In data centers, uncorrectable errors (UEs) occurring in DRAM can potentially render servers inoperative, making it a critical issue to reduce such errors. We introduce a novel UE Detective methodology to predict risky DRAMs based on data center's telemetry logs, which contain detailed information about correctable errors (CEs). First, we develop spatio-temporal features to help predict failures by utilizing domain information based on the actual UE judgment mechanism from the bit-level information of CEs. Furthermore, we implement Positive-Unlabeled (PU) learning to enhance our predictive model's robustness in managing the label uncertainty of normal DRAMs that, due to the stochastic nature of server operations, display UE symptoms in telemetry logs but have not yet manifested UEs. Subsequently, we apply cutting-edge deep learning models for tabular data to predict UEs, exhibiting superior performance compared to traditional tree models. Our proposed methodologies have been empirically validated through long-term real-world experiments using extensive telemetry data from a data center customer, showcasing the potential to preemptively identify over 70% of DRAMs encountering UEs. Our methodology can trigger a pullout process that proactively remove potentially faulty DRAMs, preventing actual UEs from manifesting and thus contributing to the reliability of the server.

4 - Reinforcement Learning-based scheduling of PV panel cleaning in arid regions considering uncertain dusty weather conditions

Heungjo An, Kumoh National Institute of Technology, Gumi, Korea, Republic of, Hyunsoo Lee

Airborne dust easily accumulates on the surfaces of solar panels, diminishing power output particularly in arid regions. A common strategy to mitigate dust deposition involves periodic cleaning of photovoltaic (PV) panels. However, the frequency of cleaning impacts the economic viability of solar PV systems, presenting a trade-off between cleaning costs and energy loss. To tackle this challenge, this study explores various metrics and devises a generic framework based on Reinforcement Learning to dynamically determine the cleaning intervals for PV panels, accounting for uncertain dusty weather conditions. Additionally, a simulation and optimization model is developed to establish a constant cleaning interval for the entire planning horizon (i.e., 20 years) for comparative analysis. Finally, this study contrasts the economic and energy-related metrics derived from the proposed RL-based method with those from the simulation optimization approach.

5 - Is ESG "Worth" Anything? On the Economic Value of Climate Pledges on Amazon

Nuo Yuan, Boston University, Boston, MA, United States, Yuze Li, Dokyun Lee

In response to the growing consumer demand for sustainability, many firms have adopted product certifications issued by third-party agencies to signal their products' social and environmental sustainability. In this study, we make the first empirical attempt to examine the economic impact of these sustainable product certifications. Using a unique cross-sectional dataset of facial skincare products sold on Amazon, we employ a mixed-method approach that combines machine learning and causal inference to examine the causal effect of "Climate-Pledge" certification on product sales rank in a cross-category fashion, while accounting for other product attributes identified by prior literature as drivers of sales rank (e.g., reviews and Q&As). We also conduct a series of moderation analyses based on further segmentations by product category and certificate type. Focusing on climate-pledge product certificates that have emerged due to increasing demands for product transparency from "green" consumers, the results of this study hold important implications for Amazon's partnering manufacturers and the platform itself.

Warm Starting for Mixed-Integer Linear Programming

Invited Session

OPT: Integer and Discrete Optimization

Chair: Shannon Kelley, Lehigh University, 337 South New Street, Chicago, IL, 18015, United States

1 - Warm Starting of Mixed Integer Linear Optimization Problems via Parametric Disjunctive Cuts

Shannon Kelley, Lehigh University, Bethlehem, PA, United States, Aleksandr Kazachkov, Ted Ralphs

Many applications require solving a series of closely-related mixed integer linear optimization problems that all share the same variables and number of constraints. In such cases, warm starting — reusing information from a previous solve — provides an opportunity to improve overall solution time. In this paper, we explore the use of valid disjunctions generated from branch-and-bound trees arising during previous solves, along with so-called Farkas certificates that prove the validity of associated disjunctive cuts, to warm start the solution of instances later in the sequence. The combination of a disjunction and a Farkas certificate yields a parametric class of disjunctive cuts that can be inexpensively applied to any instance in the sequence. We implemented this idea and performed computation experiments to test its potential.

2 - Mixed integer branch and bound reoptimization for parametric problems

Stefan Clarke, Princeton University, Princeton, NJ, United States, Gabriele Dragotto, Bartolomeo Stellato

We study a parametric family of mixed integer linear programs. We present a model which creates a branch-and-bound tree in an offline phase, and then rapidly searches over it in an online phase to ensure fast online optimization.

3 - A Cycle-Cancelling Heuristic for The Traveling Salesman Problem

Steffen Borgwardt, University of Colorado-Denver, Denver, CO, United States, Zachary Sorenson

The Traveling Salesman Problem (TSP) is one of the most-studied hard problems in combinatorial optimization. We developed a new algorithm that uses a connection between Minimum Cost Flow Problems (MCF) and the TSP to improve on a given local optimum.

MCF problems can be solved efficiently through linear programming or combinatorial algorithms such as cycle-cancelling. We investigated the potential of cycle-cancelling in the context of the TSP. Through a restriction of the search space of cycles to cancel for a given tour, practical results exhibit that only a low number of subtours is created, and a simple patching step suffices for a high success rate and gap closure towards an optimum.

4 - New cutting planes for two-stage stochastic integer programming: neighbor cut

jingye xu, Georgia Institute of Technology, Atlanta, GA, United States, Santanu Dey, Diego Cifuentes

cutting plane methods are the most popular method for solving two-stage stochastic integer programs where one iteratively generates cuts to approximate the second-stage value function. Those cuts are usually generated from certain optimal dual variables of some convex programs. One can also view cutting plane methods as iteratively conducting sensitivity analysis on the second-stage value function. However, from the perspective of sensitivity analysis, optimal dual variables provide good predictions only if the perturbation is small. This contradicts the fact that in many two-stage stochastic integer programs, the distance of any two distinct state variables are large (at least one). This motives us to derive new cutting planes from near optimal dual variables instead of optimal dual variables. Such cuts lead to much better prediction on "neighbors" of any state variables and are very easy to implemented. Results of numerical experiments are presented. In many cases, such new simple cuts leads to speed up solving time by magnitudes.

Summit - 421

Large Scale Supply Chain Network Design

Invited Session

OPT: Computational Optimization and Software

Chair: Arash Haddadan, Amazon.com, Bellevue, WA, United States

Co-Chair: Chun Ye, Amazon.com, Seattle, WA, United States

1 - Solving the Continuous TIME Service Network Design Problem (Ctsnd) by Column Generation

Marcus Poggi, Amazon, Seattle, WA, United States, Arash Haddadan, Daniel Ulch, Jochen Koenemann, Madison Van Dyk

Given a network and a set of commodities, the CTSND seeks a set of vehicle trips to transport the commodities from their origins to destinations minimizing the total cost. Each commodity has a release time at origin, a due time at destination, and an associated quantity. Transit times, vehicle capacities, fixed cost and cost per unit transported are specified for each arc. A feasible solution describes the set of trips on each arc, their departure times and the commodities they carry. We show that considering at most two times the number of commodities departures times for each arc is enough to determine the continuous time optimal solution. Our approach models the commodities as flows on the untimed network and require the flow of each commodity through each arc to be associate with a vehicle trip. Time constraints assure the commodities start their trip after their release date, depart at from any intermediary node only after its arrival, and completes its journey before its due time. A column generation subproblem is solved for each potential departure time on each arc. Candidate commodities are selected for each potential trip in order to minimize the associated trip reduced cost. We present results for instances from the main CTSND benchmarks and for large instances from the logistics operation of a large web-commerce company. They show the model proposed provide strong lower bounds. The linear relaxation solution is the input for a sequential rounding procedure which produces high quality primal solutions.

2 - Designing Delivery-Anchors for Amazon's Middle Mile Network

Arash Haddadan, Amazon.com, Bellevue, WA, United States, Jochen Koenemann, Leian Chen, Nityansh Seth

Amazon's ability to deliver on estimated shipping speeds and build customer trust hinges on the design and scheduling of its "middle-mile" supply chain network. The objective is to optimize not just costs, but also delivery speed estimates provided to customers. Amazon utilizes "delivery-anchors" to offer concrete estimated delivery dates. Delivery-anchors are deadlines for performing operations in the network, such as transportation along a lane. They act as delivery certificates, allowing Amazon's fulfillment systems to make accurate shipping estimates. Designing delivery-anchors effectively is a complex optimization problem that requires considering both fulfillment software and operational constraints. In this work, we propose a mixed-integer-programming model for delivery-anchor design, building on the Service Network Design problem. The delivery-anchor optimization enables Amazon to cost-effectively design its middle-mile network to achieve faster customer delivery speeds. Our design considers fulfillment engine requirements and real-world operations. Since our model uses a time-expanded network, solving large-scale instances is computationally challenging without heuristics. We employ size-reducing assumptions and model simplifications to enable scalability. Experimental results validate our model's usefulness for optimizing Amazon's delivery-anchor network design against the dual objectives of cost and delivery speed targets..

3 - Designing Optimization Software for Use-Case Scalability

Semih Atakan, Amazon.com, Seattle, WA, United States

The scalability of optimization models is a common concern in academic literature, but in industry, scalability to multiple use cases is equally critical. Often overlooked, this aspect results in a proliferation of optimization models, each with similar mathematical structures, but specialized software for solving distinct problems. This presentation delves into the design of software solutions that enable resolution of diverse business challenges at scale.

4 - Region-Based Network Design

Baris Burnak, Amazon.com, Bellevue, WA, United States, Semih Atakan, Jochen Koenemann

In 2023, Amazon launched Regionalization of the US network, which partitioned the US into smaller and roughly self-contained regions. This work presents a two-stage region-based decomposition algorithm for the fixed-charge multicommodity flow problem by leveraging the Regionalization structure to reduce the search space and improve the computational time to close the optimality gap. The first stage involves solving region-level subnetworks and fixing a subset of region-level decisions. In the second stage, we solve for the full network with fixed regional decisions. The key challenge to decompose the US network is the a priori allocation of the shared resources across subnetworks. Our proposed methodology distributes these resources for the fulfillment of regional and cross-regional commodities. This decomposition algorithm significantly reduces the computational time to close the optimality gap compared to a generalized monolithic algorithm, while producing solutions that are within 1% of the cost of the true global optimum solution.

Summit - 422

Promises and Challenges of Nonconvex Optimization in Machine Learning

Invited Session

OPT: Nonlinear Optimization

Chair: Salar Fattahi, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Jianhao Ma, University of Michigan, Ann Arbor, MI, United States

1 - Parsimonious Trajectories in Gradient Descent: Emerging Low-dimensionality in Over-parameterized Models

Jianhao Ma, University of Michigan, Ann Arbor, MI, United States, Salar Fattahi, Geyu Liang

Recent studies have shown that Gradient descent (GD) and its variants inherently favor "parsimonious" solutions, tending towards optimal solutions in a low-dimensional region even within overparameterized spaces. This paper explores the underlying mechanics of this phenomenon, establishing minimal requisite conditions under both convex and nonconvex settings. We demonstrate that certain GD variants, under these conditions, efficiently target parsimonious solutions. Intriguingly, we find that Perturbed Gradient Descent (PGD) that reaches second-order stationary points efficiently in the classic nonconvex settings underperforms in standard overparameterized nonconvex problems like matrix factorization. To address this, we introduce the Two-Sided Perturbed Gradient Descent (TSP-GD), an algorithm tailored for complex nonconvex optimization. TSP-GD achieves rapid convergence to second-order stationary points in the overparameterized regime, akin to PGD in low-dimensional spaces. This innovation in TSP-GD could be of independent interest to the nonconvex optimization community.

2 - On the Trajectories of SGD Without Replacement

Pierfrancesco Beneventano, Princeton University, Princeton, NJ, United States

We examine the implicit regularization effect of Stochastic Gradient Descent (SGD). We consider the case of SGD without replacement, the variant typically used to optimize large-scale neural networks. We analyze this algorithm in a more realistic regime than typically considered in theoretical works on SGD, as, e.g., we allow the product of the learning rate and Hessian to be O(1) and we do not specify any model architecture, learning task, or loss (objective) function.
Our core theoretical result is that optimizing with SGD without replacement is locally equivalent to making an additional step on a novel regularizer.
This implies that the expected trajectories of SGD without replacement can be decoupled in (i) following SGD with replacement (in which batches are sampled i.i.d.) along the directions of high curvature, and (ii) regularizing the trace of the noise covariance along the flat ones.
As a consequence, SGD without replacement travels flat areas and may escape saddles significantly faster than SGD with replacement.
On several vision tasks, the novel regularizer penalizes a weighted trace of the Fisher Matrix, thus encouraging sparsity in the spectrum of the Hessian of the loss in line with empirical observations from prior work.
We also propose an explanation for why SGD does not train at the edge of stability (as opposed to GD).

3 - Trained Transformers Learn Linear Models In-Context.

Ruiqi Zhang, University of California, Berkeley, Berkeley, China, People's Republic of

Attention-based neural networks, particularly transformers, excel at in-context learning (ICL), where they make accurate predictions for new tasks without updating parameters given some examples. By embedding labeled training data and unlabeled test data within a prompt, transformers can perform like supervised learning algorithms. Recent studies show that transformers trained on random linear regression problems can mimic ordinary least squares (OLS) predictions. We explore ICL in transformers with a single linear self-attention layer trained via gradient flow on linear regression tasks. Despite the non-convex nature of the problem, gradient flow with appropriate initialization reaches a global minimum. At this point, the transformer achieves prediction errors comparable to the best linear predictor for new tasks. However, the study also highlights that while the trained transformer can handle certain distribution shifts, it struggles with shifts in the covariate distribution of the prompts. In a generalized ICL setting where covariate distributions vary across prompts, the transformer remains brittle under mild covariate shifts.

4 - Why Transformers Need Adam: A Hessian Perspective

Yushun Zhang, The Chinese University of Hong Kong, Shenzhen, shenzhen, China, People's Republic of

SGD performs worse than Adam by a significant margin on Transformers, but the reason remains unclear. In this work, we provide an explanation of SGD's failure on Transformers through the lens of Hessian: (i) Transformers are heterogeneous": the Hessian spectrum across parameter blocks vary dramatically, a phenomenon we callblock heterogeneity"; (ii) Heterogeneity hampers SGD: SGD performs badly on problems with block heterogeneity. To validate that heterogeneity hampers SGD, we check various Transformers, CNNs, MLPs, and quadratic problems, and find that SGD works well on problems without block heterogeneity but performs badly when the heterogeneity exists. Our initial theoretical analysis indicates that SGD fails because it applies one single learning rate for all blocks, which cannot handle the heterogeneity among blocks. The failure could be rescued if we could assign different learning rates across blocks, as designed in Adam.

5 - Accelerating Convergence of Score-Based Diffusion Models, Provably

Yu Huang, Department of Statistics and Data Science, The Wharton School, University of Pennsylvania, PHILADELPHIA, PA, United States

Score-based diffusion models, while achieving remarkable empirical performance, often suffer from low sampling speed, due to extensive function evaluations needed during the sampling phase. Despite a flurry of recent activities towards speeding up diffusion generative modeling in practice, theoretical underpinnings for acceleration techniques remain severely limited. In this paper, we design novel training-free algorithms to accelerate popular deterministic (i.e., DDIM) and stochastic (i.e., DDPM) samplers. Our accelerated deterministic sampler converges at a rate O(1/T^2) with T the number of steps, improving upon the O(1/T) rate for the DDIM sampler; and our accelerated stochastic sampler converges at a rate O(1/T), outperforming the rate O(1/\sqrt{T}) for the DDPM sampler. The design of our algorithms leverages insights from higher-order approximation, and shares similar intuitions as popular high-order ODE solvers like the DPM-Solver-2. Our theory accommodates ℓ2-accurate score estimates, and does not require log-concavity or smoothness on the target distribution.

Distributional Robustness

Invited Session

OPT: Optimization Under Uncertainty

Chair: Sloan Nietert, Cornell University, Ithaca, NY, United States

Co-Chair: Soroosh Shafiee, Cornell, Ithaca, NY, United States

1 - From Distributional Robustness to Robust Statistics

Mohammed Amine Bennouna, Massachusetts Institute of Technology, Cambridge, MA, United States

Distributionally Robust Optimization (DRO) has been commonly considered in stochastic optimization settings under no parametric assumption or prior on the out-of-sample distribution. This lack of prior typically results in very conservative estimators. We consider here the problem of statistical estimation (and stochastic optimization) when the true distribution is known to belong to some parametric family. We study how DRO approaches extend to this setting and develop new DRO estimators that provide "optimal" statistical guarantees in a certain sense. We show then that classical robust statistics approaches naturally spur from these new DRO estimators.

2 - On Tractability, Complexity, and Mixed-Integer Convex Programming Representability of Distributionally Favorable Optimization

Nan Jiang, Georgia Tech, Atlanta, GA, United States, Weijun Xie

Distributionally Favorable Optimization (DFO) is an important framework for decision-making under uncertainty, with applications across fields such as reinforcement learning, online learning, robust statistics, chance-constrained programming, and two-stage stochastic optimization without relatively complete recourse. In contrast to the traditional Distributionally Robust Optimization (DRO) paradigm, DFO presents a unique challenge-- the application of the inner infimum operator often fails to retain the convexity. In light of this challenge, we study the tractability and complexity of DFO. We establish sufficient and necessary conditions for determining when DFO problems are tractable or intractable. Despite the typical nonconvex nature of DFO problems, our findings show that they are mixed-integer convex programming representable (MICP-R), thereby enabling solutions via standard optimization solvers. Finally, we numerically validate the efficacy of our MICP-R formulations.

3 - Outlier-Robust Wasserstein Dro

Sloan Nietert, Cornell University, Ithaca, NY, United States, Ziv Goldfeld, Soroosh Shafiee

Distributionally robust optimization (DRO) is an effective approach for data-driven decision-making in the presence of uncertainty. Geometric uncertainty due to sampling or localized perturbations of data points is captured by Wasserstein DRO (WDRO), which seeks to learn a model that performs uniformly well over a Wasserstein ball centered around the observed data distribution. However, WDRO fails to account for non-geometric perturbations such as adversarial outliers, which can greatly distort the Wasserstein distance measurement and impede the learned model. We address this gap by proposing a novel outlier-robust WDRO framework for decision-making under both geometric (Wasserstein) perturbations and non-geometric (total variation (TV)) contamination that allows an ε-fraction of data to be arbitrarily corrupted. We design an uncertainty set using a certain robust Wasserstein ball that accounts for both perturbation types and derive minimax optimal excess risk bounds for this procedure that explicitly capture the Wasserstein and TV risks. We prove a strong duality result that enables tractable convex reformulations and efficient computation of our outlier-robust WDRO problem. When the loss function depends only on low-dimensional features of the data, we eliminate certain dimension dependencies from the risk bounds that are unavoidable in the general setting. Finally, we present experiments validating our theory on standard regression and classification tasks.

4 - Continuous Time Distributionally Robust Bayesian Utility Maximization

Lukas-Benedikt Fiechtner, Stanford University, Stanford, CA, United States, Jose Blanchet

We consider a utility maximization stochastic control problem in continuous time. In our market, prices are driven by unobserved factors. The controller thus faces a partially observed decision making problem. We consider a full Bayesian model for which the unobserved factors can be filtered out and the control problem can be explicitly solved. Then, we consider a distributionally robust partially observed formulation involving the adapted Wasserstein distance. The formulation is non-trivial for several reasons, but one that is conceptually interesting involves asymmetric information. Precisely, the information available to the agent and the adversary is fundamentally different (with the adversary is allowed to see information about the factors which is hidden to the agent). We present a solution for the optimal investment policy under an extension of Merton's model for portfolio selection.

Summit - 424

Methods and Applications in Stochastic and Chance-Constrained Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Yiling Zhang, University of Minnesota, Minneapolis, MN, United States

1 - On the ReLU Lagrangian Cuts for Stochastic Integer Programs

Haoyun Deng, Georgia Institute of Technology, Atlanta, GA, United States, Weijun Xie

We study stochastic integer programs where both first-stage and recourse decisions can have mixed-integer values. A new family of Lagrangian cuts, termed ``ReLU Lagrangian cuts,'' is developed by reformulating the nonanticipativity constraints using ReLU functions. These cuts can be integrated into scenario decomposition algorithms. We prove that the inclusion of ReLU Lagrangian cuts is sufficient to solve the original stochastic integer programs. Without solving the Lagrangian dual problems, we derive closed-form expressions for these cuts. Furthermore, to speed up the cut-generating procedures, we introduce linear programming-based techniques to enhance the coefficients of the cuts. Numerical studies demonstrate the effectiveness of the proposed cuts compared to existing methods.

2 - Optimization with Multi-Sourced Reference Information and Unknown Trust: a Distributionally Robust Approach

Yanru Guo, University of Michigan, Ann Arbor, MI, United States, Bo Zhou, Ruiwei Jiang, Siqian Shen

Navigating the complexities of decision-making processes relies heavily on the ability to integrate information from multiple sources, especially in environments where uncertainty exists. In this study, we investigate a stochastic optimization problem where the probability distributions of uncertain parameters are estimated using data from various sources. We conduct non-parametric data fusion based on trust over different sources to construct the Wasserstein ambiguity set and formulate a distributionally robust optimization (DRO) model to minimize potential worst-case losses. We reformulate the DRO model into a computationally tractable linear program (LP). In addition, we design a dynamic trust update framework based on actual losses under trust misalignment or data misalignment and introduce probability dominance to identify information sources with dominant trust. We demonstrate the effectiveness of our approaches using instances of portfolio optimization and resource allocation for wildfire control.

3 - Integer Programming Approaches for Distributionally Robust Chance Constraints with Adjustable Risks

Yiling Zhang, University of Minnesota, Minneapolis, MN, United States

We study distributionally robust chance-constrained programs (DRCCPs) with individual chance constraints. The DRCCPs treat the risk tolerances associated with the distributionally robust chance constraints (DRCCs) as decision variables to trade off between the system cost and risk of violations by penalizing the risk tolerances in the objective function. We consider individual chance constraints with uncertainty either on the right-hand side or on the left-hand side. By exploring the discrete structures, we develop mixed integer programming reformulations for the two types of uncertainty to determine the optimal risk tolerance for the chance constraint. Valid inequalities are derived to strengthen the formulations. We test diverse instances of diverse sizes.

Evolution and Impact in Cyber-Social Environments

Contributed Session

Chair: Yasmin Merali, University of Hull, Hull, HU17 8DE, United Kingdom

1 - Deploying the Complex Adaptive Systems Paradigm to Address Cyber-Social Dynamics

Yasmin Merali, University of Hull, Hull, United Kingdom

This paper focuses on the challenges posed by the emergence of *cyber-social* phenomena across networks straddling the embodied world and cyberspace. The internet and emergent technologies resulted in a step change in the level of complexity inherent in the effective world, i.e. the world as perceived, experienced, and understood by players, constituting the context within which decisions are made, actions taken, and consequences realised. The subsequent incorporation of AI-based functionality has further accelerated generation of discontinuities in the global socio-economic and geo-political context.

These developments have resulted in an increasing dependence on *representations* of reality and a deceasing capacity for experiential or embodied participation in interactions with the effective world, precipitating a shift from:

- *social* networks to *cyber-social* networks;
- the *social construction* of the world to the *informational construction* of *multiple* worlds;
- discontinuity in the world over a *time line* to discontinuity of *contemporaneous parallel worlds.*

The pace of technological advances outstrips the ability of legislators to develop adequate safeguarding measures against mis-information and disinformation: consequently organisations and institutions must develop strategies for resilience and co-evolution in an informational landscape characterised by dynamism and uncertainty.

This paper deploys the information lens and the *Complex Adaptive Systems* paradigm to:

- define key features of the landscape, highlighting potential dangers inherent in the way that BigData and AI approaches impact on the cognitive, social and contextual filtering of information, and

- develop the conceptual scaffolding for countering these dangers, attending to the evolution of semantic and semiotic dimensions over time.

2 - Platform-Driven Collaboration Patterns: Structural Evolution Over Time and Scale

Babak Heydari, Northeastern University, BOSTON, MA, United States, Negin Maddah

This study explores the dynamics of decentralized collaboration within a digital organizational landscape, contrasting these with traditional models. We introduce a novel methodology that captures high-level collaboration dynamics, extending beyond direct messages to include both temporal and content dimensions of user interactions. This approach utilizes an Alternating Timed Interaction (ATI) metric for temporal analysis and a quantitative strategy for assessing thematic similarity via Natural Language Processing (NLP). The findings validate three hypotheses that collectively underscore the complexities of digital team dynamics within sociotechnical systems: Firstly, it establishes the significant influence of problem context on team structures in work environments, emphasizing the need to consider the specific nature of tasks in analyzing collaborative dynamics. Second, we identify significant evolving patterns of team structures (such as decentralized leadership, information accessibility, diffusion speed of ideas, and the formation of sub-communities and polarization) versus team size and artifact maturity (age). Lastly, we demonstrate notable differences in team structure patterns between digital platforms (exemplified by the editorial collaboration networks of Wikipedia articles) and traditional organizational settings (using the results of a previous study of 65 US firms). By mapping out network structures and collaborative patterns on Wikipedia, this study not only illustrates unexplored aspects of digital platform dynamics but also sets the stage for strategic interventions to optimize digital team dynamics to align with broader organizational goals. These findings are instrumental for organizations navigating the digital era.

3 - The Impact of Misinformation on Government Policy Performance: Moderating Effects Through Public Risk Perception

Meichen Lu, University of Essex, SOUTHEND-ON-SEA, United Kingdom, Maged Ali, Niraj Kumar, Wen Zhang

Influenced by subjective public risk perceptions, misinformation can either be magnified or minimized during transmission, thereby impacting the efficacy of government policies in managing crises. However, various risks perceived during crises remain relatively unexplored. Drawing on the Protection Motivation Theory, which considers diverse individual decision-making processes when confronted with risks, we proposed a conceptual model to uncover the nuanced role of risk perception during a crisis. Using the COVID-19 pandemic as the case of this paper, we tested hypotheses using data collected on perceived risks at three different levels: overall (macro-level), interpersonal (meso-level), and individual (micro-level), covering the period from February 2020 to January 2022. Consequently, we found a detrimental impact of misinformation diffusion on the effectiveness of government policies during the crisis. This deleterious impact could be further alleviated through heightened macro- and meso-level risk perceptions but exacerbated by an escalation in micro-level risk perception. The findings provide insightful discussion to elucidate the risk perception paradox: why individuals can be vulnerable to misinformation's impact on policy performance under specific circumstances yet exhibit resilience against its influence in other situations. Accordingly, we advocate for policymakers and public health authorities to craft refined and targeted risk communication strategies by considering the heterogeneous nature of the public's risk perception.

4 - How elasticity of organizational identity shape technological innovation: From Chinese special new enterprises

Yang Rong, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Youmin Xi, Jing Ge

Abstract:

In order to reveal the relationship between organizational core attributes and technological innovation, elasticity of organizational identity plays an essential role. This case study show that the orientation of technological innovation was set for balancing the renewal or conflict of value labels, through timing contrast or time point comparison of socially constructed identity. The inner tension from professional identity and innovation identity drives technological innovation models and maintains organizational identity resilience. The evolution of Professional label shapes innovative search for opportunities and product serialization strategy. As for innovation capability label, the elasticity lies in creative resources of balance, focus, coordination and leverage. Those were shaped by the harmonious coupling of "psychological capital storage and hardware support system completion", as wellas the mechanism of action manifested as the release of innovative vitality. Innovation capability elasticity reduces the volatility of innovation willingness, update technology track. Based on the technical feature and innovation environment openness, the nature of organization influence the decision on binary equilibrium of exploratory and exploitative innovation, independent and cooperative innovation. Effective mode of technological innovation further balance the dialectic tensions between innovation efficiency and innovation quality, cognitive legitimacy and uniqueness, flexibility and durability when the organizational identity is pulling apart.

5 - Design Structure Matrices and Modularity in Services

Cheryl Druehl, George Mason University, Fairfax, VA, United States

Using higher education as the context, we examine mirroring in service organizations to explore organization structure, service offerings, and internal service design processes. The mirroring hypothesis suggests modular organizations will have modular products and vice versa. Design structure matrices are used to identify modular organizations and modular offerings. The difference in methods used to design modular services in mirrored organizations versus cross functional services or integrated services is highlighted.

Advancing Innovations in Mobility: International Collaboration and Technological Innovations in Transportation

Invited Session

TSL: Intelligent Transportation Systems

Chair: Yudai Honma, The University of Tokyo, Meguro-ku, 153-8505, Japan

1 - Required Battery Capacity of EVs Assuming Optimal Locations of In-motion Wireless Power Transfer System

Yudai Honma, The University of Tokyo, Meguro-ku, Japan

In-motion Wireless Power Transfer System (WPTS) is gaining attention as infrastructure to support electric vehicle (EV) mobility. This study assumes optimal locations of WPTSs in urban areas and analyzes battery consumption patterns in EV mobility. By simulating EV charging and discharging patterns while considering acceleration, deceleration, and traffic signals, the study discusses the required battery capacity. This research highlights two major novelties. First, it is demonstrated that the feasibility of EV mobility demand largely depends on the location of WPTS. Specifically, when optimally located, the total installation distance is reduced, while a uniform location at each intersection significantly increases the total installation distance required to meet mobility demands. Second, regarding battery capacity, it is shown that approximately 5kWh is sufficient when assuming optimal placement, which is significantly less than the current standard capacity. This underscores the promising potential of WPTS.

2 - From Disruption to Recovery: Enhancing Resilience for Transportation Networks Capacity

MOHAMMAD ABBASI, Arizona State University, Tempe, AZ, United States, Xuesong (Simon) Zhou

Resilience in transportation systems relies on both absorptive and adaptive capacities to mitigate disruptions and restore normal operations efficiently. A disruptive incident triggers a decline in a system capacity, which can be mitigated through strategic decision-making, such as routing and rerouting strategies. By controlling these parameters, the system can gradually recover lost capacity, depending on the severity of the disruption and the system's healing capability.

However, challenges such as accurately defining resilience metrics, incorporating emerging technologies like connected and autonomous vehicles, and balancing different objectives, such as mobility, accessibility, and environmental impact, requires integrated modeling approaches.

To address these challenges, this study explores the intersection of adaptive capacity using optimization techniques such as column generation. Integrating optimization models, including discrete choice and system dynamics models, offers a comprehensive approach to simulating disruption scenarios and evaluating system responses. Moreover, quantifying absorptive and restorative capacities enables the identification of strategies to enhance resilience. Practical applications range from informing infrastructure investments to guiding policy-making decisions.

3 - Designing Urban Road Hierarchies for Pedestrian Safety with a Mathematical Optimization Approach

Hiroyuki Hasada, The University of Tokyo, Meguro, Japan, Fuma Ikeya, Azusa Toriumi, Yudai Honma, Takashi Oguchi

Crossing or walking along high-speed roads poses a significant risk of traffic accidents for pedestrians. It is essential to improve pedestrian accessibility by properly defining road hierarchies to ensure a safe walking environment. However, especially in Japan, zone 30 areas are often limited and arbitrarily designated, which does not effectively protect pedestrians. This study aims to identify an optimal road hierarchy that facilitates pedestrian-friendly urban environments through mathematical theory. We formulate an optimal location problem that enables pedestrians to safely reach their destinations while maintaining vehicle travel to a certain degree of smoothness. Our proposed model is the first to position this optimal location problem within the context of the inverse shortest path problem, which simultaneously finds the shortest paths for given origin-destination pairs and assigns discrete link costs. The assigned road hierarchy can inform the creation of traffic safety zones and the strategic placement of physical devices such as speed humps and chicanes. Furthermore, it is expected to be useful in evaluating how new services, such as micromobility and autonomous driving services, can expand safe activity areas for residents. Our study provides a comprehensive framework for enhancing pedestrian safety and accessibility in urban areas, ultimately contributing to the creation of more livable, pedestrian-friendly and sustainable cities.

4 - Optimizing Real-Time Transportation Operations of Reusable Packages: A Dynamic Vehicle Routing Approach Considering Managerial and Operational Factors

Monireh Mahmoudi, Michigan State University, East Lansing, MI, United States, Irandokht Parviziomran, Alireza Boloori

Transporting reusable packages involves delivering full packages from depots to customers' doors and picking up empty ones, usually modeled as a vehicle routing problem with backhauls (VRPBs). Traditional static VRPBs assume all input data, like customer requests and locations, are known beforehand. However, the rise of on-demand services requires real-time operations where data is updated during transportation, leading to dynamic VRPBs (DVRPBs). Our study utilizes an analytical framework for DVRPBs, which dynamically incorporates newly revealed customer information, decides on request acceptance/rejection based on constraints, and updates pre-planned routes accordingly. Through numerical experiments, we analyze the trade-off between transportation cost and responsiveness under various factors like urbanism, customer accessibility, dynamism degree, vehicle capacity, request time frame, and decision epoch length.

5 - Strategic Optimization of Logistics Networks for Next-Generation Mobility in Japan

Daisuke Watanabe, Tokyo University of Marine Science and Technology, Koto, Tokyo, Japan

This research explores the reform of Japan's logistics by strategically optimizing logistics networks to incorporate emerging technologies such as truck platooning and autonomous trucks. The study formulates the optimal location of logistics hubs for line haul transport in Japan using the hub location problem, considering cost reductions from increased capacity and automation due to truck platooning implementation between hubs. The findings indicate that, under various automation scenarios, as the number of hubs increases, they tend to be located in areas with high traffic demand along the Pacific Ocean. Furthermore, despite technological advancements, the study found no significant differences in location results, suggesting that considering base allocation as a single allocation is approximately feasible.

6 - Decarbonizing freight through automation and connectivity: challenges and opportunities

Prasad Gupte, Dept. of Transportation, washington, DC, United States

Although vehicles for freight are a small fraction of total vehicles in the transportation system, they constitute a disproportionately large impact of energy use and emissions, and this share has been increasing. This talk will present the technical challenges and opportunities that advances in connectivity and automation can have to decarbonize freight while also improving overall system resilience through enhanced network infrastructure and integration.

Behavioral-informed Analytics and Decision-Making for Urban Transportation Systems 2

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Tianming Liu, University of Michigan, Ann Arbor, United States

Co-Chair: Manzi Li, University of Michigan, Ann Arbor, N/A, China, People's Republic of

1 - Economic Analysis of Order Consolidation and Congestion in E-commerce Delivery Service

Manzi Li, University of Michigan, Ann Arbor, China, People's Republic of, Yafeng Yin, Xin Li, Zhuoye Zhang

With the rise of e-commerce, delivery vehicles have increasingly contributed to urban traffic congestion. Despite this, limited attention has been given to the role of e-commerce deliveries in exacerbating congestion, complicating efforts to implement effective congestion pricing and reduction strategies. This study addresses this gap by developing a two-sided market framework for e-commerce systems from a queuing theory perspective, focusing on order consolidation—a key factor that balances customer demand, driver supply, road congestion, and system performance.

Theoretical analysis shows that platforms and social planners align on an optimal consolidation size that maximizes system throughput given delivery fee and driver compensation, reducing the complexity of the problem to a coupled optimization. With this property, we reveal that regulatory interventions are needed to adjust consolidation sizes when congestion is accounted for. Furthermore, the gap between optimal delivery fees and driver compensation widens in the congested scenario, potentially affecting the platform's profitability. This research offers policy insights into optimizing delivery fees, driver compensation, and consolidation strategies to manage congestion in e-commerce logistics.

2 - Integrating An Agent-Based Behavioral Model In Revenue Management for Microtransit: a Case Study In Arlington, Tx

Xiyuan Ren, New York University, Brooklyn, NY, United States, Joseph Chow

Microtransit offers a flexible and efficient solution to promote affordable and sustainable mobility services. Arlington Via provides microtransit services across the city with weekly and monthly Ride Pass plans. The service has been put into operation and generated valuable data for analysis. This study utilizes Arlington Via’s backend data and Replica’s synthetic population data to identify user dynamics. A behavioral model framework is developed wherein (1) real-time microtransit performance is derived using a calibrated simulation tool based on observed travel demand; (2) an agent-based mixed logit (AMXL) model is applied to estimate mode choice parameters at individual, origin-destination (OD) pair, and generic levels, capturing taste heterogeneity and ensuring robust predictions; and (3) the utility functions from the lower-level mode choice model are seamlessly integrated into an upper-level model to predict Ride Pass subscription. The proposed model framework is applied to evaluate operating strategies regarding operating hour, number of vehicles, discounts on specific hours, and various Ride Pass plans. Microtransit ridership, total revenue, decreased vehicle-miles-traveled (VMT), and other metrics are analyzed to compare different scenarios, providing insights to support microtransit service design.

3 - What Mobile Phone Data Reveal About Mobility Patterns of Teleworkers

Tianxing Dai, Northwestern University, Evanston, IL, United States, Peeter Kivestu, Ying Chen, Marco Nie

In a short period, the COVID-19 pandemic has transformed telework into a common practice for a significant portion of the workforce. This shift has profound implications for land use, urban development, and transportation. Traditional survey-based methods for tracking these changes are struggling to keep pace with the rapidity of this transformation. Here, we propose a method to identify different types of workers from mobile phone data, which allows us to closely examine the correlation between work arrangements, mobility patterns and key socio-demographic attributes. By applying a hierarchical clustering algorithm to a set of features extracted from a mobile phone data set, six different work types are identified and their validity is confirmed using different approaches. We find teleworkers tend to travel slower than regular workers but faster than non-workers. They also travel a shorter distance to reach their primary activity location than regular workers, but a longer distance to reach other activity location than both regular and non-workers. Our regression analysis further shows that, largely in agreement with findings in literature, racial minority and low income groups are less likely to telework.

4 - Position Lottery as An Alternative to Dynamic Pricing for Terminal Ride-Sourcing Driver Queue Control

Tianming Liu, University of Michigan, Ann Arbor, MI, United States, Yafeng Yin, Vijay Subramanian

Urban transportation terminals are hot spots for ride-hailing services and often suffer from significant supply-demand imbalance. This research aims to alleviate this issue using an innovative queue discipline control scheme on the idle driver inflow. We designed a entry position queue control as an alternative to the controversial dynamic pricing, and unveil novel insights into the optimal control properties of such strategy and design a mathematical programming framework that enables efficient computation of optimal policy in ride-sourcing operations. Numerical examples shows that the the proposed position lottery can achieve similar system performance as optimal dynamic pricing.

Optimization and Learning in Recommender Systems

Contributed Session

Chair: Ziye Wu, N/A

1 - Robust portfolio optimization for recommender systems considering uncertainty of estimated statistics

Tomoya Yanagi, University of Tsukuba, Tsukuba-Shi, Japan, Shunnosuke Ikeda, Yuichi Takano

Recommender systems aim to suggest unknown but desirable items to users by predicting their preferences based on their past ratings for other items. Although previous research has often focused on improving prediction accuracy, it is also necessary to emphasize diversity and novelty in recommendations. One approach to balancing the accuracy and diversity of recommendations is the application of portfolio optimization models originally used for financial asset selection. These models consider both risk and return and have been shown to have the potential to improve both the accuracy and diversity of recommendations. However, previous studies using portfolio optimization models in recommendation systems take no account of the uncertainty of estimated statistics. When applying these models, we need to estimate user ratings and their covariances; however, these statistics are subject to unavoidable estimation errors. We thus propose a robust portfolio optimization model to determine an optimal set of recommended items by considering potential errors in the estimated statistics. Numerical experiments using public rating datasets demonstrate that our method improves not only the prediction accuracy but also the diversity of recommendations.

2 - Learning Decisions Offline from Censored Observations with ε-insensitive Operational Costs

Teng Huang, Sun Yat-sen University, Guangzhou, China, People's Republic of, Minxia Chen, Ke Fu, Miao Bai

Many important managerial decisions are made based on censored observations. Making decisions without adequately handling the censoring leads to inferior outcomes. We investigate the data-driven decision-making problem with an offline dataset containing the feature data and the censored historical data of the variable of interest without the censoring indicators. Without assuming the underlying distribution, we design and leverage ε-insensitive operational costs to deal with the unobserved censoring in an offline data-driven fashion. We demonstrate the customization of the ε-insensitive operational costs for a newsvendor problem and use such costs to train two representative machine learning models.

3 - Dynamic Asset Pricing and Allocation with Expert Forecasts

Anas Abdelhakmi, National University of Singapore, Singapore, Singapore, Andrew Lim

In this work, we explore a Bayesian inventory control framework to analyze the impact of hedging opportunities on decision-making policies when demand distribution is unknown and learned over multiple periods. We examine a multi-period Newsvendor problem with lost sales, where observed demand is right censored by inventory levels. The decision-maker faces a trade-off: overstocking to better learn the demand at the risk of surplus, or maintaining single-period optimal inventory levels at the expense of learning opportunities.

We introduce hedging opportunities, which gives the decision-maker the option to purchase the product at an additional cost, thereby reducing the cost incurred in case of overstocking. We analyze how the presence of these opportunities influence both the optimal policy and learning dynamics, showing that despite an initial cost increase, the decision-maker opts for these opportunities as they facilitate ordering additional inventory, therefore accelerating the learning process and enhancing future performance. We derive an explicit characterization for the optimal policy when demand is exponential and the rate is unknown and learned over time. Overall, the paper shows that hedging leads to quicker learning and reduced cost compared to classical models.

4 - Better and Faster Decisions with Recommendation Algorithms

Ziye Wu, National University of Singapore, Singapore, Singapore, Yiting Chen, Songfa Zhong

While recommendation algorithms have been increasingly used in daily life, little has been done to investigate their effect on decision making in terms of decision quality and preferences. Here we examine this question in an experimental setting whereby subjects from a representative US sample are randomly assigned to five conditions and make sets of binary choices between two lotteries. The two control conditions provide either no recommendations or recommendations based on a randomization device. The three treatment conditions provide recommendations developed by algorithms: one relies on choices made by the majority, while the other two employ AI-based recommenders —one based on subjects' past decisions and the other on decisions made by similar subjects. We find that subjects tend to follow recommended choices and are willing to pay a small fee to receive recommendations for their subsequent decisions. Compared to the control conditions, recommendations help to reduce noise in decisions, align preferences with the expected utility model, and accelerate decisions. These results can be explained by some classes of stochastic choice models. Our work adds to the growing literature on the behavioral underpinnings of algorithms including AI and sheds light on the design of choice architecture for decision making under risk.

1 - Contrasting Risk-Averse Investment Decisions: A Comparative Study of Real Options Analysis versus Risk Measures Optimization for Airport Facilities Capacity Expansion

Ziyue Li, Florida State University, Tallahassee, FL, United States

In the realm of investment decisions, the optimal strategies are heavily influenced by the uncertain nature of demand growth. This uncertainty renders demand growth a stochastic process, leading decision-makers to adopt risk-averse approaches in their decision-making processes. There are two primary methodologies in investment decision making under uncertainty: optimization, utilizing various risk measures such as Value-at-Risk (VaR) and Conditional Value-at-Risk (CvaR); and real options analysis, where the actual probabilities of payoffs are replaced by risk-neutral probabilities. Additionally, Knightian uncertainty can also be integrated into real options analysis to capture decision-makers' pessimistic and optimistic beliefs.

Despite the prominence of these methodologies, there remains a notable gap in the literature concerning a comparative analysis of these two approaches in investment decision-making. This study aims to fill this gap by comparing their results through an example in the context of airport facilities capacity expansion. Specifically, it explores the relationship between these approaches in determining optimal investment timing and expansion size for airport facilities capacity expansion problems, where demand follows a geometric Brownian motion (GBM) and adheres to a log-normal distribution for any given time *t*. The objective is to maximize cumulative cost savings through airport facilities capacity expansion, and the decision variables are investment timing and expansion size. Through a comprehensive analysis, this study reveals consistent results between real options analysis and risk measures optimization, shedding light on their efficacy and implications for investment decision-making in uncertain environments.

2 - Modeling Competition Between Service Providers in Urban Air Mobility

Victor Qin, MIT, Cambridge, MA, United States

Current proposals for advance air mobility (AAM) propose that third-party service providers (SPs) will be responsible for providing traffic management services for these aircraft. This paper examines two aspects of these proposals, namely that: 1) multiple SPs can operate in the same region of airspace, competing for the patronage of AAM fleet operators, and 2) SPs can themselves be fleet operators. To this end, we propose and analyze a three-tier economic model of competition between traffic management SPs. We consider several potential scenarios, including a monopolistic SP, multiple competing SPs, the presence of a public option, and a service provider who is also a fleet operator. Our analysis suggests that in the absence of excessive congestion, an SP can also be a fleet operator without significantly distorting the economic outcomes. Furthermore, we find that under certain reasonable assumptions, the presence of a public option SP can improve consumer surplus while at the same time allowing private SPs to be profitable.

3 - Terminal airspace trajectory generation with design-transferable generative models

Xinting Zhu, City University of Hong Kong, Kowloon, Hong Kong, Yongchao Ye, Lishuai Li

Generating realistic trajectories is essential for optimizing fuel economy, minimizing environmental affects, and enhancing predictive planning of airline operations, particularly within terminal airspace. This space is typically navigated via standard routes, yet actual trajectories can diverge due to factors such as air traffic control directives, pilot decisions, and aircraft performance variations. Traditional simulation methods for generating these trajectories are labor-intensive and require extensive setup for new scenarios, while existing data-driven approaches fail to adapt to new airspace designs or terminal areas lacking historical trajectory data. This study introduces a digital framework employing design-transferable generative models for terminal arrival trajectory generation. Two typical generative models with design-conditional generation, diffusion model and variational autoencoder, are employed to model the uncertainty and variability in aircraft trajectories, with integrating design profile learning. Experiments conducted at Hong Kong International Airport (HKIA) demonstrate the superior performance of our models. The results confirm the effectiveness of generative models in capturing the physical constraints and dynamics of aircraft, offering a promising, adaptable, and environmentally considerate solution for optimizing terminal airspace design and operations.

4 - Runway capacity improvement and joint TMA optimisation under data-driven dynamic wake separation prediction

Kam NG, The Hong Kong Polytechnic University, Hong Kong, Hong Kong

Runway capacity is one leading bottleneck in near-ground flight operational efficiency, as a result of a variety of operational constraints, including aircraft wake separation and runway occupancy time. “Improving capacity and efficiency” has emerged as a critical concern with the continual surge in air travel demand and the restricted potential to expand runway configuration and other infrastructure. Compared to distance-based aircraft wake separation standard regulated by International Civil Aviation Organization (ICAO), both European Union Aviation Safety Agency (EASA) and Federal Aviation Administration (FAA) proposed the aircraft type recategorization to relax wake separation distance. Furthermore, dynamic separation that aims in weather- and aircraft-related separation, is an ongoing hot issue.
Based on our previous studies of aircraft wake vortex decay prediction, two levels of crosswind-related wake separation matrixes are proposed in this paper. We further build the runway arrival sequencing and scheduling model to explore the potential of runway capacity improvement under proposed dynamic wake separation matrixes. Both theoretical and operational runway capacity at the Hong Kong International Airport are investigated using historical arrival flight data. At the meantime, we jointly verify the possibility of arrival flight scheduling in Terminal Manoeuvre Area for supporting this separation-reduced efficient runway management. The results indicate that compared to the traditional ICAO and RECAT-EU standard, the hourly runway capacity can be improved by approximately 10% with implementing the dynamic wake separation standards through integrated TMA and runway optimisation.

Co-Chair: Lishuai Li, City University of Hong Kong, Kowloon, Hong Kong

1 - The Future of Last-Mile Delivery Technology and the Importance of a Holistic Approach

Yuqian Dong, Walmart, Seattle, WA, United States

As the global e-commerce market grows, the demand for efficient last-mile delivery systems has intensified, making investment in emerging technologies essential for staying competitive. Key challenges include high costs, logistical complexity, environmental impact, and rising customer expectations. Investing in technologies such as drones, autonomous delivery vehicles, micro-fulfillment centers, and AI-powered tracking systems is critical for reducing delivery times, lowering costs, and improving sustainability. Successful adoption of these technologies must be approached holistically. It is crucial to integrate these innovations across the entire last-mile delivery ecosystem, ensuring that technological advancements align with broader business goals, optimize operations, reduce costs, and meet consumer demands for speed and transparency. Moreover, as we adopt these technologies, it is vital to mitigate potential adverse impacts on safety, legal compliance, and society at large. Ensuring that these innovations are introduced in a way that prioritizes safety, adheres to legal standards, and considers societal implications is crucial for sustainable growth and long-term success. Real-world examples from industry leaders like Amazon and Walmart demonstrate how early, responsible investments in both technology and holistic integration are already transforming last-mile delivery. A future where these responsible, integrated solutions drive a smarter, more sustainable, and customer-centric approach to logistics positions academics and businesses to not only adapt to changes but also to actively shape the future of delivery.

Emerging Topics in Behavioral Operations Management

Invited Session

Behavioral Operations Management

Chair: Behrooz Pourghannad, Lundquist College of Business, University of Oregon, Eugene, OR, United States

Co-Chair: Yuanyuan Ding, University of Oregon, Eugene, OR

1 - Behavioral Response to Priority in Deceased-Donor Kidney Allocation

Jiayi Liu, Virginia Tech, BLACKSBURG, VA, United States, Diwas KC

This study examines the impacts of priority in deceased-donor kidney allocation on patient outcomes. Using national kidney transplant data and a regression-discontinuity design, we show that allocation priority generates a positive supply shock. This supply shock not only enhances health outcomes for transplant recipients but also leads to unintended behavioral side effects.

2 - The Hidden Cost of Hidden Fees: a Dynamic Analysis of Price Obfuscation in Online Platforms

Jose Lopez, MIT, Cambridge, MA, United States, Edward Anderson

We study the effects of a common price obfuscation tactic, “shrouding hidden fees,” on consumer behavior and platform firm performance. Where traditional economic models of individual firms have shown that obfuscation tactics can be profitable for these firms even in repeated interactions, more recent work in behavioral operations management has argued that these tactics can be harmful not just to consumers but to the firms themselves. We contribute to these studies by explicitly accounting for different aspects of platform value creation to understand the role and incentives of platform firms as intermediaries that facilitate the matching process, and by using simulation modeling methods to expand model boundaries, and study appropriate time horizons. We find evidence to suggest that building consumer trust through disclosure is a dynamic attribute characterized by worse-before better outcomes. The results provide evidence that platform pricing transparency decisions may evolve differently depending on market and industrial context.

3 - How the consumers respond to responsibility initiatives in the developing world?

Neslihan Ozlu, Georgia Tech, Scheller College of Business, Atlanta, GA, GA, United States, Basak Kalkanci

With an increasing focus on sustainability, firms are starting to assess how their social responsibility efforts influence consumers. While studies evaluating consumer reaction to corporate social responsibility predominantly focus on US consumers, many firms are expanding their presence and seeking to engage effectively with consumers in developing economies. Examining the relevance of social responsibility for consumers in the developing world is particularly crucial since significant negative social impacts occur in upstream supply chains typically located in these countries (which may increase consumer sensitivity to responsibility), while consumers in these countries are also highly prone to economic concerns (potentially reducing their sensitivity to responsibility). Thus motivated, we conducted field experiments in collaboration with a major apparel retailer in Turkey to analyze the link between social responsibility initiatives and consumer purchase behavior. Our experiments leverage the digital infrastructure of retail stores to provide transparency into the firm's social responsibility initiatives through audio and videos at different times. We highlight internal (e.g., engaging women in economically disadvantaged areas as direct supply chain partners to produce handcrafted products) and external (helping women in those areas learn handicraft skills) responsibility initiatives and use transaction data to link experimental conditions to sales. We find that transparency into responsibility initiatives tends to positively affect sales, particularly when coupled with a discount. Furthermore, local socio-economic profile and store characteristics tend to moderate this link. This study underlines the importance of creating locally tailored strategies for prioritizing and communicating social responsibility activities for firms.

Network Data Insights: Algorithmic Approaches

Invited Session

Applied Probability Society

Chair: Yeganeh Alimohammadi, UC Berkeley, Berkeley, CA, United States

1 - A Method for Experiments Under Unknown Network Interference

Sadegh Shirani, Stanford University, Stanford, CA, United States, Mohsen Bayati

Randomized experiments are a powerful methodology for data-driven evaluation of decisions or interventions. Yet, their validity may be undermined by network interference. This occurs when the treatment of one unit impacts not only its outcome but also that of connected units, biasing traditional treatment effect estimations. Our study introduces a new framework to accommodate complex and unknown network interference, moving beyond specialized models in the existing literature. We present a practical algorithm for estimating the treatment effect and demonstrate its efficacy in multiple numerical scenarios.

2 - Quantitative Propagation of Chaos for Non-Exchangeable Diffusions

Lane Chun Yeung, Carnegie Mellon University, Pittsburgh, PA, United States, Daniel Lacker, Fuzhong Zhou

This talk discusses an ongoing work on quantitative propagation of chaos for non-exchangeable systems. For systems of diffusions with heterogeneous interactions, we obtain a variety of entropy bounds quantifying the degree of approximate independence of the particles in terms of the fine structure of the matrix of pairwise interaction strengths. Our proof strategy is based on adapting a recent approach for exchangeable systems, which relies on a hierarchy of differential inequalities bounding the k-particle entropy in terms of the $k+1$-particle entropy. The hierarchy is significantly more complex in the non-exchangeable setting, indexed by sets rather than numbers of particles, and we analyze it by means of an unexpected connection with first-passage percolation. Joint work with Daniel Lacker and Fuzhong Zhou.

