals and personal interaction through volunteers to elderly with limited mobility and food insecurity, we examine the incorporation of volunteer preferences for task assignment as a lever to induce provision of services and enhancement of service quality. The populations of volunteers [seniors] are of two types: individuals who prefer the base service of only delivering [only receiving] meals (type B), and individuals who are open to offering [who value] interactions alongside meal delivery (type I). We compare two policies: (i) a pooled policy, which groups volunteers together, irrespective of their task preferences (to represent the status quo); and, (ii) a preference-based policy, which incorporates volunteer preferences (as a potential improvement over the status quo). We explore the tradeoff between incorporating volunteer preferences during task assignment and pooling all volunteers to alleviate supply-demand mismatch. In doing so, we endogenize the volunteers' decisions to participate in the delivery activities at MOWA based on their expectations of the utility from serving as well as their outside options. We contrast the performance outcomes of alternative matching policies and suggest ways by which NPOs can better align incentives of all stakeholders.

3 - Enhancing Volunteer Retention: The Role of Experienced Volunteers

Vinit Tipnis, Kelley School of Business, Indiana University Bloomington, Bloomington, IN, United States, Christopher Chen, Fei Gao

Volunteers play a pivotal role in the daily operations of nonprofit organizations (NPOs), yet retaining volunteers remains a critical challenge for NPOs. This study explores a cost-effective approach to improving volunteer retention by leveraging the potential of the existing pool of experienced volunteers. Specifically, we examine how interactions between experienced and new volunteers impact the latter's retention behavior. Using data of 45,315 volunteers at a food bank over a five-year period, we estimate logistic regression model to explore interaction patterns among the volunteers. Our findings indicate that the presence of experienced volunteers in a volunteering shift increases new volunteer retention by 15.5%. Notably, this positive effect on retention is experienced by all new volunteers, regardless of whether they volunteered alone or as part of a group and across shifts with or without beneficiary interactions. However, through network analysis, we find that increased familiarity among experienced volunteers negates this positive effect. Our study contributes to the volunteer management literature by highlighting the importance of social interactions for volunteer retention and how NPOs can utilize their existing experienced volunteers to enhance new volunteer retention.

Algorithm Design for Randomized Experiments

Invited Session

Applied Probability Society

Chair: Christopher Harshaw, MIT / UC Berkeley, Cambridge, MA, United States

1 - Causal Inference & Interference in Bipartite Experiments

Jean Pouget-Abadie, Google, New York, NY, United States

When the treatment assignment of one unit affects the outcome of another, we say there is interference. Interference is especially prevalent in marketplaces, where buyer and seller interactions lead to complex dependence structures. As a violation of the stable unit treatment value assumption, the presence of interference can lead to bias of standard estimators under naive randomized designs. In this talk, we will cover a set of design and estimation paradigms used at Google to conduct causal inference research in a bipartite graph setting, inspired from, but not limited to, marketplace experiments, with specific attention paid to clustered randomized designs.

2 - Estimating Direct Effects under Interference: a Spectral Approach to Experimental Design

Anthimos Vardis Kandiros, MIT, Cambridge, MA, United States, Constantinos Daskalakis, Christopher Harshaw, Charilaos Pipis

From clinical trials to corporate strategy, randomized experiments are a reliable methodological tool for estimating causal effects. In recent years, there has been a growing interest in causal inference under interference, where treatment given to one unit can affect outcomes of other units. While the literature on interference has focused primarily on unbiased and consistent estimation, designing randomized network experiments to ensure tight rates of convergence is relatively under-explored for many problems.

In this talk, we study the problem of direct effect estimation under interference. Here, the interference between experimental subjects is captured by a network and the experimenter seeks to estimate the difference between the outcomes when (i) a unit is treated and its neighbors receive control and (ii) the unit and its neighbors receive control. We propose a Horvitz—Thompson style estimator and a new experimental design under which the normalized variance is bounded as $n * Var <= O(\lambda)$, where λ is the largest eigenvalue of the adjacency matrix of the graph. This experimental design, which is inspired by techniques from spectral graph theory, establishes the best known rate of convergence for this problem; in fact, we offer lower bounds for any experimental design, which match our rates in certain instances. In addition, we present a variance estimator and CLT which facilitate the construction of asymptotically valid confidence intervals. Finally, simulations using data from a real network experiment corroborate the theoretical claims.

3 - Finite Population Regression Adjustment and Non-Asymptotic Guarantees for Treatment Effect Estimation

David Arbour, Adobe Research, Charlottesville, VA, United States

The design and analysis of randomized experiments is fundamental to many areas, from the physical and social sciences to industrial settings. Regression adjustment is a popular technique to reduce the variance of estimates obtained from experiments, by utilizing information contained in auxiliary covariates. While there is a large literature within the statistics community studying various approaches to regression adjustment and their asymptotic properties, little focus has been given to approaches in the finite population setting with non-asymptotic accuracy bounds. Further, prior work typically assumes that an entire population is exposed to an experiment, whereas practitioners often seek to minimize the number of subjects exposed to an experiment, for ethical and pragmatic reasons. In this work, we study the problems of estimating the sample mean, individual treatment effects, and average treatment effect with regression adjustment. We propose approaches that use techniques from randomized numerical linear algebra to sample a subset of the population on which to perform an experiment. We give non-asymptotic accuracy bounds for our methods and demonstrate that they compare favorably with prior approaches.

4 - Causal Inference Under Interference Through Designed Markets

Evan Munro, Stanford University, Stanford, CA, United States

In many markets a centralized mechanism determines the allocation of goods. When an individual-level intervention affects submissions to the mechanism, program evaluation is challenging due to spillover effects that occur through the mechanism. For example, a bidder-level treatment that increases some bids in an auction will impact the market-clearing price, affecting all auction participants. We show that if the mechanism is truthful and has a ``cutoff'' structure, then interference is constrained, and it is possible to estimate the Global Treatment Effect (GTE) under a selection-on-observables assumption. Our proposed estimator is doubly-robust and has an asymptotic variance that meets the semi-parametric efficiency bound. We also characterize heterogeneous treatment effects under interference in this setting and propose estimators for the optimal targeting rule. Taking into account equilibrium effects notably diminishes the estimated impact of an information intervention on inequality in the Chilean school system.

Statistical Reinforcement Learning

Invited Session

Applied Probability Society

Chair: Kyra Gan, Cornell Tech, Cornell University, New York, NY, United States

Co-Chair: Raaz Dwivedi, Cornell Tech, Cornell ORIE, New York City, NY, United States

1 - Temporal Difference Versus Monte Carlo: An Optimal and Adaptive Resolution

Wenlong Mou, University of Toronto, Toronto, ON, Canada

Temporal difference (TD) and Monte Carlo (MC) are two basic strategies for value learning in Markov decision processes. Each approach offers unique advantages -- TD is believed to enjoy smaller asymptotic variance; while MC yields an unbiased estimator valid for any sample size. In reinforcement learning, a long-standing puzzle is to reconcile the merits of both principles, and develop algorithms with best-of-both-worlds guarantees.

In this talk, I will discuss some recent advances in resolving this puzzle. Focusing on statistical properties with a finite sample size, we develop a new class of algorithms that optimally interpolates between TD and MC, and adapts to the difficulties of problem instances. Among other results, I will highlight the impact of local structures of the Markov chains on the fundamental complexities of estimation.

2 - Settling the Sample Complexity of Online Reinforcement Learning

Zihan Zhang, Princeton University, Princeton, NJ, United States

A central issue lying at the heart of online reinforcement learning (RL) is data efficiency. While a number of recent works achieved asymptotically minimal regret in online RL, the optimality of these results is only guaranteed in a "large-sample" regime, imposing enormous burn-in cost in order for their algorithms to operate optimally. How to achieve minimax-optimal regret without incurring any burn-in cost has been an open problem in RL theory.

We settle this problem for finite-horizon inhomogeneous Markov decision processes.Specifically, we prove that a modified version of MVP (Monotonic Value Propagation), and achieves the minimax lower bound for the entire range of sample size, essentially eliminating any burn-in requirement. It also translates to a full-range minimax-optimal PAC sample complexity up to log factors.

Further, we extend our theory to unveil the influences of problem-dependent quantities like the optimal value/cost and certain variances.

The key technical innovation lies in a novel analysis paradigm to decouple complicated statistical dependency --- a long-standing challenge facing the analysis of online RL in sample-hungry scenarios.

3 - Speeding up Non-Parametric Regression via Distribution Compression

Albert Gong, Cornell University, Ithaca, NY, United States, Kyuseong Choi, Raaz Dwivedi

Modern compression methods have found diverse applications in speeding up integration, non-parametric hypothesis testing, and MCMC simulation. However, it remains unclear how to extend these recent advancements from the unsupervised learning domain to the supervised learning domain. We introduce a meta-algorithm based on Kernel Thinning that covers non-parametric regression problems and applies to general classes of kernel functions. In particular, we investigate two classical algorithms, namely the Nadaraya-Watson (NW) estimator and the Kernel Ridge Regression (KRR) estimator, for which we construct two regression meta-kernels. We show how generalization in each setting reduces to constructing the appropriate kernel and introduce the Kernel-Thinned NW and Kernel-Thinned KRR estimators, which enjoy improved computational efficiency over the vanilla estimators and improved statistical efficiency over i.i.d. subsampling of the training data. We derive excess risk rates for both estimators and validate our design choices with experiments on simulated and real-world data.

4 - Statistical Methods for Transfer Learning: Prediction Under Covariate Shift

Reese Pathak, UC Berkeley, Berkeley, CA, United States

Contemporary predictive settings pose challenges for traditional statistical methodology, partly due to distribution shifts between training and test data. These distributional mismatches are known to cause dramatic reductions in model performance. How can we optimally address these challenging predictive settings? In this talk, we study the fundamental limits of covariate shift: problems where the feature distribution changes between the train and test data. We focus on high-dimensional and nonparametric regression, revealing multiple surprises regarding the success and failures of classical methods. We introduce new measures of "shift" which are adapted to both the geometry induced by the underlying model class as well as the pair of train and test distributions. We complement upper bounds on model performance under covariate shift with lower bounds that showcase the optimality of our methods and demonstrate that our new notions can characterize the difficulty of the covariate shift problem at hand.

Based on joint work with Martin J. Wainwright (MIT), Cong Ma (Univ. of Chicago), and Lin Xiao (Meta).

1 - Model-Free Robust Φ-Divergence Reinforcement Learning Using Both Offline and Online Data

Kishan Panaganti, California Institute of Technology, Pasadena, CA, United States, Adam Wierman, Eric Mazumdar

The robust φ-regularized Markov Decision Process (RRMDP) framework focuses on designing control policies that are robust against parameter uncertainties due to mismatches between the simulator (nominal) model and real-world settings. This work makes *two* important contributions. First, we propose a *model-free* algorithm called *Robust φ-regularized fitted Q-iteration* (RPQ) for learning an ε-optimal robust policy that uses only the historical data collected by rolling out a behavior policy (with *robust exploratory* requirement) on the nominal model. To the best of our knowledge, we provide the *first* unified analysis for a class of φ-divergences achieving robust optimal policies in high-dimensional systems with general function approximation. Second, we introduce the *hybrid robust φ-regularized reinforcement learning* framework to learn an optimal robust policy using both historical data and online sampling. Towards this framework, we propose a model-free algorithm called *Hybrid robust Total-variation-regularized Q-iteration* (HyTQ: pronounced *height-Q*). To the best of our knowledge, we provide the *first* improved out-of-data-distribution assumption in large-scale problems with general function approximation under the hybrid robust φ-regularized reinforcement learning framework. Finally, we provide theoretical guarantees on the performance of the learned policies of our algorithms on systems with arbitrary large state space.

2 - Minimax Optimal and Computationally Efficient Algorithms for Distributionally Robust Offline Reinforcement Learning

Pan Xu, Duke University, Durham, NC, United States

Distributionally robust offline reinforcement learning (RL), which seeks robust policy training against environment perturbation by modeling dynamics uncertainty, calls for function approximations when facing large state-action spaces. However, the consideration of dynamics uncertainty introduces essential nonlinearity and computational burden, posing unique challenges for analyzing and practically employing function approximation. Focusing on a basic setting where the nominal model and perturbed models are linearly parameterized, we propose minimax optimal and computationally efficient algorithms realizing function approximation and initiate the study on instance-dependent suboptimality analysis in the context of robust offline RL. Our results uncover that function approximation in robust offline RL is essentially distinct from and probably harder than that in standard offline RL. Our algorithms and theoretical results crucially depend on a variety of new techniques, involving a novel function approximation mechanism incorporating variance information, a new procedure of suboptimality and estimation uncertainty decomposition, a quantification of the robust value function shrinkage, and a meticulously designed family of hard instances, which might be of independent interest.

3 - Wasserstein Distributionally Robust Policy Learning with Continuous Context

Wenhao Yang, Stanford University, Stanford, CA, United States, Miao Lu, Zhengyuan Zhou

In the offline contextual bandit problem, the optimal policy derived from an offline dataset often proves to be sensitive to changes in the environment. To handle this challenge, distributionally robust optimization (DRO) techniques are introduced to policy learning to enhance the robustness of the learned policy. However, most existing results only study the case when the context space is discrete. In this paper, we investigate the Wasserstein distributionally robust policy learning problem when the context space is continuous. We first propose a theoretical algorithm to solve this problem using the Nadaraya–Watson estimator in non-parametric statistics, and we establish both non-asymptotic and asymptotic theory to show the effectiveness of the method. To our best knowledge, this study gives the first theoretical result for Wasserstein distributionally robust policy learning problem with continuous context. Furthermore, we develop a practical algorithm to tackle the computational challenges to implement our theoretical algorithm. We evaluate its performance in the application of a contextual newsvendor problem.

4 - Sample-Efficient Robust Multi-Agent Reinforcement Learning in the Face of Environmental Uncertainty

Laixi Shi, California Institute of Technology (Caltech), Pasadena, CA, United States

To overcome the sim-to-real gap in reinforcement learning (RL), learned policies must maintain robustness against environmental uncertainties. While robust RL has been widely studied in single-agent regimes, in multi-agent environments, the problem remains understudied—despite the fact that the problems posed by environmental uncertainties are often exacerbated by strategic interactions. This work focuses on learning in distributionally robust Markov games (RMGs), a robust variant of standard Markov games, wherein each agent aims to learn a policy that maximizes its own worst-case performance when the deployed environment deviates within its own prescribed uncertainty set. This results in a set of robust equilibrium strategies for all agents that align with classic notions of game-theoretic equilibria. Assuming a non-adaptive sampling mechanism from a generative model, we propose a sample-efficient model-based algorithm (DR-NVI) with finite-sample complexity guarantees for learning robust variants of various notions of game-theoretic equilibria. We also establish an information-theoretic lower bound for solving RMGs, which confirms the near-optimal sample complexity of DR-NVI with respect to problem- dependent factors such as the size of the state space, the target accuracy, and the horizon length.

Recent Advances in Stochastic Simulation

Invited Session

Simulation Society

Chair: Dohyun Ahn, CUHK, Shatin, Hong Kong

1 - Gradient Estimation of Stationary Mean and Average Reward Reinforcement Learning

Jeffrey Wang, Northwestern University, Chicago, IL, United States, Chang-Han Rhee

First part of our work focuses on developing unbiased and efficient estimators for the gradient of steady-state mean of a parametrized Markov chain. Then we extend our results to the sequential optimization setting, specifically, reinforcement learning (RL) with long-run average reward objective. Previously developed trust region based RL methods have shown great performance for the discounted reward setting RL problems but naive implementation of those methods in the average reward setting often fails due to instability caused by the lacking of a discounting factor. We extend our results in the stationary mean gradient estimation section to this setting and develop a multi-level average reward trust region based RL algorithm that is more efficient and more importantly, more stable.

2 - Locally Robust EstimatiOn for Mitigating Input Uncertainty in Minimization of Tail Risks

Anand Deo, Indian Institute of Management Bangalore, Bangalore, India, Karthyek Murthy, Arjun Ramachandra

The ability to learn and control tail risks, besides being an integral part of quantitative risk management, is central to running operations requiring high service levels and cyber-physical systems with high-reliability specifications. Due to the paucity of relevant samples in the tail regions, formulations involving tail risks are almost always approached with the "estimate, then optimize" workflow involving a model estimation from data in the first step before plugging in the trained model to solve various downstream decision-making tasks via simulation. As biases due to model selection, misspecification, and overfitting to in-sample data are difficult to avoid in the first-step estimation, we construct novel locally robust estimators in which the input uncertainty due to the first-step estimation has no effect, locally, on the decisions obtained via downstream simulation. We show that this *local insensitivity* translates to improved out-of-sample performance freed from the first-order impact of input model uncertainty introduced in the first-step estimation.

A key ingredient in achieving this local robustness is a novel debiasing procedure that adds a non-parametric bias correction term to the objective. The debiased formulation retains convexity, and the imputation of the correction term relies only on a non-restrictive large deviations behavior conducive for transferring knowledge from representative data-rich regions to the data-scarce tail regions. The bias correction gets determined by the extent of model error in the estimation step and the specifics of the decision-making task in the optimization step, thereby serving as a scalable "smart-correction" step bridging the disparate goals in estimation and optimization.

3 - Generalized Importance Sampling for Nested Simulation

Mingbin Feng, University of Waterloo, Waterloo, ON, Canada, Amber (Qingyuan) Chen

Importance sampling (IS) is a classical variance reduction technique. Under mild conditions, an IS estimator is unbiased, so one often seeks variance-minimizing optimal sampling distribution. IS has remarkable success in many applications such as engineering, operations research, and finance. In some applications such as enterprise risk management and input uncertainty quantification, complex simulation designs such as nested simulation arises naturally: The outer-level simulation generates a set of risk factors, i.e., the scenarios, which are used as inputs for inner-level simulations. Nested simulation leads to wasteful use of computations as inner simulation outputs in each scenario are isolated from other scenarios. In this study, we propose, analyze, and test a generalized importance sampling technique for nested simulation. Our generalized IS approach reuses one set of inner simulation outputs across different outer scenarios. Numerical experiments show that our proposal is orders of magnitudes more efficient than the standard procedure.

4 - Data-Driven Sequential Sampling for Tail Risk Mitigation

Dohyun Ahn, The Chinese University of Hong Kong, Shatin, Hong Kong, Taeho Kim

Given a collection of stochastic alternatives, we study the problem of sequentially allocating a fixed sampling budget to identify the optimal alternative with a high probability, where the optimal alternative is defined as the one with the smallest value of extreme tail risk. We particularly consider a situation where these alternatives generate heavy-tailed losses whose probability distributions are unknown and may not admit any specific parametric representation. In this setup, we propose a data-driven sequential allocation rule that maximizes the rate at which the likelihood of falsely selecting suboptimal alternatives decays to zero. We rigorously demonstrate the superiority of the proposed method over existing approaches, which is further validated via numerical studies.

5 - Queuing Systems Control via Reinforcement Learning

Gabriel Nicolosi, Missouri University of Science and Technology, Rolla, MO, United States

With the proliferation of machine learning models into every area of operations research and the management sciences, the problem of stochastic queuing systems control is being reconsidered from the perspective of reinforcement learning. Industrial, economic and human-centered systems of current practical interest have gained such an intricate complexity that the established tools provided by the classical apparatus of dynamic programming are no longer suitable for their optimization and control, both from modeling and computational perspectives. Moreover, many of these systems are becoming cyber-physical, designed alongside their so-called digital twins. This new digital paradigm allows for a feedback loop between the physical system and its digital counterpart, wherein simulation-based techniques, such as reinforcement learning, gain an important role. This approach might prove beneficial in the optimization and control of world-critical systems where congestion appears, such as semiconductor manufacturing, traffic control in smart cities and healthcare supply chains. In this presentation, the reinforcement learning-based control of a M/G/k queuing system under server breakdowns is considered. A concise overview of the field will be presented. Modeling, algorithmic and implementation aspects will be discussed, followed by current computational results.

Surgical scheduling via optimization and machine learning with long-tailed data. https://link.springer.com/article/10.1007/s10729-023-09649-0 Using data from cardiovascular surgery patients with long and highly variable post-surgical lengths of stay (LOS), we develop a modeling framework to reduce recovery unit congestion. We estimate the LOS and its probability distribution using machine learning models, schedule procedures on a rolling basis using a variety of optimization models, and estimate performance with simulation. The machine learning models achieved only modest LOS prediction accuracy, despite access to a very rich set of patient characteristics. Compared to the current paper-based system used in the hospital, most optimization models failed to reduce congestion without increasing wait times for surgery. A conservative stochastic optimization with sufficient sampling to capture the long tail of the LOS distribution outperformed the current manual process and other stochastic and robust optimization approaches. These results highlight the perils of using oversimplified distributional models of LOS for scheduling procedures and the importance of using optimization methods well-suited to dealing with long-tailed behavior.

Who should see the patient? on deviations from preferred patient-provider assignments in hospitals. https://link.springer.com/article/10.1007/s10729-022-09628-x In various organizations including hospitals, individuals are not forced to follow specific assignments, and thus, deviations from preferred task assignments are common. This is due to the conventional wisdom that professionals should be given the flexibility to deviate from preferred assignments as needed. It is unclear, however, whether and when this conventional wisdom is true. We use evidence on the assignments of generalist and specialists to patients in our partner hospital (a children's hospital), and generate insights into whether and when hospital administrators should disallow such flexibility. We do so by identifying 73 top medical diagnoses and using detailed patient-level electronic medical record (EMR) data of more than 4,700 hospitalizations. In parallel, we conduct a survey of medical experts and utilized it to identify the preferred provider type that should have been assigned to each patient. Using these two sources of data, we examine the consequence of deviations from preferred provider assignments on three sets of performance measures: operational efficiency (measured by length of stay), quality of care (measured by 30-day readmissions and adverse events), and cost (measured by total charges). We find that deviating from preferred assignments is beneficial for task types (patients' diagnosis in our setting) that are either (a) well-defined (improving operational efficiency and costs), or (b) require high contact (improving costs and adverse events, though at the expense of lower operational efficiency). For other task types (e.g., highly complex or resource-intensive tasks), we observe that deviations are either detrimental or yield no tangible benefits, and thus, hospitals should try to eliminate them (e.g., by developing and enforcing assignment guidelines). To understand the causal mechanism behind our results, we make use of mediation analysis and find that utilizing advanced imaging (e.g., MRIs, CT scans, or nuclear radiology) plays an important role in how deviations impact performance outcomes. Our findings also provide evidence for a "no free lunch" theorem: while for some task types, deviations are beneficial for certain performance outcomes, they can simultaneously degrade performance in terms of other dimensions. To provide clear recommendations for hospital administrators, we also consider counterfactual scenarios corresponding to imposing the preferred assignments fully or partially, and perform cost-effectiveness analyses. Our results indicate that enforcing the preferred assignments either for all tasks or only for resource-intensive tasks is cost-effective, with the latter being the superior policy. Finally, by comparing deviations during weekdays and weekends, early shifts and late shifts, and high congestion and low congestion periods, our results shed light on some environmental conditions under which deviations occur more in practice.

Covid-19 triage in the emergency department 2.0: how analytics and AI transform a human-made algorithm for the prediction of clinical pathways. The Covid-19 pandemic has pushed many hospitals to their capacity limits. Therefore, a triage of patients has been discussed controversially primarily through an ethical perspective. The term triage contains many aspects such as urgency of treatment, severity of the disease and pre-existing conditions, access to critical care, or the classification of patients regarding subsequent clinical pathways starting from the emergency department. The determination of the pathways is important not only for patient care, but also for capacity planning in hospitals. We examine the performance of a human-made triage algorithm for clinical pathways which is considered a guideline for emergency departments in Germany based on a large multicenter dataset with over 4,000 European Covid-19 patients from the LEOSS registry. We find an accuracy of 28 percent and approximately 15 percent sensitivity for the ward class. The results serve as a benchmark for our extensions including an additional category of palliative care as a new label, analytics, AI, XAI, and interactive techniques. We find significant potential of analytics and AI in Covid-19 triage regarding accuracy, sensitivity, and other performance metrics whilst our interactive human-AI algorithm shows superior performance with approximately 73 percent accuracy and up to 76 percent sensitivity. The results are independent of the data preparation process regarding the imputation of missing values or grouping of comorbidities. In addition, we find that the consideration of an additional label palliative care does not improve the results.

5 - Panelist

Daniel Otero Leon, Harvard Medical School, Boston, MA, United States

Monitoring policy in the context of preventive treatment of cardiovascular disease. https://link.springer.com/article/10.1007/s10729-022-09621-4 Preventing chronic diseases is an essential aspect of medical care. To prevent chronic diseases, physicians focus on monitoring their risk factors and prescribing the necessary medication. The optimal monitoring policy depends on the patient's risk factors and demographics. Monitoring too frequently may be unnecessary and costly; on the other hand, monitoring the patient infrequently means the patient may forgo needed treatment and experience adverse events related to the disease. We propose a finite horizon and finite-state Markov decision process to define monitoring policies. To build our Markov decision process, we estimate stochastic models based on longitudinal observational data from electronic health records for a large cohort of patients seen in the national U.S. Veterans Affairs health system. We use our model to study policies for whether or when to assess the need for cholesterol-lowering medications. We further use our model to investigate the role of gender and race on optimal monitoring policies.

6 - Panelist

Dmitry Krass, Rotman School of Management, University of Toronto, Toronto, ON, Canada

Machine learning for optimal test admission in the presence of resource constraints. https://link.springer.com/article/10.1007/s10729-022-09624-1 Developing rapid tools for early detection of viral infection is crucial for pandemic containment. This is particularly crucial when testing resources are constrained and/or there are significant delays until the test results are available – as was quite common in the early days of Covid-19 pandemic. We show how predictive analytics methods using machine learning algorithms can be combined with optimal pre-test screening mechanisms, greatly increasing test efficiency (i.e., rate of true positives identified per test), as well as to allow doctors to initiate treatment before the test results are available. Our optimal test admission policies account for imperfect accuracy of both the medical test and the model prediction mechanism. We derive the accuracy required for the optimized admission policies to be effective. We also show how our policies can be extended to re-testing high-risk patients, as well as combined with pool testing approaches. We illustrate our techniques by applying them to a large data reported by the Israeli Ministry of Health for RT-PCR tests from March to September 2020. Our results demonstrate that in the context of the Covid-19 pandemic a pre-test probability screening tool with conventional RT-PCR testing could have potentially increased efficiency by several times, compared to random admission control.

1 - Bi-Level Optimization in a Collaborative Supply Chain: Production and Procurement Planning Based on Suppliers' Production Decisions

Ya Zhou, Hefei University of Technology, Hefei, China, People's Republic of, Jun Pei

To leverage the tremendous value of supply chain collaboration, manufacturers embrace suppliers as partners with whom to undertake collaborative supply chain planning that considers suppliers' profits and decisions. This study formulates the collaborative supply chain planning problem as a bi-level optimization problem. At the upper level, the manufacturer makes the parts procurement and products production planning with the aim of minimizing the total costs by anticipating suppliers' responses to parts procurement orders. At the lower level, the suppliers make their respective part production planning, including decisions on order acceptance, production line opening, and assignment of the accepted parts. Considering the mutual interactions between the decisions at the two levels, we develop a sequential reduction algorithm to implement the nested decomposition of the studied bi-level problem. Under the proposed reduction algorithm framework, the lower-level problem is first solved by an improved branch-and-bound-based (B&B-based) reduction algorithm with the double pruning operations and enhanced mathematical model. Then, the bi-level problem is reduced through nesting the optimal solutions for lower-level problems into the overall solution, i.e., hierarchical fusion reduction. Finally, a novel variable neighborhood search-based (VNS-based) reduction algorithm is utilized to get near-optimal solutions for the reduced bi-level problem. Computational experiments are conducted to verify the performance of the sequential reduction algorithm framework. Moreover, based on the experiment results, this study provides insightful observations on sourcing diversification and decision preferences of large manufacturing enterprises.

2 - Task Flexibility in Gig Platforms

Zhi Cao, Sichuan University, Chengdu, China, People's Republic of, Meng Li, Shujing Sun

Flexibility is a hallmark of gig-economy platforms, yet how it influences gig workers' behaviors remains underexplored, especially in the healthcare industry. Leveraging a quasi-natural experiment on a gig healthcare platform, this paper investigates the impact of task flexibility on individuals' behaviors and platform sustainability. Using the different-in-differences design, we find that the decline in task flexibility significantly decreases individuals' willingness to engage in tasks and efforts in service delivery. We further uncover the underlying mechanism through an experiment. The results show that the negative effects are attributable to changes in individuals ' psychological perceptions, particularly feelings of unfairness, disrespect, and low economic expectations stemming from the reduced task flexibility. Our findings provide novel insights into the flexibility design for gig platforms.

3 - Managing Cybersecurity: Data Access & Protection

Oleh Stupak, University of Cambridge, Cambridge, United Kingdom, George Charlson, Ruslan Momot, Marat Salikhov

A standard data access guideline is to limit employee access to only the essential data for their roles, raising the question of how to define these roles and the employees' corresponding data needs. We aim to address this question by considering a game-theoretic model of joint cybersecurity and operational decision-making. The firm chooses the level of data access for each of its employees and the overall level of cyber protection. Providing more data access to employees makes the firm more economically efficient but also more vulnerable to attacks by an adversary who steals the employees' data, inflicting damage that increases with the amount of data stolen. Adversaries may vary in their attack strength and sophistication rate (the ability to pinpoint the most attractive targets). We find that the firm may counter-intuitively decrease its overall protection level when adversarial attacks become stronger and increase its overall access level when the adversaries become more sophisticated.

1 - Revenue Sharing with Swap: Application in Digital Product Development

Xuying Zhao, Texas A&M University, College Station, TX, United States, Leon xu, Jingmiao Song

In the context of digital product development, where developers contribute creative content and publishers provide funding and marketing support, traditional revenue-sharing contracts often raise fairness concerns. This is because the dominating party usually claims a larger share of the revenue, thus discouraging the other party from exerting its best effort. To address this concern, the video game industry has introduced an innovative revenue-sharing contract with swap: the favored party will be swapped (sometimes with a different revenue-split ratio) once the publisher recovers its investment. However, it remains unclear whether such a swap contract will be mutually beneficial. Therefore, we investigate a Stackelberg game between the developer and publisher, examining three types of revenue-sharing contracts: no-swap, swap, and reciprocal swap (where the favored parties are swapped but the revenue-split ratio remains unchanged). Compared to the no-swap contract, we find that the swap contract incentivizes the publisher's investment and the developer's effort more effectively. However, the publisher may use the swap contract's inherent flexibility to its advantage, benefiting unilaterally from the contract. Only when development requires significant funding does the swap contract benefit both parties mutually. Interestingly, the reciprocal swap contract not only upholds intrinsic fairness merit but also achieves most of the optimal supply chain profit, thereby better coordinating the supply chain than both the swap and no-swap contracts. Our study provides valuable insights for developers negotiating contracts with publishers and sheds light on revenue-sharing contracts when contributions from different parties are complementary.

2 - Managing Trade-Offs Between Revenue, Access and Market Balance on Online Dating Platforms

Qiqi Hao, University of Pittsburgh, Pittsburgh, PA, United States, Titing Cui, Michael Hamilton

Online dating platforms, like many other online platforms, generate revenue by charging users for enhanced services. However, unlike other online services, for dating platforms to function properly they must maintain a large pool of users and, for heterosexual dating, maintain approximate parity between the number of male and female users. If the platform fails to maintain a large candidate pool or balance the two sides of their market, the number of matches made on the platform can plummet and the platform's value proposition can collapse. The primary lever under a platform's control to achieve these goals is segmented pricing, which, in practice, leverages a combination of geographic and demographic features to set semi-personalized prices for subsets of users.

In this study, we explore the trade-offs between revenue, access, and market balance for dating apps through the lens of segmented pricing. We present a novel model that formalizes the dating platform's problem as a non-convex mathematical program whose objective is a linear combination of the three market outcomes. Under natural assumptions we show how to solve this optimization problem and examine the resulting market outcomes. As an application of our framework, we use our model and solution to investigate regulatory calls for enforcing price and access fairness on dating platforms. We encode these proposed regulations as constraints on the platforms pricing problem and explore the potential pros and cons associated with the new outcomes they induce.

3 - The Economics of AI Foundation Models: Openness, Competition, and Governance

Fasheng Xu, University of Connecticut, Stamford, CT, United States, Wei Chen, Xiaoyu Wang, Karen Xie

AI is undergoing a paradigm shift with the rise of foundation models (e.g., GPT-4, Claude 3, Gemini, Llama 2, Stable Diffusion) trained on broad data using self-supervision at immense scale, which can then be adapted to myriad downstream tasks. This paper offers an economic theory of foundation model ecosystems that consist of upstream model developers and downstream model deployers. We model how fine-tuning games arise as downstream deployers competing in foundation model adoption and fine-tuning effort, and how foundation model openness affects the fine-tuning games. Our theory provides insights into the economic implications and trade-offs for multiple stakeholders throughout the AI value chain (including developer, deployers, and consumers) and sheds light on how to harness the full potential of the foundation model value chain interactions and avoid pitfalls. An important implication of our findings is that the policymakers should explicitly consider potential unintended economic consequences of AI regulation on the ecosystem around open foundation models, in particular, the so-called ``openness trap'' (i.e., a range of medium openness levels that should be avoided). Furthermore, we explore the welfare implications of prevalent market strategies employed by upstream developers, such as vertical integration and offering free trials. Our findings reveal that vertical integration proves effective when model openness is relatively limited. The developer's strategy of providing free trials can negatively affect the leading deployer within a moderate range of model openness, while benefiting all other stakeholders.

4 - Genai Assistance in a Professional Service Market: the Perish of Second Opinion

Rachel Chen, University of California-Davis, Davis, CA, United States, Jane Gu, Yi Liu

We investigate the impact of generative AI (GenAI) adoption in a market of professional services such as medical treatment and financial consulting, where the product is a professional opinion. Considering a vertically differentiated market of professional services where a high-expertise provider and two low-expertise providers serve consumers with heterogeneous quality preferences, our study reveals important strategic implications of AI adoption. First, we show that after service providers adopt AI assistance, the high-expertise provider may enhance profit, despite quality improvement occurring to its low-expertise rivals but not to itself. In contrast, the low-expertise providers always suffer a severe drop in margins, although their total payoffs may increase under a sufficiently large benefit in corporate image associated with AI adoption. Two interesting regions arise: a ``lose-lose'' region, where AI adoption harms all service providers, and a ``win-lose'' region, where the high-expertise provider is better off but neither of the low-expertise providers. Second, we show that after providers' AI adoption, low-type consumers always enjoy a surplus gain but high-type consumers may suffer a surplus loss. Total consumer surplus declines if low-expertise providers are highly differentiated in opinions before AI adoption. Lastly, when the two low-expertise providers make endogenous decisions regarding whether to adopt AI assistance, equilibrium may arise where neither of them adopt AI assistance or only one adopts.

Public Health Decision-Making for Infectious Diseases

Invited Session

MSOM: Healthcare

Chair: Sarang Deo, Indian School of Business, Hyderabad, India

Co-Chair: Pankaj Jindal, Indian School of Business (ISB), N/A

1 - Improving Decision-Making in Public Health Surveillance of Epidemics with Evolving Pathogens

Pankaj Jindal, Indian School of Business, Hyderabad, India, Sarang Deo, Sripad Devalkar

A key challenge to effective management of epidemics is rapid detection of novel variants which allows for implementing appropriate public health interventions. However, as demonstrated during the COVID-19 pandemic, capacity of the genomic sequencing-based surveillance systems, used for detecting novel variants, is often limited (particularly in LMICs) leading to delayed detection of the novel variants. It is thus crucial to study the impact of the design of genomic surveillance systems on the delay in detection of novel variants and effectiveness of public health interventions.

In this paper, we develop an analytical model, complemented by extensive numerical analysis, to obtain insights regarding the impact of operational characteristics such as sampling proportion and sequencing capacity on the delay in detection. We find that sequencing a higher proportion of diagnosed samples is not always optimal. This is because a higher sampling proportion can delay detection due to longer wait times at the sequencing lab due to congestion, even though it increases the probability of selecting a sample infected with the novel variant for sequencing. We also characterize the behavior of the optimal sampling proportion with other system parameters. We find that the optimal sampling proportion increases with increase in cost of non-detection and sequencing capacity and decreases with increase in holding cost and diagnosis rate.

Our results have practical implications in public health decision making for effective management of evolving epidemics and can lead to more efficient provision and utilization of genomic sequencing capacity and public health interventions.

2 - Using Simulation Modeling to Inform Strategies for the Eradication of Guinea Worm Disease

Hannah Smalley, ISyE Georgia Tech, Atlanta, GA, United States, Pinar Keskinocak, Maryann Delea, Obiora Eneanya, Adam Weiss

In 1986, there were an estimated 3.5 million human cases of Guinea worm disease (GWD) around the world. Since then, GWD has been eliminated in 17 countries, with only 14 human cases globally in 2023. However, in the same year, 407 dog infections were reported across 277 villages in Chad. Because Guinea worm (GW) can be transmitted through shared water sources, the human population remains at risk. Current interventions include tethering dogs with emerging worms and water treatment to reduce the number of infective copepods in water sources. Proactive tethering of dogs is employed to minimize exposure of dogs to potentially infected water sources, but household adherence to tethering guidelines is not always uniform or ideal, with some dogs tethered only intermittently or released at night. Tests to diagnose GW infection in dogs before signs of infection are under development. We built an agent-based simulation which models the transmission of GW among dogs in Chad to analyze intervention strategies. We find that tethering and water treatment levels need to increase to achieve GW elimination in Chad. Releasing dogs from proactive tethering for part of the day results in up to 60 times more infections after five years compared to full day tethering. A diagnostic test for prepatent infection could be helpful and support elimination efforts by decreasing time to elimination to as little as 2 years, but achieving this result relies on the implementation strategy and education as 2-year elimination requires high long-term tethering adherence following a positive test result.

3 - Pooled Testing in the Presence of Congestion

Oualid Jouini, CentraleSupelec, Gif-sur-Yvette, France, Saif Benjaafar, Benjamin Legros, Bingnan Lu

Pooled testing for infectious diseases has a rich history. However, the focus of much of the academic literature has been on maximizing testing throughput. While this approach maximizes the efficiency of the testing facility, it may not minimize the delay in obtaining test results. In this study, we provide a procedure, based on a queueing model, for choosing sample batch sizes that minimize expected delay. We show that not doing so, and relying on throughput maximization, may lead to excessive delays.

4 - Push OR Pull? -- when and How to Fund Drug Development

Peng Sun, Duke University, Durham, NC, United States, Chenxi Xu, David Ridley

Rare disease drugs often do not generate sufficient profit from the market to cover the development costs. In this case, pharmaceutical firms do not have the incentive to develop these drugs, unless receiving investments from external funding agencies. However, pharmaceutical firms often possesses much more information about the potential drug and the development processes, causing adverse selection and moral hazard issues. In order to use their resources efficiently, a funding agency needs to decide when and how to fund a pharmaceutical firm and manage the aforementioned incentive issues. For example, investing early (push) may save money, but does not offer accountability compared with paying after resolving development uncertainties (pull). We formulate the funding agency's problem as a mechanism design model, and theoretically study optimal mechanisms under different settings. An interesting finding is that it is sometimes optimal for the funding agency to reward failure.

Financing Operations

Invited Session

MSOM: iForm

Chair: Jiri Chod, Boston College, Chestnut Hill, MA, United States

1 - On the Benefits of Supplier Vs Customer Diversification: a Geographical Analysis

Deepak Agrawal, Emory University, Atlanta, GA, United States, Nikolay Osadchiy

Diversification is traditionally thought to be a risk mitigation tool. However, in our paper, we show that diversification also have first order effect on inventory productivity. We find a nonlinear relationship between geographical diversification and inventory turnover. Further, we examine the varying effects of supplier vs customer diversification by firm's upstreamness, competitive environment, and innovation.

2 - On the Interplay of Production Flexibility and Financing Strategy

Guoming Lai, The University of Texas at Austin, Austin, TX, United States, Peter Ritchken, Qi Wu

In this paper, we explore how the improved production flexibility impacts joint operating policies and financing decisions. We develop a dynamic model, in which the equity holders of the firm make the decisions of pausing and restarting of production, and the degree of flexibility is reflected by the switching cost. We find that the optimal operating policy is jointly determined with the financing choice. Debt levels, not only impact tax shields and bankruptcy costs but also the utilization of production flexibility. Debt induces risk shifting which undermines equity holders' incentive to use flexibility. We further uncover a non-monotone relationship between production flexibility and financial leverage. When the switching cost is low, production flexibility complements the benefits of debt and thus financial leverage increases in production flexibility. As the switching cost increases into an intermediate region, the firm aggressively reduces its debt to ensure the continued usage of flexibility. However, when the switching cost exceeds a threshold, the cost of reducing leverage to maintain production flexibility becomes too high, and the firm forgoes flexibility and establishes high financial leverage.

3 - Risk Mitigation Role of Trade Credit for a Dual-Channel Supplier: Theory and Evidence

Jie Ning, Case Western Reserve University, Cleveland, OH, United States, Sammi Tang, Jing Wu, Jiaqi Zhu

Trade credit is commonly perceived to exacerbate supplier risk, as delayed payments expose the supplier to buyer's uncertainties. In contrast, cash on delivery (COD) is viewed safe, as it insulates the supplier from downstream risk. Using a stylized game theoretic model, we show that this conventional wisdom may be overturned for a dual-channel supplier who operates a direct channel that sells to customers, in addition to an indirect channel that sells to a buyer who then sells to customers. When the supplier and buyer's direct sales are *negatively correlated* due to their market competition or channel risks, trade credit yields two negatively correlated payment streams for the supplier, which enables risk pooling and can yield *lower* supplier risk than COD. Interestingly, the buyer also benefits and earns higher expected payoff than under COD, as the supplier lowers the wholesale price to achieve a more "balanced" portfolio to enhance pooling. We empirically validate the risk mitigation effect of trade credit using data on manufacturing firms that sell to their competitors. We show that a supplier's short-term leverage and stock price volatility *decrease* with its accounts receivable after selling to competitors, while being invariable in accounts receivable before such transactions. These effects are concentrated on suppliers that have negatively correlated sales or high competition intensity with their buyers.

4 - Interaction of Operations Decision and Financial Derivatives: An Empirical Perspective

Gangshu Cai, Santa Clara University, Santa Clara, CA, United States, Wubo Zhang, QI ZHANG

This study aims to contribute to the underexplored area of how derivatives markets can bolster economic entities and supply chain growth. Using a sample of 289 chemical sector companies, this research employs empirical analysis with fixed effects and unsupervised machine learning to investigate firm motivations for adopting financial derivatives hedging from 2016 to 2022. Our findings reveal that operational metrics, notably inventory and turnover rates, play a significant role in influencing a company's hedging activities.

5 - Inventory, Renegotiation, and Trade Credit

Jiri Chod, Boston College, Chestnut Hill, MA, United States, Evgeny Lyandres

We study contract renegotiation between a seller and a financially constrained buyer. We compare efficiency of renegotiation and the initial trade agreement under bank financing and under trade credit financing. Our model uncovers a novel benefit of trade credit, which is the elimination of agency frictions during the bargaining process. The model also shows how this benefit depends on bargaining power distribution, level of uncertainty, and cost and revenue parameters of the good that is being traded.

1 - Blood-Donation-Inspired Aggregator Business Model for Vehicle-to-grid Services

Yangfang (Helen) Zhou, Lee Kong Chian School of Business, Singapore Management University, Singapore, Singapore, Meichun Lin, Owen Wu, John Pang

We propose a novel business model to promote individual electric vehicle (EV) owners to adopt vehicle-to-grid (V2G), where electricity flows from EVs to the electric grid. The most critical concern hindering adoption is the potential degradation of the vehicle battery due to increased discharging, leading manufacturers to invalidate the battery warranty. To address this concern, we propose in our business model that each EV owner performs V2G services *a few times a year* during peak electricity demand. This model draws inspiration from blood donation practice: Paralleling blood donors contributing twice annually without compromising health, performing V2G services a limited number of times (e.g., five) ensures negligible battery degradation, alleviating concerns over the battery life expectancy for both EV owners and manufacturers. Under this business model, an aggregator enrols individual EV owners and coordinates them to transact collectively with the grid operator. Diverging from blood donation, the aggregator compensates EV owners for their V2G service.

We examine how to design such compensation schemes for both a non-profit aggregator and for-profit aggregator. We model the sequential game between the aggregator and the pool of EV drivers using a two-stage model: In the first stage, the aggregator offers a menu of compensation for each number of V2G service calls; in the second stage, given the chosen number of service calls of each EV driver, the aggregator solves a stochastic dynamic program to determine the number of drivers to call in the event of peak electricity demand.

2 - From Curtailed Renewable Energy to Green Hydrogen: Infrastructure Planning for Hydrogen Fuel-Cell Vehicles

Long He, George Washington University, Washington, DC, United States, Nan Ke, Ruijiu Mao, Wei Qi, Hongcai Zhang

Hydrogen fuel-cell vehicles (HFVs) offer a promising solution for green transportation, particularly in regions with renewable energy curtailment. This paper examines the challenges of promoting HFVs, including uncertain adoption rates, lack of infrastructure, and spatial mismatches between hydrogen demand and renewable sources. A planning model is developed to determine the location and capacities of hydrogen refueling stations (HRSs) and plants, as well as grid upgrades. Despite complexities like driver behavior, the model is tractable and applied to Sichuan, China, known for abundant hydro resources and curtailed hydropower. Key findings include: (i) Optimal HRS deployment varies with HFV adoption targets, with larger cities emerging as adoption centers at higher targets; (ii) HFV adoption can reduce hydropower curtailment, contingent on factors like adoption goals and grid upgrade costs; (iii) Hydrogen's transportability allows strategic HRS placement apart from plant sites, enhancing cost savings and curtailment reduction compared to electric vehicles.