3 - From Signaling to Interviews in Random Matching Markets

Sophie Yu, University of Pennsylvania, Philadelphia, PA, United States, Itai Ashlagi, Amin Saberi, Maxwell Allman

In many two-sided matching markets, agents initially engage in costly interviews in order to refine their interim preferences. We study how signaling mechanisms can reduce the number of interviews in random markets. We are interested in perfect interim stability, which expands the notion of stability to ensure that no two agents regret not interviewing each other. The final match is almost interim stable if it is perfect interim stable after removing a vanishingly small fraction of agents.

For single-tiered markets, we study the impact of short-side (resp. long-side, both-side) signaling, where agents from short-side (resp. long-side, both-side) of the market signal their top d preferred candidates. The interview graphs are formed by including all pairs where at least one party has signaled to the other. When $d=\omega(1)$, we show that short-side signaling leads to almost interim stable matchings for every stable matching. Long-side signaling is effective in weakly imbalanced markets (where the difference in size between market sides is small), but fails in strongly imbalanced markets (where this difference is significant). We also demonstrate the failure of both-side signaling when the impact of interviews is negligible with $d=o(\log n)$. When $d\ge \Omega(\log^2 n)$, short-side signaling achieves perfect interim stability, while long-side signaling fails in imbalanced markets. We extend our results to multi-tiered markets, proposing a signaling mechanism that achieves interim stability across tiers. Our analysis also identifies conditions for truthful signaling for our signaling mechanisms across various market conditions.

4 - Electric Robo-Taxi Dispatching and Charging Facility Allocation Using Deep Reinforcement Learning

Zhanhao Zhang, Cornell University, Ithaca, NY, United States, Manxi Wu, Jim Dai

The adoption of autonomous driving technologies, particularly through robo-taxi services, is revolutionizing the transportation industry. Companies like Cruise and Waymo are deploying robo-taxis in several US cities, including San Francisco, Phoenix, and Austin. These robo-taxis, being electric vehicles, present operational challenges since they take longer to charge compared to traditional gasoline cars. Consequently, ride-hailing companies must optimize battery charging schedules and deploy charging infrastructures in accordance with trip demand and fleet distribution. In this work, we model the control of an electric vehicle (EV) fleet as a Markov decision process with an infinite horizon and a discrete state space. The joint control of an EV fleet is challenging because the state and action space grows exponentially with the number of EVs. To address this, we introduce a scalable control policy optimization pipeline that employs atomic action decomposition, state aggregation, and neural network function approximation. We prove that atomic action decomposition is without loss of optimality. Additionally, we propose a fluid-based linear programming (LP) approach that provides an upper bound on the long-run average daily revenue achievable by any control policy. Numerical experiments benchmarking against the objective value obtained from the fluid-based LP using the NYC For-Hire Vehicle dataset demonstrate the superb performance of our pipeline.

5 - Characterizing Tie Strength with An Algebraic Topological Stochastic Process

Arnab Sarker, Massachusetts Institute of Technology, Cambridge, MA, United States, Jean-Baptiste SEBY, Austin Benson, Ali Jadbabaie

The association between tie strength and social structure is a fundamental topic in the social sciences. This work investigates this association by analyzing tie strength in higher-order networks, an increasingly relevant model which can encode group interactions between three or more individuals. Specifically, in this talk I will compare tie strength to Edge PageRank, an algebraic topological extension of the classical PageRank measure for higher-order networks. I will first show how the stochastic process underlying Edge PageRank can be understood as a random process which models communication flow in the social network, motivating the measure's use in estimating tie strength. I will then provide a characterization of the Edge PageRank measure in terms of the Hodge decomposition, a tool from algebraic topology which can be shown to be interpretable in the context of social networks. Empirically, analysis across nine datasets reveals Edge PageRank is strongly inversely correlated with tie strength and outperforms traditional measures in predicting tie strength based on network structure. Additionally, Edge PageRank emphasizes ties that span a medium network distance and likely have informational advantages, ultimately enabling the measure to capture population-scale phenomena related to the strength of long ties. These results indicate that ties associated with higher-order interactions tend to be stronger, suggesting that group interactions reinforce strong ties -- a result not easily captured by traditional network models.

Experimentation With Interference

Invited Session

Applied Probability Society

Chair: Peter Frazier, Cornell / Uber, Ithaca, NY, 14850, United States

Co-Chair: su jia, Cornell, New York, NY, United States

1 - Causal Inference under Stochastic Congestion

Stefan Wager, Stanford GSB, Stanford, CA, United States

Whenever one runs randomized experiments in a service system, stochastic congestion can arise from temporarily limited supply and/or demand. Such congestion gives rise to cross-unit interference between the waiting customers, and analytic strategies that do not account for this interference may be biased. In this talk, I will survey some recent advances on causal inference in settings with stochastic congestion.

2 - Experimentation under Spatio-temporal Interference

su jia, Cornell, New York, NY, United States

Experimentation with interference poses a significant challenge in contemporary online platforms. Prior research on experimentation with interference has concentrated on the final output of a policy. The cumulative performance, while equally crucial, is less well understood. To address this gap, we introduce the problem of {\em Multi-armed Bandits with Interference} (MABI), where the learner assigns an arm to each of N experimental units over a time horizon of T rounds. The reward of each unit in each round depends on the treatments of {\em all} units, where the influence of a unit decays in the spatial distance between units. Furthermore, we employ a general setup wherein the reward functions are chosen by an adversary and may vary arbitrarily across rounds and units. We first show that switchback policies achieve an optimal {\em expected} regret $\tilde O(\sqrt T)$ against the best fixed-arm policy. Nonetheless, the regret (as a random variable) for any switchback policy suffers a high variance, as it does not account for N. We propose a cluster randomization policy whose regret (i) is optimal in {\em expectation} and (ii) admits a high probability bound that vanishes in N.

3 - Interference in Matching Marketplaces: From Estimation to Optimization

Arthur Delarue, Stewart School of Industrial and Systems Engineering, Georgia Tech, Atlanta, GA, United States, Kleanthis Karakolios

Marketplace companies routinely use randomized experiments to make operational decisions. Randomized controlled trials are often used to decide whether a specific intervention should be rolled out. However, marketplace experiments suffer from interference, where the treatment status of one unit can affect the outcome of another unit. In the first part of this talk, we consider interventions which stimulate demand but reduce the value of each unit to the platform (discounted demand nudges). We show that the standard estimators exhibit significant bias, which may be positive or negative depending on the experiment design. We then propose alternative, bias-reducing estimators based on linear programming shadow prices. Finally, we consider how these various estimators can influence rollout decisions of particular interventions.

4 - Price Experimentation and Interference

Orrie Page, Stanford, Stanford, CA, United States, Wassim Dhaouadi, Ramesh Johari, Gabriel Weintraub

In this paper, we examine biases arising in A/B tests where firms modify a continuous parameter, such as price, to estimate the global treatment effect of a given performance metric, such as profit. These biases emerge in canonical experimental estimators due to interference among market participants. We employ structural modeling and differential calculus to derive intuitive characterizations of these biases. We then specialize our general model to a standard revenue management pricing problem. This setting highlights a key pitfall in the use of A/B pricing experiments to guide profit maximization: notably, the canonical estimator for the expected change in profits can have the wrong sign. In other words, following the guidance of canonical estimators may lead firms to move prices in the wrong direction, inadvertently decreasing profits relative to the status quo. We apply these results to a two-sided market model and show how this “change of sign" regime depends on model parameters such as market imbalance, as well as the price markup. Finally, we discuss structural and practical implications for platform operators.

1 - Reason for Future, Act for Now: A Principled Framework for Autonomous LLM Agents with Provable Sample Efficiency

Zhihan Liu, Northwestern University, Evanston, IL, United States, Zhaoran Wang

Large language models (LLMs) demonstrate impressive reasoning abilities, but translating reasoning into actions in the real world remains challenging. In particular, it remains unclear how to complete a given task provably within a minimum number of interactions with the external environment, e.g., through an internal mechanism of reasoning. To this end, we propose a principled framework with provable regret guarantees to orchestrate reasoning and acting, which we call "reason for future, act for now" (RAFA). Specifically, we design a prompt template for reasoning that learns from the memory buffer and plans a future trajectory over a long horizon ("reason for future"). At each step, the LLM agent takes the initial action of the planned trajectory ("act for now"), stores the collected feedback in the memory buffer, and reinvokes the reasoning routine to replan the future trajectory from the new state. The key idea is to cast reasoning in LLMs as learning and planning in Bayesian adaptive Markov decision processes (MDPs). Correspondingly, we prompt LLMs to form an updated posterior of the unknown environment from the memory buffer (learning) and generate an optimal trajectory for multiple future steps that maximizes a value function (planning). The learning and planning subroutines are performed in an "in-context" manner to emulate the actor-critic update for MDPs. Our theoretical analysis proves that the novel combination of long-term reasoning and short-term acting achieves a squared-root regret. In particular, the regret bound highlights an intriguing interplay between the prior knowledge obtained through pretraining and the uncertainty reduction achieved by reasoning and acting. Our empirical validation shows that it outperforms various existing frameworks and achieves nearly perfect scores on a few benchmarks. By incorporating "classical" MDP techniques, RAFA introduces the first autonomous LLM agent with provable regret guarantees.

2 - Transformers as Decision Makers: Provable In-Context Reinforcement Learning via Supervised Pretraining

Licong Lin, UC Berkeley, Berkeley, CA, United States, Yu Bai, Song Mei

Large transformer models pretrained on offline reinforcement learning datasets have demonstrated remarkable in-context reinforcement learning (ICRL) capabilities, where they can make good decisions when prompted with interaction trajectories from unseen environments. However, when and how transformers can be trained to perform ICRL have not been theoretically well-understood. In particular, it is unclear which reinforcement-learning algorithms transformers can perform in context, and how distribution mismatch in offline training data affects the learned algorithms. This paper provides a theoretical framework that analyzes supervised pretraining for ICRL. This includes two recently proposed training methods -- algorithm distillation and decision-pretrained transformers. First, assuming model realizability, we prove the supervised-pretrained transformer will imitate the conditional expectation of the expert algorithm given the observed trajectory. The generalization error will scale with model capacity and a distribution divergence factor between the expert and offline algorithms. Second, we show transformers with ReLU attention can efficiently approximate near-optimal online reinforcement learning algorithms like LinUCB and Thompson sampling for stochastic linear bandits, and UCB-VI for tabular Markov decision processes. This provides the first quantitative analysis of the ICRL capabilities of transformers pretrained from offline trajectories.

3 - Towards Understanding the Learning and Generalization of Decision Transformers

Guanting Chen, UNC Chapel Hill, Chapel Hill,, NC, United States

We consider the supervised pretrained transformer for a class of sequential decision-making problems. The class of considered problems is a subset of the general formulation of reinforcement learning in that there is no transition probability matrix, and the class of problems covers bandits, dynamic pricing, and newsvendor problems as special cases. Such a structure enables the use of optimal actions/decisions in the pretraining phase, and the usage also provides new insights for the training and generalization of the pretrained transformer.

4 - Uncertainty Estimation and Quantification for LLMs: A Simple Supervised Approach

Linyu Liu, UNC Chapel Hill, Chapel Hill, NC, United States, Yu Pan, Xiaocheng Li, Guanting Chen

Large language models (LLMs) are highly capable of many tasks but they can sometimes generate unreliable or inaccurate outputs. To tackle this issue, this paper studies the problem of uncertainty estimation and calibration for LLMs. We begin by formulating the uncertainty estimation problem for LLMs and then propose a supervised approach that takes advantage of the labeled datasets and estimates the uncertainty of the LLMs' responses. Based on the formulation, we illustrate the difference between the uncertainty estimation for LLMs and that for standard ML models and explain why the hidden activations of the LLMs contain uncertainty information. Our designed approach effectively demonstrates the benefits of utilizing hidden activations for enhanced uncertainty estimation across various tasks and shows robust transferability in out-of-distribution settings. Moreover, we distinguish the uncertainty estimation task from the uncertainty calibration task and show that a better uncertainty estimation mode leads to a better calibration performance. In practice, our method is easy to implement and is adaptable to different levels of model transparency including black box, grey box, and white box, each demonstrating strong performance based on the accessibility of the LLM's internal mechanisms.

Optimizing Healthcare and Equity through Location Analytics

Contributed Session

Chair: Zhiyuan Wei, California Polytechnic State University, San Luis Obispo, Buffalo, NY, United States

1 - Locating Hope: Harm Reduction Smart Vending Machines Location Problem

Sara Abu Aridah, The Pennsylvania State University, University Park, PA, United States, Paul Griffin

Efficient allocation of resources for harm reduction initiatives in substance use disorder communities is crucial for mitigating the adverse impacts of drug addiction. This study focuses on developing a mathematical model to optimize the placement of Smart Vending Machines (SVMs), aimed at reducing harm associated with substance abuse while minimizing operational costs. The model considers a set of communities, each with a candidate location for an SVM, and incorporates community-level data on substance abuse indicators to inform decision-making. Demand within each community arises from both individuals directly affected by Opioid Use Disorder (OUD) and those within their social network or from concerned community members. Furthermore, SVM locations are subject to capacity constraints to ensure effective resource utilization.

We use a mixed integer linear mathematical model that integrates operations research techniques with insights from public health to address the complex challenges of harm reduction intervention. By strategically positioning SVMs based on community-level demand and operational constraints, the model aims to maximize harm reduction impact while optimizing resource allocation. Monte Carlo simulations are employed to account for uncertainty in demand, enhancing the robustness of the model's solutions.

This research contributes to the advancement of evidence-based approaches to harm reduction by providing decision-makers with a systematic framework for deploying SVMs in substance abuse communities. The findings hold implications for public health policy and intervention strategies, offering insights into the effective allocation of resources to combat substance abuse and its associated harms.

3 - Can Combinatorial Equity Models Solve Large Problem Instances?

Emily Speakman, University of Colorado Denver, Denver, CO, United States, Daphne Skipper, Drew Horton, Tom Logan

Equitable Facility Location is the problem of optimally locating vital services within a community so that equitable access is prioritized. The discussion of equity is vital because low-income neighborhoods and communities of color are consistently shown to be disproportionately impacted by poor access to amenities. Issues of equitable access are well-studied in the operations literature with several metrics having been proposed for optimization. However, a consensus on the ideal measure of equity has been elusive, in part, because metrics able to capture equity well result in highly nonlinear optimization models that are computationally expensive to solve. In this talk, we present recent work that offers a solution to this challenge and adds to the continued discussion of equity in facilty location.

4 - On Equitable Facility Location

Drew Horton, University of Colorado - Denver, Denver, CO, United States, Tom Logan, Daphne Skipper, Emily Speakman

Facility location models traditionally focus on optimizing logistical and cost-related factors and have often overlooked the crucial aspect of equity. However, there are several compelling reasons for integrating equity into facility location models; these include promoting social justice and increased urban resilience. By addressing disparities in access to essential services and resources, facility location decisions can benefit all members of society, particularly marginalized and underserved communities. Furthermore, reducing inequity enhances the long-term sustainability of communities by fostering social cohesion and inclusive economic growth. In this talk, we present recent results that address the question of how best to model equity in various instances of this important domain.

5 - Enhancing Spatial Access to Healthcare: Integrating Location Analytics with Optimization Modeling

Zhiyuan Wei, California Polytechnic State University, San Luis Obispo, CA, United States

Improving spatial access to healthcare facilities is of great interest in urban planning. However, most facility location models fall short of explicitly incorporating spatial accessibility measures when designing facility locations. Thus, we aim to develop a novel analytical framework that directly improves spatial access to healthcare facilities and minimizes access disparities across different population groups. Specifically, a set of machine learning models are trained to estimate healthcare demands from large-scale mobile phone data. Based on human mobility patterns, the travel time decay effect is calibrated based on real road networks. With all these as inputs, a variant of the facility location model is developed to tradeoff between efficiency and equity criteria in enhancing spatial accessibility. To demonstrate the applicability of the proposed framework, a case study is presented. This study could help urban planners determine the optimal locations to establish new hospitals, with the hope of improving equitable access to healthcare services among various socioeconomic groups.

1 - Identifying Risk of Intimate Partner Violence with Multi-Modal Machine Learning

Jiayi Gu, Massachusetts Institute of Technology, Cambridge, MA, United States, kimberly villalobos, Yu Ma, Dimitris Bertsimas

Intimate partner violence (IPV) refers to the abuse and aggression from previous or current partners. It is a widespread but underreported public health concern that impacts more than a third of women in the United States. Aside from potentially life-threatening injuries, IPV has a wide range of negative effects on the mental and physical well-being of individuals. This work presents multimodal machine learning models for the early detection of IPV in clinical settings, developed with a dataset of female patients who sought help and support at a violence prevention center of a major hospital in the United States. Utilizing both tabular clinical data and unstructured clinical notes, our models can identify IPV risk with an AUC of 0.88 and years before patients seek help. The models achieved consistent performance in identifying IPV risk for patients who did not seek help at the violence prevention center and patients from another hospital in the same integrated network. This work demonstrates the potential of utilizing multimodal machine learning and historical longitudinal data for the early identification of IPV risk as we work towards developing an IPV risk assessment tool for healthcare settings.

2 - Randomized Controlled Trials for Capacity-Constrained Interventions

Hannah Li, Columbia, New York, NY, United States, Justin Boutilier, Jonas Jonasson, Erez Yoeli

Randomized controlled trials (RCTs), or experiments, are the gold standard for intervention evaluation. However, the main appeal of RCTs---the clean identification of causal effects---can be compromised by interference, when one subject's actions can influence another subject's behavior or outcomes. In this paper, we formalize and study a type of interference in a subclass of interventions we term Service Interventions (SIs): interventions that include an on-demand service component provided by a costly and limited resource (e.g., healthcare providers or teachers). We show that capacity constraints, induced by staffing decisions made by the experimenter, can mediate the effect size of the intervention.

We first show that in such a system, the capacity constraints induce dependencies across experiment subjects, where an individual may need to wait before receiving the intervention. By modeling these dependencies using a queueing system, we show how increasing the number of subjects without increasing the capacity of the system can result in a smaller treatment effect size. This has implications for conventional power analysis: increasing the sample size of an RCT without appropriately expanding capacity can decrease the study's power. To address this issue, we propose a method to jointly select the system capacity and number of users using the square root staffing rule from queueing theory. We show how incorporating knowledge of the queueing structure can help an experimenter reduce the amount of capacity and number of subjects required while still maintaining high power.

3 - Optimizing Health Supply Chains with Decision-Aware Machine Learning

Tsai-Hsuan Chung, Wharton School, Philadelphia, PA, United States, Jatu Abdulai, Patrick Bayoh, Lawrence Sandi, Francis Smart, Hamsa Bastani, Osbert Bastani

This paper combines machine learning (to predict demand) with optimization (to optimize allocations) to address the problem of allocating limited supply of medical resources in developing countries, in particular, Sierra Leone. A key challenge is the need to align the loss function used to train the machine learning model with the decision loss associated with the downstream optimization problem. Traditional solutions have limited flexibility in the model architecture and scale poorly to large datasets. We propose a decision-aware learning algorithm that uses a novel Taylor expansion of the optimal decision loss to derive the machine learning loss. Importantly, our approach only requires a simple re-weighting of the training data, ensuring it is both flexible and scalable, e.g., we incorporate it into a random forest trained using a multitask learning framework. In collaboration with the Sierra Leone government, we deployed our framework in a staggered rollout across all 1,123 government healthcare facilities nationwide. We use synthetic differences-in-differences to evaluate the impact of our tool, finding a more than 20% increase of overall consumption of essential medicines, thereby significantly improving real-world patient access to care.

4 - Modeling and Scheduling Queues with Heterogeneous Resource Demand in Multi-Class Multi-Pool Systems

Weiye Xi, Columbia Business School, New York, NY, United States, Carri Chan, Jing Dong

We study the scheduling of a new class of multi-class, multi-pool queueing systems characterized by heterogeneous resource demands across customer classes. We introduce a model that incorporates multiple types of resources, some with strict capacity constraints and others with soft constraints where exceeding capacity is penalized. These constraints exert different influences on system performance, posing challenges in deriving the optimal policy. Our primary focus lies in the application of this model to hospital inpatient care, where patients require both bed occupancy and specific nursing capacities for adequate treatment. We propose an index-based scheduling policy that aims to optimize the trade-off between holding costs, policy-induced idleness, and constraint violation penalties. We provide insights into the determination of the optimal penalty coefficient based on different levels of system occupancy and its empirical significance. We demonstrate the superior performance of our policy over reasonable benchmarks in several representative scenarios.

Fair Decision-making in Healthcare

Flash Session

Health Applications Society

Chair: Wesley Marrero, Thayer School of Engineering at Dartmouth, Hanover, United States

Co-Chair: Zequn Chen, Dartmouth College, Hanover, NH, United States

1 - Fair Distributional Reinforcement Learning for Mental Intervention

Zequn Chen, Dartmouth College, Hanover, NH, United States, Wesley Marrero

The fair distributional reinforcement learning learns the fair return function. We add fair constriant under the classical structure of distributional reinforcement learning and analyze the new algorithm's statistical properties. The new architecture fulfills fairness by guaranteeing similarity of return among different subgroups.

2 - Fairness with Probabilistic Independence

Anil Aswani, UC Berkeley, Berkeley, CA, United States, Mahbod Olfat, Yoon Lee, Ilgin Dogan, Zuo-Jun Shen

There is growing interest on ensuring fairness in algorithmic decision-making. One of the challenges is that the relevant notion or definition of fairness varies based on the underlying context. This talk presents how a definition of fairness based on probabilistic independence can be incorporated into data-driven decision-making based on the framework of statistical decision problems and on the framework of principal-agent models. Examples of applications to healthcare are provided.

3 - Fairly Predicting Graft Failure in Liver Transplant for Organ Assigning

Na Zou, University of Houston, Houston, TX, United States

Liver transplant is an essential therapy performed for severe liver diseases. The fact of scarce liver resources makes the organ assigning crucial. Model for End-stage Liver Disease (MELD) score is a widely adopted criterion when making organ distribution decisions. However, it ignores post-transplant outcomes and organ/donor features. These limitations motivate the emergence of machine learning (ML) models. Unfortunately, ML models could be unfair and trigger bias against certain groups of people. To tackle this problem, this talk will discuss a fair machine learning framework targeting graft failure prediction in liver transplant. Specifically, knowledge distillation is employed to handle dense and sparse features by combining the advantages of tree models and neural networks. A two-step debiasing method is tailored for this framework to enhance fairness. Experiments are conducted to analyze unfairness issues in existing models and demonstrate the superiority of our method in both prediction and fairness performance.

4 - Stacking Machine Learning Models that Incorporate Genetics and Ancestry to Improve Phenotype Prediction: A Case Study

Nahian Tahmin, University of Tennessee, Knoxville, TN, United States, Lokesh K lchintha, Akram Mohammed, Vincenza Colonna, Tesfaye Mersha, Robert L Davis, Anahita Khojandi

This study develops a machine learning (ML) model to explore the genetics and ancestry's role in ICS response in severe asthma (SA). Asthma's progression to SA, which is unresponsive to inhaled corticosteroid (ICS) treatment, represents a significant healthcare burden despite constituting less than 10% of cases. Genetic and ancestry factors play a critical role in SA, but current risk assessment methods do not combine these factors effectively lacking comprehensiveness. Using the Biorepository and Integrative Genomics (BIG) Initiative dataset, we focus on a self-reported African-American pediatric cohort (cases=controls=125) and apply ML to whole exome sequenced SNPs data to address this gap. Data preprocessing includes linkage disequilibrium pruning, Hardy-Weinberg equilibrium filtering, and minor allele frequency filtering. Ordinal encoding marks allele frequency, and missing values are imputed using k-nearest neighbors. Local ancestry data is obtained via RFMix v2 with phased genomic data and a reference panel from the '1000 Genomes Project.' We utilize stratified 10-fold cross-validation for dimensionality reduction and ML modeling, designing two primary pipelines (P1-P2), each with two sub-pipelines. Pipeline 3 (P3) stacks these sub-pipelines into three sub-pipelines (SNP; LA; SNP-LA). P1 applies Lasso regression to SNP and ancestry data, P2 employs Recursive Feature Elimination and Elastic Net followed by Random Forest on SNP and ancestry data. P3 integrates these pipelines with weighted probabilities for a comprehensive model. Results show that incorporating local ancestry data improves ROC AUC from 0.693 ± 0.066 to 0.727 ± 0.041 ($p=0.020$). Both SNP and local ancestry data provide valuable, non-overlapping insights, enhancing genetic prediction accuracy in SA.

5 - Optimizing Vaccination Campaign Strategies Considering Societal Characteristics

Zelda Zabinsky, University of Washington, Seattle, WA, United States, Serin Lee, Shan Liu

Vaccine hesitancy remains a persistent public health challenge. This study examines the interplay between disease transmission, evolving vaccination opinions, and targeted vaccination campaigns. We employ an evolutionary game-theoretic framework to model how individuals make vaccination decisions and how word-of-mouth campaigns influence vaccination uptake. Our findings highlight that vaccination campaign effectiveness and allocation strategies depend on the specific social context. This includes factors like the levels of perceived vaccine risks and the relative weight individuals give to logic versus emotion when making vaccination decisions. In addition to maximizing vaccination uptake, we consider maximizing the minimum vaccination rate increase across demographic groups to account for fairness. Resource allocation for an optimal campaign strategy specifies demographic groups to target. A campaign is most effective when the society has moderate levels of perceived risk of vaccination, and where individuals balance emotional and rational decision-making factors. When the society has low perceived risk of vaccination, natural uptake is already high, making a campaign unnecessary. When the objective is to maximize the minimum vaccination rate increase among groups, the total vaccinated population decreases by 16% compared to the base case. Although overall campaign effectiveness decreases, this approach ensures a more equitable distribution of campaign benefits. This research underscores the importance of considering societal dynamics and demographics when tailoring messaging and targeting groups to maximize the impact of vaccination campaigns.

Sequential Decision Making in Healthcare

Invited Session

Health Applications Society

Chair: Hossein Piri, Haskayen School of Business-University of Calgary, Calgary, AB, T2R1C3, Canada

1 - Optimizing Drug Interaction Alerts: A Grouping-Based Approach to Mitigate Alert Fatigue Among Clinicians

Hossein Piri, Haskayen School of Business-University of Calgary, Calgary, AB, Canada, Michael Lingzhi Li

Computerized Physician Order Entry (CPOE) systems play a crucial role in healthcare, but the excessive generation of alerts often leads to alert fatigue among clinicians. To address this challenge, this research proposes a novel approach that utilizes artificial intelligence (AI) to categorize alerts based on their severity. By employing a Partially Observable Markov Decision Process, the research aims to strategically select and present alerts to prescribers, thereby reducing the likelihood of alert fatigue. This grouping-based methodology seeks to optimize the alert system by intelligently filtering out less critical alerts and prioritizing those of higher importance. Through the utilization of AI-driven severity classification and decision-making processes, the study endeavors to enhance the effectiveness of alert notifications within CPOE systems. By focusing on presenting alerts that are most relevant and crucial for clinical decision-making, this research strives to improve the overall alert management process and alleviate the burden of excessive alerts on healthcare providers. The implementation of this approach has the potential to streamline alert delivery, enhance provider acceptance of alerts, and ultimately contribute to more efficient and effective clinical workflows.

2 - Towards Interpretable Sequential Machine Learning

Xiaolong Luo, Harvard University, Allston, MA, United States, Michael Lingzhi Li, Scott Wang, Scott Wang

We introduce the Sequential Multiple Instance Learning (SMIL) framework, addressing the challenge of interpreting sequential, variable-length sequences of medical images with a single diagnostic label. Diverging from traditional MIL approaches that treat image sequences as unordered sets, SMIL systematically integrates the sequential nature of clinical imaging. We develop a bidirectional Transformer architecture, BiSMIL, that optimizes for both early and final prediction accuracies through a novel training procedure to balance diagnostic accuracy with operational efficiency. We evaluate BiSMIL on three medical image datasets to demonstrate that it simultaneously achieves state-of-the-art final accuracy and superior performance in early prediction accuracy, requiring 30-50\% fewer images for a similar level of performance compared to existing models. Additionally, we introduce SMILU, an interpretable uncertainty metric that outperforms traditional metrics in identifying challenging instances.

3 - Guiding Physicians with Time-dependent Patient Selection Policies Under Shift Work

Marco Bijvank, University of Calgary, Calgary, AB, Canada, Mahdi Shakeri

Patient selection in healthcare settings with walk-in patients is often a decision at a physician's discretion. Especially in overcrowded environments such as Emergency Departments (EDs), this can significantly impact the operational performance of a healthcare unit and the clinical outcomes for patients. We propose a time-dependent policy to guide physicians in their patient selection decision, where we consider new patients waiting for an initial assessment, returning patients waiting for a re-assessment, and potential patient transfers between physicians at the end of a physician's shift (also called hand-offs). We formulate a transient optimal control problem and demonstrate that a time-threshold-type policy is optimal. This patient selection policy prescibes which patient type (new or returning) and which patient class (urgent or non-urgent) to prioritize. Furthermore, the actual time thresholds when to switch priorities depend on the status of the ED when the physician starts their shift. Under special cases we are able to derive easy-to-implement selection priority rules (that can be seen as extensions of the well-known cμ-rule). Simulation results based on a case study indicate that our proposed policy significantly reduces patient hand-offs compared to alternative policies from the literature without compromising the length of stay (LOS), patient wait times, or the number of patients who leave without being seen by a physician (LWBS).

Adaptive Experimental Design in Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Chonghuan Wang, Massachusetts Institute of Technology, Cambridge, MA, United States

Co-Chair: David Simchi-Levi, Massachusetts Institute of Technology, Cambridge, MA, United States

1 - Adaptive Experimental Design in Operations

Chonghuan Wang, Massachusetts Institute of Technology, Cambridge, MA, United States, David Simchi-Levi

Experimentation serves as a cornerstone across diverse fields, from statistics to social science, enabling us to validate theories and optimize strategies. Traditional experimental designs have been largely rooted in statistical objectives—primarily aimed at minimizing bias and maximizing statistical power. Yet, when operational objectives come into play, these conventional methods encounter distinct challenges. This talk will articulate such challenges and explore how adaptive design strategies can provide solutions.

Firstly, we confront the challenge of welfare loss inherent in traditional randomized experiments. By approaching experimental design as a minimax multi-objective optimization problem, we expose the inherent trade-off between in-experiment welfare and statistical power. We introduce the concept of Pareto optimality to mathematically characterize the situation in which neither the statistical power nor the welfare efficiency can be improved without degrading the other. We derive a useful sufficient and necessary condition for the Pareto optimal solutions to the minimax multi-objective optimization problem. Additionally, we design an effective Pareto optimal multi-armed bandit experiment that can be tailored to different levels of the trade-off between the two objectives. Moreover, we reveal an optimal way to design price experiments, where the price is a continuous decision variable. Extending beyond the price elasticity estimation, we are also interested in maximizing the expected revenue through the experiment, and controlling for the tail risk that, if not controlled, may lead to significant financial losses. Finally, we challenge posed by non-stationarity, meaning that the effects of interventions may evolve over time. Neglecting this dynamic can lead to flawed decisions.

2 - Exploring Drug Candidates: All Epsilon-Best Arms Identification in Linear Bandits

Tianyi Ma, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Zhekai Li, Cheng Hua, Ruihao Zhu

Motivated by the needs to successfully identify multiple candidates that can dramatically enhance outcomes in complex and high-stakes tasks such as drug discovery, we propose a nearly optimal adaptive allocation policy to identify all epsilon-best arms. Specifically, we introduce LinFACTE, an algorithm designed to optimize the identification of all epsilon-best arms in linear bandits. To the best of our knowledge, we provide the first information-theoretic lower bound on the complexity of this problem. Additionally, we demonstrate that our algorithm achieves instance optimality, matching this lower bound up to a logarithmic term. Numerical results demonstrate the practical advantages of LinFACTE compared to baseline methods, highlighting its ability to accelerate early-stage drug development.

3 - Rebandit: Personalizing Treatment Delivery for Reducing Cannabis use

Susobhan Ghosh, Harvard University, Cambridge, MA, United States, Yongyi Guo, Pei-Yao Hung, Lara Coughlin, Erin Bonar, Inbal Nahum-Shani, Maureen Walton, Susan Murphy

As the world moves from reactive care to preventative care, digital health interventions offer an unprecedented opportunity to promote healthy behaviors at scale. However, these interventions often suffer from low engagement and adherence over time. Personalizing the delivery of interventions based on each user's evolving context and preferences can enhance engagement and efficacy. Personalizing treatment in digital intervention studies becomes challenging due to noise and short time horizons. To address this, we present reBandit, an online reinforcement learning algorithm currently utilized in the MiWaves mobile health study. MiWaves aims to deliver personalized interventions to reduce cannabis use among emerging adults. reBandit leverages population heterogeneity by utilizing random-effects, and uses informative Bayesian priors, both enabling efficient learning in noisy mobile health settings. Furthermore, reBandit employs Empirical Bayes and optimization techniques to autonomously update its hyper-parameters online. We benchmark the performance of our algorithm using a simulation testbed. We show that reBandit performs equally well or better than all baseline algorithms, with its performance increasing as population heterogeneity increases.

4 - Planning Adaptive Experiments: A Mathematical Programming Approach

Jimmy Wang, Columbia University, New York, NY, United States, Daniel Jiang, Ethan Che, Hongseok Namkoong

Adaptive experimentation can improve statistical power significantly, but typical algorithms overlook important issues that arise in practice: multiple objectives, non-stationarity, batched/delayed feedback, constraints, and personalization. Moving away from developing bespoke algorithms for each setting, we present a mathematical programming view of adaptive experimentation that can flexibly incorporate a wide range of objectives, constraints, and statistical procedures. By formulating a dynamic program in the batched limit, our modeling framework enables the use of scalable optimization methods (e.g., SGD and auto-differentiation) to solve for treatment allocations. To spur algorithmic progress, we build a suite of benchmark problems based on hundreds of real A/B tests at ASOS that model key practical issues such as non-stationarity, personalization, multi-objectives, and constraints. Our empirical results show standard Thompson sampling-based policies fail to reliably improve upon static designs, and demonstrate the effectiveness of a simple planning approach.

5 - AI-Assisted Fashion Design: LLM and Diffusion Models for Improving Market Demand

Junyi Sha, Massachusetts Institute of Technology, Cambridge, MA, United States, Xiaomin Li, David Simchi-Levi, Michelle Wu

Identifying the key features that influence consumer preferences is crucial in the fashion industry. In this study, we develop a comprehensive methodology to pinpoint the most impactful features of fashion products based on actual market sales data. We first introduce a defined scoring system for product features. Then, utilizing diffusion models, we modify product images to isolate and assess specific attributes. Subsequently, we employ machine learning algorithms—random forest and XGBoost—along with evaluations from human raters to verify the performance of AI-modified products. Through this combined approach, we demonstrate that enhancing the identified "good" features leads to significant improvements in product market performance. Our findings suggest that integrating machine learning techniques with human judgment provides a powerful tool for optimizing fashion product design and marketing strategies.

Data Collection and Analytics

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Lennart Baardman, University of Michigan, Ann Arbor, MI, United States

1 - Managing Product Availability in Rental Subscriptions

Xuening Wang, Massachusetts Institute of Technology, Cambridge, MA, United States, Lennart Baardman

The emergence of rental subscriptions in industries like clothing, furniture, and transportation provides customers access to products that may not be cost-effective to purchase outright. However, rental subscription businesses face significant challenges in reducing customer churn. In collaboration with a clothing rental firm, we identified insufficient product variety as a frequent cause of churn. To address this, we developed fast and implementable policies for the underlying product display and fulfillment dynamic optimization problem. Our prediction-based policy forecasts inventory availability for future rental dates, while the scheduling-based policy makes decisions based on a nominal schedule. Testing these policies on real-world, calibrated simulations, we achieved up to a 5% reduction in overall churn rate. Additionally, we provided theoretical performance bounds for these strategies, comparing them to the hindsight optimal solution and the current instant fulfillment approach.

2 - Costly Data Collection in the Newsvendor Problem

Zijin Zhang, University of Michigan, Ann Arbor, Ann Arbor, MI, United States, Hyun-Soo Ahn, Lennart Baardman

In recent years, data-driven algorithms and policies have flourished in many areas of operations management. While some applications can utilize the preexisting data, there are many cases where collecting plenty of high-quality data is often cost-prohibitive and time-consuming. Previous research has mainly focused on improving decision-making with given data, leaving a gap in understanding the optimal quantity and quality of data needed. Our paper studies how the the sample size (quantity) and noise scale (quality) of a dataset jointly affects the outcome of data-driven decision making in the newsvendor problem. To mitigate the effect of noise, we propose a novel denoised newsvendor policy that minimizes the noise-robust in-sample cost given a noisy dataset. Using the denoised approach, we analyze the retailer's out-of-sample newsvendor outcome as a function of sample size and noise scale. Our analysis quantifies the marginal newsvendor cost on each dimension, and we find that the newsvendor outcome is non-monotone in neither quantity nor quality dimension. Furthermore, given the cost of data collection, we develop a series of data collection policies and show that collecting a dataset of well-balanced quantity and quality is important.

3 - Exploiting Human and AI Synergies: An End-to-End Selective Classification Framework

Bradley Rava, University of Sydney Business School, Sydney, Australia, Michael Huang

Modern Artificial Intelligence (AI) tools have reached a point where policymakers can potentially engage in fast and autonomous large-scale decision-making in high-risk settings. However, despite advancements, the adoption of AI in these settings remains controversial as they can be inaccurate and disproportionally affect minority or underrepresented groups and individuals. As a result, many policymakers revert to human-based decision-making, which, unfortunately, can be equally ineffective as decisions are often delayed or require high labor costs. To demonstrate this issue, we investigate the New York Department of Transportation's speed reducer tracking system. The data from this system can inform decisions regarding the placement of speed humps within the five boroughs. Our presentation introduces an end-to-end selective classification approach that optimally divides decision-making between human expertise and artificial intelligence. The proposed method aims to automatically recommend speed hump placements, while ensuring fairness across the different boroughs. Additionally, it leverages human judgement for decisions where human input is most valuable.

4 - Nuancing majority vote recommendations with Large Language Models

Oliver Schaer, Drexel University, Philadelphia, PA, United States, Matthew Schneider, Nikolaos Kourentzes, Panos Markou

Expert committees are widely used to support decision-makers on complex issues. In many cases, these expert groups submit their recommendations via a majority vote. Although efficient, relying on voting information alone loses experts' discussion, including important nuance, concerns, or uncertainty. For example, a member might vote in favor of a question but add a caveat or other important context that does not make it to the decision table where votes are presented. We suggest Large Language Models to efficiently capture those expressed nuances. More specifically, we want to take advantage of the stochastic nature of LLMs to obtain distributions around the voters' perceived uncertainty level. We empirically evaluate the proposed methodology on FDA Advisory Committee meeting transcripts where the board evaluates novel drugs and medical devices.

MSOM: Analytics for Social Goods

Invited Session

MSOM: Healthcare

Chair: Pengyi Shi, Purdue University, West Lafayette, IN, 47907, United States

Co-Chair: Holly Wiberg, Carnegie Mellon University, Pittsburgh, PA, United States

1 - Optimizing Access to Primary Care

Holly Wiberg, Carnegie Mellon University, Pittsburgh, PA, United States

We propose a joint predictive-prescriptive framework for primary care transformation. Primary care departments traditionally take a "one size fits all" approach to panel assignment and care delivery, which can lead to over-burdened providers and long delays for booking appointments. However, the heterogeneity of patients within a panel, and the emergence of more flexible care models, provide an opportunity to transform department operations. We develop models to predict individual patient demand and an optimization framework for panel assignment. Our model accommodates multiple provider levels (e.g., MDs and APRNs) and visit modalities (in person vs. virtual), providing a tool to evaluate the tradeoffs between current practice and alternative models. The model is currently in use to inform department care delivery strategies across a large CT health system.

2 - Improving the Security of United States Elections with Robust Optimization

Bradley Sturt, University of Illinois Chicago, Chicago, IL, United States, Braden Crimmins, Alex Halderman

For more than a century, election officials across the United States have inspected voting machines before elections using a procedure called Logic and Accuracy Testing (LAT). This procedure consists of election officials casting a test deck of ballots into each voting machine and confirming the machine produces the expected vote total for each candidate.

In this talk, we bring a scientific perspective to LAT by introducing the first formal approach to designing test decks with rigorous security guarantees. Specifically, we propose using robust optimization to find test decks that are guaranteed to detect any voting machine misconfiguration that would cause votes to be swapped across candidates. Out of all the test decks with this security guarantee, the robust optimization problem yields the test deck with the minimum number of ballots, thereby minimizing implementation costs for election officials. To facilitate deployment at scale, we developed a practical exact algorithm for solving our robust optimization problems based on mixed-integer optimization and the cutting plane method.

In partnership with the Michigan Bureau of Elections, we retrospectively applied our robust optimization approach to all 6928 ballot styles from Michigan's November 2022 general election; this retrospective study reveals that the test decks with rigorous security guarantees obtained by our approach require, on average, only 1.2% more ballots than current practice. Our robust optimization approach has since been piloted in real-world elections by the Michigan Bureau of Elections as a low-cost way to improve election security and increase public trust in democratic institutions.

3 - Learning Innovation Curves

Arielle Anderer, Cornell University, Johnson School, Ithaca, NY, United States, Christian Kaps

In sectors such as healthcare and renewable energy how should investors make decisions about which new technologies to invest in? The development of these new technologies can be described using experience curves, also known as innovation curves or learning curves. These allow us model the decrease in cost of a technology as a function of the cumulative investment into it. It is important for investors to balance the tradeoff between investing into multiple different technologies and learning to better estimate the structure of these learning curves, versus dedicating resources to the technology that seems to be the best at the current decision point. We model this decision-making problem as a dynamic program, analyze the performance of different investment strategies, and offer insights into the conditions under which certain strategies might outperform others.

4 - Latent Feature Mining via LLMs: An Application in Incarceration Diversion Program

Pengyi Shi, Purdue University, West Lafayette, IN, United States, Bingxuan Li, Amy Ward

Decision making often operate under constraints of incomplete or sparse datasets with missing entries. Recent advancements in large language models (LLMs) offer a promising avenue to bridge these data gaps. In this work, we propose framework to leverages LLMs to augment observed features collected in given datasets with latent features, enhancing the predictive power of ML models for downstream tasks, and supporting the decision-making. We use data from the criminal justice setting to demonstrate the efficacy of this framework.

MSOM: Service Operations

Chair: Xu Sun, University of Miami, Miami, FL, United States

1 - Dynamic Control of Multiclass Queueing Networks in Heavy Traffic: Interpreting Solutions to Brownian Approximations

Baris Ata, University of Chicago, Booth School of Business, Chicago, IL, United States, Michael Harrison, NIAN SI

We investigate Brownian approximations for control problems in queueing networks, specifically addressing the complex scenario where the equivalent workload formulation is multi-dimensional. By employing deep learning, we solve the approximating Brownian control problem and propose a method to implement this solution in the original queueing network problem. We demonstrate the effectiveness of our method through performance comparisons with benchmarks using simulation.

2 - Real-TIME Spatial Intertemporal Pricing and Relocation in a Ride-Hailing Network

Chen Qi (George), London Business School, London, United Kingdom, Murray Lei, Stefanus Jasin

This paper studies a tactical spatial–intertemporal pricing problem where a firm uses a pool of homogeneous servers to serve price-sensitive customers within a finite horizon. We develop a simple state-dependent pricing policy and establish its asymptotic revenue loss performance which strictly improves over state-independent pricing policies. Similar insights hold when the firm is also allowed to relocate servers at a cost in addition to pricing.

3 - Cloud Cost Optimization: Model, Bounds, and Asymptotics

Zihao Qu, The University of Massachusetts Amherst, Amherst, MA, United States, Milind Dawande, Ganesh Janakiraman

Motivated by the rapid growth of the Cloud Cost Management and Optimization (CCMO) industry to support the exploding cloud-computing market, we study an infinite-horizon, stochastic optimization problem from the viewpoint of a firm that employs cloud resources to process incoming jobs over time. We model the following practical features of CCMO in our problem. There are several types of resources differing in their costs and performance attributes (e.g., processor speed, memory). For each type of resource, capacity can either be reserved over the long term at a discounted price or used on-demand at a relatively higher price. Jobs of several types arrive stochastically through time -- jobs differ in their completion-time deadlines and in their resource-specific processing-time distributions. Moreover, the progress of a job can be observed periodically and, if required, the job can be moved from one resource-type to another. Penalty costs are incurred for jobs not completed by their deadlines. The firm's goal is to minimize the long-run average expected cost per period, considering reserved-capacity costs, on-demand capacity costs, and job-delay costs. We derive a lower bound on the optimal cost by considering a set of decoupled problems, one for each job. The solutions of these problems are then used to construct a feasible policy for the original problem and derive an upper bound on that policy's optimality gap. Importantly, we show that our policy is asymptotically optimal. We also report results of a comprehensive numerical study on AWS data to demonstrate the impressive performance of our policy.

4 - Asymptotically Optimal Dispatch Policies for Emergency Medical Services

Jingwei Zhang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Cheng Hua, Tong Wang, Ziyan Zhou

Emergency medical services (EMS) play a critical role in ensuring timely and effective healthcare delivery, particularly in situations where rapid response is important. The dispatching of ambulances, a fundamental component of EMS, is a complex decision-making process that directly influences patient outcomes. Cities are faced with the challenge of managing limited resources to respond promptly to current emergency calls while maintaining the capacity to address potential future services. In this paper, we consider the dynamic nature of call arrivals and the inherent heterogeneity in service times across different station-location pairs with general distributions. Our goal is to determine which unit to dispatch to each sequentially observed call to minimize the system-wide average cost. To address this problem, we develop two easy-to-implement and near-optimal policies based on a deterministic linear program and a Lagrangian relaxation. Our case study, based on real data from New York City, demonstrates how implementing various proposed policies can effectively reduce costs under different levels of demand.

5 - Optimal Design and Re-Design of Large Scale Service Systems: Pricing and Capacity Optimization with Price and Congestion Sensitive Customers

Levent Kocaga, Sy Syms School of Business, New York, NY, United States

We study the joint pricing and capacity optimization and re-optimization problem faced by a service provider that is modeled as an unobservable queue. Customers are price and delay sensitive with heterogeneous service valuations which subsequently determine the endogenous arrival rate via a unique equilibrium for a given price and capacity. The objective of the service provider is to choose the price and/or capacity that maximizes the average profit rate in equilibrium. Since the exact analysis of such a system is only possible numerically, we pursue an asymptotic analysis by letting the market size grow large while holding parameters that define individual customer characteristics fixed. Our main theoretical contribution is to show that, under various formulations, the optimal system operates under the Quality-Efficiency-Driven (also known as the Halfin-Whitt) heavy traffic regime. An important practical implication of the QED regime is that we can derive tractable analytical expressions for the optimal price, capacity, and profit rate which enable us to glean novel structural insights that are relevant to the operation of large-scale service systems (and are otherwise not possible via exact analysis). Our results can also help guide service providers to run promotional marketing activities that increase market size such as paid advertising or free trials.

Chair: Serguei Netessine, The Wharton School, Philadelphia, PA, United States

1 - Optimizing Impact of Solar Lighting on the Lives of Poor: Evidence from Field Experiments in Ghana

Bhavani Shanker Uppari, Singapore Management University, Singapore, Singapore, Serguei Netessine

We randomly assigned solar-lighting kits with varying configurations to a large number of households in Ghanaian villages. We document the impact of these kits on these treatment households, in terms of economic improvement as well as improvements in the education of children and health of the household members, vis-a-vis control households who were not given solar kits. We also build a structural model that allows us to optimize for the impact in a fast and cost-effective manner.

2 - Harvest Picking in the Era of Global Warming: Hire Now or Later?

Masha Shunko, University of Washington, Seattle, WA, United States, Sanchita Das, Leonard Boussioux

In collaboration with the Washington Fruit Tree Research Center, we design a capacity planning tool that enables dynamic resource allocation for fruit tree growers in response to climate-based yield uncertainties. Given the fluctuations in weather and climate due to global warming, the harvest windows for multiple crops are increasingly more variable over the years. We develop a robust optimization technique that dynamically allocates resources prior to harvesting season.

3 - Beyond Cookies: Evidence about Team Environment and Engagement Retention from Girl Scouts Cookie Program

Tom Tan, Southern Methodist University, Dallas, TX, United States, Bradley Staats

The learning process requires the participation from both the individuals and their teammates, creating a “coproductive” process. Although past research has emphasized various impacts of team coproduction factors, few studies have been done to understand the engagement retention effect, and its impact on learning outcome, particularly in a nonprofit setting.

We focus on this understudied area and study five coproduction factors in the setting of Girl Scout Cookie Program. They include troop size, the disparity of sales performance within the troop, the ratio between adult and girl members, the grade level variety, and troop-sponsored booth sales.

We find that a small troop size and more evenly distributed sales performance within the troop are positively associated with the propensity to return to the Cookie Program. A high adult-to-girl ratio and a significant grade level (i.e., age) diversity in the troop are also conducive to scout retention. Furthermore, conducting troop-based booth sales encourages more scouts to return. We further find that a more evenly distributed sales performance within the troop increases the likelihood to return for both high- and low-sales-performance Girl Scouts, but the positive effect is stronger for high-performance ones than low- performance ones. By contrast, the large grade level variety increases the retention for both older and younger girls. Finally, we find evidence to support that the retained engagement and its associated "learning-by-doing" experience indeed enhance the learning outcome, and that almost all the five team coproductive factors, except troop size, directly enhance learning to sell, too.

4 - Hyperlocal P2P Food Sharing: Estimating the Effect of the Entry of the Commercial Food Donation Channel

Ekaterina Astashkina, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, Masha Shunko, Yixin Iris Wang

We are examining data from the largest global peer-to-peer food sharing platform. This platform facilitates the exchange of soon-to-expire food items among platform's users. We investigate the impact of introducing a new commercial donation channel, which allows various food establishments (e.g., supermarkets, grocery stores, bakeries) to donate surplus food directly to households. Specifically, we aim to understand how this addition influences donation patterns among users of the platform.

OM Research on Uplifting Low-income Communities

Invited Session

MSOM: Sustainable Operations

Chair: Wei Wei, University of New Hampshire, Durham, NH, United States

Co-Chair: Priyank Arora, University of South Carolina, Columbia, SC, 29208, United States

1 - Subsidizing Social Welfare Programs: Contracted Slots OR Vouchers?

Wei Wei, University of New Hampshire, Durham, NH, United States, Priyank Arora, Senay Solak

We study operational decision-making by profit-oriented service providers under two popular service-focused subsidy welfare programs—namely, vouchers and contracted slots. We analyze how program-, provider-, and market-related factors influence the quantity and quality of essential services provided by the providers. Through the comparison of resulting equilibrium outcomes under these two program types, we identify conditions under which it is beneficial (in terms of societal impact generated per cost incurred) for the government to rely on vouchers versus contracted slots.

2 - Improving Process Flow in a Child-Welfare System: A Data-Driven Approach

Shubham Akshat, Carnegie Mellon University, Pittsburgh, PA, United States, Alan Scheller-Wolf, Justin Galbraith, Lindsey Lacey

We study the problem of a case manager of a Child Welfare Organization (CWO).They receive suspected cases of child maltreatment and provide services (includes counseling, support services for independent living, and foster placement) to the child and family.

The CWOs are short-staffed; the true nature of a referral is not known upfront and requires effort (in the form of investigation by a caseworker) to reveal its true type; errors can be very damaging. For example, screening in an innocuous referral for investigation creates negative social value (inconvenience to the child and family) while this effort would have created positive social value if it were spent on investigating a true high-risk referral. Screening out of a high-risk referral carries even greater potential risk. Thus, we have two-sided errors in our setting.

This study aims to find 1. an optimal admission policy (for new referrals) and 2. determine the optimal effort allocation of a caseworker over the set of heterogeneous referrals (in their priority and age) to maximize the throughput and reduce the error rates in determining case/referral resolutions.

Overall, our study lies at the intersection of production queuing network, multi-class queues, and discretionary task completion. We apply OR/OM tool to a child-welfare system and we use real data to estimate policy parameters.

3 - The High Impact of Disasters on Prices in Low-Income Communities

Xabier Barriola, Tilburg University, Tilburg, Netherlands, William Schmidt

Responding to natural disasters requires the deployment of food, shelter, and medical assistance to relieve the immediate needs of the victims. These services are supported by, and eventually fully transitioned to, local resources, such as grocery stores. However, disparities in local infrastructure and services may result in low-income communities bearing a disproportionate burden from these disasters. We investigate this possibility by testing for differences in the percentage change in paid prices, promotions, stockouts, and substitutions for grocery products between low-income and high-income communities following three large Atlantic hurricanes. Using a triple-difference regression specification, we find that low-income communities in the disaster zones endure higher average percentage price increases within grocery categories compared to high-income communities. We establish the presence of several mechanisms that contribute to this outcome -- a larger percentage drop in price promotions, higher percent price increases at the product level, more frequent stockouts, and a larger increase in substitution from low-priced products to high-priced products.

4 - Managing Payment Flexibility in Rent-to-Own Contracts for off-Grid Energy Products

Gonzalo Romero, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Jose Guajardo, Elaheh Rashidinejad, Hosain Zaman

The diffusion of technological innovations in developing economies has been facilitated by the use of Rent-To-Own (RTO) business models, which give flexibility to consumers by allowing them to make incremental payments over time. Motivated by an application of RTO to the distribution of solar lamps in developing countries, we examine the drivers and impact of payment flexibility on repayment performance and consumer behavior in RTO contracts.
We formulate a stochastic dynamic programming model that characterizes an important dimension of payment flexibility, i.e., the ability of consumers to make bundled payments (multiple installments paid at once, in advance). We show that consumers may bundle payments because of uncertainty about budget in future periods, which leads to a non-monotonic impact of income uncertainty on repayment performance. We further show that bundled payments are more likely to occur closer to the end of the ownership cycle. We examine different flexibility levers that the firm can adjust as part of its contract design (repayment frequency/installment amount, grace period), accounting for the impact of bundled payments. Our results show that an intermediate level of flexibility could benefit both the firm and consumers under some conditions.
.

5 - Improving Cash-Constrained Smallholder Farmers' Revenue: the Role of Government Loans

Yanchong Zheng, Massachusetts Institute of Technology, Cambridge, MA, United States, Jimin Park, Somya Singhvi

The need for immediate cash often forces farmers in developing countries to sell their crops when the market price is low, thus hurting their revenue. This paper examines how cash constraints influence farmers' selling decisions across the harvest and lean seasons, and analyzes the efficacy of government loans in improving farmers' revenue. We develop a game-theoretic model to characterize the market equilibrium under the base scenario of no government loan, uncovering the impacts of cash constraints on the revenue of farmers with different production quantities. We then examine how a government loan program may counteract these negative impacts. Under a government loan, farmers store some of their production quantities at government warehouses in exchange for immediate cash. We analyze and contrast two types of loan policies, one in which all farmers are eligible for the loan (a homogeneous loan) and the other in which the loan is only offered to farmers whose production quantity is below a certain threshold (a heterogeneous loan). Our results demonstrate that heterogeneous loans are more desirable when cash constraints are moderately high. We further show that, when designed properly, the loan can simultaneously increase aggregate farmer revenue and generate more equitable revenue distribution among the farmers. Taken together, these results underscore that government loan design must carefully account for farmers' strategic response to the policy to generate positive societal outcomes. Finally, we use field data of Bengal gram farmers in India to empirically validate our insights and quantify the revenue impact of the policies studied.

1 - Seeing Beauty in Ugly Produce: Do Ugly Produce Retailers Reduce Food Waste?

Zheng Han, DePaul University, Chicago, IL, United States, Bin Hu, Milind Dawande

Ugly produce refers to cosmetically-unconventional yet taste- and nutrition-wise perfectly edible produce. Advocates of ugly produce retailers claim that they help reduce food waste. Skeptics, however, argue that ugly produce is often not wasted but meets alternative demands such as from restaurants and processed food manufacturers. Given such alternative demands, do ugly produce retailers reduce food waste? We model an agricultural cooperative producing, pricing and selling produce to a retailer and an alternative buyer, and find that the retailer selling ugly produce still strictly reduces food waste. However, doing so also generally reduces the retailer’s profit, which explains traditional grocery chains’ hesitancy to carry ugly produce. Fortunately, we find that a dedicated ugly produce retailer competing with a traditional retailer yields the same food waste reduction. Therefore, whereas traditional retailers could but would not carry ugly produce and help reduce food waste, ugly produce startups can willingly play this role in their stead. This research sheds light on the ongoing debate about whether ugly produce retailers reduce food waste and explains the development of the ugly produce movement. Our findings justify the sustainability value of ugly produce retailers—especially dedicated ugly produce startups—and inform the collaboration strategies of non-profit organizations with farmers and/or retailers to reduce food waste and combat global hunger and climate change.

2 - Using Artificial Intelligence for Reducing Food Waste in Commercial Kitchens

Karan Girotra, Cornell Tech/Johnson Cornell University, New York, NY, United States, Yu Nu, Elena Belavina

In this study, we estimate the reduction in food waste from the deployment of a system that digitally records instances of food items discarded in a commercial kitchen. We also shed light on the mechanisms that drive this impact. In a quasi-experimental setting, where the system was deployed in about 900 kitchens in a staggered manner, we estimate the impact using synthetic difference-in-differences method. We find that three months after adoption, kitchens generate 29% lower food waste, on average, than they would have in absence of the system, without any corresponding reductions in sales. Utilizing a long-short-term-memory fully-convolutional-networks classifier, we document that these reductions are accompanied by a 23% decrease in demand chasing, a known bias in human inventory management. Upgrading to a system that uses computer vision for waste classification leads to a further 30% reduction in food waste generated by the kitchen, a year after the upgrade. This further reduction is due to accurate recording of infrequent but very high-impact instances of food wasted that are often not entered in the the manual classification system. We also observe substantial effect heterogeneity by kitchen size, service type, and demand variability.

3 - Organic Waste Bans Have Failed to Divert Waste Away from Landfills in the United States&Mdash;Except in Massachusetts

Fiorentia Zoi Anglou, University of Texas at Austin, Austin, TX, United States, Robert Sanders, Ioannis Stamatopoulos

Diverting food waste away from landfills is a critical step to reduce emissions and meet emissions reduction goals set by the Paris Agreement. Accordingly, between 2014 and 2024, nine US states banned commercial waste generators—such as grocery chains—from landfilling organic waste, expecting a 10-15% waste reduction. However, no evaluation of these bans exists. We study the bans' effects on landfilled waste by compiling and analyzing a comprehensive waste dataset covering 36 US states between 1996 and 2019, and 89\% of the US population's waste disposal. Contrary to policymakers' expectations, we can reject aggregate waste reductions higher than 3.2%, and we cannot reject a zero-null aggregate effect. Moreover, we cannot reject a zero-null effect for any state in our data, except for Massachusetts, which gradually achieved an 11.2% reduction—matching expectations. Our findings reveal an urgent need to reassess the design and execution of such bans, using Massachusetts as a benchmark for success.

4 - Sustainable Technology in the Lemons Market: the Case of Battery Choices by Electric Vehicle Owners in Bangladesh

Yewon Kim, Stanford University, Stanford, CA, United States, Amrita Kundu, Erica Plambeck

We study how public and private interventions can resolve information asymmetry and value misalignment between customers and manufacturers of new sustainable durable goods in the context of electric vehicle (rickshaw) batteries in Bangladesh. Two challenges prevent the widespread adoption of new sustainable technologies. First, due to limited information available to customers at the entry phase, innovations face greater information asymmetry than existing goods. Second, as new sustainable technologies often appear as bundles of greater performance in the form of longer duration, higher prices, and lower social costs, their value proposition creates potential misalignment with customers' needs for short-term usage of products at lower private costs. Although developing economies are likely to enjoy higher benefits from sustainable technologies due to the negative externalities of existing alternatives, they impose greater challenges on these innovations because of a lack of a credible signaling system ("lemons markets") and low average income that leads to financial constraints and consumer myopia. Running qualitative interviews and field experiments in two cities in Bangladesh, we aim to measure the negative effects of information asymmetry and value misalignment in sustainable durable goods adoption and propose interventions that reduce such frictions. Our findings help sustainable technologies with high social benefits penetrate markets more effectively and offer implications for policymakers aiming at switching to sustainable markets.

Chair: Zhili Tian, Univ. of Houston, Houston, TX, United States

1 - A Multiperiod Multicommodity Capacitated International Agricultural Trade Network Equilibrium Model with Applications to Ukraine in Wartime

Dana Hassani, University of Massachusetts Amherst, Amherst, MA, United States, Anna Nagurney, Oleg Nivievskyi, Pavlo Martyshev

The world is facing immense challenges due to increasing strife and the impacts of climate change, with accompanying disasters, both sudden-onset as well as slow-onset ones, which have affected the trade of agricultural commodities needed for food security. In this paper, a multiperiod multicommodity international agricultural trade network equilibrium model is constructed with capacity constraints on the production, transportation, and storage of agricultural commodities. The model allows for multiple routes between supply and demand country markets, different modes of transport, and storage in the producing and consuming countries as well as in the intermediate countries. The generality of the underlying functions, coupled with the capacity constraints, allow for the modeling of competition among agricultural commodities for production, transportation, and storage. The capacity constraints also enable the quantification of various disaster-related disruptions to production, transportation, and storage on the volumes of commodity flows as well as on the prices. A series of numerical examples inspired by the effects of Russia's full-scale invasion of Ukraine on agricultural trade is presented, and the results are analyzed to provide insights into food insecurity issues caused by the war.

2 - Socially Responsible Newsvendor

Chen Hu, Xi'an Jiaotong-Liverpool University, Suzhou, China, People's Republic of, Ming Hu, Yongbo Xiao

We focus on a socially responsible firm that is concerned with its profit as well as consumer surplus and examine four different types of pro-social behavior by the firm: optimizing a weighted average of the expected profit and consumer surplus (referred to as the mixed-objective model), negotiating with pro-social executives or consumer activists (referred to as the Nash bargaining), charitable donations after profit maximization (referred to as the donation), and ensuring the portion of consumer surplus to be a given fraction of the social welfare (referred to as the fairness model). Our results show that under all behaviors, there is a more substantial boost to consumer surplus at the expense of a slight decrease in profit when consumer surplus consideration is lower. Among those four behaviors, while maintaining the same profit level, a donation is not the most consumer-surplus-enhancing pro-social behavior among those four behaviors, when the overhead cost is sufficiently high or when a high enough profit level needs to be maintained. This finding challenges Milton Friedman's advocacy that socially responsible businesses should indirectly fulfill their societal duties by focusing on profit maximization and then redistributing the generated profit for social causes (Friedman 1970). Our results imply and quantify that a little commitment to consumers can go a long way in balancing consumer surplus against profit loss. We also shed light on when the firm should choose a decentralized pro-social behavior, such as donations, and when it should incorporate consumer surplus consideration into operational decisions for consumer surplus enhancement.

3 - Harnessing the Potential of Generative Artificial Intelligence for Ad Hoc Logistical Disaster Response

Frank Schätter, Pforzheim University of Applied Sciences, Pforzheim, Germany, Florian Haas

Methods from Operations Research (OR) and Management Science (MS), applied within Decision Support Systems (DSS), ensure that logistical disaster response is based on analytically sound decisions, e.g., by using optimization models for resource allocation, facility location, or transportation planning. To be used for immediate disaster response, the system itself must be operational. This is a challenge when integrating OR/MS methodologies into a DSS, which are time-consuming to implement because they rely on ad hoc information such as environmental impacts and planning conditions. Making assumptions about all these contingencies in the pre-disaster phase is not targeted, as it is impossible to know in advance what will happen, when it will happen, and what the framework conditions will be. This research builds on our previous work developing ReDRiSS (Reactive Disaster and Supply Chain Risk Decision Support System) which uses a two-step scenario construction approach to handle the highly uncertain conditions of a disaster environment, coupled with an optimization model and robustness stress testing. We address the above challenges by exploring the potential of generative Artificial Intelligence (AI) to adapt the underlying methodology ad hoc in the disaster response phase to random disaster environments. This includes, for example, the reactive formulation of the optimization model according to the preferences of the decision makers and the application-specific development of scenarios that capture both the uncertainty and the dynamics of the disaster environment. The integration of AI is the next step in the development of ReDRiSS from an early prototype stage to a customized approach.

4 - Exploring Sustainable, Community-Focused Cooperative Ecosystems among Food Small-Medium Enterprises

Sofia Perez-Guzman, Georgia Insitute of Technology, Atlanta, GA, United States, Llord Brooks, Seckin Ozkul

The well-being of poor and underserved communities primarily depends on their direct access to vital resources in their vicinity. However, research concerning societal well-being and sustainability is often limited to the influence of large enterprises, while the role of small-medium enterprises (SMEs) still needs to be expanded. As such, this study aims to assess the generalization of inter-organizational systems designed to engender cooperative ecosystems that encourage inclusion, address bias towards SMEs, and impact how they serve their communities. Specifically, we focus on addressing how implementing food hubs and group purchasing systems among SME retailers can influence their competitiveness and the well-being of their communities. Thus, we develop a family of mathematical models for the logistics decision-making of the SMEs. We extend the profit maximization objective to include the impact of increased food access in the community. Furthermore, we explore conditions influencing the long-term sustainability of the cooperative ecosystems and the trade-offs between SME competitiveness and community well-being.

Advancements in Digital Twin Technologies

Contributed Session

Chair: Jaeseok Yoon, N/A

1 - A Digital Twin of Outpatient and Day Care Services in Kuwait Cancer Control Center: Data to Action

Sulaiman Aman, Kuwait University, Kuwait, Kuwait, Abdullah Alibrahim, Abdulwahab Al-Tourah, Waddah Al-Refaie

Digital Twin for Health (DT4H) technology is an emerging tool that provides an empirical foundation for optimizing healthcare systems through simulated models of actual systems. By leveraging real-time data, dynamic analysis, and validated models, DT4H can profoundly enhance operational processes in cancer care by creating no-risk and cost-effective environment for conducting what-if analyses. This technology enables healthcare providers to revolutionize patient flows, allocate medical resources more efficiently, and improve scheduling procedures, thereby enhancing patient care. This presentation describes a model-driven approach using data integrations, observations, and models to construct a DT4H to improve cancer patient care, streamline processes, and optimize operations at the Outpatient Department (OPD) in the Kuwait Cancer Center. A data collection plan was implemented to capture patients' arrival rates, visiting frequencies, medical resource capacities, and administrative requirements. Continuous meetings with stakeholders established face validity and inspired an investigation of expanding afternoon clinics in response to increasing demand for cancer care, which is currently operating above its theoretical capacity. All collected data was integrated within a user-friendly discrete-event simulation (DES) model developed on Anylogic Simulation Software. The DES model incorporates animations and live visuals of performance indicators, such as waiting times and number of patients served. Findings from the digital twin indicated that increasing breast and gastrointestinal cancer afternoon clinics could decrease the average waiting time by 32% and increase the number of patients served daily by 8.6%. These results highlight DT4H's potential to elevate healthcare delivery through real-time adjustments and operational decision aids.

2 - Proactive Digital Twins with Virtual Sensors

Mark Mahyar Nejad, University of Delaware, Newark, DE, United States

Digital Twins are a virtual representation of real-world systems and can serve as a testbed for developing and evaluating optimal strategies in real time. A significant hurdle to their development and implementation is the volume of data required, and consequently the volume of sensors required. This paper proposes to reduce this volume through the creation of "Virtual Sensors" - machine learning models which use data from their geographic neighbors to impute the state of the network at their position, considering their relative position and the time to travel between them. These spatiotemporal considerations enable the creation of realistic, detailed, context-specific data, as opposed to traditional data generation. To create these models, we propose a spatiotemporal adaptation to the traditional Variational Autoencoder (VAE) means for data generation. In our model, the virtual sensor trains a VAE on its neighbor's data. Instead of sampling randomly from the latent distribution like the traditional VAE, our model learns the relation between its neighbor's current points in the latent space and draws from the space between them. In addition, we propose a novel physics-informed deep learning to supplement sensor data, seamlessly integrating fundamental principles of network dynamics to reduce bias and increase equity through representation in sensor sparse regions while reducing the massive data requirements of conventional deep learning strategies. By considering the geographic and temporal relations between its neighbors, the Spatiotemporally-Aware Variational AutoEncoder (STAVE) generates realistic, context-specific data, filling gaps in sensor networks.

3 - Evaluation of Simulation-Based Prediction Algorithm for Digital Twin Certification in the Urban Gas Industry

Jaeseok Yoon, Korea University, Seoul, Korea, Republic of, Sung Yeon Kim, Seonghyeon Han, Jinmin Kim

In the urban gas industry, price volatility, supply chain complexity, and enhanced environmental regulation are challenges facing this industry. This can be overcome by lowering the risk of the supply chain and increasing operational efficiency while responding to environmental regulations through certification. Therefore, in this study, we aim to evaluate the predictive algorithm for the gas industry digital twin certification. In addition, we compare the pressure fluctuation predictive performance using real-time data and simulation-based synthetic data to suggest its contribution to improving the operational efficiency, safety, and sustainable development of the gas industry. Our results highlight the excellent predictive performance of the autoregressive integrated moving average (ARIMA) model. Compared to raw data, it showed the best performance in all evaluation indices, mean absolute percentage error (MAPE), root mean square error (RMSE) and determinant (R2). These results demonstrate that the integration of digital twin technology and predictive models can revolutionize the maintenance strategy, operational efficiency, and risk prediction of the gas industry. Predictive maintenance models can help prevent significant industrial risks such as gas leakage accidents. Furthermore, the innovative method of implementing the proposed digital twin technology and the proposed predictive model lay the theoretical basis for certification of the application of digital twins in the gas industry in the future.

Revolutionizing Healthcare: Innovations in Analytics and Operations

Invited Session

Health Applications Society

Chair: Liang (Leon) Xu, Singapore Management University, Singapore, 178899, Singapore

1 - Inducing Compliance with Good Machine Learning Practices In Developing Adaptive AI-Enabled Medical Devices

Liang (Leon) Xu, Singapore Management University, Singapore, Singapore, Jiayi Lai, Xin Fang, Tinglong Dai

This paper presents a two-period regulatory framework for the development and market clearance of adaptive AI-enabled software as a medical device (SaMD). The framework explores the interactions between the developer and the regulator, focusing on the developer's adherence to Good Machine Learning Practices (GMLP) and the regulator's role in ensuring compliance.

In the first period, the developer trains an AI/ML algorithm, and the regulator bases the initial approval decision on the reported efficacy and whether the developer adheres to GMLP. In the second period, the developer can retrain the algorithm using real-world data to potentially improve efficacy. The regulator then assesses compliance during retraining before granting re-clearance.

Using a Perfect Bayesian Equilibrium model, this study analyzes the decision-making dynamics between the developer and the regulator under different regulatory paths, namely, adaptive algorithm with re-inspection, pre-determined change plan, and locked algorithm. The insights provided aim to balance innovation with compliance, ensuring responsible development and deployment of AI-enabled SaMD while safeguarding patient safety.

2 - From Black to Grey: Improving Access to Antimalarial Drugs in the Presence of Counterfeits

Jiatao Ding, INSEAD, Singapore, Singapore, Michael Freeman, Sasa Zorc

In malaria-endemic countries, the limited availability of affordable antimalarial medication has contributed to the widespread distribution of inferior counterfeit drugs. We study such markets to determine how philanthropic donors can best allocate limited funds to subsidize the purchase or sales of antimalarial drugs via private-sector distribution channels. We also consider the potential effectiveness of non-subsidy interventions, e.g., traceability technology adoption, to improve outcomes in the presence of counterfeit drugs. To examine the supply chain of antimalarials, we develop a game-theoretic model in which the retailer has a strategic choice to source legitimate drugs from a certified supplier, potentially counterfeit drugs from an uncertified supplier, or both. In contrast with the extant literature, we show that in the presence of counterfeits, employing a purchase subsidy alone may no longer be optimal. In particular, when the donor's budget is small, the donor may prefer to offer a sales subsidy that covers both legitimate and counterfeit drugs; if the drug's retail price is exogenous and demand uncertainty is high, the donor may need to refrain from offering any subsidy at all. Moreover, we identify conditions under which traceability technologies may or may not help improve the outcomes. Finally, we perform an extensive numerical analysis, calibrating the models to malaria data from Mozambique. Our results indicate the need for regulators and donors to understand specific market characteristics in order to design effective subsidy schemes and select appropriate technologies and policies to improve access to life-saving medicines.

3 - Sharing in Caring: Analyzing Shared Medical Appointments Through An Operations Lens

Sundara Natarajan Panchanatham, HKU Business School, Hong Kong, Hong Kong, Enver Yucesan

Shared medical appointments (SMA) are visits in which healthcare professionals see groups of patients in a concurrent session. The setup can enhance patient experience, eliminate redundant work, and reduce costs for specific treatments. We mathematically model the operational trade-offs in SMAs and derive optimal capacity decisions using a game-theoretic framework.

4 - Medical Inequality: Helping Vulnerable Hospitals

Qiang Li, Wilfrid Laurier University, Waterloo, ON, Canada, Wei Gu, Meng Li

Healthcare resources in developing countries are often unevenly distributed, posting challenges for hospitals to provide essential medical services and supplies equitably to their communities. In response, governments and nonprofit organizations have implemented various programs to support underresourced hospitals located in remote areas. We leverage the introduction of external experts to an underresourced hospital and employ the difference-in-differences design to assess the program's impact. We find that the program has significantly improved the efficiency and quality of medical services provided by them.

1 - Safe Reinforcement Learning with Contextual Information: Theory and Application to Personalized Comorbidity Management

Esmaeil Keyvanshokooh, Mays Business School, Texas A&M University, College Station, TX, United States, Junyu Cao, Tian Liu

Optimizing the treatment regimen is a crucial sequential medical decision-making problem. Inspired by this problem, we study a sequential decision-making setting of learning a personalized, safe control policy that maximizes an objective function subject to safety constraints that need to be satisfied during the learning process. We develop a model-based reinforcement learning (RL) algorithm that accounts for (i) personalization, (ii) safe exploration, and (iii) general statistical models for modeling uncertainty, with a rigorous regret performance guarantee. We utilize a granular clinical dataset of patients with co-morbid type 2 diabetes and hypertension to evaluate the performance of our theory.

2 - Optimizing HIV Prevention Funds Allocation to Minimize New HIV Cases – It does matter!

Md Hafizul Islam, Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, Evin Jacobson, Ram Shrestha, Paul Farnham

Local U.S. health jurisdictions receive funds from the Centers for Disease Control and Prevention (CDC) to implement a comprehensive HIV prevention plan to reduce HIV incidence and improve health equity across their community. We developed a linear programming model combined with a Bernoulli process model to identify the optimal allocation of the CDC's HIV prevention funding for local health jurisdictions. The model allocates the CDC provided budget across different HIV prevention interventions serving different populations stratified by gender and transmission groups to maximize the number of new HIV cases prevented. Inputs to the model include available budget, the maximum number of persons that could be reached by the HIV prevention intervention (reach limits), and data on the costs and efficacy of HIV prevention programs for different subpopulations. In a case study, we applied the model using data from a specific health jurisdiction and analyzed the resulting solutions. We solved the model for a scenario where the model is restricted to follow the allocation practice reported to the CDC by the health department and an unrestricted scenario where the model is allowed to allocate funds to any prevention intervention within the reach limits. Comparing the optimal funding allocations recommended by the model for both scenarios suggests that there is a potential for improving the number of new HIV cases averted when considering alternate funding allocations.

3 - Pooling in-Person and Virtual Queues with An Application to Telehealth

Omer Berk Olmez, Baruch College, Graduate Center, CUNY, New York, NY, United States, Alex Mills

Healthcare services can be offered both in-person and virtually by the same providers. We study a clinic's decision of whether to pool the resources of both channels or to have dedicated resources for each channel. We consider a model in which strategic patients actively decide which channel to join and balk while observing the waiting time for both channels and the distance to the in-person facility. Contrary to the consensus in the classical pooling literature, our findings indicate that patients' expected waiting times and net utilities do not necessarily improve with pooling. Furthermore, our research highlights that pooling the two channels yields benefits for the providers only when the net profit generated from the virtual channel is substantial.

Energy-Aware Business Practices

Contributed Session

Chair: Seongkon Lee, Korea Institute of Energy Research, Daejeon, Korea, Republic of

1 - Market and Corporate Status Analysis for a self-sustaining Smart Thermal Energy Design Platform

Seongkon Lee, Korea Institute of Energy Research, Daejeon, Korea, Republic of, Mingye Lee, Wookhyun Lee, Sangkon Lee, Daekeun Lee, Gento Mogi

The importance of energy technology is becoming more and more important for carbon neutrality and addressing climate change issues. Among energy technologies, especially in the industrial field, improving energy efficiency is one of the major issues. We plan to build a smart Thermal Energy Design Platform(STED) to strengthen the product design and production capabilities of small and medium-sized companies in the energy-consuming manufacturing industry. In order to build a self-sustaining STED, this study focuses on the analysis of market and corporate status in thermal energy-intensive industry area from the industrial ecosystem perspective and draws implications for self-sustaining operation of the STED.

Key words Market analysis, Corportate Status Analysis, Thermal Energy-intensive Industry, Value Stream Analysis

Acknowledgements This research is carried out by the support of Ministry of Trade, Industry, and Energy(MOTIE) and KETEP (No. 20202020800200), Republic of Korea.

2 - A Note on ESG CAPM, Factor Models, and Carbon Reduction Index Funds

Hiroshi Ishijima, Chuo University, Tokyo, Japan, Akira Maeda

Global efforts to achieve net-zero carbon emissions by 2050 and mitigate climate change are intensively driven by capital market functions, including ESG investing. In this context, we develop an asset pricing model for ESG investing that extends the conventional model (Cochrane 2005). In our model, the asset price is the sum of the present value of future cash flows and ESG dividends. ESG dividends are a bundle of benefits related to environmental, social, and governance factors, such as reducing carbon emissions. Because ESG dividends are non-financial, they are converted to monetary value using the extended stochastic discount factor. Our model represents a concept called the double bottom line for ESG investing. We also derive several versions of the model, namely ESG consumption CAPM, ESG CAPM and ESG factor model. In addition, we show the "Green-Brown-Mix Irreverent Proposition" for ESG investing. It asserts that the sum of risk-adjusted excess returns (brown) and ESG dividends (green) for each asset must be identical to that of the market benchmark portfolio. In the literature, much empirical work - including Bolton and Kacperczyk (2021) - has been devoted to finding a double bottom line in the market. This study serves as a foundation for empirical research to show whether or not ESG investing allows us to achieve a double bottom line. As a typical application, we create the Carbon Reduction Index Fund, which invests in Japanese companies committed to reducing carbon emissions. We show that the fund delivers superior investment performance.

3 - Carbon Tracker Features and Accuracy to Measure Carbon Emissions of Algorithms

Eric Van Heck, Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands, Max Baiwir, Anna Priante

Many algorithms are developed in the information systems community. Algorithms are helping but also harming the Earth. They can help by creating business models to reduce waste, emissions, and pollution, but also can harm by emitting carbon emissions that will cause global warming. The use of carbon trackers, i.e. the monitoring and measurement tools, can minimize carbon footprints. This study aims to evaluate carbon tracker features on the accuracy of carbon measurements for algorithms. Three important features are investigated: real-time monitoring of the energy consumption, real-time monitoring of the carbon intensity of its energy sources, and the level of monitoring automation and integration. In a benchmark study, we compare three carbon trackers in terms of the accuracy to measure carbon footprints: Green Algorithms, CodeCarbon, and Tracarbon. These three carbon trackers were evaluated using the Residual Network (ResNet) algorithm with increasing levels of complexity and the MNIST data set. Tracarbon is most accurate for the lower complex and higher complex algorithms. For the ResNet-44 algorithm CodeCarbon is very accurate and for the ResNet-56 algorithm Green Algorithms is reasonably accurate. Green Algorithms stands out for its superior accuracy in estimating the carbon intensity value and underestimates the energy consumption. Conversely, CodeCarbon tends to overestimate energy consumption but is on average better in measuring carbon intensity. Tracarbon provides precise estimates for energy consumption and underestimates the carbon intensity. Recommendations of carbon tracker usage and carbon footprint reduction strategies for the members of the INFORMS community will be presented.

4 - Technology-driven decision-making forecast to enhance sustainability in the Iron and Steel Industry

Hanseul Jo, Kyung Hee University, Yongin, Korea, Republic of, Jungwoo Shin

With the growing importance of carbon neutrality, industries are undergoing significant changes. The transition to carbon-zero industries imposes substantial technological and financial burdens, requiring changes in raw materials, production process, and technologies. Consequently, the decision-making process for selecting new carbon-free technologies has become a critical issue for the industrial sectors. Governments also grapple with integrating such industry-level decision-making process into national carbon neutral strategies. By considering the industrial levels, governments can assess the appropriateness of their objectives and accelerate carbon neutrality by conducting more relevant supportive policies.

Based on this importance, this study predicts how global technology transition occurs in the iron and steel industry by combining the revealed preference (RP) data and stated preference (SP) data. In particular, the iron and steel industry is highly important as it is one of the largest carbon producing industries. To estimate the technology diffusion trajectories and learning effect of each emerging technology and country, RP data is used to figure out the current technological levels and states of national carbon neutralization. SP data is used to examine experts' forecasts on the global technology transitions and differences in technology development of each country.

By providing a comprehensive approach to the industry-level decision-making process and incorporating them into national roadmaps, this study provides meaningful insights into upcoming carbon-zero technology transitions. These make stakeholders conduct strategic decision-making and investment for carbon neutrality. Ultimately, both stakeholders and governments can gain valuable insights into potential pathways for achieving sustainability goals.

5 - "Unleashing Green Logistics: Key Factors Driving Sustainability in South Korean Logistics SMEs"

seung hee ha, Kyungpook National University, Daegu , Korea, Republic of, Sungsu Kim

Driven by stringent carbon emission regulations and environmental conservation efforts globally, enterprises across sectors are actively embracing sustainable management practices. While large corporations have spearheaded this trend, small and medium-sized enterprises (SMEs) are also experiencing mounting pressure to conform due to stakeholder influences and network relationships. The logistics industry, with its extensive operational scope from raw material procurement to product delivery, faces heightened emphasis on environmentally friendly practices and regulations. However, SMEs in this sector grapple with significant challenges in implementing green practices, stemming from technological constraints, financial limitations, and concerns over business continuity. Research specifically targeting SMEs in the logistics industry remains limited.

This study aims to identify and prioritize the key determinants influencing the adoption of green practices among Korean logistics SMEs. The variables under investigation are categorized into external factors, grounded in stakeholder theory, such as government regulations, supplier cooperation, and community responsibility, as well as an internal factor: the company's green technological readiness. These variables are hypothesized to influence the level of green logistics activities through the mediating variable of introduction intention. Furthermore, the study evaluates the performance implications of green logistics adoption levels.

Through this comprehensive analysis, the study seeks to contribute to practical policy formulation by prioritizing the determinants, thereby enhancing the perception of SMEs hesitant to embrace green management strategies. Additionally, it endeavors to verify the contribution of green practices to business survival and sustainable management practices within the Korean logistics industry.

Inventory placement and Inbound Network Design

Invited Session

The Practice Section of INFORMS

Chair: Chun Ye, Amazon.com, Seattle, WA, United States

Co-Chair: Zihao Li, Amazon, Bellevue, WA, United States

1 - Probabilistic Approach to Large-Scale Inventory Placement

Cristiana Lara, Amazon, Bellevue, WA, United States, Arash Haddadan, David Mildebrath, R Ravi

Amazon offers millions of unique items for sale on its website. The popularity of these items is not evenly distributed, and the mean weekly demand for different products on Amazon spans multiple orders of magnitude. Because of this enormous scale and selection, and asymmetries in our storage nodes, deciding how to optimally place this inventory throughout our fulfillment network is very challenging. Directly modeling the massive number of products into a monolithic formulation is intractable. On the other hand, downsampling products typically does not adequately capture the behavior of the “long tail”. We propose a scalable method for grouping products into groups based on their popularity. As we aggregate distinct products into a single group, we lose information about their specific demand and inventory, which results in overly optimistic plans. To mitigate this issue, we propose a “Selection Spread” function, a probabilistic approach to model non-fungibility of products within a group. Our model matches the shipping and storage capacity of nodes in our network with the velocity profile of demand in order to minimize fulfillment costs. We use this framework to derive insights on the relationship between placement strategy and customer experience.

2 - Evaluating Regional Decentralization of Inventory in Delivery Speed-Sensitive Retail Networks: A Comparative Study between Newsvendor Approximation and Simulation

Katja Meuche, Georgia Institute of Technology, Atlanta, GA, United States, Yuan Li, Amitabh Sinha, Benoit Montreuil

Large retailers such as Amazon offer through online channels a vast array of products, encompassing millions of unique items. The multitude of products creates a complex demand landscape where high-demand products are categorized as "head," moderate-demand as "body," and low-demand as "tail." To control complexity and achieve efficiency in the fulfillment network, Amazon has recently regionalized its operations in the US. This process involved defining the number and boundaries of regions, assigning fulfillment centers (FCs) to regions, and aiming to fulfill customer demands using the inventory of the FCs within each region versus from FCs in nearby regions or centralized FCs. This prompts a crucial question: What level of regional decentralization of inventory is economically beneficial for each product category when considering the customer's sensitivity to delivery speed?

In this talk, we analyze this question in two ways for the continental US with alternative inventory de/centralization in one to 48 regions. First, we present a Newsvendor model that considers transportation costs and order-to-delivery-time sensitivity. Our results show that more decentralization of head and body products tends to achieve more profit maximization, and the inverse for tail products. Then, we compare the results of the Newsvendor model to results from a simulation that dynamically models fulfillment of online channel demand in more detail. Based on the comparison, we determine how well the adapted Newsvendor model approximates online retail operations. We then draw insights and conclusions relative to regional de/centralization of inventory considering time-sensitive customers.

3 - A Unified Bulk Storage and Distribution Network Design

Shanshan Zhang, Amazon, Bellevue, WA, United States

Amazon operates several types of bulk distribution centers, each tailored to specific operational models and network designs. Despite their individual nuances, their major purpose remains consistent: to provide low-cost storage solutions by handling inventory in bulk formats while facilitating fast replenishment to their downstream premium storage nodes positioned proximally to Amazon end customers. Recognizing the inherent synergies within these operations, network designs, and technological requirements, this presentation presents a unified bulk storage and distribution network design strategy to streamline operations and enhance efficiency across the network.

4 - Ideal Inventory Placement with Demand Spillover

Zihao Li, Amazon, Bellevue, WA, United States, Zhongxiang Wang, Tolga Cezik

We share an ideal inventory placement strategy for designing an effective inbound network of an online retailer. In an online retailer's fulfillment network, demand is ideally fulfilled from the nearest warehouse with inventory and ship capacity before other, further-away warehouses (defined as spillover). The spillover of demand leads to variable (inventory) turn (measured as the ratio of the average daily shipment units to the average on-hand units) for each item at different warehouses. We build a two-stage stochastic model to capture the variable turns of an item at different warehouses in inventory placement and a discrete-event simulation model to assess its impact on fulfillment. We generate two inventory allocation plans under two inventory placement strategies: assuming all warehouses have the same network turn (Constant Turn) for an item or incorporating the variable turns (Variable Turn) at warehouses for an item. Simulation is used to evaluate the fulfillment of the two inventory placement strategies, showing that Variable Turn reduces total fulfillment distance.

1 - Digital Transformation in Transportation Systems: Navigating User Behavior and System Efficiency

Haripriya Pulyassary, Cornell University, Ithaca, NY, United States, Manxi Wu

This tutorial explores the impact of digitalization on today’s transportation systems, focusing on how emerging information technologies and pricing schemes are reshaping the travel behavior in congestible networks. Our focuses include: static and dynamic routing games, the impact of asymmetric information on network efficiency, and the design of incentives for system efficiency and equity. Through a combination of theoretical insights and empirical studies, the tutorial offers an in-depth analysis of models and tools for analyzing strategic user behavior, the role of information and incentive mechanisms in promoting socially desirable outcomes, and the application of these theories in real-world transportation systems.

Platform Design in the Digital Era

Invited Session

Information Systems

Chair: Xiangjing Chen, University of Nebraska-Lincoln, Lincoln, NE, United States

1 - The Tale of Two Channels: Monetizing Free and Members-Only Content on a Video-Sharing Platform

Dongsheng Li, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, Yi-Jen Ian Ho, Xiangjing Chen, Shengjun Mao

Video-sharing platforms, such as YouTube, enable content creators to monetize their videos through both advertising commissions on free channels and subscription fees on paid channels. Despite the prevalence of this monetization model, the strategic interactions among creators, consumers, and a platform remain unclear. To address this gap, we develop a game-theoretical model to study how creators optimally allocate their efforts towards content quality and set subscription fees to compete in a duopoly setting. Our analysis provides clear guidance for content creators and valuable insights for consumers.

2 - Political Impact of Social Media Fake Accounts

Zihong Huang, Texas Tech University - Rawls College of Business, Lubbock, TX, United States

Fake accounts are prevalent on social media platforms to manipulate people's opinions. Many anecdotal evidences suggest that fake accounts can impact the outcome of political campaigns. However, there is a lack of understanding of how political manipulation by fake accounts works. In this study, we incorporate two competing parties, the potential voters, and the social media platform into a game theoretical model to yield the parties' equilibrium competing strategies. In addition, we also examine the impact of the platform's anti-fake strategy on the political outcome and social welfare.

3 - Regurgitative Training: the Value of Authentic Data in Training Generative Ai Models

Jinghui Zhang, Tsinghua University, Beijing, China, People's Republic of, Dandan Qiao, Mochen Yang

What happens if we train a new Generative AI (GenAI) model using data that are at least partially generated by other GenAI models? The explosive success of GenAI models, such as ChatGPT means that a substantial amount of content online will be generated by AI rather than humans, which will inevitably enter the training datasets of next-generation GenAI models. In this paper, we evaluate the implications of such “regurgitative training” on GenAI performance. Through fine-tuning GPT-3.5 with data generated by itself in a machine translation task, we find strong evidence that regurgitative training clearly handicaps the performance of GenAI models. The ease of getting large quantities of AI-generated data does not seem to compensate for performance loss — even training with a fraction of authentic data is enough to outperform regurgitative training. Furthermore, we also explore several different mitigation strategies to reduce the performance losses of regurgitative training. These strategies can improve the performance of regurgitative training to some extent but are not able to fully close the gap. Overall, our work highlights the value of authentic, human-generated data in training GenAI models, which cannot be easily substituted by AI-generated data.

4 - The Fairy&Rsquo;S Magic for Pinocchio&Rsquo;S Nose: Designing Return Policies Against Review Manipulation

Xiangjing Chen, University of Nebraska-Lincoln, Lincoln, NE, United States, Yi-Jen Ian Ho, Shengjun Mao

Review manipulation is pervasive across online platforms, despite the existence of various technologies aimed at detecting fake reviews. Review manipulation remains rampant as platforms may lack economic incentives to mitigate the problem. While previous literature focuses on developing algorithmic solutions, we take a different approach by examining the economic incentives of platforms through their return policies. We craft a game-theoretic model, endogenizing a platform's return policies and sellers' review manipulation efforts and pricing, given heterogeneous consumers in preferences. Our results reveal that the impact of a full-refund policy on review manipulation varies depending on the level of competition among sellers. We further uncover a return-manipulation paradox: a platform is more inclined to choose the policy that encourages review manipulation. To address this paradox, we propose an autonomous scheme that can effectively lower overall manipulation level and increase social welfare.

Co-Chair: Alice Jang, Virginia Tech, Blacksburg, VA, 24061, United States

1 - Managing the Transition from Crowd Volunteerism to Paid Work: Evidence from the Field

Jiho Lee, Boston University, Boston, MA, United States, Gordon Burtch, Chrysanthos Dellarocas

Many digital platforms, particularly at their outset, rely on volunteers' contributions to create products and services of economic value. Often, these organizations subsequently elect to transition toward a system of paid work, for a variety of reasons, e.g., ethical, legal, or logistical considerations, leading to questions of how platforms should navigate the transition. Of particular importance are human capital considerations, given differences in the motivations, perspectives, and behavior of volunteers versus paid workers. To understand the determinants of volunteers' interest and motivation (or lack thereof) to engage as formal employees, we leverage data from a large online platform for language education, which initially relied on volunteers for course and lesson development before transitioning to a closed model of paid work. We first examine the factors that determine volunteers' interest in pursuing paid positions, drawing on prior theories of volunteer motivations. Subsequently, we examine how the same set of factors relates to the performance of volunteers who are eventually hired. We find that a volunteer's work patterns, their possession of a leadership role, and social considerations (i.e., their peers' interest in remaining with the organization) are all important determinants of a volunteer's desire to pursue a paid position. At the same time, we find that these same factors have varied effects on a volunteer's eventual performance in paid work. We corroborate our quantitative results using employer-conducted surveys of the paid workers, and we discuss implications for platform operators.

2 - Group sentiment polarization of social media users during emergent events: insights from China

Bairong Wang, Shanghai Maritime University, Shanghai, China, People's Republic of

This study analyzes the dynamics of social media users' sentiments by conducting 8 case studies of emergent events in China. Over 20 thousand Sina Weibos were analyzed to explore the features of users' comments, sentiment, and information-spreading behaviors, as well as how official media and grassroots media behave in leading the development of group sentiment. The results indicate that small groups present severe polarization of their sentiment and opinions, and within their discussions, limited contradicting opinions are presented. Compared to the official media accounts, grassroots media accounts are more influential on users' sentiments and opinions. However, bot-susceptible users are found to spread polarized sentiment comments, which may accelerate the polarization of group sentiment and opinions. Managerial insights are discussed.

3 - Emotional Contagion and Attenuation in Live Streaming Platform

Alice Jang, Virginia Tech, Blacksburg, VA, United States

Live streaming platforms, like Twitch, offer a space for real-time interaction among users, forming the basis for online communities. Although emotional contagion has been studied in asynchronous social media platforms, its dynamics in synchronous environments such as live streaming platforms remain less understood. These platforms feature synchronous communication and extensive use of non-textual emojis. By analyzing a large dataset of chatroom interactions on Twitch, specifically focusing on emoji usage, this study explores how emotional contagion and attenuation influence user engagement within these live streaming communities.

Data-driven Decision-making: Personalization, Practicality, Perspicuity

Invited Session

Artificial Intelligence

Chair: Linda Zhao, University of Pennsylvania, Philadelphia, PA, United States

1 - Personalized reinforcement learning: with applications to sepsis management in ICU

Junhui Cai, University of Notre Dame, Notre Dame, IN, United States, Ran Chen, Martin Wainwright, Linda Zhao

Reinforcement learning (RL) has achieved remarkable success across various domains; however, its applicability is often hampered by challenges in practicality and interpretability. Many real-world applications, such as in healthcare, have large and/or continuous state and action spaces and demand personalized solutions. In addition, the interpretability of the model is crucial to decision-makers so as to guide their decision-making process while incorporating their domain knowledge. To bridge this gap, we propose a personalized reinforcement learning framework that integrates personalized information into the state-transition and reward-generating mechanisms. We develop an online RL algorithm for our framework. Specifically, our algorithm learns the embeddings of the personalized state-transition distribution in a Reproducing Kernel Hilbert Space (RKHS) by balancing the exploitation-exploration tradeoff. We further provide the regret bound of the algorithm and demonstrate its effectiveness in sepsis management in ICU.

2 - Doubly high-dimensional contextual bandit: An Interpretable Model with Applications to Assortment/Pricing

Ran Chen, Washington University in St. Louis, St. Louis, MO, United States, Junhui Cai, Martin Wainwright, Linda Zhao

Key challenges in running a retail business include how to select products to present to consumers (the assortment problem), and how to price products (the pricing problem) to maximize revenue or profit. Instead of considering these problems in isolation, we propose a joint approach to assortment-pricing based on contextual bandits. Our model is doubly high-dimensional, in that both context vectors and actions are allowed to take values in high-dimensional spaces. In order to circumvent the curse of dimensionality, we propose a simple yet flexible model that captures the interactions between covariates and actions via a (near) low-rank representation matrix. The resulting class of models is reasonably expressive while remaining interpretable through latent factors, and includes various structured linear bandit and pricing models as particular cases. We propose a computationally tractable procedure that combines an exploration/exploitation protocol with an efficient low-rank matrix estimator, and we prove bounds on its regret. Simulation results show that this method has lower regret than state-of-the-art methods applied to various standard bandit and pricing models. Real-world case studies on the assortment-pricing problem, from an industry-leading instant noodles company to an emerging beauty start-up, underscore the gains achievable using our method. In each case, we show at least three-fold gains in revenue or profit by our bandit method, as well as the interpretability of the latent factor models that are learned.

3 - Transfer Learning with Random Coefficient Ridge Regression

Hongzhe Zhang, University of Pennsylvania, Philadelphia, PA, United States, Hongzhe Li

Ridge regression with random coefficients provides an important alternative to fixed coefficients regression in high dimensional setting when the effects are expected to be small but not zeros. This paper considers estimation and prediction of random coefficient ridge regression in the setting of transfer learning, where in addition to observations from the target model, source samples from different but possibly related regression models are available. The informativeness of the source model to the target model can be quantified by the correlation between the regression coefficients. We propose two estimators of regression coefficients of the target model as the weighted sum of the ridge estimates of both target and source models, where the weights can be determined by minimizing the limiting estimation risk or prediction risk. Using random matrix theory, the limiting values of the optimal weights are derived under the setting when p/n goes to gamma, where p is the number of the predictors and n is the sample size, which lead to an explicit expression of the estimation or prediction risks. We will show that the transfer learning prediction based on estimation risk is robust to distributional shift of the predictors. Simulations show that these limiting risks agree very well with the empirical risks. An application to predicting the polygenic risk scores for lipid traits shows such transfer learning methods lead to smaller prediction errors than the single sample ridge regression or Lasso-based transfer learning.

AI Application in Education

Invited Session

Artificial Intelligence

Chair: Zhe Deng, Saint Joseph's University, 5400 City Ave, Media, PA, 19131, United States

1 - Multimodal Video Learning: Managing Cognitive Load Patterns using Guided Attention Graphs

Yi-Yun Chu, Carnegie Mellon University, Pittsburgh, PA, United States, Zhe Deng, Wen Wang, Pedro Ferreira

This study explores the intricacies of cognitive load management within video-based learning environments, which have become pivotal in education through their integration in massive open online courses (MOOCs) and asynchronous learning models. The proliferation of technology-enhanced learning (TEL) environments accommodates diverse learning preferences globally, integrating auditory, visual, and textual elements. This requires efficient cognitive load management, which involves balancing intrinsic load (related to content complexity), extraneous load (influenced by presentation style), and germane load (associated with learner engagement). Challenges in managing cognitive load are magnified by design elements such as visual and audio quality, which may inadvertently elevate cognitive strain. To mitigate information overload, online platforms have adopted adaptive learning systems, summarization tools, and attention-guiding graphs. This study aims to construct a novel methodology for measuring cognitive load in video-based learning environments and to explore how the interplay between cognitive load and attention graphs affects learning outcomes. By enhancing cognitive load management and improving learner interaction with educational content, this research seeks to boost the effectiveness of video-based learning.

2 - AI in Education and Machines as Thought Partners: an AI researcher's perspective

Marcello Balduccini, Saint Joseph's University, Wynnewood, PA, United States

In this presentation, we will look at AI in education from the perspective of an AI researcher involved in developing cutting-edge technologies but who also needs to confront, as a teacher, the reality of the impact of AI in education. We will begin by talking about the various areas of AI and about the relation each of them has with education. Among those, we will necessarily talk about Large Language Models and their potential in education, but also all the issues they raise. We will conclude the talk by discussing how the latest advancements in AI usher a possible era of "machines as thought partners" and how AI breakthroughs that are possibly just below the horizon may affect education in the near future.

3 - Generative AI-Powered Educational Alignment: A Framework for Matching Syllabus Course Topics with Web Description

Ruben Mendoza, Saint Joseph's University, Philadelphia, PA, United States

With the burgeoning interest and advancements in generative artificial intelligence (AI), its application in the educational sector is increasingly gaining attention from researchers. This study explores a multifaceted dimension of higher education, extending beyond mere students' course registration to encompass instructors' course preparation and the broader implications for university branding: the congruence between online course descriptions and the actual course syllabi. However, discrepancies between the course catalog descriptions and the actual course content, as detailed in the syllabus, can lead to reduced learning efficiency, student disillusionment, misaligned academic expectations, and challenges in academic planning and progress. To tackle this issue, our research introduces a novel framework utilizing generative AI to systematically evaluate and rectify mismatches between course web descriptions and syllabus content. The methodology involves employing OpenAI's techniques to extract key topics from course syllabi. Subsequently, we utilize advanced embedding methods, including BERT, GPT-2, RoBERTa, and DistilBERT, coupled with cosine similarity metrics, to assess the congruence between the extracted topics and the course description content. The framework also integrates an outlier detection algorithm to identify courses with significant misalignments. Moreover, this study proposes the use of generative AI applications to refine and enhance course catalog descriptions. This approach not only aids higher education institutions in updating their course offerings with cutting-edge technology but also contributes to curriculum development. It fosters an environment conducive to improved student learning efficiency and more effectively designed courses, thereby enhancing the overall educational experience.

4 - Can Student Faces Tell Learning?

Zhe Deng, Saint Joseph's University, Media, PA, United States

We investigate the feasibility of predicting learning outcomes from the facial expressions of students while they engage with instructional videos or participate in remote sessions. The potential application of real-time facial expression analysis could enhance the personalization of educational sessions. Data for this study comes from several executive education sessions held in Lisbon, Portugal.

AI & Robotics: Impact on Perceptions and Innovation

Contributed Session

Chair: Yixuan Zhang, University of Science and Technology Beijing, Beijing, N/A

1 - Effects of AI-Powered Review Responses on Consumer Perceptions of Service

Yixuan Zhang, University of Science and Technology Beijing, Beijing, China, People's Republic of, Yang Jiang, Xiangbin Yan

Artificial intelligence (AI) has increasingly become a tool for managing user interactions, yet there is limited understanding of its involvement in review responses. In this paper, we investigate the effect of utilizing AI technologies in managerial review responses on consumers' perceptions of service. Conducting experiments on an online platform, we obtain several interesting findings. We find that AI involvement in managing review responses positively affects users' perceived service quality, perceived service effort, and satisfaction. This impact differs when responding to positive reviews and negative reviews. Additionally, we consider the moderating factors of prompt types and the disclosure of AI involvement. Results show that providing AI with more rational cues is beneficial for negative reviews by enhancing the problem-solving ability of responses, whereas emotional prompts are suitable for responding to positive reviews to bolster the empathetic tone. However, the disclosure of AI involvement in review responses tends to reduce its positive impact on user perceptions and attitudes toward service. Our study provides valuable insights for understanding the role of AI in service management and has important managerial implications for firms seeking to deploy AI to improve service delivery and shape the future practice of management.

2 - High-Risk AI System for Business? Investigating the Passive Pathway of Stereotype Threat in AI-Human Interaction

Minki Kim, KAIST College of Business, Seoul, Korea, Republic of, Seonghun Yun, Dain Jung, Dowon Kwak

AI-induced harm to individuals and society calls for the ethical employment of AI and initiatives across the globe. However, scholarly discussions have mostly focused on the harm arising from AI and its algorithmic bias in active pathways. This study centers on biases in AI-human interactions, which stem not from the design of AI, but from users' misconceptions of AI agents with human-like features. For empirical identification, we exploit a unique experimental transition of educational tutoring programs in STEM and non-STEM domains from a human-to-tablet interface to a human-to-AI interface. Our research reveals that female consumers experience gender stereotype threats when interacting with male-characterized AI in the STEM domain, leading to negatively impacting the AI's benefits on their outcomes. Our robust results underscore the importance of risk management for AI systems to prevent accidental harm arising from consumers' self-perceived gender bias. Aligned with the recent emphasis on diversity, equity, and inclusion in the application of AI in the business domain, our findings provide managerial implications regarding potential passive negative effects when implementing AI services.

3 - Reviewing Forecast Results at Scale: An ML/AI-Driven Approach for Smarter Decisions

Sriram Sambasivam, Estee Lauder, Edison, NJ, United States

In the global Consumer Packaged Goods (CPG) industry, accurate demand forecasting is paramount for optimizing production, reducing waste, and meeting customer demands across diverse markets. This work focuses on reviewing forecast results generated by a machine learning/artificial intelligence (ML/AI) system for a typical CPG manufacturer with a worldwide presence, encompassing multiple product categories, channels, and brands.

The ML/AI system generates forecasts that are critical for strategic decision-making. However, these forecasts can sometimes contain anomalies, outliers, runaways, or misalignments in run rates, which can lead to suboptimal decisions if not identified and addressed promptly.

This work presents an innovative approach to reviewing forecast results at scale, leveraging advanced analytics, ML and AI techniques. By analyzing forecast data for anomalies and outliers, identifying potential runaways or misalignments, and applying statistical tests and machine learning models, this approach aims to enhance the accuracy, stability and reliability of forecasts.

To facilitate the implementation of this approach, we introduce an accompanying R/Python package. This package provides a framework for automated forecast review, allowing CPG manufacturers to efficiently and effectively identify and address issues in their forecast results.