3 - Conditional Quadratic Hedging of Term Structure Risk in Merchant Energy Trading Operations

Nicola Secomandi, Rice University, Houston, TX, United States, Bo Yang

We apply conditional quadratic hedging to the management of term structure risk in merchant energy trading operations. We develop a model with pooled cash flows across dates and establish the structure of its optimal policy, which we use to propose a computational efficient heuristic with theoretical appeal. This method performs near optimally in a realistic numerical study in the context of long duration merchant energy storage. Our approach has potential relevance to manage market price risk embedded in energy transition projects.

4 - Optimal Mechanisms for Demand Response in Energy Systems: A Mean-Field Approach

Mohammad Mehrabi, Stanford University, Stanford, CA, United States

The increased use of renewable energy resources has led to interest in demand response programs that can shift consumer demand to better match renewable production. We find that, in large systems and under mean-field asymptotics, pricing-based mechanisms can match the demand-response benefits achievable through direct optimization methods that use detailed knowledge of consumer preferences. In addition, we show that optimal prices can be efficiently learned using a simple first-order algorithm that only requires access to market-level metrics.

5 - Optimal Batch Scheduling for Power Grid Interconnection Queues

Omer Karaduman, Stanford University, Stanford, CA, United States, Yue Hu, Lin Zang

We model the interconnection process of connecting electricity generators to the U.S. power grid as a multi-stage queueing system. Developers submit their project proposals to the queue and undergo a multi-stage evaluation process. For this queueing system, we investigate various control levers related to capacity allocation and evaluation strategies from the perspective of the system manager. The goal is to optimize queueing-related performance metrics, such as reducing waiting times and improving system throughput.

1 - Analytics for Supply Chain Resilience Strategies Using 3D-Printing Backup

Ziyu He, University of Southern California, Los Angeles, CA, United States, Vishal Gupta, Chamsi Hssaine, Nick Vyas

Conventionally, 3D printing (3DP) has been widely perceived as only adequate for limited roles in large supply chain systems, such as prototyping and producing spare parts, due to its lack of economies of scale. In this paper, we aim to expand the scope of 3DP applications by exploring its potential as a supply chain resilience strategy. Specifically, we examine a multi-product inventory system where 3DP backup is complemented by expedition services from traditional manufacturers (TM) to mitigate the risk of supplier disruptions. Here, 3DP is modeled as a flexible resource whose adoption cost does not scale with the number of protected products, albeit with a limited total recoverable capacity compared to TM expedition. To quantify the value of 3DP backup in enhancing the resilience of this system, we provide computational tools and insights on how to optimally build a backup strategy based on 3DP. This includes devising algorithms to compute optimal decisions such as which products should be protected by either backup sources and how to allocate the appropriate 3DP capacity to invest in. These numerical tools are further complemented by easy-to-implement heuristics that provide more interpretable insights into the drivers of backup policies and 3DP investments, such as marginal disruption probability and disruption correlations among suppliers.

2 - Inventory Commingling on An E-Commerce Platform

Hanqi Wen, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, Izak Duenyas, Joline Uichanco

Amazon is an e-commerce marketplace that also provides fulfillment services for its third-party sellers. A recent strategy of Amazon is to commingle inventory, referring to pooling a third-party seller's inventory with the inventory of other sellers at its fulfillment centers. Inventory commingling benefits the platform by reducing fulfillment costs, as the commingled inventory are interchangeable regardless of which seller makes the sale. For sellers, commingling inventory can reduce the cost it would otherwise incur of labeling its inventory with a seller-specific sticker. However, the seller faces the risk that the product sold under her name may be a counterfeit/defective product provided by another seller. In this talk, we study the marketplace dynamics of inventory commingling through a model where sellers with heterogeneous product qualities are choosing whether or not to participate in inventory commingling. We find that this decision to "free ride" versus protect their competitive advantage depends on the product quality, pre-handling cost, product revenue, and fulfillment fees. We design mechanisms for the platform to maximize profits. When the platform generates revenue through both commission fees and fulfillment fees, complicated trade-offs happen. By appropriately deciding the commission rate and fulfillment fee, the platform can leverage inventory commingling to its fullest advantage.

3 - Deep Learning for Visual Advertising on Digital Platforms: Asymptotically Optimal Image Selection

Bora Keskin, Duke University, Durham, NC, United States, Yuexing Li, Shaoxuan Liu, Jing-Sheng Song

We consider a digital platform that aims to crop and display a large number of images to maximize customer conversions, i.e., customer purchasing decisions. For each image, the platform chooses a cropping window and observes the resulting conversions. The platform does not know how cropped images influence conversions. We design a novel two-stage deep-learning policy that dynamically learns this relationship and adjusts images to maximize conversions. We derive a theoretical performance guarantee proving the asymptotic optimality of our deep-learning policy. Moreover, A/B testing results indicate that our deep-learning policy substantially increases the platform revenue. Finally, case studies based on a real-life data set also reveal that our policy exhibits good performance even if the functional relationship between images and conversion is misspecified.

4 - Contextual Data-Integrated Newsvendor Solution with Operational Data Analytics (Oda)

Jian Wu, Purdue University, West Lafayette, IN, United States, Qi Feng, J Shanthikumar

We study the data-integrated newsvendor problem in which the random demand depends on a set of covariates. Observing from the solutions analyzed in the existing studies, we identify the equivariant class of operational statistics (i.e., the mapping from the demand and covariate data to the inventory decision) to develop the operational data analytics (ODA) framework for the contextual newsvendor problem. The equivariant property is intuitively appealing, and it is justified by the fact that, regardless of the sample size, no other decision rule can uniformly dominate the optimal operational statistic within the equivariant class. We also demonstrate that nonequivariant solutions can produce unstable empirical performance with limited samples, where equivariant solutions exhibit robustness. When the distribution family of the demand is known but the coefficients of the demand function are unknown, we can directly validate the decision performance of operational statistics within the equivariant class, and derive the uniformly optimal solution. When the distribution family of the demand is unknown, we formulate the data-integration model as a subclass of equivariant operational statistics obtained through adaptively boosting some candidate solution. For decision validation, we project the validation data to the demand for the covariates of interests, and the projection is constructed by utilizing the structure of the candidate solution. We demonstrate the superior small-sample performance of adaptive boosting, and establish the consistency of the boosted operational statistics. Our ODA formulation, building on the inherent characteristics of the contextual newsvendor problem, highlights the importance of understanding structural properties in data-integrated decision making.

Co-Chair: Wenjia Ba, University of British Columbia, 2053 Main Mall HA576, Vancouver, BC, V6T 1Z2, Canada

1 - Data-Driven Optimization of Experimental Designs

Ruoxuan Xiong, Emory University, DECATUR, GA, United States, Mohsen Bayati

In this paper, we study the optimization of the design of experiments that are run on multiple units for one or multiple time periods. The design problem involves selecting the time periods for the treatment for each unit, with the objective of most precisely estimating the treatment effect. Solving the design problem can be challenging when the expression of the objective function in terms of treatment decision variables is complex and nonexplicit. This can happen when using complex treatment effect estimators or imposing minimal assumptions on the data-generating processes. To address this challenge, we propose a novel zeroth-order Frank-Wolfe algorithm for optimizing experimental designs, that works for general treatment effect estimators and data-generating processes. This algorithm optimizes the design using historical data of the experimental units, which is typically available for applications in digital platforms, clinical trials and other settings. We provide theoretical guarantees for the optimized experimental design from our algorithm. Finally, we show our algorithm yields designs with much lower treatment effect estimation error compared to benchmarks through synthetic experiments on both simulated and real data.

2 - Poisson Limits of Bernoulli Bandits

Wenjia Ba, University of British Columbia, Vancouver, BC, Canada, Lin Fan, Peter Glynn, Michael Harrison

We study Bernoulli bandits in the ``hard luck" parameter regime. That is, the probability of success on any given trial is assumed to be small, regardless of what action the experimenter may choose, and regardless of what exogenous context may be observed. Adopting a general model formulation propounded by Wager and Xu (2021), we prove a limit theorem that justifies approximating a Bernoulli bandit in the hard luck regime by a corresponding Poisson bandit. The latter is a continuous-time treatment selection model in which cumulative reward is driven by one of several possible Poisson processes, depending on the action or treatment selected by the experimenter; each of the Poisson processes has an average success rate that is initially unknown but can be learned through experimentation. Poisson bandits have several advantages over the Bernoulli bandits that they replace or approximate, including both sharper theoretical insights and ease of computation. We introduce policy gradient methods to optimize adjustable Thompson sampling parameters in both discrete-time and continuous-time models. Our experiments indicate that continuous-time policy gradient estimators have lower variance and yield significantly better policies than those from discrete-time policy optimization.

3 - Causal Inference for Large Dimensional Non-Stationary Panels with Two-Way Endogenous Treatment and Latent Confounders

Junting Duan, Stanford University, Stanford, CA, United States, Markus Pelger, Ruoxuan Xiong

This paper studies the imputation and inference for large-dimensional non-stationary panel data with missing observations. We propose a novel method, Within-Transform-PCA (wi-PCA), to estimate an approximate latent factor structure and non-stationary two-way fixed effects under general missing patterns. The missing patterns can depend on the latent factor model and two-way fixed effects. Our method combines a novel within-transformation for the estimation of two-way fixed effects with a PCA on within-transformed data. We provide entry-wise inferential theory for the values imputed with wi-PCA. The key application of wi-PCA is the estimation of counterfactuals on causal panels, where we allow for two-way endogenous treatment effects, time trends and general latent confounders. In an empirical study of the liberalization of marijuana, we show that wi-PCA yields more accurate estimates of treatment effects and more credible economic conclusions compared to its two special cases of conventional difference-in-differences and PCA.

Chair: Fatemeh Farajzadeh, Worcester Polytechnic Institute, WEBSTER, United States

1 - Proactive Staging of Resources along International Borders for Migratory Crises

Fatemeh Farajzadeh, Worcester Polytechnic Institute, Worcester, MA, United States, Luke Caleb Caddell, Andrew Trapp

Migration crises are complex emergencies that evolve over time and feature high levels of uncertainty concerning human needs. We use stochastic programming to position scarce border resources under demand uncertainty with redistribution recourse decisions. Our costs not only include the economic costs of efficiently operating and securing international borders but also the deprivation experienced as a consequence of accumulated time not accessing critical aid. The unexplored form of interplay between location, resource (re-)allocation, and time introduced in this study enhances strategic and operational decision-making at international borders.

2 - Value Sensitive Design of a Resource Sharing Platform for Nonprofits

Carlos Morel-Figueroa, Rensselaer Polytechnic Institute, Troy, NY, United States, Weixiao Huang, Darren Cole, Yunus Telliel, Sarah Stanlick, Andrew Trapp, Jennifer Pazour

A resource sharing platform for nonprofits, known as SWAP, is a newly developed system piloted by a cohort of Maryland-based nonprofits. Using an integer linear program, SWAP enables participating nonprofits to exchange resources with each other. A common methodology to design technologies that captures the interactions of human values and system design is Value Sensitive Design (VSD). This work uses the VSD methodology to identify the values important to nonprofits and to guide the design of the SWAP system. Our research incorporates the development of different optimization model formulations capturing the nonprofit's identified values into the resource exchange problem, including the implementation of additional SWAP policies and rules of engagement. A series of computational experiments were conducted using empirical data from the SWAP pilot episodes to quantify the proposed designs across the different values.

3 - The Dedicated Docket in US Immigration Courts: An Analysis of Fairness and Efficiency Properties

Daniel Freund, MIT, Cambridge, MA, United States, Wentao Weng

The dedicated docket was introduced by the Biden Administration to reform the immigration system. It creates a separate queue for immigration proceedings where judges are supposed to issue decisions for each case within a target timeframe. Its goals are to improve speed, accuracy, and fairness. Though it meets its first goal, legal advocacy groups report that this comes at the expense of the last. Referring to it as a ``Denial of justice", they find that cases on the dedicated docket routinely fail to access legal representation, and have a much lower asylum grant rate. Against this backdrop, we study the operational implication of the dedicated docket.

We develop a queueing model wherein a policy maker (PM) routes asylees to the regular or the dedicated docket, and sets a delay target for the latter. Constrained by the target, the court allocates its capacity to minimize the average delay. Immigration lawyers schedule their time between dockets to maximize the rate of successful asylum cases. Compared to a single docket, we show that the dedicated-docket system can Pareto-improve the speed and accuracy. However, we also prove that the dedicated docket system satisfies two natural fairness rules only if it is dominated by the single docket.

Our analysis can inform the public discourse. We prove that the lack of fairness is a fundamental design flaw of the new program. Though delay differentiation enables a surprising efficiency gain, this requires unfairness between. Policy makers and legal advocacy groups should be aware of such tradeoffs.

4 - Exposing Human Trafficking Patterns: Leveraging Natural Language Processing for Illicit Classification across US Massage Businesses

Vasuki Garg, North Carolina State University, Raleigh, NC, United States, Maria Mayorga, Osman Ozaltin, Sherrie Caltagirone

The dual nature of massage businesses, firstly as significant outliers among healthcare service facilities due to non-rigorous government scrutiny, and secondly, offering services involving physical touch in distinct privacy, has made them prime candidates for labor and sex trafficking hotspots. This hybrid overlap of human trafficking activities hinders efforts by law enforcement agencies. It also presents a challenge towards the appropriate allocation of valuable resources to identify such illicit businesses effectively. To address this, a unique bifurcated approach to building illicit classification models can be implemented which capitalizes on the business information to understand potential suppliers' aspects and also employs Natural Language Processing techniques to anatomize customer reviews and capture potential consumers' perspectives. With the aim of creating indicators of illicit behavior, these novel models explore the complex consumer–supplier dynamics of human trafficking and highlight patterns of illicit massage businesses to aid classification. These models offer easy deployment for stakeholders to optimally allocate resources. Additionally, using methodologies to identify and incorporate shifts in the indicators when exposed to diverse data offers versatility and adaptability. This allows proficiently analyzing information from different U.S. states, sources, businesses, and domains to identify illicit activities for a larger-scale application of human trafficking network discovery.

5 - A fix-and-optimize matheuristic to solve the location-allocation of vaccination facilities: the case of Jalisco, Mexico.

Marisol Sarai Romero Mancilla, MIT, Boston, MA, United States, Jaime Mora-Vargas, Angel Ruiz

Since the start of the most recent pandemic of COVID-19, around 755 million cases and 7 million deaths have been reported (WHO, 2023). Based on the availability of vaccines to contain the spread of COVID-19, different vaccination plans have been implemented around the world, some being more effective than others, depending on the social, territorial, economic, and political circumstances of each country. In

Mexico and other Latin American countries with similar situations, COVID-19 vaccination has almost exclusively relied on ephemeral mass vaccination facilities together with existing healthcare infrastructure. However, other countries (USA and Canada, for instance) have opted into Pharmacy-based Immunization (PBI), a strategy that consists of using community and/or chain pharmacies as vaccination facilities to provide more accessible immunization services to the population. The aim of this research is to evaluate the feasibility and the expected performance if PBI would have been used in Mexico. To this end, we propose a mathematical formulation to address the location-allocation problem underlying the pharmacy selection and the assignment of individuals to them. However, since commercial solvers are not able to tackle efficiently the resulting formulation for real-sized instances, the formulation is embedded into a heuristic fix-and-optimize scheme allowing to explore the solution space in a more efficient manner. The case of Jalisco, Mexico, is used to illustrate the performance of the proposed approach.

1 - Measuring Network Dynamics of Drug Overdose Deaths in the United States

Kushagra Tiwari, University of Pittsburgh, Pittsburgh, PA, United States, M. Amin Rahimian, Praveen Kumar, Jeanine M Buchanich, Mark Roberts

The U.S. opioid overdose epidemic has been a significant cause of concern in recent decades. In spite of many studies documenting the role of social networks in overdose use behavior, our current understanding of social network effects in the spatial spread of Opioid Epidemic remains limited. We use Facebook's Social Connectedness Index (SCI) as a proxy for real-life social networks across diverse spatial regions that helps quantify social connectivity across different spatial units. Using Linear Regression, we assess the effect of Opioid Overdose Deaths (OODs) of the alter counties on the ego county. To further validate our findings, we performed a series of robustness checks using cluster-robust standard errors, network autocorrelation, spatial autocorrelation, two-way fixed-effect and two-stage least squares. These checks consistently provide statistically robust evidence of a positive effect of social influence on OODs.

2 - Location and Capacity Planning of Substance use Treatment Facilities for Maximizing Access and Population Health Outcomes

Zixuan Feng, The Pennsylvania State University, University Park, PA, United States, Qiushi Chen, Paul Griffin, Pengyi Shi

The opioid epidemic has devastated communities across the nation, leading to over 500,000 overdose deaths and costing the economy more than $1 trillion over the past two decades. While robust clinical evidence has shown the effectiveness of treatment in reducing mortality and improving recovery, only 1 in 5 individuals who may benefit from medication for opioid use disorders received the treatment. One major barrier to treatment is the insufficient capacity in the current treatment facilities, which makes it difficult for patients who need to travel long distances to access the treatment and thus achieve sustained retention in treatment, particularly for those in rural and underserved areas. However, it remains unclear how the strategic location and capacity planning of treatment facilities can best meet the patient needs to maximize treatment outcomes. In this study, we develop a system dynamics model to formulate the patient flow through the process of waitlist, under treatment, recovery, and relapse for patients from multiple locations. Our model captures the effect of travel distance between patients' locations and the treatment facilities on the treatment retention rate. The policy space includes opening new facilities, expanding current ones, and managing patient assignments and priorities, e.g., delaying admissions based on expected retention rates. We compare these policy combinations by simulating the total operating cost of the treatment facilities and person-months in treatment retention under each policy. We also vary the total budget level and identify the most effective policy that achieves the highest retention outcome under the budget constraint.

3 - Analyzing Patterns of Polysubstance use in Overdose Deaths

Hyojung Kang, University of Illinois at Urbana-Champaign, Champaign, IL, United States

Drug overdose deaths have continued to increase, with synthetic opioids comprising a more significant proportion. While many studies have assessed the characteristics of individuals who misused and overused a single substance, fewer studies have been conducted to understand patterns of polysubstance use and how the epidemic has evolved over time. This study aims to investigate the patterns of co-occurring substances involved in overdose deaths. We use association analysis and clustering approaches to identify common patterns and evaluate the characteristics of individuals across different groups.

4 - Inventory Modeling for Preventing Opioid Overdose Deaths

RASHID ANZOOM, University of Illinois Urbana-Champaign, Urbana, IL, United States, Rakesh Nagi, Chrysafis Vogiatzis, Hyojung Kang

Federal and state governments in the USA are struggling to contain the opioid epidemic, which has triggered a public health crisis. The increasing cases of overdose fatalities have drawn attention to the distribution of life-saving resources such as Naloxone, prompting efforts to boost their accessibility. This talk explores a data-driven framework to derive resource distribution policies that are cost-efficient, highly responsive, and provide equitable benefits to target regions. Specifically, we focus on defining the appropriate/optimal inventory and transshipment decision parameters under various demand and supply scenarios. We demonstrate the effectiveness of our approach through a simulation model applied to the state of Illinois.

1 - The Development of Precision Medicines: An Economic Impediment OR a New Model of Drug Innovation?

Anant Mishra, Carlson School of Management, University of Minnesota, Minneapolis, MN, United States, Jingwen Yang

In recent years, the emergence of precision medicines has transformed the practice of medicine. Yet, the strategic implications of such innovations on market dynamics remain unclear. Does precision medicine curtail the market size by focusing on niche patient populations or does it enhance overall market performance due to heightened drug efficacy? Leveraging FDA approvals of precision indications for identification, we uncover that, contrary to conventional believe of market contraction, precision medicines lead to a significant market expansion. Specifically, approvals of precision indications are associated with increases in drug sales by 96% and in revenues by 90%. The presence of companion diagnostics, used exclusively for patient identification, amplifies these effects. The research findings suggest that drug markets respond to precision medicine innovation despite the concern of such innovation targeting narrower market segments. Business model challenges tied to this innovation can be mitigated by the presence of companion diagnostic devices. In essence, precision medicine innovation signifies a shift from the conventional blockbuster drug business approach, offering a promising alternative strategy for drug innovation.

2 - Opioid Control Policies Can Also Reduce Domestic Violence

Minglu Sun, RTI International, Tampa, FL, United States, Andrei Barbos

Opioid abuse is an issue of serious concern in the United States, and it has been the focus of a multitude of state and federal level policies. Such policies can raise cost vs. benefit considerations, which besides direct effects, must also account for potential second-order unintended consequences. We provide evidence for an important positive spillover of effective opioid control policies by showing that they can also reduce domestic violence. To this aim, we exploit the staggered implementation of the Mandatory Access Prescription Drug Monitoring Programs, which required health care providers to consult an electronic database before prescribing and/or dispersing controlled substances. These programs have been shown to be effective at reducing the utilization of opioids. We find that they also decreased the instances of intimate partner assaults, driven primarily by a decrease in simple assaults, although there is evidence that they also decreased the incidence of the other types of assaults. The results are robust under multiple specifications.

3 - The Difficulty of Achieving Gender Equality: Evidence from US Universities

Tiancheng Zhao, Saint Louis University, St. Louis, MO, United States, Sridhar Seshadri, Zur Shapira

Despite progress in reducing gender inequality, disparities continue in the academic labor market, particularly regarding vertical gender segregation. To investigate the feasibility of achieving gender equality at the highest academic levels in US universities, we develop a mathematical model representing promotion and hiring. Our findings, using data from 2001 to 2019, show that certain universities tend to have more favorable promotion rates for male professors than for females—for example, 15.95% higher at the assistant professor level. We discuss university-level characteristics that influence inequality. Numerical simulations reveal that, even with favorable treatment, existing gender imbalances impede progress at higher levels, with 34.9 years on average to achieve equal representation at the full professor level. This research provides valuable insights into challenges associated with promoting gender equality in academia.

2 - A Probabilistic Foundation And New Opportunities of Diffusion Models for Generative AI

Minshuo Chen, Northwestern University, Plainsboro Township, NJ, United States, Mengdi Wang

Diffusion models, a powerful and universal generative AI technology, have achieved tremendous success with multi-modality data from engineering, operations research, computer science, etc.

In this tutorial, we aim to unveil and capitalize diffusion models. Firstly, we review the applications and design philosophy of diffusion models from a probabilistic point of view. Secondly, we overview the existing theories connecting the probabilistic nature of diffusion models to their statistical properties and sampling capabilities. Thirdly, we introduce brand new opportunities embodied by diffusion models, where we highlight one example of diffusion models for generative optimization.

Strategic Supply Chain Network Optimization at Walmart

Invited Session

The Practice Section of INFORMS

Chair: Xinyue Peng, Walmart, Sunnyvale, CA, United States

1 - Large Scale Optimization Models for Evolving Walmart Next-Gen Ambient Network

Xinghua Wang, Walmart, Dallas, TX, United States, Mehmet Aydemir, Pengcheng Zhang, Sai Rajesh Mahabhashyam

Connecting vendors and more than 4600 stores in the US, Walmart’s Regional Distribution Centers (RDCs) play a critical role in its supply chain network. Where to set up these facilities, how much capacity each should have, and which stores should be supported by each RDC have significant impact on the retailer’s overall supply chain cost, efficiency and resilience. To further improve operational efficiency and lower cost, we are planning to upgrade existing RDCs to meet future demand. Key questions that need to be answered for such transformation include: 1) what’s the best timeline of the upgrades; 2) do any of the RDCs need to be supported by other RDCs during the upgrade process; 3) what are the best store-RDC alignments during and after the transformation; 4) how to better integrate with other supply chain facilities with the extra capacity that becomes available after the upgrades.

To answer these questions and ensure a smooth transition, we build a large-scale, multi-period dynamic Mixed Integer Programming model to minimize overall transportation and handling costs while observing various realistic operational constraints. To solve the model efficiently, we decompose the problem into two stages. The first stage involves finding the optimal locations and configurations for the end state. The second stage then finds the optimal strategy to transform the current RDC network to the next-gen network. In this talk, we will introduce the business context, present the mathematical model formulation, and illustrate the solution approach.

2 - Multi-commodity Network Flow Optimization for Walmart Middle Mile E-commerce Network

Anand Seshadri, Walmart E-commerce, Dallas, TX, United States, Aida Khayatian, Sai Mahabhashyam

For the Walmart e-commerce supply chain strategy team to make decisions regarding the optimal evolution of the Walmart network in the future, a robust software application is necessary that allows for rapid prototyping, data setup at scale, extensible experimentation, and detailed feedback. The purpose of this paper is to describe state of the art solution approach utilized by to formulate the middle mile strategy. The output of the application describes various product flows, paths utilized, and the choice of cross-dock nodes given the potential demand and allowable cross-dock sites which include sort centers and delivery stations. The solution also must include various business constraints such as delivery time, minimum and maximum volumes at the cross-dock nodes, and maximum number of intermediate nodes along a path. The solution also must satisfy multiple business objectives such as minimum cost, and maximum last-mile delivery volume. The solution presented solves the problem inside a modified multi commodity network flow framework and enables fast optimal solutions to be obtained quickly (within an hour) for large (~3,000 nodes and 400,000 arcs) network. The model also is executed sequentially across multiple years and ensures network consistency across the time-horizon under consideration.

3 - Optimization Models for Reducing Empty Miles in Walmart Transportation Network

Rahul Swamy, Walmart Centroid, Dallas, TX, United States

Walmart operates one of the largest transportation fleets in the United States, facilitating the movement of loads across an extensive network that includes vendors, distribution centers, consolidation centers, and retail outlets. Despite the expansive nature of this network, a significant portion of freight from vendors is currently transported by third-party carriers. Walmart's key strategic goal is to internalize a portion of these loads to enhance overall network efficiency and achieve cost savings. This talk introduces a multi-objective optimization model designed to identify and prioritize vendors whose freight can be internalized into Walmart's fleet operations. The proposed assignment model ranks vendors while optimizing several metrics, such as minimizing network inefficiencies (e.g., reducing empty miles), maximizing alignment with the existing fleet network, and enhancing temporal consistency in shipping lanes. The model is solved using the epsilon-constraint method. By internalizing these freight, Walmart's network efficiency is expected to improve, thereby reducing carbon emissions and increasing cost savings.

4 - Densifying Walmart Last Mile Delivery via Trip Planning Optimization

Lingxun Kong, Walmart Centroid, Sunnyvale, CA, United States, Yao Luo

At Walmart, we manage deliveries under various service level agreements (SLA). For scheduled deliveries, orders are delivered within a time window, whereas for unscheduled deliveries, the deliveries can be at any point throughout the day. To densify our last-mile delivery system, we are commingling both scheduled and unscheduled orders in the same trip. If we are given all scheduled and unscheduled orders for the day, we can plan commingled trips by solving a capacitated vehicle routing problem with time windows (CVRPTW). In operations, however, orders are placed continuously throughout the day, necessitating multiple trip planning sessions. The challenge lies in intelligently selecting unscheduled orders for delivery during the slots in the morning, without prior information about the orders that will be placed later. To tackle this, we amalgamate existing orders with a set of predicted synthetic orders, and solve the CVRPTW for the entire day, executing deliveries only for the current slot. This process is repeated in subsequent trip planning, using updated actual and synthetic orders for the remaining horizon. This method allows us to plan cost-effective trips for the receding horizon based on our best future estimates. Implementing this framework could result in notable cost savings and SLA enhancements for Walmart's last-mile ecosystem.

5 - Model Approach for Solving Large Scale Affinity Aware Inventory Placements at Walmart

Yaqing Wu, Walmart Centroid, Dallas, TX, United States, Bharath Rangarajan

A large number of orders are dispatched from tens of fulfillment centers at Walmart every year to satisfy the customer orders placed online. Only a selected set of items could be placed in a fulfillment center considering physical or operational capacity constraints. Order splits happen if items in an order are fulfilled from multiple fulfillment centers. Thus, it is desired to place items frequently purchased together (that is, high basket-affinity items) in the same fulfillment centers. The problem becomes complex as Walmart offers large assortments for customers to consider, it is challenging to decide the placement of items across the fulfillment network. We propose an end-to-end, scalable optimization framework for this placement problem. We run experiments to show significant performance improvements in end-to-end order fulfillment cost.

Experimental Design For Causal Inference Through An Optimization Lens

Invited Session

TutORial

Chair: Harish Krishnan, University of British Columbia, Vancouver, BC, Canada

1 - Experimental Design For Causal Inference Through An Optimization Lens

Jinglong Zhao, Boston University, Boston, MA, United States

The study of experimental design offers tremendous benefits for answering causal ques tions across a wide range of applications, including agricultural experiments, clinical trials, industrial experiments, social experiments, and digital experiments. While valu able in such applications, the costs of experiments often drive experimenters to seek more efficient designs. Recently, experimenters have started to examine such efficiency questions from an optimization perspective, as experimental design problems are fun damentally decision-making problems. This perspective offers a lot of flexibility in leveraging various existing optimization tools to study experimental design problems.

thus aims to examine the foundations of experimental design problems in the context of causal inference as viewed through an optimization lens.

1 - On the Double-Edged Effects of Peer-to-Peer Payment Systems in Consumer Banking

Ao Huang, University of Miami, Coral Gables, FL, United States, Ni Huang, Yili Hong

As a fast-growing financial technology, peer-to-peer (P2P) payment systems like Zelle offer consumers a convenient way to transfer money. Anecdotal evidence suggests the convenience of short-term liquidity management may come at the unintended cost of increased fraud. This study empirically investigates the effects of Zelle availability, focusing on bank consumers' temporary financial hardship and fraud complaints. Leveraging the staggered partnership with the Zelle payment network across U.S. banks from 2017-2021 and consumer complaint data from the Consumer Financial Protection Bureau (CFPB), we employ difference-in-differences (DID) analyses and counterfactual estimations to identify the said effects. The results show that Zelle availability led to a 14.1% decrease in complaints related to the struggle with student loan payments but a 22.9% increase in fraud complaints. Larger banks and counties with larger African American populations experienced more fraud complaints post-Zelle implementation. Zelle availability appears to present a double-edged effect - while it may help alleviate temporary financial hardship, it also increases fraud risk, disproportionately affecting socioeconomically disadvantaged groups. Our findings highlight the need for policymakers and financial institutions to enhance consumer protection and risk management efforts when implementing P2P payment technology.

2 - The Potential of Large Language Models in Revolutionizing Charitable Giving

Teng Ye, University of Minnesota, MINNEAPOLIS, MN, United States, Jingnan Zheng, Junhui Jin, Jingyi Qiu, Wei Ai, Qiaozhu Mei

Online charitable giving has provided essential alternative funding source, particularly for small businesses that often face high financial vulnerability and limited access to traditional financial support compared to larger corporations. However, as small businesses increasingly turn to online crowdfunding platforms, over 40% of these campaigns fail to raise any funds, especially those operating in low socio-economic regions. We leverage the latest advancements in AI technology to identify and strategically optimize key factors that influence the success of crowdfunding campaigns. By analyzing over 10,000 small business charitable-giving campaigns in the U.S., our best-performing machine learning model accurately predicts the fundraising outcomes of 81% of campaigns. Interpreting the machine learning model enables us to offer actionable suggestions for improving the textual description before launching a campaign. By enhancing just three aspects of its description using a large language model, a campaign becomes more preferable to 83% human evaluators. This increases the likelihood of securing financial support for originally unfunded campaigns by 13.3% and significantly improves the equity of fundraising results. Our research uncovers effective strategies for crafting descriptions for small business fundraising campaigns and opens up a new realm in integrating large language models into online charitable giving methodologies.

3 - A Simple Solution to Improving Human Supervision of Algorithms: Evidence from Smart Vending

Brian Han, Gies College of Business, UIUC, Champaign, IL, United States, Minda Zhao, Xin Chen, Tao Zhu

Humans nowadays inevitably face the human-AI interaction problem of whether to follow algorithms' suggestions. Although studies indicate human overrides degrade performance, humans sometimes possess private information that increases the profit. This paper proposes a simple solution to improve human supervision by allowing human overrides with constraints. Compared to the binary choice to either fully permit or prohibit human overrides, constraints incentivize humans to make selections more judiciously and override only with high confidence to improve performance. We partnered with FengE ZuShi (a large smart-vending company in China) and conducted a field experiment to test our solution in the context of inventory replenishment. We find strong evidence supporting our solution that constrained override increases sales by 1.3%. Besides, our method is a low-cost approach in practice and scales easily to a broader class of business operations as imposing override constraints is a general solution.

4 - Traffic Allocation Optimization on Video Sharing Platforms: Balancing Viewer Engagement and Small Creator Development

Qinlu Hu, The Chinese University of Hong Kong, Hong Kong, China, People's Republic of, Ni Huang, Renyu Zhang

Online short-form video platforms like TikTok, Triller, and Snapchat Spotlight, driven by algorithms that enhance viewer engagement, often favor established creators over emerging, small creators. This study focuses on small creators, seeking solutions to balance viewer engagement and creator development via viewing traffic allocation. In collaboration with a leading online short-form video sharing platform, we report two field experiments. The partner platform conducted a viewer-side experiment to limit the viewers' access to the small creators' videos, and our analysis shows that reducing small creators' content generally boosted viewer engagement. However, effects varied by viewer activeness -- the treatment increased video watching time for less active viewers but decreased it for active viewers. The partner platform also conducted a creator-side experiment, allocating extra viewer traffic to small creators. This led to significant increases in their content production quantity, efforts and new follower count, with insignificant changes in content quality. Notably, these effects were more pronounced among the more experienced and popular small creators. Combining all insights, we propose a novel traffic allocation policy: boosting the content visibility of small creators, especially those who are relatively more popular, to active viewers, while limiting it for less active viewers in the recommender system of the platform. This strategy enhances engagement for both viewer types and improves small creators' productivity and growth. This approach has the potential to create a tripartite win-win-win outcome, indicative of a Pareto improvement that benefits the creators, viewers, and the platform. We discuss the theoretical and practical implications.

5 - The Impact of Bifurcation on Platform Outcomes in a Q&A Community

Xiaomeng Chen, University of Pittsburgh, Pittsburgh, PA, United States

This paper studies platform bifurcation, the process in which a subgroup of users from an original platform launches an independent spin-off platform. We identify the effects of bifurcation using a difference-in-differences approach that exploits the introduction of spin-off platforms in an online platform incubator. We find that bifurcation leads to a strong overall increase in contributions. While contributions to the home platform decline, the two bifurcated platforms generate more combined user contributions and attract more new users compared to a single united platform. We further explore how interconnectivity and platform differentiation affect users' choice of platform. Our evidence indicates that users are less likely to migrate from an incumbent platform to a new, specialized platform when interconnectivity is strong but more likely to migrate when the specialized platform enables more differentiation. This paper is the first to empirically analyze the strategic implications of new platform entry at scale and to document the moderating role of interconnectivity and platform differentiation.

Data-Driven Decision Making: Harnessing Multimedia, Social Media, Big Data, and Machine Learning for Business Excellence

Invited Session

Social Media Analytics

Chair: Cuibing Wu, Framingham State University, Framingham, MA, United States

1 - Impact of Verbal and Nonverbal Cues in CEO Interview Videos on Firm Risk

Cuibing Wu, University of Massachusetts Lowell, Lowell, MA, United States, Julie Zhang, Remi Daviet

This study investigates the impact of verbal and nonverbal cues in CEO interview videos on stock volatility, analyzing a dataset of 2,404 CEO interviews from S&P 500 companies from 2010 to 2022. Using advanced machine learning techniques, the research quantifies verbal, vocal, and visual cues to examine their relationship with stock volatility. Empirical findings indicate a strong correlation between the elements of CEO interviews and stock volatility. In the experimental phase, GANs are used to generate varying emotional expressions in CEO videos, and participants are shown these videos. The results reveal that videos with happy CEO expressions lead to expectations of increased stock value, while those with sad or surprised expressions predict a decrease. This comprehensive study highlights the significant influence of CEO verbal and nonverbal cues on stock volatility.

2 - Taste or Terminate? Deciphering Factors of Restaurant Failure Through Customer Reviews

Jie LI, University of Massachusetts Lowell, Lowell, MA, United States, Asil Oztekin

This study examines the dynamics of social interactions and the impact of online reviews on Yelp, utilizing the Yelp Academic dataset to conduct a comprehensive analysis. We focus on extracting text features from consumer reviews, integrating a unique method to calculate an aggregated review score that assigns weights to individual reviews based on specific criteria. The study further explores the predictive power of restaurant features and textual data in forecasting restaurant closures. We compare the performance of several machine learning models, including ZeroR, Multi-layer Perceptron (MLP), and Logistic Regression, to assess their effectiveness in this context. Our predictive model employed is a custom-built neural network featuring ReLU activation functions within its hidden layers.

3 - When Carryover Meets Spillover: Incrementality Measurement in Catalog and Beyond

Zhengrong Gu, Boston University, Boston, MA, United States, Garrett Johnson, Ziwei Liao, Jerry Chen

Marketing channel carryover effects occur when the channel has the persistent effect of advertising after exposure. In particular, channels such as direct mail catalogs can exhibit carryover effects long after being sent. Moreover, channel carryover effects may interact with channel spillover effects: i.e., the combined effect of two marketing channels (e.g., email and direct mail catalogs) is greater than or less than the sum of each channel individually. Measuring complementarity or cannibalization between channels helps marketers understand and optimize their spend holistically. This paper addresses both spillover and carryover effects in a multi-channel marketing context at a global e-commerce firm with millions of customers. We use large-scale lift studies to measure the effectiveness of direct mail catalog channel with different numbers of catalogs and test durations. We find long-term carryover effects that persist for months after the mailing, with more substantial effects noted for groups receiving multiple seasonal catalogs. We then examine how subsequent exposures via routine email marketing campaigns interact with the experimentally measured effect of the direct mail catalog channel. This research shows the extent and nature of channel spillover effects and reveals how carryover effects interact with spillover effects, enhancing the understanding of channel interactions.

4 - Cracking the Ca(u)ses: Unraveling Urban Crime Dynamics with Agent-Based Modeling

Ann-Kathrin Meyer, University of Münster, Münster, Germany, Konstantina Valogianni, Balaji Padmanabhan, Tobias Brandt

Understanding the dynamics of urban crime is a vital aspect of contemporary societal management, enabling proactive measures for law enforcement and policy makers. However, traditional crime prediction models often fall short in capturing the intricate causal mechanisms driving criminal activities, relying heavily on statistical correlations.

Agent-Based Modeling (ABM) presents a unique approach for deriving causal frameworks and we demonstrate its potential in capturing complex relationships inherent in criminal behavior. Specifically, we employ ABM to construct causal models to explain crime dynamics in Los Angeles using, among others, georeferenced social media data as a measure of social activity. The design and implementation of Causal ABMs and leveraging genetic algorithms for their estimation enables the extraction of multiple plausible causal sets from empirical data.

Through the understanding of crime causes, we aim to pave the way for the development of targeted preventive strategies. Furthermore, this approach empowers researchers to develop robust causal ABMs that offer a deeper understanding of crime dynamics.

5 - Navigating the Storm: The Impact of Social Media Crisis Response Strategies on Stock Performance

ziqian song, The university of scranton, Dalton, PA, United States

In the contemporary business landscape, social media platforms have emerged as critical arenas for crisis communication, significantly influencing stakeholders' perceptions and market performance. This study explore the interplay between firms' crisis response strategies deployed on social media and their consequential impact on stock performance. Leveraging the Situational Crisis Communication Theory (SCCT) framework, we examine the effectiveness of various crisis response tactics employed by firms across social media channels. Through empirical analyses, we evaluate firm crisis response behaviors on social media and their subsequent influence on stock market performance. Our investigation analyze the extent to which firms' strategic communication endeavors during crises shape investor perceptions and subsequently impact market outcomes. Our findings not only illuminate the efficacy of social media crisis response strategies in mitigating financial influence but also provide actionable insights for firms endeavoring to adeptly navigate social media crises while upholding shareholder interests. This research contributes valuable knowledge to firm crisis communication using social media and offers practical implications for firms seeking to bolster their crisis management capabilities in the digital age.

Stochastic Approximation (SA) and Stochastic Gradient Descent (SGD) for Machine Learning

Invited Session

Artificial Intelligence

Chair: Siva Theja Maguluri, ISyE Georgia Tech, Atlanta, GA, United States

1 - Two-time-Scale Linear Stochastic Approximation: Tight Finite Time Bounds Under Markovian Noise

Shaan Ul Haque, Georgia Institute of Technology, Atlanta, GA, United States, sajad Khodadadian, Siva Theja Maguluri

Stochastic approximation (SA) is an iterative algorithm to find the fixed point of an operator given noisy samples of this operator. SA appears in many areas such as optimization and Reinforcement Learning (RL). When implemented in practice, the noise that appears in the update of RL algorithms is naturally Markovian. Furthermore, in some settings, such as gradient temporal difference (GTD), SA is employed in a two-time-scale manner. The mix of Markovian noise along with the two-time-scale structure results in an algorithm which is complex to analyze theoretically. In this talk, we characterize a tight convergence bound for the iterations of linear two-time-scale SA with Markovian noise. Our results show the convergence behavior of this algorithm given various choices of step sizes. Applying our result to the well-known temporal difference with gradient correction (TDC) algorithm, we show the first $O(1/\epsilon)$ sample complexity for the convergence of this algorithm, outperforming all the previous work. Similarly, our results can be applied to establish the convergence behavior of a variety of RL algorithms, such as TD-learning with Polyak-Ruppert averaging, GTD, and GTD2.

2 - Federated Offline Reinforcement Learning: Collaborative Single-Policy Coverage Suffices

Jiin Woo, Carnegie Mellon University, Pittsburgh, PA, United States, Laixi Shi, Gauri Joshi, Yuejie Chi

Offline reinforcement learning (RL), which seeks to learn an optimal policy using offline data, has garnered significant interest due to its potential in critical applications where online data collection is infeasible or expensive. This work explores the benefit of federated learning for offline RL, aiming at collaboratively leveraging offline datasets at multiple agents. Focusing on finite-horizon episodic tabular Markov decision processes (MDPs), we design FedLCB-Q, a variant of the popular model-free Q-learning algorithm tailored for federated offline RL. FedLCB-Q updates local Q-functions at agents with novel learning rate schedules and aggregates them at a central server using importance averaging and a carefully designed pessimistic penalty term. Our sample complexity analysis reveals that, with appropriately chosen parameters and synchronization schedules, FedLCB-Q achieves linear speedup in terms of the number of agents without requiring high-quality datasets at individual agents, as long as the local datasets collectively cover the state-action space visited by the optimal policy, highlighting the power of collaboration in the federated setting. In fact, the sample complexity almost matches that of the single-agent counterpart, as if all the data are stored at a central location, up to polynomial factors of the horizon length. Furthermore, FedLCB-Q is communication-efficient, where the number of communication rounds is only linear with respect to the horizon length up to logarithmic factors.

3 - Order-Optimal Convergence Rates with Adaptive Sgd

Matthew Faw, Georgia Institute of Technology, Atlanta, GA, United States

We study convergence rates of AdaGrad-Norm as an exemplar of adaptive stochastic gradient descent (SGD) methods, which adjust their step sizes based on observed stochastic gradients, for minimizing non-convex, smooth objectives. Despite their popularity, the analysis of adaptive SGD lags behind that of non-adaptive methods in this setting. Specifically, all prior studies rely on some subset of the following assumptions which are unnecessary in the analysis of fixed step-size SGD: (i) uniformly bounded gradient norms, (ii) uniformly bounded stochastic gradient variance (or even noise support), (iii) conditional independence between the step size and stochastic gradient. In this work, we show that AdaGrad-Norm exhibits an order optimal (up to polylogarithmic factors) convergence rate scaling inversely with the square-root of T after T iterations under the same standard assumptions as a well-tuned fixed step-size SGD (unbounded gradient norms and affine noise variance scaling). We also go beyond the standard smoothness assumption, proving similar results for (L_0, L_1)-smooth (non-convex) functions (where the Hessian can scale affinely with the gradient, e.g. such as the exponential function). This is the first rate of convergence for any algorithm in this smoothness and noise regime, even for the special case of uniformly-bounded variance. This talk is based on joint works with Isidoros Tziotis, Litu Rout, Constantine Caramanis, Aryan Mokhtari, Rachel Ward, and Sanjay Shakkottai. References: https://arxiv.org/abs/2202.05791 (COLT 2022) and https://arxiv.org/abs/2302.06570 (COLT 2023).

4 - Rates of Convergence in the Central Limit Theorem for Markov Chains, with An Application to Td Learning

R Srikant, University of Illinois at Urbana Champaign, Urbana, IL, United States

We prove a non-asymptotic central limit theorem for vector-valued martingale differences using Stein's method, and use Poisson's equation to extend the result to functions of Markov Chains. We then show that these results can be applied to establish a non-asymptotic central limit theorem for Temporal Difference (TD) learning with averaging.

Tip Your Farmer? Implications of Tipping in Agriculture on Sustainability and Financial Inclusion

Saed Alizamir, University of Virginia, Charlottesville, VA, United States, Basak Kalkanci

An emerging financial innovation enabled by technological advancements in agricultural supply chains is the capability to "tip the farmers." This innovation empowers socially-conscious customers to identify the individual farmers of their sustainably-sourced products and reward these farmers by sending them direct payments, or tips, through mobile apps. We examine the implications of this new capability on farmers' and consumers' welfare and agricultural firm profits. We characterize the equilibrium of the game with and without tipping and show how different types of equilibria emerge depending on the model parameters. We investigate the implications of tipping on various stakeholders such as farmers, customers, and the agricultural firm and identify the conditions under which they may be better off or worse off. Furthermore, we find that even when farmers benefit from tipping in expectation, this financial innovation may create disparity and exacerbate inequity in the farmer population, which is undesirable from a social responsibility standpoint. Firms must exercise caution in implementing the tipping capability as farmers' expected and actual income and consumer welfare may reduce in the presence of tipping. In contrast, if tipping is implemented under the right conditions, it can create a triple win for agricultural firms, farmers, and customers.

2 - Empowering OR Exploiting? the Implications of Direct Market Access for Improving Smallholder Farmers&Rsquo; Welfare

Xi Lin, The Paul Merage School of Business, UC Irvine, Irvine, CA, United States, Luyi Gui, Yixin Lu

Poor market access is a major hurdle to poverty reduction for smallholder farmers. Traditional market access strategies that connect farmers with wholesale intermediaries are criticized for exposing farmers to exploitation. While many believe that this issue can be resolved by direct market access under which farmers sell directly to consumers, practice indicates that farmers often need to work with service intermediaries to facilitate such direct sales and continue to suffer from exploitation. Hence, it remains unclear whether and under what circumstances direct market access can benefit smallholder farmers. In this paper, we address these questions through a comparative study of two prevalent strategies: contract farming, which provides farmers with assured sales of their output to a buying firm at a pre-determined wholesale price, and rural livestreaming, whereby farmers sell to consumers in a live broadcast run by a media company that charges a percentage commission fee. We show that compared to contract farming, the direct market access enabled by livestreaming can mitigate exploitation and improve farmers' income if they plant niche crops or incur low planting costs. Otherwise, direct market access may aggravate exploitation and hurt farmers' income. Furthermore, direct market access can become more effective in improving farmers' income under yield uncertainty or if farmers' bargaining power improves, but may cause agricultural subsidies to backfire and reduce farmers' income. Our results indicate that policy makers should account for the operational characteristics of local crops and other poverty reduction policies when choosing between direct versus indirect market access strategies.

3 - Urban Mining and Material Scarcity in Clean Energy Supply Chains

Clara Carrera, INSEAD, Fontainebleau, France, Atalay Atasu, Luk Van Wassenhove, Serasu Duran

The low-carbon economy is a materials economy. Clean energy technologies – essential for the reduction of carbon emissions – require large amounts of critical raw materials such as cobalt for energy storage, rare earth minerals for wind turbines, and silver for solar panels. The supply of these critical materials cannot keep up with skyrocketing demand, which may be a roadblock against the ongoing clean energy transition. In this paper we study two practical approaches that can sustain the clean energy industry's momentum: (i) Material Reduction, i.e., changes to production technology to reduce the critical materials used; (ii) Urban Mining, i.e., recovering and recycling critical materials from end-of-life clean energy technology products. We show that the effectiveness of these two approaches depends on the levels of material scarcity and systemic leakage in circular infrastructures. A long-term focus on clean energy production favors Urban Mining (Material Reduction) when material scarcity is high (low). Furthermore, there is an optimal level of circularity in the design of urban mining systems that maximizes clean energy generation in the long run. Meanwhile, an urban mining strategy is the most likely to maintain the profitability of the clean energy industry. Policy support to moderate the capital costs and systemic leakage in circularity infrastructures can motivate the clean energy industry to invest in urban mining.

1 - Sensitivity analysis for mixed binary quadratic programming

Jingye Xu, Georgia Institute of Technology, Atlanta, GA, United States

We consider sensitivity analysis for Mixed Binary Quadratic Programs (MBQPs) with respect to changing right-hand-sides. We leverage Burer's completely-positive (CPP) reformulation of MBQPs. Its dual is an instance of co-positive programming (COP) and can be used to get sensitivity bounds. We give a constructive proof that strong duality between the CPP and COP problems holds iff the feasible region is bounded, or the objective function is convex. We provide a method for finding good nearly optimal dual solutions and present preliminary computational results on sensitivity analysis for MBQPs.

2 - Branch-and-Bound Performance Estimation Programming: A Unified Methodology for Constructing Optimal Optimization Methods

Shuvomoy Das Gupta, Columbia IEOR, NYC, NY, United States

We present BnB-PEP, the first unified methodology for constructing the optimal first-order methods for both convex and nonconvex optimization. BnB-PEP poses the problem of constructing the optimal method as a nonconvex but practically tractable quadratically constrained quadratic optimization problem and solves it to certifiable global optimality using a customized branch-and-bound algorithm. We apply BnB-PEP to various practically relevant setups to construct optimal methods that surpass previous state-of-the-art results and also systematically generate analytical convergence proofs.

3 - The (Surprising) Sample Optimality of Greedy Procedures for Large-Scale Ranking and Selection

Zaile Li, Fudan University, Shanghai, China, People's Republic of

Ranking and selection (R&S) aims to identify the best alternative from a finite set by mean performance. Ideal large-scale R&S procedures should be sample optimal, i.e., the total sample size for a nonzero probability of correct selection (PCS) grows linearly with the number of alternatives. Surprisingly, we find that the naïve greedy procedure appears sample optimal. We develop a boundary-crossing perspective to understand the discovery, prove the sample optimality, and further analyze the probability of good selection. Our discovery may suggest a new mindset for designing R&S procedures.

4 - Differential Privacy via Distributionally Robust Optimization

Aras Selvi, Imperial College Business School, London, United Kingdom

Differential privacy, the de facto standard for privately sharing statistics about datasets, inherently involves a trade-off between privacy and accuracy of the released information. We develop a class of mechanisms that optimally balance these conflicting objectives. To this end, we formulate the mechanism design problem as an infinite-dimensional distributionally robust optimization problem and show that the problem affords a strong dual, and we exploit this duality to develop converging hierarchies of finite-dimensional upper and lower bounding problems.

1 - Clean up the Act: Impact of Privacy Regulation on Live Streaming Influencers

Yuan Yuan, Carnegie Mellon University, Pittsburgh, PA, United States, Nikhil Malik, Wen Wang, Kannan Srinivasan

In the digital age, live-streaming influencers on platforms like TikTok and Douyu.com have seen a surge in popularity. These influencers often strategically leverage a portion of their "privacy assets", such as by revealing private details, to garner rewards like engagement and intimacy. How- ever, this strategy has led to significant privacy concerns and safety issues, prompting policy regulations in recent years. This study empirically investigates such phenomena and quantifies the impact of privacy regulations on influencers. Our analysis, using observational data from Douyu.com and multimodal video analytics, shows that self-disclosure is associated with higher audience engagement for influencers. Leveraging a natural policy shock, we find that regulatory policies on such behavior have led to a notable decrease in audience engagement, with heterogeneous effects across influencers creating different styles of content, suggesting widespread economic losses due to these regulations. Interestingly, midst the general negative effects on the platform, some influencers have proactively adapted by switching to different styles of content creation, resulting in in- creased engagement. We leverage a game theoretical model to explore the underlying mechanisms and examine the reasons behind influencers' decisions to change content categories in response to policy shocks. This study provides vital insights into the dynamics of the digital economy, especially in the live-streaming domain. It highlights the significant implications for future policy development, platform management, and the evolution of content creation strategies, balancing live-streaming costs with the pursuit of gains on online platforms.

2 - She? the Role of Perceived Agent Gender in Social Media Customer Service

Junyuan Ke, University of Rochester, Rochester, NY, United States, Yang Gao, Huaxia Rui, Shujing Sun

Understanding the effect of gender in business interactions is of significant importance to companies and society. Inspired by practical concerns about how gender affects customer support interactions, the present study investigated the role of perceived agent gender in customer behavior using a unique dataset consisting of all public customer service interactions handled on Southwest Airlines' Twitter platform from March 2018 to September 2019. We inferred agent gender based on the first names provided by agents when responding to customers. In addition, we measured customer behavior using the following outcomes: whether a customer decided to continue the service conversation upon receiving an agent's initial response as well as the emotional reactions in their second tweet if the customer chose to continue the interaction. Our identification was based on the backdoor criterion and hinged on the assumption that customers are assigned to the next available agent, independent of agent gender. The findings revealed that customers were more likely to continue interactions with female agents than with male agents. Customers' emotional reaction to perceived agent gender is more nuanced. We find that customers' messages were more negative in valence but less intense in arousal with the former group than with the latter. These results offer valuable insights both to practitioners and to academics regarding gender stereotypes and bias in the service industry.

3 - Empathic Algorithm Delegation: Fostering Optimal Human-AI Collaboration in Decision-Making

Thomas Ware, Arizona State University, Tempe, AZ, United States, Tian Lu, Raghu Santanam, Benjamin Shao

Effective collaboration between humans and artificial intelligence (AI) involves leveraging complementary skills and expertise, requiring humans to contribute critical thinking, contextual sensitivity, and judgment in final decisions. This becomes particularly salient when others are impacted by AI generated choice. According to behavioral decision-making literature, affect plays a crucial element in enhancing problem-solving capabilities. Understanding this effect in decision environments assisted by AI warrants further consideration. We introduce empathic algorithm delegation (EAD) to describe the fundamental empathic considerations decision-makers should take during AI decision delegation (interpersonal perspective-taking, contextual understanding, and final decision responsibility). We investigate the implications of this framework on deliberation behaviors and decision accuracy using a Chinese-based micro-lending context. We find the individual components of this framework, separately and together, yield significant improved human-AI synergies in contexts where choices have significant interpersonal impacts.

4 - Generative Policy Learning via Diffusion Models

Zekai Fan, Carnegie Mellon University, Pittsburgh, PA, United States, Michael Lingzhi Li, Shixiang Zhu

Data-driven decision-making tools are widely used in critical applications but often require decision-makers to explicitly define target value functions and constraints. As Michael Polanyi observed, "We can know more than we can tell," highlighting the challenge of formalizing tacit knowledge and preferences. To address this, we propose a framework called "generative policy learning," which leverages a conditional diffusion model to produce diverse, near-optimal, and potentially high-dimensional policies for any chosen value function. Our approach introduces a re-weighting scheme for training diffusion models based on the probability of each sample being near-optimal. This framework allows decision-makers to focus on primary objectives and apply their tacit knowledge to evaluate generated decisions, rather than developing explicit specifications. We demonstrate the effectiveness of this method through extensive synthetic and real-world experiments.

Climate Finance and Transition Risk

Invited Session

Energy: Natural Resources

Chair: Felipe Verastegui, Columbia University, 421 W 118th, New York, United States

Co-Chair: Agostino Capponi, Columbia University, New York, NY, United States

1 - Sustainable finance under regulation

Alexandr Kopytov, University of Rochester, Rochester, NY, United States, Shiyang Huang

We build a model analyzing optimal environmental regulation in the presence of socially responsible investors. Investors care about sustainability of their portfolios but cannot fully resolve the pollution externality. Regulations, such as pollution tax and subsidies to clean firms, reduce dirty firms' size but also reshape firms' shareholder compositions. Under the regulations, dirty firms' shareholders become on average less averse to holding polluting shares and hence these firms are less willing to adopt green technologies. We show that pollution can increase with regulation stringency. Optimal regulations do not always fully correct the externality and can deviate from the Pigouvian benchmark.

2 - Climate Regulatory Risks and Corporate Bonds

Lee Seltzer, Federal Reserve Bank of New York, New York, NY, United States, Laura Starks, Qifei Zhu

Investor and policymaker concerns about climate risks suggest these risks should affect the risk assessment and pricing of corporate securities, particularly for firms facing stricter regulatory enforcement. Using corporate bonds, the authors find support for this hypothesis. Employing a shock to expected climate regulations, they show climate regulatory risks causally affect bond credit ratings and spreads. A structural credit model indicates that the increased spreads for high carbon issuers, especially those located in stricter regulatory environments, are driven by changes in firms' asset volatilities rather than asset values, highlighting that regulatory uncertainty affects security pricing. The results have important implications for policy-making.

3 - Green Intermediary Asset Pricing

Maxime Sauzet, Boston University, Boston, MA, United States

Can environmentally-minded investors impact the cost of capital of green firms even when they invest through financial intermediaries? To answer this and related questions, I build an equilibrium intermediary asset pricing model with three investors, two risky assets, and a riskless bond. Specifically, two heterogeneous retail investors invest via a financial intermediary who decides on the portfolio allocation that she offers between a green and a brown equity. All investors can tilt towards the green asset, beyond pure financial considerations. Perhaps surprisingly, the green retail investor can have significant impact on the pricing of green assets, even when she invests via an intermediary who does not tilt: a sizable green premium can emerge on the equity of the green firm. This good news comes with important qualifications, however: the green retail investor has to take large leveraged positions in the portfolio offered by the intermediary, her strategy must be inherently state-dependent, and economic conditions or the specification of preferences can overturn or limit the result. When the financial intermediary decides (or is made) to tilt instead, the impact on the green premium is substantially larger, although it is largest when preference are aligned with retail investors. I also study what happens when the green retail investor does not know the weights in the portfolio offered by the intermediary, the potential impact of greenwashing, and the effect of portfolio constraints. Taken together, these findings highlight the central role that financial intermediaries play in channeling financing (or not) towards the green transition.

4 - Sustainable Investing Strategies with Tradable Assets

Felipe Verastegui, Columbia University, New York, NY, United States, Agostino Capponi

Many sustainable investing strategies employ green-screening, setting pollution thresholds that firms must meet to receive financing from socially responsible investors. However, if the aim is to cut emissions, this method may be ineffective, as firms can change the composition of their asset portfolios without adopting cleaner technologies. To address this, we introduce a competitive equilibrium model featuring heterogeneous firms and a single sustainable fund, which aims to promote decarbonization across a finite asset pool. We contrast green-screening with conditional decarbonization, where the fund mandates a minimum emission reduction. Firms make ex-ante commitments to effort allocations and engage in real asset trades, to then face a random match process which determines whether they secure funding for their operations or not. We show that compliance decisions exhibit strategic complementarity when the size of the sustainable fund is small. When including asset trades, we find that the presence of a sustainable fund can lead to carbon leakage, where assets shift from compliant to non-compliant firms. If transaction costs are small relative to the cost of clean technology, trade decisions over pollutive assets also exhibit strategic complementarity. While green-screening concentrates leakage in carbon-intensive assets, conditional decarbonization mitigates this risk, reverting the relative ordering of compliance costs. We demonstrate that conventional sustainable investment targets fail to minimize total emissions under worst-case scenarios of ex-post firm-investor matches.

1 - Data-Analytic Opportunities and Challenges in Solar Eruption Forecasting

Victor Verma, University of Michigan, Ann Arbor, MI, United States, Yang Chen

In recent years, there has been a growing awareness of space weather impacts on critical infrastructure in the civilian, commercial, and military sectors. The interest will continue to grow as we gain a better understanding of the physical processes of the Sun and their effects here on Earth and in space itself. Among all space weather events, the solar flare is a relatively intense, localized emission of electromagnetic radiation in the Sun's atmosphere. Flares occur in active regions and are often, but not always, accompanied by coronal mass ejections, solar particle events, and other eruptive solar phenomena. In recent years, machine learning models have been employed to forecast solar eruptions, including strong solar flare events.

In this talk, I will discuss data-analytic opportunities and challenges in solar eruption forecasting, given the availability of massive solar imaging data and other relevant data products. Scientifically, it is essential to (a) identify the solar active regions that have high potential to erupt in an automated fashion, (b) extract features from observed solar images using principled statistical algorithms, (c), most importantly, provide a probabilistic forecast for the eruption time, magnitude and magnetic field configuration, and (d) facilitate new understandings of the mechanism/physics of disruptive space weather events. In particular, I will present one of our novel statistical models, the Tensor Gaussian Process with Contraction, for solar flare forecasting, combining data from various types and sources. I will conclude with ongoing and future work on operational solar eruption forecasting.

2 - Generation of He I 1083 Nm Images from HA Images by Deep Learning

Marco Marena, New Jersey Institute of Technology, Newark, NJ, United States, Qin Li, Haimin Wang, Bo Shen

This research introduces an innovative method for augmenting the Helium 10830 Å dataset using advanced deep learning techniques, specifically through the Pix2PixHD conditional Generative Adversarial Network (cGAN). The primary objective of this study is to overcome the temporal limitations of the existing Helium 10830 Å dataset, which spans from 2011 to 2020. This augmentation leverages the abundant H-alpha (Hα) spectral line data as a foundational predictor for generating Helium 10830 Å images. The introduction of Helium 10830 Å observations marked a transformative era in solar physics by providing unprecedented detail of the sun's surface and atmospheric behavior. Our work aims to extend the temporal range and enhance the utility of the Helium 10830 Å dataset by integrating it with an extensive repository of Hα data. We employed the Pix2PixHD model, training it on correlated pairs of Hα and Helium 10830 Å images, to facilitate an accurate conversion from Hα data into the Helium 10830 Å domain. This approach not only expands the scope of the Helium 10830 Å dataset but also significantly improves our understanding of solar atmospheric activities over an extended timeline. The generated Helium 10830 Å images demonstrate a strong correlation with actual observational data, with a correlation coefficient (CC) of 0.91 and a Root Mean Square Error (RMSE) of 8.62. These results attest to the model's ability to intricately replicate features of the solar atmosphere. Consequently, this advancement heralds a new epoch in solar physics and data generation methodologies, emphasizing the study's significance within the scientific community.

3 - Automatic Fault Characterization of Multiple Signals Using Bayesian Tensor Modeling with Semiconductor Inspection Data

Qing Zou, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Andi Wang, Jian Li

Drawing inspiration from historical semiconductor inspection datasets, this paper introduces a novel Bayesian modeling framework tailored for unsupervised learning tasks involving high-dimensional, smooth, and low-rank tensor data. To enhance the detection of abnormal events, our proposed model integrates a smooth and sparse components tensor decomposition method, employing Gaussian process priors and sparsity priors, respectively. Additionally, we incorporate Bayesian CP decomposition with automatic rank determination to facilitate efficient modeling of high-dimensional tensor data. Within this innovative Bayesian framework, we present an efficient Gibbs sampling approach to tackle the model inference problem. Both numerical experiments and a real-world case study utilizing semiconductor datasets demonstrate the efficacy of our proposed methodology.

4 - Direct Ink Writing Process Analysis from a Multi-Stage System Perspective

Wuyang Chen, University of Georgia, Athens, GA, United States, Chenyu Xu, Chi Zhou, Hongyue Sun

This research focuses on the multi-stage analysis of Direct Ink Writing (DIW) 3D printing. DIW can be used for the printing of various functional materials, which often exhibit complex properties that affect the subsequent printing and drying processes. Traditional physical modeling usually cannot handle such dynamic interactions. To address this challenge, we adopt a data-driven approach, collecting extensive data across all stages, from the initial material properties to real-time sensing and imaging during printing, and detailed evaluations of the final products like 3D scans and thermal properties. We analyze and decode the interdependencies among the DIW stages, which facilitates the comprehensive understanding and optimization of the DIW process.

Sequential Learning: Optimization and Prediction Under Uncertainty

Invited Session

Data Mining

Chair: Imtiaz Ahmed, West Virginia University, Morgantown, WV, United States

Co-Chair: Hamed Khosravi, West Virginia University, Morgantown, WV, United States

1 - Active Learning of Piecewise Gaussian Process Surrogates

Chiwoo Park, University of Washington, Seattle, WA, United States, Robert Waelder, Bonggwon Kang, Benji Maruyama, Soondo Hong, Robert Gramacy

Active learning of Gaussian process (GP) surrogates has been useful for optimizing experimental designs for physical/computer simulation experiments, and for steering data acquisition schemes in machine learning. Here, we present a method for active learning of piecewise, Jump GP surrogates. Jump GPs are continuous within, but discontinuous across, regions of a design space, as required for applications spanning autonomous materials design, configuration of smart factory systems, and many others. Although our active learning heuristics are appropriated from strategies originally designed for ordinary GPs, we demonstrate that additionally accounting for model bias, as opposed to the usual model uncertainty, is essential in the Jump GP context. Toward that end, we present an estimator for bias and variance of Jump GP models. Illustrations, and evidence of the advantage of our proposed methods, are provided on a suite of synthetic benchmarks, and real-simulation experiments of varying complexity.

2 - Lnucb-Ta: Linear-Nonlinear Hybrid Bandit Learning with Temporal Attention

Imtiaz Ahmed, West Virginia University, Morgantown, WV, United States, Hamed Khosravi

In this study, we present LNUCB-TA, a novel hybrid contextual multi-armed bandit algorithm that effectively combines linear and non-linear estimation strategies to enhance decision-making accuracy in stochastic contextual bandit problems. This model introduces significant advancements over the vanilla Linear Upper Confidence Bound (LinUCB) algorithm by integrating an adaptive k-nearest neighbors (k-NN) method alongside an attention-based exploration mechanism, designed to enhance the precision of reward estimations and adaptability in complex environments.These novel features adjust the confidence bands and reward estimations for each option or "arm," by utilizing learned data-driven similarities among the feature vector and reward history associated with each arm. This significantly reduces the likelihood of selecting non-optimal arms. By leveraging both temporal and spatial complexities, our model transitions from static to dynamic exploration rates, effectively balancing exploration and exploitation in real time.We demonstrate the model’s efficiency and robustness through a theoretical analysis, proving that the regret bound is sub-linear. Furthermore, empirical results demonstrate that LNUCB-TA outperforms several state-of-the-art bandit models.

3 - Optimal Resource Allocation in a Collaborative Production System at Subtask Level

Congfang Huang, UW Madison, Madison, WI, United States

This talk will introduce a resource allocation problem in a serial manufacturing production line consists of multiple workstations. The available resources include human workers, independent robot and collaborative robots. At the subtask level, we consider the precedence relationship between different subtasks. The objective is to improve the throughput, reduce the economic cost and release ergonomic strain. A reinforcement learning guided evolutionary algorithm is proposed to solve the problem and a real world case study will be illustrated.

4 - Attention Enhanced Damage Prediction in Electrode Materials

Quan Zeng, Georgia Institute of Technology, Atlanta, GA, United States

In this talk, we report our recent progress in damage prediction based on application of a recurrent neural network model to fracture videos. Specifically, we are able to apply physically meaningful stress gradients as attention guidance and to accurately predict damage propagation for the next image frame. In this research, the damage and stress videos were simulated using phase-field model, but should the X-ray microscopy data be available, we are confident that the resulting method is applicable as well.

Emerging Trends in Interpretable Machine Learning

Invited Session

Data Mining

Chair: Lesia Semenova, Microsoft Research, NY, 27713, United States

1 - Recent Work in Dimension Reduction for Data Visualization

Cynthia Rudin, Duke University, Durham, NC, United States

Dimension reduction (DR) for data visualization is unsurpassed in its ability to provide insight from data. I will discuss recent work from the Interpretable Machine Learning Lab in dimension reduction and applications.

2 - Interpreting CLIP with Sparse Linear Concept Embeddings (SpLiCE)

Usha Bhalla, Harvard University, Cambridge, MA, United States, Alex Oesterling, Suraj Srinivas, Flavio Calmon, Himabindu Lakkaraju

CLIP embeddings have demonstrated remarkable performance across a wide range of computer vision tasks. However, these high-dimensional, dense vector representations are not easily interpretable, restricting their usefulness in downstream applications that require transparency. In this work, we empirically show that CLIP's latent space is highly structured, and consequently that CLIP representations can be decomposed into their underlying semantic components. We leverage this understanding to propose a novel method, Sparse Linear Concept Embeddings (SpLiCE), for transforming CLIP representations into sparse linear combinations of human-interpretable concepts. Distinct from previous work, SpLiCE does not require pre-defined concept labels and can be applied post hoc to unlabelled data. Through extensive experimentation with multiple real-world datasets, we validate that the representations output by SpLiCE can explain and even replace traditional dense CLIP representations, maintaining equivalent downstream performance while significantly improving their interpretability. We also demonstrate several use cases of SpLiCE representations including detecting spurious correlations, model editing, and quantifying semantic shifts in datasets.

3 - The Dataset Multiplicity Problem: How Unreliable Data Impacts Predictions

Anna Meyer, University of Wisconsin - Madison, Madison, WI, United States, Aws Albarghouthi, Loris D'Antoni

We introduce dataset multiplicity, a way to study how inaccuracies, uncertainty, and social bias in training datasets impact test-time predictions. The dataset multiplicity framework asks a counterfactual question of what the set of resultant models (and associated test-time predictions) would be if we could somehow access all hypothetical, unbiased versions of the dataset. We discuss how to use this framework to encapsulate various sources of uncertainty in datasets' factualness, including systemic social bias, data collection practices, and noisy labels or features. We show how to exactly analyze the impacts of dataset multiplicity for a specific model architecture and type of uncertainty: linear models with label errors. Our empirical analysis shows that real-world datasets, under reasonable assumptions, contain many test samples whose predictions are affected by dataset multiplicity. Furthermore, the choice of domain-specific dataset multiplicity definition determines what samples are affected, and whether different demographic groups are disparately impacted. Finally, we discuss implications of dataset multiplicity for machine learning practice and research, including considerations for when model outcomes should not be trusted.

4 - Revolutionizing Clinician Diagnosis of Seizure and Seizure-like EEG Patterns using Interpretable AI

Alina Barnett, Duke University, Durham, NC, United States

We designed a first-of-its-kind AI assistive tool to prevent serious brain injury and death for critical care patients by illuminating important patterns in their electroencephalogram (EEG) signals. Our solution addresses the societal issue of low clinician trust in AI models by inventing novel technical solutions to elucidate the decision-making of famously opaque neural networks. With our model, clinician classification accuracy improves substantially. This technology can greatly improve patient care both in well-served areas and especially in poorly-served areas.

5 - Provably-Optimal Sparse Trees

Rui Zhang, Duke University, Durham, NC, United States, Rui Xin, Cynthia Rudin

Decision trees are one of the oldest form of AI models. Within its vast literature, a large number of work rely on heuristic (or greedy) algorithms to produce tree models, which risk yielding sub-optimal models. Researchers have made recent success on fully optimized classification trees, but they fail to extend it to more generalized tasks (regression, survival analysis and multi-label learning). Our work fill this gap by providing provably-optimal sparse trees for more generalized tasks in a fast and efficient way.

Long-Term Power System Expansion Planning with New Renewable Fuels

Invited Session

ENRE: Electricity

Chair: Enzo Sauma, Pontificia Universidad Catolica de Chile, Santiago, Chile

1 - Impact of on-grid ammonia production on power system expansion planning under European Union definitions of renewable fuels

Cristóbal Zuazagoitia, Pontificia Universidad Católica de Chile, Santiago, Chile, Enzo Sauma

The Commission Delegated Regulation (EU) 2023/1184, supplementing Directive (EU) 2018/2001 of the European Parliament and of the Council was published in the Official Journal of the European Union in June 2023. This regulation establishes a methodology, among other statements, describing specific rules for considering electricity taken from the grid as fully renewable to produce renewable liquid and gaseous transport fuels of non-biological origin (RFNBO). In this work, we investigated the impact of on-grid ammonia production on the long-term expansion planning of the Chilean power system, aligning with European Union definitions of RFNBO for future exports. We propose a comprehensive model formulated as a Mixed-Integer Linear Program (MILP) to minimize investment and operational costs, while considering technical constraints such as Kirchhoff's Voltage Law (KVL). The incorporation of renewable energy quotas and/or maximum CO2 emission factor per period results in a generation mix and installation of new transmission lines that significantly vary temporally and spatially from the base case. By modeling ammonia production as a partially flexible load, we explore its impact on the entire power system, including systemic costs, line congestion, curtailments, and seasonal production profiles.

2 - Long-term expansion planning of power systems with the integration of green ammonia under different economic and regulatory scenarios for the year 2060: the case of Chile

Francisca Meriño Fariña, Pontificia Universidad Catolica de Chile, Santiago, Chile, Enzo Sauma

Climate change is a significant global challenge. Due to the Chile's large renewable-energy potential, green hydrogen emerges as an energy vector that can support the decarbonization of the various energy-demanding sectors. Since the transport of hydrogen is complex and expensive, ammonia emerges as one of the best options for its transportation. This work proposes a long-term expansion planning model of the Chilean National Electric System, which integrates hydrogen and green ammonia to the year 2060, addressing the urgent need for decarbonization. This long-term expansion planning model of the power system for the year 2060 optimizes the installation of ammonia production plants subject to some technical constraints.

Results suggest that the high penetration of renewable energy and the use of storage systems will make viable an economic production of hydrogen and green ammonia by the year 2060. We also analyze the main interactions between the optimal electricity system plan and the production of these clean fuels under various economic and regulatory scenarios

3 - Evaluation of the economic and environmental impacts of implementing different public policy mechanisms to accelerate the development of the H_2 industry in Chile

Enzo Sauma, Pontificia Universidad Catolica de Chile, Santiago, Chile, Andrés Pereira, Francisco Manríquez, Sonia Vera

We first formulate and implement a model that co-optimizes, from a system-wide perspective, the expansion of the H_2 industry and the expansion of the associate power system, when considering the main technical features of both the power system operation and the H_2 production. This model is implemented in the "Platform for Long-Term Planning Analysis of National Electric System" (PLANES) developed. Using PLANES, we evaluate the economic and environmental impacts of implementing different public policy mechanisms aimed at encouraging and accelerating the development of the H_2 industry in Chile. Our results indicate that aligning electrolyzer operations with the hourly availability of renewable resources (i.e., encouraging a coordination between the hydrogen system operation and the electricity system operation) can lead to a reduction in the operation hours of fossil fuel power plants, decreased reliance on Battery Energy Storage Systems (BESS), and curtailed electricity, resulting in a lower global total cost of electricity.

4 - What duality theory tells us about giving the market operator the authority to dispatch energy storage

Yuzhou Jiang, Verse Inc., San Francisco, CA, United States, Ramteen Sioshansi

Energy storage has becoming an important participant in modern electricity markets. The question of which entity should have the authority to make operational decisions for energy storage has been ongoing. Some stakeholders raise concerns that market operators' independence can be undermined if they make operational decisions for energy storage. The rationale that underlies this concern is that operating energy storage can affect the balance of the system and price formation. We formulate optimal-power-flow problem as well as its dual problem, and demonstrate that having market operators make operational decisions for energy storage does not change its fundamental nature. We show that if market operators co-optimize the operation of energy storage with that of generators and transmission, the optimal-power-flow problem yields short-run and long-run efficiency. These findings are analogous to those for having market operators co-optimize transmission use with generator dispatch. Our work suggests that concerns around giving market operators the authority to dispatch energy storage are misplaced.

Climate Uncertainty and Healthcare

Invited Session

ENRE: Energy-Climate

Chair: Chunjie Zhao, Clark University, LA PUENTE, United States

Co-Chair: Tianyi Yang, City of Hope, Monrovia, CA, United States

1 - From Policy to Power Savings: Role of Smart Technology Installations in Reducing Household Electricity Bills

Chunjie Zhao, Clark University, Worcester, MA, United States

Smart technologies play one important role in improving quality of life and fostering sustainable development. This study investigates the factors influencing smart thermostat adoption, with a specific focus on the different policy measures that encourage such adoption. Moreover, it explores how these policies potentially narrow the adoption gap between urban and rural regions. Through the logistic regression, we identified a positive relationship between the implementation of policies and the promotion of smart thermostat adoption, with the tax rebate policy being the most effective in mitigating urban-rural adoption disparities. These findings contribute to the broader discourse on sustainable development, technology diffusion, and equitable socio-economic progress.

2 - Mitigating the Healthcare Impacts of Climate Change through Sustainable Energy and Environmental Policies

Grace Babalola, Binghamton University (SUNY), Johnson City, NY, United States, Timilehin Halim, Lyndia Yusuf, Oluwatunmise Halim, Simeon Ogunbunmi

Climate change poses significant risks to public health, with potential consequences such as increased air pollution, water scarcity, vector-borne diseases, and extreme weather events. This work explores how sustainable energy and environmental conservation policies can help mitigate these healthcare impacts by reducing greenhouse gas emissions, promoting clean energy sources, and fostering a more resilient environment – delving into the link between climate change and healthcare challenges, including respiratory diseases, heat-related and the spread of infectious diseases.

The role of sustainable energy in mitigating these impacts is highlighted, focusing on transitioning to renewable sources like solar and wind power, which improves air quality and reduces air pollution-related respiratory issues. Energy efficiency measures in healthcare are also discussed, as they contribute to lowering the carbon footprint and promoting sustainability.

Environmental conservation strategies, such as reforestation, sustainable agriculture, and water conservation, are examined for their potential to mitigate the effects of climate change and protect public health. Additionally, it explores the benefits of circular economy practices and waste management strategies in reducing environmental pollution and associated healthcare costs.

Furthermore, the importance of interdisciplinary collaborations between healthcare professionals, policymakers, energy experts, and environmental advocates is emphasized, underscoring the need for comprehensive policy frameworks and incentives to drive sustainable energy and environmental conservation efforts illustrated with real-world success stories.

Ultimately, this work provides a forward-looking perspective on the potential of sustainable energy and environmental policies to address climate uncertainty and its healthcare implications, offering recommendations for stakeholders to promote and support these vital initiatives.

3 - Adaptive Hidden Factor Structured Bayesian Networks and the Applications

Peng Jiang, Sichuan University, Chengdu, China, People's Republic of

Bayesian networks are appropriate candidates for systematic modeling with complex causalities and decision-making under uncertainties. However, multi-dimensional influencing variables incorporated in the networks would result in non-robust parameter estimations and expensive computations. To simplify the number of parameters and enhance parameter estimations, this study proposes a novel Adaptive Hidden Factor Structured Bayesian Network (AHFSBN) whose parameters and hidden structure are adaptively learned through multivariate spatial-temporal data in a semi-supervised learning manner. Theoretical analyses are given regarding the network structure, the parameter space, and the convergence of the related parameter learning algorithm. Then, the AHFSBN has been applied to health risk prevention modeling and risk management of emerging contaminants including cyanotoxins and antimicrobial resistance genes in natural aquatic environments. These real-world cases have demonstrated that the AHFSBN can provide intelligent data-driven decision support and offer several managerial insights.

4 - Echo State Networks For Short-Term Regulation Reserve Deployment Forecasting

Hugo Santarem de Araujo, Cornell University, Ithaca, NY, United States, Jose Daniel Lara, Jacob Mays, Bri-Mathias Hodge

Hybrid merchants in a competitive wholesale electricity market may seek to minimize their operational costs by storing low marginal-cost resources to provide energy or ancillary services. To provide frequency-regulation services, merchants employ past data and all sorts of models and heuristics to decide how to position their storage resources to fulfill their binding offer. Despite the growing proliferation of storage, the highly irregular nature of the frequency-regulation services data makes the prediction task rather challenging and the operation of batteries risky. In response to this challenge, we employed Echo State Networks to carry out the predictions of frequency-regulation services aiming at integrating the forecasts to the operation of the day-ahead market in the Electricity Reliability Council of Texas and the California ISO. Adopting a recursive framework, predictions refreshed every 5 minutes for about 22 days employing classical and ML methods. Results show that the proposed approach successfully captures the signal in the data as error metrics can be up to 10 times more competitive than the next best option.

5 - Compilation, Interpretation, and Integration of Wasted Food within Optimization-Based Models

Sauleh Siddiqui, American University, Washington, DC, United States

We present an expansion of US FEAST, a partial-equilibrium model of the US Food System, to include Wasted Food dynamics for projecting future outcomes. The food system represents an integrated series of systems that constitutes various stages of production, processing, distribution, and consumption. Each segment in the supply chain is tightly interconnected where alterations in one area reverberate throughout the entire system. Moreover, it intersects with other critical infrastructures like energy and transportation and impacts economics, public health, and the environment. Optimization models are frequently utilized in the mathematical representation of food system models and have played a crucial role in analyzing various dimensions of the food system. We explore methods for integrating the latest data and dynamics related to wasted food within food system models. Such types of models play a crucial role in quantifying the effects of wasted food on various parts of the supply chain. The model presented here offers insights into the potential impacts of wasted food reduction on food production, flow, and consumption.

Energy Systems Modeling and Optimization II: EV Integration Under Uncertainty

Invited Session

ENRE: Other Energy

Chair: Tanveer Bhuiyan, The University of Texas at San Antonio, San Antonio, TX, 78249, United States

1 - Adoption of EVs in Municipalities in Ma

Edgar Campos, Bentley University, Waltham, MA, United States, Zana Cranmer

We conducted a study in Massachusetts to understand why some towns have lower rates of electric vehicle (EV) adoption than others. Our goal was to identify the factors that influence EV adoption, including various demographic factors, EV charging and public transit infrastructure, and environmental attitudes. To achieve this, we used a multivariate linear model and found that the only factors that were not significant were our infrastructure variables. We found that income, voting results, urban/rural measurements of the town, homeownership, and environmental attitudes were significant in explaining EV adoption rates. Our findings have important implications for policymakers who are interested in promoting EV adoption, as outlined in the Massachusetts Clean Energy and Climate Plan.

2 - A Stochastic Game-Theoretic Optimization Approach for Managing Local Electricity Markets with Electric Vehicles and Renewable Sources

Sayed Hamid Hosseini Dolatabadi, The University of Texas at San Antonio, San Antonio, TX, United States, Tanveer Bhuiyan, Yang Chen

Local electricity markets (LEMs) are pivotal in optimizing active distribution systems, driven by renewable energy sources (RESs), and electric vehicles (EVs). Our study presents a stochastic bi-level model for managing LEMs, where the local transaction center (LTC) and other market participants (agents) (load aggregator (LA), charging station (CS), and their lower-level prosumers) aim to maximize their profits in a competitive game-theoretic structure. To ensure grid stability and profitability, LTC as the leader seeks to design a robust dynamic pricing strategy under uncertainty, whereas LA and CS, as followers, decide on the energy transaction amounts under uncertainty in their generation and consumption. We address several novel aspects of LEMs, such as heterogeneous behaviors of entities, uncertainties in renewable generation and load profiles, and the consumption profile of the EV fleet. We offer two solution methodologies including an exact centralized and a hybrid decentralized solution approach. Based on a realistic case study, we provide key insights into the effect of decision-making on the market dynamics, the benefit of our proposed dynamic pricing, the benefit of modeling stochasticity in generation and load profiles, and the performance of different solution approaches. Specifically, numerical results demonstrate that increasing the capacity of LTC's energy storage and its initial state of charge increases LTC's profit by 255%. Results also demonstrate that modeling the LEM under uncertainty as a two-stage stochastic program provides a robust pricing decision resulting in a 433% higher profit compared to the deterministic modeling that ignores the uncertainties in the key parameters.

3 - Optimizing E-commerce Electric Delivery Vehicle Charger Locations under Stochastic Demand

Taner Cokyasar, Argonne National Laboratory, Lemont, IL, United States, Omer Verbas, Tanveer Bhuiyan

As the demand for online shopping surges, the need for efficient last-mile delivery solutions becomes increasingly important, with electric vehicles (EVs) emerging as a sustainable option. However, the stochastic nature of delivery demand and the resulting inconsistent routing scheme across operational days poses a significant challenge in determining optimal charger locations to ensure timely and uninterrupted service. This study proposes a novel methodology that integrates stochastic location modeling and queueing theory to pinpoint optimal charger locations. Using a mixed-integer non-linear program, the problem is formulated, and an exact solution method employing cutting planes as lazy constraints is devised. The model aims to minimize costs associated with stations, chargers, detours, and queueing and charging times, thereby determining the optimal location, type, and quantity of EV chargers. The exact solution method contributes to the existing literature on stochastic location modeling. To enhance scalability, the study develops clustering heuristics and simulated annealing metaheuristic approaches. The research outcomes contribute to the advancement of understanding in sustainable urban logistics systems, providing actionable insights for businesses and policymakers aiming to improve the efficiency and sustainability of e-commerce delivery operations amid shifting consumer behaviors and environmental considerations.

4 - Planning of Networked Microgrids for Hydrogen-powered Vehicles: A Study on Induced Refueling Demand

Bo Zeng, University of Pittsburgh, Pittsburgh, PA, United States, Xunhang Sun, Xiaoyu Cao, Qiaozhu Zhai, Tamer basar, Xiaohong Guan

A planning model is presented for networked microgrids for hydrogen-powered vehicles, which considers the impact of induced demand.

5 - Shared Electric Vehicle Fleet for Stable and Fair Ride-Sharing Service

YANTAO HUANG, Argonne National Laboratory, Lemont, IL, United States, Hui Shen, Krishna Murthy Gurumurthy, Joshua Auld

Centralized ride-sharing service provides optimized fleet performance by picking the best candidate riders for vehicles, but with no considerations to rider preferences. This study explores how energy consumption and network performance will change when a ride-sharing service is provided by an electric vehicle (EV) fleet, which follows a vehicle and passenger matching rule that respects the preference considerations from both riders and fleet. That means fair considerations of the routing and charging on the fleet side, and wait times, seating availability and driver ratings on the riders' side, which eventually matches vehicles and riders to achieve a preference equilibrium. This paper advances the traditional stable and fair matching algorithm (SFMA) from one-to-one matching to many-to-one matching, extending the use case from transportation network companies' (TNC's) ride-sourcing service to ride-sharing service. This new many-to-one SFMA (MSFMA) will be evaluated using large-scale agent-based simulator POLARIS (Auld et al., 2016), which is capable of simulating millions of trips over a 24-hour simulation period in large metro areas. An optimization-based matching algorithm from Alonso-Mora (2017), often used as a benchmark, will give a baseline of vehicle-related events (e.g., routing, charging, and wait times), riders' experience (e.g., wait time) and network performance (e.g., average vehicle occupancy and road congestion). Comparisons would detail changes between an optimization-driven matching method and an equitable matching method for the electric ride-sharing service, in order reveal how two-sided market situation differs from centralized optimal fleet operations in terms of energy consumption and network performance.

Computation in Conic Programming

Invited Session

Computing Society

Chair: Boshi Yang, Clemson University, Clemson, SC, United States

Co-Chair: Hao Hu, Clemson University, Clemson, SC, United States

1 - The Maximum Singularity Degree for Linear and Semidefinite Programming

Hao Hu, Clemson University, Clemson, SC, United States

The singularity degree plays a crucial role in understanding linear and semidefinite programming, providing a theoretical framework for analyzing these problems. It is defined as the minimum number of facial reduction (FR) steps needed to reach strict feasibility for a convex set. On the other hand, the maximum singularity degree (MSD) is the maximum number of steps required. Recent progress in the applications of MSD has motivated us to explore its fundamental properties. For semidefinite programming, we establish a necessary condition for an FR sequence to be the longest. Additionally, we propose an upper bound for MSD, which can be computed more easily. By leveraging these findings, we prove that computing MSD is NP-hard. This complexity result complements the existing algorithms for computing the singularity degree found in the literature. For linear programming, we provide a characterization for the longest FR sequences, which also serves as a polynomial-time algorithm for constructing such a sequence. In addition, we introduce two operations that ensure the longest FR sequences remain the longest. Lastly, we prove that MSD is equivalent to a novel parameter called the implicit problem singularity.

2 - Revisiting Spectral Bundle Methods: Primal-Dual (Sub)Linear Convergence Rates

Lijun Ding, Texas A&M University, College Station, TX, United States, Benjamin Grimmer

The spectral bundle method proposed by Helmberg and Rendl is well established for solving large-scale semidefinite programs (SDP) thanks to its low per iteration computational complexity and strong practical performance. In this paper, we revisit this classic method showing it achieves sublinear convergence rates in terms of both primal and dual SDPs under merely strong duality, complementing previous guarantees on primal-dual convergence. Moreover, we show the method speeds up to linear convergence if (1) structurally, the SDP admits strict complementarity, and (2) algorithmically, the bundle method captures the rank of the optimal solutions. Such complementary and low rank structure is prevalent in many modern and classical applications. The linear convergent result is established via an eigenvalue approximation lemma which might be of independent interest. Numerically, we confirm our theoretical findings that the spectral bundle method, for modern and classical applications, speeds up under these conditions. Finally, we show that the spectral bundle method combined with a recent matrix sketching technique is able to solve an SDP with billions of decision variables in a matter of minutes.

3 - Cone product reformulation for global optimization

Theodoros Koukouvinos, MIT, Cambridge, MA, United States, Dimitris Bertsimas, Dick den Hertog, Danique de Moor, Jianzhe Zhen

In this paper, we study nonconvex optimization problems involving sum of linear times convex (SLC) functions as well as conic constraints belonging to one of the five basic cones, that is, linear cone, second order cone, power cone, exponential cone, and semidefinite cone. By using the Reformulation Perspectification Technique, we can obtain a convex relaxation by forming the perspective of each convex function and linearizing all product terms with newly introduced variables. To further tighten the approximation, we can pairwise multiply \rev{(parts of)} the conic constraints. In this paper, we analyze all possibilities of multiplying conic constraints. Especially the results for the cases in which a power cone or an exponential cone is involved are new. Particularly noteworthy are the novel results involving the power cone and exponential cone. We delineate methods for deriving new, valid linear and second-order cone inequalities for pairwise constraint multiplications involving these cones, thereby enhancing the strength of the approximation. Numerical experiments on a quadratic optimization problem over exponential cone constraints and on a robust palatable diet problem over power cone constraints, demonstrate that including additional inequalities generated from the proposed pairwise multiplications improve the approximation. Moreover, when incorporated in branch and bound the global optimal solution of the original nonconvex optimization problem can often be obtained faster than BARON.

Recent Advances in Decision Rules for Stochastic and Robust Optimization

Invited Session

Computing Society

Chair: Zolykha Rezaei, Texas Tech University, Lubbock, TX, United States

1 - A Group Sparsity-Based Stochastic Gradient Descent Algorithm for Beam Angle Optimization in Impt

Hadis Moazami Goudarzi, University of Houston, Houston, TX, United States, Gino Lim, Radhe Mohan, Wenhua Cao

This study introduces a new beam angle optimization (BAO) approach for Intensity-Modulated Proton Therapy (IMPT) by considering biological aspects of cancer treatment. Unlike conventional BAO methods that focus mainly on physical dose, our approach integrates proton therapy's biological effects incorporating Linear Energy Transfer (LET) into BAO to improve treatment effectiveness. This integration is critical as LET significantly affects the biological effectiveness of the treatment, promoting more personalized cancer therapies. We will present (1) a new group sparsity-based model for BAO, (2) a mini batch semi stochastic gradient descent algorithm (mS2GD PGCD) to enhance the speed of the BAO process without sacrificing dosimetric accuracy, and (3) a comparative analysis showing that incorporating LET into BAO with the LETinc mS2GD PGCD algorithm yields better OAR sparing than the LETinc FISTA algorithm and clinical angles. Our findings reveal that LETinc mS2GD PGCD not only enhances the overall treatment efficacy but also improves the sparing of organs-at-risk (OAR) compared to LETinc FISTA, emphasizing the importance of computational efficiency and biological impact in treatment plan optimization. Specifically, LETinc mS2GD PGCD achieves better control of mean and maximum doses across critical structures such as the brainstem and spinal cord, with reductions in cLET×D that suggest a lower risk of radiation-induced complications. These results underscore the superiority of the LETinc mS2GD PGCD algorithm in balancing the need for effective tumor control while minimizing damage to surrounding healthy tissues.