Advancements in Statistical Methods and AI

Contributed Session

Chair: Angela Morrison, University of Colorado - Denver, Denver, CO, United States

1 - One-at-a-time Knockoffs: Controlled False Discovery Rate with Higher Power

Charlie Guan, Northwestern University, Evanston, IL, United States, Zhimei Ren, Daniel Apley

Linear regression is a versatile tool ubiquitous in scientific analysis and machine learning. Consider the standard model y=Xβ+z where y is the response, X is the design matrix, β is the vector of unknown coefficients, and z is noise. We study the case where β is sparse, i.e., a small subset of β is nonzero. One application of this problem is genome-wide association studies where researchers seek to discover a small set of genes that affect cancer drug resistance from hundreds of thousands of genes. The objective is variable selection: recover the variables with corresponding nonzero coefficients ("nonnull variables"), while screening out variables with corresponding zero coefficients ("null variables"). This is commonly achieved by regularized regression using the Lasso penalty which returns a sparse estimator of β. In this case, the variables corresponding to nonzero estimated coefficients are returned as the nonnull variables. While asymptotic results show Lasso recovers the full set of nonnull variables, it also returns many null variables in practice, resulting in a high false discovery rate. Other developed algorithms, such as the knockoff filter (Barber and Candes 2015), conduct variable selection while ensuring the false discovery rate never exceeds a user-specified threshold. We propose a new procedure, "one-at-a-time knockoffs" (OATK), which relaxes the constraints of the knockoff filter and results in a more computationally efficient algorithm. Through simulations and real genetics data, we demonstrate OATK's higher power compared to competing methods and discuss OATK's theoretical properties to show that it also controls the false discovery rate.

2 - Optimal Inspection Policy under Imperfect Predictions: Structural Analysis and Insights

Guanlian Xiao, Vrije Universiteit Amsterdam, amsterdam, Netherlands, Alp Akcay, Lisa Maillart

We consider a critical component that deteriorates according to a three-state discrete-time Markov chain with a self-announcing failed state and two unobservable operational states: good and defective. The component is periodically monitored by a defect-prediction model that generates binary signals, but the signals are imperfect. The problem is to decide how to use the signals to make the inspect-or-not decision with the objective of minimizing the expected total discounted cost. We build a partially observable Markov decision process to address the problem.

3 - The General Symmetric Form of Linear Programs

Sion Ledbetter, SimpleRose, Saint Louis, MO, United States, Carl Ledbetter

There are several well known forms used to model linear programs, namely the canonical form, the standard form, and the general form. We present a novel formulation of linear programs, called the general symmetric form, which is a non-trivial extension of the general form. This extension is motivated by the fact that the dual of a general form linear program cannot be described in general form. In particular, the variable type which is dual to the bound variable type has never been characterized. We define and classify the dual of bound variables, called restricted variables, and demonstrate the necessity of objective coefficients for the logical variables defined by the constraints to generalize the dual decision variable bounds in general symmetric form. The symmetry between the primal and dual variable types and bounds in the general symmetric form provides the advantage of being able to construct a linear program from the primal and dual perspective simultaneously, giving modelers access to more tools and information with which to define their programs and resulting in a more accurate model. We establish and prove proper extensions of the canonical versions of Farkas' lemma, the duality equation, the existence-duality theorem, the weak duality theorem, the strong duality theorem, and the complementary slackness theorem for linear programs in general symmetric form.

4 - Peer Prediction for Verifier's Dilemma

Zishuo Zhao, University of Illinois Urbana-Champaign, Urbana, IL, United States

The security of blockchain systems is fundamentally based on the decentralized consensus in which the majority of parties behave honestly, hence the process of block verification is essential to keep the robustness of blockchain systems. However, the phenomenon that a secure blockchain system with few or no cheaters could not provide sufficient incentive for verifiers to honestly perform the costly verification, referred to as the Verifier's Dilemma, could severely undermine the fundamental security of blockchain systems. While existing works have attempted to insert deliberate errors to disincentivize lazy verification, the decentralized environment makes it impossible to directly judge the correctness of verification or detect malicious verifiers. In this work, we adopt the peer prediction method to design a Bayesian truthful mechanism for the verification game among multiple verifiers, incentivizing all verifiers to perform honest verification without access to the ground truth even in the presence of noisy verifications. With theoretically guaranteed truthfulness of our mechanism for the verification game, our work provides a framework of verification mechanisms that enhances the security and robustness of blockchain systems.

5 - Dynamic Time-Expanded Networks for Evacuation Planning

Angela Morrison, University of Colorado-Denver, Denver, CO, United States, Steffen Borgwardt, Nicholas Crawford, Drew Horton, Emily Speakman

We study the problem of evacuation planning for natural and human disasters, such as fire or venue evacuations. By creating pre-planned evacuation routes which can be updated based on real-time data, and by building on and pre-processing public data, we provide a holistic approach to fire evacuation planning and implementation. Evacuations can be formulated as max-flow problems on time-expanded networks. An initial flow is found based on a predicted fire, and then updated based on revised fire information at later time instances.We run test cases on three locations with historic deadly fires using data available through OpenStreetMaps on a NetworkX Python script. The results validate viable running times and quality of information for application in practice.

Chair: Stephen Hill, Samford University, Birmingham, AL, United States

1 - Gaming the NET: Improving NCAA Tournament Outcomes with Scheduling

Stephen Hill, Samford University, Birmingham, AL, United States

Participation and placement in the the NCAA Men's Basketball Tournament is greatly affected by the NCAA's NET Rankings. In this presentation, the proprietary NET Ranking is reverse engineered and the effect of non-conference scheduling approaches on the NET is examined.

2 - Expected Points Above Average: A Novel NBA Player Metric Based on Bayesian Hierarchical Modeling

Ryan Elmore, University of Denver, Denver, CO, United States, Benjamin Williams, Erin Schliep, Bailey Fosdick

Team and player evaluation in professional sport is extremely important given the financial implications of success/failure. It is especially critical to identify and retain elite shooters in the National Basketball Association (NBA), one of the premier basketball leagues worldwide because the ultimate goal of the game is to score more points than one's opponent. To this end we propose two novel basketball metrics: “expected points” for team-based comparisons and “expected points above average (EPAA)” as a player-evaluation tool. Both metrics leverage posterior samples from Bayesian hierarchical modeling framework to cluster teams and players based on their shooting propensities and abilities. We illustrate the concepts for the top 100 shot takers over the last decade and offer our metric as an additional metric for evaluating players.

3 - College Football Survivor Pool

Eric Huggins, Katz School of Business, Fort Lewis College, Durango, CO, United States

NFL survivor pools are a game well-known to most fans of American football. Players must pick a different team to win each week for the entire season until they lose a game and are out; the last remaining “survivor” wins the pool. We discuss a related game, but using the college football Top 25 rather than the 32 NFL teams. This creates several twists: The Top 25 changes every week based on the previous week’s results – teams move in and out of the Top 25 and their rankings change from week to week. The pool also has multiple objectives which makes strategic decisions even more interesting.

I created this game about two decades ago and have been playing it ever since with friends, mostly for pride. Over time, it has evolved into a game with interesting and challenging decision-making that touches on many areas of analytics. With this in mind, I have started hosting the game in my Business Analytics class every Fall term – for fun and prizes, not for grades – although the students must discuss their decision-making processes and make calculations for class points.

In this talk, I will discuss the rules of the game, possible “optimal” strategies and if the timing works out, I will let the audience make my real picks for the following week! Further I will discuss how I use the game in class to reinforce understanding of various analytics topics.

4 - Go for It? Analyzing the Impact of Fourth Down Decisions in the NFL

Thomas Robbins, East Carolina University, Greenville, NC, United States

The decision to go for it on fourth down remains one of the most pivotal—and hotly debated—decisions an NFL coach can make. From Dan Campbell's perceived "reckless" choices to the Eagles' seemingly "unstoppable" tush push, these decisions have played a significant role in shaping the 2023-24 NFL season. This talk delves into the analytics behind fourth down decisions, presenting a standard framework for making the decision and an empirical analysis of game decisions and results. We will explore the alignment between coaches' decisions and analytical models, investigating the tangible effects of these decisions on game outcomes.

5 - Changing the Game: Analytics in Shaping Modern Sports On and Off the Field

Scott Nestler, Analytic Solutions, Granger, IN, United States

This presentation provides an overview of the transformative role of analytics in modern sports. It explores how data-driven approaches are revolutionizing performance on the field, enabling athletes and teams to optimize their strategies, enhance physical conditioning, and achieve superior results. Beyond the field, we examines the impact of analytics on the business side of sports, from talent scouting and player valuation to fan engagement and revenue generation. By integrating real-world examples and cutting-edge research, the presentation highlights the symbiotic relationship between analytics and sports, illustrating how data is not just reshaping strategies but also redefining the very essence of excellence in the sports industry.

Electricity Storage

Invited Session

ENRE: Electricity

Chair: Dirk Lauinger, MIT, Cambridge

1 - Pricing Energy Storage for Social-Welfare Maximization

Ning Qi, Columbia University, New York, NY, United States, Ningkun Zheng, Bolun Xu

Existing market designs require energy storage to design bids strategically for profit maximization based on the future opportunity value. This benefits large and sophisticated storage participants who are experienced in price prediction and exercising market power. While, system operator and small storage participants unwilling to spend additional cost or intelligence to exercise market power will lose profit. Hence, this paper derives a novel theoretical framework to propose the opportunity pricing of energy storage for social welfare maximization. The opportunity price is formulated based on a two-stage chance-constrained framework, which guarantees the market equilibrium and social welfare maximization while incorporating uncertainties from renewables and load. We present tractable and deterministic reformulation for joint chance-constraints and different types of uncertainty realizations. Analytical results show that opportunity price decreases as the state of charge increases but rises with greater net load uncertainty. The key finding highlights the interconnected linear relationship between the opportunity price, electricity price, and reserve cost, demonstrating how energy storage can exercise market power in the energy and reserve market. We demonstrate the effecitveness of the proposed stochastic market design via the case study carried out on an 8-zone ISO-NE test system. Simulation results show that the proposed market design significantly reduces system costs and electricity payments, enhances decarbonization, and improves adaptability to uncertainty.

2 - Modeling Impacts of Multistage Operational Uncertainty on Long Duration Energy Storage

Thomas Lee, Massachusetts Institute of Technology, CAMBRIDGE, MA, United States, Andy Sun

Long duration energy storage may play a crucial role in highly decarbonized energy systems, in order to alleviate renewable energy shortages on multi-day and even seasonal timescales. However, out of system planning models to date which incorporate long duration storage, most assume perfect foresight during the operations of storage resources due to computational tractability. This conflicts with the limited skill of meteorological forecasts over climatology beyond the 1 to 2 week horizon, due to data/model limitations and inherent chaos in the weather system. The realism of this perfect foresight assumption is reexamined by considering a stochastic scenario tree based on historical weather data. Stochastic dual dynamic programming is used to study the behavior of long duration storage dispatch within an energy systems model under multistage operational uncertainty. Implications are studied for system planning, investment, and operations of energy storage portfolios with long
duration technologies.

3 - Arbitrage and Regulation with Electricity Storage

Dirk Lauinger, MIT, Cambridge, MA, United States, Andy Sun

Electricity storage is used for intertemporal price arbitrage and for balancing unforeseen fluctuations in electricity supply and demand, also known as regulation. We present an optimization model that computes bids for both arbitrage and regulation, and ensures that storage operators can honor their market commitments at all times for all fluctuation signals in an uncertainty set that is inspired by applicable legislation. We encode this requirement with an infinite number of functional constraints. We show that the robust constraints with functional uncertainties are equivalent to a finite number of deterministic constraints, which leads to an exact bilinear reformulation that can be solved with commercially available optimization software.

4 - Market Equilibria with Energy Storage as Flexibility Resources

Weiying Gu, The ohio state university, Columbus, OH, United States, Ramteen Sioshansi

Uncertain and variable real-time availability of renewable generation can increase the need for supply-side flexibility in power systems. Energy storage is a potential source of such flexibility. This paper examines the participation of multiple competing strategic profit-maximizing energy storage in a spot electricity market and its impact on consumers, producers, and market equilibria. To this end, we develop a two-stage stochastic bi-level model that has each energy-storage firm determine its market offers at the upper level to maximize its expected profit. The lower level represents market clearing under scenarios with different flexibility needs. We recast the bi-level model as a single-level optimization. A small illustrative example and a larger case study show that energy storage can increase market efficiency and reduce renewable-energy curtailment. We show that energy-storage firms neglecting uncertainty in optimizing their market offers can yield profit losses.

Artificial Intelligence and Big Data Applications in Global Operations and Management

Invited Session

Data Mining

Chair: Pankaj Kumar, Virginia Tech, Blacksburg, VA, United States

Co-Chair: Xiaojin Liu, Virginia Commonwealth University, Richmond, VA, United States

1 - Safe Adoption and Supervision of Generative AI Systems

Shubhranshu Singh, Johns Hopkins University, Baltimore, MD, United States

Generative AI systems often suffer from AI hallucinations in that they may provide confident responses unjustified by their training data. Given the increasing reliance on generative AI systems, it is hard to overstate the damage that AI hallucinations may engender. In this paper, we explore the question of whether AI developers or human decision makers should be liable for the harm the AI systems may cause. We develop a novel theoretical framework to study and compare implications of liability for developers of AI systems versus liability for human decision makers. We find that in some cases AI developer liability can interestingly result in over-supervision and under-adoption by the human decision makers. Although AI operator liability leads to efficient accuracy investment when AI accuracy is publicly observed, developer liability achieves efficient accuracy investment when it is privately observed by the developer.

2 - Navigating the Communication Divide: Using Large Language Models for Enhanced Patient-Provider Interaction in Opioid Disorder Treatment

Murtaza Nasir, Barton School of Business, Wichita State University, Wichita, KS, United States, Anton Ivanov, Jasmina Tacheva

<p break-words="">The opioid epidemic presents significant challenges to public health, and communication issues often arise when patients with opioid use disorder (OUD) interact with healthcare providers. The use of stigmatized language by clinicians can hinder effective dialogue and treatment plans. Adaptive AI-based systems utilizing large language models (LLMs) could potentially provide real-time communication support to practitioners, but the quality of the generated feedback is crucial, especially when dealing with sensitive populations like OUD patients.

<p break-words="">This study investigates whether LLMs can improve patient-provider communication by reducing stigmatized language and enhancing health outcomes. Adapting the Communication Accommodation Theory (CAT), the researchers collected a dataset of conversations and health outcomes for 192 OUD patients from an online health community on Reddit. They benchmarked several LLMs and compared their performance in reducing stigmatized language, using survival analysis to examine the effects of machine- vs. human-generated content on patient survival in terms of sobriety and relapse.

<p break-words="">The results suggest that machine-generated content lacking stigmatized language is associated with a 17% increase in the probability of a patient reaching a subsequent clean stage and a 9% reduction in the probability of relapse. The study highlights the potential of LLMs to enhance communication in healthcare settings and support patients across various domains.

3 - Text-data Mining of Ridesharing Firms: An Integrated NLP-MCDM Approach

Arnab Bisi, Johns Hopkins Carey Business School, Baltimore, MD, United States, Souradeep Koley, Mukesh Barua

The past decade witnessed an upsurge in the operation of the Transportation Network Companies (TNCs) like Uber and Lyft on a global level. Leveraging online platforms and mobile technology, these organizations have a substantial influence on travelers, transportation systems, and international communities. While existing literature centered on passenger adoption and drivers' motivation, our study addresses identifying the challenges faced by these ridesharing firms. We use large-scale publicly available data from social media to gain an initial understanding of consumer issues related to organizations. We use a machine learning approach to identify the latent themes, followed by emotion analysis to understand the sentiments. The findings highlight issues related to *'legal activity and regulatory compliance'* and *'service availability'* among consumers from the ridesharing firms. Although most riders have positive sentiments (34.13%), there is a relative increase in anger and fear among the consumers. Following these, empirically, using decision-making, we identify and quantitatively address five major inhibitors faced by these organizations. Contrary to conventional perception, our study highlights the *'government'* as a major inhibitor due to stringent government regulations and the discrepancy between central and state. Additionally, the negative word-of-mouth and network effects have created significant issues for ridesharing firms over the years. The findings from the integrated methods provide multiple insights for the policymakers and managers in TNCs to increase the overall efficiency of the firms.

Advances in Data-Driven Decision-Making in Operations Management

Invited Session

Data Mining

Chair: Yonggab Kim, Purdue University, West Lafayette, IN, United States

1 - Developing Protocols for Autonomous Mobile Robots in Material Handling Using an Inductive Learning Approach

Byeongmok Kim, Purdue University, West Lafayette, IN, United States

In a manufacturing environment, autonomous mobile robots (AMRs) operate autonomously and with greater operational flexibility than automated guided vehicles (AGVs), which are controlled by a central system. On the other hand, the inability to find an operationally optimal solution from a global perspective partially offsets the operational efficiency of AMRs. In our study, we propose a new learning framework to achieve both operational efficiency and flexibility of operations of AMRs by learning the operating policies of AMRs based on the optimal solution of a centralized system.

2 - Enhancing Genetic Algorithm with Explainable AI for Last-Mile Routing

Yonggab Kim, Purdue University, West Lafayette, IN, United States, Reem Khir, Seokcheon Lee

Traditional evolutionary optimization algorithms often presuppose straightforward constraints and objective functions. However, in many real-world optimization problems, a clear-cut objective function may be absent or hard to evaluate. Given these challenges, surrogate models have gained attention as proxies for evaluating objectives or constraints. Surrogate models, when integrated into Evolutionary Algorithms (EAs), result in Surrogate-Assisted EAs (SAEAs). In this research, we leverage machine learning and Explainable Artificial Intelligence (XAI) to enhance the performance of Genetic Algorithms (GAs) for combinatorial optimization. Our framework utilizes a surrogate model to capture the nuanced interplay within environmental data. We interpret these models using SHapley Additive exPlanations (SHAP) values, identifying key features for prioritization. This understanding enables us to enhance the design of the genetic algorithm, covering the development of its structure and operators, as well as the calibration of fitness functions. Such tailored adjustments enhance the GA's efficiency and effectiveness. We demonstrate our framework on a sequencing problem that arise in last-mile routing using data from the Amazon 2021 Last Mile Challenge. Our methodology extracts drivers' preferred routing characteristics and applies these insights to generate new routes. Our method achieved a 0.0411 score, ranking fourth and demonstrating improvements in the convergence and effectiveness of GAs.

3 - Generative AI-Driven Socio-Economic Agent-based Simulation

Seung ho woo, Purdue University, West Lafayette, IN, United States, Seonho Woo, Young-Jun Son

Contemporary society faces a range of disruptions of natural or human-made crises, such as pandemics, hurricanes, and cyber-attacks that destabilize social and economic system dynamics. To enhance the resilience of our society under various disruptions, predicting socio-economic outcomes utilizing a high-fidelity agent-based socio-economic simulation is essential. However, constructing reliable agent-based simulations is costly, time-consuming, and complex. This novel research pioneers high-fidelity socio-economic prediction by integrating generative AI with agent-based simulation. This study employs Generative Artificial Intelligence (AI) to construct realistic environments and develop human-like agents for high accuracy economic simulations. The aim is to predict societal outcomes accurately under various disruptions, providing a practical tool for policymakers and economists. Generative models are applied to create a small city with diverse infrastructures that resemble real-world settings. Additionally, reinforcement learning-induced generative models are used to create human-like agents with realistic purchasing behaviors, reflecting the complex social phenomena of the real world. Our generative agent-based simulation framework aims to generate multi-agent societal system simulations with continuously learning agents in a generated environment. This study simulates small town-level multi-agent diverse scenarios to observe market dynamics, including market trends with supply and stock level assessment under disruption, by applying the potential of a generative AI model.

4 - Integrated Dynamic Rebalancing and Charging for Electric Scooter Sharing System

Zhuoli Yin, Purdue University, West Lafayette, IN, United States, Reem Khir, Hua Cai

Electric-Scooter Sharing System (ESS) is a popular dock-less micro-mobility option for first and last mile trips in cities. ESSs can reduce traffic congestion and lower greenhouse gas emissions by replacing private cars and enhancing public transit usage. Because of spatiotemporally imbalanced customer demands and limited battery ranges, ESSs face operational challenges in sustaining their functionality throughout the day. Customers unable to find available, sufficiently charged e-scooters are likely to leave the system, resulting in unsatisfactory service experiences. To address this issue, providers must regularly rebalance e-scooters across zones and return them to depots for charging. However, prior studies on rebalancing and charging of ESS are limited. Research has primarily focused on isolated strategies for either rebalancing or charging, or on overnight operations that do not account for dynamic daytime customer demands. In this study, we proposed an integrated dynamic rebalancing and charging model based on mixed integer programming. This model considers both the real-time battery levels of e-scooters and their distribution across service zones and depots. To efficiently address real-world, large-scale instances, we applied Lagrangian Dual Decomposition and Local Search methods to approximate solutions, breaking the problem into three subproblems: rebalancing vehicle routing, e-scooter allocation, and charging restoration. Our numerical experiments demonstrate that our model generates high-quality solutions for large-scale instances. Our model offers an approach for dynamically maintaining the service of shared mobility systems with electrified fleets.

Recent Advances in Multi-Agent and Preference-Based Reinforcement Learning

Invited Session

Data Mining

Chair: Junzi Zhang, Citadel Securities, New York, NY, 60654, United States

1 - MF-OML: Online Mean-Field Reinforcement Learning with Occupation Measures for Large Population Games

Anran Hu, Oxford University, Oxford, United Kingdom

Reinforcement learning for multi-agent games has attracted lots of attention recently. However, given the challenge of solving Nash equilibria for large population games, existing works with guaranteed polynomial complexities either focus on variants of zero-sum and potential games, or aim at solving (coarse) correlated equilibria, or require access to simulators, or rely on certain assumptions that are hard to verify. This work proposes \texttt{MF-OML} (Mean-Field Occupation-Measure Learning), an online mean-field reinforcement learning algorithm for computing approximate Nash equilibria of large population sequential symmetric games. \texttt{MF-OML} is the first fully polynomial multi-agent reinforcement learning algorithm for provably solving Nash equilibria (up to mean-field approximation gaps that vanish as the number of players N goes to infinity) beyond variants of zero-sum and potential games. When evaluated by the cumulative deviation from Nash equilibria, the algorithm is shown to achieve a high probability regret bound of $\tilde{O}(M^{3/4}+N^{-1/2}M)$ for games with the strong Lasry-Lions monotonicity condition, and a regret bound of $\tilde{O}(M^{11/12}+N^{-1/6}M)$ for games with only the Lasry-Lions monotonicity condition, where M is the total number of episodes and N is the number of agents of the game. As a by-product, we also obtain the first tractable globally convergent computational algorithm for computing approximate Nash equilibria of monotone mean-field games.

2 - Beyond Equilibrium Learning

Chi Jin, Princeton University, Princeton, NJ, United States

While classical game theory primarily focuses on finding equilibria, modern machine learning applications introduce a series of new challenges where standard equilibrium notions are no longer sufficient, and the development of new efficient algorithmic solutions is urgently needed. In this talk, we will demonstrate two such scenarios: (1) a natural goal in multiagent learning is to learn rationalizable behavior, which avoids iteratively dominated actions. Unfortunately, such rationalizability is not guaranteed by standard equilibria, especially when approximation errors are present. Our work presents the first line of efficient algorithms for learning rationalizable equilibria with sample complexities that are polynomial in all problem parameters, including the number of players; (2) In multiplayer symmetric constant-sum games like Mahjong or Poker, a natural baseline is to achieve an equal share of the total reward. We demonstrate that the self-play meta-algorithms used by existing state-of-the-art systems can fail to achieve this simple baseline in general symmetric games. We will then discuss the new principled solution concept required to achieve this goal.

3 - Actions Speak What You Want: Provably Sample-Efficient Reinforcement Learning of the Quantal Stackelberg Equilibrium from Strategic Feedbacks

Siyu Chen, Yale University, New Haven, CT, United States, Mengdi Wang, Zhuoran Yang

We study reinforcement learning (RL) for learning a Quantal Stackelberg Equilibrium (QSE) in an episodic Markov game with a leader-follower structure. In specific, at the outset of the game, the leader announces her policy to the follower and commits to it. The follower observes the leader's policy and, in turn, adopts a quantal response policy by solving an entropy-regularized policy optimization problem induced by leader's policy. The goal of the leader is to find her optimal policy, which yields the optimal expected total return, by interacting with the follower and learning from data. A key challenge of this problem is that the leader cannot observe the follower's reward, and needs to infer the follower's quantal response model from his actions against leader's policies. We propose sample-efficient algorithms for both the online and offline settings, in the context of function approximation. Our algorithms are based on (i) learning the quantal response model via maximum likelihood estimation and (ii) model-free or model-based RL for solving the leader's decision making problem, and we show that they achieve sublinear regret upper bounds. Moreover, we quantify the uncertainty of these estimators and leverage the uncertainty to implement optimistic and pessimistic algorithms for online and offline settings. Besides, when specialized to the linear and myopic setting, our algorithms are also computationally efficient. Our theoretical analysis features a novel performance-difference lemma which incorporates the error of quantal response model, which might be of independent interest.

Co-Chair: Aleksander Grochowicz, University of Oslo, Oslo, Norway

1 - Funplex: A Modified Simplex Algorithm to Efficiently Explore Near-Optimal Spaces

Linda Brodnicke, ETH Zurich, Zurich, Switzerland, Christoph Funke, Francesco Lombardi, Giovanni Sansavini

Modeling to generate alternatives (MGA) is an increasingly popular method in energy system optimization. MGA explores the near-optimal space, namely, system alternatives whose costs are within a certain fraction of the globally optimal cost. Real-world stakeholders may prefer these alternatives due to intangible factors. Nonetheless, widespread MGA adoption is hampered by its additional computational burden. Current MGA methods identify boundary points of the near-optimal space through repeated, independent optimization problems. Hundreds of model runs are usually required, and such individual runs are often inefficient because they repeat calculations or retrace previous trajectories. In this study, we transcend such limitations by introducing a novel algorithm called Funplex, which uses methods from multi-objective Simplex to optimize many MGA objectives with minimal computational redundancy. For a simple linear-programming energy hub case study, we show that Funplex is ten times faster than existing methods and yields higher-quality near-optimal spaces. Furthermore, sensitivity analyses suggest that Funplex scales well with the number of investment variables, making it promising for capacity planning models. The current proof-of-concept implementation based on a full multi-objective tableau may face memory and stability limitations for large models. Nonetheless, future developments based on more advanced versions of Simplex may overcome such barriers, thereby making MGA more accessible and standard among modeling teams.

2 - A Computationally Efficient Modelling to Generate Alternatives Algorithm using Benders Decomposition

Michael Lau, Princeton University, Princeton, NJ, United States, Filippo Pecci, Anna Jacobson, Jesse Jenkins

Contemporary macro-energy systems modelling is characterized by the need to represent energy systems strategic and operational decisions with high temporal and spatial resolution, which provides more accurate results than more abstracted models. This drive towards greater fidelity, however, conflicts with a push towards greater model representation of inherent complexity in decision-making, including methods like Modelling to Generate Alternatives. Modelling to Generate Alternatives aims to map the feasible space of a model within a cost slack by varying investment parameters without changing the operational constraints, a process which frequently requires hundreds of solutions. For large, highly representative energy system models, solving for large numbers of highly detailed solutions is impossible with traditional methods, leading researchers to reduce complexity with through zonal or temporal aggregation. This research presents a new solution method for Modelling to Generate Alternatives-type problems. Using Benders Decomposition, we break down the problem structure into a strategic master problem and operational subproblems and pass information between master problems to accelerate convergence with each new objective. We find that our new solution method is several times faster and requires less memory than existing parallelized monolithic Modelling to Generate Alternatives solution methods, enabling rapid computation of a greater number of solutions to highly resolved models.

3 - Charging Fleets of Electric Vehicles at Airport Rental Car Centers

Devon Sigler, National Renewable Energy Laboratory, Crested Butte, CO, United States

At major airports hundreds of vehicles are returned to the rental car center every hour. These vehicles must be cleaned and refueled to be rented out again. As rental car fleets transition to electric vehicles (EV), naïve first come first serve charging strategies have the potential to create peak power loads in the tens of megawatts range, which existing airport infrastructure may not be equipped to handle. However, through strategic scheduling of charging start times and charging power levels these peak loads can be mitigated to not over stress existing infrastructure. In this talk we present work on a column generation algorithm for solving this EV scheduling problem at realistic scales fast enough to be practically useful.

4 - Diverse developments of European green hydrogen production

Koen van Greevenbroek, UiT The Arctic University of Norway, Tromsø, Norway, Johannes Schmidt, Marianne Zeyringer, Alexander Horsch

Green hydrogen is seen by the EU as a key technology in the energy transition towards carbon net neutrality; the Commission has committed to domestic production and imports of 10Mt (~330TWh) each by 2030. The prospects for green hydrogen production in the following decades, however, is the subject of much debate. While domestic green hydrogen could improve energy security and enable the switch away from fossil fuels, it is dependent on ample renewable energy sources and may face competition from oil and natural gas combined with carbon capture and storage, as well as imports from outside of Europe.

We introduce a novel way of exploring different development pathways for a single resource such as green hydrogen. Our work builds on ideas from the Modelling to Generate Alternatives (MGA) framework, which can be used to find near-optimal system designs. By applying MGA-type steps at each point in a sequence of optimisations modelling the evolution of the European energy system from 2025 to 2050, we reveal a wide variety of feasible scenarios for the growth of green hydrogen production. While a moderate domestic production level is often cost-optimal, we find that anything from large production volumes to no production at all can be accommodated for under most assumptions with only a minor total system cost increase. Near-optimal methods thus indicate that there is ample space for social and political considerations in cost-effective green hydrogen policy.

5 - Exploring Robust pathways for Incentivizing DAC deployment across power systems under uncertainty

Franklyn Kanyako, University of Michigan, Ann Arbor, MI, United States, Michael Craig

Direct Air Capture (DAC) technology has the potential to play a crucial role in achieving negative emissions, but its widespread deployment depends on effective public policy support. Designing policies that accelerate DAC adoption while hedging against premature investment and long-term delays is challenging due to inherent uncertainties in technology costs, mitigation policies, timelines, and the availability of alternative low-carbon energy sources. The combination of multiple policy instruments and technical pathways further complicates decision-making for policymakers, as the effects of specific policies on future DAC deployment are highly uncertain. Limited research exists on policy intervention and investment needs to accelerate DAC deployment robust to near-term and long-term uncertainties. This examines the role of R&D subsidies and climate policy in accelerating the near-term and long-term deployment of DAC across the United States electric power system. By developing a comprehensive framework that incorporates multiple uncertainties and policy instruments, this research aims to provide policymakers with insights into designing effective and robust policies for accelerating DAC deployment while managing the risks associated with premature investment and long-term delays.

Analysis Toward Net-Zero Transportation

Invited Session

ENRE: Environment and Sustainability

Chair: Wenquan Dong, Texas State University, San Marcos, TX, 78666, United States

1 - On the mathematical modeling of the multi-depot green vehicle routing problem with multiple one-to-many pickup and delivery operations and time windows

Alejandro Fernandez Gil, Texas State University, San Marcos, TX, United States, Eduardo Lalla-Ruiz, Martijn Mes, Wenquan Dong

This work focuses on freight distribution and introduces the multi-depot green vehicle routing problem with pickup and delivery operations and time windows (MDGVRP-PD-TW), aiming to minimize emissions through reduced fuel consumption. A mathematical formulation is proposed that respects the time windows established for each customer and considering multiple one-to-many pickups and deliveries, where each pickup customer is associated with a set of delivery customers. By including the sumproduct between flow and distance traveled over the arcs, routing decisions incorporate the environmental impact of CO2 emissions, allowing for a balance between emissions and weight transported along the routes. To solve this problem, we propose a matheuristic approach based on the POPMUSIC framework (Partial Optimization Metaheuristics under Special Intensification Conditions). The proposed solution approaches are tested on a new benchmark suite designed to evaluate this variant.

2 - Developing Sustainable Transportation with Enhanced System Efficiency and ITS Technologies

Fengxiang Qiao, Texas Southern University, Houston, TX, United States, Jianbang Du, Qing Li

The United States Bipartisan Infrastructure Law supports the development of sustainable transportation with low- to zero-emission, energy-efficient, and affordable transportation modes. The benefits include (1) savings on fuel and vehicle costs, (2) less carbon and toxic emissions and less air pollution, (3) increased economic productivity (e.g., more job opportunities in new energy and vehicle productions), (4) more reliable and affordable transportation with improved travel equality and environmental justice, and (5) enhanced security and independence. Sustainable transportation involves efforts such as developing new energy and fuel, managing travel demand and mode shift, and integrating equity, justice, and community engagement. In this presentation, the presenters wish to share several examples of sustainable transportation strategies with enhanced transportation efficiency and the technologies related to Intelligent Transportation Systems (ITS). Typical exemplary strategies include (1) improving congestion-pricing strategies for reduced emissions (e.g., ozone) along freeway corridors with High-Occupancy Vehicle (HOV) / High-Occupancy Toll (HOT) lanes, (2) improving freeway ramp metering strategies for reduced environmental impacts, (3) developing reinforced learning-based eco-transportation strategies at intersections and transportation networks with minimized ecological impacts, (4) improved car-following strategies along an arterial street with multiple coordinated signalized intersections, (5) characterizing roadway pavement roughness impacts on vehicle emissions with minimized air pollution, and (6) improving roadway design (e.g., the length and type of freeway weaving area) with less impacts on vehicle emissions and drivers' health. It is recommended that advanced technologies such as artificial intelligence, machine learning, and deep learning be employed more systematically for more environmentally friendly transportation systems.

3 - Locating and Allocating Battery Electric Bus Chargers with Stochastic Charging Demand

Sadjad Bazarnovi, University of Illinois at Chicago, Chicago, IL, United States, Taner Cokyasar, Omer Verbas, Abolfazl (Kouros) Mohammadian

Bus electrification accelerates the transition towards sustainable urban transportation. Battery Electric Buses (BEBs) often require periodic recharging intervals between service trips. The strategic placement and allocation of charging stations are crucial in facilitating operations, optimizing costs, and minimizing downtime. In this study, we develop a model, the Stochastic ELECTRic vehicle charger Allocation (SELECTRA) framework, to address the optimal distribution of various plug types at candidate locations under the stochastic charging demand of BEBs. Our strategic planning framework aims to minimize long-term system costs while balancing considerations among station, charger, and value of time expenses. We develop a mixed-integer non-linear program (MINLP) to solve this model. Leveraging existing stochastic location literature, we use an exact solution method to address this computationally challenging problem. The program optimizes the generalized cost associated with building charging stations, allocating charger types, travel to charging stations, and average queueing and charging times. Queueing dynamics are modeled using an M/M/s queue, with the number of servers as a decision variable. The linearization process, which excludes queueing variables, is succeeded by introducing associated constraints through cutting planes. This step guarantees global optimality due to the convexity properties of the problem. To enhance scalability, we implement a simulated annealing metaheuristic and devise heuristic clustering strategies, facilitating the effective resolution of real-world, large-scale instances. We conduct comparative analyses across garage-only, other-only, and mixed-location scenarios, along with sensitivity analyses on key parameters.

Energy System Modeling and Optimization V: ML-based Multi-Energy System Optimization

Invited Session

ENRE: Other Energy

Chair: Qifeng Li, University of Central Florida, Orlando, FL, United States

1 - An ML-accelerated solution method for real-time optimization of energy-water-hydrogen nexus

Qifeng Li, University of Central Florida, Orlando, FL, United States

The micro Energy-Water-Hydrogen (m-EWH) nexus, which utilizes renewable energy sources (RES) to produce hydrogen by electrolysis, which is then combined with carbon captured from fossil fuel power plants, is investigated for reducing carbon emissions from the power sector. To address RES uncertainty, this paper proposes a real-time decision-making scheme for the m-EWH nexus that requires quickly solving large-scale mixed-integer convex programming (MICP) problems. For this purpose, a machine learning-accelerated solution method for real-time optimization (MARO) consisting of three modules is developed. First, an active constraint and integer variable prediction approach is introduced to rapidly solve MICP problems using historical optimization data. Second, a feasible rank-optimal strategy selection module is proposed to ensure the feasibility of the obtained solutions. Last but not least, a feature space extension module is developed to improve the accuracy of obtained solutions by creating new features and refining existing ones.

2 - Enhancing Resilience of Grid-Interactive Efficient Buildings Against Heat Waves Using Reinforcement Learning

Chenxi Hu, The University of Hong Kong, Hong kong, China, People's Republic of, Yujia Li, Yixuan Chen, Yunhe Hou

Heat waves, characterized by abnormally high temperatures, can significantly increase electricity demand within Grid-Interactive Efficient Building (GEB) clusters, challenging grid power capacity and potentially leading to failures in cooling and power supply. This study explores the resilience of GEBs during extreme heat waves using reinforcement learning. To achieve resilient operation under heat wave conditions, this study aims to find the optimal control policy for multiple flexible resources within GEB clusters. We employ the Proximal Policy Optimization (PPO) algorithm to develop an adaptive control strategy that dynamically responds to changing conditions and optimizes the use of available resources. The performance of the PPO-based method is compared against rule-based controls to assess improvements in operational resilience. Preliminary results demonstrate that the PPO-based RL approach enhances the resilience of GEBs by effectively managing electricity usage and maintaining thermal comfort, even when grid power is restricted. This study underscores the potential of RL in developing robust, adaptive control policies for GEB clusters, offering a promising method for mitigating the impacts of extreme heat waves on urban energy systems.

3 - ML-based optimization for accelerating complex grid reliability assessment under extreme weather events

Qiuhua Huang, Colorado School of Mines, Golden, CO, United States, Xiaolin Chen

In the face of increasing extreme weather events, the resilience and reliability of electrical grids are paramount. This talk explores the application of machine learning (ML) techniques to optimize and accelerate the optimization module within the grid reliability assessment process under such conditions. Traditional methods for evaluating grid reliability can be computationally intensive and slow, especially when simulating complex scenarios influenced by severe weather due to large number of scenarios involved. By leveraging advanced ML algorithms, we can significantly enhance the speed of these assessments with good accuracy. This presentation will cover the development and integration of ML models for short-term power system reliability assessment, the challenges encountered, and the solutions implemented.

4 - Physics-Informed Machine Learning to Enhance Electric Distribution System Situational Awareness

Ying Zhang, Okalahoma State university, Stillwater, OK, United States

Modern distribution systems are confronted with degraded and even stranded operational performances subject to growing complexity, uncertainty, and volatility from large-scale integration of renewable and distributed energy resources (DERs). This talk brings new perspectives to learning-to-optimize (L2O) distribution system operation by focusing on fast yet accurate nonlinear power flow calculation with DERs–combining power engineering knowledge with data-aided machine learning techniques, i.e., physics-informed machine learning – to replace a blind application of "black-box" data-intensive ones, and the latter has limited practicality in real-world grids. The proposed physics-informed L2O method achieves significant performance synergy in terms of accuracy, calculation time, topology adaptivity, and robustness against data errors, outliers, or cyberattacked measurements. As power flow calculation is of fundamental importance for grid monitoring, control, and management, the proposed framework has the potential as a building block to accelerate and advance various optimization tasks to improve the situational awareness towards the next-generation distribution grids.

Advances in Decomposition Algorithms

Invited Session

Computing Society

Chair: Geunyeong Byeon, Arizona State University, Tempe, AZ, United States

1 - Benders Lift-and-Project Cuts

Kaiwen Fang, Arizona State University, Phoenix, AZ, United States, Geunyeong Byeon

In this paper, we explore the utilization of disjunctive system to enhance the strength of cuts within a Benders decomposition algorithm. At a broad level, the proposed algorithm leverages integrality information and Benders cuts to generate cuts tightly aligned with the convex hull of the Benders reformulation. Importantly, this is achieved via iteration of standard Benders subproblem. Specifically, our study highlights that normalization plays a crucial role in eliminating the generation of overly weak cuts. Meanwhile, we found that utilizing the cut-and-project technique can make the generated disjunctive benders cuts more effective. We conduct a comparative analysis to assess the impact of Benders disjunctive cuts under various normalization settings in facility location problems.

2 - Characterizing and Learning the Lagrangian Multipliers for the Bin Packing Problem

Yoonju Sim, Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of, Hyeonah Kim, Changhyun Kwon, Sungbin Lim

We consider the Lagrangian relaxation method for finding a dual bound for the Bin Packing Problem. A tight dual bound plays a critical role in closing the gap for any exact algorithm. Furthermore, in the context of vehicle routing problems, all capacity inequalities require fast computation of a good dual bound. In this paper, we study the characteristics of optimal Lagrangian dual solutions such as the relationship between the primal and dual solutions, dual polyhedron, and so on. By using them, we aim to speed up the subgradient optimization method used in the Lagrangian relaxation method.

3 - The Chance-Constrained Stochastic Diversion Path Problem with Sample Average Approximation

Woojin Kim, University of Wisconsin-Madison, Madison, WI, United States, Jim Luedtke, Cole Smith

The diversion path problem is a network interdiction problem in which the leader modifies arc lengths, and the follower finds the shortest path from the source node to the sink node using the modified arc lengths. The leader's goal is to minimize the cost of having the follower choose a special path called the diversion path. When arc lengths are deterministic, this problem is solvable by linear programming. We study the situation where arc lengths are random, and the leader wishes to minimize the cost to ensure the follower follows the diversion path with the probability of at least a desired target. This chance-constrained stochastic diversion path problem has been studied by Baycik, Nguyen, and Smith in the special case when arc lengths are independent and normally distributed. We explore the use of sample average approximation (SAA) to approximately solve this problem with a general distribution. We first derive a compact mixed integer programming formulation of the SAA problem but find that it is challenging to solve due to poor linear programming relaxation quality. We thus explore a method based on a branch-and-cut decomposition algorithm. Computational results will be presented.

4 - A Gpu-Based Distributed Algorithm for Linearized Optimal Power Flow in Distribution Systems

Minseok Ryu, Arizona State University, Tempe, AZ, United States, Geunyeong Byeon, Kibaek Kim

We propose a GPU-based distributed algorithm, aimed at controlling optimal power flow in distribution systems. Typically, conventional algorithms employed in such scenarios rely on parallel execution with multiple CPUs. However, this often leads to significant computation time primarily due to the need for optimization solvers to solve subproblems. To address this computational challenge, we propose a distributed algorithm that eliminates solver dependencies and harnesses GPU acceleration. We demonstrate the computational performance of our approach through numerical experiments on four IEEE test instances ranging from 13 to 8500 buses. Our results affirm the scalability and superior speed of our GPU-based approach compared to the CPU-based counterpart.

Federated Learning and Optimization: II

Invited Session

Computing Society

Chair: Kibaek Kim, Argonne National Laboratory, Lemont, IL, United States

Co-Chair: Farzad Yousefian, Rutgers University, Piscataway, NJ, United States

1 - Asynchronous Federated Stochastic Optimization for Heterogeneous Local Objectives under Arbitrary Delays

Charikleia Iakovidou, Argonne National Laboratory, Lemont, IL, United States, Kibaek Kim

Federated learning (FL) was recently proposed to securely train models with data held over multiple locations ("clients") under the coordination of a central server. Two major challenges hindering the performance of FL algorithms are long training times caused by straggling clients and a decrease in training accuracy induced by non-iid local distributions, modeled as heterogeneous local functions. To address these limitations, we propose a new stochastic (sub)gradient algorithm that is robust to client drift and utilizes asynchronous communication to speed up convergence in the presence of stragglers. Moreover, the proposed algorithm is, to the best of our knowledge, the first method that is both guaranteed to converge under arbitrarily long delays, and converges to an error neighborhood whose size depends only on the variance of the stochastic (sub)gradients used and thus is independent of both the heterogeneity between the local datasets, and the length of client delays, without the use of delay-adaptive stepsizes. Our numerical results confirm our theoretical analysis and suggest that the proposed method outperforms the state-of-the-art when local datasets are highly non-iid.

2 - Federated low-rank image reconstruction with multimodal CT

Julie Anh Nguyen, Northwestern University, Evanston, IL, United States, Zichao Di, Diego Klabjan, Minseok Ryu, Kibaek Kim

Tomographic image reconstruction is an important scientific problem that has significant applications in many fields. Tomographic projections in many cases are of large volumes and/or three-dimensional. Previous works have shown that joint reconstruction using data from different modalities can alleviate the ill-posedness of the single-modality problem, which is typically due to insufficient measurements and noise. In addition, exploiting the underlying tomographic structure through low-rank approximation of the object of interest has shown promising results, especially with limited-angle projections. Within the federated framework in which clients with different modalities collaborate and perform joint image reconstruction, we develop an algorithm that leverages low-rank approximation to not only capture latent multilinear structure but also improve communication efficiency.

3 - An Online Optimization Perspective on First-Order and Zero-Order Decentralized Nonsmooth Nonconvex Stochastic Optimization

Muhammet Emre Sahinoglu, Northeastern University, Boston, MA, United States, Shahin Shahrampour

We investigate the finite-time analysis of finding (δ,ϵ) stationary points for nonsmooth nonconvex objectives in decentralized stochastic optimization. A set of agents aim at minimizing a global function using only their local information by interacting over a network. We present a novel algorithm, called Multi Epoch Decentralized Online Learning (ME-DOL), for which we establish the sample complexity in various settings. First, using a recently proposed online-to-nonconvex technique, we show that our algorithm recovers the optimal convergence rate of smooth nonconvex objectives. We further extend our analysis to the nonsmooth setting, building on properties of randomized smoothing and Goldstein-subdifferential sets. We establish the rate of $O(\delta^{-1}\epsilon^{-3})$, which to the best of our knowledge is the first finite-time guarantee for general decentralized nonsmooth nonconvex objectives in the first-order oracle setting, matching its optimal centralized counterpart. We further prove the same rate for the zero-order oracle setting without using variance reduction.

4 - Improved guarantees for optimal Nash equilibrium seeking and bilevel variational inequalities

Sepideh Samadigharahbalagh, Rutgers university, Piscataway, NJ, United States, Farzad Yousefian

We consider a class of hierarchical variational inequality (VI) problems that subsumes VI-constrained optimization and several other important problem classes including the optimal solution selection problem and the optimal Nash equilibrium (NE) seeking problem. Our main contributions are threefold. (i) We consider bilevel VIs with monotone and Lipschitz continuous mappings and devise a single-timescale iteratively regularized extragradient method, named IR-EG(m,m). We improve the existing iteration complexity results for addressing both bilevel VI and VI-constrained convex optimization problems. (ii) Under the strong monotonicity of the outer level mapping, we develop a method named IR-EG(s,m) and derive faster guarantees than those in (i). We also study the iteration complexity of this method under a constant regularization parameter. These results appear to be new for both bilevel VIs and VI-constrained optimization. (iii) To our knowledge, complexity guarantees for computing the optimal NE in nonconvex settings do not exist. Motivated by this lacuna, we consider VI-constrained nonconvex optimization problems and devise an inexactly-projected gradient method, named IPR-EG, where the projection onto the unknown set of equilibria is performed using IR-EG(s,m) with a prescribed termination criterion and an adaptive regularization parameter. We obtain new complexity guarantees in terms of a residual map and an infeasibility metric for computing a stationary point. We validate the theoretical findings using preliminary numerical experiments for computing the best and the worst Nash equilibria.

1 - Strata design for variance reduction in stochastic simulation

Jaeshin Park, University of Michigan, Ann Arbor, Ann arbor, MI, United States, Young Myoung Ko, Sara Shashaani, Eunshin Byon

Stratified sampling is one of the powerful variance reduction methods for analyzing system performance with stochastic simulation. However, strata design faces the curse of dimensionality and data scarcity as the input dimension increases. We analytically derive the optimal stratification structure that minimizes the estimation variance for univariate problems. Further, reconciling the optimal stratification into decision trees, we devise a robust algorithm for multi-dimensional problems.

2 - An uncertainty-informed neural network-based prognostic model for multi-type data

Ye Kwon Huh, University of Wisconsin-Madison, Madison, WI, United States

Modern prognostic systems generate multi-type data, typically in the form of event logs with discrete event data and signal records with continuous signal data. Although each data type provides unique insights into the degradation status of the system, existing prognostic methods are limited as they focus solely on either data type to predict the remaining useful life (RUL). To fill this gap, we propose a novel neural network-based model that can harness prognostic insights from both discrete event data and continuous signal data. Specifically, the proposed model contains an event predictor for the event time and types, a signal predictor for the degradation signals, and an RUL predictor that integrates the signal and event predictions to ultimately predict the RUL. To prevent unwanted bias and under/overfitting issues during model training, the proposed model adopts an uncertainty-informed joint training process that leverages uncertainty information to automatically learn the relative weights of each prediction task. Evaluations on simulated and real-life battery data reveal the following insights: 1) Incorporating both data types result in superior RUL prediction performance than models that only consider a single data type; 2) Using uncertainty information to weigh each prediction task results in better signal/event/RUL prediction performance than the unweighted counterparts. The proposed model is generic and can be applied to any engineering system that collects both discrete event data and continuous signal data.

3 - Decision-Aware Robust Remanufacturing Planning

JUN ZHOU, University of Houston, Houston, TX, United States, Yisha Xiang, Ming Zhao

In this study, we develop a novel decision-aware robust remanufacturing decision model to determine the optimal remanufacturing time. Due to limited data or errors in data, the estimation of transition probabilities for a product to be remanufactured is subject to large statistical errors. Robust Markov decision process is a powerful decision tool for mitigating the effects of parameter uncertainties due to estimation errors. However, conventional robust MDPs may prescribe overly conservative policies. To better control conservatism in robust remanufacturing planning, we introduce innovative decision-aware constraints to construct ambiguity sets that leverage policies from nominal models without consideration of parameter uncertainty. These decision-aware constraints are designed to reduce the search space for the worst-case transition probabilities so that the resulting policies are robust yet not overly conservative. Numerical experiments are conducted to demonstrate the utility of the decision-aware Robust remanufacturing planning model.

4 - Motion Tracking in Ultrasound Imaging via Variational Bayesian Optical Flow

Shenghao Xia, University of Arizona, Tucson, AZ, United States

Motion tracking and segmentation in carpal tunnel ultrasound imaging is a critical step in the early diagnosis the carpal tunnel syndrome. However, traditional methods heavily rely on domain experts' annotations which are expensive. Optical flow was implemented to perform motion tracking, but it lacks uncertainty quantification and fails in Rayleigh-distributed noisy ultrasound imaging. In this research, a new Bayesian optical flow method is proposed to track motion by incorporating the characteristics of ultrasound imaging. The experiments in case studies have shown the performance improvement of the proposed model over benchmarks.

1 - Physics-Informed Deep Learning for Steady-State Thermal Distribution Prediction Across Diverse Geometric Domains

Amirul Islam Saimon, Virginia Tech, Blacksburg, VA, United States, Raghav Gnanasambandam, Zhenyu Kong

Thermal phenomena are fundamental in many additive manufacturing (AM) processes such as laser powder bed fusion (L-PBF). Advanced understanding of thermal phenomena assists in optimizing process parameters, and subsequently, avoiding defects such as warping, residual stresses, and microstructural anomalies. Thus, thermal distribution plays a critical role in determining the microstructure, mechanical properties, and overall quality of the manufactured parts. Most of the existing thermal prediction models are restricted to single geometry, which makes the prediction for unknown geometries almost impossible. Therefore, generalizing thermal prediction model across diverse geometries is a challenging research question in the AM community. This presentation aims at introducing a deep learning-based technique for predicting steady-state thermal distribution across diverse geometries which holds promise for extending its applicability to dynamic thermal phenomena in AM processes.

2 - Modular Calibration of a Digital Twin Model for Planning-Level Decision-Making in a Semiconductor Fab's AMHS

Bonggwon Kang, Department of Industrial Engineering, Pusan National University, Busan, Korea, Republic of, Chiwoo Park, Haejoong Kim, Bosung Kim, Soondo Hong

Field practitioners in automated material handling systems (AMHSs) in semiconductor fabrication plants (fabs) widely employ digital twin models to capture highly uncertain and dynamic material handling processes for planning-level decision-making. For obtaining credible decision-making, digital twin calibration has emerged as an essential step when the models allow for all sources of uncertainty and discrepancy, e.g., code uncertainty and parametric uncertainty. In practice, field practitioners have manually adjusted tuning parameters and compensated for discrepancies in the models whenever they experience significant operational fluctuations. However, no systematic application for the AMHS digital twin calibration has been presented. This study proposes a modular Bayesian calibration for an AMHS digital twin based on the Kennedy-and-O'Hagan approach. We use surrogate models to account for the parametric uncertainty and the digital twin’s discrepancy. The experiment results indicate that the proposed approach can improve the prediction accuracy of the digital twin over a broad range of input parameters.

3 - Transformer Based Offline Printing Strategy Optimization for Large Format Additive Manufacturing

Feng Ju, Arizona State University, Tempe, AZ, United States, haoyang xie, Dylan Hoskins, Kyle Rowe

In the realm of Large Format Additive Manufacturing (LFAM), determining an effective printing strategy before actual printing involves predicting temperature behaviors and controlling layer time, which has consistently been challenging. Currently, temperature prediction for controlling layer time in LFAM is primarily conducted through offline simulations or online monitoring. However, these approaches are typically tailored to specific cases and lack generalizability. Consequently, there exists a significant gap in the development of a universal model that can leverage historical data to predict temperature across various new geometries and positions. In this paper, we propose a novel approach to optimize the printing strategies for LFAM through the development and application of a transformer-based model focused on the dynamic prediction and management of temperature profiles across the print surface. Subsequently, we input the predicted temperature into an optimization model to determine the optimal layer time. We conducted a series of experiments to validate the effectiveness of our proposed model. Using historical temperature data collected from the real printing processes, the model demonstrated a high degree of accuracy in predicting temperature profiles for new design, enabling the optimization of layer time settings far beyond the capabilities of traditional fixed-time methods. This process significantly enhances the printing strategy, thereby increasing both the efficiency of the printing process and the quality of the printed objects.