2 - A parametric column-and-constraint generation algorithm for a class of robust optimization problems under endogenous uncertainty

Jnana Sai Jagana, University of Minnesota, Minneapolis, MN, United States, Qi Zhang

Traditional robust optimization (RO) problems consider exogenous (or decision-independent) uncertainty sets, which can be limiting when the decisions affect the underlying probability distribution or the time of realization of the uncertain parameters. Recently, such endogenous (or decision-dependent) uncertainty has been considered in RO, where the resulting optimization problems have mostly been solved using reformulation techniques [1].

Previous works exploring solution strategies have shown that cutting plane methods also perform competitively for RO problems under exogenous uncertainty [2]. To our knowledge, only one existing work has developed a cutting plane method for RO with decision-dependent uncertainty [3]. The proposed cutting plane method scales better compared to the reformulation approach but is limited to problems where the decisions affecting the uncertainty are discrete.

In this work, we develop a cutting plane algorithm using a column-and-constraint generation (C&CG) strategy for RO under certain polyhedral endogenous uncertainty sets, where the decisions affecting the uncertainty can be both continuous and discrete. The proposed algorithm is applied to several numerical examples, and its performance and scalability compared to the reformulation technique are investigated.

3 - Graph-based Learning to Accelerate Two-Stage Robust Optimization in Power Grids

Rohit Dube, Texas A&M University, College Station, TX, United States, Harsha Nagarajan, Natarajan Gautam, Amarnath Banerjee

This talk presents a novel approach to accelerate mixed-integer two-stage adaptive robust optimization (ARO) problems within power grids with load and generation uncertainties by leveraging graph-based deep learning models. The problem involves mixed-integer “here-and-now” decisions for generator commitments and/or network topology variables, as well as an adversarial “wait-and-see” problem with non-convex recourse due to AC power-flow constraints. Traditional ARO methods face challenges in scalability and computational efficiency, particularly in large-scale power grid systems. To address these challenges, we propose a graph-based deep-learning ARO framework. In the framework, the first stage involves selecting decisions for the master problem by solving a mixed-integer program. Subsequently, in the second stage, the worst-case uncertainties corresponding to the first-stage decisions are determined based on the value function of a graph-based learned neural network model. Graph-based methods are used to capture local and global structural sparsity properties of power grids by updating node and edge representations based on relational dependencies within the grid. We demonstrate the effectiveness of our approach against the traditional column-and-constraint generation algorithm, through extensive experiments on realistic power grid datasets. The results showcase significant acceleration with a speed-up of about 10 to 20 times in solving ARO problems compared to traditional methods, with negligible compromise in solution robustness.

4 - K -Adaptability via Orthogonal Partition and Lifting

Zolykha Rezaei, Texas Tech University, Lubbock, TX, United States, Ningji Wei, Eojin Han

In numerous practical scenarios, professionals prefer policies that are not only interpretable but also straightforward to implement, particularly in settings involving sequential decision-making. In this research, we explore the concept of finite adaptability to construct robust optimization policies. More specifically, we address a general setting where uncertainty affects both the objective function and the constraints within the model. Our aim is to construct policies by partitioning the uncertainty realization and assigning a contingent decision to each segment. To effectively solve the robust optimization model under these conditions, we employ two distinct computational methods: Benders' decomposition and the dualization technique for linear functions.

1 - A New View of Neural Network-based Health Index: Connecting Visualization, Prediction, and Operational Decision Making

Zihan Li, University of Florida, gainesville, FL, United States, Minhee Kim

Multisensor signals are now easily accessible for remaining useful life (RUL) prediction and health state monitoring due to the quick advancement of sensor technologies. In order to optimize these signals for improved health condition assessment and RUL prediction, a variety of data fusion approaches are frequently used to generate health indices. However, most of the existing methods hardly consider the interactions between Prognostics and condition-based maintenance (CBM), which may not be effective for practitioners' asset management. To address the issue, we provide a new view of the Health Index that provides Connection Visualization between Prognostics and CBM, Prediction, and Operational Decision-Making Suggestions. In particular, a neural networks-based structure is used, and a novel loss function is developed by taking into account the variability of the generated health index at the failure time as well as its monotonicity. Once the prognostic model is trained, then we search for the best model weights that minimize the maintenance costs along “low loss curves” connecting various trained prognostic model weights. A case study on the degradation of aircraft gas turbine engines is also constructed which shows an improvement in maintenance costs of the proposed method.

1 - Relaxation Methods for Hierarchical Time Series Projection

Alkiviadis Mertzios, Massachusetts Institute of Technology, Cambridge, MA, United States, Georgia Perakis, Wei Sun, Yada Zhu

We consider the problem of Hierarchical Time Series (HTS) prediction to predict accurately time series that follow a hierarchical pattern i.e., the nodes are embedded in a tree graph and values of children nodes sum to the values of their parent. We introduce simple approaches to this problem that rely on linear regression, as well as more complicated methods based on projecting the predictions computed by linear regression. To calculate this projection we need to solve a non-convex optimization problem which is NP-hard. We use the Alternating Direction Method of Multipliers (ADMM) algorithm as a heuristic approach. This projection approach can be extended to any model that produces predictions for univariate time series, such as Random Forests or Neural Networks. We demonstrate the performance of our proposed methods to various applications including demand prediction.

2 - Food-Delivery Platforms: Near-Optimal Policies for Capacity Sizing, Order-Batching and Routing

Yang Bo, Chinese University of Hong Kong, Shatin, N.T., Hong Kong, Milind Dawande, Ganesh Janakiraman

We study the one-time capacity sizing and infinite-horizon real-time orders' batching and routing problem for a food delivery platform. The objective is to minimize the long-run average cost incurred per unit time, where the cost includes wages to servers plus the delay penalty cost. We characterize the fundamental trade-off between spatial economies of scale and orders' waiting time, and leverage this relationship to establish a lower bound on the cost under any policy for the platform. We then identify a simple, near optimal policy whose performance gap with respect to this lower bound vanishes in a meaningful asymptotic regime.

3 - Optimal Design for Revenue-Based Financing

Eryn Juan He, University of Utah, Salt Lake City, UT, United States, Joel Goh

Small businesses are a vital part of the American economy and workforce. However, the road to success for small business is not smooth. The second most common reason that small business fail is struggling to access capital. Revenue-based financing emerges as an alternative to allow small business to get financing without giving up equity or the burden of not flexible debt conditions. This work aims to compare this model with traditional loan model and aim to develop insights into the value of revenue-based financing as well as its optimal design.

4 - Extracting Efficiency from Chaos: Rider Behavior, Design and Performance of Dockless Bike Sharing Systems

Tunay Tunca, Robert H. Smith School of Business, College Park, MD, United States, Huan Cao, Jianfeng Lin, Weiming Zhu

We empirically explore rider incentives and efficiency of dockless bike sharing systems. Using transactional data from a major Chinese bike sharing company, we estimate the usage drivers for the system. We also study measures to improve efficiency, and compare the effectiveness of dockless versus dock-based systems.

5 - Share or Solo? Platform Design and Social Choices in Ride-Hailing

Ming Hu, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Jianfu Wang, Hengda Wen, Zhoupeng Zhang

Ride-hailing platforms offer riders pooling services, enabling them to share rides with other riders. The introduction of shared rides can mitigate the driver shortage and reduce rider wait times, especially in rush hours, but it may compromise riders' privacy, space, and security. We investigate a queueing model in which riders decide whether to join the queue and, if joining, whether to opt for a shared or solo ride based on past experiences of the wait times of each option. In the event of choosing a shared ride, riders may need to wait for another fellow rider for carpooling. We examine the optimal prices for inducing self-interested riders to choose a joining rate and a sharing likelihood that maximizes throughput, revenue, or social welfare. The optimal joining rate and sharing likelihood under revenue maximization are consistently lower than those under social welfare maximization and volume maximization. As the sharing experience improves (i.e., the potentially negative sharing externality stochastically increases) and the sharing likelihood remains constant (in alignment with observations from the Chicago ride-hailing data), the revenue-maximizing shared price rises while, surprisingly, the revenue-maximizing solo price decreases. This is because the platform needs to compensate solo riders more due to a more congested system resulting from increased ride uptake. Under social welfare maximization, the price difference between solo and shared rides is less than that under revenue maximization, yet, counterintuitively, the actual prices are not necessarily lower. We corroborate our theoretical findings with a numerical study using the Chicago ride-hailing data.

1 - Enhancing Semiconductor Yield Prediction Through Integrated Multi-View Analysis of TIME Constraint Tunnel and Equipment Usage Data

Young-Mok Bae, POSTECH, Pohang, Korea, Republic of, Chan-Young Jang, Kwang-Jae Kim

In the field of semiconductor manufacturing, yield is a crucial metric that affects the cost of overall fabrication. Yield prediction allows engineers to estimate the final cost before initiating production, effectively reducing the project risk associated with low yield. Previously, yield prediction was constrained by isolated data sources and expert judgment, particularly in the early phases of product development. As data collection capabilities within semiconductor companies have expanded, data-driven yield prediction using equipment usage data has gained traction. However, the usefulness of the equipment usage data is limited in nature because it can only show the status of the equipment. It is important to additionally leverage domain knowledge of the engineers because the semiconductor fabrication is highly process-intensive. In particular, the chemical property changes associated with the time wafers are exposed to air are known to affect the yield. This case study presents a methodology for yield prediction that integrates Time-Constrained Tunnel (TCT) data with equipment usage data through a three-step multi-view analysis approach. To enhance the interpretability of the yield prediction model, SHapley Additive exPlanations (SHAP) are also incorporated. This multi-view analysis approach enables engineers to capture the detailed temporal dynamics and equipment status, and thereby predict the yield more accurately. A case study, which utilizes actual data from a leading semiconductor manufacturer, demonstrates the effectiveness and scalability of this multi-view analysis approach.

2 - Enhancing Reduced-Order Modeling in High-Dimensional Engineering Applications through Hybrid XGBoost

Melika Baghi, Georgia Institute of Technology , Atlanta, GA, United States, Xiao Liu, Kamran Paynabar

Addressing forward problems with high-fidelity models like Computational Fluid Dynamics (CFD) and Finite Element Analysis (FEA) presents significant challenges due to their computational demands from high-dimensional spatial discretization. These models are expensive, requiring powerful solvers and extensive computational resources to achieve precise results. Additionally, their sensitivity to parameter variations complicates the accurate development of Reduced-Order Models (ROMs). Projection-based methods such as Proper Orthogonal Decomposition (POD) are typically employed to extract optimal basis modes from snapshot data for ROMs. However, these methods struggle to robustly quantify uncertainty, affecting their reliability and accuracy in practical applications.

My research explores a novel integration of XGBoost, known for its predictive accuracy and capability to handle complex relationships, with an innovative mapping technique between a multi-dimensional Euclidean space and the Grassmann Manifold, which represents low-dimensional subspaces. This mapping includes an injectivity constraint to enhance optimization, making XGBoost suitable with minor modifications. The approach involves mapping the subspaces from the Grassmann Manifold back to the Euclidean space to formulate a multivariate XGBoost regression. When introduced to a new parameter, this method projects the corresponding vector onto the Grassmann Manifold, facilitating the identification of the optimal subspace or POD basis. This process allows for a detailed understanding of how variations in settings affect the optimal representation in ROMs and quantifies the confidence in these insights, addressing limitations in traditional projection-based methods.

3 - Modeling and analysis of ambient drying process for biomass materials

Chenyu Xu, University of Georgia, Athens, GA, United States, Licheng Liang, Wuyang Chen, Zipeng Guo, Dan Li, Chi Zhou, Hongyue Sun

Traditional freeze-drying techniques, while preserving the 3D structure of biomass products, are notably time and energy-intensive. This study introduces an ambient drying approach, which not only accelerates the drying process and conserves energy, but also minimizes product deformation, surpassing the capabilities of both freeze drying and conventional ambient drying methods. We developed a drying setup equipped with an adjustable-speed fan, a camera and sensors to monitor weight, humidity, temperature, and visual changes during drying. Based on degradation analysis, we aim to accurately predict the drying process for future drying optimization and control, achieving an efficient balance between time, quality, and energy consumption.

4 - Integrating Physics Information for Material Degradation Modeling and Reliability Analysis

Ali Asgari, Wichita State University, Wichita, KS, United States, Wujun Si

In recent years, there has been a growing trend in using Machine Learning (ML) to predict the Remaining Useful Lifetime (RUL) due to its robust predictive capabilities. However, traditional ML and Artificial Neural Network (ANN) algorithms often require a large amount of data during the training phase, posing a challenge in real-world industrial environments where data collection is expensive. To overcome this challenge, we propose integrating physics knowledge with machine learning for material degradation modeling and life prediction. By incorporating physics information, the data demand for training can be significantly reduced. To validate the proposed method, we conducted multiple simulation studies and a real case study regarding material degradation and life prediction.

2 - Efficient parallel Bayesian parameter estimation of a simulation model via surrogates-assisted multiple-try Metropolis

Hyungjin Kim, Hanyang University, Seoul, Korea, Republic of, Chuljin Park, Heeyoung Kim

In semiconductor manufacturing, metrology methods have been developed to identify geometric measures, such as line width or height, of grating structures over different wafers. Among the metrology methods, the optical critical dimension (OCD) measurement is required to efficiently solve a set of parameter estimation problems of a simulation model to identify the geometric measures over different grating structures. In this work, we consider a set of parameter estimation problems in the Bayesian approach, called parallel Bayesian parameter estimation, which is motivated by the OCD measurement. The main objective is to efficiently identify the posterior distributions of parameters of a simulation model for a set of parameter estimation problems. Existing approaches focus on solving an individual parameter estimation problem, by sampling vectors that are assumed to follow a posterior distribution of parameters, via Metropolis-Hastings. However, the computational efficiency of the existing approaches significantly depends on the selection of the proposal distribution. We develop a novel framework, namely surrogates-assisted multiple-try Metropolis, that facilitates the multiple-try Metropolis with a surrogate model. Specifically, our framework introduces the proposal distributions with a surrogate model and simultaneously samples candidate vectors that are shared by a set of parameter estimation problems. We tested our framework in numerical examples and a case study in semiconductor manufacturing. The empirical results show that the proposed framework results in a high quality of the posterior distributions of parameters concerning both bias and precision while the limited simulation budget is used.

3 - Monitoring Energy Consumption from State-Space Models with Latent Variables Using Transfer Learning

Afshin Asadi, University of Miami, Coral Gables, FL, United States, Ramin Moghaddass

Identifying factors that influence the consumption behavior of industrial equipment, such as compressors and chillers, is a significant challenge that requires a comprehensive understanding of both the dynamic behavior of the equipment and hidden variables like efficiency and degradation status. Leveraging the capabilities of Variational Recurrent Neural Networks (VRNNs), our model uncovers latent patterns, contributing to a more accurate estimation of power consumption. By feeding real-time measurements into a Seq2Seq framework, enhanced with the power of LSTM (Long Short-Term Memory) networks, the model dynamically predicts power consumption over time. This VRNN architecture effectively encodes sequences into a compact representation and then decodes them to forecast future states, offering a comprehensive view of equipment performance.
Our approach stands out by combining advanced VRNN capabilities with the sequential processing strengths of the Seq2Seq architecture, enabling precise real-time predictions of power consumption in large industrial devices. This model not only captures immediate operational data but also delves into identifying underlying trends and patterns, providing insights for proactive energy management. The integration of these techniques results in a robust tool that goes beyond traditional monitoring, offering predictive analytics and optimization strategies for complex industrial environments. Additionally, a transfer learning method can be implemented to utilize vast historical data, making the model more accurate and effective by leveraging previously learned patterns and knowledge.

1 - Multitask Process Adjustment for Similar-but-non-identical Products and Processes in Cyber Manufacturing Systems

Yingyan Zeng, University of Cincinnati, Cincinnati, OH, United States, Xiaoyu Chen, Lening Wang, Ran Jin

A cybermanufacturing system aims to facilitate interconnected manufacturing processes with computational services, such as modeling and control. However, highly customized demands and heterogeneous manufacturing equipment in Cyber Manufacturing systems have posed significant challenges to the modeling and control needs of products' quality. For example, limited samples extracted from a customized product design with invariable process settings cannot meet the degree of freedom requirement of many quality-process models, hence leading to unsatisfactory modeling accuracy and control performance.
Therefore, it is important to consider the information (i.e., process settings and *in situ* process variables) shared from similar-but-non-identical products and equipment. In this research, we propose a multitask process adjustment (MPA) method to adjust process setting variables by jointly modeling setting-process and quality-process relationships. Defining a task as one product design or one manufacturing equipment, MPA method introduces variability to invariable process settings for one task by considering different settings from multiple tasks. Therefore, MPA method can adjust the process by optimizing setting parameters especially for the task without variability. The merits of the proposed method are illustrated by a feedforward control case studies in a selective laser melting (SLM) process.

Mengqi Shen, Columbia University, New York, NY, United States

TBD

3 - Distribution-in-distribution-out Regression

Xiaoyu Chen, University at Buffalo, Buffalo, NY, United States, Mengfan Fu, Yujing Huang, Xinwei Deng

Regression analysis with probability measures as predictor and response has gained increasing attention. However, extending existing univariate regression model to multiple linear regression model is challenging due to the non-flat Riemannian geometry of the Wasserstein space, hindering the definition of arithmetic operations, hence additivity is not well-defined. In this paper, a distribution-in-distribution-out regression model is defined by introducing parallel transport to enable provable commutativity and additivity of newly defined arithmetic operations in Wasserstein space. The Frechet least squares estimator is hence employed to obtain the best linear unbiased estimate via the newly established Frechet Gauss-Markov Theorem. To accommodate the practical needs, we further investigate a special case when predictors and response are all univariate Gaussian measures, resulting in a close-form solution of linear model coefficients and R-square metric. A simulation study and real case study in intra-operative cardiac output prediction are performed to evaluate the performance.

4 - Deep Distribution-in-distribution-out Neural Networks on Riemannian Manifold

Yujing Huang, University at Buffalo, Buffalo, NY, United States, Mengfan Fu, Xiaoyu Chen

Data collected from real-world systems commonly displays uncertainty, due to the randomness introduced by imperfect measurements and unknown physical processes. A natural method for addressing such uncertainty involves representing the data through probability distributions. However, existing statistical models are predominantly tailored for Euclidean data (e.g., scalar-, vector-, matrix-valued data) and thus fail to directly quantify relationships among probability distributions residing in non-Euclidean spaces.
Few studies have examined univariate regression models that regress a distribution-valued response on a distribution-valued predictor. Extension of these models to multiple regression is impeded by the lack of well-defined arithmetic operations, such as addition and scalar multiplication. A novel approach, the distribution-in-distribution-out (DIDO) regression model, establishes a linear additive framework on Riemannian manifolds, specifically Wasserstein spaces, enabling the construction of multilinear regression models for probability densities. Nevertheless, considering nonlinear regression model on a Riemannian manifold remains unclear, owing to undefined higher-order effects in the DIDO framework.
To model nonlinear relationships, this work defines a neural network structure based on the DIDO regression model on a Riemannian manifold. This research presents the first model capable of effectively handling distribution-valued data, expanding DIDO from single output to multiple outputs with a nonlinear structure. Additionally, our neural network architecture more accurately approximates underlying nonlinear relationships, thus enabling the modeling and inference of nonlinear system dynamics. Quantifying the nonlinear relationships among probability distributions is expected to broadly transform the current analytical tools by directly considering uncertainties in individual samples.

1 - Fair Fares for Vehicle Sharing Systems

Hyemi Kim, Columbia University, New York, NY, United States, Adam Elmachtoub

Vehicle sharing systems, like those for bicycles, scooters, and cars, have become essential transportation options, with fares often set by companies through mobile apps. This can result in users in different locations paying varying prices and experiencing unequal access. Platforms and regulatory bodies should consider how to set prices fairly to minimize the inequalities experienced by users across locations, for which we provide a framework and insights in this work. We consider two notions of fairness corresponding to price and access. Price fairness is a measure of how close the prices at two locations are to one another. Access fairness compares the fraction of demand at each location that has access to the system, where access is a product of affordability and vehicle availability. We analyze the impact of imposing these fairness measures on the revenue, consumer surplus, and social welfare using a stylized model with two locations. Under price fairness, we analytically identify regimes where consumer surplus at both locations can increase or can both decrease. We show that access fairness decreases consumer surplus at both locations, making all parties worse off. To address the non-convexity in generalized networks with multiple locations and vehicles, we design a sliding window method for price fairness and employ a convex relaxation technique achieving asymptotic optimality for access fairness. Lastly, a case study using real-word data of a vehicle sharing system operating in New York City shows that a significant gain in fairness can be achieved with a relatively small loss in revenue

2 - Foundations for Equitable Transit Networks

Sophie Pavia, Vanderbilt University, Nashville, TN, United States, abhishek dubey, Ayan Mukhopadhyay, J. Carlos Martinez, Philip Pugliese, Samitha Samaranayake

Public transit is vital for accessing essential services such as education, healthcare, and employment. While transit accessibility is important in general, some sections of the population depend critically on it. However, existing paradigms for public transit design neglect equity as a design objective, which hampers systemic progress toward equitable transit infrastructure. We present a mathematical formulation for transit network design that explicitly considers different constructs of equity and welfare. Our formulation is a mixed-integer linear program (MILP) based on a (linearized) piece-wise linear utility function that quantifies the utility a passenger reaps from the installed network compared to using personal vehicles. We also present two algorithmic approaches for equity-aware transit network design. To inform our model, we conduct a community survey of 673 residents from the city of Chattanooga, USA. We study the interaction between network design and different concepts of equity and showcase trade-offs based on real-world data from two metropolitan cities.

3 - Potty Parity: Process Flexibility via Unisex Restroom

Setareh Farajollahzadeh, University of Toronto, Toronto, ON, Canada, Ming Hu

We address unequal restroom access for women and LGBTQ+ individuals, known as the ``potty parity" problem. We propose a utility model where users consider gender identity, wait time, and safety concerns when choosing restrooms. We evaluate different layouts' efficiency by total utilities (totalitarian principle) and assess their fairness using minimum utility gain (Rawlsian fairness) and the gap between maximum and minimum gains (distributive fairness). While it may initially seem intuitive to assume that converting all restrooms to unisex facilities would be efficient due to the pooling of servers and increased flexibility and fairness due to all users standing in the same line, our findings demonstrate that this design can be neither efficient nor fair. In contrast, we show that converting some of the men's restrooms to unisex facilities can enhance both efficiency and fairness of access. This highlights that a moderate level of flexibility can surpass a fully flexible system. Moreover, conventional wisdom suggests that removing a unit of restroom from the men's room would negatively impact users from the men's side. However, our analysis reveals a counterintuitive result that such a change can lead to a Pareto improvement, benefiting all users involved. We also analytically explore additional benefits of unisex restrooms under different user behaviors and situations and present numerical results to support our findings. Moreover, we provide guidelines for inclusive renovation plans of restroom layouts based on the comfort levels of different population groups regarding sharing restrooms with users of other genders.

Location Analysis for Architectural Planning

Invited Session

Location Analysis

Chair: Kaori Isawa, Institute of Industrial Science, The University of Tokyo, Meguro, Japan

Co-Chair: Yudai Honma, The University of Tokyo, Meguro-ku, 153-8505, Japan

1 - Possibility of energy saving management through demolition and renovation of existing building stock

Kaori Isawa, The University of Tokyo, Meguro, Japan, Yudai Honma

In recent years, there has been a growing emphasis on adhering to the Sustainable Development Goals (SDGs); if we adhere to the SDGs to reduce CO2 emissions, we should consider replacing old, low-performance building stocks with new, high-performance ones. However, if we also follow the SDGs to utilize limited resources, we should continue using the existing building stocks. This dilemma presents a challenge in urban planning, as it involves balancing the objectives of demolishing and utilizing existing building stocks, namely, promoting new construction and encouraging renovation efforts. Therefore, in this study, we aim to address this conflict by proposing a framework for sustainable urban development, focusing on energy-efficient practices supported by quantitative evidence. Specifically, we seek to explore strategies integrating new construction and renovation initiatives to achieve optimal urban metabolism. Concerned with the current situation in Japan, which is a strong preference for new construction, we analyze the optimal effective subsidy investment pattern on Energy saving policy to design systems that make renovation a strong and attractive option. Specifically, we analyze it, focusing on the relationship between annual income and household distribution. In addition, we pay attention to the public's aversion to second-hand property and the mismatch between the utility of the public, who prefer to reduce construction costs without worrying about CO2 emissions and the government, who prefer to reduce CO2 emissions, which enables more real-world results to obtain.

2 - Proposal and Mathematical Examination of a Trajectory Estimation Model from Sparse and Noisy Location Data

Junya Maruyama, The University of Tokyo, Meguro, Japan, Yudai Honma

It is important to observe the actual behavior of users in order to analyze the utilization of buildings and the value of the space. On the other hand, indoor positioning within buildings, compared to outdoor positioning using GPS, presents technical difficulties due to the details of the space and the effects of obstacles. Regarding this problem, the trajectory estimation model, which is a mathematical model for estimation actual trajectories based on observation data, has been evolving. Existing trajectory estimation techniques have pursued the technology to observe as much observation data as possible and to observe very detailed trajectories. However, introducing such observation modules is often difficult, and the accuracy of the trajectory is often excessive. Therefore, this study naturally constructs a model to observe trajectories with appropriate detail using sparse and noisy location data and redefines the model as an estimation algorithm using the Hidden Markov Model (HMM) commonly used in existing research. The goal of this trajectory estimation model is to extract trajectories at the meter level from room-level observation data. The initial trajectory estimation model is formulated as a natural and intuitive mathematical model that minimizes the sum of the squares of the distances between stay points and location information, as well as the moving distance. This formulation can be redefined as an algorithm using the HMM. By performing this redefinition, it becomes possible to examine the characteristics and advantages of the proposed model, which will provide useful information for future studies on the accuracy of trajectory estimation.

3 - Year-Round Shadow Analysis for Pedestrian Space in Vertical Urban Environments

Hiroko Watanabe, Institute of Industrial Science, The University of Tokyo, Meguro, Japan, Yudai Honma

In recent years, as urban areas have increasingly developed vertically, there has been a growing trend toward creating walkable cities that maintain a human scale. However, with the intensifying effects of global warming, summer heat has become more severe, with last summer's unprecedented heatwaves still fresh in memory. Despite these harsh outdoor conditions, people still desire to walk through the city and enjoy its attractions. In Japan, people prefer walking in sunny spots during winter and shaded areas during summer, indicating a need for comfortable pedestrian spaces. This study aims to understand the shadows cast by buildings throughout the year, which is crucial for designing pleasant pedestrian environments. In highly vertical urban areas, the extensive shadows from tall buildings significantly impact pedestrian spaces. Given that the preferred shadow conditions for pedestrians vary with the seasons, it is essential to monitor building shadows throughout the year. Therefore, this research conducts large-scale and detailed spatiotemporal shadow simulations to capture these dynamics. By understanding the annual variations in shadows, we can demonstrate their impact on pedestrian spaces, ultimately contributing to the design of more comfortable urban environments.

4 - A Study on Spatial Cognition of Visitors Using Mathematical Analysis of Visitor's Movement Within An Art Museum Gallery

Yunqing Hu, Institute of Industrial Science, The University of Tokyo, Meguro, Japan, Junya Maruyama, Kaori Isawa, Yudai Honma

In China, art museums are gaining more attention nowadays but visiting them is still not a popular lifestyle. With the emergence of open-plan galleries with non-fixed routes in the beginning of 21st century, the necessity of the then trendy large-scale central space and the traditional sequential art viewing experience is challenged. In this research, we aim to understand the navigation patterns of visitors and through which to identify their spatial cognition in open-plan gallery spaces. First, to understand the navigation patterns of visitors, a random Delaunay network (rDn) is applied to the target plan, and the hidden Markov model is introduced, in which the hidden state being the location of visitor, and the observation state as the artwork being viewed. Given various artwork viewing sequences, we are able to discover the best hidden state sequences of transition from locations to locations, thus obtain possible viewing routes within the target art gallery. Second, to identify visitor's spatial cognition with in the target art gallery, the resulted viewing routes is clustered and analyzed. The goal of this research is to develop a methodological reference for future art museum design, to create more relaxed and welcoming art viewing and interacting environment, and to assist with the promotion of art museum culture and lifestyle to the society from an architectural point of view.

5 - Mathematical Consideration on the Method for Enumerating Spaces "Without Omissions and With Omnipresence" for the Algorithm of Automatic Generation of Architectural Spaces

Keito Nakagawa, The University of Tokyo, Setagaya-city, Tokyo, Japan, Yudai Honma

Previous studies have focused on the "form" of the architectural space and conducted mathematical studies of methods to analyze it. One such method is to consider the inner-convex space. Convex space has the property that any people in it can interact with each other, and it can be one of the indicators to estimate where in the architectural space the interaction of people is promoted. However, the proposed algorithm for enumerating inner-convex spaces does not enumerate them in a spatially "without omissions and with omnipresence" manner. In this study, we assume that enumerating a space "without omissions and with omnipresence" is an important factor in human consideration of the inner space. Enumerating the space "without omissions and with omnipresence" is also useful in the construction of automatic design algorithms. It is realistic to use an automatic design algorithm in which several plausible patterns are presented and compared with each other, and the final plan is determined by human consideration. In order to enumerate spaces "without omissions and with omnipresence," we first focus on the generation probability of inner spaces. The existence of boundaries causes variations in the probability of its creation. We will examine this using geometrical methods and mathematical optimization algorithms, and clarify the characteristics of inner spaces. Next, we clarify the conditions necessary to enumerate spaces "without omissions and with omnipresence" from the viewpoints of both computer experiments and mathematical theory.

Innovations in Logistics and Transportation Networks

Flash Session

Contributed

Chair: Amin Keramati, Widener University, New York, 19082, United States

1 - Introducing a Web Application Leveraged by An Optimized Proximity Algorithm to Improve Logistics Network Efficiency and Reduce Travel TIMES

Amin Keramati, Widener University, Chester, PA, United States

This study introduces a web application powered by a proposed Optimizing Proximity Algorithm designed to enhance logistics network efficiency by improving travel time. The application leverages advanced spatial analysis and data-driven approaches to identify the nearest facilities—such as restaurants, retailers, storage units, and warehouses—based on user-defined criteria in the search function. It performs routing and travel duration analyses to minimize travel distances and optimize delivery speeds, taking into account various business factors like transportation modes, departure times, and operating hours.

The presentation will highlight how the application and its algorithm adeptly process both real-time and historical logistics data, considering elements like traffic patterns and geographical constraints, utilizing tools like the Google API and Google Places library. By offering interactive maps and outputs, the application supports more informed decision-making in logistics management. This leads to optimized resource and location utilization, cost reductions, and a significant decrease in the environmental footprint of logistics activities.

2 - Density Tensor Factorization for Sediment Source Analysis

Nicholas Richardson, University of British Columbia, Vancouver, BC, Canada, Naomi Graham, Michael Friedlander, Joel Saylor

Detrital zircon grains carry history about the formation of geological structures and sources of precious minerals. DZ Grainalayser is a new tool we develop for identifying sediment sources from mixtures of detrital zircon grains with arbitrary number of features. We test the model's effectiveness at using constrained tensor factorization to demix high dimensional distributions on real world sediment data. Finally, we show its portability to diverse tasks like identifying cell types in spatial transcriptomics.

3 - A Neural Optimization Machine Approach for the Fixed-Price Game Among E-hailing Drivers

Hanwen Dai, Tsinghua University, Beijing, China, People's Republic of

This study introduces a novel approach to optimize the allocation of fixed-price drivers in a dynamic ride-sourcing environment. Initially, a forecasting neural network is trained to predict the joint order matching probabilities for various driver types. Leveraging the forecasting model, a Neural Optimization Machine (NOM) is devised to determine the optimal number of fixed-price drivers.

Ride-sourcing market involves diverse drivers with varying characteristics such as vehicle types and activeness. This heterogeneity poses a significant challenge in accurately forecasting order matching probabilities across different driver categories. Employing neural networks, which excel in capturing intricate nonlinear relationships, we analyze real-world operational data from a Chinese ride-sourcing company.

Drivers' decision to accept fixed-price orders impacts the supply structure. With our fitted model, we investigate the ideal proportion of fixed-price drivers for each driver type, aiming to either maximize total service reward or ensure fairness among drivers. Yet, neural networks are often perceived as opaque due to their layered structure and nonlinear activation function. To address this challenge, we introduce a NOM that operates on top of the forecasting model. It incorporates an additional objective construction layer to translate predicted matching probabilities into a target objective. Furthermore, a decision layer, powered by a customized softmax activation function, categorizes drivers into fixed-price and non-fixed-price groups. During the optimization process, the network's backpropagation algorithm updates only the parameters of the decision layer while keeping other layers fixed. Once the objective function converges, the updated weights of the decision layer yield the optimal driver allocation strategy.

4 - Chance Constrained Problem Based On Compound Poisson-gamma Distribution

LANQING DU, Drexel University, Philadelphia, PA, United States, Jinwook Lee

This study combines a compound probability distribution with a chance-constrained model to enhance its capacity in representing various intricate business operations. Specifically, we focus on the numerical techniques used to manage uncertainties, introducing an algorithm that effectively implements multivariate p-quantile (p-level) efficient points under independent and identically distributed (i.i.d.) conditions. To elaborate on the numerical results, our algorithm is applied within a framework of finite-period equipment portfolio problem.

5 - Interpretable Tabular Reinforcement Learning Applied to Revenue Management Problems

Adam Page, Lancaster University, Lancaster, United Kingdom, Anna-Lena Sachs, Christopher Kirkbride, James Grant

Motivated by the challenge of pricing pre-bookable airport car parking, we consider revenue management problems with non-stationary demand. Customers differ by each having their own willingness to pay, buying preferences, lead time and length of stay. Instead of using classical dynamic programming approaches which suffer from the curse of dimensionality, we propose tabular reinforcement learning methods to find an interpretable solution while reducing the effect of added dimensionalities. These methods can be implemented online which allows an agent to react to changes in customer buying patterns. We show the effectiveness of algorithms such as Q-learning with cross-learning to tackle these challenges.

Operations Planning to Ensure Food Security

Contributed Session

Contributed

Chair: Clara Novoa, Texas State University, 601 University Dr, San Marcos, TX, United States

1 - A Conceptual Framework for Decision Support Systems in Food Safety Investigations

Sandra Rudeloff, Kühne Logistics University, Hamburg, Germany, Hanno Friedrich

Unsafe food results in approximately 600 million cases of foodborne illnesses and 420,000 deaths worldwide, posing a significant global health and economic challenge. Despite advancements in food safety practices and investigations, these outbreaks continue to occur and often remain unsolved or are resolved too late to prevent further illnesses.

Traditional methods for investigating outbreaks, predominantly relying on patient interviews, are hampered by recall bias and substantial time demands. To address these limitations, emerging methods that leverage previously untapped data sources, such as retail data or food supply networks, show promise. However, the practical implementation of these methods is often restricted by a lack of awareness or understanding, as well as constraints related to data availability. This creates a significant gap in the comprehensive overview and effective use of both traditional and new methods, preventing investigators from fully utilizing all available options to resolve ongoing outbreaks.

To bridge this gap, we propose a conceptual framework designed to guide the development of decision support systems for food safety investigations. This framework systematically outlines potential investigative pathways and pinpoints relevant data sources for identifying contaminated food items and their origins. It assesses how data quality and availability may vary based on geographical location and outbreak contexts. Additionally, by demonstrating effective utilization of pre-collected data, the framework promotes their systematic collection, thereby enhancing preparedness for future outbreaks. Our framework broadens the investigative toolbox for food safety by incorporating alternative methods and data, offering more diverse options to effectively tackle foodborne outbreaks.

2 - Measuring Food Waste Impact of Perishable Inventory Management Solutions

Clement Micol, Afresh Technologies, Brooklyn, NY, United States, Marc Goessling, Aaron Stern, Mark Velednitsky, Carl Vogel

As sustainability goals are receiving ever-increasing attention, grocery corporations are incentivized and expected to track their food waste. The common approach in the industry is to compute some notion of missing product units, referred to as "shrink." However, accurately calculating food waste at the store level over a given time period is a difficult task in the presence of imperfect shipment, sales, and inventory data.

In this talk, we discuss three different food waste metrics, the practical challenges we encountered when using them and the corresponding solution approaches we explored. One source of large measurement noise when tracking food waste is the inaccuracy of ending inventory counts, caused for example by typos or wrong item lookups. Item-level errors can be combated through data quality checks and data filtering. We also discovered that subtle differences or changes in truck delivery schedules can cause an outsized effect on food waste metrics for a given accounting period. As a solution in synthetic control analyses, we propose a post-hoc alignment procedure on delivery schedules.

Lastly, we discuss the benefits and difficulties of food waste measurement through scan-outs, which are unit counts of expired items provided by grocery store associates.

3 - Preventing Food loss and Food waste in Food Supply/Value Chains

Ramesh Bollapragada, San Francisco State University, San Francisco, CA, United States

This project motivated by the Food loss and Food waste that is prevalent in current Food supply chains. Food loss occurs before the consumer and supermarket level that includes crop loss due to pests, farming techniques, insufficient storage space, and obsolescence due to logistics bottlenecks in the supply chain. Food waste happens at the end consumer level (e.g. restaurants, households discarding food due to lower consumption than the amount produced, and obsolescence arising from poor inventory management). The Food loss and waste in the world is estimated at 30-40% (i.e. more than a third of the food made is wasted). The estimated loss and wastage for fruits and vegetables is even higher (40-50%). These numbers amount to a loss of over $2.5 trillion USD per year globally (with half a trillion USD in United States alone), while over a billion people globally are suffering from malnutrition and unavailability of food.

We present a framework that outlines the above issues in developed and developing countries, identifying the areas of improvement to make a significant impact in savings in the above loss.

4 - Identifying Critical Factors Affecting Inventory Costs and Optimizing the Pick-up and Delivery of Donated food at the Central Texas Food Bank

Clara Novoa, Texas State University, San Marcos, TX, United States, Jakir Hassan

We present the results of experimenting with a multi-period multi-product inventory model developed for assisting the Central Texas Food Bank with their food procurement plans. The factors (i.e., model parameters) that affect more significantly the model costs are identified.

We also present a mixed-integer programming model to optimize the pick up and delivery of food procured and donated considering an heterogeneous fleet of vehicles. The routing model provides a cost-efficient plan for designing the daily routes.

5 - Heterogeneity of willingness to accept for using reusable cups based on framing effect: A causal forest approach

Sung-Eun Chang, Korea University, Seongnam-si, Korea, Republic of, JongRoul Woo

Worldwide, 139 million tons of single-use plastic waste was generated in 2021. Accordingly, governments and commercial facilities implement a variety of efforts to encourage consumers to continue their sustainable behavior. Among them are incentive programs that offer monetary benefits when customers bring their own reusable containers/cups. Persuasive communications could be a key part of increasing consumer acceptance of these programs. Relatedly, framing messages in terms of gains and losses has been extensively studied and has been shown to be effective in many cases. However, the impact of this framing can also be heterogeneous depending on the consumer. In this study, we analyze the treatment effects of framing on the intention to use reusable cups for individuals. Causal Forest, a machine learning methodology, can effectively identify the heterogeneity of treatment effects between subgroups in the data and capture complex non-linear relationships and interactions. These findings provide policy implications for effective incentive programs for the use of reusable cups.

Operations and Market Design for Education

Invited Session

Auctions and Market Design

Chair: Faidra Monachou, Yale University, New Haven, CT, United States

1 - Optimal Cohort Partitions

Faidra Monachou, Yale University, New Haven, CT, United States, Sofoklis Goulas

The optimal cohort partition problem involves the partition of a heterogeneous population of individuals into distinct groups to optimize the objective of a social planner. Unifying results from optimization and majorization theory, we characterize the structure of optimal cohort partitions across various objectives and applications. Our primary focus is on a common educational application: how to optimally partition students into classes in the presence of peer effects. We employ the workhorse linear-in-means (LIM) model from the empirical literature on peer effects in education and study two different behavioral microfoundations: the LIM spillover model and the LIM conformist model. We theoretically characterize the optimal partition for various objectives---performance, welfare, diversity, inequality---and find that, within the same behavioral model, trade-offs are not always inevitable. We derive several policy-relevant insights. First, in both behavioral models, we show that as the planner's highest priority shifts from the top-performing class to the least-performing class, the optimal partition becomes progressively less assortative. Second, we show that, while both behavioral models agree on the optimal partition policy for performance, diversity, and inequality, they disagree on the welfare-optimal policy. Third, we find that the commonly used uniform partition, despite achieving lower inequality than any integral partition, does not achieve perfect equality. We illustrate these theoretical findings in simulation exercises with student data from a novel dataset of public high schools in Greece. Finally, we showcase how our theoretical framework extends beyond educational contexts by characterizing the optimal assignment of experts to teams and the design of Tullock contests.

2 - Stable Matching with Contingent Priorities

Ignacio Rios, The University of Texas at Dallas, Richardson, TX, United States, Federico Bobbio, Margarida Carvalho, Alfredo Torrico

We study stable matching problems under contingent priorities, whereby the clearinghouse prioritizes some agents based on the allocation of others. Using school choice as a motivating example, we first introduce a stylized model of a many-to-one matching market where the clearinghouse aims to prioritize applicants with siblings assigned to the same school and match them together. We provide a series of guidelines to implement these contingent priorities and introduce two novel concepts of stability that account for them. We study some properties of the corresponding mechanisms, including the existence of a stable assignment under contingent priorities, its incentive properties, and the complexity of finding one if it exists. Moreover, we provide mathematical programming formulations to find such stable assignments whenever they exist. Finally, using data from the Chilean school choice system, we show that our framework can significantly increase the number of siblings assigned together while having no large effect on students without siblings.

3 - Rethinking the Role of Teacher Evaluation: An Analysis of Its Impact on Quality, Workforce Dynamics, and Student Outcomes

Hemanshu Das, Yale University, New Haven, CT, United States, Edieal Pinker

In the realm of public education, the quality of teachers is an influential factor that shapes student outcomes and, subsequently, their future prospects. The study delves into the impact of teacher evaluation programs, on teacher quality, student outcomes, budget considerations, workforce dynamics, and hiring requirements. A case study of the District of Columbia Public Schools (DCPS) illustrate the diverse outcomes of evaluation systems. DCPS's IMPACT evaluation system yields 0.46 standard deviation increase in teacher quality, leading to incremental classroom incomes of $67,403 but comes at an additional cost of $16,992 per teacher annually. The study elucidates the multifaceted considerations involved in teacher evaluation systems, emphasizing the need to weigh factors such as retention probabilities, availability of proficient teachers, correlation between evaluation measures, and budgetary implications. By offering quantitative insights into these dynamics, we hope to equip policymakers and educators with guidance for enhancing teacher quality and elevating student outcomes within public education systems.

4 - 30 Million Canvas Grading Records Reveal Widespread Sequential Bias and System-Induced Surname Initial Disparity

Jiaxin Pei, University of Michigan, Ann Arbor, MI, United States, Zhihan Wang, Jun Li

The widespread adoption of learning management systems in educational institutions has yielded numerous benefits for teaching staff but also introduced the risk of unequal treatment towards students. We present an analysis of over 30 million Canvas grading records from a large public university, revealing a significant bias in sequential grading tasks. We find that assignments graded later in the sequence tend to (1) receive lower grades, (2) receive comments that are notably more negative and less polite, and (3) exhibit lower grading quality measured by post-grade complaints from students.

Furthermore, we show that the system design of Canvas, which pre-orders submissions by student surnames, transforms the sequential bias into a significant disadvantage for students with alphabetically lower-ranked surname initials. These students consistently receive lower grades, more negative and impolite comments, and raise more post-grade complaints as a result of their disadvantaged position in the grading sequence. This surname initial disparity is observed across a wide range of subjects, and is more prominent in social science and humanities as compared to engineering, science and medicine. The assignment-level surname disparity aggregates to a course-level surname disparity of students' GPA and can potentially lead to inequitable job opportunities. For platforms and education institutions, the system-induced surname grading disparity can be mitigated by randomizing student submissions in grading tasks. Education institutions should keep the workload of graders at a reasonable level to reduce fatigue and/or have multiple graders as a cross validation to enhance grading quality.

Job Market Candidates Session Focusing on Social Impact Operations

Invited Session

Auctions and Market Design

Chair: Alp Sungu, Wharton, Philadelphia, PA, United States

1 - You Can't Shake Your Past -- Prior Ratings, Gender and Instructor Outcomes in Higher Ed

Tong Wang, London Business School, London, United Kingdom, Kamalini Ramdas, Monika Heller

Instructor ratings facilitate students' course choice decisions. While theory suggests that quality signals can introduce bias, the impact of prior teaching ratings remains unstudied in Higher Ed – where there is evidence of gender bias in traditional classrooms. We ran controlled experiments to examine these sources of bias in online Higher Ed delivery. Experimental findings indicate that low prior ratings significantly diminish the likelihood of positive evaluations, particularly for novice learners and for instructor-focused outcomes. Also, gender bias persists online. Female learners exhibit bias against male instructors, while male learners exhibit bias against female instructors, with effects concentrated on conditions where learners face high cognitive load due to time pressure. The bias against male instructors is more pronounced among older or less educated learners, whereas the bias against female instructors is more pronounced among younger and more educated learners. Furthermore, we find evidence of a strong interaction between prior ratings and instructor gender for male learners. Without time pressure, male learners exposed to low prior ratings correct the unfairly low ratings for male rather than female instructors. Under high time pressure, male learners exposed to high prior ratings increase their ratings for male instructors, exhibiting confirmation bias. Our research highlights the deleterious consequences of the widespread practice of sharing instructor ratings with learners. We also provide evidence of gender inequity under different prior ratings and time pressure conditions, highlighting potential levers to mitigate such bias.

2 - Designing Algorithmic Recommendations to Achieve Human-AI Complementarity

Bryce Mclaughlin, University of Pennsylvania, Philadelphia, PA, United States, Jann Spiess

Algorithms frequently assist, rather than replace, human decision-makers. However, the design and analysis of algorithms often focus on predicting outcomes and do not explicitly model their effect on human decisions. This discrepancy between the design and role of algorithmic assistants becomes of particular concern in light of empirical evidence that suggests that algorithmic assistants again and again fail to improve human decisions. In this article, we formalize the design of recommendation algorithms that assist human decision-makers without making restrictive ex-ante assumptions about how recommendations affect decisions. We formulate an algorithmic-design problem that leverages the potential-outcomes framework from causal inference to model the effect of recommendations on a human decision-maker's binary treatment choice. Within this model, we introduce a monotonicity assumption that leads to an intuitive classification of human responses to the algorithm. Under this monotonicity assumption, we can express the human's response to algorithmic recommendations in terms of their compliance with the algorithm and the decision they would take if the algorithm sends no recommendation. We showcase the utility of our framework using an online experiment that simulates a hiring task. We argue that our approach explains the relative performance of different recommendation algorithms in the experiment, and can help design solutions that realize human-AI complementarity.

3 - Improving compliance to enhance outcomes in algorithmic refugee assignment

Anand Kalvit, Stanford University, Stanford, CA, United States, Yonathan Gur, Jens Hainmüller

The assignment of refugees to resettlement locations within a host country presents complex challenges, particularly given the limited capacities at these locations. Traditionally, placements are decided by case officers based on their experience and expertise, which may not align with the recommendations of data-driven algorithms designed to optimize long-term outcomes while considering capacity constraints. This misalignment can lead to inefficiencies and suboptimal matches. To address this issue, we propose an innovative approach that incorporates future-accountability into the decision-making process by linking a case officer's utility to both immediate and future allocations. This approach increases compliance with algorithmic recommendations, thereby enhancing the overall effectiveness and efficiency of the resettlement system. We demonstrate the benefits of our approach through numerical experiments, showing significant improvements in match quality and system performance.

4 - Childcare Shortage and Talent Retention in the Knowledge Industries

Zhihan (Helen) Wang, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, Damian Beil, Jun Li

Achieving an equitable workplace goes beyond ensuring unbiased treatment at work; it also involves addressing the hidden burdens employees face in managing household responsibilities, where childcare is a critical component. The shortage of reliable childcare services can hinder the career progression of young professionals, resulting in higher turnover rates and a more volatile workforce. This challenge is especially pronounced in knowledge-driven sectors like finance, technology, and professional services, where high turnover and frequent handoffs create significant inefficiencies due to the costly nature of knowledge transfer. Leveraging a comprehensive national job profile data from 1997 to 2019, we investigate how the turnover rates of workers in knowledge industries are influenced by the availability of childcare services nearby their working sites. This research offers practical implications for both social planners and employers, emphasizing the need for accessible, conveniently located childcare services to enhance the well-being and productivity of working parents.

Vehicle Routing and Last Mile Delivery

Flash Session

Flash

Chair: Hyeseon Lee, 1400 Townsend Dr, 49930

1 - Evaluating Temporally-Consolidated Last mile Delivery Model: Integrating Per-order and Subscription Pricing

Behnaz Naeimian, York University, Toronto, ON, Canada, Opher Baron, Mehdi Nourinejad, Peter Park

As same-day delivery continues to appeal for its convenience and efficiency, its substantial operational costs remain a barrier to broader adoption. This study proposes a "Temporally-Consolidated" (TC) delivery model, specifically designed for recurring purchases such as groceries, which schedules deliveries on predetermined days to minimize the transportation costs linked to sporadic same-day deliveries. This model depends on customer flexibility to adhere to predefined delivery schedules. We explore two pricing strategies within the TC framework: per-order charges and a subscription model. Our analysis assesses customer utility for each pricing strategy, including comparisons to traditional same-day delivery. By employing a profit model that incorporates these utilities, we assess the impact of these strategies on overall profitability. Results indicate that a mixed approach, combining both per-order and subscription plans, maximizes profitability by accommodating varying customer buying patterns: infrequent purchasers prefer per-order plans, while frequent buyers opt for subscriptions. This study offers significant insights into the viability of TC delivery, underscoring its potential to enhance profitability and meet the needs of diverse consumer segments.

Keywords: Last mile delivery, temporally-consolidated delivery, customers' utility, frequent and infrequent customers, subscription pricing, per-order pricing, transportation costs, profit model.

2 - Key Factors of Service Time for Urban Deliveries in the U.S.

Oriana Calderon, Rensselaer Polytechnic Institute, Troy, NY, United States, Andres Regal Ludowieg, Jose Holguin-Veras

The significant growth of e-commerce in recent years has led to a higher number of packages delivered to households and an increase in truck stops across the United States, which has, in turn, affected the service time for urban deliveries. In light of this, this research aims to identify the key socio-economic, spatial, and package attributes that determine service time—defined as the time between when the truck driver parks and when the package is delivered—for urban deliveries. This research utilizes the publicly available dataset from the 2021 Amazon Last Mile Routing Research Challenge and focuses on five major metropolitan areas: Austin, Boston, Chicago, Seattle, and Los Angeles. An interaction index was used to identify the economic center of the cities. Through econometric modeling, the research identifies the most significant factors that determine service time for urban deliveries in these areas. The results reveal interesting commonalities across the metropolitan areas considered, including shorter service times associated with larger household sizes, shorter service times with increased distance from the delivery location to the economic center of the cities, and longer service times for larger package sizes. Understanding these key factors is essential for optimizing delivery processes, reducing delivery times, and enhancing overall efficiency in urban logistics, thereby promoting more sustainable delivery systems.

3 - Add to Order in Contingent Free Shipping

Yuxuan Tang, National University of Singapore, Singapore, Singapore, Xiaobo Li, Rowan Wang, Xuan Wang

This paper explores the impact of a contingent free shipping policy combined with an "add to order" option, recently implemented by online grocery and food delivery platforms such as Amazon Fresh, Instacart, and Doordash. The "add to order" feature allows customers to append items to their existing orders without incurring additional shipping fees before a specified cutoff time. This study investigates the balance between immediate revenue increases and potential long-term profitability impacts. The central questions addressed include the overall value of the "add to order" feature to the platform and the optimal adjustment of free shipping thresholds and shipping fees following its implementation.

4 - An Exact Solution for Chance-Constrained Two Echelon Vehicle Routing Problem with Autonomous Delivery Robots

Dan Liu, Kean University, Union, NJ, United States, EVANGELOS KAISAR

This paper investigates the challenges of planning and operating an efficient E-grocery delivery system utilizing Autonomous Delivery Robots (ADRs) during peak demand periods. ADRs, critical in facilitating last-mile deliveries from vans at satellite nodes, operate within a structured two-echelon network. This study addresses key operational constraints such as customer delivery deadlines, and ADR energy limitations. We formulate a two-echelon vehicle routing problem that incorporates stochastic service times and demands. To tackle this problem, we employ a chance-constrained model and develop an efficient solution approach based on column generation. Central to our approach is a novel labeling algorithm that integrates two strategies for constructing the routes. To enhance the solution's reliability, we apply statistical inference techniques to ensure compliance with the chance constraints. Our results demonstrate the effectiveness of the stochastic formulation in reducing costs, showcasing significant improvements over traditional methods.

5 - Temporary medical shelter location-routing problem with manpower allocation in disaster situation

Joonghoo Park, Korea University, Seoul, Korea, Republic of, Hyungjoo Cha, San Kwon, Taesu Cheong

In this study, we focus on developing an efficient algorithm for medical operations system. We present a mathematical programming model addressing temporary medical shelter location-routing problem with manpower allocation (TMSLRPwMA). The proposed model integrates the ambulance routing problem and the temporary medical relief shelter location problem by considering the healthcare staffing requirements of patients. It is novel in the sense that we consider number of rescue staffs required in response to the patient demand. We aim to minimize the response time under patient's status, together with the staff allocations and vehicle usages. The concomitant problem is NP-hard, as TMSLRPwMA is a general case of the location-routing problem, and thus we design a hybrid genetic algorithm to retrieve good-enough solutions under a reasonable calculation time. Computational results under different scenarios are provided to demonstrate the validity of the proposed algorithm for various situations.

6 - Locomotive Routing for Torpedo Ladle Car Transportation in the Steel Industry

Ohhyun Kweon, POSTECH, Pohang, Korea, Republic of, Byung-In Kim

The locomotive routing problem (LRP) deals with the optimization of locomotive routes for transporting torpedo ladle cars in the steel industry. LRP belongs to a family of pickup and delivery problem time windows with Last-In First-Out constraints. We extended LRP considering many-to-one and one-to-many requests, along with additional facilities and practical constraints. Two mathematical models and a matheuristic algorithm based on logic-based Benders decomposition approach are proposed. For the 20 randomly generated small-sized instances, the mathematical model could mostly provide solutions optimally, while the matheuristic algorithm provided near-optimal solutions. In the case of 20 medium- and large-sized instances, the mathematical model failed to find a solution, whereas the matheuristic algorithm generated good feasible solutions, outperforming Adaptive Large Neighborhood Search algorithm for all instances.

7 - Heuristic Strategies for Optimizing MDVRP Bridging Transshipment and Assignment Problems in Supply Chain Logistics

Pitchaya Pongmanawut, Chiang Mai University, Chiang Mai, Thailand, Chulin Likasiri

In this work, we address the Multiple Depot Vehicle Routing Problem (MDVRP), a complex optimization task involving depots, suppliers, and customers. Our problem includes a general structure in which routes start at depots, pass through suppliers to gather raw materials, then return to depots to be transformed before delivering the final product to customers. We decompose the problem into transshipment and assignment sub-problems, tackling them sequentially to optimize resource utilization and minimize operational costs. We propose heuristic methods designed for the MDVRP setting in order to tackle the natural complexity. The algorithm is made to minimize overall distance traveled and match vehicle constraints, all the while navigating the complex network of suppliers, depots, and customers in an efficient way. Our approach is continually compared with current methods after being established through considerable experimentation on benchmark instances. The results demonstrate the effectiveness of our proposed heuristics in achieving competitive solutions for real-world supply chain logistics optimization.

Keywords: MDVRP, transshipment problem, assignment problem, heuristics

8 - Heuristic Approaches for Vehicle Routing Problems with Collaborative Multiple Heterogenous Robotic Systems in Complex Scenarios

Hyeseon Lee, Michigan Technological University, Houghton, MI, United States, Abhishek Patil, Myoungkuk Park, Jung Yun Bae

Finding efficient task allocation and routes, known as the vehicle routing problem (VRP), is crucial for the operations of multi-robot systems, particularly in scenarios involving heterogeneous agents with collaborative motion. When applications involve large and complicated scenarios, prioritizing a solution that offers a good approximation within a reasonable timeframe proves more beneficial than striving for an exact solution. This research addresses this necessity by introducing two heuristic approaches capable of resolving VRPs with various constraints.

The first approach utilizes the Large Language Model (LLM) to tackle generalized problems. We initially provide feasible solutions to small-size problems to the LLM, optimizing the prompts with detailed descriptions of task attributes, constraints, and environmental conditions. By guiding the LLM through iterative prompt refinement, it learns the user requirements and generates feasible routes for each robot while minimizing the objective function. On the other hand, the second heuristic approach adopts a greedy strategy, iteratively enhancing solution quality from an initial feasible solution while satisfying all pertinent constraints. While the LLM-based approach accommodates a broader spectrum of problems, its tendency to produce infeasible solutions necessitates caution. In contrast, the heuristic approach offers stability, guaranteeing feasibility by incorporating all constraints within its mathematical formulations.

Both approaches are implemented and tested in simulations with multiple scenarios, varying the number of tasks, robots, and constraints to validate the effectiveness of the proposed methods. The computational results are presented, showing the potential of the approaches to be utilized in real-world applications.

Chair: Devin Zhang, 352 Business Building, 16802

1 - The Best Time to Play the Lottery

Christopher Rump, Bowling Green State University, Bowling Green, OH, United States

The best time to play the lottery is when the jackpot has rolled over several times and grown large, but not so large that you must share the prize if you win. We examine maximizing the expected value of a winning ticket as well as that in a random ticket. The derived optimality criteria depend on the prize elasticity of ticket demand. A regression analysis on data obtained from the Mega Millions® and Powerball® multistate lotteries suggests ticket sales grow quadratically in the size of the advertised lump-sum cash jackpot prize. With quadratic growth, the best time to play is when ticket sales are 1.25 to 2.5 times the jackpot odds, currently about 300 M to one for these two lotteries. Since ticket sales are not known to ticket buyers, we invert the regression function to prescribe the best time to play in terms of the cash prize. It turns out that these lotteries offer a (pre-tax) fair wager with positive expected value in a surprisingly wide interval of jackpot prizes. That is a good time to play; the best time is in the neighborhood of the nearly 1 $B record cash jackpot awarded in these lotteries in recent years.

2 - Credit risk guarantee and contagion in supply chains

Hariprasad Bellamkonda, Indian Institute of Management-Indore, Indore, India

The diverging interests of suppliers and buyers about trade-credit maturity are to be resolved using supply chain finance programs. While these programs relax suppliers' liquidity constraints for small- and medium-sized enterprises, the credit risk shifted to credit guarantee networks thereby the potential risk contagion increases. A payment-and-clearing model based on capital-constrained firms and suppliers has been examined. When certain event risks occur, the proposed debt-payment and asset-clearing strategy improves their payment ability and minimizes suppliers' clearing losses. While the credit guarantee networks present in the supply chain system can facilitate complex guarantee relationships, the guarantee financing scheme under the linear threshold model can minimize risk spillover. The study enhances understanding of effectiveness and efficiency of the schemes in diminishing systemic risks thereby providing sustainable credit arrangements in the supply chains.

Keywords: risk analysis, Credit guarantees, Risk contagion, Asset clearing

3 - You Are What You Like： the Relations Between Daily Preferences and Higher Order Risk Attitudes

Peng Du, Southwestern University Of Finance And Economics, Chengdu, China, People's Republic of, Lin Zhao, Hua Chen

Higher-order risk preferences, including risk aversion, prudence, and temperance, play a fundamental role in economic decision-making, including daily consumption/saving behaviors, portfolio allocation, and retirement planning. Their importance stimulates a growing interest to gauge individuals' risk preferences through easily observable and reliable data. Extant literature has suggested that some daily preferences like diets and sports can reflect an individual's risk preferences, but such relations have not been thoroughly investigated and existing evidence is restricted to the second-order risk preference. We, therefore, conduct a systematical survey including thirty daily preferences across six categories (food, clothing, exercise, reading, music, and video), and three lottery-choice experiments to measure subjects' higher-order risk preferences. Our results indicate that, after controlling for individual characteristics, some daily preferences reveal strong associations with higher-order risk preferences. We also find that cognitive ability and personal traits are important mediating factors. We are the first to systematically study the relations between daily preferences and higher-order risk preferences. Additionally, our research provides a valuable demonstration of identifying risk preferences through mining individuals' behavioral data in the big data era.

4 - Corporate default prediction using advanced machine learning techniques

Stefanos Delikouras, University of Miami, Miami Herbert Business School, Coral Gables, FL, United States, Erotokritos Skordilis, Emily Struble

Corporate default, i.e., the inability of a corporation to meet its debt obligations, is one of the most important corporate events both for corporate finance and asset pricing. From a corporate finance perspective, the likelihood of default determines the debt capacity of a firm and the importance of debt in its capital structure (debt vs. equity). From an asset pricing standpoint, the probability of default dictates the fair value of debt securities. Ultimately, the likelihood of default affects the firm's cost of capital, i.e., the ease with which corporations can engage in new investments and labor hiring. Despite its paramount importance, the literature has not yet provided an accurate (both in- and out-of-sample) methodology to predict default. This is mainly due to the fact that corporate defaults, especially for highly-rated firms that constitute the majority of debt securities happen very scarcely: < 0.2% for investment rated bonds, 1.1% for BB-rated, 4.8% for B-rated bonds. In this work, we utilize state-of-the-art machine learning techniques on a large database of >22,000 companies to accurately predict corporate default from accounting information despite the sparsity of default events.

5 - Catastrophe Risk Sharing among Individuals, Private Insurance, and Government

Hanyang Wang, Indiana University Kelley Business School, Bloomington, IN, United States, Ruo Jia, Jieyu Lin, Michael Powers

Limited research has been conducted on optimal public-private risk-sharing programs for catastrophe insurance markets. In the present work, we employ a game-theoretical framework to study the risk-sharing interactions of three types of catastrophe-market participants: a continuum of individuals, a private primary insurer, and a government that can choose between alternatives of (re)insurance or ex-post relief. Our analysis shows that the optimal government-intervention program varies depending on the correlation structure among individual catastrophe-loss exposures. For moderately positive levels of correlation, it is optimal for government to offer an ex-post relief program to supplement private insurance, but for higher levels of correlation, government reinsurance becomes optimal (although not to the extent of replacing the private market if government is less efficient than private firms). In sum, as catastrophe-loss correlations increase, more risk-sharing channels and funding are needed to maximize social welfare.

6 - CRADLE: Cyber Risk Assessment and Disclosure Language Evaluator

HILAL PATACI, University of Texas at San Antonio, San Antonio, TX, United States, Shen Chang, T Ravichandran

Effective corporate disclosure is crucial for informed stakeholder engagement. However, the pervasive use of standardized, boilerplate language, a form of discretionary behavior often hides critical information, increasing risks for investors and the broader economy. This issue is particularly acute in cyber risk reporting within annual statements, which are typically repetitive and vague. Despite calls from the Securities and Exchange Commission (SEC) for more transparent cybersecurity disclosures and the upcoming requirement for a dedicated Cyber risk factors section by 2024, the entrenched practice of using opaque language continues, often driven by economic motives. Employing principles from deterrence theory and integrating the National Institute of Standards and Technology's (NIST) Risk Assessment Framework, we developed CRADLE: Cyber Risk Assessment and Disclosure Language Evaluator, a novel method to detect and eliminate generic cybersecurity risk disclosures. In this work, we ask the question of how economic incentives and competitive pressures by shaping the persistence of boilerplate language impact the litigation outcomes for companies. We argue that merely introducing a (1.C) cybersecurity risk section in annual statements may not be sufficient due to the strategic use of boilerplate language for economic incentives and competitive pressures Further, this improved understanding of the consequences associated with discretionary behavior in cybersecurity risk disclosures aims to inform regulatory policies and corporate governance practices, to foster more transparent and effective risk disclosure.

7 - A Model for Determining Threshold Guarantee Levels in Supported Infrastructure Projects

Luiz Brandao, PUC-Rio, Rio de Janeiro, Brazil, Glaucia Fernandes, Naielly Marques, James Dyer

There is a growing reliance on private capital for funding infrastructure projects globally, particularly through Public-Private Partnerships (PPPs). However, private investors may perceive certain projects as excessively risky, potentially leaving governments without viable bidders. To incentivize private investment, governments often provide risk mitigating mechanisms such as subsidies, incentives, revenue guarantees or even term extensions. The Minimum Revenue Guarantee (MRG) is a common risk mitigating mechanism in PPPs, but the optimal procedure to determine its optimal design remains unclear. Building on existing literature, this paper proposes the use of the cap and floor model, widely used in European electricity markets, to mitigate risks in infrastructure projects in transportation. Unlike revenue-based approaches, the model's cost-based cutoff values offer simplicity and transparency. The floor guarantees minimum revenues to cover project costs, while the cap restricts excessive returns. Although successfully applied in electricity markets, its application to transportation infrastructure remains underexplored. The paper contributes to the literature by showing how this approach can be successfully applied to infrastructure financing. We model the cap and floor regime under the real options approach and apply this model to a numerical example.

Our results suggest that this model is effective in assisting policy makers determine the optimal cap and floor levels while minimizing the cost to the government and taxpayers

8 - Developing a potential assessment framework for startups: Bridging the gap between traditional methods and venture capital needs

woojin cho, seoul national university, seoul, Korea, Republic of, sungjoo lee

Corporate potential assessment is a critical area in economics and management, particularly important for startups in their early stages. Accurate assessment of a startup's potential is crucial for securing venture capital and devising long-term growth strategies. However, startups pose unique challenges for potential assessment due to their innovative nature, generally low revenue, and frequent operational losses. Traditional methods often prove inadequate for assessing the potential of these startups because of their distinct financial profiles.

This study seeks to address these challenges by developing a potential assessment framework specifically designed for startups. It will explore the key factors that venture capitalists consider when evaluating early-stage companies, including market potential, technological innovation, and the competitive environment. This analysis aims to provide a nuanced approach that caters to the unique needs and circumstances of startups. It will facilitate more informed investment decisions by venture capitalists, enhancing the efficacy of their evaluations.

By proposing a new approach to assessing startup potential, the anticipated impact of this research is significant. It aims to provide a clearer, more adaptable assessment framework that could contribute substantially to the field of venture capital and entrepreneurship. The proposed framework is expected to encourage more strategic and judicious investment practices, bridging the gap between traditional assessment methods and the dynamic, often unpredictable startup ecosystem. This could lead to more sustainable business ventures and a healthier investment climate, ultimately benefiting the broader economic landscape.

9 - The Working Capital Channel of Investment under Uncertainty

Devin Zhang, Pennsylvania State University, State College, PA, United States, Devin Zhang

This study documents a novel working capital channel of investment under uncertainty, wherein uncertainty affects investment not through adjustment costs or irreversibility but through working capital and cash flows. The uncertainty comes from a prevalent supply chain phenomenon known as the bullwhip effect (the BWE), where demand volatility is amplified upstream along the supply chain from retailers to raw materials suppliers. Analyzing a sample of over 155,000 supply chains, I find that a high bullwhip effect leads firms to increase their inventory levels, raising working capital demands and reducing cash available for investment, especially for financially constrained firms. This channel links the investment under uncertainty and investment-cash flow sensitivity literatures by showing how uncertainty can be transmitted through working capital and cash flow, ultimately impacting investment decisions. Furthermore, while extensively studied in supply chain management, the impact of the bullwhip effect on corporate finance remains largely unexplored. My study is also one of the first to explore how this well-known supply chain issue affects corporate finance and firms' investment decisions.

1 - Allocating Divisible Resources on Arms with Unknown and Random Rewards

Ningyuan Chen, Rotman School of Management, Toronto, ON, Canada, Wenhao Li

We consider a decision maker allocating one unit of renewable and divisible resource in each period on a number of arms. The arms have unknown and random rewards whose means are proportional to the allocated resource and whose variances are proportional to an order b of the allocated resource. In particular, if the decision maker allocates resource A_i to arm i in a period, then the reward is $Y_i=A_i\mu_i+A_i^b \xi_i$, where μ_i is the unknown mean and the noise ξ_i is independent and sub-Gaussian. When the order b ranges from 0 to 1, the framework smoothly bridges the standard stochastic multi-armed bandit and online learning with full feedback. We design two algorithms that attain the optimal gap-dependent and gap-independent regret bounds for $b\in[0,1]$, and demonstrate a phase transition at $b=1/2$. The theoretical results hinge on a novel concentration inequality we have developed that bounds a linear combination of sub-Gaussian random variables whose weights are fractional, adapted to the filtration, and monotonic.

2 - Multi-Armed Bandits with Network Interference

Justin Whitehouse, Carnegie Mellon University, Pittsburgh, PA, United States, Abhineet Agarwal, Anish Agarwal, Lorenzo Masoero

We consider a multi-armed bandit (MAB) problem where an agent sequentially assigns one of A possible actions to N units across T rounds. Unlike traditional MAB problems, the reward of each unit depends on the treatments assigned to other units, i.e., there is interference across the underlying network of units. Online experimentation with network interference is a common challenge in applications such as e-commerce and medicine. Even though there is a large literature on performing statistical inference with interference in the offline setting, far less is known about how to adaptively assign treatments to maximize average reward. With A actions, and N units, minimizing regret is combinatorially difficult since there is a total of A^N actions for the agent to explore. To overcome this issue, we impose a natural and widely-assumed structure on the interference pattern, where the reward of a unit is only affected by the treatments assigned to s neighboring units. Under this model, we use tools from discrete Fourier analysis to develop a sparse linear representation of the underlying rewards, and propose a simple Lasso-based algorithm to estimate this function and minimize regret. Our algorithms can not only take advantage of the interference structure if it is known, but learn the underlying network structure when it is unknown. Our paper significantly generalizes other works on MABs with network interference, which impose stricter conditions on a known interference pattern, and also compare regret to a markedly weaker optimal action.

3 - Regulating Discriminatory Pricing in the Presence of Tacit Collusion

Zongsen Yang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Xiao Lei, Pin Gao

Price-setting algorithms have facilitated widespread awareness-based price discrimination, in which firms charge high prices to customers unaware of alternative choices and low prices to those in competitive markets. This unethical behavior has increased customer complaints and prompted policymakers to enact fairness regulations in response. However, while limiting price discrimination may improve consumer welfare under genuine competition, it also affects firms' incentives to form tacit collusion, another regulatory concern arising from the proliferation of pricing algorithms.
We develop an analytical model to examine the interplay between fairness regulation and tacit collusion, and discuss its impact on consumer welfare and policymaking. Firms utilize customers' product unawareness to implement price discrimination and decide whether to collude by comparing profits from collusion and deviation. We then explore the consequences of price fairness regulation on the sustainability of tacit collusion. For homogeneous products, fairness regulation can substantially weaken collusion, potentially rendering it unattainable. However, for differentiated products, strict fairness inadvertently supports collusive behavior, harming consumer welfare. In this case, mild fairness permitting moderate price differentiation can prevent market collusion and optimize welfare. We conduct a numerical experiment using simple Q-learning algorithms to demonstrate the realism of our analytical findings. To address fairness-induced collusion, we propose a novel approach that randomizes over the fairness levels, achieving the desired fairness in expectation. Our randomized policy is effective in both obstructing collusion and improving consumer surplus.
Overall, our study emphasizes the importance of a nuanced approach to regulating discriminatory pricing in the presence of tacit collusion.

4 - When Should you Offer an Upgrade: Online Upgrading Mechanisms for Resource Allocation

Zijie Zhou, MIT, Cambridge, MA, United States, Patrick Jaillet, Chara Podimata, Andrew Vakhutinsky

In this work, we study an upgrading scheme for online resource allocation problems. We work in a sequential setting, where at each round a request for a resource arrives and the decision-maker has to decide whether to accept it (and thus, offer the resource) or reject it. The resources are ordered in terms of their value. If the decision-maker decides to accept the request, they can offer an **upgrade-for-a-fee** to the next more valuable resource. This fee is dynamically decided based on the currently available resources. After the upgrade-for-a-fee option is presented to the requester, they can either accept it, get upgraded, and pay the additional fee, or reject it and maintain their originally allocated resource.

We take the perspective of the decision-maker and wish to design upgrading mechanisms in a way that simultaneously maximizes revenue and minimizes underutilization of resources. Both of these desiderata are encapsulated in a notion of **regret** that we define, and according to which we measure our algorithms' performance. We present a fast algorithm that achieves **O(log T)** regret. Finally, we implemented our algorithm utilizing data akin to those observed in the hospitality industry and estimated our upgrading mechanism would increase the annual revenue by over **17%**.

Advances in Revenue Management: From Theory to Practice

Invited Session

Revenue Management and Pricing

Chair: Anran Li, The Chinese University of Hong Kong, Hong Kong

Co-Chair: Zhe Liu, Imperial College London, London, United Kingdom

1 - Managing Newsvendors via Demand Nudging

Jiaqi Lu, the Chinese University of Hong Kong (Shenzhen), Shenzhen, China, People's Republic of, Yilun Chen

The increasingly prevalent "fulfillment by platform" practice in the digital economy presents platforms with the unique challenge of managing their third-party sellers' autonomous inventory decision-making. In this work, we explore a novel idea to mitigate this challenge through nudging demand among sellers, which reshapes their perceived demand and incentivizes them to make platform-favorable inventory decisions. To this end, we study a stylized Stackelberg game between a platform and a continuum of third-party sellers selling substitutable products on the platform. The platform aims to design a demand nudging policy to maximize her profit, while the sellers, in response, determine their inventory according to the post-nudge demand in a newsvendor manner. We establish in closed form the platform's optimal policy. It employs a simple cut-off structure called defluctuating and resembles risk pooling in the centralization setting where the platform can make joint demand-substitution and inventory decisions. Despite the power of this control on the off-equilibrium path, we show that it is Pareto-improving for both the platform and the sellers under a mild condition. Furthermore, when the products are substitutable enough, the platform can achieve the centralization benchmark. On the contrary, if the products are not substitutable enough, the platform's service level to the customers may, in certain primitive regimes, decrease.

2 - Assortment Optimization with Market Share Threshold under Multinimal Logit Choice Model

Wenchang Zhu, Cornell Tech, New York, NY, United States, Paat Rusmevichientong, Huseyin Topaloglu

We consider assortment optimization problem with market share threshold constraints under multinomial logit choice model.

3 - Dynamic Pricing Under Self-Exciting Arrival Processes

Longyuan Du, University of San Francisco, San Francisco, CA, United States, Ming Hu, Quan Yuan

We study dynamic pricing problems with a non-linear stochastic Hawkes arrival process where demand is influenced by previous customers. We prove that the seller would first set a low price to attract customers and increase the price over time. The optimal price increases in the exciting factor when the exciting function is concave and decreases in the exciting factor when the exciting function is convex. We further study easy-to-compute heuristics and their performances in the asymptotic regime. We show that the heuristic adopting the optimal price in the deterministic problem incurs a constant performance loss. The paper is extended to consider general information spreading and multiple identical products.

4 - Speed Service with Spotlight Products: Assortment Optimization and Pricing in a Queue

Zhe Liu, Imperial College London, London, United Kingdom, Kalyan Talluri, Shixin Wang

Quick-service restaurants, such as fast-food franchises and coffeehouse chains, recommend items with spotlight menu that may shorten customers' decision time and hence speed up the service, but with a trade-off of possibly lower profit margin. We study such assortment optimization problems when service rate is affected by the recommendation and plays a role in the revenue rate objective. Formulated as a sequential recommendation problem in a queueing setting under the multinomial logit model, we obtain structural properties of the impact of arrival rate and system capacity on optimal assortment, and find optimality conditions for attractiveness-ordered or fare-ordered nested policies. We also characterize the optimal joint assortment and pricing under common price sensitivity.

How Competition Can Disrupt Machine Learning

Invited Session

Revenue Management and Pricing

Chair: Meena Jagadeesan, UC Berkeley, Berkeley, CA, United States

Co-Chair: Nika Haghtalab

1 - Impact of Decentralized Learning on Player Utilities in Stackelberg Games

Kathleen Donahue, Cornell, Ithaca, NY, United States, Nicole Immorlica, Meena Jagadeesan, Brendan Lucier, Alex Slivkins

When deployed in the world, a learning agent such as a recommender system or a chatbot often repeatedly interacts with another learning agent (such as a user) over time. In many such two-agent systems, each agent learns separately and the rewards of the two agents are not perfectly aligned. To better understand such cases, we examine the learning dynamics of the two-agent system and the implications for each agent's objective. We model these systems as Stackelberg games with decentralized learning and show that standard regret benchmarks (such as Stackelberg equilibrium payoffs) result in worst-case linear regret for at least one player. To better capture these systems, we construct a relaxed regret benchmark that is tolerant to small learning errors by agents. We show that standard learning algorithms fail to provide sublinear regret, and we develop algorithms to achieve near-optimal O(T^{2/3}) regret for both players with respect to these benchmarks. We further design relaxed environments under which faster learning (O(T^{0.5})) is possible. Altogether, our results take a step towards assessing how two-agent interactions in sequential and decentralized learning environments affect the utility of both agents.

2 - How and Why to Manipulate Your Own Agent: On the Incentives of Users of Learning Agents

Yoav Kolumbus, Cornell University, Ithaca, NY, United States, Noam Nisan

The usage of automated learning agents is becoming increasingly prevalent in many online economic applications such as online auctions and automated trading. Motivated by such applications, we study the fundamental modeling and analysis of the strategic situations that the users of automated learning agents are facing. We consider strategic settings where several users engage in a repeated online interaction, assisted by regret-minimizing learning agents that repeatedly play a "game" on their behalf. We propose to view the outcomes of the agents' dynamics as inducing a "meta-game" between the users. Our main focus is on whether users can benefit in this meta-game from "manipulating" their own agents by misreporting their parameters to them. We define a general framework to model and analyze these strategic interactions between users of learning agents for general games and analyze the equilibria induced between the users in several classes of games, including repeated auctions. We show that, in many games, users have incentives to misreport their parameters to their own agents, and that such strategic user behavior can lead to very different outcomes than those anticipated by standard analysis.

The talk is based on two joint works with Noam Nisan:

https://arxiv.org/pdf/2112.07640 (NeurIPS 2022)

https://arxiv.org/pdf/2110.11855 (WWW 2022)

3 - Algorithmic Collusion by Large Language Models

Sara Fish, Harvard University, Cambridge, MA, United States, Yannai Gonczarowski, Ran Shorrer

The rise of algorithmic pricing raises concerns of algorithmic collusion. We conduct experiments with algorithmic pricing agents based on Large Language Models (LLMs), and specifically GPT-4. We find that (1) LLM-based agents are adept at pricing tasks, (2) LLM-based pricing agents autonomously collude in oligopoly settings to the detriment of consumers, and (3) variation in seemingly innocuous phrases in LLM instructions ("prompts") may increase collusion. These results extend to auction settings. Our findings underscore the need for antitrust regulation regarding algorithmic pricing, and uncover regulatory challenges unique to LLM-based pricing agents.

4 - Understanding Competition-Driven Content Ecosystems

Fan Yao, University of Virginia, State College, PA, United States

The ever expanding of content creation platforms has nurtured a booming of digital content ecosystems, which are driven by a competitive dynamics among content creators vying for user attention or revenue. This competitive environment poses significant challenges to the health of content ecosystems, including the risk of diminishing content diversity and the potential pursuit of popularity may drive out high-quality content. Our research establishes a game-theoretical framework to analyze these dynamics by viewing creators as strategic agents aiming to maximize platform-allocated resources. We will assess how platforms' algorithmic decisions and revenue allocation models impact content distribution and social welfare, providing insights for platform designers to enhance content quality and fairness, thereby fostering a healthier and more sustainable digital content ecosystem. We will also discuss how the advent of Generative AI might influence the content ecosystem and possible interventions to mitigate the potential adverse effects.

5 - Algorithmic Content Selection and the Impact of User Disengagement

Eric Zhao, University of California, Berkeley, Berkeley, CA, United States, Emilio Calvano, Nika Haghtalab, Ellen Vitercik

The content selection problem of digital services is often mathematically modeled as a decision-process where a service chooses, over multiple rounds, an arm to pull from a set of arms that each return a certain reward. This classical model does not account for the possibility that users disengage when dissatisfied and thus fails to capture an important trade-off between choosing content that promotes future engagement versus immediate reward. In this talk, I will discuss a new model for the content selection problem where dissatisfied users may disengage and where content that maximizes immediate reward does not necessarily maximize the odds of future user engagement. I will share theoretical results on the learnability of optimal content selection policies in this model, including efficient planning algorithms and online learning algorithms for serving users with unknown engagement patterns. I will also discuss the use of this model for identifying key primitives that determine how digital services should weigh engagement against revenue. For example, when it is more difficult for users to rejoin a service they are disengaged from, digital services naturally see a reduced payoff but user engagement may—counterintuitively—increase.

Learning and Optimization in Risk and Revenue Management

Invited Session

Revenue Management and Pricing

Chair: Zhenyu Hu, National University of Singapore, Singapore, Singapore

Co-Chair: Yifan Feng, National University of Singapore, Singapore, Singapore

1 - Customer Lifetime Value and Algorithmic Pricing

Anton Ovchinnikov, Smith School of Business, Queen's University, Kingston, ON, Canada, Jue Wang

Customer Lifetime Value (CLV) is commonly defined as “the present value of the future cash flows attributed to the customer relationship,” Pfeifer et al. (2005). A large body of CLV literature focused on retention, loyalty, and other nuances of how to calculate “the present value of the future,” but how much value is obtained from each customer transaction received little attention: most studies adopted the aforementioned cash-flow-based approach. In this paper we show that certain pricing algorithms utilized across many industries such as transportation, hospitality, retail, advertising, and sports & entertainment, make the cash-flow-based approach systematically biased, overvaluing high-price transactions and undervaluing low-price ones. We prove that the bias depends on the elasticity properties of the demand function used by the firm’s pricing algorithms. Building on that, we also show that certain non-stationary customer arrival patterns could restore the “intuitive” directional relationship that higher-priced transactions are more valuable. Lastly, we present an intuitive refined approach to corrects for this bias.

2 - Credit Rating Design Under Adverse Selection

QINZHEN LI, National University of Singapore, Singapore, Singapore, Yifan Feng, Jussi Keppo

We introduce a model of the credit rating market where investors depend on Credit Rating Agency's (CRA) ratings to predict firms' default probabilities. Firms seeking funding may pay the CRA for solicited ratings. The revenue-maximizing CRA strategically designs a rating system based on each firm’s quality and solicitation action. We find that in equilibrium, high-quality firms tend to solicit ratings more aggressively and receive higher ratings than low-quality ones. Although solicited ratings are generally higher than unsolicited ones, this difference diminishes when controlling for firms' true underlying qualities. Our model suggests that the reported discrepancy between unsolicited and solicited ratings in the existing literature can be primarily due to adverse selection on the demand side of the credit rating market. Additionally, we conduct robustness checks to validate variations of our model.

3 - Fragility-Aware Classification for Understanding Risk and Improve Generalization

Chen Yang, Hong Kong University of Science and Technology, Hong Kong, China, People's Republic of, Jin Qi, Ruohan Zhan

In various applications, including medical diagnosis and default detection, the classification model is applied, and managers make decisions based on the classifier's predictions. Many performance metrics have been developed by comparing the actual label and the classifier's prediction. However, the confidence of the model prediction is also essential and neglected by commonly used performance metrics. Confidence represents the risk and uncertainty of the model prediction, and managers may consider conducting different operations in instances with different confidence. Due to the growing complexity of learning models, state-of-the-art classification models like neural networks are known to be more accurate but suffer from the overconfidence issue, which can lead to a high risk in decision-making as the models cannot indicate when they are probably incorrect. These two points invoke the need to understand and regulate the model's confidence. In this paper, we propose a novel metric, the Fragility Index (FI), to evaluate the risk of wrong prediction by capturing the magnitude of the ranking error from a risk-averse perspective. To strengthen the generalization ability, we adopt the robust satisficing (RS) framework to design FI. We show that FI can identify the information that conventional metrics like accuracy cannot capture. On top of that, we design a model training framework based on FI and RS. We demonstrate the effectiveness of FI and FI-based classification models using synthetic data, real data, and deep neural networks. With FI, the decision makers can understand the risk inside the learning model predictions and make better decisions.

4 - Multi-Objective Assortment Optimization: Profit, Risk, Customer Utility, and Beyond

Zhen Chen, Arizona State University, Tempe, AZ, United States, Heng Zhang, Hongmin Li, Scott Webster

Assortment optimization is a fundamental problem in revenue management, where the goal is usually to select a subset of products to offer to customers in order to maximize expected revenue or profit. Indeed, although revenue is of predominant importance, it is rarely the sole objective of a firm's product assortment decisions. Business practices often involve multiple, and potentially conflicting goals. In this work, we propose a general framework and a novel reformulation method for solving multi-objective assortment optimization problems. We focus on problems with a separable sum of multiple convex objective functions on linear combinations of choice probabilities, presenting a reformulation that effectively "linearizes" the problem. We prove that the reformulated problem is equivalent to the original and leads to a unified solution approach for multi-objective assortment optimization problems in various contexts. Our approach encompasses a wide range of operational objectives, such as risk, customer utility, market share, costs with economies of scale, and dualized convex constraints. We first illustrate our method using the multinomial logit model, both without constraints and with totally unimodular constraints. We further show that our framework provides to tractable solutions under the nested logit model and the markov chain choice model. Together with large-scale numerical experiments to demonstrate the efficiency and practicality of our methods, we highlight that our work provides a powerful and flexible tool for solving multi-objective assortment problems, which arise frequently in practical revenue management settings.

Pricing and Yield Management at Amazon

Invited Session

Revenue Management and Pricing

Chair: Ozge Sahin, Johns Hopkins Carey Business School, Baltimore, MD, United States

Co-Chair: Samyukta Sethuraman, Amazon, Folsom, CA, United States

Co-Chair: Samyukta Sethuraman, Amazon, Folsom, CA, United States

1 - Early Stopping Methods at Pricing Lab

Sid Sanghi, Amazon.com, Seattle, WA, United States, Daria Zelenia, James Nordlund, Mohsen Bayati

In this paper we implement two methods to enable early lab terminate once enough evidence of strong positive or strong negative effect has been collected. We implement the approach on historic labs and find that both methods could help save 50% of experiment duration.

2 - Price Optimization with Neural Thompson Sampling with Dropout

Ru Wang, Amazon, Cupertino, CA, United States, Hyungjun Lee, Laleh Jalali

The single-product price optimization problem aims to find the optimal prices for Amazon while assuming that the demand of each product is independent of each other. We present a novel solution to the single-product price optimization problem using a neural network-based contextual bandit methodology called Neural Thompson Sampling with Dropout (NTSD). NTSD is a Thompson Sampling method that uses a neural network with dropout to estimate the reward distributions of the arms. It allows a neural network with any architecture to be used as the underlying reward estimation model, and provides computationally efficient methods for training the neural network estimator as well as sampling from the implied reward distributions of the arms. In simulation studies, NTSD generates 4-8% improvements in cumulative rewards over the baseline production model under simulations.

3 - Combining ML & OR for Efficient Amazon Locker Utilization

Samyukta Sethuraman, Amazon, Santa Clara, CA, United States

Amazon Locker is a self-service delivery or pickup location where customers can pick up packages and drop off returns. A basic first-come-first-served policy for accepting package delivery requests to lockers results in lockers becoming full with standard shipping speed (3- to 5-day shipping) packages, leaving no space for expedited packages, which are mostly next-day or two-day shipping. This paper proposes a solution to the problem of determining how much locker capacity to reserve for different ship-option packages. Yield management is a much-researched field with popular applications in the airline, car rental, and hotel industries. However, Amazon Locker poses a unique challenge in this field because the number of days a package will wait in a locker (package dwell time) is, in general, unknown. The proposed solution combines machine learning techniques to predict locker demand and package dwell time with linear programming to maximize throughput in lockers. The decision variables from this optimization provide optimal capacity reservation values for different ship options. This resulted in a year-over-year increase of 9% in Locker throughput worldwide during the holiday season of 2018, impacting millions of customers.

1 - Evaluating Infant Development Through a Hybrid Intuitionistic Fuzzy Classification System

TING YU LIN, Tunghai University, Taichung City, Taiwan, YA CHI HSU, KUO PING LIN

This study proposes a hybrid approach using clustering algorithms and classification methods to enhance the accuracy and granularity of infant developmental assessments. The classification system adopts k-means determine the difference in infant development between 6 months and 1 year of age while the input datasets are percentage and over time, which are vague sets. The classification algorithm adopts long short-term memory network (LSTM) offer a robust framework for vagueness inherent in developmental assessments. Through a comprehensive evaluation using real-world infant development data, we demonstrate the superior performance of the proposed classification system. The hybrid classification system can achieve superior performance for cognitive scores which accurate rate is 0.95. This study contributes to ongoing efforts to advance assessment methodologies in early childhood development and underscores the potential of hybrid computational approaches in pediatric healthcare.

2 - Construct a novel SCAN method of unsupervised learning for dealing with the auto-annotation task in semiconductor manufacturing processes

CHIH-HUNG JEN, Lunghwa University of Science and Technology, Taoyuan City, Taiwan, SHU-KAI S. Fan, Yu-Ching Huang

Semiconductor manufacturing is developing rapidly, and related production technology has made significant progress. In practical semiconductor processes, defect analysis of wafer maps is a crucial step in enhancing product quality and yield. Additionally, these defect patterns can provide valuable process information, allowing process engineers to pinpoint the causes of process anomalies. However, in supervised learning, manually labeling data for wafer maps is a tedious and time-consuming task that can lead to misjudgments when performed over long periods. To address these shortcomings, this paper focuses on automatically grouping data into semantically meaningful clusters without real labels, a process known as pseudo-labeling. It utilizes a novel Semantic Clustering by Adopting Nearest-neighbors (SCAN) method to help the model learn data representations and extract meaningful features, reducing reliance on low-level features for subsequent clustering. Within the new SCAN model, a fine-tuning process generates pseudo-labels. The self-labeling model uses confident samples to correct the pseudo-labels of their nearest neighbors, gradually improving the accuracy of initially misclassified neighbors using the FixMatch loss function. Experimental results show that the auto-annotation system achieves significantly improved performance, potentially eliminating the need for extensive manual labeling.

3 - Applying Constraint Theory and Resource-Based Views: A Case Study of Problem-Solving in the Traditional Auto Parts Industry

Wu Sheng-pin, National Cheng Kung University/Department of Business Administration, Tainan, Taiwan, Lin Tai-Yu, Wang Chien-Chih

Since the onset of COVID-19, global business models have evolved significantly. This study explores these transformations within the context of supply chain management, focusing on transitioning from risk diversification strategies to centralized procurement. This strategic shift aims to empower suppliers by enhancing their negotiating power over raw materials and transportation costs. Our investigation centers on a multinational auto parts supplier, which, despite the predominance of price and purchase volume considerations, continues to face challenges in production scheduling and manpower deployment, primarily due to delays in raw material supply. This research identifies three critical areas of concern: procurement negotiation skills, personnel recruitment and the management capabilities of middle and senior managers. Employing the Theory of Constraints and a Resource-Based View, this analysis not only addresses the delays in production delivery but also reveals the underlying deficiencies in management capabilities at middle and senior levels. Consequently, this paper proposes targeted improvement plans to augment managerial effectiveness and streamline supply chain operations.