Service Science Best Student Paper I

Award Session

Service Science

Chair: Weiwei Chen, Rutgers University, Piscataway, NJ, United States

1 - Ranking Quality and User Engagement on an Online B2B Platform

Rakesh Allu, Cornell University, Ithaca, NY, United States

Online business-to-business (B2B) platforms are increasingly investing in data science teams to develop machine-learning algorithms for providing personalized rankings-based recommendations for their users. Consequently, there is growing need to develop ways to evaluate the performance of these algorithms. Two key questions faced by platforms in such evaluation are: (i) how to periodically measure the quality of rankings using real-time ranked transactions data generated by the users and, (ii) how to examine the effect of improving ranking quality on usage (i.e., the number of transactions) and browsing effort. These questions are challenging to address because of simultaneity between usage and effort and censoring in ranked transactions data. Using detailed transaction-level data from a B2B platform in India for more than 61K sellers over one year, we propose methods to measure ranking quality, develop a position-level model of a user’s decision to transact and scroll, and develop estimation approaches to overcome censoring. Our analysis reveals a position-wise dynamic that results in an increase in platform usage and a decrease in browsing effort with improvement in ranking quality. We further show that nudging a user to scroll at least up to a predefined position can enable the platform to realize higher value from improving rankings quality.

2 - AI-Powered Philanthropy: Effects on Volunteer Productivity

Vinit Tipnis, Kelley School of Business, Indiana University Bloomington, Bloomington, IN, United States

Artificial intelligence (AI) boosts employee productivity, but its effect on nonprofit volunteers, who lack monetary incentives, is unclear. This study examines AI's impact on volunteers on an online platform that recently adopted an AI tool. Using an analytical model and difference-in-differences event study design, we find AI reduces weekly contributions by 7.5% on average. The impact varies with experience: less-experienced volunteers' productivity drops, while highly experienced volunteers increase their contributions. Nonprofit managers should avoid introducing AI to inexperienced volunteers without proper education but can leverage AI for experienced volunteers and use them to advocate for AI adoption.

3 - Transparent or Not? Optimal Performance Feedback in Services

Lin Chen, INSEAD, Fontainebleau, France

In many gamified services, users receive individual performance feedback upon service completion, which shapes their perception of goal achievement (through prospect theory) and relative status (when users are ahead-seeking or behind-averse). This feedback can vary in degrees of transparency, from disclosing individual scores to revealing only ranges of scores (e.g., top 5%). How transparent should service providers be in their individual performance feedback to maximize the utility users derive from their service? We employ a Bayesian persuasion framework to determine the optimal information disclosure policy, depending on whether a goal has been specified and whether the other users' scores are communicated. Without a goal, if the other users' scores are not available, any information policy is optimal; if they are available, the provider should be fully transparent (resp., opaque) when users are ahead-seeking (resp., behind-averse). With a goal, if the other users' scores are not available, the users who have exceeded or just fallen short of the goal should only be told that they lie in that range, whereas the lowest-performing users should be told their exact scores; if the other users’ scores are available, the range of opaque disclosure may not extend to the top performers when users are ahead-seeking. Comparing the aggregate user utility across conditions, we also characterize when setting a goal or sharing the score of the other users leads to a higher aggregate utility. Our paper offers guidelines to service providers to enhance user utility by engineering the design of their relative performance feedback.

Chair: Weiwei Chen, Rutgers University, Piscataway, NJ, United States

1 - Algorithm Reliance, Fast and Slow

Clare Snyder, Michigan Ross, Ann Arbor, MI, United States

In algorithm-augmented service contexts where workers have decision authority, they face two decisions about the algorithm: whether to follow its advice, and how quickly to do so. The pressure to work quickly increases with the speed of arriving customers. In this paper, we ask: how do workers use algorithms to manage system loads? With a laboratory experiment, we find that superior algorithm quality and high system loads increase participants' willingness to use their algorithm's advice. Consequently, participants with the superior algorithm make higher-quality recommendations than those with no algorithm (participants with the inferior algorithm make slightly lower-quality recommendations than those without). However, participants do not necessarily speed up by using algorithms' advice; their throughput times only decrease compared to the no-algorithm baseline when the system load is high and algorithm quality is superior, although participants would benefit from working faster in all treatments. This happens in part because participants in the high-load, superior-algorithm treatment serve customers more quickly than participants in the other treatments, conditional on using the algorithm. Participants in the high-load, superior-algorithm treatment work especially quickly in later periods as they increasingly default to their algorithm's advice. Our findings show that algorithms can have benefits for both decision quality and speed. Quality benefits come from workers' decision to use their algorithms' advice, while speed benefits depend on workers' algorithm use and the time they spend deliberating about their algorithm use. Ultimately, algorithm quality and system load are mutually reinforcing factors that influence both service quality and especially speed.

2 - Regulating Discriminatory Pricing in the Presence of Tacit Collusion

Zongsen Yang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of

Price-setting algorithms have facilitated widespread awareness-based price discrimination, wherein firms charge high prices to customers unaware of alternative choices and low prices to those in competitive markets. This unethical behavior has increased customer complaints and prompted policymakers to enact fairness regulations in response. However, while limiting price discrimination may improve consumer welfare under genuine competition, it also affects firms' incentives to form tacit collusion, another regulatory concern arising from the proliferation of pricing algorithms. We develop an analytical model to examine the interplay between fairness regulation and tacit collusion, and discuss its impact on consumer welfare and policymaking. Firms utilize customers' product unawareness to implement price discrimination and decide whether to collude by comparing profits from collusion and deviation. We then explore the consequences of price fairness regulation on the sustainability of tacit collusion. For homogeneous products, fairness regulation can substantially weaken collusion, potentially rendering it unattainable. However, for differentiated products, strict fairness inadvertently supports collusive behavior, harming consumer welfare. In this case, mild fairness permitting moderate price differentiation can prevent market collusion and optimize welfare. Our key results are valid under various robustness checks such as incorporating Q-learning or using alternative demand models and punishment strategies. We also propose a novel randomized approach to tame fairness-induced collusion. Overall, our study emphasizes the importance of a nuanced approach to regulating discriminatory pricing in the presence of tacit collusion.

3 - Homomorphic Encrypted Revenue Management

Mojtaba Abdolmaleki, University of Michigan, Ann Arbor, MI, United States

We develop a novel homomorphic encryption-based approach to privacy preservation in a dynamic personalized pricing setting. In each period, the firm offers a personalized price to an incoming customer based on (i) this customer's observable characteristics and (ii) the firm's estimate of the demand function (obtained using the data of the historical customers with whom the firm interacted in the past). Our method enables the firm to use homomorphic encryption to encrypt the data of incoming and historical customers, then estimate the demand function and personalize prices directly based on these encrypted data without the need to decrypt them. In contrast to the previous literature, which only preserves the privacy of historical customers via adding statistical noise to their data (so-called statistics-based approach), our approach allows the firm to protect the privacy of all customers -- both incoming and historical. Our theoretical analysis further reveals that our approach i) provides perfect privacy protection (achieving 0-differential privacy) and ii) does so at no cost to the firm's expected revenue, thus achieving better revenue performance than statistics-based algorithms, but (iii) it is computationally expensive. We thus develop a hybrid approach to privacy preservation that leverages the strengths of both statistics- and encryption-based methods, achieving the required privacy protection at a comparatively lower computational cost without significant compromise on the expected revenue. We confirm our theoretical findings through a numerical example based on synthetically generated data.

1 - Operating Three-sided Marketplace: Pricing and Spatial Staffing in Food Delivery Systems

Zhe Liu, Imperial College London, London, United Kingdom, Yiwen Shen, Yanwei Sun

We study a food delivery platform's joint pricing and staffing problem under the endogenous participation of three sides—restaurants, customers, and deliverers—each with its own incentives and heterogeneous features. With deliverer pooling and nearest matching, we represent the spatial multi-server system as a state-dependent Markovian queueing model, where the service rate depends on the imbalance of all three sides due to spatial frictions. We then analyze the system's equilibrium behavior and limiting service regimes in heavy traffic, and solve the platform's revenue maximization problem in large systems. Our explicit approximate solutions circumvent the tedious exact optimization by exploiting large-system asymptotics and economic implications. We show that the platform's asymptotically optimal solutions decouple into leading terms that neglect stochastic effects, and lower-order terms that reveal a balance of server utilization and service quality by a power-of-2/3 scaling (contrasting the classic square-root scaling). The main insights gleaned from our analytical results include: both the Efficiency-Driven (ED) and Quality-Driven (QD) regimes may prevail, depending primarily on customers' delay sensitivity; the revenue-maximizing platform still generates remarkable value to all three parties as well as social welfare, thanks to deliverer pooling and spatial matching; restaurants with intermediate profit margins join the platform, reaping demand boost and logistic savings.

2 - How Forced Intervention Facilitates Long-term Algorithm Adoption

Chenshan Hu, Washington University in St. Louis, Saint Louis, MO, United States, Xinyu Cao, Dennis Zhang

While artificial intelligence (AI) technologies become increasingly powerful and useful, human workers often resist adopting algorithmic recommendations, known as algorithm aversion. This aversion undermines the algorithms' performance in practice. While numerous studies explored short-term mitigation strategies, this paper investigates whether and why forced interventions can promote long-term algorithm adoption. Data from a leading online education company reveal that sales workers underutilize a new matching algorithm. The company then conducted a field experiment where sales workers were forced to use or not use the algorithm for three weeks. Results show that this forced intervention during the experiment causally increases workers' algorithm usage one month after the experiment by 15.8 percentage points. We develop a theoretical model to derive empirical strategies for exploring the mechanisms behind this. Contrary to the traditional literature focusing on habit formation, our findings suggest that learning is a key driver for long-term algorithm adoption. Specifically, forced algorithm usage allows workers to experience the algorithm's unbiased performance and positively adjust their beliefs about it. Consequently, workers use the algorithm not only more frequently but also more on high-quality leads post-experiment. We provide empirical evidence that forced intervention can effectively improve long-term algorithm adoption. More importantly, we demonstrate that forced intervention works by enabling workers to experience an algorithm's unbiased performance and adjust their prior misinformed assumptions about its effectiveness. This suggests that firms can implement extrinsic interventions to help workers recognize the benefits of algorithms and develop unbiased beliefs about their capabilities, thus facilitating sustained algorithm usage.

3 - Workforce Configuration in Charity Settings: A Forward-looking Approach

Chao Wu, Wayne State University, Detroit, MI, United States, Mahyar Eftekhar, Joline Uichanco

Volunteers form the backbone of many charities but pose challenges due to their variability in commitment and affinity. This study builds on existing research to propose a novel volunteer scheduling model aimed at optimizing resource allocation while nurturing future donor relationships. By integrating volunteer heterogeneity and donation potential into scheduling decisions, the model mitigates staffing costs and enhances volunteer satisfaction, thereby increasing their likelihood of future donations. Strategic adoption of this integrated approach challenges traditional organizational structures, further emphasizing the importance of robust data management in advancing charitable missions.

4 - Keep the Water Flowing: The Hidden Crisis of Rural Water Management

Chengcheng Zhai, Univeristy of Notre Dame, South Bend, IN, United States, Rodney Parker, Kurt Bretthauer, Alfonso Pedraza-Martinez, Jorge Mejia

In rural sub-Saharan Africa, people rely on water points like communal handpumps for clean drinking water, but these often break down, requiring reactive repairs. Local NGOs face tough decisions on allocating limited resources to reduce water point downtime, which affects health outcomes. They could invest in gathering more functionality data, increase repair capacity, or source more reliable parts. To minimize water point downtime, we propose a comprehensive maintenance service approach, which includes preventive maintenance and reactive repairs. In collaboration with local NGOs, we conducted field research in Ethiopia and Malawi. We collected 47,240 observations on water point functionality from NGOs in Malawi, the Central African Republic, and Ethiopia. Then, we built a Markov decision process (MDP) based on real-world field practices. This approach helped us determine the optimal schedule for NGO mechanics to visit and maintain water points. We applied the model to field data from the three countries and found that comprehensive maintenance can reduce water point downtime by up to 61.9%, at a minor increase in logistics cost, if any. Our findings challenge the belief that preventive maintenance is prohibitively expensive, recommending its integration into NGO programs. We further recommend that resource-constrained NGOs prioritize improving water point reliability, increasing repair capacity, or reducing the cost of major repair before investing in extensive data collection.

Service Science Best Cluster Paper II

Award Session

Service Science

Chair: Weiwei Chen, Rutgers University, Piscataway, NJ, United States

1 - Consider or Choose? The Role and Power of Consideration Sets

Yi-Chun Akchen, University College London, London, United Kingdom, Dmitry Mitrofanov

Consideration sets play a crucial role in discrete choice modeling, where a large class of non-parametric models can be understood as a two-stage decision making process. In this process, customers first form consideration sets and then follow a choice mechanism, such as a ranking system or a decision tree, to navigate their way towards a purchase decision. Rather than delving into a more sophisticated second-stage choice mechanism, this paper takes a step back and focuses on the fundamental properties of the decision-making process based on the consideration sets. We consider a class of nonparametric choice models that is only specified by a distribution over consideration sets and has a bounded rationality interpretation. We call it the consideration set model. Intriguingly, we show that this class of choice models can be characterized by the axiom of symmetric demand cannibalization and enable full statistical identification. We further consider the model's downstream assortment planning as an application. We first provide an exact characterization of the optimal assortment and show that it is revenue-ordered on the blocks defined with respect to the consideration sets. Despite the existence of the exact structure, we prove that the optimal assortment is NP-hard to approximate. This result shows that the existence of consideration sets inevitably cause inapproximability in assortment planning, despite that the consideration set model does not involve a sophisticated second-stage mechanism. Finally, using a real-world dataset, we show that the consideration set model offers comparable prediction power to other advanced choice models.

2 - Learning the Minimal Representation of a Continuous State Space MDP from Transition Data

Mohammed Amine Bennouna, Massachusetts Institute of Technology, Cambridge, MA, United States, Georgia Perakis, Dessislava Pachamanova

In this talk, we introduce a framework for learning the most concise (minimal) MDP model of a continuous state space dynamic system from observed transition data.
Our work is motivated by data-driven personalized patient treatment—an increasingly sought-after machine learning application. In this reinforcement learning problem, as in most high-stakes applications, interpretability is crucial: physicians cannot rely on a black-box algorithm for prescribing treatments. We introduce theoretically the problem of learning the most concise representation that preserves the system’s dynamics. In the patient treatment setting, this corresponds to identifying treatment groups based on the evolving features of patients under treatment. Surprisingly, we prove theoretically that it is statistically possible to learn the most concise representation of a dynamic system solely from observed historic sample path data. We subsequently develop an algorithm, MRL, which learns such a concise representation, thereby enhancing interpretability and tractability.

3 - Coordinate Package Delivery and On-Demand Rides: A Zoning Policy and Analysis

Junyu Cao, The University of Texas at Austin, Austin, TX, United States, Sheng Liu

Cities are facing mounting pressure from the surging demand for package delivery and on-demand ride services. Meanwhile, more drivers are empowered by platforms to provide flexible transportation and logistics services with their own vehicles. Integrating freight and passenger transportation services, termed co-modality, has been promoted as a promising means to improve vehicle utilization, driver productivity, and logistics efficiency. Motivated by these issues, we investigate the value of co-modality to the driver in the context of joint package delivery and ride-hailing from a revenue-maximizing perspective. The driver must decide when and how on-demand ride jobs should be coordinated with package deliveries. Because the general optimal coordination problem is intractable, we develop a zoning-based coordination policy that allows us to capture the synergies between these two types of jobs and characterize its revenue performance analytically. We find that the optimal policy reduces to three forms: the pure package delivery policy, the four-zone policy (limited ride opportunity), and the switching policy (flexible ride opportunity). We show that co-modality is most beneficial when the package volume is relatively low. Offering limited flexibility is optimal when the ride profit and package volume are moderate. In the limit, the zoning-based coordination policy scales similarly to the pure package delivery policy and enjoys a bounded performance ratio to the perfect coordination policy. We also complement our analysis using numerical studies based on taxi data from New York City and discuss the practical implications.

4 - Machine Learning-Augmented Optimization of Large Bilevel and Two-stage Stochastic Programs: Application to Cycling Network Design

Bo Lin, University of Toronto, North York, ON, Canada, Timothy Chan

Motivated by a cycling infrastructure planning application, we present a machine learning approach to solving bilevel programs with a large number of independent followers, which as a special case includes two-stage stochastic programming. We propose an optimization model that explicitly considers a sampled subset of followers and exploits a machine learning model to estimate the objective values of unsampled followers. Unlike existing approaches, we embed machine learning model training into the optimization problem, which allows us to employ follower features that cannot be represented using leader decisions. We prove bounds on the optimality gap of the generated leader decision as measured by the original objective that considers the full follower set. We develop follower sampling algorithms to tighten the bounds and a representation learning approach to learn follower features, which are used as inputs to our machine learning model. Through numerical studies, we show that our approach generates leader decisions of higher quality compared to baselines. Finally, we perform a real-world case study in Toronto, Canada, where we solve a cycling network design problem with over one million followers. Compared to the current practice, our approach improves a transportation metric by 19.2% and can lead to a potential cost saving of $18M.

Global Optimization

Invited Session

OPT: Computational Optimization and Software

Chair: Zelda Zabinsky, University of Washington, Seattle, WA, United States

1 - Multiple model consistency for global optimization

Danielle Morey, University of Washington, Seattle, WA, United States, Giulia Pedrielli, Cherry Wakayama, Zelda Zabinsky

Complex systems are often modeled with multiple models, including simulations, Gaussian processes, and data regression. In the absence of a known ground truth model, it is important to reconcile the consistency of different models in a region of interest. In a heterogeneous space, model accuracy may depend on subregions of the space. We combine state space partitioning with model consistency measures to refine model estimation near global optima. We also incorporate ideas of statistical consistency with the concept of consistency sets in linear and convex programming to identify near-optimal regions of interest based on shared trends. While model outputs may differ, regions can be compared with regards to the global objective function via consistency and improvements across models. By evaluating the same points with each model, a point-wise comparison can be drawn to determine model consistency and can be used as an indirect measure of accuracy. As a proof of concept, we apply a multiple model consistency approach to global optimization on test problems as well as maritime and biomanufacturing applications.

2 - Scalable Global Optimization with Adaptive Surrogate Search and Subspace Decomposition

Pariyakorn Maneekul, University of Washington, Seattle, WA, United States, Giulia Pedrielli, Zelda Zabinsky

Global optimization of large-scale black-box functions is being pursued using surrogate modeling, partitioning, and adaptive sampling distributions. Recent finite-time analyses on Branching Adaptive Surrogate Search (BASSO) highlight the importance of consistently improving the incumbent objective function value. One condition of the analysis is that the implicit adaptive sampling distribution stochastically dominates a uniform sampling distribution on the level set of improving points. We explore decomposing the high-dimensional space into many low-dimensional subspaces to enable surrogate modelling within practical limits. We combine the subspace variables using an adaptive subspace distribution to create a full-dimensional point for objective function evaluation. We numerically compare the performance of several BASSO implementations with state-of-the-art methods on several benchmark objective functions with dimensions ranging from 20 up to 1,000. We also test whether the BASSO implementations satisfy the assumptions of the BASSO finite-time analysis.

3 - Algorithm-Guided Experimentation for Systematic Engineering of Perovskite Solar Cells

Donghyun Oh, Georgia Institute of Technology, Atlanta, GA, United States, Sanggyun Kim, Carlo Andrea Riccardo Perini, Juan-Pablo Correa-Baena, Nikolaos Sahinidis

Perovskite solar cells hold significant potential for renewable and sustainable energy generation. However, research into perovskite photovoltaics has been predominantly experimental and hampered by a lack of systematic approaches for optimizing key design parameters. In this work, we present a combined experimental-computational framework to systematically enhance the photovoltaic performance of these devices. By employing black-box optimization algorithms, our framework guides the sampling of the design space to identify optimal designs. We then fabricate devices based on this algorithm-guided experimental design and test them under illumination to validate and refine the optimization process. The results show notable performance enhancements, demonstrating an effective combination of mathematical optimization and experimental research.

4 - AI-Driven Laser Parameter Search (ALPS): Inverse Design of Photonic Surfaces using Optimization Techniques

Luka Grbcic, Lawrence Berkeley National Laboratory, Berkeley, CA, United States, Juliane Muller, Wibe Albert de Jong

Photonic surfaces with tailored optical characteristics are increasingly utilized in various energy harvesting and storage systems. In this work, we introduce ALPS—a computational optimization framework specifically developed for the inverse design of photonic surfaces. ALPS uses a greedy, prediction-based exploration strategy to optimize laser fabrication parameters that are crucial for creating photonic surfaces with minimal discrepancy from user-defined target optical characteristics. We have applied ALPS to a series of inverse design benchmarks and conducted comparisons with established optimization algorithms to evaluate its performance. Our results highlight a significant advantage of ALPS: its ability to efficiently warm-start the inverse design process when adapting to new target optical characteristics.

5 - Embedding ReLU neural networks in dynamic optimization: scaling mixed-integer formulations using bounds propagation

Calvin Tsay, Imperial College London, London, United Kingdom, Philip Sosnin

Neural networks are often embedded in dynamic optimization as surrogate models of a system or as efficient controllers, e.g., approximate explicit MPC. Applications include optimization of the surrogate/controlled system itself, scheduling, or certification of (worst-case) system behavior. The latter is particularly important in safety-critical domains such as autonomous vehicle driving. Discretizing, or "unrolling", the time domain produces a large, monolithic global optimization problem. This work studies the case where all components are piecewise linear, e.g., ReLU neural networks and hybrid discrete systems, resulting in a mixed-integer linear program, or MILP. Solution as a MILP can certify global optimality but suffers from scalability issues. We discuss how these issues can be (partially) mitigated via bound-tightening techniques prior to forming the mixed-integer program, generating tighter continuous relaxations and, consequently, expediting optimisation procedures. Specifically, we investigate how bounds can be efficiently and tightly propagated through neural network layers and time steps. Using certification of neural network controllers as a case study, we evaluate several strategies for bounds tightening in terms of both computational complexity and tightness of the bounds.

Chair: Sepehr Soltani, American Airlines, 4444 Cole Avenue, Dallas, TX, 75205, United States

1 - Convergence-Guaranteed Elastic Net Graphical Model Estimation for Anomaly Localization

Dzung Phan, IBM Research, Yorktown Heights, NY, United States, Tsuyoshi Ide, Matt Menickelly, Jayant Kalagnanam

Estimating dependency structures from noisy multivariate variables is crucial across various applications, with anomaly localization being particularly vital. Anomaly localization involves computing variable-wise anomaly scores by comparing a target dependency structure to a reference one. Stable and accurate estimation of dependency structures is essential for this task. Firstly, we present an L0-elastic net model designed to estimate sparse inverse covariance matrices. Subsequently, we introduce a framework for anomaly localization that integrates the L0-elastic net model with a transfer learning approach. Despite the known challenges of L0-constrained optimization, we introduce a hard thresholding line-search algorithm to efficiently solve these graphical models. Through experiments on synthetic and real-world datasets, we demonstrate that our proposed L0-based method consistently outperforms alternative methods across numerous use cases.

2 - Hierarchical Forecasting for Amazon EC2 demand

Yiming Wang, Amazon, Seattle, WA, United States, Ebrahin Nasrabadi

Amazon's Stores, Digital, and Other (SDO) is the largest user of AWS EC2 capacity. This poster introduces our in-house Hierarchical Bayesian and Hierarchical Reconciliation forecasting methods to forecast SDO EC2 demand. The demand forecasts are published at bi-monthly cadence, covering a rolling 2-year horizon, and at granularity of business group (Stores, Digital, Other), availability zone (e.g., us-east-1a), and instance type (e.g., c5.12xlarge) level. The forecasts can be used for AWS capacity planning to drive operational and financial decisions on global AWS data center infrastructure and space plan. To address the cold-start challenges in forecasting new instance generation and availability zones's demand, we developed a novel Hierarchical Bayesian time series forecasting model. In back-testing, our model was proven to reduce the forecast error measured in Weighted Absolute Percentage Error (WAPE) to 18.6% from 30.0% using Meta's open-source Prophet package for new AWS EC2 instances launched in 2023.

3 - Securing through evaluating: An autonomous cloud security assessment artifact based on large language models

Qin Su, School of Management, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Yue Fang, YING GAO

Cloud security has emerged as a pivotal concern that postpones the development of online cloud systems in multiple areas. Conventional cloud platform security assessment techniques suffer from low assessment accuracy and reliance of subjective viewpoints on security, rendering their applications in the digital era. To overcome these vulnerabilities and drawing from the design science theory, we designed a comprehensive cloud security assessment artifact enabled by large language model based autonomous system (LLMAS). The proposed artifact presents a dynamic and adaptive mechanism for continuous online platform security assessment including two distinct system architectures: the algorithm architecture and the process architecture. The algorithm architecture refers to a multi-dimensional sentiment classification generator driven by a hybrid algorithm of large language models (LLM) and domain knowledge graph, and the process architecture refers to an autonomous system security assessment process including a loop of construction-validation-evaluation steps. To validate the effectiveness of our artifact, we collected standard documents text data in the cloud ERP context and constructed a comprehensive evaluation system as an illustration. The hybrid LLM algorithm is superior to existing text analysis methods with an increase of around 27% in prediction accuracy. Our paper contributes to existing literature by promoting the applications of LLM in the cloud domain, proposing an autonomous assessment process which balances between users' heterogeneous security perception and assessment costs, and constructing a viable tool of cloud ERP security based on standard documents.

4 - A Deep Reinforcement Learning-Based Technique for Optimal Power Allocation in Multiple Access Communications

Sepehr Soltani, American Airlines, Dallas, TX, United States, Ehsan Ghafourian, Diego Martin, Milad Vahidi, Reza Salehi

Addressing the escalating demands of modern wireless networks, this study introduces a sophisticated deep Q-learning (DQL) framework to optimize power allocation (PA) in wireless multiple-access communications. Central to our approach is the employment of a model-free Deep Q-Network (DQN), which leverages the current sumrate as the reward function, aligning PA strategies with the overarching goal of maximizing network efficiency and fairness. This innovative method enhances decision-making by enabling precise sumrate predictions across diverse power settings based on specific channel state information (CSI). Our results demonstrate that the DQN with a zero discount factor not only achieves superior average sumrates but also significantly outperforms conventional methods such as fractional programming (FP) and weighted minimum mean squared error (WMMSE), especially in varied user density scenarios. The robustness of our approach is further validated through offline centralized learning, where the DQN is initially trained in simulated environments and then adeptly applied in real-time through distributed executions. Our findings demonstrate not only improved sumrate performance but also robust generalization capabilities, showcasing how advanced analytical techniques can lead to smarter resource management in next-generation wireless networks. This study underscores the potential of machine learning in enhancing the decision-making processes within complex communication systems, promoting more effective and sustainable technological advancements.

Innovations in Market Design

Invited Session

Auctions and Market Design

Chair: Gerard Cachon, University of Pennsylvania, Philadelphia, PA, United States

1 - Platform Disintermediation: Information Effects and Pricing Remedies

Auyon Siddiq, University of California, Los Angeles, Los Angeles, CA, United States, Shreyas Sekar

Two-sided platforms, such as labor marketplaces for hiring freelancers, typically generate revenue by matching prospective buyers and sellers and extracting commissions from completed transactions. Disintermediation, where sellers transact offline with buyers to bypass commission fees, can undermine the viability of these platforms. Although transacting offline allows sellers to avoid commission fees, it also leaves them fully exposed to risky buyers (given the absence of the platform's payment protections) and imposes switching costs (given the absence of the platform's transaction infrastructure). In this paper, we consider interventions for addressing disintermediation, focusing on the pricing and informational levers available to the platform, where the latter refers to the accuracy of the signal sellers receive about buyers' riskiness. First, while intuition suggests platforms should counter disintermediation by lowering commission rates, in a high-information environment a platform may be better off raising them. Further, a platform may strictly benefit from sellers receiving a partially-informative buyer signal (i.e., not perfectly revealing nor concealing a buyer's riskiness), particularly when switching costs are low. Finally, while charging sellers platform-access fees can immunize the platform from disintermediation, it can fall short of the optimal revenue under commission-based pricing. We also examine the efficacy of banning sellers if caught disintermediating and extend our findings to a setting with repeated

transactions. Overall, our results shed light on how disintermediation disrupts platform operations and offers prescriptions for platforms seeking to counteract it.

2 - Optimal Auction Design with Deferred Inspection and Reward

Alexandre Belloni, Duke University, Durham, NC, United States, Saeed Alaei, Ali Makhdoumi, Azarakhsh Malekian

Consider a mechanism run by an auctioneer who can use both payment and inspection instruments to incentivize agents. The timeline of the events is as follows. Based on a pre-specified allocation rule and the reported values of agents, the auctioneer allocates the item and secures the reported values as deposits. The auctioneer then inspects the values of agents and, using a pre-specified reward rule, rewards the ones that have reported truthfully. Using techniques from convex analysis and calculus of variation, for any distribution of values, we fully characterize the optimal mechanism for a single agent. Using Border's theorem and duality, we find conditions under which our characterization extends to multiple agents. Interestingly, the optimal allocation function, unlike the classic settings without inspection, is not a thresholding strategy and instead is an increasing and continuous function of the types. We also present an implementation of our optimal auction and show that it achieves a higher revenue than auctions in classic settings without inspection. This is because the inspection enables the auctioneer to charge payments closer to agent's true value without creating incentives for them to deviate to lower types.

3 - Battery Operations in Electricity Markets: Strategic Behavior and Distortions

Jerry Anunrojwong, Columbia Business School, New York, NY, United States, Santiago Balseiro, Omar Besbes

Electric power systems are undergoing a major transformation: integrating intermittent renewable energy sources, and batteries to smooth out variations in renewable energy production. As privately-owned batteries grow from their role as marginal "price-takers" to significant players in the market, a natural question arises: How do batteries participate strategically in electricity markets, and how much do the incentives of independent batteries align with those of the system as a whole? We propose an analytically tractable model that captures salient features of the highly complex electricity market that are crucial in understanding the strategic role of batteries and their impact on system cost. We derive in closed form the resulting battery behavior and generation cost in three operating regimes: (i) no battery, (ii) centralized battery (first-best), and (ii) decentralized profit-maximizing battery (second-best). The battery can strategically withhold its capacity in three ways. First, withholding in quantity, or discharging less than socially optimal. Second, withholding in time, or discharging later than socially optimal. Third, withholding in responsiveness, or discharging less in response to smoothing real-time demand than socially optimal. We quantify each of the three forms of withholding in terms of market fundamentals. We further analyze the impact of battery competition. To illustrate our results, we calibrate our model to California and Texas markets and show that the loss from incentive misalignment can be consequential.

4 - Design of Resale Platforms

Daniela Saban, Stanford University, Stanford, CA, United States, Ilan Morgenstern, Divya Singhvi, Somya Singhvi

We study resale platforms, an emerging type of online marketplaces in developing countries. These platforms are designed for individuals (resellers) to sell products to others as opposed to buying for themselves, enabling them to supplement their income by earning a margin on the transactions they generate. One challenge these platforms face is that competition among resellers may emerge as more of them join the platform, as their social circles increasingly overlap. We investigate the mechanisms by which competition affects resellers and the role of the platform's design in shaping this relationship. We combine analytical modeling with empirical analysis. Our model captures the resellers' interactions with the platform (in searching for products to sell) and with consumers (in offering these products for purchase). We find that as competition intensifies, resellers not only lower their margins but also reduce the effort they exert in searching for products to sell. We empirically validate these equilibrium predictions using data from a major platform: as competition increases, resellers earn lower margins and reduce the number of products they view while browsing on the app, which we interpret as lower search effort. We explore two interventions that aim to benefit resellers: centralizing margin decisions (a practice adopted by several platforms) and optimizing its product ranking algorithm, offering insights to guide key design choices for resale platforms, aiming to foster sustainable online entrepreneurship in developing economies.

Advances in Queueing Theory and Applications

Contributed Session

Chair: Himanshu Arha, Indian School of Business, Hyderabad, Hyderabad, India

1 - Crowdsensing for Informed Decision-Making: Exploring the Role of data contributors ratio and Congestion

Elham Heydarigharaei, York University, Guelph, ON, Canada, Hossein Abouee Mehrizi, Mehdi Nourinejad

Crowdsensing platforms collect data from individual users, reducing the need for extensive data collection infrastructure. The accuracy of the gathered data relies on the proportion of users contributing. However, due to concerns about privacy or limitations in device accessibility, only a subset of users actually contribute data. By integrating crowdsensing into service facilities, customers can share queue information, aiding others in deciding when to join the queue. Through the analysis of a single-server queue model, we examine how this shared data affects decisions regarding queue participation. Additionally, we explore the impact of the contributor ratio on social welfare. Our findings reveal that changes in social welfare relative to the contributor ratio are contingent upon the load factor—the balance between service demand and completion rate. In systems with high load factors, maintaining a contributor ratio below one maximizes social welfare, whereas in low-load factor systems, social welfare consistently improves as the contributor ratio increases. Moreover, our results suggest that limiting customer access to crowdsensing platforms diminishes social welfare.

2 - Asymptotic analysis of queueing systems with impatient customers and stochastic agent availability

Arash Asgari, University of Alberta, Edmonton, AB, Canada, Saied Samiedaluie, Amir Rastpour

Most queueing models for call centers assume that the number of available agents is known and controllable. In reality, though, the availability of human agents varies stochastically in a way that cannot be fully controlled due to a variety of factors such as post-call tasks, breaks, or meetings. We formulate a queueing system with impatient customers and stochastic agents' availability as a phase-type queueing model. We then proceed with an asymptotic analysis of such model in the Halfin-Whitt heavy-traffic regime which simultaneously addresses both important aspects of a queuing system: the quality of service delivered to customers and the system's efficiency. Guided by the asymptotic behavior, we first derive the diffusion limits characterizing a multidimensional piecewise Ornstein-Uhlenbeck process. However, deriving approximations from this complex process encounters significant challenges, primarily due to boundary issues. To address this challenge, we employ an innovative methodology to transform the multidimensional diffusion process into a tractable one-dimensional form. Solving this process allows us to propose high-quality approximations for key steady-state performance metrics, including customers' probability of delay, abandonment likelihood while waiting, and expected wait time. Our findings hold significant implications for system managers, providing actionable insights into setting staffing levels to meet desired service standards effectively.

3 - Posterior Sampling Learns the Best to Earn the Most

Mohamad Kazem Shirani Faradonbeh, Southern Methodist University, Plano, TX, United States

A classical problem in decision-making under uncertainty is that of sequentially learning to choose the best among multiple options. Each option yields a stochastic reward value that is determined by its own unknown parameter together with some time-varying contextual information. So, to sequentially learn the option of highest reward in an online fashion, one needs to try all different options to collect the so-called contextual bandit feedback data. At the same time, by experimenting options of lower rewards, we defeat our purpose of gaining the maximum possible reward over time. Accordingly, a fundamental dilemma is the trade-off between learning the best and earning the most. We present an algorithm that samples from the posterior belief about the unknown parameters and uses that to choose the seemingly best option. Our setting allows for additional uncertainties such that the context signals are observed only in a partial and noisy manner. We theoretically establish that the algorithm learns the best option fast to incur a minimal compromise in reward, and showcase that with real data experiments.

4 - Priority Queueing: Impact of Heterogenous Buffer and Service Time

Himanshu Arha, Indian School of Business, Hyderabad, Hyderabad, India, Vishwakant Malladi, Milind Sohoni

We study an M/D/1 queuing model with finite buffer capacity and two customer classes. We show that the control policy is of threshold type where a low-priority customer is held up to a threshold in anticipation of a high-priority customer. We examine how buffer capacity and service time influence the threshold. We also study the impact of visibility of future arrivals and compare the results with the no visibility case.

Advances in Optimization Methods for Inventory Management

Contributed Session

Chair: Menglei Jia, N/A

1 - Multi-period data-driven inventory control: performance of deep neural network policies

xun zhang, National University of Singapore, Singapore, Singapore, Shen Guohao, Hu Xiangbin

We study finite-horizon periodic-review inventory control with dependent demands, in which the retailer has no access to the true demand distribution and makes inventory decisions based only on historical data. The demand distribution in each period is determined by some external features that have Markovian temporal dependence. It is first shown that the state-dependent base-stock policies are optimal. However, without the full knowledge of demand and covariate distributions, we must estimate these optimal order-up-to level functions from data. To this end, we look at the empirical average of the cumulative cost from each period to the terminal period and recursively minimize the empirical cost-to-go functional backward in time over the space of deep neural networks (DNN) to estimate optimal order-up-to functions. The construction of the data-driven policy is intuitive but the analysis is challenging. Due to the multi-period nature, estimation error in future periods propagates backward. This renders the existing non-parametric statistic theory inapplicable. We must leverage the special cost structure of the inventory model to establish various structural properties of the total expected cost function so that different sources of estimation error can be dissected. We establish finite-sample upper bounds of expected regret of implementing the proposed data-driven policy compared with optimal policies.
This upper bound for DNN-based policy is new in both statistics and operations research literature. It is also shown that the established upper bound matches the lower bound for arbitrary data-driven inventory policies up to some logarithm factors, and so is nearly tight.

2 - Optimal Policies for Decentralized Multi-Echelon Inventory Problems with Endogenous Markov-Modulated Demand Models

Byeong Kwon Lee, Seoul National University, Seoul, Korea, Republic of, JeongWook Lim, Kun Soo Park

We study the optimal inventory policy in a decentralized multi-echelon system, where a warehouse serves a retailer that faces independent and identically distributed customer demand. The retailer follows an (s, S) inventory policy, which causes the warehouse to experience non-stationary demand from the retailer. To effectively analyze this non-stationary retailer demand, we develop an endogenous Markov-modulated demand model. We also develop an efficient algorithm to calculate the lead-time demand distribution for the warehouse by utilizing generating function and its inversion. Based on this model, we propose a novel inventory modeling scheme incorporating impact horizon and state progression phase to address the overshoot issue arising from non-stationary retailer demand. Then, we prove the optimality of a state-dependent base-stock policy for the warehouse and propose an exact algorithm to efficiently compute the optimal base-stock levels. Our approach provides a rigorous foundation for managing inventory in a decentralized supply chain and provides a potential for significant saving in inventory costs.

3 - Optimal Production Policy Under TIME- and Price-Dependent Demand and Reliability

Sarbjit Singh, Institute of Management Technology Nagpur, Nagpur, India, Shivraj Singh, Dipti Singh

In this paper, we study an inventory system for products where demand depends on time and price. We consider the effect of reliability and a two-level trade credit. We suppose that the demand rate is a price- and time-dependent function. The objective is to determine the economic lot size and the best selling price to maximize the total profit per unit of time given a product's reliability and trade credit. We present an efficient procedure to determine the optimal solution to the inventory problem for all possible scenarios. This procedure is illustrated with several numerical examples. A sensitivity analysis of the optimal inventory policy with respect to the parameters of the demand rate function is also given. Finally, the main contributions of this paper are highlighted, and future research directions are introduced.

4 - Bandit Algorithm for Online Learning in Inventory Problems with Lead Times

JeongWook Lim, Seoul National University, Seoul, Korea, Republic of, Byeong Kwon Lee, Kun Soo Park

While data-driven approaches have been successfully utilized to many inventory problems, they are either offline learning or problem specific algorithms. In addition, while deep reinforcement learning approaches has been known to be capable of being a universal methodology for inventory problems, they do not support online learning capability. Thus motivated, we develop an efficient online inventory management algorithm that is applicable to various inventory problems universally. Our algorithm adjusts vanilla bandit algorithm with a virtual inventory cost framework, and it utilizes merits of both UCB-type algorithm and Thompson-sampling algorithm. We obtain regret upper bound of this algorithm and evaluate its performance with numerical experiments.

5 - Distributionally Robust Optimization of the Cyclic Inventory Routing Problem

Menglei Jia, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Albert Schrotenboer, Ahmadreza Marandi, Feng Chen

We study the cyclic inventory routing problem. The demand faced by retailers is stochastic, and its distribution is unknown. Such demand uncertainty is characterized by a moment-based ambiguity set. Instead of considering fixed replenishment intervals as in most cyclic-setting studies, we allow for variable intervals, which can cope with non-stationary demand and, therefore, are more relevant to practical applications but, at the same time, introduce significant complexity to the solving.

Our contributions can be summarized as follows. First, we formulate the problem with chance constraints on vehicle capacity and, under the back-ordering assumption, to minimize total transportation, holding, and backorder costs. Then, we reformulate the chance constraints into linear ones. In addition, we show that, for a given retailer and an interval, the worst-case distribution is a multi-point distribution. To solve the problem, we design a branch-and-price framework and provide a tailored labeling algorithm for the complex pricing problem. We conduct experiments on synthetic data and a case study on real-life data from our industry partner. The results show that our distributionally robust optimization setup outperforms stochastic programming that considers a single distribution. We also compare our setting with the fixed interval setting, illustrating that the variable interval setting can significantly reduce the operational cost. Our method does not require daily solving or rely on distributional assumptions, making it an efficient tool in practice.

Drone Based Operations and Delivery Systems

Contributed Session

Chair: Ziping Wang, Morgan State University, Baltimore, MD, United States

1 - Characterizing Rural Resident Acceptance of Drone Delivery Services: A Large Language Model Empowered Approach

Ziping Wang, Morgan State University, Baltimore, MD, United States, Henan Zhu, Xiaozheng He

With the increasing demand for rural logistics services and the notable disparities in service provision between urban and rural areas, there arises a compelling need to explore innovative drone-based delivery solutions. This study aims at addressing the challenges hindering the adoption of drone-based delivery, due to technological and physical barriers, that consequently affect service quality for rural residents. Such disparities amplify concerns regarding delivery equity and residents' acceptance of the potential drone delivery services. Our research presents an inaugural investigation into residents' direct willingness and sentiment toward accessible drone delivery services in rural areas using a Large Language Model (LLM)-empowered machine learning framework. Leveraging the advanced LLM-driven Light Gradient-Boosting Machine (LightGBM) method, our prediction model mitigates the cognitive bias and significantly enhances the predictive accuracy of residents' acceptance categories, compared to traditional ordinal logistic regression models. Our research advances the understanding of rural residents' acceptance to adopt drone delivery services, addressing pertinent challenges within the rural logistic landscape and the evolution of the drone delivery market. Moreover, it reveals the gap between the supply of rural drone delivery services and the demand from the rural consumer base, exploring the intricate interplay between socioeconomic factors and delivery preferences. This approach fosters a comprehensive drone-based delivery ecosystem that inclusively benefits all rural residents, irrespective of their geographical location.

2 - Strategic Fleet Composition and Efficiency Prediction for Drone-Enabled Last-Mile Delivery

Bahar Dehqani Viniche, York University, Toronto, ON, Canada, Opher Baron, Oded Berman, Mehdi Nourinejad

Last-mile delivery, the final and most costly leg of the supply chain, demands innovative solutions to enhance efficiency in both urban and suburban areas. Drones offer advantages to this sector by avoiding congested routes and follow aerial pathways at higher speeds and lower cost. This study introduces models of drone-assisted delivery strategies, whereby trucks travel to designated hubs to launch and retrieve drones. This research bridges the gap of incorporating routing-based operational-level constraints, including drone flight range, coordinating truck and drone trajectories, and multi-launching- sending more than one drone from a single hub. Our analysis reveals three scenarios where delivery efficiency is restricted by truck capacity, drone range, or synchronization between trucks and drones. Nevertheless, the effectiveness of drone delivery varies across different urban settings due to network structures and socio-geographic factors. In second phase of our research, we use machine learning methods to evaluate the effectiveness of drone delivery in different urban settings. We use our interactive tool "Drone Sidekick Tool," to gather data on travel distances, times, and environmental effects. This comprehensive approach enhances our understanding of drone delivery's potential and aids in developing more efficient and adaptable drone delivery solutions.

3 - Truck and drone delivery problems under travel time uncertainty

Chung-Wei Shen, National Cheng Kung University, Tainan, Taiwan, Bo-Xuan Qiu, Chia-Yu Cheng

With the rapid development of e-commerce, the volume of goods handled by logistics companies is gradually increasing. Meanwhile, the travel time during the distribution process may change due to traffic conditions, such as road congestion leading to travel time increases. Therefore, how to complete the delivery within the predefined time window under travel time uncertainty is an issue that logistics companies are eager to solve. In recent years, the continuous advancement of automation technology has given the possibility of combining drones with trucks for delivery. To improve the robustness of the delivery network under uncertain circumstances, a systematic method is required to develop a robust solution. Few studies were focused on the distribution problem of trucks combined with drones considering travel time uncertainty. Therefore, this study intends to develop a robust optimization model for a collaborative truck-and-drone delivery under travel time uncertainty. Furthermore, an adaptive variable neighborhood search algorithm is proposed to tackle large instances. A Monte-Carlo simulation tests the robustness of the obtained solutions. The proposed models can be applied to some practical applications and can be used as a reference for logistics decision-makers to make relevant decisions.

4 - On the Design of Electric Charging Infrastructure for Drones

Fateme Hafizi, Illinois Institute of Technology, Chicago, IL, United States, Mohammad Miralinaghi

Freight transportation stands as a critical contributor to urban traffic congestion and air pollution, especially with the growth of electronic commerce. To address this challenge, both government and logistics corporations are actively exploring sustainable alternatives to traditional delivery systems. Among these alternatives, electric, biofuel, and hydrogen-fueled transportation have garnered attention for their potential to reduce emissions and alleviate urban congestion. Drone innovations offer promising solutions because of their inherent advantages, including lower costs and increased accessibility, especially in areas with challenging terrain. However, one significant limitation of drones is their limited flying range, which presents a significant barrier to their widespread adoption for urban parcel delivery. To overcome this constraint, the strategic placement of charging points has emerged as a viable solution to enhance the operational capabilities of drones. This study presents a theoretical framework that optimizes the location of drone charging stations in urban areas. By leveraging advanced optimization models, this framework facilitates the effective allocation of charging locations, thereby addressing the challenge of managing delivery demands. The findings of this study offer valuable insights for metropolitan authorities, logistics companies, and urban planners seeking to mitigate congestion and improve air quality in urban settings. By embracing innovative solutions like optimized charging station placement, cities can pave the way for a more sustainable and efficient future in urban logistics.

Advanced Inventory and Supply Chain Management

Contributed Session

Chair: Ishtiak Sikder, North Carolina State University, Raleigh, NC, United States

1 - An always feasible multi-period sourcing and mixing model with inventory considerations

Brian Schaefer, SimpleRose, St. Louis, MO, United States

We developed a linear, mixed integer mathematical optimization model expected to yield savings in freight cost of 6%, or $70,000 annually, for a food company. We formulated the model such that it will always return a feasible solution to the customer by using soft constraints, which are assigned a penalty factor in the objective function. The user can vary the penalty factors to prioritize certain outcomes that they desire.

Inputs to the model include a 12-month forecast for raw materials, supplier characteristics, and capacity and safety stock constraints at the production plants. Binary decision variables are used to determine which production facility each supplier should ship their raw materials. Continuous decision variables are used to determine which mix of products should be used each month as well as to track the deviations from the target values for the soft constraints. The model is constructed using Python and solutions within 1% of optimal can be found in under five minutes for 25 suppliers, 4 production facilities, 2 product types, and 12 time periods.

2 - Risk Aversion in a Data-Driven Multi-Period Inventory Control Problem

Xianghua Jiang, National university of Singapore, Singapore, Singapore, Zhisheng Ye, Loon Ching Tang, Xun Zhang

We study the multi-period risk-averse inventory control problem in a data-driven setting. In this problem, a risk-averse retailer makes periodic decisions on inventory levels based only on historical demand observations without full knowledge of the demand distribution. We adopt the popular nested formulation for risk-averse programs to formulate this multi-period problem and its data-driven counterpart under a coherent risk measure. Our objective is to study the sample complexity bound such that with high probability, the data-driven policy is near-optimal, i.e., the relative error of risk under the data-driven policy compared with the optimal risk is arbitrarily small. Analysis of this problem is inherently challenging, because the multi-period nature requires solving the risk-averse program and its data-driven version recursively backward in time, while the (empirical) risk-to-go functions in this process do not have closed-form derivatives for most risk measures, which renders existing first-order methods for the risk-neutral newsvendor model invalid. In this study, we develop a zero-order framework to establish the complexity bound on sample sizes to guarantee near-optimality of the data-driven policy with given accuracy levels. Instead of using first-order derivative information on the risk-to-go function, our analysis directly examines the class of functions that underpin each cumulative risk function and derives maximum inequalities for this functional class by computing the covering numbers. Finite-sample complexity bounds are then used to establish asymptotic properties of the estimated risk, including consistency and convergence rate. To speed computation, we propose an approximation scheme to obtain a modified data-driven inventory policy.

3 - A Clustering-based Matheuristic Approach for A Two-stage Production and Inventory Planning Problem with Family-based Setups

Jiawen Cui, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, 110819, Shenyang, China, People's Republic of, Lixin Tang, Gongshu Wang

This study investigates a two-stage production and inventory planning problem with family-based setups. In the first stage, raw materials are processed into semi-finished products, which are then transformed into final products during the second stage. Products with similar characteristics are grouped into families during processing, allowing them to share the family-based setup. The study considers different grouping rules for each stage. A linear programming model is established to address this problem. In large-scale instances, the problem becomes computationally challenging to solve due to the combination of different family groupings across stages and delivery time windows of orders. To tackle this complexity, we propose a clustering-based matheuristic approach. By grouping orders with similar delivery time windows into clusters, we can significantly reduce the total number of orders and get a relaxation of the problem. This reduced-size problem is easier to solve and a lower bound can be found. To refine the solution, we apply a matheuristic algorithm to adjust the incumbent solution values, thereby approximating the solution to the original problem. We also apply the well-known relax-and-fix heuristic to quickly obtain feasible solutions on large instances. Extensive computational experiments are conducted to evaluate the effectiveness of the model and the approach. Experimental results show that the combination of this clustering-based approach and relax-and-fix is highly effective, consistently yielding promising solutions.

4 - Optimal Production and Inventory Decisions for End of Life Products

Ishtiak Sikder, North Carolina State University, Raleigh, NC, United States, Russell King

The typical life cycle of a given product can usually be divided into three distinct phases based on market demand. The initial ”ramp-up” phase would see an upward increase in product demand upon market launch. A steady-state phase then ensues which covers the majority of the product life when demand is stable. The End-of-Life (EOL) phase comes last when demand would start to decline and eventually reach a value of zero with said product line being discontinued.

Throughout all three phases manufacturers run production cycles to produce lot sizes of their product and meet current market demand. This demand is expected to be sporadic during the EOL phase and as such running production cycles throughout the entire phase can drastically increase production and inventory costs. In this paper we propose an optimization model to find a time limit during the EOL phase by when it would be economically optimal to discontinue a given product line. An opportunity cost for the rest of the EOL phase is assumed under the convex cost function being minimized. A linear decrease in demand is assumed with extensions considered for non-linear demand trends, namely convex and concave.

Advancements in Grocery Retail Operations

Contributed Session

Chair: Sunil Chopra, Northwestern University

1 - A Multi-Echelon Framework for Ordering Prepared Items in Grocery

Andy Chen, Afresh Technologies, San Francisco, CA, United States

Grocery stores often transform ingredients, such as whole fruit or meat subprimals, into prepared items, such as fruit salads or cut steaks. In recent years, the popularity of these items have continued to grow. Today, in-store prepared items can comprise up to 30% of total sales depending on the department. However, since data representing these transformations is limited, ordering their ingredients adds complexity to the ordering process.

We present a multi-echelon framework for representing in-store prepared items in a full ML-OR ordering pipeline. Providing optimal ordering decisions for single items requires understanding factors such as item inventories, floor capacities, and shelf lives. These concepts do not immediately generalize to a multi-echelon framework; for example, items may change in perishability once they are cut. We discuss how these concepts can be adapted and reimagined in the multi-echelon context to serve optimal ordering of ingredients. We then discuss empirical results from implementing this framework at scale, impacting 2% of all produce ordered in the United States.

2 - Sales Elasticity and Merchandizing Standards In Grocery

Randy Jia, Afresh Technologies, San Francisco, CA, United States, Emily Meigs

The prevailing assumption in the grocery business is that shelf fullness is essential - that fuller shelves lead to more sales. Furthermore, grocers also assume that the prominence (type, location, etc.) of the display also influences how well a particular item sells. For example, “promotional” items may be placed in a special “front of store” display that is expected to drive additional sales. While the assumptions surrounding these merchandising decisions are intuitive and completely reasonable, unfortunately, they may lead to over-ordering and over-stocking if applied too liberally. Not only does this lead to food waste, a growing global concern as upwards of 30% of fresh produce is being thrown away in U.S. grocery stores, but this cuts into profits and harms the grocer’s bottom line. In this work, we partner with our U.S. grocery store customers, and use actual sales and merchandising data to study the empirical effect of merchandising standards on sales and food waste. Of particular interest is measuring the elasticity of demand with respect to factors such as display size and shelf fullness. We leverage our data-driven insights to determine and recommend best practices on merchandising standards for our customers, reducing food waste and increasing their financial performance.

3 - A Cut Above: Representing and Recommending on Complex Cutting in Grocery Stores

Mark Velednitsky, Afresh Technologies, Bothell, WA, United States

Meat departments in grocery stores undertake significant in-store preparation, involving the transformation of large meat chunks (sub-primals) into retail cuts for customer sale. However, this process presents numerous challenges for effective inventory management.

Foremost among these challenges is the sheer variety of possible "cutting plans" — different methods for dividing a sub-primal into retail cuts. Even when executing identical cuts, different meat managers may yield varied results based on their individual skill levels. Moreover, the act of cutting the sub-primal transforms it from a storable entity into a set of retail cuts with limited shelf life. Conversely, labor constraints necessitate careful consideration, as only a finite amount of cutting can be accomplished each day.

In this presentation, we outline a comprehensive solution for managing the complexities of in-store meat cutting. Beginning with the development of robust data models to represent diverse cutting plans, our approach culminates in a system that provides actionable production planning recommendations. Ultimately, our system not only maintains sales rates but also achieves a remarkable waste reduction of over 10%.

4 - A “Smart Predict, then Optimize” application to Multiproduct Pricing Problem

Matias Marcos, Universidad Adolfo Ibañez, Concón, Chile, Luis Aburto

One of the primary activities in the retail industry involves obtaining the demand for various products and calculating daily prices, which is known as Multiproduct Pricing Optimization Problem. The significance of this issue lies in estimating both own and cross-price elasticities. However, due to incomplete information regarding external and internal factors affecting demand, biases and endogeneity issues arise. Consequently, under or overestimated elasticities lead to erroneous pricing decisions, significantly impacting retailer sales.

To address this challenge in the predictive phase, various approaches in the field of Sequential Learning Optimization (SLO) have been explored, including different types of regressions and machine learning models. Following the training of predictive models, the estimated demand is utilized as an input coefficient in the objective function of the pricing optimization problem. Despite the potential for accurate predictions, price decisions often tend to be overestimated compared to values observed in competitive price markets. Therefore, this research focuses on a novel and contemporary paradigm known as Integrated Learning Optimization (ILO) or End-to-end Learning. In this approach, predictive models are trained to obtain better decisions. A significant contribution in this realm is "Smart Predict, the Optimize" (SPO), which emphasizes minimizing a loss function oriented towards optimization.

Our methodology aligns with the SPO framework, and its performance is compared with other two-stage approaches. Leveraging a database containing prices and demand for different orange juices, our preliminary results indicate a robust result in sales between 4.18% and 9.57% respect to overestimated sequential models.

Key words: Pricing, Retail, Integrated Learning Optimization.

5 - Fast-Food Stores with a Drive-Through Recovered Post-Pandemic; Stores Without DiD Not

Sunil Chopra, Northwestern University, Evanston, IL, United States, Partha Mishra, Ioannis Stamatopoulos

We document a profound, permanent change in the US fast-food consumer demand after the COVID-19 pandemic. In short, after a big pandemic slump, visits to drive-through stores almost recovered to pre-pandemic levels, but visits to non-drive-through stores stayed permanently suppressed. We use store-visit data between 2018 and 2022 from McDonald's, Starbucks, and Dunkin' Donuts, accounting for about 10% of all US fast-food stores. Comparing December 2019 to December 2022, average monthly visits to drive-through stores changed by a moderate -4.43% (CI: [-6.46%, -2.40%]). Meanwhile, non-drive-through-store visits changed by a massive -48.14% post-pandemic (CI: [-52.33%, -44.17%]). Consistent with drive-through usage being the operating mechanism, this differential recovery pattern was driven by a 9.36% increase in short-duration visits at drive-through stores (CI: [7.15%, 11.55%]). These results' magnitudes survive a more thorough difference-in-difference analysis as well as matching on store observables, and their statistical significance survives placebo inference. For perspective, the effects we document are analogous to a migration of 25% of all Starbucks' customers and 50% of its total revenue from non-drive-through stores to drive-through stores.

Frontiers in Data-driven Revenue Management

Invited Session

Revenue Management and Pricing

Chair: Chonghuan Wang, Massachusetts Institute of Technology, Cambridge, MA, United States

Co-Chair: Tu Ni, Harvard Business School, Boston, United States

Co-Chair: Tu Ni, Harvard, Boston, MA, United States

1 - Mitigating the Spiral Down Effect: Online Learning Under Branded Fare Structure

Lan Wu, National University of Singapore, Singapore, Singapore, Changchun Liu, Chung-piaw Teo, Xun Zhang

In the dynamic landscape of airline revenue management, accurately predicting customer behavior and adjusting ticket-selling strategies in response to fluctuating demand is critical. Traditional models often overlook intricate customer buy-down patterns, resulting in a detrimental downward spiral of revenue. Furthermore, the assumption prevalent in much of the existing literature—that arrival rates and purchasing probabilities are known a priori—is rarely practical. This study combines the adjusted fare concept with the Bayes Selector algorithm to create an innovative approach for optimizing airline ticket-selling strategies under a mixed fare structure. By dynamically adjusting fare structures based on purchase probabilities and expected profits, and utilizing the probabilistic estimates and adaptability of the Bayes Selector algorithm, this integrated methodology enables airlines to dynamically refine their seat allocation strategy for maximum profitability. Our findings show that constant regret is attainable for the problem under the independent differentiated product demand setting. More interestingly, we establish a logarithmic regret bound in the case of a mixed fare structure, where tickets are priced based on the inclusion or exclusion of additional services, such as checked baggage, seat selection, meals, and flight changes or cancellations. Furthermore, we illustrate the practical application of our approach through extensive simulation and a case study under a real-world airline revenue management scenario. This study concludes that by learning and adapting to the nuances of customer behavior, airlines can significantly enhance their revenue management capabilities, leading to more accurate demand estimation and seat allocation strategies in alignment with the existing environment.

2 - Reinforcement Learning for Intensity Control: An Application to Choice-Based Network Revenue Management

HUILING MENG, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Ningyuan Chen, Xuefeng Gao

Intensity control is a class of dynamic optimization problems featuring a continuous-time horizon and a discrete state space. Many well-known problems in Operations Research including queueing control and dynamic pricing/assortment in revenue management fall into this category. To apply reinforcement learning (RL) as a computational framework to intensity control, the major obstacle is the continuous-time horizon, as RL is mostly developed for discrete-time MDPs. Naïve uniform discretization of the time horizon is typically used, without a clear understanding of the stability, convergence or computational trade-off of such discretization. In this study, we propose to use the intrinsic discretization provided by the realized jump process and adapt RL algorithms to the continuous-time intensity control problems. By focusing on the choice-based network revenue management as a case study, we theoretically analyze the framework and develop the corresponding policy evaluation (Monte Carlo and TD), policy gradient, and Actor-Critic algorithms. Our approach is computationally efficient and does not have discretization errors compared to naïve discretization when the function approximations are chosen properly. In the numerical experiments, we show the strength of our approach compared to a number of benchmarks in the literature, including choice-based deterministic linear programming and approximate dynamic programming.

3 - From Data to Donations: Optimal Fundraising Campaigns for Non-Profit Organizations

Zhengchao Wang, Imperial College Business School, London, United Kingdom, Heikki Peura, Wolfram Wiesemann

Non-profit organizations play a crucial role in mitigating social problems around the world, but often rely on raising funds from donors through costly campaigns for their financial viability. We collaborate with a major international charity to develop and test a data-driven approach to improve the targeting of their campaigns to boost net revenue. We develop novel dynamic clustering approaches, based on the amount of historical donation data available, to learn donors' preferences among campaigns for different causes, estimate donation probabilities, and inform customized campaign strategies. Besides showing the value off this approach theoretically, we demonstrate its effectiveness empirically using both synthetic and real data from the partner organization. Our approach significantly increases net revenues by improving the speed and accuracy of estimating donor campaign preferences, thus demonstrating the potential for data-driven approaches to improve the success of non-profit fundraising campaigns.

4 - Order Stacking in On-Demand Delivery Platforms

James Scott, Duke University, Durham, NC, United States, Bora Keskin, Robert Swinney

Food delivery platforms can "stack" orders together and assign them to a single driver to pick them up and deliver them sequentially. Using a theoretical model in which each entity participates only when it is rational for them to do so, we investigate the impact of order stacking on customers, drivers, and the platform.

5 - Data-Driven Knowledge Transfer in Batch Q* Learning

Wenbo Jing, New York University, New York, NY, United States, Elynn Chen, Xi Chen

In data-driven decision-making in marketing, healthcare, and education, it is desirable to utilize a large amount of data from existing ventures to navigate high-dimensional feature spaces and address data scarcity in new ventures. We explore knowledge transfer in dynamic decision-making by concentrating on batch stationary environments and formally defining task discrepancies through the lens of Markov decision processes (MDPs).

We propose a framework of Transferred Fitted Q-Iteration algorithm with general function approximation, enabling the direct estimation of the optimal action-state function Q* using both target and source data. We establish the relationship between statistical performance and MDP task discrepancy under sieve approximation, shedding light on the impact of source and target sample sizes and task discrepancy on the effectiveness of knowledge transfer. We show that the final learning error of the Q* function is significantly improved from the single task rate both theoretically and empirically.

Electricity Market Pricing focusing on the impact of uncertainties and competition on day-ahead market pricing efficiency

Invited Session

Revenue Management and Pricing

Chair: Subhojit Biswas, Texas A&M University, College Station, TX

1 - Analyzing Day-Ahead vs. Real-TIME Price Mismatch and Mitigating Risks

Subhojit Biswas, Texas A&M University, College Station, TX, United States, Bahar Cavdar, Alfredo Garcia, Joseph Geunes

Day-ahead markets for electrical power allow participants to reserve capacity for the following day, while real-time markets provide immediate pricing based on real-time supply and demand conditions. Renewable energy sources such as wind and solar have injected substantial uncertainty and complexity into energy markets because of their dependence on unpredictable weather and environmental factors. This dynamic has given rise to apparent arbitrage opportunities resulting from differences between day-ahead and real-time prices. Market participants are increasingly seeking to harness these opportunities to optimize energy storage and trading strategies, but the inherent risks associated with these strategies are not well understood. We analyze prior industry data and characterize the degree of mismatch between day-ahead and real-time prices. We then propose a model that uses risk measures to explain price differences and quantify risk-related costs. By investigating the dynamics of day-ahead and real-time prices, we propose strategies that may help market participants navigate the inherent uncertainties stemming from renewable energy variations and the associated system disruptions.

2 - Electricity Market-Clearing with Extreme Events

Tomas Tapia, Johns Hopkins University, Baltimore, MD, United States, Yury Dvorkin

Extreme events threaten power network operations, causing beyond-design failures, abrupt variations, and supply interruptions. Existing market designs fail to internalize and provide a complete risk assessment for extreme and rare events. Efficiently maintaining the reliability of renewable-dominant power systems during extreme events requires co-optimizing system resources while differentiating between large/rare and small/frequent deviations. To address this research gap, we propose a new approach using novel developments in Large Deviation Theory (LDT) integrated into chance-constrained OPF models (LDT-CC OPF). This approach aims to efficiently manage the uncertainties associated with extreme events by offering a reliable and computationally tractable solution, capable of producing a competitive equilibrium. Moreover, to improve preparedness for extreme events, we integrate extreme event statistics endogenously via including LDT-CC to model and price extreme events and use weighted chance constraints (WCC) to reduce its conservatism.

3 - Abscores, Managing Risk and Uncertainty in Electricity Systems Using Banking Scoring and Rating Methodologies

Alberto Lamadrid, Lehigh University, Bethlehem, PA, United States

We present a usable multi-layered framework that facilitates the implementation of data-enabled recourse actions, instead of worst-case risk management, and handles prospective decisions about the system dispatch and planning. The ABSCORES platform establishes an Electric Assets Risk Bureau, with different scores customized according to the application required. We leverage scoring and ratings methodologies from banking and financial institutions alongside current optimization methods in dispatching power systems to help system operators and electricity markets schedule resources. This approach is based on the observation that there are major discrepancies between the power scheduled by a system operator and the actual power generated/consumed. These discrepancies—exacerbated by unplanned contingencies (e.g., natural disasters)—are caused by multiple factors, including the different financial, environmental, and risk preferences of power producers, consumers, and aggregators. This presentation is made on behalf of the ABSCORES team at Lehigh, MIT, Argonne and Livermore National Laboratorie

4 - The role of forward markets in decarbonizing electricity markets

Dongwei Zhao, Argonne National Laboratory, Cambridge, MA, United States

This work studies the role of forward markets for decarbonizing electricity markets. We model and analyze the strategic behaviour of energy suppliers, inlcuding renewable energy and enegy storage operators, in both the forward market and the spot market. We build up a two-stage game-theoretic model for such strategic behaviors and compute the market equilibirum. We demonsrate how the existence of forward markets can improve market efficiency and reduce market prices. Besides, we explore how the uncertainty of renewables and the flexbility of storage can impact the marekt equilibrium.

TE17

Inventory Replenishment in Marketplaces

Invited Session

Revenue Management and Pricing

Chair: Deniz Akturk, Washington University in St. Louis, 1 Snow Way Dr, St. Louis, MO, 63130, United States

1 - Managing Inventory in a Network: Performance Bounds for Simple Policies

Deniz Akturk, Washington University in St. Louis, St. Louis, MO, United States

We consider the joint optimization of rebalancing/sourcing inventory on a graph. We focus on the lost-sales setting with customer induced relocations. Through a coupling analysis, we provide worst-case performance bounds, with tight instances, for policies commonly used in practice. We provide further insights on the performance of these policies and discuss cost regimes where they are effective.

2 - Learning and Control of Inventories and Allocations in Multi-Warehouse Multi-Store Systems

Recep Yusuf Bekci, University of Waterloo, Montreal, ON, Canada, Mehmet Gumus, Sentao Miao, Yining Wang

With ever changing market dynamics and growing supply chain networks (i.e., warehouses and stores) for large retailers, it is crucial to study the inventory replenishment and allocation decision with unknown demand under a multi-warehouse multi-store (MWMS) network. This paper proposes a novel primal-dual learning algorithm, to tackle this challenge when demand is censored. Regret analysis shows that our algorithm achieves a good regret bound.

3 - Asymptotic Optimality of Simple Replenishment Policies for A Lost-Sales Inventory System with Delivery Lead TIME and Purchase Returns

Jinzhi Bu, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Huanan Zhang, Stefanus Jasin

We study a multi-period inventory control problem with a fixed replenishment lead time and stochastic returns. Each unit of sales can be returned within a fixed return window after the purchase time, and the returned unit can be immediately used to fulfill new demands. Unmet demand in each period is lost. The objective is to find a replenishment policy that minimizes the long-run average cost. Due to the presence of stochastic returns, even the optimal policy for the system with zero lead time is already complex since we need to keep track of the volume of unreturned sales in past periods. Naturally, computing the optimal cost is numerically intractable. In this paper, we focus on analyzing the performance of two simple replenishment policies: (1) the “base-stock policy”, which orders to maintain a constant inventory level or position in each period, and (2) the “myopic policy”, which orders to minimize the expected cost for the period when the order arrives. For both systems with zero and a positive lead time, we prove that when the so-called “unreturned lead-time demand” satisfies a mild condition, both base-stock and myopic policies are asymptotically optimal as the unit lost-sales penalty cost goes to infinity. This suggests their potential use for practical implementation, especially for retail applications where the target service level is known to be very high. Our numerical results further demonstrate that, by appropriately incorporating the return processing cost and return probabilities, the empirical performances of both base-stock and myopic policies can be improved.

4 - Exact Characterization of the Jointly Optimal Restocking and Auditing Policy in Inventory Systems with Record Inaccuracy

Naveed Chehrazi, Olin Business School, SAINT LOUIS, MO, United States

We present a continuous-time stochastic model of an inventory system with record inaccuracy. In this formulation, demand is modeled by a point process and is observable only when it leads to sales. In addition to demand that can reduce the stock, an unobservable stochastic loss process can also reduce the stock. The retailer’s goal is to identify the restocking and auditing policy that minimizes the expected discounted cost of carrying a product over an infinite horizon. We analytically characterize the optimal restocking and jointly optimal auditing policy. We prove that the optimal restocking policy is a threshold policy. Our proof of this result is based on a coupling argument that is valid for any demand and loss model. Unlike the optimal restocking policy, the jointly optimal auditing policy is not of threshold type. We show that a complete proof of this statement cannot be obtained by solely resorting to the first-order stochastic dominance property of the Bayesian shelf stock distribution induced by the demand and loss process. Instead, our characterization of the jointly optimal auditing policy is based on proving that the dynamics of the shelf stock distribution constitute a (strictly) sign-regular kernel. To our knowledge, this is the first paper that characterizes the optimal policy of a complex control problem by establishing sign regularity of its underlying Markovian dynamics.

Summit - 338

Learning and Pricing in Operations Management

Invited Session

Revenue Management and Pricing

Chair: Amy Guo, UC Berkeley, Berkeley, CA, United States

Co-Chair: Zuo-Jun Shen, JD.com & University of Hong Kong, Moraga, CA, United States

1 - Learning and Collusion in Multi-Unit Carbon Auctions

Negin Golrezaei, Massachusetts Institute of Technology, Cambridge, MA, United States, Simina Brânzei, Mahsa Derakhshan, Yanjun Han

We consider repeated multi-unit auctions with uniform pricing, which are widely used in practice for allocating goods such as carbon licenses. In each round, K identical units of a good are sold to a group of buyers that have valuations with diminishing marginal returns. The buyers submit bids for the units, and then a price p is set per unit so that all the units are sold. We consider two variants of the auction, where the price is set to the K-th highest bid and (K+1)-st highest bid, respectively.

We analyze the properties of this auction in both the offline and online settings. In the offline setting, we consider the problem that one player i is facing: given access to a data set that contains the bids submitted by competitors in past auctions, find a bid vector that maximizes player i's cumulative utility on the data set. We design a polynomial time algorithm for this problem, by showing it is equivalent to finding a maximum-weight path on a carefully constructed directed acyclic graph.

Leveraging our offline algorithm, we design efficient online learning algorithms for bidding. The algorithms have sublinear regret, under both full information and bandit feedback structures. We complement our online learning algorithms with regret lower bounds.

Finally, we analyze the quality of the equilibria in the worst case through the lens of the core solution concept in the game among the bidders.

2 - PASTA: A General Framework for Offline Assortment Optimization

Juncheng Dong, Duke University, Durham, NC, United States, Weibin Mo, Zhengling Qi, Cong Shi, Ethan Fang, Vahid Tarokh

We investigate a class of assortment optimization problems in an offline, data-driven setting. The combinatorial nature of these problems often results in insufficient data coverage, creating challenges in designing provably effective solutions. To address this, we introduce the Pessimistic Assortment Optimization (PASTA) framework. PASTA, grounded in the principle of pessimism, can accurately identify the optimal assortment, requiring only that the offline data includes the optimal assortment under general conditions. We establish the first finite-sample regret bounds for offline assortment optimization across widely used models, including the multinomial logit (MNL), nested logit, and mixed logit models. Additionally, we derive a regret lower bound for the MNL model, proving that the framework is information-theoretically optimal. Numerical studies show that PASTA consistently outperforms existing baseline methods.

3 - Last-Iterate Convergence in No-Regret Learning: Games with Reference Effects Under Logit Demand

Mengzi Amy Guo, University of California, Berkeley, Berkeley, CA, United States, Donghao Ying, Javad Lavaei, Zuo-Jun Shen

This work is dedicated to the algorithm design in an oligopoly price competition, with the primary goal of examining long-run market behavior. We consider n firms engaging in a multi-period price competition within a partial information setting---each firm can only access its first-order feedback and lacks information about competitors---under the influence of reference effects. Consumers assess their willingness to pay by comparing the current price against the memory-based reference price, and their choices follow MNL model. We use the notion of stationary Nash equilibrium (SNE), defined as the fixed point of the equilibrium pricing policy, to simultaneously capture the long-run equilibrium and stability. With loss-neutral reference effects, we propose the online projected gradient ascent (OPGA) algorithm, where each firm adjusts the price using the first-order derivatives of its log-revenues. Despite the absence of typical properties required for the convergence of online games, such as strong monotonicity and variational stability, we demonstrate that under diminishing step-sizes, the price and reference price paths generated by the OPGA attain last-iterate convergence to the unique SNE, and thereby guarantee the no-regret learning. Moreover, with appropriate step-sizes, we prove that this algorithm exhibits a convergence rate of \tilde{O}(1/t^2) and achieves a constant dynamic regret. The asymmetry nature of reference effects motivates the exploration beyond loss-neutrality. When loss-averse reference effects are introduced, we propose the conservative-OPGA (C-OPGA) algorithm to handle the non-smooth revenue functions and show that the price and reference price achieve last-iterate convergence to the set of SNEs with the rate of O(1/\sqrt{t}).

4 - Algorithmic Decision-Making Safeguarded by Human Knowledge

Wenhao LI, Shanghai University of Finance and Economic, Shanghai, China, People's Republic of, Ningyuan Chen, Ming Hu

Commercial AI solutions provide analysts and managers with data-driven business intelligence for a wide range of decisions, such as demand forecasting and pricing. However, human analysts may have their own insights and experiences about the decision-making that is at odds with the algorithmic recommendation. In view of such a conflict, we study the problems in which humans and AI interact in the decision-making process and characterize when human knowledge adds value to AI decision-making. In this paper, we provide a general analytical framework to study the augmentation of algorithmic decisions with human knowledge: the analyst uses the knowledge to set a guardrail by which the algorithmic decision is clipped if the algorithmic output is out of bound and seems unreasonable. We show that when the algorithmic decision is asymptotically optimal with large data, the non-data-driven human guardrail usually provides no benefit. However, we point out three common pitfalls of the algorithmic decision: (1) lack of domain knowledge, such as the market competition, (2) model misspecification, and (3) data contamination. In these cases, even with sufficient data, the augmentation from human knowledge can still improve the performance of the algorithmic decision. We propose a model to capture a practical and pervasive type of human-AI interaction in the decision-making process. We derive insights on when should the human analyst follow the algorithmic recommendation. We conclude that even in the era of big data, human knowledge can still play an important role and contribute to decision-making.

On Recommendation Systems

Contributed Session

Chair: Ernan Haruvy, McGill University, Montreal, QC, Canada

1 - Music festivals and smart tourism: big data analysis from communication operators

Mengyin Li, China Conservatory of Music, Beijing, China, People's Republic of, Nan Chen, Linyan Liu, Ying Li

Festivals and special events can attract people to gather in a short time, promote the development of local tourism. It is known to have a great impact on the local community, society, economy, and culture. It also brings challenges to destination management and operation. Communication operators' big data information can real-timely, dynamically, completely and systematically record population flow routs. This paper analyzes the characteristics and population migration of music festival visitors through big data information of communication operators.It also discusses how these quantitative findings fit into tourism studies and research on public value creation by cultural industries. With festivals occupying a central position in the music industry, investigations into the data they generate hold opportunities for researchers to better understand industry dynamics and cultural impact, and for organizers, policymakers, and industry actors to make more informed, data-driven decisions. We hope our proposed methodological approach to festival data paves way for more comprehensive music festival studies and large-scale cultural event analytics in general.

2 - Graph Machine Learning to Estimate the Value of the Lower Bound of Orienteering Problems

Krystal Coleman, SUNY University at Buffalo, Buffalo, NY, United States, Rajan Batta, Prashant Sankaran, Moises Sudit

Orienteering, an international competitive sport, mirrors real-life challenges where agents must select a permutation of locations to visit to maximize their reward. The mathematical formulation of this, the Orienteering Problem (OP), has real-world applications in maintenance and tourist excursion planning. Optimal solutions can be found with a branch-and-cut algorithm. This is computationally expensive. In this study we exploit the graph properties of intermediate problems, using machine learning to predict the value of the lower bound of the OP. These predictions are fed to optimizing solvers to accelerate the solution process. Furthermore, when the OP instance is more complex or urgency is required, or both, heuristics such as ant colony optimization and local search can be employed to generate solutions. In this work our predicted lower bounds empower decision makers by providing a standard by which to evaluate heuristic solutions to the OP.

3 - Optimal Design of Bad Recommendations

Ernan Haruvy, McGill University, Montreal, QC, Canada, Yefim Roth

Using the insight that decision makers retrieve historical rank information more easily than historical payoffs, we argue and demonstrate that this behavioral pattern leaves decision makers exploitable by recommendation systems which recommend inferior actions, as long as the recommendations are correct most of the time. In a newsvendor setting, we show that experimental participants learn to follow recommendation systems which recommend the higher payoff action most of the time, even when the recommendation is on average disadvantageous.

Strategy in Mechanism Design

Invited Session

Decision Analysis Society

Chair: Rojin Rezvan, University of Texas at Austin, Austin, TX, United States

1 - Sequential Strategic Screening

Ali Vakilian, Toyota Technological Institute at Chicago (TTIC), Chicago, IL, United States

We initiate the study of strategic behavior in screening processes with multiple classifiers.
We focus on two contrasting settings: a ``conjunctive" setting in which an individual must satisfy all classifiers simultaneously, and a sequential setting in which an individual to succeed must satisfy classifiers one at a time. In other words, we introduce the combination of strategic classification with screening processes. We show that sequential screening pipelines exhibit new and surprising behavior where individuals can exploit the sequential ordering of the tests to ``zig-zag" between classifiers without having to simultaneously satisfy all of them. We demonstrate an individual can obtain a positive outcome using a limited manipulation budget even when far from the intersection of the positive regions of every classifier. Finally, we consider a learner whose goal is to design a sequential screening process that is robust to such manipulations, and provide a construction for the learner that optimizes a natural objective.

2 - Financial Networks: Modeling, Inference, and Strategy

Akhil Jalan, UT Austin, Austin, TX, United States

Financial networks help firms manage risk but also enable financial shocks to spread. Despite their importance, existing models of financial networks have several limitations. Prior works often consider a static network with a simple structure (e.g., a ring) or a model that assumes conditional independence between edges. We propose a new model where the network emerges from interactions between heterogeneous utility-maximizing firms. Edges correspond to contract agreements between pairs of firms, with the contract size being the edge weight.

We show that, almost always, there is a unique "stable network." All edge weights in this stable network depend on all firms' beliefs. Furthermore, firms can find the stable network via iterative pairwise negotiations. When beliefs change, the stable network changes. We show that under realistic settings, a regulator cannot pin down the changed beliefs that caused the network changes. Also, each firm can use its view of the network to inform its beliefs. For instance, it can detect outlier firms whose beliefs deviate from their peers. But it cannot identify the deviant belief: increased risk-seeking is indistinguishable from increased expected profits.

Finally, we model how firms can exploit information about their counterparties to gain better contract terms during iterative pairwise negotiations. In our formulation, any subset of firms can be strategic. We give a polynomial-time algorithm to find the Nash equilibria, if they exist, and certify their nonexistence otherwise. Simulations on OECD trade data between 46 large economies demonstrate that network outcomes are sensitive to these strategic negotiations.

3 - Improved Mechanisms and Prophet Inequalities for Graphical Dependencies

Vasilis Livanos, University of Chile, Santiago, Chile

Over the past two decades, significant strides have been made in stochastic problems such as revenue-optimal auction design and prophet inequalities, traditionally modeled with n independent random variables to represent the values of n items. However, in many applications, this assumption of independence often diverges from reality. Given the strong impossibility results associated with arbitrary correlations, recent research has pivoted towards exploring these problems under models of mild dependency.
In this work, we study the optimal auction and prophet inequalities problems within the framework of the popular graphical model of Markov Random Fields (MRFs), a choice motivated by its ability to capture complex dependency structures. Specifically, for the problem of selling n items to a single buyer to maximize revenue, we show that the max of SRev and BRev is an $O(\Delta)$-approximation to the optimal revenue for subadditive buyers, where Δ is the maximum weighted degree of the underlying MRF. This is a generalization as well as an exponential improvement on the $\exp(O(\Delta))$-approximation results of Cai and Oikonomou (EC 2021) for additive and unit-demand buyers. We also obtain a similar exponential improvement for the prophet inequality problem, which is asymptotically optimal as we show a matching upper bound.

Public Health Applications in Decision Analysis

Invited Session

Decision Analysis Society

Chair: Jacob Jameson, Harvard University, Cambridge, MA, United States

1 - Improving Hypertension Care Cascades and Financial Risk Protection in Low- and Middle-income Countries

Dorit Stein, Harvard University, Boston, MA, United States, Stéphane Verguet

Purpose. This research estimates the distributional financial risk protection impacts of improving hypertension management across socioeconomic groups in low- and middle-income countries.

Methods. We developed a microsimulation model using nationally-representative, individual-level survey data from 44 low- and middle-income countries. We simulated improvements in the proportion of people with hypertension on treatment up to 80%. We applied relative risk reductions to baseline CVD risk estimates for untreated individuals randomly initiated on anti-hypertensives. We estimated the proportion that experienced catastrophic health expenditure (CHE), defined as direct (inpatient out-of-pocket costs) and indirect (income loss) costs exceeding a percentage of household consumption.

Results. Without improvements in hypertension management and assuming individuals seek inpatient care after a CVD event, 7.5% (11.9%) of people living with hypertension in the bottom quintile across countries would experience CHE at a 40% (25%) threshold. With improved treatment coverage, 6.2% (10.0%) of individuals in the bottom quintile would experience CHE at a 40% (25%) threshold. Including indirect costs averted slightly greater numbers of CHE cases across all quintiles, but especially among the top quintiles that would experience larger income losses due to hospitalization. Considering socioeconomic-based disparities in care-seeking, 1.5% (40% threshold) and 2.5% (25% threshold) of individuals in the bottom quintile would experience a CHE event.

Conclusion. Equitable coverage in hypertension treatment could avert CHE cases by averting CVD cases and hospitalizations. Unequal access to inpatient care may undervalue the potential financial risk protection benefits of improved CVD prevention among the poorest who are often less likely to seek care.

2 - "Time travel" calibration: an approach to multi-cohort disease model calibration with partially observed target data

Valeria Gracia Olvera, Stanford University, Stanford, CA, United States, Fernando Alarid-Escudero, Jeremy Goldhaber-Fiebert

Implementation of health policies at different points in time can impact populations consisting of multiple birth cohorts. The effects of these policies must be estimated by accounting for differences between prior exposures and future risks for each birth cohort. A common challenge is that empirical data often does not contain each birth cohort's complete lifetime exposures, risks, and outcomes.

We propose a simulation model-based approach to estimating past cohort trends and then extrapolate future trends of incidence and mortality using only the observed portions of cohorts' lifetime data. We illustrate this approach by examining diseases related to outdoor air pollution in Mexico City. We specified a continuous-time, age-period-cohort, multi-disease system of ordinary differential equations fitted to data on age- and sex-specific all-cause and cause-specific mortality, and disease prevalence from the Global Burden of Disease Study 2019 (1990-2019) with historical information on all-cause mortality from the Mexican government (1970-1990). A sequential calibration approach was used to estimate cohort trends in the model. Calibration began with cohorts observed from birth, recovering any time trends in disease incidence and mortality for early ages. These trends inform priors on early-age incidence and mortality for subsequent calibration of earlier birth cohorts, only observed in middle ages. This process is repeated for cohorts whose first observations are at progressively older ages. Once we "time travel" as far back as there is data available, we use the calibrated trends in middle and older ages to extrapolate future trends for later ages of more recent birth cohorts.

3 - Decision science in low-resource, data-deserts: A case study in global digital health

Sarah Skye Yoden, Harvard University, Cambridge, MA, United States

More than 1,000 digital health innovations have been funded by philanthropic agencies and piloted in low- and middle-income countries with the hopes of achieving improvements in health, and financial sustainability, which is typically defined as being financially supported by domestic tax revenues and/or consumers rather than donor funds. More than 2,000 pages of guidance, and a suite of different tools, exist to guide decision-makers on identifying which digital health interventions may be cost-effective. Yet despite these available resources and the widespread piloting of digital tools, normative agencies such as the WHO have noted a paucity of rigorous published research assessing the health impacts and cost-effectiveness of digital health interventions. This talk will provide an overview of digital health in low-resource settings today, a landscape of cost-effectiveness tools developed by the World Bank and others to assess digital health tools in low-resource settings, and perspectives from governments, implementers and funding agencies outlining why these cost-effectiveness tools are rarely, if ever, used. The talk will close with reflections on 2-3 small changes, and one big change, decision scientists could make to their digital health cost-effectiveness tools to increase uptake in the global digital health community, and potentially other communities that struggle with data deserts and few financial resources.

4 - Analyzing the impact of telehealth modalities on hospital readmissions

Emad Abed, Binghamton University , Binghamton , NY, United States, Alireza Boloori, Kathy Li, Rupinder Jindal

The COVID-19 pandemic accelerated the adoption of telehealth. While telehealth solutions were used in the early period post pandemic to ensure continuity of care, many believe they are here to stay in the near future. To this end, utilizing U.S. patients' claims data, we investigate the impact of various telehealth modalities (e.g., audio-video vs. audio only) on hospital readmission rates. We establish associations between modalities of telehealth interventions and 30-day hospital readmissions, offering insights for improving patient care, healthcare delivery, and optimizing resource utilization.

Analytics in Action: Decision Excellence, Risk Modeling, and Pedagogy

Contributed Session

Chair: Michelle Song, University of Washington, Seattle, WA, United States

1 - Data-Driven Decision Excellence: Integrating Decision Analysis and Data Analytics in Business Cases for Informed Decision-Making

Alan Ferrandiz, Core Analitica LLC, Tampa, FL, United States

Originating from Harvard Business School in 1921, the concept of business cases has long provided a structured framework for evaluating strategic initiatives. As data volumes surge and data analytics technologies become ubiquitous, the conversion of raw data into actionable insights underscores the critical interaction between data experts and decision-makers.

This presentation revolves around the imperative for data professionals to effectively communicate with decision-makers throughout the process of transforming raw data into informed business decisions, specifically, on the pivotal role of grouping and aggregating raw data to create meaningful measures, and strategically select the most pertinent ones to serve as key performance indicators (KPIs), guided by their direct impact on business objectives.

Expanding on this basis, the presentation highlights the crucial role of articulating the narrative of effective business cases, starting with the delineation of precise business objectives derived from KPIs, to outline strategic initiatives aimed at achieving these objectives and a thorough numerical assessment of the associated costs and returns.

Additionally, the presentation also emphasizes the crucial role of dashboards in querying and visualizing KPIs, offering decision-makers real-time insights into organizational performance, as well as the importance of reports to effectively communicate the evolution of KPIs over time and the importance of storytelling with data in these reports.

By combining theoretical insights with practical examples, participants will develop a comprehensive understanding of the complexities associated with integrating decision analysis and data analytics into business cases. Furthermore, they will obtain practical strategies for articulating data-driven insights effectively to decision-makers.

2 - Exploring the Possible: Decision Support Using Heuristics in Stochastic Programming- Optimizing Force Structure Under Uncertainty

Aron Wing, United States Air Force Academy, Colorado Springs, CO, United States

A framework is introduced to heuristically explore a Stochastic Program's solution space between the optimist and the pessimist to provide better decision support to senior leaders. While previous work is in the field focuses on chance constraints or maintaining robust solutions, this work focuses on the overall probability that the unknown parameters, once realized in the future, will be detrimental to the solution. This work is a response to “The Case for Change, Optimizing the Air Force for Great Power Competition”, General Allvin, CSAF (Feb 2024) and “Accelerate Change or Lose”, Gen Brown, CSAF (Aug 2020). By applying this framework, Statistically Robust Non-Linear Programming/Optimization may provide meaningful analysis concerning the optimal combination of available platforms both now and for future airpower competition.

3 - A Hierarchical Approach for Risk Modeling of System Availability

Michelle Song, University of Washington, Seattle, WA, United States

Predicting part obsolescence is an important aspect of understanding system availability. Naval and defense industries have long-lived systems where accurate prediction of system availability is critical to fleet sustainment and system health and reliability. The data used in obsolescence prediction is focused on the part-level and the lack of subsystem-level data makes it difficult to leverage machine learning techniques to determine relationships between parts and systems. A new approach is needed to overcome the challenging characteristics of obsolescence or availability data. A hierarchical system availability logic tree (H-SALT) leverages the structure of reliability block diagrams (RBD) and fault trees (FT) to mathematical model system availability. A system availability tree is created from an existing RBD. Then the tree is analyzed using a top-down successive Boolean substitution method, which eliminates all intermediary subsystems between individual parts and the overall system. This method overcomes the issue of data scarcity and allows system-level availability to be determined using only part-level obsolescence data. A minimal cut set is used to determine the set of groups of parts and/or subsystems that will cause the overall system to become unavailable. H-SALT determines both system-level availability and the parts and/or subsystems that are critical to overall system availability.

Supply Chain Learning and Sourcing

Contributed Session

Chair: Xin Xu, Shanghai Jiaotong University, Shanghai, N/A, China, People's Republic of

1 - The Formation Mechanism of Internal Bullwhip Effect: Evidence from Chinese Manufacturing Enterprises

Yi Yang, College of Economics and Management, China Agricultural University, Beijing, China, People's Republic of, Jianjun Lu, Jiawei Xu

The bullwhip effect not only occurs between upstream and downstream enterprises, but also exists within a single enterprise, which poses a great challenge to the orderly production and distribution. This study introduces an intra-firm perspective to investigate the impact of enterprise management styles and operational behaviors on internal bullwhip effect. Using a survey data from 304 Chinese manufacturing enterprises, the result showed that demand information distortion, order batch processing and rationing game can amplify the effects of IBE. Furthermore, although good management practices at the organization, process and information levels cannot directly diminish IBE, it can have an effect on IBE through the indirect effect of poor operational behavior. According to the fsQCA analysis, we obtained three configurations of basic preconditions that lead to high IBE. Finally, we discussed the implications of the research findings from both theoretical and practical dimensions.

2 - Financing and Sourcing Model Under Quality Improvement: Credit Guarantees and Equity Financing

Cheng-Feng Wu, National Taipei University, Taipei, Taiwan

This study discusses a financing and sourcing model under quality improvement in a two-echelon supply chain, utilizing Stackelberg game theory. It aims to identify the optimal sourcing strategy for brand manufacturers adopting either buyer credit guarantees or equity financing when considering supplier quality improvement. Brand manufacturers facilitate suppliers in acquiring operational funds for production and quality improvement, aiming to maximize the efficiency of supply chain operations. Improvements in production and quality by suppliers not only enhance their operations but also assist the end market, thereby strengthening the competitiveness of the supply chain. However, suppliers lacking funds face financial difficulties and operational risks, unable to secure bank loans independently. To resolve these financial issues, downstream brand manufacturers assist upstream suppliers by providing buyer credit guarantees or equity investments, ensuring the smooth operation of the supply chain. Findings from the results indicate that among suppliers, a self-selection mechanism allows those with superior operational performance to secure orders, while less efficient suppliers may be excluded from the supply chain. For manufacturers, the requirement to assume a higher assessment rate correlates with an increased default probability of suppliers.

3 - Joint Emission Reduction and Competition in Supply Chain

Xin Xu, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Qinghua Zhu, Wenbin Wang

The growing concern over climate change has led to heightened scrutiny of product carbon footprints, prompting collaborative efforts across supply chain entities to reduce emissions. This move aligns with regulatory measures aimed at reducing emissions across supply chains and is further bolstered by consumer demand for low-carbon products, which is driving firms to invest in greener practices. This study explores a supply chain with a supplier and two competing manufacturers under emission regulations, integrating consumer preferences for low-carbon products. It investigates both vertical collaboration in green investment between the upstream supplier and downstream manufacturers and horizontal competition among manufacturers targeting eco-conscious consumers under emission regulations. Our research delves into how market potential and regulatory constraints interact to shape the green investment along the supply chain. Until a certain market size threshold is reached, the supply chain prioritizes regulatory compliance. Beyond this threshold, there's a significant increase in joint investment, surpassing regulatory requirements. Furthermore, intensified competition in price consistently encourages green investment. However, the impact of competition on greenness varies according to market potential: it discourages green investment in contexts with low market potential but fosters more significant investment in scenarios with high market potential. We also find that information asymmetry regarding market potential reduces the supplier’s willingness to invest in green initiatives. Lastly, we emphasize the intricate environmental impact of emission regulations, highlighting how stricter regulations may lead to increased total carbon emissions, contingent upon market size.

Logistics and Network Optimization Challenges

Contributed Session

Chair: Austin Saragih, Massachusetts Institute of Technology, 70 Amherst St, Cambridge, MA, 02142, United States

1 - Execution Time Estimation for Amazon Last Mile Route Planning

Bharath Veluri, Amazon, Hyderabad, India, Duo Zheng

Amazon's logistics operations are growing significantly year over year. One of the key challenges it faces is the complexity of the "last mile" of delivery—the final stage where packages are transported from the delivery station to customers' doorsteps. To address this, Amazon is focused on creating safe and sustainable route planning and execution processes. To assist in the route planning process, accurately estimating the length and duration of delivery routes is crucial, as inaccurate estimates result in sub-optimal routes leading to poor transporter experience. In this talk, we discuss a deep learning-based solution developed by Amazon for predicting accurate execution times at different granularities.

2 - Dynamic Resilience and Risk Propagation in Copper Supply Networks: A Complex Network Analysis

QIYAN LIU, University of Michigan, Ann Arbor, Ann Arbor, MI, United States, Adriaens Peter

Copper, a critical mineral for renewable energy technologies, faces significant supply chain disruption risks due to its uneven global distribution. This research examines vulnerabilities within the copper industry's supply chain, which is highly interconnected from raw material extraction to finished goods production.

Using complex network theory, we construct a weighted, multi-tier supply chain network model at the firm level, based on real-world data from the FactSet Supply Chain Relationship database. We analyze the network's structural characteristics and employ degree-based removal scenarios to simulate risk propagation in the network, providing insights into the network's robustness and the potential for cascading failures.

Our study enriches the literature by offering a detailed firm-level analysis of the copper supply chain and employing dynamic risk transmission modeling to assess supply risks across different levels. We identify key vulnerabilities and propose strategies to enhance network resilience, such as diversfying suppliers and imporving communication channels. Through this comprehensive framework, we provide new insights into mitigating supply chain vulnerabilities in the copper industry, emphasizing the critical role of network structure and interdependencies in supply chain resilience. Our findings highlight the necessity for proactive risk management and strategic planning to ensure the stability and sustainability of the cooper supply chain in the face of global disruptions.

3 - UPS Sleeper Network: Routing and Scheduling

Ahmed El-Nashar, UPS, Alpharetta, GA, United States

UPS middle mile network plays a pivotal role in the transportation of parcels across a sequence of hubs, orchestrated by a fleet of trucks strategically stationed at depots dispersed throughout the network's expanse.

This logistical framework is designed to efficiently consolidate volume into full truckloads, with these trucks traversing between the network's locations and hubs, facilitating the seamless conveyance of truckloads from their origination points to their designated endpoints.

To optimize resource allocation and meet stringent delivery schedules, the trucks are operated by a two-driver team, commonly referred to as a sleeper team.

This operational framework encapsulates the vehicle routing and scheduling problem, wherein the primary aim is to devise a set of feasible vehicle schedules that cover the network's loads while minimizing operational costs and accounting for a set of federal regulations and operational constraints.

In this paper, a mathematical model is formulated to address an extended variant of the vehicle routing and scheduling problem, encompassing multiple depots while also incorporating considerations for teams assignments and load time windows.

Given the NP-hard nature of the problem under consideration and the inherent difficulty in solving large-scale instances with exact algorithms, a hybrid approach integrating meta-heuristics and exact methods is proposed. This approach seeks to leverage the runtime enhancements afforded by meta-heuristics while simultaneously harnessing the solution quality improvements provided by exact methods.

4 - Analyzing School Bus Electrification in Richmond, Virginia

Yi He, National Renewable Energy Laboratory, Golden, CO, United States

School buses are an essential component of the transportation infrastructure, serving as a lifeline for students across the globe. However, the widespread use of diesel school buses has raised concerns about the health impact on millions of students exposed to harmful emissions daily. Recognizing this issue, school districts worldwide are urgently seeking cleaner energy alternatives. Electric school buses emerge as an environmentally friendly and sustainable option, fostering a healthier environment for both students and communities. However, school bus electrification faces the challenges of high upfront cost, cumbersome charging management, and constraints from power grids. To help school bus operators address those challenges, this study presents a data-driven analysis for school bus electrification. This study considers a real-world school bus system in Richmond, Virginia, and develops a mathematical programming model to analyze the system design, charging strategies, and charging load profiles for the electrification scenario. The study evaluates different charging strategies based on model outcomes, aiming to optimize efficiency and effectiveness. Ultimately, this research generates electric school bus charging demand profiles under various scenarios, shedding light on the feasibility and implications of transitioning to electric-powered school buses.

5 - The Capacitated r-Hub Interdiction Problem with Congestion: Models and Solution Approaches

Sneha Bhatt, Management Development Institute, Gurugram, India, Sachin Jayaswal, Ankur Sinha

We study the r-hub interdiction problem under the case of possible congestion. Hub interdiction problems are modelled as attacker-defender problems to identify a set of r critical hubs from a set of p hubs, which when attacked, cause the maximum damage to the network restoration activities of the defender. In this work we consider that in addition to the routing cost, the defender also aims to minimize the congestion cost. Incorporating the congestion cost in the problem introduces non-linearity in the objective function of the interdiction problem, which makes the problem challenging to solve. To address this, we propose two alternate exact solution approaches. The first approach is an inner-approximation-based approach (IBA), which overestimates the convex non-linear objective function and provides an upper bound. A lower bound is obtained from solving the lower-level problem exactly corresponding to the upper bound solution. The upper bound is tightened using improved approximation with new points generated in successive iterations. In the second approach (referred to as SBA), the problem is reformulated as a second-order
conic program, which can be solved using an off-the-shelf solver. From our computational experiments on benchmark datasets (CAB and AP), we demonstrate the efficacy of both the proposed methods. However, IBA consistently outperforms SBA by a significant margin

6 - Modern Supply Chain Design Under Uncertainty

Austin Saragih, Massachusetts Institute of Technology, Cambridge, MA, United States

In this work, we present new three results in to design a supply chain network under uncertainty and modern lens. We first show which uncertainties we should resolve in the network. We then leverage contextual optimization from data to make data-driven facility decisions. We finally integrate policy and supply chain optimization and leverage approximation to solve this efficiently.

Technology Showcase

1 - Building Classification Prediction Models for Image Recognition using Torch Deep Learning

Kevin Potcner, JMP Statistical Discovery, San Francisco, CA, United States

Images are rich with information. Contained in the thousands of pixels within an image are patterns in shapes, colors, and textures. These features often correspond to attributes that classify images into belonging to a particular category. Advancements in deep neural network modeling have been made providing analysts with a mechanism train models on a set of images and then apply that model to new images to predict the categories those new images belong to.

In this presentation, a statistical scientist from JMP software will demonstrate a new add-in tool -Torch Deep Learning- in JMP to model and classify images.

2 - Building and Solving Optimization Models with SAS

Rob Pratt, SAS, Cary, NC, United States

SAS offers extensive analytic capabilities, including machine learning, deep learning, natural language processing, statistical analysis, optimization, and simulation. SAS analytic functionality is also available through the open, cloud-enabled design of SAS® Viya®. You can program in SAS or in other languages – Python, Lua, Java, and R. SAS Analytics is also equipped with AI-enabled automations and modern low-code or no-code user interfaces that democratize data science usage in your organization and offer unparalleled speed to value.

OPTMODEL from SAS provides a powerful and intuitive algebraic optimization modeling language and unified support for building and solving LP, MILP, QP, conic, NLP, constraint programming, network-oriented, and black-box models. This showcase will include an overview of the optimization capabilities and demonstrate recently added features.

Market Dynamics and Predictive Modeling

Contributed Session

Chair: Max Hill, Intel

1 - Stock Investment Strategies: Introducing SIRIF and SIRI for Enhanced Stock Return Monitoring and Trading Decisions

Dr. Jayanta Pokharel, Siena College, Latham, NY, United States

Monitoring returns through stock price prediction is a daunting task in the real world, given the multitude of non-numerical factors and the inherent noise in the market. Our current research endeavors to tackle this challenge by introducing two innovative tools: the stochastic-index-return-intensity-function (SIRIF) and the stochastic-index-return-indicator (SIRI). Utilizing the Power Law process, these tools are crafted to effectively monitor weekly index returns and assist investors in formulating trading strategies for buy-sell-hold decisions. By harnessing data from the Information Technology Sector Index of the S&P 500, SIRI offers valuable insights for generating trading signals, thereby streamlining investment planning and decision-making processes for investors.

2 - Beyond Accuracy: Navigating the Association between Hierarchical Forecasting and Decision Making

Mahdi Abolghasemi, University of Queensland, Brisbane, Australia

Time series forecasting often involves forecasting a collection of series that are organised in a group or hierarchical form, e.g., across geographical regions, brands, or categories. Hierarchical forecasting methods can potentially improve forecast accuracy and promise to generate coherent forecasts that are meant to be used for consistent decision-making across different levels of a hierarchy. However, it is not evident if consistent forecasts lead to consistent decisions, and if coherency is necessary for better decision-making in practice. Studies show that forecasts do not translate directly to decisions. We show how reconciled forecasts can lead to various decisions in hierarchical time series. We discuss how relaxing strict coherency of forecasts across the levels can impact the forecast accuracy and decision quality accordingly. We then propose a novel approach to generate harmonic forecasts by considering decisions across the hierarchy.

3 - Sufficient dimension reduction in vector autoregressive models for multiple time series

Jiaying Weng, Bentley University, Waltham, MA, United States, Yaser Samadi

Vector autoregressive (VAR) models are fundamental tools for analyzing multivariate time series data across diverse domains such as economics, finance, and climate studies. However, modeling high-dimensional time series data poses challenges due to the curse of dimensionality, especially when incorporating multiple time series and escalating model complexity. Sufficient dimension reduction (SDR) is a concept in statistics and machine learning aimed at finding a lower-dimensional subspace of the original feature space that preserves the relevant information for the target variable(s) or response variable(s). This paper explores the SDR in nonlinear vector autoregressive (NVAR) models, where the current state depends on multiple indices defined in past lags with an unknown relationship such that the variations in the data that are relevant to predicting the target variable(s) are retained, while irrelevant variability is removed or minimized. We propose a novel time series martingale difference divergence matrix (TS-MDDM) approach tailored for non-sparse estimation, albeit suitable only for low-dimensional scenarios. However, in the context of high-dimensional complexities where the dimensions grow rapidly by increasing the size of series and lag order, we design a sparse estimation procedure within our proposed MDDM method, leveraging a regularized optimization framework equipped with the LASSO penalty. We rigorously present theoretical foundations for both non-sparse and sparse estimators. Through simulations and real data analyses, we demonstrate the efficacy of our methodology in handling high-dimensional time series data within NVAR frameworks.

4 - Joint Prediction and Optimization: a Case Study of University Course Timetabling

Guisen Xue, Kent State University, KENT, OH, United States

Enhanced accuracy in demand forecasts enables practitioners to effectively strategize and optimize subsequent operations, aiming to maximize profits or minimize costs. Therefore, demand forecasting holds a pivotal position in management practices. Typically, the optimization method is used to generate decisions, while a machine learning model can predict the key parameters, such as demands, of the optimization model in advance. However, this predict-then-optimize paradigm becomes inappropriate when the predicted parameters are affected by the decision variables in optimization. In such instances, the joint prediction and optimization method is preferred for smarter decisions. This study constructs a mixed integer non-linear programming model for this framework, applicable to various real-world optimization scenarios. The focal application context is university course timetabling problem (UCTP), where factors such as assigned instructors, timeslots, and delivery methods impact estimated student course demands, determined during the optimization phase. The predict-then-optimize paradigm and the joint prediction and optimization are analyzed and compared in the UCTP in a department with multiple disciplines at a comprehensive public university. The results demonstrate the superiority of the objective over the predict-then-optimize paradigm and that of the solution complexity over other joint prediction and optimization methodologies.

5 - Modeling markets as dynamical systems

Max Hill, Intel, Ridgefield, WA, United States, Aparna Komarla

Autoregressive forecasting techniques are useful for short-term predictions but offer little guidance in unfamiliar or rapidly changing markets. Despite the growing complexity of modern market dynamics, customer purchasing behavior can be understood and anticipated if analyzed through a dynamical systems lens similar to those used to model diseases, populations, and many other physical systems. In the context of market modeling, it is helpful to think about interrelated “nodes" that could be customer or product segments. Once the nodes are defined, one can write differential equations for the size of the nodes over time as functions of customer population sizes and purchasing behavior drivers (e.g. device age, quality, price, etc. of the various products). In many cases, good estimates of the equation parameters can be obtained through global constrained optimization. While some drivers of demand are less predictable (including “black-swan” events and major technological disruptions), we will show how the likely consequences of these events can be determined more quickly than might otherwise be possible, resulting in a more rapid response or greater organizational readiness for future market changes. An implementation of this methodology is being developed at Intel and is being applied to the PC market. In this talk, we will discuss this approach, our initial results, and how the approach can be extended to other industries.