Keywords: supply chain management, theory of constraints, resource-based view

4 - Using Graph Convolutional Network to Solve the Uncapacitated Single Allocation p-Hub Median Problem

Kang-Ting Ma, National Dong Hwa University, Hualien, Taiwan, You-Qin Wang

Logistics networks need restructuring to handle increased transportation demands and distribution complexity with the rise of Omni-channel retail. Previous heuristic algorithms for solving the P-Hub Median Problem failed to obtain optimal solutions for complex networks with many transfer points. This paper proposes a graph convolutional network (GCN) method to solve the uncapacitated single allocation p-hub median problem. Unlike traditional CNNs limited to Euclidean data, GCNs can learn better solutions by propagating and aggregating node features. The study clusters nodes, identifies suitable transfer locations, tests large-scale random examples, and explores graph attention mechanisms and loss functions to improve model generalization and performance.

Machine Learning and Data Analytics for Robust Decision-Making in Complex Systems

Invited Session

Decision Analysis Society

Chair: Faraz Dadgostari, Montana State University, Bozeman, MT, 59718, United States

1 - AI-Enhanced Early Warning and Environmental Decision Support Systems: Real-Time Management of Harmful Algal Blooms

Neda Nazemi, Montana State University , Bozeman, MT, United States

The increasing frequency, intensity, and complexity of climate-induced hazards necessitate robust and adaptive decision-making in risk management. Advances in Artificial Intelligence (AI), especially in machine learning and deep learning, offer scalable solutions for forecasting models. These models integrate multi-level, multi-frequency, and multi-source data, making them essential in addressing environmental challenges like harmful algal blooms (HABs), which threaten water quality, marine life, and public health globally. HABs are characterized by their sudden occurrences and complex triggers, presenting challenges to traditional forecasting methods that often fail to provide timely and accurate predictions. This research leverages deep learning to overcome these limitations, enhancing early warning systems and decision-support tools that facilitate proactive responses and help mitigate environmental and economic impacts. We have developed a deep-learning framework to forecast chlorophyll-a levels, a primary indicator of algal bloom formation. This framework supports short and mid-term decision-making, enabling real-time monitoring and management of bloom events. Its ability to provide actionable insights swiftly outperforms conventional methods, empowering stakeholders with enhanced responsiveness. Additionally, this paper proposes integrating these AI-driven tools into existing environmental management frameworks to boost resilience and sustainability. By improving decision-making processes, these tools enable adaptive strategies that effectively respond to dynamic environmental threats, fostering a more sustainable interaction between humans and their environment. This approach not only addresses the immediate challenge of managing HABs but also illustrates the broader applicability of AI in environmental risk management. It sets a pathway for future research in similar contexts, demonstrating significant potential for technological advancement in ecological conservation.

2 - Towards explainable artificial intelligence through expert-augmented supervised feature selection

Meysam Rabiee, University of Colorado Denver, Denver, CO, United States

This paper presents a comprehensive framework for expert-augmented supervised feature selection, addressing pre-processing, in-processing, and post-processing aspects of Explainable Artificial Intelligence (XAI).

3 - Graph Neural Networks as surrogates for simulation-based decision-making in infrastructure systems

Negin Alemazkoor, University of Virginia, Charlottesville, VA, United States

In recent years, there has been a growing emphasis on integrating uncertainty into decision-making processes for civil infrastructure systems. This involves calculating expected costs and failure probabilities through high-fidelity simulations, which can be computationally intensive due to high-dimensional uncertainty. To mitigate this, various studies have explored using analytical surrogates like polynomial chaos expansion, radial basis function, and Gaussian processes, which have shown promise in accelerating probabilistic analysis under specific conditions. However, there's a rising interest in utilizing machine-learning models as surrogates due to their ability to capture complex relationships within uncertain inputs and quality of interest (QoI). Nonetheless, this approach requires substantial data for training and meticulous calibration of hyperparameters and model architecture, which can be challenging when estimating numerous QoIs across a system. Additionally, calling a large number of surrogate models within the analysis can lead to error aggregation and complicate result interpretation. Graph neural networks (GNNs) offer a potential solution by providing node- and link-level approximations, reducing the need for multiple surrogate models. Despite this, their application in civil infrastructure systems remains limited, especially for large-scale systems under high-dimensional uncertainty. This work aims to address the challenges of training GNN surrogates for large-scale CIS in probabilistic analysis. Specifically, we propose a novel multi-fidelity approach that substantially reduces the computational cost of surrogate development. We demonstrate its advantages by applying it to the optimal power flow problem under high-dimensional uncertainty.

4 - Verification, Validation, Assurance, and Trust of Machine Learning Models and Data for Safety Critical Applications

Shane Hall, Montana State University, Bozeman, MT, United States

As the use of machine learning (ML) models proliferates in commercial and defense applications, military organizations face significant challenges in evaluating the effectiveness, robustness, and safety of these ML models in military systems. Relying on ML-informed recommendations and decisions in these systems requires very high confidence that any resultant behaviors will fall within intended operational and mission bounds. Ensuring reliable and safe behaviors involves both ensuring accurate and comprehensive data is used in the creation and training of these ML systems and that the ML models are robust, accurate, and appropriately behaviorally bounded when employed using real data in military operations. ML models come in many forms, and the technologies used to create them are rapidly evolving, and hence, military organizations need 1) a process and framework to assess and measure the quality of training data and identify shortcomings that may lead to poorly trained ML models, and 2) a process and tools for ML model exploration that can assure confidence of model behavior within defined data boundaries and can also identify unintended or poor behavior in ML models if they exist. This presentation outlines the existing literature on the metrics and measures used to verify and validate (V&V) ML training data and models and describes the process, framework, and tools to analyze these metrics and measures. Results that demonstrate these metrics, measures, framework, and tools are provided for an open-source classification ML model and an autonomous vehicle reinforcement learning (RL) model.

5 - A Multi-Agent Inverse Sequential Decision Learning for Causal Behavioral Learning

Faraz Dadgostari, Montana State University, Bozeman, MT, United States

Understanding the emergent patterns and dynamics within complex adaptive systems, such as social or economic networks, requires analytical tools capable of modeling intricate behavioral interactions and uncovering underlying causal mechanisms. In this paper, we propose a multi-agent inverse sequential decision learning framework that addresses the limitations of existing approaches. Our framework integrates advanced decision-making theories from behavioral economics, mathematical neuroscience, and computational psychology, extending traditional inverse reinforcement learning (IRL) methodologies with novel mathematical formulations and algorithmic innovations. The proposed framework is uniquely designed to efficiently model heterogeneous agent behaviors, capture their adaptive responses to dynamic environmental stimuli, and infer the underlying reward functions driving their decisions. We demonstrate its ability to analyze causal relationships within the system and provide interpretable insights that go beyond the capabilities of rationality-based or simulation-focused methods.

Integrating Generative AI with Sequential Decision-Making: Theoretical Advances and Practical Applications (I)

Invited Session

Decision Analysis Society

Chair: Yingru Li, The Chinese University of Hong Kong, Shenzhen, Shenzhen, N/A

Co-Chair: Ming Yin, Princeton University, Princeton, NJ, United States

1 - Training Language Model Agents via Hierarchical Multi-Turn RL

Andrea Zanette, Carnegie Mellon University, Pittsburgh, PA, United States

A broad use case of large language models (LLMs) is in goal-directed decision-making tasks (or "agent" tasks), where an LLM needs to not just generate completions for a given prompt, but rather make intelligent decisions over a multi-turn interaction to accomplish a task (e.g., when interacting with the web, using tools, or providing customer support). Reinforcement learning (RL) provides a general paradigm to address such agent tasks, but current RL methods for LLMs largely focus on single-turn rewards. Most single-turn RL methods cannot endow LLMs with the ability to intelligently seek information over multiple turns, perform credit assignment, or reason about their past actions -- all of which are critical in agent tasks. This raises the question: how can we design efficient multi-turn RL algorithms for LLMs? We develop a framework for building multi-turn RL algorithms for fine-tuning LLMs, that preserves the flexibility of existing single-turn RL methods for LLMs (e.g., proximal policy optimization), while accommodating multiple turns, long horizons, and delayed rewards effectively. To do this, our framework adopts a hierarchical RL approach and runs two RL algorithms in parallel: a high-level off-policy value-based RL algorithm to aggregate reward over utterances, and a low-level RL algorithm that utilizes this high-level value function to train a token policy within each utterance or turn. Our hierarchical framework, Actor-Critic Framework with a Hierarchical Structure (ArCHer), can also give rise to other RL methods. Empirically, we find that ArCHer significantly improves efficiency and performance on agent tasks, attaining a sample efficiency of about 100.

2 - Transferred Decoding for LLM Alignment

Ming Yin, Princeton University, Princeton, NJ, United States

Aligning foundation models is essential for their safe and trustworthy deployment. However, traditional fine-tuning methods are computationally intensive and require updating billions of model parameters. A promising alternative, alignment via decoding, adjusts the response distribution directly without model updates to maximize a target reward r, thus providing a lightweight and adaptable framework for alignment. However, principled decoding methods rely on oracle access to an optimal Q-function ($Q*$), which is often unavailable in practice. Hence, prior SoTA methods either approximate this $Q*$ using $Q\pi\mathtt{sft}$(derived from the reference $\mathtt{SFT}$ model) or rely on short-term rewards, resulting in sub-optimal decoding performance. In this work, we propose Transfer $Q*$, which implicitly estimates the optimal value function for a target reward r through a baseline model $\rho\mathtt{BL}$ aligned with a baseline reward $\rho\mathtt{BL}$ (which can be different from the target reward r). Theoretical analyses of Transfer $Q*$ provide a rigorous characterization of its optimality, deriving an upper bound on the sub-optimality gap and identifying a hyperparameter to control the deviation from the pre-trained reference $\mathtt{SFT}$ model based on user needs. Our approach significantly reduces the sub-optimality gap observed in prior SoTA methods and demonstrates superior empirical performance across key metrics such as coherence, diversity, and quality in extensive tests on several synthetic and real datasets.

3 - GPT-HyperAgent: Adaptive Foundation Models for Online Decisions

Yingru Li, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Zhi-Quan Luo

Foundation models pretrained on historical data often struggle with uncertainty in new and rare situations, leading to errors that require feedback for correction and policy refinement. We introduces GPT-HyperAgent, a scalable reinforcement learning algorithm designed for continual learning and adaptation in uncertain complex environments. GPT-HyperAgent leverages GPT for expressive feature embeddings and integrates HyperAgent as an uncertainty-aware reward model for exploration in contextual bandit problems with natural language inputs.

Theoretical analysis confirms HyperAgent achieves fast incremental uncertainty estimation with logarithmic per-step computational complexity, matching the performance of exact Thompson sampling in linear contextual bandits and Randomized Least-Square Value Iteration in tabular RL environments.

Empirical results confirms GPT-HyperAgent's effectiveness in real-world safety-critical applications, such as automated content moderation on digital platforms via human-AI collaborations.

We will also explore open questions about reinforcement learning with foundation models.

4 - Cost-Aware Decoding for Safe Language Model Deployment

Hao Liang, CUHK-SZ, Shenzhen, China, People's Republic of

In the rapidly evolving field of artificial intelligence, deploying large language models effectively and safely remains a formidable challenge. This talk presents "Cost-Aware Decoding," an innovative strategy designed to simultaneously optimize for performance and safety. This method integrates cost-aware mechanisms into the decoding process of language models, enabling dynamic evaluation and adjustment of responses to minimize potential harm without compromising utility.

The cornerstone of this approach is a novel cost model, crafted from human-aligned feedback, which assesses the potential harm of text outputs. This model facilitates real-time adjustments to the decoding strategy, ensuring that generated responses not only adhere to safety thresholds but also align with user intentions.

During the session, we will explore the development and integration of the cost model within the decoding framework, address the challenges associated with balancing harmlessness against helpfulness, and discuss the practical implications of deploying safer language models across various applications. Empirical validations of our method demonstrate its efficacy in enhancing the safety of AI outputs, setting the stage for wider and more responsible deployment of AI technologies.

Multi-Criteria Decision-Making Under Uncertainty

Invited Session

Multi Criteria Decision Making

Chair: Shervin Zakeri, 7 rt. de Drize,, 1206

Co-Chair: Milosz Kadzinski, Poznan University of Technology, Poznan, Poland

1 - Review and experimental comparison of ranking and choice procedures for constructing a univocal recommendation in a preference disaggregation setting

Milosz Kadzinski, Poznan University of Technology, Poznan, Poland, Michal Wojcik

We account for the preference disaggregation setting given multiple criteria ranking and choice problems. An assumed preference model is a set of additive value functions compatible with the Decision Maker's pairwise comparisons of reference alternatives. The incompleteness of such indirect preferences implies the multiplicity of feasible functions and the ambiguity in indicating the most preferred alternative or ordering alternatives from the best to the worst. We review approaches that construct a univocal recommendation under such scenarios. They represent four groups of methods: procedures selecting a representative value function, decision rules, scoring methods, and mathematical models for constructing a robust ranking. The use of all thirty-five approaches is illustrated on a simple decision problem. Then, they are compared in an extensive computational study in terms of their abilities to reconstruct the DMs' true preferences and robustness of delivered recommendations given the support they are given in the set of all compatible models. The results are quantified in terms of seven performance measures. Their analysis indicates that in the context of choice, it is beneficial to consider the rank acceptabilities for the best ranks. For ranking problems, the most advantageous outcomes are attained by procedures that emphasize the most frequent relations or positions in the feasible polyhedron. Apart from the average results, we discuss how the performance of all approaches changes for different parameterizations of the decision problem and preference model.

2 - The Problem of Sensitivity Analysis in MCDA / MCDM

Evangelos Triantaphyllou, Louisiana State University, Baton Rouge, LA, United States, Juri Yanase

Multi-Criteria Decision Analysis (MCDA), also known as Multi-Criteria Decision Aiding, or Multi-Criteria Decision Making (MCDM), is a family of approaches that analyze a finite set of alternatives which are described in terms of a finite set of evaluative criteria. Perhaps the most crucial role in the implementation of such decision-making approaches is the use of the evaluative criteria. The reason is that almost always the weights of the evaluative criteria are subjective and thus hard to elicit accurately. Hence, performing a sensitivity analysis on the role these weights play in the determination of the final solution is a task that should be considered in any decision-making setting that involves such approaches. We analyze the sensitivity analysis problem from three perspectives. The first perspective is the type of the decision problem (also known as the “problematic”) to be considered. For instance, is the focus on the ranking of the alternatives? Or on determining the best alternative? The second perspective is the impact ranking changes of the alternatives have. The third perspective is the likelihood the decision maker(s) may consider different weight values than the ones assumed initially. This sensitivity analysis problem is proposed to be treated in a universal manner that is applicable to a wide range of MCDA / MCDM approaches. Early findings suggest that existing sensitivity analysis approaches may yield dramatically misleading results. If the quest is the development of smart decision-making approaches, then the proposed sensitivity analysis approach must become an integral component of such smart approaches.

3 - Evaluating Blockchain-IoT Adoption in Supply Chains: A Fuzzy Entropy-Based MCDM Approach for Enhancing Environmental Sustainability

Atefeh Shoomal, University of Texas at Arlington, Arlington, TX, United States, Mohammad Jahanbakht

In the context of modern supply chains, the integration of blockchain and Internet of Things (IoT) technologies presents a significant opportunity to enhance environmental sustainability. Our study adopts a Multi-Criteria Decision Making (MCDM) approach, grounded in the Technology-Organization-Environment (TOE) frameworks, to critically assess the factors that influence the adoption of Blockchain-IoT in supply chain. We initiate our investigation by conducting a Delphi study to achieve a consensus among industry experts regarding the critical criteria for technology adoption, emphasizing environmental sustainability, technological readiness, and organization maturity.

Following the expert consensus, we employ a fuzzy entropy method to evaluate these criteria. This method allows for handling the inherent uncertainty and subjectivity in the decision-making process, providing a robust mechanism to quantify the efficiency of different solutions. The fuzzy entropy approach facilitates a nuanced assessment of the trade-offs and synergies among the identified criteria, enabling stakeholders to make informed, sustainable choices.

To validate the efficacy of our proposed model, we will conduct a results comparative analysis. This study helps policymakers and business leaders in strategic decision-making that aligns with sustainability goals.

1 - Cultural Values Impact on Perceptions of Intrusiveness and Legitimacy of AI-Based Managerial controls: A Cross-Country Examination

Akram Khattab, The University of Toledo, Toledo, OH, United States, HEBA ABDEL-RAHIM, Euisung Jung, Paul Hong

Emerging Information and Communication Technologies (ICT) have made employee monitoring a quite prevalent practice. The extensive and intrusive managerial controls which heavily rely on recently emerged artificial intelligence have caused much debate on its legitimacy. Yet, a perspective of AI-Based Managerial controls that has received less attention is how workers perceive Artificial Intelligence (AI) controls. This study aims to exam two research questions: First, what is the general perception of employees to the companies' use of AI controls such as surveillance tools? Second, does the perception of employees to the company's use of AI controls depend on their cultural values? A conceptual model based on Technology Mediated Controls (TMC) theory and Hofstede's cultural value is developed to theorize the effects of AI controls. To test the model, a mixed-source approach is adopted. Individual level data will be collected using a questionnaire with respondents from countries with different cultural values. Country level data will be derived from Hofstede's study (2001). Specifically, the study focuses on the important and pressing issue of perceptions of intrusiveness of AI-based managerial controls in the workplace given employees' national cultural backgrounds. Theoretical and practical implications are presented.

2 - Effect of Interruption On Knowledge Hiding: A Multilevel Study

Rushatey Feroze, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Ruonan Zhao, YuFan Shang

With the advancement of information communication technologies (ICT), job interruptions received through ICT have been widely investigated, while interruptions happened from humans have received less attention. Differentiating these two types of interruptions, this research identifies knowledge hiding as the consequence of human work interruption, and explores the mechanism through which work interruptions impact knowledge hiding based on the conservation of resource theory (COR) from a time management perspective. The data was collected from established countries (over six years) with over 500 employees across several industries. Data were analyzed using Mplus for mediation and cross-level moderation. The results reveal that human work interruption significantly precedes knowledge hiding. In addition, perceived control of time negatively mediates the relationship between work interruptions and knowledge hiding. Also, the team temporal leadership strengthens the negative impact of interruption and perceived control of time and effect of perceived control of time on knowledge hiding. This study seeks to expand the existing research on work interruptions and knowledge hiding by incorporating aspects of team dynamics, particularly temporal leadership, to foster a more comprehensive understanding of knowledge management practices within organizations. Besides, we show a new direction of how strong team temporal leadership not just have positive effect but also negatively affect employees in managing time when faced with human work interruption. These theoretical and practical insights will aid organizations to better manage their work interruption.

3 - A Patent-Based Approach to Analyzing Technological Changes: the Impact of COVID-19 Pandemic on Digital Healthcare Technology

Hyunjin Shin, Ajou University, Suwon-si, Korea, Republic of, Sungjoo Lee

Unexpected social events such as pandemics have radical and far-reaching effects on technological change. Accurately identifying and understanding the ripple effects of these social issues on technological development is essential to strengthening technological responsiveness and establishing long-term development strategies. This study proposes a systematic approach to analyzing technological change made to respond to such events. To achieve this, patents were adopted to extract technological content, based on which pre- and post-event technology trees were developed to be compared for investigating technological changes. The proposed approach was applied to analyzing technological changes in the digital healthcare field before and after the COVID-19 pandemic. This study is expected to contribute to establishing faster and effective technological response strategies, promoting technological development, and securing long-term competitiveness by identifying and interpreting technological changes brought about by social events.

4 - The aggregate effects of firms' IT investments on the structure of a production network and the industry-level prices of intermediate inputs

Fengmei Gong, University of La Verne, La Verne, CA, United States, Byungwan Koh, Barrie Nault

A growing body of literature argues that as firms change their suppliers in response to technological innovations, the structure of their production network is endogenous to technological innovations. Furthermore, it suggests that information technology (IT) has plays a crucial role in technological innovations and in subsequent economic outcomes. Drawing from these insights, we investigate whether firms' IT investments are associated with the structure of a production network and, subsequently, whether the structure of a production network is associated with industry-level prices of intermediate inputs while controlling for the direct relationship between firms' IT investments and the industry-level prices of intermediate inputs. Our measure of the structure of a production network is structural holes. A structural hole is the absence of a direct tie between two alters within an ego network. Using the data constructed from input-output tables, we find that aggregate

IT investments made by firms in an industry are positively associated with structural holes at the industry level. Furthermore, we find that the firms' IT investments are negatively associated with industry-level prices of intermediate inputs not only directly but also indirectly through structural holes at the industry level.

5 - ReEDS Performance Improvement

Merve Olmez Turan, National Renewable Energy Laboratory, Golden, CO, United States, Atharv Bhosekar, Maxwell Brown, Adam Christensen, Wesley Cole

The Regional Energy Deployment System (ReEDS) is an open-source, spatially explicit, long-term capacity expansion model for the bulk electric power system of the contiguous United States, encompassing multiple scenarios with technological and political assumptions (see https://github.com/NREL/ReEDS-2.0). With the increased needs for capabilities, higher temporal and spatial resolutions to model the evolution of the power system with modern technologies and low-carbon pathways, ReEDS' model solution times have increased significantly from 4-6 hours in 2018 to 18-48+ hours in 2023 . Also, the model size for commonly-run ReEDS scenarios reached 22 and 28 million equations and variables, respectively. These runtimes can be especially challenging under certain scenario settings (e.g., very high temporal or spatial resolution) or with limited computational power. In this presentation, we will discuss several methods we used to improve model runtime, including data preparation, model modification, and solver tuning. The implementation of these methods shrank the model size to 7.2 and 7.3 million equations and variables, respectively. Furthermore, this led to a 77% reduction in the model's run time for commonly-run ReEDS scenarios. We will discuss the process of identifying areas for solve time improvements and how the specific enhancements for the ReEDS model might be applied to other similar large-scale models.

Summit - 345

Information Seeking Behavior in Decision Analysis

Invited Session

Decision Analysis Society

Chair: Zack Zhu, University of British Columbia, Surrey, BC, Canada

1 - Learning from Consideration Sets

Canan Ulu, Georgetown University, Washington, DC, United States, Bharadwaj Kadiyala, Dorothee Honhon

We consider the optimal assortment under the Random Consideration Set model when the firm can learn about consumers' product consideration probabilities and show that it depends on the consumers' preference order and the product informativeness order. When these orders are identical, the optimal assortment is a popular set.

2 - Search in the Dark

Sasa Zorc, University of Virginia, Darden School of Business, Charlottesville, VA, United States, Manel Baucells

The classic sequential search problem rewards the decision maker with the highest sampled value, minus a cost per sample. If the sampling distribution is unknown, then a Bayesian decision maker faces a complex balance between exploration and exploitation. We solve the stopping problem of sampling from a Normal distribution with unknown mean and unknown variance and a conjugate prior, a longstanding open problem. The optimal stopping region may be empty (it may be optimal to continue the search regardless of the offer one receives, especially at the early stages), or it may consist of one or two bounded intervals. While a single reservation price cannot describe the optimal rule, we do find an optimal index policy taking the form of a standardized reservation rule: stop if and only if the standardized value of the current best exceeds a threshold that depends on the standardized search cost. We also provide an algorithm to compute the index function, producing a practical way to implement the optimal stopping rule for any given prior, sampling history, and sampling horizon.

3 - Decision Analytic Explanations for Information Avoidance and Willful Ignorance

Zack Zhu, University of British Columbia, Surrey, BC, Canada, Steven Shechter, Woonghee Huh

In formalizing information acquisition decisions as combined instrumental hedonic utility maximization problems, we develop insights on the degree to which individuals seek vs. avoid information in different settings. These settings include both decisions that affect primarily oneself (e.g., test results leading to disease treatment decisions) as well as those involving self vs. others tradeoffs (e.g., quarantining after a positive Covid test). We bring a behavioral lens to our model, which allows for a negative VOI, and thus rigorously explains why for some people, "ignorance is bliss."

Convex and Stochastic Optimization

Contributed Session

Contributed

Chair: Fatih Cengil, University of Arkansas, Fayetteville, AR, United States

1 - Training Neural Networks with User-Defined Dimension-Specific Convexity

Hyunho Kim, Sungkyunkwan University, Suwon, Korea, Republic of, Jong-Seok Lee

Convex functions play an important role in many areas of mathematics, such as optimization and probability theory, due to their convenient properties. This study proposes a novel neural network architecture that approximates convex functions over a user-defined specific subset of features. To estimate such a dimension-specific convex function, we perform data augmentation through symmetrization, utilizing all possible symmetrical combinations for the dimensions requiring convex constraints. Additionally, we employ a partially connected neural network with exponentiated weights to preserve convexity and monotonicity. The proposed method integrates these convex monotonic neural networks to make a final prediction. This approach ensures convexity for user-defined dimensions while providing highly expressive function estimation based on neural networks. We validated the effectiveness of the proposed method through various experiments, showing that it is both effective and practically applicable across different areas.

2 - Approximate IP Models for Lot Sizing and Cardinality Constraints in Portfolio Optimization

Raphael Hauser, University of Oxford, Oxford, United Kingdom

Portfolio optimization with lot sizing or cardinality constraints leads to quadratic mixed integer programming problems that can usually only be solved in limited dimension. While thresholding and rounding approaches are fast and work well most of the time, they can be substantially suboptimal in certain circumstances. We discuss mixed linear integer programming approximations that are scalable in practice and perform favorably in comparison with rounding on practical portfolio problems.

3 - EXPRESS: Automatic Convexity Detection and Transformation to Conic Forms for Nonlinear Optimization

Qiuwei Li, Alibaba US, DAMO Academy, Bellevue, WA, United States, Liang Zhao, Minghan Yang, Wotao Yin, Kuo-Ling Huang

Nonlinear optimization problems are often more effectively solved when converted into conic optimization forms, which leverage advanced conic solvers. These solvers generally require prior transformations into canonical forms, a step that is often laborious. To streamline this process, we introduce EXPRESS, an innovative optimization toolkit designed to automatically detect the convexity of nonlinear functions and transform these problems into their equivalent conic forms. When direct transformation is infeasible, EXPRESS provides symbolic analysis of function convexity to guide the choice of a solver. We validate the effectiveness of EXPRESS with experimental results on the MINLPLib and CUTEST datasets, demonstrating its proficiency in simplifying and accelerating nonlinear optimization processes.

4 - Perturbed Gradient Descent using Tempered Linear Fractional Stable Noise

Farzad Sabzikar, Iowa State University, Ames, IA, United States, Mohammad Fili, Guiping Hu

Navigating the complex landscapes of non-convex optimization presents significant challenges in machine learning, particularly when traditional gradient descent methods with Gaussian assumptions fail to escape local minima or reach more favorable, flat regions. To tackle these challenges, our approach perturbs the gradient descent by introducing tempered linear fractional stable noise (TLFSN), derived from the increments of tempered fractional stable motion (TLFSM), significantly enhancing the optimizer's ability to overcome these limitations. Our methodology is distinguished by incorporating a tempering technique that controls the magnitude of noise-induced jumps. This innovative approach manages the impact of heavy-tailed, correlated noise and marks a pioneering advancement in optimization. By integrating TLFSN and TLFSM, we transform how gradient descent navigates non-convex functions, offering a structured and effective exploration strategy. Theoretically, we establish a comprehensive framework to analyze the effects of tempering on the noise characteristics and the resulting behavior of optimizers. We derive critical bounds that elucidate the influence of heavy-tailed noise on optimization dynamics, providing profound insights into stochastic processes. Empirical validations of our approach demonstrate significant improvements in optimizer performance, showing deeper landscape exploration and more efficient convergence. These findings highlight the transformative potential of our TLFSN method, setting new standards for optimization practices in machine learning.

5 - On the convex hull of bilinearly constrained set

Hyun-Ju Oh, Clemson University, Clemson, SC, United States, Margaret Wiecek, Boshi Yang

In this talk, we address convexification of sets defined by functions with multiple bilinear terms. We present conditions for the sets to have polyhedral convex hulls and for obtaining the closed form of defining constraints for the convex hull. By exploiting these results, we propose polyhedral approximations of the convex hulls. We present computational experiments to compare our approach with the classical methods in terms of tightness and convergence.

6 - Learning to Accelerate Tightening of Convex Relaxations of the AC Optimal Power Flow Problem

Fatih Cengil, University of Arkansas, Fayetteville, AR, United States, Harsha Nagarajan, Russell Bent, Sandra Eksioglu, Burak Eksioglu

We propose a machine learning (ML)-based method aimed at accelerating convergence to global solutions for the Alternating Current Optimal Power Flow (AC-OPF) problem. Our method enhances the efficiency of the optimality-based bound tightening (OBBT) algorithm, known in the literature for effectively tightening variable bounds in the non-convex AC-OPF problem. While the OBBT algorithm provides nearly global optimum solutions through tight convex relaxations, its inherent computational burden persists, even for medium-scaled power networks. The proposed novel ML-based policy, integrated into the OBBT algorithm, replaces the exhaustive OBBT without compromising optimality guarantees. This policy dynamically selects a subset of variables whose sequential bound tightening contributes to tighten the convex relaxation of the AC-OPF problem. To this end, we leverage historical data to learn a correlation between the load profiles and variable subsets via their rankings. Our policy, coupled with the parallel implementation of the OBBT algorithm, facilitates the discovery of near-global optimal solutions in significantly reduced computation times. We demonstrate this through detailed numerical experiments on medium to large-scale instances with up to 3,375 buses. Across the held-out set of instances, we observe up to 20x speed-up in run times of the ML-accelerated OBBT algorithm. To our knowledge, this is the first ML-based approach to demonstrate such large speed-ups for tightening convex relaxations on realistic large-scale power grid instances.

Recent Development in Sustainable and Socially Responsible Operations

Invited Session

MSOM: Sustainable Operations

Chair: Anyan Qi, The University of Texas at Dallas, Richardson, TX, United States

1 - Area Conditions and Positive Incentives: Engaging Local Communities to Protect Forests

Xavier Warnes, Indiana University, Bloomington, IN, United States, Joann de Zegher, Dan Iancu, Erica Plambeck

Agricultural production is a dominant driver of tropical deforestation, causing alarming CO2 emissions and loss of biodiversity and ecosystem services. Complex land tenure systems coupled with low enforcement of conservation laws enable farmers to convert tropical forests into productive land for a better income. We propose positive incentives with area conditions for local communities to prevent this deforestation while increasing farmer welfare. We model the deforestation decisions of the community using a cooperative game in partition correspondence form and show how these area-conditional incentives can leverage the existing social capital in agricultural communities. Finally, we demonstrate the effectiveness of these conditions by using data from the Indonesian context.

2 - Managing Online Service Platforms: Service Provision, Contract Design, and Customer Review

Xin Fang, Singapore Management University, Singapore, Singapore, Linqiu Li, Qiyuan Deng, Yun Fong Lim

This paper studies the service provision, contract design, and customer review of online service platforms in the presence of asymmetric quality information. We consider an accommodation-sharing platform on which a landlord lists a house for booking. The house can be of high or low quality, which is unknown to customers. To increase customers' willingness to pay, the landlord can provide value-added service. For every successful booking, the platform charges a commission fee. By analyzing the equilibrium decisions of the three parties, we find that the high-quality landlord can adopt a higher service level and price to signal quality. A costless separating equilibrium emerges if the high-quality landlord has a significant advantage in service cost. To maximize its profit, the platform's optimal commission fraction changes based on the service cost factor and the reservation profit difference between the high and low-quality landlords. We further develop a two-period model in which the second period's customer may learn the house quality from the review left by the first period's customer. We find that the emergence of review makes a costless separating equilibrium achievable even if the two types of landlords have similar service costs. The high-quality landlord benefits from a higher review access rate, but interestingly, a moderate review access rate and service cost factor may maximize social welfare.

3 - Reusable Packaging with Consumer Incentives

Yunlong Peng, University of Warwick, Coventry, United Kingdom, Fei Gao, Jian Chen

An increasing number of consumers have begun using their own reusable packaging to mitigate disposable packaging waste. However, the considerable inconvenience associated with using reusable packaging has constrained consumer adoption. This paper explores two strategies implemented by profit-maximizing firms to encourage the adoption of reusable packaging: (i) offering incentives, including monetary and pro-environmental incentives, and (ii) providing firm-owned reusable packaging to consumers. We study the effectiveness of these strategies and examine their environmental implications.

4 - Combating Excessive Overtime in Global Supply Chains

Chuanya Jiao, University of Science and Technology of China, Hefei, China, People's Republic of, Anyan Qi, Jiayu Chen

Suppliers operating in developing economies may resort to compelling their workforce to engage in excessive overtime, resulting in severe physical and mental health issues for workers and the potential for significant damage to the brand image of multinational enterprises (MNEs) if these practices are exposed to the public. In this paper, we develop a game-theoretic model of a dyadic supply chain to analyze a manufacturer's operational strategies to combat the use of excessive overtime by a supplier. These strategies encompass a stick strategy of auditing the supplier's practice (i.e., the auditing strategy) and carrot supplier-development strategies of subsidizing the supplier's capacity improvement initiative (i.e., the capacity-subsidy strategy) and cross training the supplier's workers to increase their versatility (i.e., the cross-training strategy). When both capacity subsidy and auditing are viable, interestingly, capacity subsidy may be a complement for auditing, contrary to the naive belief that the strategies are always substitutes in combating excessive overtime. Compared to the case when auditing is the sole viable strategy, we find that capacity subsidy may backfire, increasing excessive overtime and decreasing social welfare, when capacity subsidy and auditing are substitutes. Furthermore, the capacity subsidy could lead to social welfare that is even higher than that in a centralized supply-chain benchmark without the capacity subsidy. In situations where both cross-training and auditing are viable, cross training may also be a complement for auditing, driven by the enhanced flexibility of the labor force. However, cross-training may also backfire, resulting in increased excessive overtime and decreased social welfare.

5 - Index-Based Yield Protection for Smallholder Farmers

Can Zhang, Duke University, Durham, NC, United States, Kehan Lu, Jing-Sheng Song

Government subsidies are common in the agricultural sector to protect farmers from unexpected losses. Two major forms of agricultural subsidies are price protection, under which farmers are subsidized when the market price is low, and yield protection, under which farmers are subsidized when the crop yield is low. While price protection is popular in both developed and emerging economies, implementing yield protection in emerging economies is challenging due to the high costs of yield assessment for small farms. This research examines the design of a recently emerged index-based yield protection policy, which triggers subsidies when a pre-determined index (e.g., rainfall) predicts a low yield, thereby avoiding costly yield assessment. Our analysis highlights how the (in)accuracy of the index can lead to nuanced trade-offs and novel insights, and provides recommendations for the design of index-based subsides.

Infrastructure Network Resilience

Invited Session

OPT: Network Optimization

Chair: Pelin Kesrit, Texas A&M University, College Station, TX, United States

Co-Chair: Bahar Çavdar, Rensselaer Polytechnic Institute, Troy, NY, United States

1 - Simple v/s non-simple repair policies for networks under simultaneous failures of its components

Guido Lagos, Universidad Adolfo Ibáñez, Viña del Mar, Chile, Cristóbal Reyes, Héctor Olivero, Jorge Navarro

In this work, we study repair policies for reliability networks that are subject to simultaneous failures of its components. Indeed, we assume that “shocks” arrive in a continuous-time Markovian fashion, each shock hits a subset of the components, and once a component is hit it stops working. Depending on the configuration of working and failed components, the network can be either working or non-working. Furthermore, a failed component can be repaired at a component-repair cost, and also the whole network can be repaired once it fails, at a (higher) network-repair cost. Hence, a trade-off arises between saving the component-repair cost by letting them fail, and saving the network-repair cost by repairing components so the network has less chance of failing. We study several repair policies in this setting. Indeed, we consider a family of simple but interpretable repair policies where all failed components are repaired when r or more components have failed, and derive exact expressions for the expected network failure time and for the long-term average cost. Then we consider more involved policies derived using Markov Decision Processes, and compare their performance to the simple repair policies. We study conditions under which one policy is better than the other.

2 - Logistics of Infrastructure Network Restoration under Incomplete Inforamtion

Bahar Çavdar, Rensselaer Polytechnic Institute, Troy, NY, United States, Joseph Geunes, Subhojit Biswas

In this paper we study repair crew routing problem for infrastructure network restoration under incomplete information. We consider a disrupted infrastructure network where the dispatchers know the locations of service losses but not necessarily the actual fault locations. We model this problem as a finite horizon Markov decision process and develop efficient solution methods using reinforcement learning methods. Our solution method uses structural results and state-space aggregation to address the time-sensitive nature of such decisions.

3 - Fortifying Distribution Network Nodes Subject to Disruptions

Pelin Kesrit, Texas A&M University, College Station, TX, United States, Bahar Çavdar, Joseph Geunes

We consider a distribution network for delivering a natural resource or physical good to a set of nodes, each of which serves a set of customers, in which flow disruptions may occur at one or more nodes. Each node receives flow through a path from one or more source nodes, implying that a node experiences a disruption if a disruption occurs at one or more nodes on each path from a source node. All nodes in the network are subject to a future disturbance of an uncertain degree of severity, and we assume we can quantify the degree of severity, and that it follows some well-defined probability distribution. For each node in the network, we wish to determine a fortification level that enables the node to withstand a disturbance up to some level of severity. The cost of fortification is nondecreasing in the maximum-severity fortification level chosen, and we wish to maximize the expected number of customers who do not experience a disruption following the occurrence of a disturbance, given a limited fortification budget. We formulate this problem as a mathematical program, characterize useful properties of optimal solutions, and provide methods for determining optimal fortification levels under various assumptions on the probability distribution of the disturbance severity and the network structure.

4 - Balanced Design of Important Components in Multi-Commodity Infrastructure Networks

Kash Barker, University of Oklahoma, Norman, OK, United States, Andres Gonzalez, Himadri Sen Gupta

In multi-commodity networks, determining which components to focus on for reducing the impact of a network disruption can be done by evaluating a metric of importance of each component to the network’s operation. On the other hand, having components in a multi-commodity network that are much more critical than others may expose the network to potentially significant disruptions as well as targeted attacks. To address this issue, we propose a novel bi-objective optimization formulation to determine optimal actions for balancing the importance of components, illustrating with a multi-commodity infrastructure network example.

Summit - 421

Advances in Conic Optimization

Invited Session

OPT: Linear and Conic Optimization

Chair: Pouya Sampourmahani, Lehigh University, Bethlehem, PA, United States

1 - Interior Point Methods for Nearly Linear Time Algorithms

Aaron Sidford, Stanford University, Stanford, CA, United States

In this talk I will survey recent advances in designing and applying interior point methods to obtain improved running times for foundational continuous and combinatorial optimization problems. I will discuss how recent interior point methods can be leveraged to reduce linear programming, maximum cardinality bipartite matching and more to data structures problems that how these problems can be solved efficiently with techniques from randomized numerical linear algebra and graph theory. In particular, I will highlight joint work that showed linear programs with d variables and n constraints can be solved with high probability to high precision in time O~(nd + poly(d)) and touch upon its implications for solving combinatorial optimization problems.

2 - Faster LP Solvers via Robust Interior Point Methods

Jan van den Brand, Georgia Tech, Atlanta, GA, United States

In this talk, I will outline techniques that led to major improvements in the theoretic performance of linear program solvers. A key element is the development of “Robust Interior Point Methods” designed to handle larger numeric or approximation errors. This allows for sublinear time per iteration via more aggressive variants of Karmarkar' acceleration scheme and cruder approximation from randomized linear algebra techniques. A crucial aspect here is measuring the centrality via softmax-functions, which provide a natural relaxation of wider neighborhoods like those based on L_∞-norms, while offering better analytic properties.

3 - On Quadratic Convergence for Semidefinite Optimization Problems

Pouya Sampourmahani, Lehigh University, Bethlehem, PA, United States, Mohammadhossein Mohammadisiahroudi, Ali Mohammad-Nezhad, Brandon Augustino, Saugata Basu, Tamás Terlaky

Attaining a fast convergence rate for interior point methods (IPMs) for solving semidefinite optimization (SDO) problems has historically depended on assuming non-degeneracy and strict complementarity assumptions. Literature shows that failing strict complementarity results in the convergence rate of IPMs not to accelerate. In this presentation, we discuss two approaches where a fast convergence rate can be attained without such assumptions. The first approach is based on higher-order IPMs applied to reparametrized weighted central paths, and the second one is based on a novel approach called iterative refinement for SDOs. We show that the weak assumption of interior point condition is all you need to achieve superlinear or quadratic convergence rates in each approach, respectively. We present numerical results for the first approach. We further show the second approach can be applied to improve the complexity of inexact classical and quantum solvers for SDO.

New Min-max Optimization Algorithms and Their Applications in Machine Learning and AI

Invited Session

OPT: Machine Learning

Chair: Yang Tianbao, Texas A&M University, College Station, TX, United States

Co-Chair: Bokun Wang, Texas A&M University, College Station, TX, 77840, United States

1 - An Optimal Single-Loop Algorithm for Convex Finite-Sum Coupled Compositional Stochastic Optimization

Bokun Wang, Texas A&M University, College Station, TX, United States

Our work revisits a class of convex Finite-Sum Coupled Compositional Stochastic Optimization (cFCCO) problems with many applications, including group distributionally robust optimization (GDRO), reinforcement learning, and learning to rank. To better solve these problems, we introduce a unified family of efficient single-loop primal-dual block-coordinate proximal algorithms, dubbed ALEXR. This algorithm leverages block-coordinate stochastic mirror ascent updates for the dual variable and stochastic proximal gradient descent updates for the primal variable. We establish the convergence rates of ALEXR in both convex and strongly convex cases under smoothness and non-smoothness conditions of involved functions, which not only improve the best rates in previous works on smooth cFCCO problems but also expand the realm of cFCCO for solving more challenging non-smooth problems such as the dual form of GDRO. Finally, we present lower complexity bounds to demonstrate that the convergence rates of ALEXR are optimal among first-order block-coordinate stochastic algorithms for the considered class of cFCCO problems.

2 - Advancing Tractability and Generalization for Smart "Predict-Then-Optimize" via Stochastic Minimax Reformulation

Jiawei Zhang, MIT, Cambridge, MA, United States

In stochastic optimization, certain parameters are often unknown, and contextual information is sometimes used to help estimate these key unknown parameters to solve the optimization problem accurately. This approach is known as contextual optimization. In this talk, I will introduce our algorithm designed to solve contextual optimization problems with computational tractability, optimality, and a generalization guarantee. This is achieved through a minimax reformulation.

3 - Nearly Optimal L-p Risk Minimization

Zhichao Jia, Georgia Institute of Technology, Atlanta, GA, United States, Guanghui Lan, Zhe Zhang

Convex risk measures play a foundational role in the area of stochastic optimization. However, in contrast to risk neutral models, their applications are still limited due to the lack of efficient solution methods. In particular, the mean L-p semi-deviation is a classic risk minimization model, but its solution is highly challenging due to the composition of concave-convex functions and the lack of uniform Lipschitz continuity. In this paper, we discuss some progresses on the design of efficient algorithms for L-p risk minimization, including a novel lifting reformulation to handle the concave-convex composition, and a new stochastic approximation method to handle the non-Lipschitz continuity. We establish an upper bound on the sample complexity associated with this approach and show that this bound is not improvable for L-p risk minimization in general.

4 - Doubly Smoothed Optimistic Gradients: A Universal Recipe for Smooth Minimax Problems

Taoli Zheng, The Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong, Jiajin Li, Anthony So

Smooth minimax optimization finds widespread applications in machine learning and operation research, but existing algorithms often rely on specific structural conditions like convexity, Kurdyka-Łojasiewicz properties and weak minty type conditions, which can be challenging to verify in practice. More importantly, even convex and nonconvex minimax optimization are typically treated separately. Our work takes the first step to provide a universal recipe to handle all of them through the doubly smoothed optimistic gradient descent ascent method (DS-OGDA), a universally applicable algorithm for smooth minimax problems. With a single set of parameters, DS-OGDA achieves $\mathcal{O}(\epsilon^{-4})$ complexity for both nonconvex-concave and convex-nonconcave optimization problems, and $\mathcal{O}(\epsilon^{-2})$ for convex-concave cases. With additional information at hand, DS-OGDA is also able to achieve the optimal or best-known results under each scenario.

SE32

Summit - 423

Robustness at the Intersection of Optimization, Statistics, and Machine Learning

Invited Session

OPT: Optimization Under Uncertainty

Chair: Peter Zhang, Carnegie Mellon University, Pittsburgh, PA, United States

Co-Chair: Hao Hao, Carnegie Mellon University, Pittsburgh, PA, United States

1 - An Adversarially Robust Formulation of Linear Regression with Missing Data

Yue Xing, Michigan State University, East Lansing, MI, United States, Alireza Aghasi, Saeed Ghadimi, Mohammad Javad Feizollahi

We present a robust framework to perform linear regression with missing entries in the features. By considering an elliptical data distribution, and specifically a multivariate normal model, we are able to conditionally formulate a distribution for the missing entries and present a robust framework, which minimizes the worst-case error caused by the uncertainty in the missing data. We show that the proposed formulation, which naturally takes into account the dependency between different variables, ultimately reduces to a convex program, for which we develop a customized and scalable solver. We analyze the consistency and structural behavior of the proposed framework in asymptotic regimes, and present technical discussions to estimate the required input parameters. We complement our analysis with experiments performed on synthetic, semi-synthetic, and real data, and show how the proposed formulation improves the prediction accuracy and robustness, and outperforms the competing techniques.

2 - A Smooth Clipping and Error-Feedback Approach for Distributed Optimization Under Heavy-Tailed Noise

Shuhua Yu, Carnegie Mellon University, Pittsburgh, PA, United States, Dusan Jakovetic, Soummya Kar

Motivated by understanding and analysis of large-scale machine learning under heavy-tailed gradient noise, we study distributed optimization with gradient clipping, i.e., in which certain clipping operators are applied to the gradients or gradient estimates computed from local clients prior to further processing. While vanilla gradient clipping has proven effective in mitigating the impact of heavy-tailed gradient noise in non-distributed setups, it incurs bias that causes convergence issues in heterogeneous distributed settings. To address the inherent bias introduced by gradient clipping, we develop a smoothed clipping operator, and propose a distributed gradient method equipped with an error feedback mechanism, i.e., the clipping operator is applied on the difference between some local gradient estimator and local stochastic gradient. We establish that, for the first time in the strongly convex setting with heavy-tailed gradient noise that may not have finite moments of order greater than one, the proposed distributed gradient method has mean-square error (MSE) that converges at a rate $O(1/t^\iota)$, $\iota \in (0, 0.4)$, where the exponent ι stays bounded away from zero, and is shown to be independent of the existence of higher order gradient noise moments $\alpha > 1$. Numerical experiments on both synthetic and real-world data validate our theoretical findings.

3 - On the Adversarial Robustness of Benjamini Hochberg

Louis Chen, NPS, Monterey, CA, United States

The Benjamini-Hochberg (BH) procedure is widely used to control the false detection rate (FDR) in multiple testing. Applications of this control abound in drug discovery, forensics, anomaly detection, and, in particular, machine learning, ranging from nonparametric outlier detection to out-of-distribution detection and one-class classification methods. Considering this control could be relied upon in critical safety/security contexts, we investigate its adversarial robustness. More precisely, we study under what conditions BH does and does not exhibit adversarial robustness, we present a class of simple and easily implementable adversarial test-perturbation algorithms, and we perform computational experiments. With our algorithms, we demonstrate that there are conditions under which BH's control can be significantly broken with relatively few (even just one) test score perturbation(s), and provide non-asymptotic guarantees on the expected adversarial-adjustment to FDR. Our technical analysis involves a combinatorial reframing of the BH procedure as a ``balls into bins'' process, and drawing a connection to generalized ballot problems to facilitate an information-theoretic approach for deriving non-asymptotic lower bounds.

4 - Finding Pareto Efficient Solutions in Robust Optimization with First-Order Methods

Hao Hao, Carnegie Mellon University, Pittsburgh, PA, United States, Peter Zhang

When designing and using robust optimization models, a key concern is to balance efficiency and robustness. For instance, trading-off between clean performance and adversarial performance in adversarial robust machine learning. Typically, model designers control this trade-off by adjusting either the uncertainty set's shape and radius hyperparameters or the so-called globalized/comprehensive robust optimization penalty hyperparameters. In both cases, finding each solution requires solving a different instance of robust optimization problem (with potentially additional computational steps to arrive at the Pareto frontier). This makes balancing efficiency and robustness computationally challenging in practice. In this paper, we show that an approximate efficiency-robustness Pareto frontier can be obtained efficiently in a single-shot via first-order methods for minimax optimization, where the Pareto frontier corresponds to the trajectory of the first-order methods.

Summit - 424

Distributional Robustness and Learning

Invited Session

OPT: Optimization Under Uncertainty

Chair: Mohammed Amine Bennouna, Massachusetts Institute of Technology, Cambridge, MA, United States

Co-Chair: Bahar Taskesen, EPFL, Lausanne, Switzerland

1 - Distributionally Robust Path Integral Control

Grani Adiwena Hanasusanto, University of Illinois Urbana-Champaign, Urbana, IL, United States, Hyuk Park, Duo Zhou, Takashi Tanaka

<div zzyype="">

We address a continuous-time continuous-space stochastic optimal control problem where the controller lacks exact knowledge of the underlying diffusion process. Instead, the controller relies on a finite set of historical disturbance trajectories. To tackle this challenge, we propose a novel approach called Distributionally Robust Path Integral control (DRPI). This method utilizes distributionally robust optimization (DRO) to make the resulting policy robust against the unknown diffusion process. Notably, the DRPI scheme bears resemblance to risk-sensitive control, allowing us to leverage the path integral control (PIC) framework as an efficient solution method. We establish theoretical performance guarantees for the DRPI scheme, which facilitates the determination of an appropriate risk parameter for the risk-sensitive control. Through extensive validation, we demonstrate the effectiveness of our approach and its superiority over risk-neutral and risk-averse PIC policies in scenarios where the true diffusion process is unknown.

2 - Diagnosing Model Performance Under Distribution Shift

Tiffany Cai, Columbia University, New York, NY, United States, Steve Yadlowsky, Hongseok Namkoong

Prediction models can perform poorly when deployed to target distributions different from the training distribution. To understand these operational failure modes, we develop a method, called DIstribution Shift DEcomposition (DISDE), to attribute a drop in performance to different types of distribution shifts. Our approach decomposes the performance drop into terms for 1) an increase in harder but frequently seen examples from training, 2) changes in the relationship between features and outcomes, and 3) poor performance on examples infrequent or unseen during training. These terms are defined by fixing a distribution on X while varying the conditional distribution of Y|X between training and target, or by fixing the conditional distribution of Y|X while varying the distribution on X. In order to do this, we define a hypothetical distribution on X consisting of values common in both training and target, over which it is easy to compare Y|X and thus predictive performance. We estimate performance on this hypothetical distribution via reweighting methods. Empirically, we show how our method can 1) inform potential modeling improvements across distribution shifts for employment prediction on tabular census data, and 2) help to explain why certain domain adaptation methods fail to improve model performance for satellite image classification.

3 - Bayesian Risk-Averse Reinforcement Learning

Yuhao Wang, georgia institute of technology, atlanta, GA, United States, Enlu Zhou

In this work, we study the Bayesian risk-averse formulation in reinforcement learning (RL). We adopt the Bayesian risk Markov Decision Process (BRMDP) to account for the parameter uncertainty of the unknown underlying model, for which we derive the asymptotic normality that characterizes the difference between the Bayesian risk value function and the original value function under true unknown distribution. The result indicates the Bayesian risk-averse approach tends to pessimistically underestimate the original value function and such a gap increases with stronger risk-aversion but decreases with more available data. We then utilize this adaptive property in the setting of online RL as well as the online contextual multi-arm bandits (CMAB), a special case of online RL. We provide two procedures using posterior sampling for both the CMAB problem and the general RL problem, where for CMAB we establish the sub-linear regret bound with the regret defined as either the conventional regret or the Bayesian risk regret. Finally, we run several numerical experiments to test the performance of the proposed algorithms and verify the theoretical argument.

4 - It's All in the Mix: Wasserstein Machine Learning with Mixed Features

Aras Selvi, Imperial College Business School, London, United Kingdom, Reza Belbasi, Wolfram Wiesemann

The recent advent of data-driven and end-to-end decision-making across different areas of operations management has led to an ever closer integration of prediction models from machine learning and optimization models from operations research. A key challenge in this context is the presence of estimation errors in the prediction models, which tend to be amplified by the subsequent optimization model – a phenomenon that is often referred to as the Optimizer's Curse or the Error-Maximization Effect of Optimization. A contemporary approach to combat such estimation errors is offered by distributionally robust problem formulations that consider all data-generating distributions close to the empirical distribution derived from historical samples, where 'closeness' is determined by the Wasserstein distance. While those techniques show significant promise in problems where all input features are continuous, they scale exponentially when binary and/or categorical features are present. This work demonstrates that such mixed-feature problems can indeed be solved in polynomial time. We present a practically efficient algorithm to solve mixed-feature problems, and we compare our method against alternative techniques both theoretically and empirically on standard benchmark instances.

Co-Chair: Raghu Bollapragada, The University of Texas at Austin, Austin, TX, United States

1 - Inexact Sequential Quadratic Programming for Noisy Equality Constrained Optimization with Rank-Deficient Jacobians

Jiahao Shi, University of Michigan, Ann Arbor, MI, United States

We design, analyze and implement an inexact sequential quadratic programming (SQP) methods for solving noisy constrained equality optimization problems with an adaptive step size scheme in the absence of constraint qualifications.

2 - Variance-Reduction Method for Variational Inequality Problems

Afrooz Jalilzadeh, The University of Arizona, Tucson, AZ, United States

In this talk, we address variational inequalities (VI) with a finite-sum structure. We introduce a novel single-loop stochastic variance-reduced algorithm, incorporating the Bregman distance function, and establish an optimal convergence guarantee under a monotone setting. Additionally, we explore a structured class of non-monotone problems that exhibit weak Minty solutions, and analyze the complexity of our proposed method, highlighting a significant improvement over existing approaches. Numerical experiments are presented to demonstrate the performance of our algorithm compared to state-of-the-art methods.

3 - A Parameter-Free Gradient Method for Convex Optimization

Shiqian Ma, Rice University, Houston, TX, United States, Danqing Zhou, Junfeng Yang

We propose AdaBB, an adaptive gradient method based on the Barzilai-Borwein stepsize. The algorithm is line-search-free and parameter-free, and essentially provides a convergent variant of the Barzilai-Borwein method for general unconstrained convex optimization. We analyze the ergodic convergence of the objective function value and the convergence of the iterates for solving general unconstrained convex optimization. Compared with existing works along this line of research, our algorithm gives the best lower bounds on the stepsize and the average of the stepsizes. Moreover, we present an extension of the proposed algorithm for solving composite optimization where the objective function is the summation of a smooth function and a nonsmooth function. Our numerical results also demonstrate very promising potential of the proposed algorithms on some representative examples.

4 - Stochastic Algorithms for Constrained Optimization for Informed Learning

Frank E. Curtis, Lehigh University, Bethlehem, PA, United States, Qi Wang

I will present our work on stochastic Newton-based algorithms for solving constrained continuous optimization problems for informed supervised learning. The learning process is informed through the presence of constraints. Using physics-informed learning test problems, we demonstrate that our methods, which are backed by convergence guarantees, are computationally efficient and advantageous in practice. Of particular interest is our newly proposed projection-based variant of the Adam diagonal scaling scheme.

Summit - 427

Labor Planning at Amazon: Handling Uncertainty

Invited Session

Transportation Science and Logistics (TSL)

Chair: Martin Savelsbergh, Amazon Australia, Darlington, Australia

1 - Workforce Composition: Fixed of Flexible Labor?

Saba Neyshabouri, Amazon, New York, NY, United States

Amazon's Last Mile operations has access to different labor types to address its labor needs for both under-the-roof and on-the-road use cases. These labor types are broadly categorized into fixed and flexible labor pools. Each category offers its specific characteristics regarding cost, reliability, flexibility, and productivity. Coupled with business specific requirements, the existing trade-offs between cost and performance makes the prescription of the optimal workforce composition a non-trivial task.
In this talk, we present simple flow-type models that aim to address the optimal workforce optimization question by accounting for the

interactions between above mentioned characteristics. Our results show the benefits of simplified models to help stakeholders to develop a deeper understanding of the trade-offs and thus develop confidence in more sophisticated models.

2 - Labor Pooling: Nodal Planning

Hadi Panahi, Amazon, Bellevue, WA, United States, Thomas Fillebeen, Roman Levkin

Labor planning is challenging due to demand volatility and supply reliability. Traditionally sites rely on their own labor pool to fulfill demand. However, labor imbalance in geographically neighboring sites can be an opportunity to reduce over and under-staffing by leveraging their shared labor pool. In 2023, Amazon conducted the 'nodal planning' pilot in which adjacent sites, namely 'nodes', shared their labor pool to explore the potential benefits of cross site labor sharing. We leveraged a capacity simulation to estimate the benefits of nodal labor sharing. In addition, we propose an approach for nodal posting policy.

3 - Capacity-Aware Flexible Shift Planning for Under-The-Roof Operations at Amazon

Ramon Auad, Amazon, Santiago, Chile, Thomas Fillebeen, Roman Levkin

Amazon's Last Mile operations have traditionally relied on Fixed associates, who work recurring weekly schedules to meet labor demands. These associates can flex their hours up or down through voluntary extra time (VET) or voluntary time off, respectively. However, the flexibility provided by Fixed associates falls short in accommodating the variability in demand. To address this challenge, Amazon introduced Ready associates, a program that offers its members on-demand voluntary schedules, providing greater flexibility. While flexible labor (VET and Ready) helps reduce overstaffing costs, each option has its own business requirements, costs, capacities, and associate preferences.
In this talk, we present two mixed-integer programming models aimed at improving the overall effectiveness of flexible shift planning. A first long-term planning model utilizes historical data to estimate the distribution of capacity that Ready associates can offer throughout the week's hours; this model influences downstream hiring decisions and better aligns Fixed schedules with Ready associate preferences. The second short-term model jointly optimizes the planning of on-demand VET and Ready shifts, subject to lever-specific capacity constraints, business rules, and the hired Fixed capacity; these planned shifts are then offered to flexible associates to fill any remaining labor gaps. We show preliminary results that showcase the effectiveness of this approach.

4 - Intraday Under-the-Roof Staff Allocation for the Ultra-Fast Delivery at Amazon

Zeynep Sargut, Amazon, Bradenton, FL, United States, Ramon Auad

Same-Day Delivery is an ultra-fast business that offers delivery only a few hours after an order is placed for a selection of time-sensitive and essential items. Finding the best Under-the-Roof staff allocation across multiple processes just before the time of operations is a highly complex problem. Incorrect staff allocation may result in situations where we stop receiving orders for a given fast delivery window, leading to late deliveries or low staff utilization. The goal is to generate a robust plan that respects complex operational constraints and minimizes the risk of being out of capacity while maintaining acceptable staff utilization. For example, plans that involve frequent labor movements are not easy to execute and result in unproductive time. In this talk, we will introduce an optimization-based approach to support intraday staff allocation decisions.

Design and Optimization of Societally-aware Mobility Systems

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Devansh Jalota, Stanford University, Stanford, CA, United States

Co-Chair: Matthew Tsao, Lyft, San Francisco, CA, United States

Co-Chair: Gioele Zardini, Stanford University, Stanford, United States

1 - Designing and Operating Large-Scale Multi-Modal Transit Systems

Samitha Samaranayake, Cornell University, Ithaca, NY, United States

Affordable, equitable and efficient access to personal mobility is a fundamental societal need---with broad implications for personal well-being, economic mobility, education, and public health. Achieving this goal with a transportation system that is sustainable and scalable is unlikely to be possible without a significant mass-transit component supported by other modes. This raises many interesting questions on how new (and old) technologies can be integrated with mass transit to improve personal mobility and related societal goals (e.g., sustainability and equity). This talk will focus on some algorithmic and practical questions related to designing and operating integrated multi-modal transit systems. We will discuss the problem setting at a high-level and talk about some specific challenges/solutions in the context of bus line-planning in the multi-modal setting.

2 - Accessibility Insufficiency Minimizing Mobility Hub Design Using Stochastic Assignment Games with Recursive Logit

Joseph Chow, New York University, Brooklyn, NY, United States, Bingqing Liu, Xiyuan Ren

Mobility hubs are facilities that integrate multiple mobility services together, with the intent of not only facilitating transfers, but also providing support for fleets with idling/parking, charging/refueling, and maintenance as necessary. There is a lack of understanding of how mobility hubs can serve as control levers for public agencies to engage with mobility providers. In this study, we customize the platform framework from our earlier stochastic assignment game work to specifically design for mobility hubs in which subsidies are considered to incentivize mobility providers to serve. We solve a Stackelberg game using recursive logit to determine lower level flows and upper level prices to minimize accessibility insufficiency for equity. Measures are shown for quantifying the welfare and equity impacts of a mobility hub siting decision.

3 - A Unified Toll Lane Framework for Autonomous and High-Occupancy Vehicles in Interactive Mixed Autonomy

Ruolin Li, University of Southern California, Los Angeles, CA, United States, Philip Brown, Roberto Horowitz

We propose a toll lane framework for autonomous vehicles and high-occupancy vehicles on shared freeways where autonomous vehicles, capable of maintaining shorter headways, enhance traffic throughput. We designate a restricted, tolled lane, free for autonomous high-occupancy vehicles to boost social mobility, while other vehicles need to pay a toll for access. Assuming vehicles aim to minimize individual travel costs, we explore lane choice equilibria and rank vehicle types by their mobility-enhancing potential—introducing the "mobility degree". Using numerical examples, we address design challenges spanning optimal toll, occupancy threshold, and lane policy, demonstrating the framework's potential to harmonize high-occupancy and autonomous vehicle integration. We develop an algorithm for rational toll differentiation across vehicle types to efficiently reduce total commuter delay and assess the impact of potential vehicle misbehavior, like unauthorized toll lane use at reduced rates. Results show that self-interest-driven behaviors help mitigate impacts of moderate toll non-compliance, highlighting the framework's resilience. This study marks the first systematic exploration of a toll lane framework that facilitates the coexistence of autonomous and high-occupancy vehicles, providing insights for enhancing traffic management and integrating autonomous vehicles into existing transport infrastructure.

4 - Bottleneck Reservation Games: Stable Equilibrium and Its Inefficiency Bounds

Xi Lin, University of Michigan, Ann Arbor, MI, United States, Yafeng Yin

Connected and automated driving technologies could potentially mitigate congestion by letting drivers reserve time slots during peak hours. This study investigates how well this reservation system would work. Specifically, we explored the notion of stable equilibrium resulting from this type of games, and established theoretical bounds on the inefficiency of worst-case stable equilibrium under a range of general and specific scenarios.

5 - Quantifying Uncertainty: Advancing Robustness, Reliability, and Fairness in AI-Driven Transportation Demand Modeling

Dingyi Zhuang, MIT, Canbridge, MA, United States

This research addresses the limitations of traditional AI-driven transportation demand models, which predominantly focus on accuracy at the expense of robustness, reliability, and fairness. Robustness ensures models can handle unexpected data variations, reliability guarantees consistent performance across different conditions, and fairness ensures equitable service provision across diverse user groups. The lack of these attributes can lead to transportation systems that are unprepared for emergencies, inefficient resource allocation, and systemic biases that exacerbate social inequalities. To address these challenges, the study integrates Uncertainty Quantification (UQ) into AI-driven transportation demand models. UQ measures potential inaccuracies in model predictions, enhancing robustness by revealing performance under various scenarios, contributing to reliability by identifying prediction stability, and promoting fairness by highlighting disparities across different groups. The proposed framework not only achieves high accuracy but also emphasizes robustness, reliability, and fairness, thereby improving the overall efficiency and equity of transportation systems. This research includes the development of theoretical and practical methodologies for UQ and assesses the social impacts to ensure equitable transportation planning.

Robust and Fair Optimization Problems in Transportation and Supply Chain

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Hao Hao, Carnegie Mellon University, Pittsburgh, PA, United States

Co-Chair: Yidi Miao, Carnegie Mellon University, 5000 Forbes Ave, Hamburg Hall, Pittsburgh, PA, 15213, United States

Co-Chair: Peter Zhang, Carnegie Mellon University, Pittsburgh, PA, United States

1 - Retail on Autonomous Wheels: a TIME-Sensitive Traveling Salesman Problem

Zhuolun Dong, University of Texas at Austin, Austin, TX, United States

The rapid advancement in self-driving technology has brought mobile retail into the spotlight. Motivated by its tremendous potential, we present a model, theory, and insights into the operations of the business model, where a wheeled store traverses across a service region, selectively seeks locations in which to perch, and fulfills local customer demand. The goal of the retailer is to balance between perching and migrating to maximize the total revenue during a service time window. To dispatch such a store, the retailer needs to consider the following time-sensitive factors: (i) How busy the service is, (ii) how soon customers come to the store, and (iii) how fast the product freshness decays. We propose and analyze a model that incorporates these factors into the classical traveling salesman problem (TSP), which we call the "time-sensitive TSP" (TSTSP). Using the continuous approximation approach, we derive the order of the optimal revenue, as well as the upper and lower bounds in the asymptotic regime as demands increase to infinity. The tightness of bounds is validated. Our analytical and numerical analysis demonstrates that store mobility creates value by bringing proximity to customers and by taking advantage of flexible repositioning to reach high-profit areas. In particular, the store opts to migrate more frequently during the initial period of the business hours than later on. The store also shifts more time to perching if customer response time becomes longer. These findings demonstrate the potential of mobile retail to emerge as a competitive new retail form.

2 - Inventory Management for Promotional Sales Under Limited Information

Doran Wood, Southern Methodist University, Dallas, TX, United States, Sila Cetinkaya, Eojin Han

We consider a retailer operating in a promotional sales setting and evaluate both risk-neutral and risk-averse inventory policies under limited information. Our primary goal is to analytically characterize the worst-case demand distribution and identify optimal operational policies in closed-form. In addition to analytical takeaways and managerial insights, numerical experimentation is conducted across varying demand distributions to verify our results and to show the advantages and disadvantages between the various policies and modeling approaches.

3 - Fair Optimization of Mobility Subsidies in Multimodal Transportation Networks

Lindsay Graff, Carnegie Mellon University, PITTSBURGH, PA, United States

Several American cities recently piloted Universal Basic Mobility programs with the intention of removing the monetary cost barrier to transportation. In these pilots, the government distributed a mobility subsidy to eligible residents to be used on various mobility services: public transit, transportation network company, bikeshare, and shared scooters. Despite research showing that accessibility indicators vary across space, all participants received the same monetary benefit regardless of residence. The consequence of this policy is that some residents are required to use more of their mobility funds to reach the same destination in the same amount of time, relative to other residents. This highlights a potential limitation in the current approach to program design. In this work, we address this shortcoming and present a method for the optimization of mobility subsidies, where the objective is to maximize job accessibility for eligible subsidy recipients. Our method explicitly accounts for fairness by ensuring that recipients can each reach a similar number of jobs using the city's multimodal transportation network. This is accomplished by differentially allocating the program budget based on a recipient's residence to account for the fact that transit service and micromobility infrastructure are location dependent. We illustrate the method using open-source data from Pittsburgh, PA, one of the cities to implement a Universal Basic Mobility program. Our results show that mobility subsides are a promising instrument to improve access to jobs and alleviate transportation discrepancies.

4 - Transportation Service Region Design Under Distributional Uncertainty

Yidi Miao, Carnegie Mellon University, Pittsburgh, PA, United States

We propose a novel framework for the design of dedicated transportation service regions, aimed at optimizing operations cost through the partitioning of the service region. By leveraging the accumulated operational data over time, our framework assumes that dedicated regions for vehicles can be effectively managed and optimized. To address the inherent ambiguity in demand realization, we adopt a data-driven distributionally robust optimization approach, preventing decisions from out-of-sample effects. Our primary objective is to partition the entire service area into several contiguous and independent districts, while minimizing overall operational costs. This is achieved through a discrete approximation of the worst-case distribution within the ambiguity set, coupled with contiguity constraints to ensure practical implementation. The proposed framework is robust and adaptable, making it applicable to similar transportation and logistics problems.

5 - Optimal Allocation and Route Design for Station-Based Drone Inspection of Large-Scale Facilities

Lei Cai, wuhan university, wuhan, China, People's Republic of

The utilization of drones to conduct inspections on industrial electricity facilities, such as large-sized wind turbines, has recently received significant attention, mainly due to its potential to enhance inspection efficiency and save maintenance costs. Motivated by the advantages of drones for facility inspection, we present a novel station-based drone inspection problem (SDIP) for large-scale facilities. The objective of SDIP is to determine the locations of multiple homogeneous automatic battery swap stations (ABSSs) equipped with drones, assign facility inspection tasks to the ABSSs with operation duration constraints, and design drone inspection routes with battery capacity constraints, such that minimize the sum of fixed ABSS costs and drone travel costs. The SDIP can be regarded as a variant of the location-routing problem, which is NP-hard and difficult to solve optimally. To obtain the optimal solution of SDIP efficiently, we firstly formulate this problem into an arc based formulation and a route based formulation, and then develop a logic-based Benders decomposition (LBBD) algorithm to solve it. The numerical results on five scales of randomly generated instances validate the effectiveness of the LBBD algorithm. Specifically, the LBBD can solve all small- and middle-sized instances, and seven out of ten large-sized instances in 1000 seconds. Furthermore, we conduct a sensitivity analysis by varying the attributes of ABSSs and drones, and provide valuable managerial insights for large-scale facility inspection.

Intelligent Suggestions: Empowering Human Decision Dynamics

Invited Session

Behavioral Operations Management

Co-Chair: Lijia Tan, Eindhoven University of Technology, Helmond, Netherlands

1 - Demand Forecast for Product Selection with Signals: An Experimental Study

Wanshan Zhu, Renmin University of China, Beijing, China, People's Republic of, Manqi Li, Juan Li

In live streaming e-commerce, selecting the right product to be live-streamed is a crucial decision that relies on available signals indicating the products' market popularity. However, human bias in decision makers' interpreting these signals may result in a product selection mistake, where a less profitable product is chosen for live-streaming. To address this issue, we develop a behavioral theory and characterize the necessary and sufficient conditions of signal strength and quantity for product selection mistakes. By conducting experiments, we estimate the parameters of human bias and validate the conditions for such mistakes. The experiments validate our theoretical findings, showing that when faced with two products, human subjects may select a less profitable product due to either overestimation or underestimation. Specifically, these mistakes occur when one product has higher signal strength but lower signal quantity compared to the other, or vice versa. This highlights the importance of considering both signal strength and quantity for correct product selection in live streaming e-commerce.

2 - Algorithm Reliance in Queueing Systems

Stephen Leider, University of Michigan, Ann Arbor, MI, United States, Clare Snyder, Samantha Keppler

Decision-support algorithms promise potential gains to service efficiency and quality, but the realized value of these tools depends on whether and how workers actually use them to serve their customers. How do workers within queueing systems use algorithms to manage system loads? With a laboratory experiment varying system load and algorithm quality, we find people are sensitive to both dimensions: they are more willing to follow their algorithm's advice when its quality is superior or their system loads are high. However, algorithm use does not necessarily lead to better performance, in particular, faster throughput times. In fact, subjects' throughput times only improve over the no-algorithm baseline when the system load is high *and* algorithm quality is superior, although participants would benefit from working faster even under low loads. Results from regressions and a simulation show that there is a mutually-reinforcing effect of system load and algorithm quality on not only whether but also *how* subjects use the algorithm, affecting service and waiting times. The interaction of the high load and superior algorithm lead subjects to serve customers faster than they would with the inferior algorithm or under low loads. We also test the effect of two interventions on participants' performance outcomes and show that these can improve service quality and speed, especially for workers facing low loads. We discuss the role of two mechanisms, learning by using and task reduction, that best explain our results, and the managerial implications for piloting new algorithms and implementing algorithms to promote service scale.

3 - Human-Adaptive Maintenance Optimization

Melvin Drent, Eindhoven University of Technology, Eindhoven, Netherlands, Rob Basten, Bas Van Oudenhoven, Collin Drent, Philippe Van de Calseyde

High-tech systems, infrastructure, and other capital assets require maintenance to remain operational. Sensors are installed to monitor the health of the asset, but these sensors are typically imperfect in that they may predict a breakdown of an asset when nothing is wrong, or they may predict that nothing is wrong, while a breakdown is imminent. We model this problem as a partially observable Markov decision process. Using sensor readings, we develop a belief of the underlying health condition of the asset. This belief can be used to warn a service engineer when it is time to inspect the asset, giving more accurate information on the underlying health condition. However, a service engineer may decide to ignore a warning if (s)he already received a few warnings, performed inspections, but did not find an issue. We perform an experiment to test how people react to warnings, i.e., to what extent they follow up the warnings and what determines their follow-up decision, e.g., the number of warnings that led to an inspection that was not necessary. We use our findings from the behavioral experiment to improve the model in that we optimize the warning signal, knowing how people may react to it. We perform a second experiment to see if our improved model leads to improved performance indeed.

Experimental Design and A/B Tests in Practice

Invited Session

Applied Probability Society

Chair: NIAN SI, HKUST, Hong Kong, Hong Kong

Co-Chair: Zeyu Zheng, University of California, Berkeley, Berkeley, CA, United States

1 - Cluster-Randomized Designs for One-Sided Bipartite Experiments

Jennifer Brennan, Google Research, Kirkland, WA, United States, Jean Pouget-Abadie, David Holtz, Vahab Mirrokni

The conclusions of A/B tests may be biased when the outcome of one unit depends on the treatment status of other units, a problem known as interference. We study interference in the setting of one-sided bipartite experiments in which the experimental units do not interact directly. Instead, their interactions are mediated through their connections to interference units on the other side of a bipartite graph. This type of interference is common in marketplaces and two-sided platforms. We present a natural model for interference in one-sided bipartite experiments using the exposure mapping framework. Minimizing the bias of the difference-in-means estimator under our model results in a balanced partitioning clustering objective with appealing robustness properties. We explore the use of cluster-randomized designs in the setting of symbiosis bias in recommender systems, in which users (experimental units) experience interference due to an algorithm's recommendations of a shared corpus of content (interference units).

2 - Statistical Inference and A/B Testing for First-Price Pacing Equilibria

Luofeng Liao, Columbia University, NYC, NY, United States, Christian Kroer

We initiate the study of statistical inference and A/B testing for first-price pacing equilibria (FPPE). The FPPE model captures the dynamics resulting from large-scale first-price auction markets where buyers use pacing-based budget management. Such markets arise in the context of internet advertising, where budgets are prevalent.

We propose a statistical framework for the FPPE model, in which a limit FPPE with a continuum of items models the long-run steady-state behavior of the auction platform, and an observable FPPE consisting of a finite number of items provides the data to estimate primitives of the limit FPPE, such as revenue, Nash social welfare (a fair metric of efficiency), and other parameters of interest. We develop central limit theorems and asymptotically valid confidence intervals. Furthermore, we establish the asymptotic local minimax optimality of our estimators. We then show that the theory can be used for conducting statistically valid A/B testing on auction platforms. Numerical simulations verify our central limit theorems, and empirical coverage rates for our confidence intervals agree with our theory.

3 - Producer-Side Experiments Based on Counterfactual Interleaving Designs for Online Recommender Systems

Shan Ba, LinkedIn, Mountain View, CA, United States, Yan Wang

Recommender systems have become an integral part of online platforms, providing personalized recommendations for purchases, content consumption, and interpersonal connections. These systems consist of two sides: the producer side comprises product sellers, content creators, or service providers, etc., and the consumer side includes buyers, viewers, or customers, etc. To optimize online recommender systems, A/B tests serve as the golden standard for comparing different ranking models and evaluating their impact on both the consumers and producers. While consumer-side experiments is relatively straightforward to design and commonly employed to assess the impact of ranking changes on the behavior of consumers (buyers, viewers, etc.), designing producer-side experiments for an online recommender/ranking system is notably more intricate because producer items in the treatment and control groups need to be ranked by different models and then merged into a unified ranking to be presented to each consumer. Current design solutions in the literature are ad hoc and lacking rigorous guiding principles. In this paper, we examine limitations of these existing methods and propose the principle of consistency and principle of monotonicity for designing producer-side experiments of online recommender systems. Building upon these principles, we also present a systematic solution based on counterfactual interleaving designs to accurately measure the impacts of ranking changes on the producers (sellers, creators, etc.).

4 - Metric Decomposition in A/B Tests

Nathaniel Stevens, University of Waterloo, Waterloo, ON, Canada, Alex Deng, Luke Hagar, Tatiana Xifara, Amit Gandhi

More than a decade ago, CUPED (Controlled Experiments Utilizing Pre-Experiment Data) mainstreamed the idea of variance reduction leveraging pre-experiment covariates. Since its introduction, it has been implemented, extended, and modernized by major online experimentation platforms. Despite the wide adoption, it is known by practitioners that the variance reduction rate from CUPED utilizing pre-experimental data varies case by case and has a theoretical limit. In this talk, we propose a new direction for sensitivity improvement whereby a target metric of interest is decomposed into components with high signal-to-noise disparity. Inference in the context of this decomposition is developed using both frequentist and Bayesian theory. We provide three real world applications demonstrating different flavors of metric decomposition; these applications illustrate the gain in agility metric decomposition yields relative to an un-decomposed analysis.

Navigating Distributions using Optimal Transport

Invited Session

Applied Probability Society

Chair: Bahar Taskesen, EPFL, Lausanne, Switzerland

1 - Empirical Martingale Projections via the Smoothed Adapted Wasserstein Distance

Johannes Wiesel, Carnegie Mellon University, Pittsburgh, PA, United States

Given a collection of multidimensional pairs $\{(X_i,Y_i):1\leq i\leq n\}$, we study the problem of projecting the associated suitably smoothed empirical measure onto the space of martingale couplings (i.e. distributions satisfying $\mathbb{E}[Y|X]=X$) using the adapted Wasserstein distance. We call the resulting distance the smoothed empirical martingale projection distance (SE-MPD), for which we obtain an explicit characterization. We also show that the space of martingale couplings remains invariant under the smoothing operation. We study the asymptotic limit of the SE-MPD, which converges at a parametric rate as the sample size increases if the pairs are either i.i.d. or satisfy appropriate mixing assumptions. Additional finite-sample results are also investigated. Using these results, we introduce a novel consistent martingale coupling hypothesis test, which we apply to test the existence of arbitrage opportunities in recently introduced neural network-based generative models for asset pricing calibration. (Joint work with J. Blanchet, M. Larsson, J. Park, E. Zhang, Z. Zhang)

2 -

Geometry of Constrained Mirror Flows: Insights and Applications in Diffusion Modeling

Ya-Ping Hsieh, ETH Zürich, Zürich, Switzerland

The emergence of diffusion models marks a significant milestone in data science, offering a versatile paradigm for tackling various tasks. Yet, despite their promise, developing efficient algorithmic solutions remains a formidable challenge. In addressing this, we propose an innovative approach that combines two fundamental mathematical frameworks: dynamical system theory and differential geometry. At the heart of our method lies a novel Riemannian geometric structure customized for probability measures, enabling the refinement of training schemes for diffusion models and thereby advancing their efficacy.

3 - Wasserstein Mirror Flows as Limit of the Sinkhorn Algorithm

Nabarun Deb, University of Chicago, Chicago, IL, United States, Young-Heon Kim, Soumik Pal, Geoffrey Schiebinger

We prove that the sequence of marginals obtained from the iterations of the Sinkhorn algorithm or the iterative proportional fitting procedure (IPFP) on joint densities, converges to an absolutely continuous curve on the 2-Wasserstein space, as the regularization parameter \varepsilon goes to zero and the number of iterations is scaled as 1/\varepsilon (and other technical assumptions). This limit, which we call the Sinkhorn flow, is an example of a Wasserstein mirror gradient flow, a concept we introduce here inspired by the well-known Euclidean mirror gradient flows. In the case of Sinkhorn, the gradient is that of the relative entropy functional with respect to one of the marginals and the mirror is half of the squared Wasserstein distance functional from the other marginal. Interestingly, the norm of the velocity field of this flow can be interpreted as the metric derivative with respect to the linearized optimal transport (LOT) distance. An equivalent description of this flow is provided by the parabolic Monge-Ampère PDE whose connection to the Sinkhorn algorithm was noticed by Berman (2020). We derive conditions for exponential convergence for this limiting flow. We also construct a Mckean-Vlasov diffusion whose marginal distributions follow the Sinkhorn flow.

4 - Distributionally Robust Control Using Optimal Transport

Bahar Taskesen, University of Chicago, Chicago, IL, United States, Dan Iancu, Cagil Kocyigit, Daniel Kuhn

Linear-Quadratic-Gaussian (LQG) control is a fundamental control paradigm that is studied in various fields such as engineering, computer science, economics, and neuroscience. It involves controlling a system with linear dynamics and imperfect observations, subject to additive noise, with the goal of minimizing a quadratic cost function for the state and control variables. In this work, we consider a generalization of the discrete-time, finite-horizon LQG problem, where the noise distributions are unknown and belong to Wasserstein ambiguity sets centered at nominal (Gaussian) distributions. The objective is to minimize a worst-case cost across all distributions in the ambiguity set, including non-Gaussian distributions. Despite the added complexity, we prove that a control policy that is linear in the observations is optimal for this problem, as in the classic LQG problem. We propose a numerical solution method that efficiently characterizes this optimal control policy. Our method uses the Frank-Wolfe algorithm to identify the least-favorable distributions within the Wasserstein ambiguity sets and computes the controller's optimal policy using Kalman filter estimation under these distributions.

1 - Learning-Based Pricing and Matching for Two-Sided Queues

Zixian Yang, The University of Michigan, Ann Arbor, Ann Arbor, MI, United States, Lei Ying

We consider a dynamic system with multiple types of customers and servers. Each type of waiting customer or server joins a separate queue, forming a bipartite graph with customer-side queues and server-side queues. The platform can match the servers and customers if their types are compatible. The matched pairs then leave the system. The platform will charge a customer a price according to their type when they arrive and will pay a server a price according to their type. The arrival rate of each queue is determined by the price according to some unknown demand or supply functions. Our goal is to design pricing and matching algorithms to maximize the profit of the platform with unknown demand and supply functions, while keeping queue lengths of both customers and servers below a predetermined threshold. This system can be used to model two-sided markets such as ride-sharing markets with passengers and drivers. The difficulties of the problem include simultaneous learning and decision making, and the tradeoff between maximizing profit and minimizing queue length. We use a longest-queue-first matching algorithm and propose a learning-based pricing algorithm, which combines gradient-free stochastic projected gradient ascent with bisection search. We prove that our proposed algorithm yields a sublinear regret $O(T^{5/6})$ and queue-length bound $O(T^{2/3})$, where T is the time horizon. We further establish a tradeoff between the regret bound and the queue-length bound: $O(T^{1-\gamma/4})$ versus $O(T^{\gamma})$ for $0<\gamma\leq 2/3$ (ignoring logarithmic factors).

2 - Online Learning and Optimization for Queues with Unknown Arrival Rate and Service Distribution

Guiyu Hong, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Xinyun Chen, Yunan Liu

We investigate an optimization problem in a queueing system where the service provider selects the optimal service fee p and service capacity μ to maximize the cumulative expected profit (the service revenue minus the capacity cost and delay penalty). The conventional predict-thenoptimize (PTO) approach takes two steps: first, it estimates the model parameters (e.g., arrival rate and service-time distribution) from data; second, it optimizes a model taking these parameters as input. A major drawback of PTO is that its solution accuracy can often be highly sensitive to the parameter estimation errors because PTO is unable to effectively account for how these errors (step 1) will impact the solution quality of the downstream optimization (step 2). To remedy this issue, we develop an online learning framework that automatically incorporates the aforementioned parameter estimation errors in the optimization process; it is an end-to-end approach that can learn the optimal solution without needing to set up the parameter estimation as a separate step as in PTO. Effectiveness of our online learning approach is substantiated by (i) theoretical results including the algorithm convergence and analysis of the regret ("cost" to pay over time for the algorithm to learn the optimal policy), and (ii) engineering confirmation via simulation experiments of a variety of representative examples. We also provide careful comparisons between PTO and our online learning method.

3 - Online Optimization for Network Resource Allocation

Yiqiang Zhao, Carleton University, Ottawa, ON, Canada

In this talk, we consider an on-line optimization problem in network resource allocation. In the network, there are N servers with resources which can be reserved at time t based on data at previous time slots to meet the unknown requests from the clients. Cost for reservation, for resource transfer, and also for violation occurs if the client request cannot be met. On-line algorithms based on randomized exponentially weights are proposed for minimizing the cost for both problems without and with a constrain, respectively. Performance of the algorithm is studied in terms of the regret.

This talk is based on joint work with Ahmed Sid-Ali, loannis Lambadaris, Gennady Shaikhet, and Amirhossein Asgharnia

4 - Dynamic Pricing for Make-to-Order Production Systems under Throughput Time Constraints: An effective computational method in the high-dimensional case

Chun Li, University of Chicago, Booth School of Business, Chicago, IL, United States, Baris Ata, NIAN SI

We consider a dynamic control problem in a make-to-order production setting, focusing on a multiclass, multi-server queueing system that serves multiple price-sensitive customer classes, each bound by specific throughput time constraints. To meet these constraints, the system manager can either dynamically adjust prices or reject orders when backlogs become excessive, thus incurring revenue losses. The objective is to minimize these discounted revenue losses through dynamic pricing, admission control, and scheduling decisions.

We approximate this problem by a multi-dimensional Brownian control problem in heavy traffic, and develop a neural network-based computational method tailored for high-dimensional problems. By interpreting the solution in the context of the original model, we propose an integrated dynamic pricing, admission control, and scheduling policy. The effectiveness of this policy is demonstrated through simulation.

Bayesian Optimization

Invited Session

Simulation Society

Chair: Peter Frazier, Cornell / Uber, Ithaca, NY, 14850, United States

Co-Chair: Raul Astudillo, California Institute of Technology, Pasadena, CA, United States

1 - Unexpected Improvements to Expected Improvement for Bayesian Optimization

Sebastian Ament, Meta, NYC, NY, United States, David Eriksson

Expected Improvement (EI) is arguably the most popular acquisition function in Bayesian optimization and has found countless successful applications, but its performance is often exceeded by that of more recent methods. Notably, EI and its variants, including for the parallel and multi-objective settings, are challenging to optimize because their acquisition values vanish numerically in many regions. This difficulty generally increases as the number of observations, dimensionality of the search space, or the number of constraints grow, resulting in performance that is inconsistent across the literature and most often sub-optimal.

Herein, we propose LogEI, a new family of acquisition functions whose members either have identical or approximately equal optima as their canonical counterparts, but are substantially easier to optimize numerically. We demonstrate that numerical pathologies manifest themselves in “classic” analytic EI, Expected Hypervolume Improvement (EHVI), as well as their constrained, noisy, and parallel variants, and propose corresponding reformulations that remedy these pathologies.

Our empirical results show that members of the LogEI family of acquisition functions substantially improve on the optimization performance of their canonical counterparts and surprisingly, are on par with or exceed the performance of recent state-of-the-art acquisition functions, highlighting the understated role of numerical optimization in the literature.

2 - Bayesian Optimization for Nonconvex Two-Stage Stochastic Optimization Problems

Jack Buckingham, University of Warwick, Coventry, United Kingdom, Juergen Branke, Ivo Couckuyt

Stochastic programming concerns optimization under uncertainty where average performance is the quantity of interest. In the first stage of a two-stage problem, here-and-now decisions must be made in the face of this uncertainty, while in the second stage, wait-and-see decisions are made after the uncertainty has been resolved. Typically, methods in stochastic programming assume that the objective is linear or convex, while Bayesian optimization allows to tackle non-convex problems that are expensive to evaluate. We present two knowledge-gradient based acquisition functions and demonstrate empirically that they outperform the naive approach of optimizing the two types of variables sequentially, both on synthetic and real-world examples.

3 - Pseudo-Bayesian Optimization

Haoxian Chen, Columbia University, New York, NY, United States

Abstract: Bayesian Optimization is a popular approach for optimizing expensive black-box functions. Its key idea is to use a surrogate model to approximate the objective and, importantly, quantify the associated uncertainty that allows a sequential search of query points that balance exploitation-exploration. Gaussian process (GP) has been a primary candidate for the surrogate model, thanks to its Bayesian-principled uncertainty quantification power and modeling flexibility. However, its challenges have also spurred an array of alternatives whose convergence proper- ties could be more opaque. Motivated by these, we study in this paper an axiomatic framework that elicits the minimal requirements to guarantee black-box optimization convergence that could apply beyond GP-related methods. Moreover, we leverage the design freedom in our framework, which we call Pseudo-Bayesian Optimization, to construct empirically superior algorithms. In particular, we show how using simple local regression, and a suitable “randomized prior” construction to quantify uncertainty, not only guarantees convergence but also consistently outperforms state-of-the-art benchmarks in examples ranging from high-dimensional synthetic experiments to realistic hyperparameter tuning and robotic applications.

4 - Gittins Indices as an Acquisition Function Design Principle in Bayesian Optimization

Alexander Terenin, Cornell University, Ithaca, NY, United States, Qian Xie, Raul Astudillo, Peter Frazier, Ziv Scully

Bayesian optimization is a popular class of black-box global optimization, which works by (a) building a probabilistic model for the objective function, and then (b) using the model to carefully decide where to evaluate the function gather data next by optimizing what is known as the acquisition function. Understanding how correctly design acquisition functions is a fundamental question in Bayesian optimization research, because choosing where to gather data next in the face of uncertainty leads to explore-exploit tradeoffs that must be balanced. The right balance can depend on the details of the precise setting at hand in non-obvious ways, and a thorough understanding of acquisition function design tends to only be available for problems with bandit feedback and other classical variants. In this talk, we show how Gittins index theory can provide new angles of attack for acquisition function design, especially in problems with explicit evaluation costs. Specifically, we map Bayesian optimization problems onto certain simplified analogues which can be solved exactly using Gittins index theory to derive an acquisition function for the setting at hand. In classical settings, the resulting acquisition functions are shown to perform strongly compared to baselines, especially once problem difficulty becomes large enough.

1 - The Sooner, The Better? Optimal Vaccination Policy with Limited Vaccine Supply

Miao Bai, University of Connecticut, Storrs, CT, United States, George Chen, Cuihong Li

We study the optimal vaccination policy in an infectious disease outbreak, considering the limited supply of the vaccine and its imperfect efficacy. The inclusion of imperfect efficacy introduces an additional compartment to the celebrated Susceptible-Infectious-Recovered model, giving rise to an infinite horizon optimal control problem. To facilitate theoretical analysis, we propose a novel variable transformation that converts the problem into an equivalent form with linear dynamics. Leveraging this transformation, we derive a closed-form expression for the optimal vaccination policy under infinite administrative capacity and establish theoretical structures for the optimal policy under finite capacity. Our results suggest that delaying the vaccination process may be optimal, especially when the vaccine is less effective, the vaccine supply is more limited, and the disease is more infectious. The optimality of delay occurs because the individual-level benefit of vaccination with imperfect vaccines, in terms of the reduction of infection risk, is non-monotonic in time; hence maximizing the benefit of vaccination requires a strategic allocation of limited vaccine supply over time. Building on these theoretical findings, our numerical study demonstrates the significant benefit of delay in reducing the total number of infections compared to policies without delay. Our study contributes to the methodology of solving optimal control problems in the context of infectious disease outbreaks. Moreover, it highlights scenarios in which delaying the start of the vaccination process can be beneficial -- an aspect of vaccination policy design that has been overlooked in the literature but has important implications for practice.