Emerging Strategies in Platform Competition and Innovation Management

Invited Session

New Product Development

Chair: Junghee Lee, University of Notre Dame, Notre Dame, IN, United States

1 - Cooperative OR Non-Cooperative New Product Development

Sara Rezaee Vessal, ESSEC Business Scchool, Paris, France, Timofey Shalpegin

In a product development project, the buyer might have some uncertainties about the characteristics or requirements of the product at the time of awarding the contract to a supplier. To include the possibility of revising and/or extending the scope of the contract, the buyer can consider coordination or renegotiation with suppliers. Our goal is to track the effect of cooperation between the buyer and the supplier on the outcome of the project. We consider three settings, with no-, partial, and full cooperation, considering sequential game with risk-neutral players and analyse their equilibrium strategies. We find that buyer's barraging power or share of cost and the development cost impact players' optimal strategy. We also study how their strategy is impacted by projects' and environment' characteristics.

2 - Access to Science in the Town Square: The Role of Social Media in Science Communication

Yang Yang, University of Notre Dame, Notre Dame, IN, United States, Tanya Tian, Brian Uzzi, Benjamin Jones

Science is increasingly communicated to the public through social media, raising significant questions about the role that social media serves in how scientific knowledge is consumed in public domains. Here, we engage in systematic investigation combining large-scale datasets and establish several core findings. First, social media massively expands the communications of science beyond mainstream media outlets. Second, despite prevailing skepticism about social media in the age of misinformation, we find that social media covers high-quality works in the domain of science. Third, in contrast to mainstream media that emphasizes eminence in the coverage of science, social media enables more diverse voices to be heard more evenly across dimensions of field, institutional and journal prestige, and gender. Lastly, at the scientist level, there is remarkable alignment between impact in social media and impact within science. Contrary to prevalent concerns about social media across domains, these findings highlight that social media presents diverse scientific communication, communicating a greater volume and range of high-quality scientific works while drawing more evenly from a broader set of voices on distinctive dimensions.

3 - Token Incentives and Platform Competition: A Tale of Two Swaps

Xiaofeng Liu, Baruch College - The City University of New York, New York, NY, United States, Wei Chen, Kevin Zhu

In the digital economy, platforms compete intensively to attract users, often using expensive subsidies. Token incentives emerge as a new incentive for crypto platforms to attract participants. In this paper, we study the impacts of cost-effective token incentives in the competition between two decentralized exchange platforms. The entrant platform, Sushiswap, launched token incentives to lure liquidity providers away from the incumbent, Uniswap, who then retaliated with its own token incentives. Our analysis shows that the incumbent's own token incentives attract more liquidity to the platform. Yet, surprisingly, the token incentives from its competitor also bring more liquidity and trade volume to the incumbent. To understand the mechanisms behind the impact, we examine the role of network effects and information diffusion. The findings of this study provide theoretical insights and practical guidelines for platform managers on the design of token incentives in platform competition.

Chair: Tianyu Pan, University of Florida, Gainesville, FL, United States

1 - Retail Investment Under Aggregate Fluctuations

Zhide Wang, Southern Methodist University, Dallas, TX, United States, Yanling Chang, Nathan Yang, Alfredo Garcia

Although local market conditions are normally considered to be the key drivers of forward-looking and strategic retail chain expansion (or contraction), broader aggregate states and their movements (i.e., aggregate fluctuations) might also be of relevance; however, the extent to which these aggregate states actually impact retail investment decisions remains unknown. This paper develops a new framework for modeling, identifying, and estimating dynamic investment games that accommodates for aggregate states. In particular, firms in our model make strategic investment decisions based on beliefs they have about the evolving aggregate state. With this novel model framework, we present a set of identification results, as well as a likelihood-based estimation methodology. We then conduct an empirical case study about fast food industry dynamics. Analysis of estimated models reveals that while aggregate states do indeed impact retail investment, these effects are heterogeneous, as some of the retail chains are noticeably more/less sensitive to the aggregate state. Furthermore, the estimated model demonstrates a connection between heightened volatility in the aggregate fluctuations and dampened retail investment. Finally, the relationship between volatility of the aggregate state and investment has the potential to further reinforce the market presence of already dominant firms.

2 - Integrating Reinforcement Learning Algorithms into Markov Decision Process for Hotel Dynamic Pricing Optimization

Aysajan Eziz, Ivey Business School, Western University, London, ON, Canada

This research article presents a novel approach for dynamic pricing in the hotel industry by integrating reinforcement learning (RL) algorithms into a Markov decision process (MDP) formulation. The model optimizes booking prices for multi-day stays, taking into account room availability and demand fluctuations. The RL algorithm helps find optimal pricing strategies, yielding higher revenues and minimizing losses during high-demand periods, as validated by computational experiments. While primarily focused on the hotel industry, the findings can be applied to other sectors with capacity constraints and variable demand, like transportation and e-commerce, providing valuable insights for dynamic pricing and revenue management.

3 - Strengthening Financial Sustainability of Community Mini-Grids: A Capacity Utilization Optimization Approach

Madhav Sharma, Indian Institute of Technology Kanpur, KANPUR, India

While community minigrids (MGs) in low- and middle-income countries (LMICs) hold promise for expanding rural electrification, ensuring their long-term financial viability remains a critical hurdle. This paper proposes a strategic framework to enhance the financial sustainability of these MGs by optimizing their capacity utilization factor (CUF). We introduce a unique approach that integrates energy-intensive processes, specifically crop processing activities (e.g., milling, drying), with periods of low CUF. This innovative approach not only increases CUF but also reduces operational costs, ultimately leading to lower tariffs for end-users. Through a comprehensive case study and rigorous analysis, we demonstrate the effectiveness of this strategy in meeting energy demands while ensuring the long-term viability of these MG systems. Our research emphasizes the crucial role of community mini-grids in fostering sustainable rural development and provides valuable insights for policymakers, practitioners, and stakeholders in the renewable energy and agricultural sectors.

4 - Information Leakage Prior to SEC Form Filings—Evidence from TAQ Millisecond Data

Weiting Hong, Yale School of Management, New Haven, CT, United States, Steven Ho, Mingrui Zhang

We investigate the stock price movements prior to the publication of publicly-listed firms' SEC form filings. By analyzing the time-stamps of all SEC form filings as well as the stock prices in the 30-minute interval pre- and post-publication, utilizing the TAQ millisecond data, we find strong evidence indicating that price movements in the 30-minute pre-announcement intervals can strongly predict the direction of the price movement for the post-30-minute interval, in that if the stocks are ranked into 5 portfolios based on the price run-up prior to filing release, the events with the highest run-up would also have the highest price increase post filing release, and vice versa (excluding form-types with directional implications, e.g., Forms 13G, will strengthen the results, though their inclusion does not invalidate the statistical significance of the overall results). Regressing pre-announcement return on buyer-initiated (classified according to Lee and Ready, 1991) minus seller-initiated trade volume fraction yields a positive and highly statistically-significant coefficient. The results are not explained away by momentum, common controls, the removal of filings potentially complicated by recent firm-specific-news, or the presence of 5-minute-interval fixed effects, and they remain after the SEC's server fix in March 2015 and after the prosecution of hackers trading on information obtained from filing agents in September 2020. To the best of our knowledge, this is the first paper that systematically documents the pervasiveness of the phenomenon by simply investigating prices in a model-free setup, though our results are also corroborated through other angles beyond prices (e.g., buyer-initiated proportions).

Computational Integer Optimization and Applications

Invited Session

OPT: Integer and Discrete Optimization

Chair: Ozge Aygul, Worcester Polytechnic Institute, WORCESTER, MA, 01609, United States

1 - Scheduling Cybersecurity Mitigations to Delay Attacker Projects

Ashley Peper, University of Wisconsin-Madison, Madison, WI, United States, Jim Luedtke, Laura Albert

We study the problem of deploying cybersecurity mitigations to delay the completion times of a set of attacker projects. Existing literature studies how to select a portfolio of mitigations subject to a budget constraint to optimally delay such attack projects, but lacks consideration of the time it takes to implement the mitigations. We assume attackers are working on their projects at the same time the defender is working to complete mitigations to delay those attacks. Our proposed model captures the importance of scheduling mitigations, since to be useful they must be completed before an attacker exploits a vulnerability. This paper introduces an integer programming model of this problem that

combines a defender's mitigation scheduling problem with the attackers' project completion problem. We consider alternative solution methods and examine the benefit of the proposed model.

2 - New Explorations in Integer Optimization for Minimal Egyptian Fraction Representations

Sepideh Sedghi, Worcester Polytechnic Institute, WORCESTER, MA, United States, Andrew Trapp

Egyptian fractions are a mathematical challenge of antiquity concerned with representing fractions as sums of reciprocals. One fundamental open question is: What is the fewest number of terms required to represent a given fraction? We propose an innovative integer optimization model to address this question. Our solution approach integrates a custom-designed Branch and Bound algorithm coupled with an exact solver for the LP relaxations. This approach ensures result accuracy through exact computation and overcomes roundoff errors encountered with traditional solvers. We incorporate a number of computational enhancements including valid inequalities to accelerate the solution process. We evaluate our model with thousands of instances and show our approach on average can quickly identify minimal representations, while demonstrating improved accuracy over traditional solvers and performance gains over alternative methods.

3 - Strategies for Dual Overhead Crane Scheduling

Deniz Nigar Yoltay, Ozyegin University, Istanbul, Turkey, Erhun Kundakcioglu

In this study, we examine scheduling algorithms for two overhead cranes operating on the same parallel tracks. Efficient scheduling of these dual cranes is crucial for improving productivity and functionality in manufacturing and logistics facilities. The problem involves tasks that need to be completed at the beginning of a planning horizon, with each task associated with a specific origin-destination pair and required time. As the cranes cannot pass over each other horizontally, conflicting assignments can lead to potential crane stops. The objective is to maximize the sum of priorities for scheduled tasks within the given timeframe.

We introduce a Dynamic Programming (DP) approach that systematically evaluates all feasible schedules. However, the computational complexity of the DP algorithm restricts its use in large-scale scheduling tasks. To overcome this limitation, we propose two modifications: Restricted Dynamic Programming (RDP) and Approximate Dynamic Programming (ADP). RDP reduces the state space at each stage, while ADP approximates upcoming crane conflicts, thereby decreasing solution time.

Finally, we propose a Time-Space Network approach, which represents crane actions across spatial locations and discrete time intervals. In this model, nodes denote location-time pairs, and arcs represent crane movements and task processing. We evaluate the performance of our algorithms across various instance sets and parameters, and our numerical studies demonstrate the effectiveness of the Time-Space Network approach.

4 - Dynamic Course Scheduling for Strategic University Scaling

Özge Aygül, Worcester Polytechnic Institute, WORCESTER, MA, United States, Shima Azizi, Andrew Trapp

Universities face significant challenges in long-term planning due to fluctuating student enrollments, changing course demands, and the need to optimize resource utilization. Traditional methods often fall short in effectively managing these complexities, leading to inefficiencies and unmet educational goals. In this study, we present a novel mathematical optimization formulation designed to assist universities in making informed decisions for long-term planning. Our approach addresses the critical need to manage course section splits and merges, enabling more effective planning over extended periods. First, we estimate major distributions and course demand for the next four years, which serve as key parameters for our model. The mixed integer optimization formulation then assigns course sections to time patterns and locations, splitting and merging sections, and allows capacity extension as necessary. This model incorporates multiple competing objectives, including minimizing the splitting of course sections, honoring faculty preferences, and reducing unused classroom space. By simulating various growth scenarios, we evaluate the impact of these factors on university scheduling. Our formulation represents the first optimization model specifically tailored for long-term student body planning in higher education. The results demonstrate how strategic adjustments can enhance scheduling efficiency and resource utilization, offering valuable insights for university administrators and policymakers. This innovative approach offers a scalable solution for universities aiming to improve planning and adapt to changing student needs.

Randomized Methods for Combinatorial Scientific Computing

Invited Session

OPT: Computational Optimization and Software

Chair: Sven Leyffer, Argonne National Laboratory, Lemont, IL, United States

Co-Chair: Dominic Yang, Argonne National Laboratory, Lemont, IL, United States

1 - Randomized Construction of Approximate Optimality Certificates for Combinatorial Problems

Dominic Yang, Argonne National Laboratory, Lemont, IL, United States

Primal algorithms for combinatorial optimization problems generally proceed by repeatedly augmenting a feasible point using a collection of moves. When this set of moves is suitably expansive enough that if we cannot find an augmenting move, we are at the optimum point, we have an optimality certificate. For select problems, such collections are well-known, for example augmenting paths in the maximum flow problem or negative cost cycles in the minimum cost flow problem. For general integer programs, there have existed several notions of optimality certificates, e.g., Groebner bases and Graver bases, but these sets are generally too large to be of practical use. In this talk, we will consider the problem of relaxing the optimality requirement of an optimality certificate and attempt to establish a weaker criterion so that the produced sets are more manageable. We will present a reinforcement learning algorithm for learning a partial construction of these larger optimality certificates adapting the classic algorithms for producing Groebner bases, Buchberger's algorithm. This method will be based on randomized variants of Buchberger's algorithm to effectively learn how to construct a manageable set of moves.

2 - Sampling-based Progressive Hedging for Large Scale Stochastic Programming

Di Zhang, University of Southern California, Los Angeles, CA, United States, Suvrajeet Sen

The Progressive Hedging Algorithm (PHA) is a cornerstone for solving large-scale stochastic programming (SP) challenges. However, its traditional implementation is hindered by several limitations, including the requirement to solve all scenario subproblems in each iteration, reliance on an explicit probability distribution, and a convergence process that is highly sensitive to the choice of the so-called “prox” parameter. This paper introduces a sampling-based PHA that aims to overcome these limitations. Our approach employs a dynamic sampling process for the number of scenario subproblems solved per iteration. The new algorithm incorporates a) an adaptive sequential sampling process for determining sample sizes, b) a stochastic conjugate subgradient method for direction finding, and c) a line-search technique to update the dual iterates. Experimental results demonstrate that this novel algorithm not only addresses the bottlenecks of the conventional PHA but also potentially surpasses its scalability, representing a substantial improvement in the field of stochastic programming.

3 - Randomization for Fiber Sampling in Discrete Optimization

Ivan Gvozdanovic, Illinois Institute of Technology, Chicago, IL, United States, Sonja Petrovic, Miles Bakenhus

We consider the problem of optimizing some (linear) objective function over lattice points in a polytope. For large, sparse, high-dimensional problems, one natural way to tackle the problem is using randomization, for example Markov Chain Monte Carlo (MCMC) algorithms, to search the feasible region. A priori, any MCMC algorithm requires a Gr\"obner or Graver basis as input in order to guarantee connectivity of the chain. These bases act as optimality certificates and are central to non-linear algebra, but are generally too difficult to compute. In contrast, lattice bases are much easier to compute using linear algebra, and their linear combinations can be used to construct the larger bases and discover new feasible points in the polytope. The main open question is how to find these combinations in order to improve upon an existing feasible solution with respect to some objective function. This talk will review recent work on using reinforcement learning and biased randomized search algorithms to explore the lattice points in a polytope. We will discuss the application of the method to discrete optimization problems. This is joint work with Miles Bakenhus and Sonja Petrovi\'c.

4 - Construction of Hierarchically Semi-Separable Matrix Representation using Adaptive Johnson-Lindenstrauss Sketching

Yotam Yaniv, Lawrence Berkeley National Lab, Berkeley, CA, United States

In this talk we present an adaptive, partially matrix-free, Hierarchically Semi-Separable matrix construction algorithm that leverages randomized sampling via matrix sketching. We focus on adaptively applying the Johnson-Lindenstrauss transform (JLT) to approximate the range of our compressible operator. This algorithm is an extension of Gorman et al. [SIAM J. Sci. Comput. 41(5), 2019] which leveraged Gaussian sketching operators. We first present theoretical work which justifies this extension via concentration bounds. Then, we discuss the implementation details of applying Sparse JLT efficiently. Finally, we demonstrate experimentally that using structured or sparse random matrices instead of Gaussians leads to a speedup of the HSS construction implementation in the STRUMPACK C++ library while maintaining similar relative error in both the parallel shared memory and parallel distributed memory settings.

Advances in Data-Driven Distributionally Robust Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Tianyu Wang, Columbia University, New York, NY, United States

Co-Chair: Henry Lam, Columbia University, New York, NY, United States

1 - Stability Evaluation via Distributional Perturbation Analysis

Jiashuo Liu, Tsinghua University, Beijing, China, People's Republic of, Jose Blanchet, Jiajin Li

The performance of learning models often deteriorates when deployed in out-of-sample environments. To ensure reliable deployment, we propose a stability evaluation criterion based on distributional perturbations. Conceptually, our stability evaluation criterion is defined as the minimal perturbation required on our observed dataset to induce a prescribed deterioration in risk evaluation. In this paper, we utilize the optimal transport (OT) discrepancy with moment constraints on the (sample, density) space to quantify this perturbation. Therefore, our stability evaluation criterion can address both data corruptions and sub-population shifts—the two most common types of distribution shifts in real-world scenarios. To further realize practical benefits, we present a series of tractable convex formulations and computational methods tailored to different classes of loss functions. The key technical tool to achieve this is the strong duality theorem provided in this paper. Empirically, we validate the practical utility of our stability evaluation criterion across a host of real-world applications. These empirical studies showcase the criterion’s ability not only to compare the stability of different learning models and features but also to provide valuable guidelines and strategies to further improve models.

2 - Hedging Complexity in Generalization via a Parametric Distributionally Robust Optimization Framework

Tianyu Wang, Columbia University, New York, NY, United States, Garud Iyengar, Henry Lam

Empirical risk minimization (ERM) and distributionally robust optimization (DRO) are popular approaches for solving stochastic optimization problems that appear in operations management and machine learning. Existing generalization error bounds for these methods depend on either the complexity of the cost function or dimension of the random perturbations. Consequently, the performance of these methods can be poor for high-dimensional problems with complex objective functions. We propose a simple approach in which the distribution of random perturbations is approximated using a parametric family of distributions. This mitigates both sources of complexity; however, it introduces a model misspecification error. We show that this new source of error can be controlled by suitable DRO formulations. Our proposed parametric DRO approach has significantly improved generalization bounds over existing ERM and DRO methods and parametric ERM for a wide variety of settings. Our method is particularly effective under distribution shifts and works broadly in contextual optimization. We also illustrate the superior performance of our approach on both synthetic and real-data portfolio optimization and regression tasks.

3 - Robust Decisions with Heavy Tailed Data: Statistics and Algorithms

Bart Van Parys, Massachusetts Institute of Technology, Cambridge, MA, United States, Bert Zwart

Most data-driven decisions formulations in the literature explicitly assume light-tailed or even bounded distributions. However, many real-world phenomena exhibit heavy-tailed distributions, characterized by rare but extreme events with may have significant impact. In this work we particular investigate a setting in which the data distribution merely has a bounded α-moment with $\alpha\in (1, 2)$. In particular this means that the variance of the data generating distribution may not any longer be bounded. In such heavy tailed setting classical approaches based on for instance the Wasserstein distance may fail due to their inherent sensitivity to outliers. Perhaps surprisingly, we show that despite that the variance may be infinite standard empirical variance formulations still retain some of their statistical efficiency properties which are well known in the $\alpha\in [2, \infty)$ regime. Finally, we indicate that a judiciously scaled Kullback-Leibler formulation is statistical efficient as well as computationally tractable.

4 - Master Surgery Scheduling Problem Considering Uncertainty in Length of Stay in Downstream Units

Nadia Lahrichi, Polytechnique Montreal, Montreal, QC, Canada, Erfaneh Nikzad

This study introduces an innovative mathematical model for the master surgery scheduling problem, a critical aspect of operating room planning at the tactical level. Failing to consider resource availability in downstream units, such as wards and ICU beds, which patients require during post-surgery recovery, can lead to impractical scheduling, resulting in surgery cancellations or premature discharge, ultimately impacting patient satisfaction. The length of stay post-surgery, both in the surgical unit and ICU, is uncertain and influences bed availability. Therefore, this study incorporates post-surgery length of stay as stochastic parameters, defined within a limited set of scenarios. A two-stage stochastic programming model is employed to address uncertainties. The results show that considering uncertainty affects surgery scheduling in the planning horizon and significantly reduces the number of canceled surgeries due to lack of capacity in wards and ICU beds. In this study, patients are categorized into different classes for each service based on their diagnoses. Additionally, to ensure that operating room time capacities are respected, patterns are generated, indicating all possible combinations of classes that can take place in the same room in one day. Furthermore, a two-phase matheuristic algorithm based on a fix-and-optimize procedure is proposed to efficiently solve the model. In the first phase of the developed algorithm, an initial solution is generated, and then in the second stage, the initial solution is improved using the fix-and-optimize approach. The results demonstrate that the proposed matheuristic can obtain high-quality solutions in reasonable time, especially when the number of scenarios is large.

Summit - 423

Recent Advancements in Accelerated Optimization

Invited Session

OPT: Global Optimization

Chair: Mikhail Bragin, University of California, Riverside, Marina del Rey, CA, United States

1 - Polyhedral Analysis of Quadratic Optimization Problems with Stieltjes Matrices and Indicators

Peijing Liu, University of Southern California, Los Angeles, CA, United States, Alper Atamturk, Andres Gomez, Simge Kucukyavuz

We consider convex quadratic optimization problems with indicators on the continuous variables. In particular, we assume that the Hessian of the quadratic term is a Stieltjes matrix, which naturally appears in sparse graphical inference problems and others. We describe an explicit convex formulation for the problem by studying the Stieltjes polyhedron arising as part of an extended formulation and exploiting the supermodularity of a set function defined on its extreme points. Our computational results confirm that the proposed convex relaxation provides an exact optimal solution and may be an effective alternative, especially for instances with large integrality gaps that are challenging with the standard approaches.

2 - A linearly convergent Gauss-Newton subgradient method for ill-conditioned problems

Tao Jiang, Cornell University, Ithaca, NY, United States, Damek Davis

We analyze a preconditioned subgradient method for optimizing composite functions $h\circ c$, where h is a locally Lipschitz function and c is a smooth nonlinear mapping. We prove that when c satisfies a constant rank property and h is semismooth and sharp on the image of c, the method converges linearly. In contrast to standard subgradient methods, its oracle complexity is invariant under reparameterizations of c.

3 - Indefinite Quadratic Programs and Complementarity Constraints by a Progressive MIP Method

Xinyao Zhang, University of Southern California, Los Angeles, CA, United States, Shaoning Han, Jong-Shi Pang

Indefinite quadratic programs (QPs) are known to be very difficult to solve to global optimality, so are linear programs with linear complementarity constraints. Treating the former as a subclass of the latter, we present a progressive mixed integer linear programming method for solving a general linear program with linear complementarity constraints (LPCC). Instead of solving the LPCC with a full set of integer variables expressing the complementarity conditions, the presented method solves a finite number of mixed integer subprograms by starting with a small fraction of integer variables and progressively increasing this fraction. After describing the PIP (for progressive integer programming) method and its various implementations, we demonstrate, via a set of computational experiments, the superior performance of the progressive approach over the direct solution of the full-integer formulation of the LPCCs. It is also shown that the solution obtained at the termination of the PIP method is a local minimizer of the LPCC, a property that cannot be claimed by any non-enumerative method for solving this nonconvex program. In all the experiments, the PIP method is initiated at a feasible solution of the LPCC obtained from a nonlinear programming solver; such a solution is always improved by PIP in the subsequent iterations. Thus, the PIP method can improve a stationary solution of an indefinite QP, something that is not likely to be achievable by a nonlinear programming method.

4 - A Machine Learning Approach for Rank-1 GMI Cuts

Berkay Becu, Georgia Institute of Technology, Atlanta, GA, United States, Santanu Dey, Qiu Feng, Alinson Xavier

Many optimization problems involve solving similar MILP instances repeatedly within a short time window. These instances typically have the same set of variables and constraint matrix but differ in objective coefficients and right-hand-side (RHS) values. Rank-1 GMI cuts are an important class of cutting-planes, being numerically stable compared to higher rank GMI cuts, which are generated from a row of the simplex tableau corresponding to a fractional basic variable. Heuristics that provide effective approximation of the (rank-1) GMI closure are not efficient enough to be implemented within a solver. RHS changes imply problem changes which prevents learning and using cutting planes from a similar instance and ensure its validity. Since rank-1 GMI cuts can be characterized by the basis and the corresponding tableau row needed to generate it, we try to learn which fractional rows produce a good cut. Our conjecture is that if two instances are very similar, in terms of objective or RHS, then the rank-1 GMI closure can be obtained approximately with the same set of bases and fractional rows. This conjecture is the motivation for using a simple k-neighborhood learning algorithm to efficiently select Gomory mixed-integer (GMI) cuts from historical data of similar instances. We generated families of instances by perturbing the right-hand-side and objective functions of MIPLIB 2017 Benchmark. On instances where cuts generated by our implementation of GMIC closure approximation improves Gurobi's performance, cuts learnt from historical data were able to reduce running time of default Gurobi by 22% on average.

Data-driven Stochastic Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Yuang Chen, Georgia Tech Shenzhen Institute, Tianjin University, Shenzhen, N/A

1 - Exploring Statistical Properties of Structured Optimal Policies Using Bootstrap Methods in Data-Driven Dynamic Programming

Yuang Chen, Georgia Tech Shenzhen Institute, Shenzhen, China, People's Republic of, Shiming Deng, Wanpeng Wang

Dynamic programming (DP) is fundamental in solving multi-period decision-making problems, where structurally optimal policies, such as the (S,s) policy in inventory control and the scheduling threshold policy in maintenance planning, are commonly used. However, analyzing the distributional properties of the estimated policy and corresponding total cost becomes challenging in the presence of unknown seasonal data. This challenge is primarily due to two factors: the recursive nature of the DP solution, which leads to error propagation, and the dependence of the estimated policy on all data samples, causing the total costs correlated. To address these challenges, we first transform the optimality conditions across multiple periods into a system of equations and apply the Z-Estimator Master Theorem to ascertain the asymptotic properties of policy parameters. Then, we introduce bootstrap methods to compute the distribution of the estimators for the policy parameters and their associated total costs, and prove the validity of these methods. Additionally, we also develop techniques for estimating the necessary sample size to achieve a specified precision in total cost estimates. Numerical studies in the contexts of inventory control and maintenance planning demonstrate that our methods outperform existing approaches in estimating statistical properties, thereby providing more reliable and accurate results.

2 - Data-Driven Contextual Inventory Policy with Censored Demand Based on Kaplan-Meier Estimators

Wanpeng Wang, Huazhong University of Science and Technology, Wuhan, China, People's Republic of

We investigate the data-driven inventory problem faced by retailers of perishable products who lack knowledge of the true demand distribution, but have historical sales data (demand censored by available stock) along with a large number of features potentially related to demand. We propose a non-parametric method named censored kernel-weights optimization (CKO) and a parametric method named censored empirical risk minimization (CERM). Both CKO and CERM integrate optimization with demand estimation using appropriate contextual Kaplan--Meier estimators. We prove that the inventory policies computed using CKO and CERM converge in probability to the true optimal policy, considering demand censoring and observed features. Additionally, we characterize the finite-sample performance bounds on out-of-sample costs. To handle scenarios with a large number of features, we develop a high-dimensional CERM (H-CERM) algorithm considering adaptive Lasso penalty terms. We prove that, as the sample data size increases, H-CERM exhibits not only policy consistency, but also model selection consistency. That is, the probability of accurately identifying the true model with the right features approaches one. Numerical experiments confirm that our proposed algorithms outperform existing methods by converging to the true optimal policies with significantly lower out-of-sample total costs. Furthermore, our H-CERM algorithm has a higher probability of selecting the right features than existing approaches.

3 - Decisional SVM with Operational Constraints

Xianghui C, Huazhong University of Science and Technology, Wuhan, China, People's Republic of, Shiming Deng

We propose a decisional classifier framework that addresses operational constraints in personalized decision-making scenarios. Unlike traditional classifiers that solely focus on accurate classification by minimizing misclassification probability, our approach, Decisional SVM (DSVM), aims to maximize(minimize) the profit(cost) of personalized decisions based on observed features. Furthermore, DSVM incorporates operational constraints commonly associated with specific decision-making processes, which are often overlooked by traditional classifiers. To accommodate both constrained and unconstrained scenarios, we develop exact mixed-integer programming models for DSVM based on observed data. We also introduce approximate linear programming models tailored for constrained and unconstrained DSVM to present a balance between profitability and computational efficiency. For unconstrained DSVM, we demonstrate the universal consistency of both the exact and approximate models in relation to the theoretically optimal cost-oriented classifier. For operationally constrained DSVM, we provide a convergence rate for the feasible region defined by empirical constraints to the true feasible region. Through experiments conducted on synthetic and real-world datasets, we compare the performance of DSVM, approximate DSVM, and SVM, and analyze the circumstances where DSVM outperforms SVM.

1 - Variable selection in convex nonparametric least squares via structured Lasso penalty: An application to Swedish electricity market

Zhiqiang Liao, Aalto University, Espoo, Finland

We study the problem of variable selection in convex nonparametric least squares (CNLS). Whereas the Lasso is a popular technique for simultaneous estimation and variable selection, its performance is unknown in nonparametric convex regression problems. In this work, we investigate the performance of the Lasso regularized CNLS estimator in a high-dimensional setting and propose new Lasso methods by considering the unique structure of the subgradients. The proposed Lasso regularization approaches are further extended to doubly penalized methods when the regression model is assumed to be semi-nonparametric. The doubly penalized approach is applied to predict the total cost of Swedish electricity distribution system operators and empirically analyze the effects of variable selection. The results from the simulation and application confirm that our proposed methods perform favorably, while generally leading to sparser models, relative to the other penalties used in the CNLS estimator.

2 - A Novel Multivariate Grey Forecasting Model with Hausdorff Fractional Derivative and Its Applications

Gazi Duman, University of New Haven, West Haven, CT, United States, Elif Kongar

This research proposes a new forecasting method called the Hausdorff fractional NBGMC(p,n), which is an extension of the original nonlinear grey Bernoulli model with convolution integral, NBGMC(1,n). The new approach incorporates the Hausdorff fractional accumulation operator, providing more flexibility. Furthermore, recurrence relation of the binomial in the discrete solution provides simpler computation due to the elimination of the Gamma function calculation. The Jaya Algorithm is also employed to optimize the parameters of this new model, enhancing its ability to adapt. To validate the model's effectiveness, a case study on forecasting electronic waste is conducted. The results demonstrate that the proposed fractional model outperforms existing grey models in terms of its accuracy and predictive capability.

3 - Theoretical Approximation Ratios for QAOA on 3-Regular Max-Cut Instances at Depth p=1

Reuben Tate, Los Alamos National Laboratory, Los Alamos, NM, United States, Stephan Eidenbenz

We generalize Farhi et al.'s 0.6924-approximation result technique of the Max-Cut Quantum Approximate Optimization Algorithm (QAOA) on 3-regular graphs to obtain provable lower bounds on the approximation ratio for warm-started QAOA. Given an initialization angle θ, we consider warm-starts where the initial state is a product state where each qubit position is angle θ away from either the north or south pole of the Bloch sphere; of the two possible qubit positions the position of each qubit is decided by some classically obtained cut encoded as a bitstring b.

We illustrate through plots how the properties of b and the initialization angle θ influence the bound on the approximation ratios of warm-started QAOA. We consider various classical algorithms (and the cuts they produce which we use to generate the warm-start). Our results strongly suggest that there does not exist any choice of initialization angle that yields a (worst-case) approximation ratio that simultaneously beats standard QAOA and the classical algorithm used to create the warm-start.

Additionally, we show that at θ=60°, warm-started QAOA is able to (effectively) recover the cut used to generate the warm-start, thus suggesting that in practice, this value could be a promising starting angle to explore alternate solutions in a heuristic fashion.

4 - Exact Recovery Guarantees for Parameterized Non-linear System Identification Problem under Adversarial Attacks

Baturalp Yalcin, University of California, Berkeley, Berkeley, CA, United States, Haixiang Zhang, Javad Lavaei

In this work, we are interested in solving the system identification problem for parameterized non-linear systems using basis functions under adversarial attacks. Motivated by the LASSO-type estimators, we study the exact recovery property of a non-smooth estimator, which is a global solution to the embedded ℓ_1-loss minimization problem. First, we derive necessary and sufficient conditions for the well-specifiedness of the estimator and the uniqueness of global solutions to the underlying optimization problem. Next, we provide exact recovery guarantees for the estimator when the basis functions is bounded or Lipschitz. The non-asymptotic exact recovery is guaranteed with high probability, even when there are more noisy data than clean data. Finally, we numerically illustrate the validity of our theory. This is the first study for sample complexity analysis of a non-smooth estimator for non-linear system identification problem.

5 - New Sample Complexity Bounds for Convex Stochastic Programming Under Heavy-Tailed-Ness

Hongcheng Liu, University of Florida, Gainesville, FL, United States, Jindong Tong

We study the sample average approximation (SAA) and its simple regularized variation in solving convex or strongly convex stochastic programming problems. Under heavy-tailed assumptions and comparable regularity conditions as in the typical SAA literature, we show --- perhaps for the first time --- that the sample complexity can be completely free from any metric entropy that measures the complexity of the feasible region (e.g., logarithm of the covering number). As a result, our new bounds can be more advantageous than the state-of-the-art in terms of the dependence on the problem dimensionality.

1 - A Dynamic Coordinated Joint Routing and En-Route Charging Mechanism for Traffic Congestion Mitigation Built upon Distributed Asynchronous Optimization

Yuqiang Ning, University of Florida, Gainesville, FL, United States, Lili Du

As electric vehicles (EVs) grow in popularity, new challenges emerge regarding congestion at charging stations and on roads. Real-time traffic and charging station availability information enables travelers to make informed routing and charging decisions to avoid congestion. However, if travelers react independently to similar information, it can exacerbate congestion due to the flash crowd effect. This study aims to alleviate such problems by developing a dynamic coordinated joint routing and en-route charging mechanism (DcRC) to provide routing and charging guidance for a mix of EVs and internal combustion engine (ICE) vehicles, reducing congestion on roads and at charging stations. By considering traffic flow and charging station queueing dynamics, the DcRC is formulated as a mixed strategy congestion game with an equivalent mathematical programming model, generating equilibrium routing and charging decisions (ERCD) to mitigate the flash crowd effect and reduce traffic congestions without violating each vehicle's self-interest. To integrate the DcRC into online navigation services, an asynchronous distributed ADMM-aided Branch-and-Bound (DAB) solution algorithm is developed to efficiently solve the DcRC with hundreds of participants. The DAB decomposes the complex program into sub-problems using a customized branch and bound algorithm, and utilizes an asynchronous distributed ADMM to solve each sub-problem, leveraging individual vehicles' computing resources while sustaining resilience against vehicles' unstable computing and communication performance. Numerical experiments on the Sioux Falls network validate the DcRC's effectiveness in reducing congestions and system costs, and the DAB's efficiency in supporting real-time navigation services involving hundreds of participants with unstable performance.

2 - Evaluating Integrated Fixed-Route Transit and Microtransit System Designs with a Flexible Modeling Approach

Michael Hyland, University of California, Irvine, Irvine, CA, United States, Siwei Hu

Our research addresses a timely problem related to the design of integrated fixed-route transit and more flexible microtransit service. Specifically, we develop an agent-based simulation modeling framework to evaluate alternative integrated system designs. Unlike existing studies in the literature, our modeling approach can readily handle a wide variety of design variables. Moreover, our modeling framework provides a breadth of performance metrics of particular interest to transit agencies, including required subsidy per transit user and employment accessibility in addition to mode share, vehicle miles traveled, and user travel time and cost metrics. Our modeling framework includes (i) a logit mode choice model to capture endogenous demand for public transit, (ii) a supernetwork model with fixed-route transit, microtransit, and pedestrian infrastructure layers and a pathfinding algorithm to capture multi-modal path choice, and (iii) a mobility-on-demand fleet simulator, FleetPy, to capture the supply-demand dynamics of microtransit service. We illustrate the capabilities of the modeling framework by analyzing integrated system designs that vary the following design parameters: fixed-route frequencies and microtransit fleet size, service region structure, virtual stop coverage, and operating hours. We also analyze several different fare structures for microtransit. Preliminary results suggest that microtransit service increases system costs while substantially increasing accessibility to jobs, groceries, etc. Also, preliminary results suggest that partitioning one large microtransit service region into several smaller subregions may increase the number of fixed-route transit trips. Yet, it decreases overall accessibility, mobility, and non-car mode share.

3 - Promoting Sustainable Mobility: Behavioral Interventions for Transportation Sustainability and Equity

Viswa Sri Rupa Anne, Georgia Tech, Atlanta, GA, United States, Srinivas Peeta

Communities across the U.S. face transportation-related challenges of mobility, environmental sustainability, accessibility, and equity. Low adoption of sustainable modes such as transit and active transportation modes (e.g., walking, biking) along with high private vehicle usage negatively impact mobility and environmental sustainability by increasing congestion and greenhouse gas emissions. Personalized behavioral interventions such as informational messages, nudges, gamification, and tangible incentives (e.g., coins, points) that target different socio-demographic groups to promote sustainable routes or modes can represent a promising paradigm to address these challenges. Emphasizing the need for system-level improvements, this study proposes a behavioral intervention design. Unlike traditional travel behavior approaches that rely on penalty-based approaches such as tolls or congestion pricing, the proposed interventions are sustainable as they are not limited by funding, and equitable by being accessible to all income groups. A bi-level transportation network design problem is used to model and design behavioral interventions. The upper-level consists of a multi-objective optimization model with system-level mobility, environmental sustainability, accessibility, and equity as the objectives to design the interventions. The lower level formulates a user equilibrium model for travel behavior under the interventions. The study findings offer valuable insights for policymakers, urban planners, and transportation agencies seeking to promote sustainable mobility options. They contribute to advancing knowledge on the effectiveness of behavioral interventions in achieving broader societal goals related to transportation sustainability.

4 - Statistical Inference of Traffic States Using a Generalized Bathtub Model

Zihan WAN, The Hong Kong Polytechnic Univeristy, Hong Kong, Hong Kong, Wei Ma

The modeling of traffic dynamics in various scenarios is a key component in the management of intelligent transportation systems. The bathtub model, proposed in Vickrey (1991) and generalized in Jin (2020), incorporates the Macroscopic Fundamental Diagram (MFD) to model the traffic flow in a homogeneous region, in which the travel speed is solely determined by vehicle density. This framework enables the stochastic modeling of traffic dynamics. In real life, it is often the case in which we have access only to partial observations of traffic states, which are not enough for the decision makers to get a panoramic view of the traffic system. Therefore, based on the partially observed variables, an attempt to make inference for the underlying latent variables and other unknown parameters is valuable. In our work, we develop such a stochastic variational inference framework through a hierarchy of latent and observed variables, which is useful for stochastic demand estimation and parameter calibration. For example, suppose we have a time series consisting of the counts of trips that exit a region; based on speed-density relation induced by MFD, it is possible to infer the number of trips generated inside the region, the distribution of the trip distances, and MFD parameters, which are useful to improve the performance of the traffic system.

5 - Leveraging Partnership between Public Transit and Emerging Private Modes to Enhance Accessibility Equity for Low-Income Populations

Md Gulam Kibria, Georgia Institute of Technology, Atlanta, GA, United States, Srinivas Peeta

Low-income populations, largely consisting of transit-dependent individuals, often reside in transit deserts. They face significant challenges due to the first-mile/last-mile (FMLM) problem, which hinders their ability to access transit services and other essential needs such as employment, education, healthcare, and groceries. The landscape of urban mobility is undergoing a transformative shift with the emergence of private modes like ride-hailing and micromobility. This shift presents an opportunity for synergy between these emerging modes and public transit. By providing convenient FMLM connectivity, these emerging modes can complement transit, thereby enhancing access to transit services and other essential needs. This study explores how partnerships between public transit and emerging modes can be leveraged to address the accessibility issues faced by low-income populations. It develops an optimization model aimed at maximizing access to essential needs while minimizing accessibility disparities across different zones within a city through strategic allocation of transit lines and optimal fleet sizing for emerging transportation modes. Additionally, we propose an individual-level pricing mechanism designed to ensure affordability. It considers the unique sociodemographic characteristics of each individual to offer customized pricing structures tailored to varying income levels. By making transportation services more accessible and affordable for low-income populations, we aim to alleviate the cycle of poverty perpetuated by accessibility inequities. Our findings indicate that leveraged partnerships can significantly improve access for low-income zones and reduce accessibility disparities across different geographical areas. Moreover, our proposed pricing mechanism enhances both affordability and overall utility for each individual.

1 - Network Flow Problems with Electric Vehicles

Haripriya Pulyassary, Cornell University, ORIE, Ithaca, NY, United States, Kostas Kollias, Aaron Schild, David Shmoys, Manxi Wu

Electric vehicle (EV) adoption in long-distance logistics faces challenges such as range anxiety and uneven distribution of charging stations. Two pivotal questions emerge: How can EVs be efficiently routed in a charging network considering range limits, charging speeds and prices? And, can the existing charging infrastructure sustain the increasing demand for EVs in long-distance logistics? This talk addresses these questions by introducing an EV network flow model that incorporates range constraints and nonlinear charging rates. We identify conditions under which polynomial-time solutions can be obtained for optimal single EV routing, maximum flow, and minimum-cost flow problems.

2 - Market Mechanism for Community-Based EV Charging

Minjae Jeon, Cornell, Ithaca, NY, United States, Lang Tong

In this talk, we will present our findings regarding the pricing mechanism within an energy community that includes electric vehicles. An energy community is a coalition of individual households possibly sharing their distributed energy resources, such as rooftop solar, energy storage, flexible controllable devices, and electric vehicles. We assume that this energy community is ran by a profit-neutral community operator who coordinates power transmission between the utility and the community members. The community operator incentivizes members through price signals, which they use to schedule their electric vehicles and other flexible devices, considering uncertainties in renewable generation.
We first formulated the individual scheduling problem as a stochastic dynamic programming problem with continuous state and action spaces. In general, solving such a problem is intractable but we have shown that the optimal scheduling policy follows a threshold structure based on the principle of procrastination, which delays charging EV until the last possible moment. Next, we investigated the pricing mechanism for

community operator. We formulated a community operator's central scheduling optimization, determining community energy price. We showed that these price incentives guarantee community operator breaks even. Additionally, individual community members are more profitable than staying outside of the community, following the price incentives provided by community operator.

3 - Equity and Efficiency for Congestion Pricing

Ben Rosenblad, University of Michigan, Ann Arbor, MI, United States

Advancing urban transit systems has emerged as a vital strategy for reducing vehicular congestion within city environments. Nevertheless, the underutilization of transit infrastructure is frequent, attributed to factors such as prolonged journey times and reduced comfort. To enhance transit ridership, implementing a blend of congestion pricing and transit subsidies (PS) is a widely endorsed policy. Under such a policy, within a bimodal transportation network that accounts for heterogeneous user valuation of time (VOT), at equilibrium, individuals with a VOT surpassing a set threshold invariably prefer to drive rather than utilize public transportation. Contemporary research has introduced an innovative "Credit Charge-Cum-Reward" (CCR) strategy, distinct in its capacity to sustain a state of equilibrium that fosters "mixed mode users"—commuters who interchange between transit and personal automobile use. This study conducts a comparative analysis of the two strategies, focusing on both efficiency and equity through the lens of the alpha-fair utility function, where the alpha parameter assigns the degree of emphasis on equity. Our findings suggest that in a system-optimal scenario prioritizing maximum efficiency, the phenomenon of mixed mode users is inviable. Moreover, under specific assumptions on the VOT distribution, the presence of mixed mode users is inviable, irrespective of the equity weight ascribed by alpha. Yet, we delineate VOT distribution characteristics where the existence of mixed-mode users can be conducive to enhanced equity, thus promoting a balanced and inclusive urban transportation system.

4 - Near-Optimal Mechanisms for Resource Allocation Without Money

Moise Blanchard, MIT, Cambridge, MA, United States, Patrick Jaillet

We consider a sequential resource allocation problem with strategic agents competing for a single resource at each step. Standard mechanism design approaches for resource allocation heavily rely on the use of money to align incentives. In some applications however, enforcing payments to the central planner may not be desirable. We focus on the setting when money transfers are not allowed. In this case, prior information on the agents is necessary and we suppose that the central planner has complete access to the utility distributions of the agents. Following the "promised utility" framework introduced in Balseiro et al. (2019), we first design non-monetary mechanisms for arbitrary number of agents and utility distributions, then show these are essentially optimal as the discount factor converges to one, or equivalently when the number of iterations T grows. In particular, we show that the average social welfare loss for the optimal mechanism is between 1/T and 1/T^(1/2), which corresponds respectively to smooth agent utility distributions and discrete distributions; and we can characterize the precise convergence rate for any input agent distributions.

1 - Go Green: Electric Vehicles in a Ride Hailing Platform

Xiuyi Zhang, Tsinghua University, Beijing, China, People's Republic of, Yongbo Xiao, Yue Zhang

Carbon emissions from ride-hailing are a serious concern for both ride-hailing platforms and governments. One way to address this concern is by allowing electric vehicle (EV) drivers to serve riders instead of fuel vehicle (FV) drivers. In this paper, we consider how a ride-hailing platform can introduce a green option that pairs riders exclusively with EV drivers. Specifically, we model three systems: the pooling system, where the wages for EV and FV drivers are equal; the semi-dedicated system, where the wages for EV and FV drivers are not equal; and the dedicated system, where the platform operates two separate subsystems for EV and FV drivers, and riders join one subsystem. We use the percentage of transactions fulfilled by EVs to measure the system's environmental performance and consider that the platform may face environmental constraints. We investigate the platform's decisions on prices and wages in each system and compare their performance in terms of profit and environmental impact. We show that, compared to the pooling system, the semi-dedicated system must be more environmentally friendly, but the dedicated system may not necessarily be so. We highlight the "mixing effect" of the semi-dedicated system and the "environmental concern effect" of the dedicated system and demonstrate that when riders' environmental concern is moderate, the dedicated system can achieve a "win-win" scenario.

2 - Online Operations of a Mixed-fleet Car-sharing Service System Catering Specialized Needs of the Senior

Xindi Tang, Central University of Finance and Economics, Beijing, China, People's Republic of, Xiaozhuang Li, Fang He, Yang Liu

In this study, we focus on the online operations of a mixed-fleet car-sharing service system. This system not only meets regular ad-hoc demands but also addresses the unique travel needs of seniors by integrating healthcare services. Given the increasing demand for personalized travel and an aging population, such integration is crucial. We propose a four-layer framework termed 'Chaining-Conducting-Matching-Relocation', designed to enable a closed-loop for dynamic operations management of the system. Additionally, we have developed algorithms to efficiently resolve online operational challenges. These algorithms approach problems through a learning-and-optimization method and successfully apply a model-supported implicit neural network with deep reinforcement learning for intelligent decision-making in car-sharing scenarios.

3 - Resilience and Vulnerability in Transportation Networks: A Comprehensive Review of Methods and Future Directions

Ahmad Ghasemkhani, The University of Oklahoma, Norman, OK, United States, Charles Nicholson

This research provides an overview of the current literature on the resilience of transportation networks. The role of these networks in promoting economic prosperity and societal well-being is crucial. With increasing challenges posed by natural disasters, there is a shift towards resilience-centric strategies that depart from conventional risk assessment methodologies. Studies examine how networks respond to disruptions, assessing factors such as recovery time, robustness, survivability, and the impact of aging and environmental aggressiveness on infrastructure performance. Vulnerability is often the primary focus when exploring resilience metrics, and maintenance plays a vital role in evaluating life-cycle resilience frameworks. Frameworks are evolving to accommodate network complexity, including multimodal aspects and interdependencies among diverse infrastructure systems. This research scrutinizes the role of graph theory in studying topological structures and the influence of recent advancements in data analysis and model simulation technology. It also emphasizes the importance of equitable resilience metrics and the need for a universally accepted measure of resilience. Also, this research addresses uncertainties and interdependencies, exploring approaches such as robust optimization and machine learning. Overall, the research provides a comprehensive overview of transportation network resilience analysis, highlighting key metrics, frameworks, and methodological advancements. It identifies research gaps and future directions to enhance the resilience of transportation networks.

4 - Optimal Subsidy and Pricing Decisions to Promote E-vehicle Adoption with Consideration of Range Anxiety and Market Segmentation

Lan Wang, Cal State University, East Bay, Hayward, CA, United States, Kunpeng Li

E-vehicles are a great solution to climate change by reducing carbon emissions. However, high upfront purchase cost and range anxiety are the top barriers against e-vehicle adoption. Purchasing subsidy, a government regulatory policy, has been an efficient tool in overcoming the cost barrier. In this paper, we study the roles of governments, firms and customers in promoting e-vehicle adoption for sustainable production and consumption, through subsidy, pricing and purchasing decisions respectively. We consider a market consisting of two segments of consumers who are heterogeneous in e-vehicle valuations. Both segments have range anxiety for e-vehicles. E-vehicle purchase decisions are influenced by consumers' range anxiety, preference for e-vehicles, social planner's subsidy level and retail prices for both e-vehicles and traditional vehicles. We formulate an analytical model with profit and social welfare maximization to study the impact of market segmentation, consumers' range anxiety and e-vehicles' environmental benefits on optimal subsidy and pricing decisions.

1 - Multi-Echelon Mix and Blend Optimization in Grains Supply Chain

Madhushini Narayana Prasad, Cargill R&D, Houston, TX, United States

This work focuses on designing an agile supply chain model to optimize the flow of soybean and corn grains through a multi-echelon network of facilities located in and around Brazil. The key objective of this model is multifold such as, but not limited to, maximizing the throughput utilization of facility assets, maximizing the gains from mixing and blending and minimizing the demurrage of river barges, while proactively tackling business constraints such as limited storage capacity, drying capacity and higher production volumes during the peak harvest seasons. While the problem statement seems straight-forward, the main challenge arises from blending equations being quadratic in nature rendering the problem computationally intractable. We employ novel approximation techniques to replace the large MINLP formulation with a MIP model. In addition, multiple inherent conflicting objectives such as minimizing demurrage and maximizing asset utilization are handled via goal programming approach. Finally, the proposed bi-level MILP is solved using Gurobi, to derive a 15-day tactical plan of good solution quality within reasonable computational effort.

2 - Analyzing Panama Canal Transit Equilibrium: A Complex Queueing System with Priority Pricing and Auctions

Zhongjun Ma, Tsinghua University, Beijing, China, People's Republic of, Xiwen Bai, Xi Lin

The Panama Canal serves as a crucial gateway between the Atlantic and Pacific Oceans, facilitating approximately 3% of the world's maritime trade as of 2023. With a focus on business profitability and customer satisfaction, the Panama Canal Authority (ACP) has devised complicated navigation regulations to manage the growing demands for transits, employing market mechanisms such as priority pricing and slot auctions. This study delves into the equilibrium dynamics between customers and the ACP, modeling the Panama Canal as a complex queueing system. Specifically, we establish a novel queueing system model incorporating priority rules and heterogeneous customers to characterize the market-oriented transit policies of the Panama Canal and the diverse service restrictions imposed by vessels. The model captures the decision-making process of vessels across multiple stages: 1) vessels are afforded the choice to either join the queue or opt for an alternative route; 2) vessels may compete for a limited number of booking slots for priority transits; 3) winners of the slot auction process gain priority access. Equilibrium behaviors within the Panama Canal transit are analyzed based on the queueing system model from two dimensions, including individual maximization and social optimization. We investigate strategies of shipping companies to minimize their transit costs and total transit time. Additionally, we assess the impact of market mechanisms proposed by the APC on the profitability of the Panama Canal and the overall welfare of both shipping companies and the authority.

3 - Mapping the likely routes of illicit cocaine trafficking in Costa Rica

Hashir Tanveer, The University of Alabama, Tuscaloosa, AL, United States, Nicholas Magliocca, Nicholas Freeman

Globalization of economic networks provides opportunities to expand businesses not only in the legal domain but also in illegal trafficking, especially cocaine trafficking. Despite the global reach and economic scale of cocaine trafficking, our geographic understanding of the trade remains limited. Available information aggregated at the country level leads to assumptions of homogeneous activities across countries, while information at the actor level adds complexity to generalizing and scaling up to the transnational scope. A high-resolution and more spatially disaggregated understanding of how the cocaine supply chain embeds across multiple locations and the spatial movement of traffickers is necessary. Drug traffickers prioritize established routes for efficiency but alter them to avoid capture and deliver cocaine to maximize profit and meet demands from the U.S. and EU. Limited data exists on these routes, however, qualitative and quantitative data from media reports, drug-related seizures, airstrips, aggregation/storage locations, and likely geographical drop-off locations of cocaine from South America to Costa Rica's eastern Pacific shores provide insights into drug flow. This research aims to utilize these multisource data and route optimization modeling approach to map likely transportation routes used by traffickers to deliver cocaine from the eastern Pacific side to the Atlantic side of Costa Rica. The model employs various versions with different constraints and scenarios to incorporate stochasticity. Mapping these trafficking routes helps overcome spatial limitations and provides anticipation of trafficking network spread.