2 - Stopping the Revolving Door: MDP-Based Decision Support for Community Corrections Placement

Xiaoquan Gao, Purdue University, West Lafayette, IN, United States, Pengyi Shi, Nan Kong

We study the incarceration-diversion decision problem to reduce jail overcrowding and recidivism rates by leveraging community corrections. We build a large-scale Markov decision process (MDP) model to balance the tradeoffs among congestion, recidivism, and violation. The salient features of the criminal justice setting, including deterministic service times and occupancy-dependent costs, present significant theoretical and algorithmic challenges. We propose a unified approach with system coupling and policy deviation bounding to compare value functions. We establish the superconvexity of the value function, which provides a theoretical basis for developing an efficient algorithm based on a separation of time scales. We showcase the effectiveness of our algorithm in solving real-world problems through a case study using data from our community partner.

3 - Optimizing Portability in Affordable Housing Allocation

Yifeng Cao, University of British Columbia, Vancouver, BC, Canada, Yichuan Ding, Daniel Granot, Hao Zhang, Weihua Zhang

This study investigates the allocation of affordable housing for low-income families, focusing on the decision-making process of housing authorities. We explore dynamic allocation models to optimize "portability", which refers to the easiness for an applicant's request being met. Findings indicate that myopic strategy and linear approximation have their respective domains of applicability. In particular, when the moving requests have stationary arrival rates, we prove that a myopic policy is asymptotically optimal; whereas the myopic policy can perform suboptimal under nonstatinary arrival rates. In the latter case, we propose a forward looking policy that achieves asymptotic optimality. Our findings offer insights for policymakers grappling with the complexities of affordable housing provision.

4 - Analyzing the Effects of Judicial Rotation on Criminal Sentencing: An Operations Management Perspective

Yuwei Zhou, University of Chicago, Chicago, IL, United States, Baris Ata, Rhys Hester, Lawrence Wein

A distinctive aspect of South Carolina's judicial system, which consisted of 50 judges presiding over 46 counties, was judicial rotation: although judges spent much of their time in their home circuit, they traveled to an average of 12 counties (typically holding court for a week in each county) and counties encountered an average of 13 different judges throughout the year. The empirical findings of Hester (2017) revealed that judicial rotation led to judge shopping, where defendants would strategically wait for a lenient judge before agreeing to a plea bargain. In this study, we construct a mathematical model that attempts to capture the effects of judge shopping. By simulating the mathematical model, we compute the mean and standard deviation of the sentence length as a function of three operational characteristics: the amount of judicial rotation, the allowable shopping time window for defendants, and the capacity utilization of the judicial system. We observe that both the mean and standard deviation of the defendant sentence length decreases in the amount of judicial rotation and the allowable shopping window for defendants, and increases in the capacity utilization. The average reduction is modest (≤ 10%), although a small proportion of defendants are impacted in a significant way. In a variant of the model adapted to an urban setting where all defendants have access to all judges, the mean and standard deviation of the sentence length decreases in the number of judges, even in the absence of intertemporal judge shopping.

1 - Closer to Home: An Estimate-then-Optimize Approach to Improve Access to Healthcare Services

Jingyuan Hu, UCLA Anderson School of Management, Los Angeles, CA, United States, Fernanda Bravo, A Ghandi, Elisa Long

Geographic inequalities in access to essential health services extend beyond rural-urban differences to include socioeconomic, racial, and other disparities. Proximity to hospitals, clinics, and pharmacies varies greatly, complicating decisions about where to place these facilities to maximize access and utilization. Factors such as population health, individual preferences, and provider capacity all influence demand for services. This study introduces a novel estimate-then-optimize framework that combines structural demand estimation with an optimal facility location model. Unlike traditional approaches, this method uses aggregated data, such as market share, instead of relying on individual choices or outcomes, offering a more comprehensive understanding of health service needs.

2 - Policy Optimization for Personalized Interventions in Behavioral Health

Jackie Baek, New York University, New York City, NY, United States, Justin Boutilier, Vivek Farias, Jonas Oddur Jonasson, Erez Yoeli

We study the problem of optimizing personalized interventions for patients to maximize some long-term health outcome, in a setting where interventions are costly. We present a new algorithm we dub DecompPI, which consists of a prediction task from offline data. Theoretically, we show that under a natural set of assumptions on patient dynamics, DecompPI recovers at least 1/2 of the improvement between a naive baseline policy and the optimal policy. Through an empirical study on a mobile health platform for improving treatment adherence for tuberculosis, we find that DecompPI can provide the same efficacy as the status quo with approximately half the capacity of interventions.

3 - Large Language Models for Preventing Medication Direction Errors in Online Pharmacies

Cristobal Pais, University of California Berkeley, Berkeley, CA, United States, Jianfeng Liu, Robert Voigt, Vin Gupta, Elizabeth Wade, Mohsen Bayati

Errors in pharmacy medication directions can increase patient safety risks and operational inefficiencies. This study introduces MEDIC, a human-in-the-loop AI system that integrates domain knowledge with large language models (LLMs) to reduce these errors. MEDIC fine-tunes a first-generation LLM to extract core prescription components and assemble them into complete directions. In a retrospective study, MEDIC outperformed two LLM-based benchmarks. Prospectively, MEDIC reduced near-miss events —errors caught and corrected before reaching the patient— by 33% and enhanced overall operational efficiency.

4 - Disease Bundling or Specimen Bundling? Cost- and Capacity-Efficient Strategies for Multi-disease Testing with Genetic Assays

Hussein ElHajj, Santa Clara University, Santa Clara, CA, United States, Douglas Bish, Ebru Bish

We develop innovative models to optimize testing designs for infectious diseases that manifest with similar symptoms but often require different interventions. Our approach integrates multiplex assays (detecting multiple diseases from a single specimen) and pooled testing (combining specimens from multiple subjects). We construct the Pareto frontier for cost- and capacity-efficient solutions, derive structural properties and key insights on optimal designs, and develop efficient solution procedures for special cases. A case study on respiratory diseases, including COVID-19, demonstrates the advantage of our integrated, multi-disease testing design over existing methods.

1 - Payers and Waiters: Allocating Capacity in a Market with Line Sitting

Martin Lariviere, Northwestern University, Evanston, IL, United States, Achal Bassamboo

When capacity for an event is limited, consumers may queue for access. Alternatively, a consumer could hire someone to wait in their stead. Some thus compete via time and others via money. We examine such markets through a model in which consumers are subject to both time and monetary budget constraints. We show that the market outcome depends on whether consumers view time and money as substitutes or complements. When time and money are substitutes, line sitting does not change the allocation of who receives capacity. When they are complements, line sitting alters the market outcome with those earning low wages waiting for capacity while those earning high wages hire line sitters. Those with intermediate wages are squeezed out of the market.

2 - Why Do Managers Underdelegate? a Co-Productive Principal-Agent Model

Guillaume Roels, INSEAD, Fontainebleau, France, Vladimir Smirnov, Ilia Tsetlin, Andrew Wait

We consider a co-productive principal-agent (PA) model. Unlike traditional PA models, the principal can choose to work alone, i.e., to not hire the agent. We show that the problem of underdelegation stems from managers not partnering enough, but when they do, they tend to overdelegate the execution to the agent. Rather than controlling the agent, as the PA literature suggests, we propose to control the principal instead.

3 - The Enigma of Ticket Exchanges (and Other Reselling Markets)

Gerard Cachon, University of Pennsylvania, Philadelphia, PA, United States, Pnina Feldman

Abstract

The literature establishes (and practice confirms) that sellers can benefit from allowing consumers to purchase in advance of the date of actual consumption (e.g., concert tickets, sporting events, etc.). Because of this advance purchasing, consumers can find themselves either with a ticket that they no longer want, or without a ticket that they wish to have. In the past, scalpers would facilitate transactions among these consumers, for a fee. Sellers historically disliked those practices and actively worked to prevent them. In fact, we obtain a stark finding: an unfettered and efficient reselling market eliminates all of the benefits of advance selling, which justifies sellers' historic hostility to reselling. But now ticket exchanges are common, growing, and even embraced by the sellers. What changed? We present a theory that demonstrates reselling is actually beneficial for sellers under one crucial condition - the seller must have some control over the reselling process, thereby allowing the seller to earn something from each transaction through licensing fees to third-party sellers. The old-fashioned paper ticket did not give such control, but technology now enables electronic tickets, which do. In fact, a seller cannot earn more than what it receives from a properly designed reselling market (i.e., reselling is optimal for the seller), especially for popular events with limited capacity. Furthermore, speculators do not disrupt the market: i.e., the seller has no need for scalpers nor should fear them. In sum, our results explain why the seller's view towards reselling has shifted dramatically.

4 - What is the Impact of Labor Productivity on the Optimal Staffing Level?

Terry Taylor, U.C. Berkeley, Berkeley, CA, United States

No decision is more central to operations management than capacity, and no performance measure is more central to operations than productivity, i.e., output per unit time. What is the impact of this fundamental performance measure on this fundamental decision? This paper addresses this foundational question in the context of services: What is the impact of labor productivity on the optimal staffing level? To do so, the paper addresses one of the most basic questions that can be posed regarding a queueing system: What is the impact of the service rate μ on the optimal number of servers? The paper reveals that the answer exhibits a surprising, simple structure.

1 - Adaptive Server Behavior to Schedule Deviations and Its Consequences: Evidence from Operating Rooms

Yiwen Jin, University of Calgary, Calgary, AB, Canada, Yichuan Ding, Steven Shechter, Jugpal Arneja

We investigate how clinical teams in operating rooms (ORs) adaptively respond to real-time deviations from their scheduled plans. We examine if clinical staff modify their service speed based on being ahead or behind schedule, and the implications of these adjustments on patient readmissions and reoperations.

Utilizing a unique dataset of surgery times, both actual and scheduled, we employ a dynamic panel model with the Arellano-Bond approach to identify adaptive behaviors and use an instrumental variable (IV) approach to address endogeneity issues, thus estimating the impact of surgical speed on quality.

We discover a new type of adaptive behavior in OR scheduling. Our findings show that surgical and cleaning teams increase their speed when they are behind schedule and decrease it when ahead. Specifically, surgical teams expedite surgeries by an average of 5.6% per standard deviation delay in the planned start, while taking 10.5% longer when ahead. Cleaning teams adjust their turnover times by accelerating 10.3% or slowing down 22.1% based on their scheduling status. These deviations are leveraged as IVs to demonstrate causally that speeding up surgeries beyond the planned schedule decreases surgical quality, indicated by higher rates of readmissions and reoperations within 30 days.

Our study highlights how surgical and cleaning teams' response to schedule deviations affects surgical quality. This insight can help hospital managers better predict end-of-shift times and plan surgeries to balance efficiency and quality, evidenced by a counterfactual analysis revealing a convex relationship between surgical outcomes and schedule discrepancies.

2 - Untangling the Effect of Physician Cross-Platform Exposure: Who Reap the Benefits?

Sijia Gao, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Tingting Song

A growing number of physicians are exploiting social media as a means of exposure to reach potential patients, deliver healthcare information, and offer guidelines for patients seeking healthcare services. This study investigates how physicians' content creation on social media influences patients' demands and satisfaction towards the physicians on online health platforms. Using the difference-in-differences approach, we uncover asymmetric influences of cross-platform spillovers for high- and low-awareness physicians. Specifically, low-awareness physicians do not enjoy the benefits (i.e., the increased volume of consultation orders) from content creation, but their ratings turn to decline due to attention distraction caused by cross-platform activities. Conversely, for high-awareness physicians, we find a positive cross-platform spillover effect for consultation orders without decreasing their ratings. A further test shows that despite the existence of attention distraction from cross-platform services for high-awareness physicians, the negative impact on feedbacks is offset by higher ratings from their cross-platform consumers. Our findings enrich previous literature on cross-platform spillover and provide insights into leveraging inter-platform impacts to reap benefits for physicians and online health communities.

3 - Efficiency Gains in the Health Sector Through Data-Driven Patient Scheduling: the Case of Paediatric Rehabilitation Service

Benjamin Ravenscroft, University of Waterloo, Waterloo, ON, Canada, Nasser Barjesteh, Hossein Abouee Mehrizi

Leveraging data from a large outpatient pediatric rehabilitation network, this study investigates two mechanisms affecting throughput in a multi-appointment healthcare setting: the number of appointments patients require and appointment attendance. First, we employ discrete time survival analysis methods to estimate the relationship between initial wait times and appointment modality and the number of appointments patients will require. We find that longer initial waiting times and mixing appointment modalities (i.e., some in-person, some virtual) is associated with patients requiring more appointments before discharge. However, these effects are modulated by patient severity. We also collected a large dataset of outpatient appointment booking data. This data was used to investigate the relationship between factors such as patients' distances from their clinic, appointment modalities, and the number of patients' known future bookings on the likelihoods of appointment attendance, no-show, and cancellation. Building upon these empirical results, we use a simulation study to assess the impacts of using priority-based waitlist queues on overall system throughput in a setting where wait times affect the number of appointments patients will require. Our findings yield important empirical insights in a multi-appointment service setting. Furthermore, we demonstrate the value of 'personalizing' scheduling systems in settings where client classes respond differently to waiting times and appointment modality.

4 - The Impact of Hospitals' Annual Award Display on Patient Consultation: Evidence from a Natural Experiment

Yangzi Jiang, The Chinese University of Hong Kong (Shenzhen), Shenzhen, China, People's Republic of, Hao Wang, Jingqi Wang

Leveraging on an exogenous shock occurred on Haodf.com, a prominent medical consultation service platform in China, we explore how displaying the award sign influences the consultation volume in departments with different award status, including award-winning departments (AWD), non-awarded departments in hospitals with award (NAD), and departments in hospitals without any award (NAH). Haodf began displaying award signs (i.e., annual best hospital in various departmental categories) next to department names since November 2020. We also collected consultation data on the same set of hospitals and departments from Chunyu.com, another prominent online medical consultation platform in China. Using a difference-in-differences approach, we find that displaying award signs significantly increase the consultation volume in AWD, without reducing the consultation volume in NAD or NAH. In addition, the increase in consultations to AWD mainly comes from users with prior consultation experience with the focal department. Intriguingly, we also demonstrate that the financial barrier deters user migration from NAD to AWD. Our findings yield important managerial implications for expert service platforms by showing the effects of displaying the award sign on the user traffic distribution.

Innovations in Health Care Delivery

Invited Session

MSOM: Healthcare

Chair: Kamalini Ramdas, London Business School, London, United Kingdom

Co-Chair: Nazli Sonmez, ESMT Berlin, Berlin, Germany

1 - Increasing the Follow-up Rate of Patients Requiring Emergency High-Consequence Treatment

Nazli Sonmez, ESMT Berlin, Berlin, Germany, Kamalini Ramdas

A low attendance rate for urgent, high-consequence treatment is prevalent in the developing world. In poorer countries, ignorance about the illnesses people have, allied to the financial costs of attending for treatment, are two of the main reasons why they fail to show up for medical appointments. Yet, for many diseases, patients may need surgical treatment soon after diagnosis to prevent severe disability. This project aims to identify ways to increase the attendance rate of patients who need emergency high-consequence treatment. Traditionally, in care systems across the world, information about why patients must undergo a particular treatment or care plan is communicated by emphasising medical aspects of the disease, typically in scientific terms. This research, in contrast, analyses the effect of providing emotionally engaging information about how a patient's life experience can be changed by their medical condition. The study runs a two-stage, randomised controlled trial at the world's largest eye hospital, the Aravind Eye Hospital in India. Although this research focuses on urgent high-consequence care contexts in the developing world, poorer patients in both developing and developed countries are less likely to show up for medical appointments for both urgent and non-urgent care. This study hopes to improve the chances of poorer populations receiving the care they need and to help reduce needless blindness. Furthermore, it hopes to inspire other healthcare providers globally to adopt the proposed methods.

2 - Improving Decision-Making in Resource Allocation: Evidence from Inpatient Admission Decisions

Harriet Jeon, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States, Song-Hee Kim, Hummy Song

Routing mechanisms are crucial for efficiently matching specialized resources to customer needs at the lowest cost. Improving allocation, then, is of first-order concern for many organizations. But when human decision-makers are tasked with allocation in a complex environment, it can be challenging to understand their decision processes and design systems that enhance their decision quality. Leveraging rich data derived from electronic medical records, we explore how, in the context of physicians making routing decisions of patients from the ED to inpatient medical units, decision-makers incorporate new information and adapt their decision-making processes.

3 - When Should Doctors and Patients Use Shared Decision-Making Under Bounded Rationality?

Feray Tuncalp, Bilkent University, Ankara, Turkey, Rouba Ibrahim, Song-Hee Kim, Jordan Tong

In recent years, shared decision-making (SDM), where doctors and patients jointly decide on appropriate treatment options, has drawn a lot of attention in the healthcare domain. SDM promises to improve patient utility, in part, through personalized care. Doctors inform patients about their personalized prognosis regarding risk and outcome predictions, and patients can incorporate their personalized lifestyle and risk preferences. To provide insights into when to personalize diagnoses and patient preferences, we study the decision-making process between two treatments using a stylized model where we account for both patients' and doctors' bounded rationality in decision-making, as well as doctors' miscalibration in their attempt to account for the random errors. Contrary to the common medical belief which advocates personalization of both medical diagnoses and patient preferences for all conditions, we find that there is no one-size-fits-all policy for the healthcare decision-making process.

4 - Impact of Empirical Research on Operations Management

Nalin Shani, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Maria Ibanez

Empirical research has contributed significantly to the field of operations management (OM). There has been a steady increase in empirical research being generated. Given this trend, an important question arises: how empirical research shapes the OM literature. We plan to investigate the impact empirical research has on recent publications.

Commodities, Risk Management, Hedging, and Analytics

Invited Session

MSOM: iForm

Chair: Danko Turcic, The School of Business at the University of California, Riverside, Riverside, CA, United States

Co-Chair: Ye Liu, Syracuse University, Syracuse, United States

1 - Stochastic Capacity Investment in the Presence of Production Resource Uncertainty and Its Implications for Hedging

ONUR BOYABATLI, Lee Kong Chian School of Business, Singapore Management University, Singapore, Singapore, Guiyun Feng

Motivated by the recent incidents of production resource (component and financial resource) shortages, this paper studies a manufacturing firm's joint capacity investment and hedging decisions under demand and production resource uncertainties where the latter can be engineered by hedging. To this end, we consider a firm who produces and sells a single product in a single selling season to maximize its expected profit. We formulate a two-stage stochastic model. We conduct sensitivity analyses to examine the impact of production resource variability and its correlation with demand on the firm's optimal decisions and profitability as well as value of hedging. We identify correlation between demand and production resource uncertainty and the capacity investment cost as the key drivers of the optimal hedging decision. In particular, when the correlation is non-positive, the firm always fully hedges and production resource uncertainty is inconsequential for the firm. When the correlation is positive, full hedging is optimal only when capacity investment cost is sufficiently high. Otherwise, the firm chooses a partial hedging policy. Interestingly, the optimal partial hedge is chosen in such a way that there is no effect of production resource variability on the firm's profitability or capacity investment decision. We also find that the firm may optimally choose not to hedge at all, specifically, when the correlation is sufficiently high and the capacity investment cost is sufficiently low. Interestingly, we find that value of hedging decreases in correlation.

2 - Newsvendor&Rsquo;S Supplier Selection Problem with Correlated Supply and Demand Uncertainties

Liao Wang, The University of Hong Kong, Hong Kong, Hong Kong, Jin Yao, Sean Zhou, Hanyan Duan

We examine the supplier selection problem for a risk-averse newsvendor who faces stochastic demand and supply uncertainties. In addition to a single reliable supplier, we introduce multiple unreliable suppliers. Each unreliable supplier delivers the smaller of the ordered amount or its own stochastic capacity. Previous literature (Dada et al., A Newsvendor's Procurement Problem when Suppliers Are Unreliable, M&SOM, 2007, 9(1), 9-32) has established that with independent capacities and demand, a risk-neutral newsvendor will always prioritize cheaper suppliers (referred to as the "DPS's rule"). In this study, our objective is to maximize CVaR (Conditional Value at Risk) for the risk-averse newsvendor, while considering correlated demand and supply uncertainties. Our study reveals two key findings. First, we demonstrate that risk aversion alone does not influence the DPS's rule . Second, we establish general conditions under which the DPS's selection rule is reversed. Specifically, we identify a general sufficient condition, without assuming any specific relationship among the random variables, that leads to the selection of a more expensive supplier over cheaper ones. Our insight is that a positive relationship between demand and a supplier's capacity, combined with a negative relationship between this supplier's capacity and those of the other suppliers, can provide an advantage to the more expensive supplier and alleviate its cost disadvantage.

*This research is supported by the General Research Fund of Research Grants Council of HKSAR, with project code 17200521.

3 - Operational Resilience Anew

Andrea Roncoroni, ESSEC Business School, Cergy-Pontoise, France, Gianna Figà-Talamanca, Paolo Guiotto

Extreme events, such as pandemics or geopolitical crises, may lead to unexpected and sudden disruptions in the global supply chain. This reality may necessitate prompt and significant adjustments in physical operations, e.g., reshoring. Empirical evidence indicates that while many companies recognize this necessity, far fewer actually implement or are capable of doing so. In such contexts, academic research provides a range of operational tools to foster operational resilience. We propose a novel purely financial instrument to enable firms to enhance their operational resilience. Our approach is normative. We develop, analyze, and evaluate it using two integrated risk management (IRM) models. One is a stylized risk-averse newsvendor model featuring a decision maker contending with an unreliable supplier. We derive our IRM policy and empirically assess its effectiveness in bolstering operational resilience. The other model is a multinational capacity allocation model encompassing both reliable and unreliable suppliers. We calibrate it using historical gas market data and evaluate the resulting recommendations in light of the European gas supply chain disruption subsequent to the Russian attack on Ukraine. Our findings reveal that: (Operational contraction) A reduction in reliability prompts a decrease in optimal ordering/allocation; (Financially-driven resilience) IRM can mitigate this decrease compared to mere operational management; (All-weather feature) Traditional single-claim hedging offers uneven mitigation across reliability reductions compared to utilizing a combined custom hedge. In summary, our analysis indicates that the presence of an optimal IRM strategy mitigates the need for relocation, thereby offering managers a new avenue to strengthen operational resilience.

4 - Deep Hedging Strategies for a Risk Averse Hog Farm

Ye Liu, Syracuse University, Syracuse, NY, United States, Panos Kouvelis, Danko Turcic, Yunzhe Qiu

We investigate how a privately owned hog farm manages its inventory and uses hedging strategies when the farmer is concerned about risk. The farm faces risks from changing numbers of hogs, production costs, and the prices they can sell. The farm can use financial contracts to reduce these risks.

We find that a farmer who dynamically maximizes the mean-variance utility will keep a smaller inventory than a farmer who doesn't consider risk. However, they will keep a larger inventory than a farmer who doesn't have the option to hedge. We show that the decision to hedge revenue or costs depends on both operational and financial characteristics. Revenue hedging is more advantageous when there is high volatility in selling prices, a high correlation with factor markets, and large sales volumes. Conversely, cost hedging is more valuable in the presence of high volatility in operational costs, a high correlation with the fodder market, and large inventory sizes. We also find that a more risk-averse farm is likely to hedge costs, whereas a less risk-averse farm finds greater value in hedging revenue. Lastly, hedging is more valuable when the volatility of factor markets is lower. As the volatility of these markets increases, hedging loses its value since the risks from financial markets begin to propagate to the farm, contributing more variance to cash flow.

The hedging strategies are difficult to evaluate analytically because the farmer's problem is inherently dynamic, so we obtain the exact hedging policy through deep reinforcement learning.

1 - Learning While Repositioning in on-Demand Vehicle Sharing Networks

Hansheng Jiang, University of Toronto, Rotman School of Management, Toronto, ON, Canada, Chunlin Sun, Shunan Jiang, Zuo-Jun Shen

We consider the vehicle repositioning problem for a one-way, on-demand vehicle sharing service with a fixed number of rental units distributed across the network. Due to uncertainty in both customer arrivals and vehicle returns, the service provider needs to periodically reposition the vehicles to match the supply with the demand while minimizing the total costs of repositioning labor and lost sales. The optimal repositioning policy under a general multi-location network is intractable without knowing the optimal value function. We define the best base-stock repositioning policy as a generalization of the popular inventory control policy to the vehicle repositioning problem, and we establish its asymptotic optimality in two different limiting regimes under general network structures. We provide reformulations to solve the offline problem of finding the best base-stock policy, and prove that the offline solution has favorable generalization properties. In the online setting, we develop an Online Gradient Repositioning algorithm utilizing only censored demand and, under a mild cost structure condition, we prove that it achieves an optimal regret, which matches the regret lower bound. Our online algorithm is designed by carefully decomposing the cumulative costs and formulating a linear programming problem whose dual solution serves as the gradient. Moreover, we provide and discuss three other online algorithms to elucidate the inherent challenges of learning while repositioning, and our analysis offers new insights into learning with censored data in networks. Numerical experiments illustrate the effectiveness of our proposed approach.

2 - Bundling OR Discounting? a Field Experiment for Healthy and Unhealthy Food

Nymisha Bandi, McGill University, Montreal, QC, Canada, Maxime Cohen, Saibal Ray

How can retailers decide between Bundling and Discounting as incentives to increase sales of healthy and unhealthy products? In this paper, we conducted a field experiment with a global convenience store chain to better understand how bundle and discount promotions influence healthy and unhealthy food choices. We considered six types of incentives: (i) discount a healthy product, (ii) discount an unhealthy product, (iii) bundle a healthy product with coffee, (iv) bundle an unhealthy product with coffee, (v) discount both healthy and unhealthy products, and (vi) choice bundle (offering either a unhealthy or a healthy snack with coffee). We conduct the field experiment in 7 different stores and observe the sales, revenue and profit impact for each of the above promotions on different category of products.

3 - Iot-Based Nudging for Energy Saving: More Can be Less for Organizations and Environment

Jacob Zeng, Gonzaga University, Spokane, WA, United States, Nur Sunar, Nil Karacaoglu, Serasu Duran

Excessive energy consumption results in substantial financial and environmental costs, yet the effectiveness of real-time feedback to correct overuse in commercial settings has not been investigated. In this paper, we collaborate with one of the largest Internet of Things (IoT) energy platforms in Europe to analyze a rich dataset on IoT-based nudging for energy saving.

4 - Greening Ride-Hailing: Impact on Environment and Consumers

Yuexing Li, Johns Hopkins Carey Business School, Baltimore, MD, United States, Bora Keskin, Nur Sunar

Ride-hailing services are an essential mode of transportation, providing convenience to millions worldwide. Many ride-hailing platforms have launched green initiatives to introduce and promote green vehicles. However, it remains a question of how adding green vehicles would impact the environment and consumers. To our knowledge, this paper is the first to analyze this question theoretically. We formulate a model where drivers decide on whether to serve local customers or reposition to serve customers in a different location. We consider two types of vehicles: regular (gas-fueled) and green. Some customers are environmentally sensitive and inclined to take rides in green vehicles, whereas others are inclined to take rides in regular vehicles. We find that, in contrast to common belief, adding more green vehicles to a ride-hailing platform may increase emissions. Our analysis also reveals that the environmentally optimal price margin for green vehicles can be positive or negative. Besides, we show that adding green vehicles may be a win-win for both customers for regular vehicles and those for green vehicles. Finally, we investigate several extensions, including the consideration of more locations, pricing for regular and green vehicles independently, pricing for profit maximization, and replacing regular vehicles while adding green ones. We verify that our main insights are robust to these scenarios. Our paper highlights that policymakers and ride-hailing platforms should make prudent decisions about introducing green vehicles to reduce emissions. Simply adding green vehicles without careful consideration may lead to unintended consequences.

5 - Dynamic Randomized FIFO Mechanism

Hongyao Ma, Columbia University, New York, NY, United States, Francisco Castro, Chiwei Yan

Ridesharing platforms match rider trips at airports to drivers who wait in a virtual queue. Under FIFO dispatching, the heterogeneity in trip earnings incentivizes drivers to cherrypick, increasing riders' waiting times and leading to a loss of efficiency and reliability. Castro et al. (2022) proposed a family of Randomized FIFO mechanisms that use waiting times to align incentives and reduce variabilities in drivers' total payoffs. The design of such mechanisms, however, requires full information on trip earnings and arrival rates for different destinations, which are challenging to estimate in practice. In this work, we introduce the Dynamic Randomized FIFO mechanism, which is very simple and does not rely on any information on market conditions.

We also develop a framework for computing approximate market equilibria in stochastic settings via best-response iterations. Extensive simulations demonstrate that our mechanism outperforms existing mechanisms guaranteed to achieve second-best outcomes in the fluid setting. Additionally, it shows robust performance when drivers exhibit heterogeneity in waiting costs or location preferences.

Managing Supply Chain Risks with Emerging Considerations

Invited Session

MSOM: Supply Chain

Chair: Xin Geng, University of Miami, Coral Gables, FL, United States

Co-Chair: Guang Xiao, Hong Kong Polytechnic University, N/A

1 - Optimizing Procurement Tactics: Navigating Unreliable Suppliers and Quantity Constraint

Ning Ma, Arizona State University, Tempe, AZ, United States, Yimin Wang, Heng Zhang

As uncertainties such as yield, quality, and delivery duration continue to challenge supply chain functions, the imperative of supply base emerges. Observing the real-world trend of corporations streamlining their supplier bases, we seek to understand the best strategies for supplier selection and order allocation, especially when faced with uncertain delivery and a predefined upper limit on the number of suppliers selected from a broad pool. To this end, a multiple-supplier framework is proposed, reflecting suppliers as producers with varying reliabilities. We offer a quadratic approximation of the original problem and show the approximation's theoretical properties, enabling the proposal of a tractable algorithm and its fully polynomial-time approximation scheme (FPTAS).

2 - Adoption of Precision Agriculture Technologies in Farming

Shuhui Dong, Fudan University, Shanghai, China, People's Republic of, Lusheng Shao, Xiaole Wu

Precision agriculture (PA) is an emerging technology that intends to improve production efficiency and environmental sustainability by precisely allocating inputs to areas where crops require them most. Despite widespread encouragement from numerous countries, farmers' reluctance towards PA adoption persists. This hesitation primarily arises from a fundamental misunderstanding of how PA technologies can bolster their agricultural practices. In this study, we develop an analytical model to elucidate farmers' fertilizer application process and investigate the role of PA in their decision-making. We explore whether farmers should adopt PA when engaging in Cournot competition. Our findings reveal that PA enhances efficiency by reducing input losses and mitigating nutrient imbalance. However, it may intensify competition particularly when fertilizer costs are relatively high, thereby yielding mutual losses among farmers in the event of simultaneous PA adoption, even under complimentary adoption schemes. Furthermore, we find a mutually reinforcing relationship between adopting farmers, wherein the adoption of PA by one enhances the value for the other to adopt PA. Accordingly, we propose that governments with constrained financial resources stimulate widespread PA adoption by incentivizing initial adoption endeavors. We also explore the implications of PA across three dimensions: farmer welfare, environmental sustainability, and food security. Our analysis reveals that while PA does not consistently enhance farmer welfare or environmental outcomes, it emerges as a key driver of food security through its capability to augment crop output.

3 - Product Rollover and Timing Strategies in the Presence of Demand Uncertainty

Jian Li, Northeastern Illinois University, Chicago, Illinois, IL, United States, Panos Kouvelis

Within a stylized setting, we study the optimal timing and rollover strategy selection for the introduction of a new product. We examine two distinct timing strategies: the Static approach and the Dynamic approach. We consider two product rollover strategies: Solo-Rollover, and Dual-Rollover. Again, the selection of the rollover strategy can be made either statically, or dynamically over time.

Our focus is on formulating an optimization model that integrates the above-mentioned three layers of decisions in selecting strategy for product rollover and timing. We obtain a straightforward rule for determining whether the introduction of a new product is warranted in a given period and what is the optimal rollover strategy. Our decision approach relies on average demands, profit margins and the use of two straight lines segmenting the two-product demand space.

Within the rich modeling framework for the Dynamic Timing and Rollover Selection, we also study as special cases five other timing and rollover strategies that differ along the static/dynamic nature of timing of introduction and choice rollover approach.

4 - Sourcing Under Supply Uncertainty: Impact of International Commercial Terms

Jingwen Xu, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Yulan Wang, Guang Xiao, Lei Chen

Problem definition: In this study, we consider a three-tier decentralized global supply chain that consists of a domestic buyer, a reliable supplier located outside a free trade area, an unreliable supplier situated within a free trade area, and a logistics service provider that transports products from oversea suppliers to the domestic buyer. First, based on who shall bear the tariff and shipping cost, the buyer and the supplier can undertake one of the following three trade agreements: Ex Works, Delivered at Place, or Delivered Duty Paid. Second, depending on the basis of the dutiable value on which the tariff is calculated, Free on Board and Cost Insurance Freight are considered. Methodology: We propose a three-tier decentralized supply chain game and fully solve it to characterize each member's preference about the aforementioned trade agreements. Results: Among other results, we find that, as the tariff rate increases, counter to our intuition, the buyer is more willing to bear the tariff and freight rate. Interestingly, we also show that dual sourcing remains as the equilibrium for the buyer under FOB based tariff, whereas single sourcing from the unreliable supplier located in a free trade area can emerge when CIF is adopted and the tariff rate is relatively high. Managerial implications: Based on these findings, our paper proposes a short-term strategy associated with tariff adjustments and a long-term strategy with respect to trading term adjustments to help an import market keep business in its own free trade areas.

1 - Ranking Quality and User Engagement on an Online B2B Platform

Rakesh Allu, Cornell University, Ithaca, NY, United States, Vishal Gaur

Online business-to-business (B2B) platforms are increasingly investing in data science teams to develop machine-learning algorithms for providing personalized rankings-based recommendations for their users. Consequently, there is growing need to develop ways to evaluate the performance of these algorithms. Two key questions faced by platforms in such evaluation are: (i) how to periodically measure the quality of rankings using real-time ranked transactions data generated by the users and, (ii) how to examine the effect of improving ranking quality on usage (i.e., the number of transactions) and browsing effort. These questions are challenging to address because of simultaneity between usage and effort and, censoring in ranked transactions data. Using detailed transaction-level data from a B2B platform in India for more than 61K sellers over one year, we propose methods to measure ranking quality, develop a position-level model of a user's decision to transact and scroll, and develop estimation approaches to overcome censoring. Our analysis reveals a position-wise dynamic that results in an increase in platform usage and a decrease users' browsing effort with improvement in ranking quality. We further show that nudging a user to scroll at least up to a predefined position can enable the platform to realize higher value from improving rankings quality. Our paper underscores the importance of operational improvements for platforms and highlights the need to pair ranking algorithms with appropriate behavioral prompts.

2 - Last-mile delivery of malaria prevention products in the DRC: An inventory management model under supply chain disruptions

ROBERT MONTGOMERY, International Rescue Committee, New York, NY, United States, Baris Ata, Amy Lehman

This paper studies inventory management policies to improve the last-mile delivery of healthcare products in remote settings prone to supply chain disruptions. It is motivated by the need for a reliable and cost-effective delivery system to resupply new mosquito-repellent products to combat malaria in the Lake Tanganyika region of The Democratic Republic of the Congo. The primary delivery methods used around Lake Tanganyika can become inoperable during periods of flooding, machinery breakdowns, and armed conflict. To ensure continuous coverage, our model allows for emergency delivery methods, with high variable costs, to be used during disruptions. In normal operating times, we use a large-capacity fixed-cost delivery method. We model the changes in the operating environment between normal and multiple disruption states using a Markov chain with disruption-specific parameters. We use an infinite-horizon discounted objective, which consists of ordering costs and a linear holding cost. We show that a novel periodic hybrid policy, which corresponds to an (s,S) policy for the normal environment state and a series of base-stock policies for the disrupted states, is optimal and provide the means to calculate the policy parameters. Additionally, we propose two easier to calculate heuristic policies based on widely used inventory management policies and show their relative effectiveness through simulation.

3 - Generative AI, Social Interaction, and Entrepreneurial Performance

Nicholas Otis, UC Berkeley, Berkeley, CA, United States

Access to high-quality information and advice is an important determinant of firm performance. As people increasingly turn to generative Artificial Intelligence (AI) for advice, it raises an important question: Is AI a complement or substitute for individuals' social networks? I explore this question through a seven-month-long pre-registered field experiment with small and medium enterprise (SME) entrepreneurs, which cross-randomizes access to an AI business assistant, a human business mentor, a combination of both, or neither. Among entrepreneurs assigned to receive access to AI alone, I find that AI crowds out use of entrepreneurs' business networks, leading to significant declines in business performance (profits and revenue). However, simultaneous access to both AI and a human mentor produces significant improvements in performance, which are considerably larger than the additive effect of the AI assistant and the human mentorship alone. These results suggest that individuals must leverage their networks in order to benefit from AI. However, access to AI alone crowds out those serendipitous conversations that help entrepreneurs discover new opportunities.

4 - Transmission Interaction Persistence (TIP): A Supply Chain and Epidemiological Model for Zoonotic Diseases Outbreaks

El Ghali Ahmed Zerhouni, Massachusetts Institute of Technology, Cambridge, MA, United States, Retsef Levi, Nicholas Renegar

Zoonotic viruses that jump from animals to humans have been the cause of major pandemics in the last several decades. Meanwhile farms could be a source of such diseases, most of the outbreaks have been linked to live animal markets in China. This suggests that markets potentially amplify zoonotic infections, a phenomenon that could not be explained by traditional epidemiologic models. This talk introduces a novel supply-chain motivated transmission, interaction, and persistence (TIP) stochastic epidemiology model that seeks to explain the mechanism of disease amplification in markets, with a case study on avian influenza. The analytical results demonstrate how major outbreaks could occur in markets, even when the infection rates among animals sourced from farms are very low, and the animals stay in the market for less than one day. This is the result of two important dynamics. The first of these dynamics concerns with the fact that markets serve as a consolidation point for agricultural inputs from many small farms. The other dynamics are based on the in-market operations that affect the environmental in-market infection evolution, particularly, persistent infection through two-sided interactions between animals and wastewater, surfaces, and feed. Thus, the study highlights the important role of supply chain structure and market operations in driving the spread of zoonotic viruses. Furthermore, there are direct managerial implications with respect to critical infection control strategies to reduce the risk of outbreaks, including aggressive and frequent sanitation of the market environment, as well as market design to reduce environmental infection.

1 - Operations Research and Analytics Applications for Community-Engaged Climate Response

Michael Johnson, University of Massachusetts Boston, Boston, MA, United States

Advancing climate justice agenda is a complex challenge facing policymakers and the society. Decision-support systems that are increasingly used to inform and aid policymaking process are rarely equipped to address equity concerns. Partly because decision-support systems are often built within disciplinary silos, do not recognize communities as experts, and prioritize efficiency over equity in model building exercises. In this position paper, we present a brief review of literature on six research fields that commonly engage with developing decision-support systems: i) Agent-based Modeling (ABM); ii) Artificial Intelligence; iii) Community-based Operations Research; iv) Decision-making under Deep Uncertainties; v) Green Information Systems; and vi) Systems Dynamics. We identify major challenges in each of these fields concerning climate justice agenda, with a specific focus to advance equity and transdisciplinarity with community-engagement. We also identify opportunities to build decision-support systems that can build on complementarity of each of these fields to overcome the limitations and suggest an integrative approach.

2 - Strategic Framework for Social Welfare Programs: Integrating Direct Cash and In-Kind Aid for Diverse Community Needs

Gulten Busra Karkili, University of Massachusetts-Amherst, Amherst, MA, United States, Senay Solak, Michael Johnson

The combination of expanding direct cash initiatives nationwide and existing in-kind programs targeting specific needs prompts the question of the optimal design of government policies to effectively assist those in need. Our study aims to develop a framework for designing benefit programs that cater to the diverse needs of targeted populations while balancing short-term urgencies with long-term wellbeing objectives. We propose an approach that integrates various forms of assistance, including direct cash transfers and in-kind aid, customized to specific recipient groups and their evolving circumstances. As we navigate resource constraints, our research explores methods for efficiently allocating funds towards long-term investments for unbanked and financially vulnerable communities, while simultaneously considering approaches to promote self-sufficiency. Through ongoing investigation, we seek to provide insights that will inform policymakers about the complexities of poverty alleviation strategies, with a focus on fostering sustainability and economic empowerment.

3 - Decision Modeling for Home-Matching Among Disadvantaged Residents

Karla Corres Luna, University of Massachusetts Boston, Boston, MA, United States

The urban housing crisis, driven by a lack of affordable homes and underused units, has not been effectively mitigated by government policies. In response, home-matching programs are emerging as promising solutions for low-income renters. In collaboration with Front Porch and using a community-engaged operations research approach, this study focuses on the housing challenges faced by marginalized groups such as the elderly, disabled, and low-income earners. The research goal is to apply problem-structuring methods to better understand the decision models and processes associated with home matchmaking using descriptive analysis of participant and organization data. This work yields insights regarding stakeholder values and identifies decision problems to improve housing outcomes for program participants. Moreover, the study seeks to formulate and solve stylized decision models based on field data. The problem structuring approach exercises and decision model solutions with simulated data can help determine the efficacy and social impacts of the Home Match business model and recommend improvements to Home Match's planning and operations. The findings will contribute to the literature by learning the complexities of the housing crisis and recommend effective strategies for promoting policies aimed at affordable housing solutions.

4 - Decision Modeling for Community-based Adaptation to Climate Change

Mubarak Iddrisu, University of Massachusetts Boston, Quincy, MA, United States

In response to increasing climate-driven hazards like floods, Massachusetts introduced the Municipal Vulnerability Preparedness (MVP) program to support local government efforts in climate adaptation planning and project prioritization. However, the MVP program does not meaningfully accommodate the experiences of disadvantaged residents with limited community involvement in flood adaptation regarding transit challenges. Thus, integrating the framework of community-based adaptation (CBA) with community-engaged operational research, we study flood-induced transit challenges faced by marginalized groups such as the elderly, disabled, and low-income earners. By exploring the gaps between expressed needs of disadvantaged residents and solution opportunities presented by MVP, we use problem structuring methods to identify a variety of decision problems in climate change adaptation, as defined by disadvantaged residents, with the belief that if solved, could improve their mobility needs. Moreover, there is a potential to apply community-engaged operational research principles to formulate and solve decision models that enable residents to generate alternative ways to cope with flood-induced transit challenges and achieve equitable mobility. The findings are anticipated to enhance the integration of equitable mobility and flood adaptation processes for marginalized communities in urban settings to adapt to climate change. The study contributes to the field of CBA in the urban context of a developed country by exploring its applicability and intersection with community-engaged operational research. Further, the community-engaged operational research framework bridges the gap between the various actors in CBA and serves as a decision tool for steering decision-making.

Minority Issues Forum

Chair: Gian-Gabriel Garcia, Georgia Institute of Technology, Atlanta, GA, United States

1 - Honorable Mention: Toward a Healthy, Fair, Resilient, and Connected World

Karmel Shehadeh, Lehigh University, Bethlehem, PA, United States

In this talk, we present an overview of our contributions toward a healthy, fair, resilient, and connected future. We focus on two main areas: (1) advancing stochastic and robust optimization methodologies with practical applications in healthcare, facility location, and transportation, and (2) developing fairness-promoting optimization frameworks. Additionally, we will highlight our service to the Operations Research and Management Science community, our dedicated efforts to advance diversity, equity, and inclusion, and our initiatives to promote STEM awareness among the younger generation.

2 - Winner: A Data-driven Journey to Health Equity

Karen Hicklin, Icahn School of Medicine at Mount Sinai, New York, NY, United States

Join me as we journey along my career path where I use my academic training to analyze, model, and optimize systems and processes that impact the treatment and care of patients. I have dedicated my research to integrating operations research to model complex stochastic systems with a major focus on health equity for vulnerable and underserved populations. Thus far, my journey has led me to (1) develop strategies to evaluate public health programming and interventions, (2) use mathematical modeling for improved decision making, and (3) identify opportunities for intervention for improved health care quality and delivery. I will outline my contributions to maternal health, health disparities, and workforce development through my research and service interests.

1 - Fast Stochastic Epidemic Simulations and An Adaptation of the Next Generation Matrix for a COVID-19 Epidemic Model of Social Distancing

Isabelle Rao, University of Toronto, Toronto, ON, Canada, Stephen Chick

Direct stochastic simulations of medium to large scale Markovian processes with population dynamics may have runtimes that are proportional to the population size, if they account for each state transition of each individual in the population. Several approaches to speed up such simulations have been proposed. We use a discrete-time, Euler-forward type approximation for state transition functions that simulates all transitions within a given time step in an effort to improve run times, at the expense of some (potentially correctable) bias. We illustrate this with a stylized model of COVID-19 social distancing interventions in the United Arab Emirates. We also adapt the next generation matrix method of Hill and Longini (2003) to a continuous time, discrete state model. The approach accelerates simulation run times from a linear scaling of run times in population size to a constant that depends on the number of possible state transitions.

2 - Cost-Effectiveness of Contingency Management for Methamphetamine use Disorder: a Model-Based Analysis

Gary Qian, Stanford University, Stanford, CA, United States, Yupeng Chen, Richard Rawson, Keith Humphreys, Margaret Brandeau

The escalating methamphetamine use disorder (MUD) in the United States represents a significant public health challenge. As of 2021, an estimated 1.6 million individuals aged 12 or older were diagnosed with MUD. Individuals with MUD can experience severe psychological and physical symptoms, including cognitive impairments and emotional dysregulation, and is often complicated by polydrug use, especially with opioids, leading to a sharp rise in overdose deaths.