4 - Understanding the ADMM algorithm via High-Resolution Differential Equations

Bin Shi, Academy of Mathematics and Systems Science, CAS, Beijing, China, People's Republic of, Bowen Li

In the fields of statistics, machine learning, image science, and related areas, there is an increasing demand for decentralized collection or storage of large-scale datasets, as well as distributed solution methods. To tackle this challenge, the alternating direction method of multipliers (ADMM) has emerged as a widely used approach, particularly well-suited to distributed convex optimization. However, the iterative behavior of ADMM has not been well understood. In this paper, we employ dimensional analysis to derive a system of high-resolution ordinary differential equations (ODEs) for ADMM. This system captures an important characteristic of ADMM, called the \lambda-correction, which causes the trajectory of ADMM to deviate from the constrained hyperplane. To explore the convergence behavior of the system of high-resolution ODEs, we utilize Lyapunov analysis and extend our findings to the discrete ADMM algorithm. Through this analysis, we identify that the numerical error resulting from the implicit scheme is a crucial factor that affects the convergence rate and monotonicity in the discrete ADMM algorithm. In addition, we further discover that if one component of the objective function is assumed to be strongly convex, the iterative average of ADMM converges strongly with a rate O(1/N), where N is the number of iterations.

Behavior Study in Supply Chain Management

Invited Session

Behavioral Operations Management

Chair: Xiaobo Zhao, Tsinghua University, Beijing

Co-Chair: Wanshan Zhu, Renmin University of China, Beijing, N/A

1 - Process Data and Lies in Supply Chain Collaboration

Fadong Chen, Zhejiang University, Hangzhou, China, People's Republic of, Zhi Zhu, Yingshuai Zhao

As remote communication via online platforms expands collaboration opportunities, it simultaneously reduces the opportunity cost of lying in information exchanges among potential supply chain partners. This study investigates the value of process data, response times (RTs) and mouse trajectories, in recognizing lies from truth-telling in online supply chain collaborations. Specifically, we consider a representative setting where a seller with private demand information sends a non-binding demand message to the manufacturer, who then decides the production quantity. Accordingly, the seller is motivated to inflate demand so that to ensure adequate supply. Our laboratory experiments demonstrate that RTs for lying are consistently longer and the Area Under the Curve (AUC) for lying is larger than those for truth-telling, unaffected by the detectability of lies or the collaboration duration. Moreover, the differences in RT and AUC between lying and truth-telling decisions increase with the seller's lying aversion. Employing machine learning, we further show that incorporating RT and mouse trajectory data significantly enhances the accuracy of distinguishing lies from truths. These findings underscore the effectiveness of process data in detecting lies in supply chain practice as well as the value of process data in capturing decision patterns for future research and management.

2 - Performance Improvement in Supply Chain Management: An Experimental Study

SHUAIKUN HOU, TSINGHUA UNIVERSITY, BEIJING, China, People's Republic of

Behavioral biases displayed by humans in decision-making can lead to either beneficial or detrimental effects on system performance. We propose a method aiming at mitigating the adverse effects of behavioral biases on system performance and promoting supply chain coordination. First, we conduct human-to-human experiments to model the behaviors of the supplier and the retailer under the buyback contract. We find that the retailer exhibits several behavioral biases, leading to non-coordinating contracts. Then we design bots to help implement buyback contracts in supply chain management: After a supplier proposes a wholesale price, the bots decide a buyback price according to coordination requirements. That is, the decision of bots makes that the game equilibrium of the supplier and the retailer in the behavioral models achieves supply chain coordination. The bots are called coordinating bots because of their purposes. We conduct human-to-human experiments of the buyback contract with coordinating bots, to understand the effect of coordinating bots on performance improvement. We find that the coordinating bots significantly improve the buyback contracts by always providing high-profit contracts thus leading to retailers ordering more. According to behavioral model analyses, the coordinating bots render the supply chain parties' profit allocation to be fairer under the buyback contract.

3 - Impact of Returns Risk in a Buyback Contract: An Experimental Study

Ao Zhuo, Renmin University of China, Beijing, China, People's Republic of, Wanshan Zhu

Manufacturers may fail to fulfill their buyback commitments within the buyback contract, thereby inducing returns risk for retailers. Furthermore, the probabilities of breaching these commitments vary among different manufacturers. Through laboratory experiment, our research aims to empirically test the impact of returns risk.

Our experimental study comprises two parts. In the first part, we conducted experiment with symmetric information of returns risk where both retailers and manufacturers are aware of buyback probabilities. The objective of this part is to examine the underlying impact of returns risk on supply chain decision-making. We observe significant mental accounting behavior among manufacturers and probability-weighting behavior among retailers.

In the second part, we focus on the scenario of asymmetric information, where manufacturers possess private information of buyback probabilities while retailers do not. The objective of this part is to test whether manufacturers indeed send signals separately based on their types, as hypothesized, and whether these signals are effectively received by retailers. Contrary to the theoretical prediction of separate equilibrium, we find that separating equilibrium is not favored when manufacturers set their contract prices. This suggests a divergence from traditional models and prompts an exploration of the underlying drivers. We posit the driver behind is mental accounting effect and we seek to uncover novel explanations for results.

Graphs and Networks: Bridging Theory and Practical Applications in Causal Inference, Experimentation, Community Detection, and Ranking Aggregation

Invited Session

Applied Probability Society

Chair: Shuangning Li, University of Chicago, Chicago, IL, United States

1 - Spectral Ranking Inferences Based on General Multiway Comparisons

Mengxin Yu, University of Pennsylvania, Philadelphia, PA, United States

This paper studies the performance of the spectral method in the estimation and uncertainty quantification of the unobserved preference scores of compared entities in a general and more realistic setup. Specifically, the comparison graph consists of hyper-edges of possible heterogeneous sizes, and the number of comparisons can be as low as one for a given hyper-edge. Such a setting is pervasive in real applications, circumventing the need to specify the graph randomness and the restrictive homogeneous sampling assumption imposed in the commonly used Bradley-Terry-Luce (BTL) or Plackett-Luce (PL) models. Furthermore, in scenarios where the BTL or PL models are appropriate, we unravel the relationship between the spectral estimator and the Maximum Likelihood Estimator (MLE). We discover that a two-step spectral method, where we apply the optimal weighting estimated from the equal weighting vanilla spectral method, can achieve the same asymptotic efficiency as the MLE. Given the asymptotic distributions of the estimated preference scores, we also introduce a comprehensive framework to carry out both one-sample and two-sample ranking inferences, applicable to both fixed and random graph settings. It is noteworthy that this is the first time effective two-sample rank testing methods have been proposed. Finally, we substantiate our findings via comprehensive numerical simulations and subsequently apply our developed methodologies to perform statistical inferences for statistical journals and movie rankings.

2 - Spectral Clustering in the Gaussian Mixture Block Model

Shuangping Li, Stanford University, Stanford, CA, United States, Tselil Schramm

Gaussian mixture block models are distributions over graphs that strive to model modern networks: to generate a graph from such a model, we associate each vertex i with a latent feature vector u_i in R^d sampled from a mixture of Gaussians, and we add edge (i,j) if and only if the feature vectors are sufficiently similar, in that <u_i,u_j> > \tau for a pre-specified threshold \tau. The different components of the Gaussian mixture represent the fact that there may be different types of nodes with different distributions over features --- for example, in a social network each component represents the different attributes of a distinct community. Natural algorithmic tasks associated with these networks are embedding (recovering the latent feature vectors) and clustering (grouping nodes by their mixture component).
In this paper we initiate the study of clustering and embedding graphs sampled from high-dimensional Gaussian mixture block models, where the dimension of the latent feature vectors d goes to infinity as the size of the network n goes to infinity. This high-dimensional setting is most appropriate in the context of modern networks, in which we think of the latent feature space as being high-dimensional. We analyze the performance of canonical spectral clustering and embedding algorithms for such graphs in the case of 2-component spherical Gaussian mixtures, and begin to sketch out the information-computation landscape for clustering and embedding in these models.

3 - Experimentation for Different Scheduling Policies on Queueing Networks: Mixed Difference-in-Q Estimators Based on the Little's Law

NIAN SI, HKUST IEDA, Hong kong, Hong Kong, Nanshan Jia, Ramesh Johari, Zeyu Zheng

In data centers, tasks are dispatched to various servers to evenly distribute the workload. When a data center considers implementing a new scheduling algorithm, it typically conducts an A/B test prior to deployment to assess the real-world impact of this new method. However, a straightforward A/B test might be interfered with so-called ``Markovian'' interference. We utilized the difference-in-Q estimator, as developed by Farias et al. [2022], and introduced mixed Difference-in-Q estimators grounded in Little's Law. We show that our A/B testing methods significantly reduce bias and variance when testing various power-of-d policies. Extensive simulations were conducted under scenarios like non-stationary arrival rates, heterogeneous service rates, and communication delays. These simulations highlight the robustness and efficacy of our A/B testing approach.

4 - Design of Panel Experiments with Spatial and Temporal Interference

Tu Ni, Harvard Business School, Boston, MA, United States, Iavor Bojinov, Jinglong Zhao

Companies constantly test new features on millions of users, but a hidden issue can skew results: interference. This happens when someone's experience depends on what others get. Ignoring this can lead to misleading conclusions.

Researchers have proposed designs that limit interference, but they can be weak when testing periods are limited. This paper offers a novel design for "panel experiments" (testing across multiple groups over time) that accounts for both interference and lingering effects from past treatments.

Our design involves two key features: "random shaking," which groups users randomly, and "balanced temporal randomization," which randomizes treatment timing within groups. We prove this design's effectiveness mathematically, develop analysis techniques, and demonstrate its superiority through simulations, including real-world ride-sharing data. Companies can potentially achieve over 50% more reliable results with the same number of users by using this new approach.

Flexibility Design and Demand Fulfillment for Service Platforms

Invited Session

Applied Probability Society

Chair: Yue Hu, Stanford University, Palo Alto, CA, United States

Co-Chair: Shixin Wang, The Chinese University of Hong Kong, Hong Kong, N/A

1 - Online Demand Fulfillment Problem with Initial Inventory Placement: A Regret Analysis

Irem Nur Keskin, Duke University, Durham, NC, United States, Alessandro Arlotto, Yehua Wei

We investigate a joint inventory placement and online fulfillment problem. At the beginning, the inventory of a single item is distributed to different warehouses. Then, at each period, an order arrives from one of the demand regions, and the decision maker makes an irrevocable decision on whether to accept or reject the order. In our model, we propose the minimum-inventory regret, a notion that includes both the selection of initial inventories and the performance of the selected fulfillment policy. We consider two state-of-the-art fulfillment policies: probabilistic fulfillment and score-based fulfillment. We prove that probabilistic fulfillment has a minimum-inventory regret that scales with the square root of the time horizon. On the other hand, we show that the score-based fulfillment policy has a minimum-inventory regret bound that is independent of the time horizon and polynomial with respect to the number of warehouses and demand regions. Our results have the following implication: the score-based fulfillment policy, when paired with offline inventory placement, outperforms probabilistic fulfillment with any inventory placement, and the performance gap increases with the time horizon.

2 - Flexibility designs for parallel server systems with general processing rates

Yuan Zhong, University of Chicago/Booth School of Business, Chicago, IL, United States, Gorkem Unlu

Process flexibility design is a central topic in operations management, but to date, all existing literature adopts a restrictive flow conservation assumption, which supposes that exactly one unit of resource capacity is required to process one unit of demand, no matter what the demand type is. We significantly relax this assumption by considering the design of sparse flexibility structures in parallel server systems with general processing rates. Our main contribution is a computationally efficient procedure that constructs, from any given system, a sparse flexibility structure with no more than m+n+min{m,n}-2 flexibility arcs, where m is the number of demand nodes and n the number of resources. We establish that in heavy traffic, our flexibility design has asymptotically optimal performance, as long as complete resource pooling can be achieved in the original system. This is joint work with Gorkem Unlu (Wayfair).

3 - Value of Sparse Structures in Dynamic Reusable Resource Allocation with Waiting

Yue Hu, Stanford University, Stanford, CA, United States, Jing Dong, Shixin Wang

We study the dynamic resource allocation problem in online service platforms featuring reusable resources, waiting space, and heterogeneous demands and resources. The service provider aims to balance the trade-off between maximizing revenue and minimizing waiting times across various demand types. For this problem, we propose a comprehensive framework to minimize the long-run average revenue loss and waiting cost by simultaneously designing the 1) flexibility structure, 2) admission control, and 3) scheduling policy. The flexibility structures are tailored to systems with varying levels of workload intensity, and the number of arcs in the network is linear in the number of resource and demand types. In these sparse networks, we show that simple static priority rules and threshold-based admission controls are asymptotically optimal in the many-server regimes. Furthermore, our proposed algorithm for designing system flexibility, along with the scheduling and admission control policies, is both easy to interpret and straightforward to implement. Numerical experiments demonstrate the effectiveness of our approach, particularly for smaller systems, in non-asymptotic environments.

4 - Online Rack Placement in Large-Scale Data Centers

Konstantina Mellou, Microsoft Research, Redmond, WA, United States, Saumil Baxi, Kayla Cummings, Alexandre Jacquillat, Rob McDonald, Ishai Menache, Marco Molinaro

This paper optimizes the configuration of large-scale data centers toward cost-effective, reliable and sustainable cloud supply chains. We formulate an integer optimization model that optimizes the placement of racks of servers within a data center to maximize demand coverage, adhere to space, power and cooling restrictions, and pace resource utilization for future demand. We also define a tractable single-sample online approximation (SSOA) approach to multi-stage stochastic optimization, which approximates unknown parameters with a single realization and re-optimizes decisions dynamically. Theoretical results provide strong performance guarantees of SSOA in the canonical online generalized assignment and online bin packing settings. Computational results using real-world data show that our optimization approach can enhance utilization and reduce power stranding in data centers. Following iterative improvements in collaboration with data center managers, our algorithm has been packaged into a software solution deployed in Microsoft's data centers worldwide. Deployment data indicate a significant increase in adoption, leading to improved power utilization, multi-million-dollar annual cost savings, and concomitant savings in greenhouse gas emissions. Ultimately, this paper constitutes one of the first large-scale deployments of a decision-making tool in data centers, contributing an interactive decision-making process at the human-machine interface.

Drift Methods for Stochastic Systems

Invited Session

Applied Probability Society

Chair: Lucy Huo, Cornell University, Ithaca, NY, United States

Co-Chair: Jim Dai, Cornell University, Ithaca, NY, United States

1 - Explicit steady-state approximations for parallel server systems with heterogeneous servers

Yaosheng Xu, University of Chicago , Chicago, IL, United States, Jim Dai

The weighted-workload-task-allocation (WWTA) load-balancing policy is known to be throughput optimal for parallel-server systems with heterogeneous servers. This work concerns the heavy traffic approximation of steady-state performance for parallel-server systems operating under WWTA policy. Under a relaxed complete-resource-pooling condition, we prove that WWTA achieves a “strong form” of state-space collapse in heavy traffic and that the scaled workload for each server converges in distribution to an exponential random variable, whose parameter is explicitly given by system primitives. Various steady-state performance measures are shown to be approximated from this exponential random variable. Instead of proving a stochastic process limit followed by an interchange of limits – a method that dominates the literature, our method works directly with a pre-limit basic adjoint relationship (BAR) that characterizes the stationary distribution of each pre-limit system.

2 - Drift method in restless bandits

Weina Wang, Carnegie Mellon University, Pittsburgh, PA, United States

Drift method in restless bandits

3 - Steady-State Convergence of the Continuous-Time JSQ System with General Distributions in Heavy Traffic

Jin Guang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Jim Dai, Xu Yaosheng

This paper studies the continuous-time join-the-shortest-queue (JSQ) system with general interarrival and service distributions. Under a much weaker assumption than the one in the literature, we prove that each station's scaled steady-state queue length weakly converges to an identical exponential random variable in heavy traffic. Specifically, we establish our results by only assuming $2+\delta$ moment on the arrival and service distributions for some $\delta>0$. Our proof exploits the Palm version of the basic adjoint relationship (BAR) approach as a key technique. Additionally, our method is applicable to the power-of-two choices.

4 - Uniform Moment Bounds for Multiclass Queueing Networks with SBP Service Policies in Multi-scale Heavy Traffic

Lucy Huo, Cornell University, Ithaca, NY, United States, Jim Dai

In Dai and Huo (2023), the authors justify that the stationary distribution of the scaled queue length vector process in multiclass queueing networks operating under static buffer priority (SBP) service policies has a product-form limit under a multi-scale heavy traffic condition. A major assumption is the moment state space collapse (SSC) property exhibited by the steady-state queue length process. In this work, we prove that the moment-SSC of scaled low-priority queue lengths holds if the moment-SSC of unscaled high-priority queue lengths holds, which has been carefully studied in the work of Cao, Dai, and Zhang (2022).

Healthcare Innovation and Collaboration

Contributed Session

Chair: Alireza Kasaie, Loyola University Chicago, Forest Park, IL, 60130, United States

1 - The Assessment of the Emergency Medical Services Workflow for Implementing An AI-Driven Stroke Detection Tool to Improve the Patient Outcomes

Alireza Kasaie, Loyola University Chicago, Forest Park, IL, United States, Michael Saban, Samie Tootooni, Dima Elissa

Identifying severe stroke patients in Emergency Medical Services (EMS) is vital, as they need advanced care only available at comprehensive stroke centers. Current stroke scales, like the Cincinnati Prehospital Stroke Scale (CPSS), often lead to patients being taken to inadequate facilities, resulting in costly and time-consuming transfers. Our long-term goal is to implement an AI-driven tool in the EMS workflow. To ensure this solution meets existing needs, our study aimed to: (1) assess the inefficiencies of existing tools, (2) conduct customer discovery to identify key stakeholders and their needs, and (3) develop a workflow incorporating an AI-driven solution for EMS.

Using the I-Corps@NCATS Value Proposition Design framework, we conducted structured interviews with individuals across stroke centers and EMS systems in the Chicagoland EMS region. We collected EMS data from 2015-2020 to evaluate CPSS-based stroke assessments retrospectively.

The sensitivity and specificity for our region were 29.4% and 98.3%, respectively, significantly lower than the literature-reported 81.1% and 51.7%. This inefficiency was confirmed by several interviewees. We identified EMS medical directors as final decision-makers, EMTs as end-users, and other stakeholders, like dispatch agencies, as influencers. We provided an EMS workflow diagram and identified where our solution could be implemented with minimal changes to existing protocols, ensuring EMTs are not overburdened.

By validating the importance of accurate prehospital stroke diagnosis and assessing potential improvements in EMS workflow, our study significantly advances the development and implementation of AI-driven solutions in EMS. This study can serve as a valuable guideline for researchers focusing on similar solutions.

2 - Hospital collaboration network foster health resilience during pandemics

Lu Zhong, Rensselaer Polytechnic Institute, Troy, NY, United States, Jianxi Gao

Understanding hospital collaboration emerges as pivotal for ensuring healthcare resilience, especially during the COVID-19 crisis time. However, existing studies are limited by the dataset and method for quantifying such collaboration. This study addresses the gap by analyzing millions of patients' electronic health records across the United States. By mapping patient visits between hospitals, we build the collaboration network among hospitals in each state, and introduce a model to simulate the dynamics of hospital burden. Using this model, we identify the key strategies that facilitate efficient collaboration to mitigate the burden of disruption from pandemics. Supported by empirical evidence and analytical insights, this study highlights the critical importance of hospital collaboration in strengthening the resilience of healthcare systems.

3 - Optimal Integration of In-Person and Telemedicine Outpatient Consultations

Aparna Venkataraman, Department of Mechanical Engineering, Indian Institute of Technology Delhi, New Delhi, India, Varun Ramamohan, Sisira Edirippulige

In the evolving healthcare landscape, optimising the concurrent delivery of in-person and telemedicine outpatient consultations in hospital settings presents a complex operations management challenge. This study introduces a discrete-event simulation analysis to optimise a rolling-horizon patient appointment schedule for telemedicine and in-person consultations for both scheduled and walk-in patients. The study considers new and follow-up in-person and telemedicine consultations, including pre-scheduled appointments and walk-ins. Specifically, we consider the following operational questions: (a) Is having separate blocks for telemedicine consultations more efficient than an integrated in-person and telemedicine consultation schedule? (b) How many slots should be reserved for scheduled appointments versus walk-ins of each type (in-person versus telemedicine)? (c) What is the optimal consultation slot duration for each consultation type? (d) Corresponding to the optimal consultation slot duration, what should be the actual consultation slot duration to be communicated to patients? These questions are answered considering the varying levels of uncertainty in consultation durations, patient no-show rates and infrastructure disruptions for in-person and telemedicine consultations. The setting we consider is that of paediatric outpatient care in a large multi-speciality hospital in urban India, and the simulation is parameterised using real-world data from this setting. Through these experiments, we provide evidence-based recommendations for the optimal integration and scheduling of telemedicine and in-person consultations, underscoring the importance of data-driven decision-making in enhancing the efficiency of patient care in a modern healthcare delivery environment.

4 - Information Sharing in Outpatient Clinic Settings

Murray Côté, Texas A&M University, College Station, TX, United States, Jon Stauffer

A perennial challenge in outpatient clinic management is efficient patient flow. This hinges on patients to fully disclose the scope of their healthcare needs in advance. However, the full scope of a patient's health concerns may not be revealed and appointments are typically selected to satisfy a single primary health concern. We surveyed patients and providers from two large outpatient practices to identify the prevalence additional health concerns and patient and provider preferences in addressing additional health concerns. Our results provide important contributions to agenda setting in outpatient care and patient/provider communication. Additionally, information sharing is essential to better designed online appointment applications, improved patient flow, and provider utilization.

Applications of Mathematical Models in Health and Public Policy

Invited Session

Health Applications Society

Chair: Suyanpeng Zhang, Northwestern University, Chicago, IL, United States

1 - Optimizing Vaccine Site Locations While Considering Travel Inconvenience and Public Health Outcomes

Suyanpeng Zhang, University of Southern California, Los Angeles, CA, United States, Sze-chuan Suen, Han Yu, Maged Dessouky, Fernando Ordonez

During the COVID-19 pandemic, there were over three million infections in Los Angeles County (LAC). To facilitate distribution when vaccines first became available, LAC set up six mega-sites for dispensing a large number of vaccines to the public. To understand if another choice of mega-site location would have improved accessibility and health outcomes, and to provide insight into future vaccine allocation problems, we propose a multi-objective mixed integer linear programming model that balances travel convenience, infection reduction, and equitable distribution. We provide a tractable objective formulation that effectively proxies real-world public health goals of reducing infections while considering travel inconvenience and equitable distribution of resources. Compared with the solution empirically used in

LAC in 2020, we recommend more dispersed mega-site locations that result in a 28% reduction in travel inconvenience and avert an additional 1,000 infections.

2 - Evaluating Co-Response Models for Crisis Calls

Veronica White, FAMU-FSU College of Engineering, Tallahassee, FL, United States, Laura Albert

A crisis call is when one or more individuals suffer from a mental- or behavioral health-related issue that may require a police response. Many police departments have introduced specially trained crisis response teams to replace the traditional police response with new response paradigms that may involve sending different or multiple types of vehicles to a crisis call. We introduce queueing models and performance measures to capture the dynamics of new response paradigms. We evaluate the queueing models using discrete event simulation with a case study based on data from Seattle, WA and we compare the crisis response to a traditional response to elucidate performance across a range of input parameters.

3 - Improving the Equity and Efficiency of Cystic Fibrosis Screening

Hussein El Hajj, Santa Clara University, Santa Clara, CA, United States, Douglas Bish, Ebru Bish

Newborn screening detects life-threatening genetic disorders, one of the most prevalent is Cystic fibrosis (CF). More than 700 variants of the CFTR gene cause CF. These are detectable through genetic testing; CF is also associated with elevated immunoreactive trypsinogen (IRT) levels. For cost-effectiveness, most CF screening starts with an inexpensive biochemical IRT test; genetic testing is reserved for a small fraction of newborns with elevated IRT levels, based on a threshold. However, setting an optimal threshold presents challenges, particularly due to variations in IRT levels and CF prevalence among different racial and ethnic groups. The current practice of using a single IRT threshold for all newborns leads to inefficiencies and equity/fairness issues. Additionally, newborns' racial/ethnic identifiers are unreliable; and using race-based thresholds may lead to poor public perception.

We introduce an innovative screening approach, integrating an inexpensive, small-panel genetic test (DNA) before the IRT test, to develop a strategy that can customize IRT thresholds without relying on race-based information. This approach leads to novel optimization problems, involving variant selection for the small-panel DNA, and IRT threshold customization based on the number of variants detected by the small-panel DNA. (As an autosomal recessive disease, CF requires two variants.) We establish key structural properties of optimal IRT thresholds. The case study, utilizing CF data from the state of New York, compares the proposed approach with the current practice and race-based benchmarks, and demonstrates the potential improvements, in both the efficiency and equity of screening, possible by this novel approach.

4 - Metamodeling Colorectal Cancer for a User Interface and Improved Intervention Scenario Interpretation

Ashley Stanfield, North Carolina State University , Raleigh, NC, United States, Maria Mayorga, Meghan O'Leary, Kristen Lich

Colorectal cancer is the second most common cause of death by cancer in the United States. Additionally, many colorectal cancer deaths are preventable given increased screening rates. The NC-CRC Simulation model considers an input population, input screening levels, and the natural history of colorectal cancer to model colorectal cancer occurrence and progression. This model was used to create a user-interface, where policymakers could generate outcomes given the original input population. While this model is highly effective in predicting various outcomes such as cancer cases averted and life years lost, it is computationally expensive when multiple populations are considered. Our study uses metamodeling techniques to develop predictions for cancer cases and life years lost due to colorectal cancer. These metamodels are validated against results from the widely-used NC-CRC model. We explore diverse intervention scenarios, ensuring comprehensive coverage of potential policy options. Our approach includes the creation of individual-level metamodels, allowing for predictions for multiple input populations at no additional computational cost. These metamodels can be used to create a user interface that allows policymakers to input demographic information and generate predictions for cancer cases and life years lost at both individual and population levels. This conceptual framework facilitates informed decision-making by policymakers for colorectal cancer intervention planning.

5 - Single-Agent Learning Multi-Agent Decision Making (Slmd) & Ndash; a New Reinforcement Learning Approach for Epidemic Modeling

Sonza Singh, University of Massachusetts, Amherst, Amherst, MA, United States, Chaitra Gopalappa

Public health interventions during new epidemic outbreaks include simple measures, such as increasing awareness, and extreme measures, such as lockdowns, the trade-off being the costs and effectiveness. Taking jurisdiction-specific intervention measures are key to effective and optimal epidemic control. As such decisions are highly dynamic, reinforcement learning (RL) methods are suitable tools for identifying optimal decisions. Current RL algorithms include single-agent RL models and multi-agent RL (MARL) models. Single-agent RL models evaluate decisions in isolation to each jurisdiction, however, are insufficient representations of highly dynamic real-world epidemic settings. MARL models evaluate decisions specific to each jurisdiction while considering the interactions between all jurisdictions. They are computationally complex and this complexity grows with the number of jurisdictions, as each jurisdiction trains a separate deep learning model. This makes it challenging to solve large-scale problems, which are typical for epidemics. For example, in the United States, every county should have its own intervention policy based on the state of its epidemic. However, because of travel, there is a chance that infections from any county may spread to any other county, and thus these interactions should still be considered in the decisions made. To model the interactions between jurisdictions while reducing the computational complexity, we propose a new approach: single-agent learning multi-agent decision-making (SLMD). SLMD utilizes the unique features of epidemics to train a single deep learning model that considers the interactions between all agents, but each agent makes its own decision based on the state of their epidemic.

Innovative Modeling to Inform Infectious Disease Prevention and Control

Invited Session

Health Applications Society

Chair: Yuming Sun, Georgia Institute of Technology, ATLANTA, GA, United States

Co-Chair: Lauren Steimle, Georgia Tech ISyE, Atlanta, GA, United States

1 - A Comprehensive Analysis of Methods to Incorporate Behavior in Agent-Based Models for Infectious Diseases

Sebastian Rodriguez Cartes, North Carolina State University, Raleigh, NC, United States, Maria Mayorga, Osman Ozaltin, Julie Swann

Individual behavior is the first protective barrier to prevent contagion from infectious diseases. Hence, accurate modeling of such actions is needed for simulation tools to represent the spread of a disease through a community. Starting from a theory-based modeling framework that incorporates people's beliefs and perceptions, we investigate the performance of several methods used to model individual-level behavior in agent-based models. We calibrated these approaches with survey data collected during the latest COVID-19 pandemic, and assess model performance in predicting future behavior. We aim to shed light on the usefulness of using empirical models to represent behavior. Moreover, we illustrate the impact of these models in quantifying differences in health outcomes between distinct demographic groups that are expected to behave differently. Our results highlight the need of incorporating individual behavior to properly evaluate equity goals in heterogeneous communities.

2 - Application of Discrete Event Simulation in Cost-Effectiveness Evaluation of Prognostic Tests: A Case of Host-Response-Based Transcriptional Signatures for Tuberculosis Among Migrants to the United States

Yuli Lily Hsieh, Interfaculty Initiatives in Health Policy, Harvard University, Boston, MA, United States, C Robert Horsburgh Jr, Ted Cohen, Jeffrey W Miller, Joshua A Salomon, Nicolas A Menzies

Purpose

Host-response-based transcriptional signature (HrTS) tests have been developed to identify individuals at high near-term risk of progressing to tuberculosis (TB) disease (“incipient” TB). The accuracy of these prognostic tests depends on the time between testing and TB onset, while individuals’ times-to-TB depend on individual risk factors. In this study, we show that discrete event simulation can be useful for evaluating the cost-effectiveness of prognostic tests in post-arrival screening strategies among migrants to the U.S.

Methods

We used a discrete-event simulation model to compare four strategies: (1) no screening for TB infection or incipient TB; (2) ‘IGRA-only’, screen all with interferon gamma release assay (IGRA), provide TB preventive treatment for IGRA-positives; (3) ‘IGRA-HrTS’, screen all with IGRA followed by HrTS for IGRA-positives, provide incipient TB treatment for individuals testing positive with both tests; and (4) ‘HrTS-only’, screen all with HrTS, provide incipient TB treatment for HrTS-positives. We assessed outcomes over the lifetime of migrants entering the U.S. in 2019 and conducted sensitivity analyses to evaluate the robustness of results.

Results

The IGRA-only strategy dominated the HrTS-based strategies under both healthcare sector and societal perspectives, with incremental cost-effectiveness ratios of $78,943 and $89,431 per quality-adjusted life-years (QALY) gained, respectively. This conclusion was robust to varying costs ($15–300) and characteristics of HrTS, and the willingness-to-pay threshold ($30,000–150,000/ QALY gained), but sensitive to the rate of decline in TB progression risk after U.S. entry.

Conclusions

Discrete event simulation can be a useful decision analytic modelling approach for evaluating prognostic tests.

3 - Optimizing Outbreak Response: Using a Spatiotemporal Model of Disease Spread to Support Polio Eradication

Arie Voorman, Gates Foundation, Seattle, WA, United States

One of the key challenges for the Global Polio Eradication Initiative is to prevent outbreaks from spreading to new areas by containing and stopping them quickly, typically through house-to-house vaccination campaigns. Outbreak response campaigns must cover all infected populations, but are often constrained by available budget and vaccine supply. Further, the sparse and delayed detection of poliovirus make it hard to determine the size of the infected area and the trend of an outbreak in real-time.

We introduce a spatiotemporal statistical model that we use to support outbreak response activities and discuss how we collaborate with decision makers in challenging operational contexts in Africa and the Middle East. We provide an overview of the technical performance in terms of predictive value, the strategic implications of the model, and how it is integrated into the decision-making process of the Global Polio Eradication Initiative.

4 - Mechanistic Modeling of Social Conditions into Disease Predictions for Public Health Intervention-Analyses: Application to Hiv

Amir Khosheghbal, University of Massachusetts, Amherst, Amherst, MA, United States, Chaitra Gopalappa

Epidemic models typically simulate the spread of diseases as functions of behaviors, e.g., sexual and care behaviors for sexually transmitted diseases. However, multi-level factors, including poverty, housing or food insecurity, mental health, and substance use disorder etc., (we will collectively refer to these as social determinants of HIV (SDH)), are drivers of those behaviors. Therefore, there is increasing awareness for the need to model SDH into epidemic simulations to evaluate structural interventions alongside behavioral and care interventions.

However, the multivariate joint associations between SDH and behaviors are not available. Data for SDH are mostly available as county level marginal distributions, and associations between SDH and behaviors are mostly bivariate.

We combined copula probability theory and probabilistic graphical models for estimating the multivariate joint distributions. We estimate bivariate associations between SDH using copula. As data for associations between SDH and behaviors are mostly available through small sample literature studies, we used the bivariate SDH associations derived using copula and between SDH and behaviors from literature studies, as links in undirected graphical models, to estimate the joint density.

To illustrate, we used the joint distributions to model HIV-risk related behaviors as function of SDH in a national-level HIV/AIDS (PATH 4.0) model and studied the impact of hypothetical 100% efficacious SDH interventions on HIV prevention. We found that this intervention could lead to a cumulative 10-year reduction of 29% in HIV incidence.

Healthcare Analytics

Invited Session

Health Applications Society

Chair: Susan Lu, Purdue University, West Lafayette, IN, United States

Co-Chair: Yao Li, Southern University of Science and Technology, N/A

1 - Inter-Organizational Healthcare Delivery between Emergency Departments: A Dynamic Network Perspective

Yao Li, Southern University of Science and Technology, Shenzhen, China, People's Republic of, Wenwen Li, Yukun Yang

To explore the interorganzational care delivery with tangled structure, we empirically investigate the ED-to-ED interhospital transfer from a dynamic network perspective, which is little addressed by existing studies. Using interhospital ED-to-ED transfers from 178 hospitals in the State of Florida from 2013 to 2017, our temporal exponential random graph model (TERGM) analysis provides encouraging empirical evidence.

2 - Combatting Opioid Use Disorder: The Role of Drug Dosage Alert Systems

Lin Qiu, Southern University of Science and Technology, ShenZhen, China, People's Republic of, Yongchun Fang, Yao Li

The opioid epidemic has swept the United States. Opioid overprescribing by prescribers is a primary contributing factor, as it could facilitate opioid use disorder. Drug dosage alert systems provide real-time alerts to prescribers when they prescribe doses exceeding the recommended ranges. This would prevent opioid overprescribing and consequently reduce opioid use disorder. Utilizing a hospital-level panel dataset encompassing 165 hospitals in New York State from February 2012 to December 2017, we employ difference-in-differences and counterfactual estimators to analyze the impacts of drug dosage alert systems implementation. Our results suggest that the implementation of these systems significantly reduces outpatient hospital visits due to opioid use disorder. Additional analyses suggest that the effectiveness of these systems is moderated by the number of full-time physicians and dentists within hospitals. Through an analysis of panel data involving 231 prescribers and 16,868 observations, we find that a reduction in the dosages of opioid prescriptions following system adoption may explain the observed effectiveness. Specifically, drug dosage alert systems significantly reduce the prescribed dosage of opioid medications. This effect is moderated by the abuse potential of the prescribed opioids and the prescribers' years of practice. Our findings highlight the important role of these systems in promoting safer prescribing practices and curbing opioid use disorder.

3 - Evolution of Patient Perceptions and Experiences with Telehealth: Insights from Reddit Communities

Xinying Liu, University of Houston - Clear Lake, Houston, TX, United States

Telehealth has evolved over multiple decades in the US, with the COVID-19 pandemic acting as a catalyst for the removal of regulatory and reimbursement barriers, thereby accelerating its adoption. Despite this rapid growth, there remains a significant gap in understanding patients' perceptions of telehealth, which is crucial for optimizing healthcare delivery and ensuring patient satisfaction.

In this research, we investigate the evolution of patient perceptions toward telehealth over time and identify the factors influencing these changes through text mining. Additionally, we focus on patients with mental disorders, specifically those with anxiety, to understand how telehealth affects their healthcare experiences.

Data is collected from Reddit, a highly popular social media platform where user posts are organized by subject into user-created boards called "subreddits." We examine three subreddits: r/telemedicine, r/telehealth, and r/anxiety.

This research provides valuable insights into the dynamic nature of patients' perceptions of telehealth. Understanding how these perceptions change over time can inform strategies to enhance telehealth adoption, address barriers, and tailor services to meet evolving patient needs. By examining telehealth utilization, satisfaction, and preferences, healthcare providers and policymakers can better design interventions to sustain positive patient experiences and increase the acceptance of telehealth services.

4 - Is Continuity All We Need? A Modeling Approach to Evaluating Relational Continuity in Primary Care

Nicos Savva, London Business School, London, United Kingdom, Naireet Ghosh, Yueyang Zhong

Relational continuity of care, defined as a consistent therapeutic relationship between a patient and a physician across multiple healthcare events, has been shown to improve health outcomes, thereby reducing the load on the healthcare system through fewer physician visits.

Despite these benefits, maintaining continuity presents significant operational challenges by restricting resource pooling among physicians, leading to longer patient wait times and potentially increasing system load. Our study employs a novel queueing model to analyze the tradeoffs involved and to explore patient decision-making strategies between waiting for their regular physician or opting for another with shorter wait times. Our analysis reveals that, from the perspective of a social planner, it is optimal to maintain intermediate levels of continuity wherein the patients with the most complex needs visit their regular physician while those with lower complexity visit the physician that is available earliest. This balance depends on factors such as the size of the primary care practice (PCP), the patient mix, and the level of congestion. If, on the other hand, the continuity decision is left to individual patients, they are unable to account for the externality of their decision and, consequently, end up in an equilibrium where all patients choose to either always maintain continuity or always abandon it. Our study identifies conditions under which such suboptimalities are most pronounced, offering policymakers insights to guide decisions on the desired level of relational continuity, ensuring better patient outcomes and more efficient system functioning.

1 - Rapid Response Teams for Proactive Sepsis Treatment

Chia-Hao Chang, Columbia University, New York, NY, United States, Vineet Goyal, Carri Chan, Benjamin Ranard

Sepsis is an emergent medical condition in which one's immunological responses cause end-stage organ dysfunction and death. In a typical year, around three hundred and fifty thousand people die of sepsis in the United States. Its high mortality renders the timeliness of detection and treatment crucial. Some recent evidence has shown that providing early treatment to patients before they develop sepsis may lower their mortality. Often, early treatment for sepsis is administered by a rapid response team (RRT), which is a team of clinicians. However, the increased workload resulting from proactive care may block the emergent needs of other patients, including those who already have sepsis. Hence, the focus of this work is to design a policy to manage RRT for proactive sepsis treatment in a resource constrained setting to improve overall patient outcomes. Motivated by the structural insights from fluid approximation, we propose a one-step-look-ahead reservation policy. We justify our policy by showing its long-run asymptotic optimality. Finally, we perform simulations using the data from Columbia University Irving Medical Center//NewYork Presbyterian Hospital. Our simulations demonstrate that our proposed policy can potentially save an additional life following a shock of patient admissions to the hospital.

2 - Multi-Wave Infections: The Role of Variants and Population Immunity

Retsef Levi, Massachusetts Institute of Technology, Cambridge, MA, United States, Yanzhe Ma, El Ghali Ahmed Zerhouni

Respiratory viruses are characterized by their infection spread into multiple successive waves. To explain these patterns, biological and epidemiological evidence suggest that the emergence of new variants with immune-escape mutations can enable them to target previously immune sub-populations and lead to new waves of infection. Yet, existing epidemiology models, such as the Susceptible-Infectious-Recovered (SIR) model and its derivatives, do not yet account for these dimensions. Although these models enable to mathematically obtain the multi-wave infection spread patterns, they still rely on artificial modifications of their parameters during the infection spread process. This talk introduces the *Immunity-Variants Epidemic (IV-Epidemic)* model to capture the observed biological and epidemiological drivers of multi-wave infections into a single mechanism. By leveraging SARS-CoV-2 data to calibrate the model parameters, the study shows that the *IV-Epidemic* model can replicate the observed multi-wave infection spread patterns standalone. It also reproduces similar distributions of infections among variants and the observation that every new infection wave is driven by a few new variants. Additionally, it enables to assess the effect of pre-existing immunity on the early infection spread. The study thus provides several useful implications to better anticipate the spread of a new respiratory virus and enhance preparedness for future pandemics.

3 - Harmonizing Safety and Speed: A Human-Algorithm Approach to Enhance the FDA&Rsquo;S Medical Device Clearance Policy

Mohammad Zhalechian, Indiana University, Kelley School of Business, Bloomington, IN, United States, Soroush Saghafian, Omar Robles

For a medical device to be approved under the FDA’s Premarket Notification 510(K) pathway, the manufacturer can submit a claim indicating that it is as safe and effective as another legally marketed device. This vague regulatory process has led to a high recall rate for devices approved under this pathway, raising important concerns over the approach used by FDA. We develop a combined human-algorithm methodology to assist the FDA in improving the 510(k) medical device clearance process by reducing the risk of potential recalls and the workload of the FDA. We first develop machine learning methods to estimate the risk of recall of 510(k) medical devices based on the information available at the time of submission. We then propose a data-driven clearance policy that recommends acceptance, rejection, or deferral to FDA's committees for in-depth evaluation. We conduct an empirical study using a unique large-scale dataset, and our results show a 38.9% improvement in the recall rate and a 43.0% reduction in the FDA's workload. Our analyses also indicate that implementing our policy could result in significant cost-savings.

4 - Enhancing Uptake and Efficiency in Healthcare: Behavioral Interventions and Group Consultations

Soledad Giardili, University of Edinburgh, Edinburgh, United Kingdom, Kamalini Ramdas, Monica Heller, Amalia Miller, Sanjay Jain

Traditional clinician-patient consultations often involve repetitive exchanges of information and advice. A proposed solution to alleviate workload pressures in healthcare is group consultation, which offers a structured yet socially interactive environment for managing health in a group setting. As a relatively new concept in primary care, uptake might initially be low. We conducted a randomised controlled trial among

4,539 women aged 45 to 60 years to test the effect of behavioural interventions on the uptake of group consultations for menopause management. We introduced two intervention arms: peer testimony, where individuals with prior experience in group consultations shared their experiences, and expert description, which provided more detailed insights from healthcare professionals about the group consultation process. The peer testimonial intervention led to a 15.3 percentage point increase in group clinic uptake, while the expert description intervention resulted in a 13.4 percentage point increase, compared to an 11.1% baseline in the control group, who received the standard invitation. Additionally, both interventions significantly enhanced decision-making variables, such as certainty and clarity about the benefits of group consultations. Lastly, among participants who initially preferred a one-on-one appointment or no appointment, 21.5% changed their preference to a group consultation when it was offered at an earlier date. This shift underscores that patients are sensitive to the scheduling of their appointments. Our findings inform the design of behavioural nudges for promoting group consultations among the population and demonstrate how operational efficiency, achieved by shortening waiting times, significantly influences participants' decision-making processes.

5 - MedDRA-Standardized Drug Label Change Dataset for Postmarketing Analysis

Bonnie Akhavan, MIT, Cambridge, MA, United States, Retsef Levi

Adverse drug events (ADEs), otherwise informally known as drug side effects, are a widespread concern with detrimental consequences for patients and healthcare systems alike. We present a comprehensive drug label change dataset of over 45,000 entries which captures the listed adverse events for more than 5,000 prescription products. Significant label changes are extracted from a chronological label version history which we compile for each available product. After aggregating label changes, we utilize semi-supervised learning techniques to classify each entry into one of 27 standardized MedDRA System Organ Classes (SOCs). Through this classification, we enable the comparison of drug adverse event profiles across different products despite medication labels not adhering to a standardized medical terminology. We assess the accuracy of our SOC classification model on a labeled validation set compiled in collaboration with pharmacovigilance experts. To our knowledge, this is the first public dataset of its kind with comprehensive, historical drug label change information and associated MedDRA SOC classifications. By developing this dataset, we hope to facilitate a better understanding of ADE trends across drug classes in the postmarketing setting. Additionally, this dataset has potential to enable predictive technologies which could be used to detect unlisted ADEs earlier. In turn, early detection of these side effects could lead to improved clinical trial design and better patient outcomes.

New Topics in Dynamic Assignment

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Parshan Pakiman, Chicago Booth, 5751 S Woodlawn Ave, Chicago, IL, 60637, United States

Co-Chair: Daniel Adelman, University of Chicago, Booth School of Business, Chicago, IL, United States

1 - Dynamic Assignment of Personalized Coupons under Reference Price Effects

Will Ma, Columbia University, Cambridge, MA, United States, Jackie Baek, Dmitry Mitrofanov

This work is motivated by our collaboration with an online retailer with a large email marketing campaign, where millions of customers each receive a daily email with a personalized discount amount. Based on past data, we build a personalized reference price model for each customer, where they are most likely to purchase if they receive a large discount after receiving small discounts for many days. There is a monthly promotional budget constraining the total discount that can be claimed across all customers. We introduce a new personalized reference price model and derive optimal controls for this model for long-term revenue, based on cycling different coupon values. Our analysis also simplifies understanding of reference price models, which could be of independent interest.

2 - Optimal Sharing of a Reusable Medical Resource During a Pandemic

Canan Uckun, University of Illinois at Chicago, Chicago, IL, United States, Daniel Adelman

Motivated by ventilator sharing between states in the US during the recent COVID-19 pandemic, we develop an optimal control model that maximizes lives saved by transferring ventilators across geographic regions to take advantage of inter-temporal differences in peak times.Our model captures the patient holding times of ventilators, which in practice was on the order of weeks, and show that ignoring them results in significant error in the number of ventilators needed to save a fixed number of lives, and vice versa. More generally, our framework could be used in the next pandemic to optimize the flow of any reusable medical resource to save lives.

3 - Optimizing Nurse-Shift Assignments Considering Nurse Preferences with No-Shows and Overbooking

HEDIEH SAZVAR, Northwestern University, Evanston, IL, United States, Seyed Iravani, Sanjay Mehrotra

The escalating demand for nurses, driven by an aging population and increased preventive care, has exacerbated the nursing shortage crisis and left hospitals struggling to fill shifts. This paper addresses the challenge of optimizing nurse-shift assignments to maximize the number of vacancies filled. Our model considers the different preferences and show-up probabilities for each nurse-shift pair, as well as shifts with different vacancies.

We propose a nurse-shift assignment model for implementation on a matching platform. The goal is to maximize the number of vacancies filled by nurses by ensuring that they choose to work the shifts and show up as scheduled, using a static policy. Given the infeasibility of directly solving the stochastic optimization problem due to its large state space, we characterize the optimal policy within a static framework to effectively manage large-scale scenarios. A heuristic solution method is proposed to closely approximate the optimal policy, and an overbooking strategy is integrated to mitigate potential losses from no-shows.

4 - Dynamic Assignment of Jobs to Workers with Learning Curves

Parshan Pakiman, University of Chicago Booth School of Business, Chicago, IL, United States, Daniel Adelman, Adam Mersereau

We study the problem of dynamically assigning jobs to workers over an infinite time horizon where the availability of both jobs and workers evolves stochastically over time. Workers develop familiarity with jobs when assigned to them, with higher familiarity levels resulting in lower costs when workers are assigned to the same jobs in the future. This problem gives rise to a high-dimensional Markov decision process (MDP) with stochastic combinatorial constraints encoding feasible job-worker assignments and endogenous-state dynamics capturing the evolution of familiarity levels. We propose a class of tractable control policies that relax the combinatorial constraints, another class of policies based on ignoring state dynamics, and generalizations of both classes. We provide supporting theory and insights into the policies' performances and numerically test them on different problem instances.

Summit - 442

Empirical Perspectives on Healthcare Challenges

Invited Session

MSOM: Healthcare

Chair: Michael Freeman, INSEAD, Singapore, Singapore

1 - From Full-Time to Flexi: Investigating the Impact of Workforce Shifts in Primary Care on Service Provision and Quality

Michael Freeman, INSEAD, Singapore, Singapore

Primary care practices worldwide are experiencing a shift away from traditional full-time roles toward increased part-time and temporary staffing models. This transformation necessitates understanding the implications for primary healthcare delivery. Our paper provides an empirical analysis examining the evolving work patterns and schedules of general practitioners (GPs) in the UK over the past decade. Using primary care records, we first examine how GP work volume impacts healthcare service utilization and patient outcomes. We also explore factors that may mediate this relationship. Going further, given the seeming inevitability of more flexible staffing models, our investigation also aims to inform effective workforce strategies that optimise healthcare delivery. Specifically, we examine scheduling approaches that may allow primary care practices to adapt to part-time and locum GPs. Our findings aim to inform healthcare leaders seeking to adapt to emerging flexible staffing models while maintaining high-quality and accessible primary care.

2 - To Consult or not to Consult - When Should Algorithms Seek Physicians' Advice for Predicting Surgery Durations?

Laura Poreschack, University of Cologne, Cologne, Germany, Dominik Walzner, Andreas Fuegener, Ulrich Thonemann, Christof Denz

Humans are a scarce resource, which is particularly problematic in healthcare. Hospital understaffing can have negative effects on the employees' physical and mental health as well as the quality of care. Thus, automation with AI is a valuable strategy to reduce human effort. In many healthcare management applications, AI augmented by human expertise has proven to perform better than full automation or humans working alone. However, while augmentation might increase the performance, it still requires human input, and thus does not decrease the human effort, which would be the case if humans were replaced by the AI.

In this paper, we propose a new approach to human-AI collaboration in healthcare operations addressing both performance and human effort. We develop a framework to decide which tasks should be automated and for which tasks the algorithm should seek input by a physician. We evaluate our framework considering the case of surgery duration predictions based on a data set from a large university hospital. The data set comprises 70,610 surgeries with 3,163 different procedure types. For each surgery, we have information on specific characteristics that can be grouped into patient-related, surgery-related, and physician-related features.

We observe that while human-augmented AI leads to an overall better performance than full automation, employing our framework can lead to an even higher forecasting accuracy with considerably lower human effort. Our results indicate that a partial automation of tasks that are easy for the AI allows physicians to focus on their medical duties instead of administrative tasks.

3 - Female FDA Inspectors and Medical Device Plant Inspections

Shirin Shahsavand, Washington State University, Pullman, WA, United States, Kevin Mayo, George Ball, Kaitlin Wowak

The Food and Drug Administration inspects medical device manufacturing plants on a recurring basis to ensure compliance with federally-regulated quality standards. FDA inspectors should apply these standards in an objective manner regardless of who inspects the plant. Research that examines how males and females perform their work differently, however, indicates this may be a flawed expectation. We examine how the gender of the FDA inspector influences inspection outcomes and the subsequent quality of medical devices manufactured at the plant. We theorize that female FDA inspectors will assign the most serious inspection outcome, an Official Action Indicated (OAI), more frequently than male inspectors. We also propose that OAIs assigned by female inspectors will lead to higher quality products made at the plant than OAIs assigned by male inspectors. Analyzing 19,722 inspections conducted at 4,590 plants in the U.S. from 2005 to 2019, we find that female inspectors assign significantly more OAIs than male inspectors. In addition, OAIs assigned by female inspectors lead to higher quality products from the plant compared to OAIs assigned by male inspectors. An instrumental variables analysis in robustness checks indicates a low risk of endogeneity bias in our model. Post-hoc analysis demonstrates support for a mechanism explaining our results, female inspectors take more time in conducting inspections that lead to OAIs than male inspectors. We offer contributions to research on product quality, plant inspections, and gender diversity, as well as implications for the FDA about how inspector gender may impact regulatory oversight and medical device quality.

4 - Opioid Scarcity and Health Outcomes

Basil Isaac, University of Michigan, Ann Arbor, MI, United States, Xinyu Liang

This paper examines the effects of a 2017 shortage of parenteral opioids, leveraging geographic variation to provide insights into how such shortages exacerbate care delays and opioid misuse.

Morphine, Fentanyl, and Hydromorphone are parenteral opioids given to patients who require fast and reliable analgesia on being admitted, and to those who have undergone surgeries. They are subject to DEA's production quotas aimed at containing illegal diversion of drugs. Therefore, their shortages are caused by both manufacturing issues and policy levers exercised by the DEA. The 2017 shortage of parenteral opioids was precipitated by supply side issues for the biggest manufacturer of the opioids which was compounded by supply restrictions imposed by the DEA.

We use two sources of data. First, the DEA's administrative data on legal shipments of opioids. This dataset, called ARCOS, was made publicly available for the period between 2006 and 2019 because of a court order. The second source is the Merative Truven Databases, which contain outpatient, emergency department (ED), and inpatient services, and drug prescription usage.

In this paper, we use a geographically varying measure of the incidence of the parenteral opioid shortage. We follow two different approaches to address the potential endogeneity between the volume of shipments and demand-side factors. First, we construct a shift-share instrument which exploits features of this specific shortage. The second approach is an event-study design which categorizes states as control and treatment states.

Fairness and Matching in Service Operations

Invited Session

MSOM: Service Operations

Chair: Luyi Yang, University of California, Berkeley, Berkeley, CA, United States

Co-Chair: Shiliang Cui, Georgetown University, McDonough School of Business, McLean, VA, United States

1 - Treating to the Priority in Heart Transplantation

Philipp Afeche, University of Toronto, Rotman School of Management, Toronto, ON, Canada, Burhan Sandıkçı, Sait Tunc

The US heart transplantation system prioritizes transplant candidates according to the severity of their pre-transplant medical therapy: *The more severe the therapy, the higher the priority*. It is widely suggested that this rule opens up room for gaming the system, by over-treating certain patients to increase their priority on the waiting list. To study this issue, we consider an overloaded multi-class priority queueing model in a game-theoretic framework that captures the interplay among the key factors that may affect a transplant center's gaming behavior. The analysis of this model yields results on the conditions that yield such strategic gaming, and how it this behavior can be mitigated.

2 - Tight Bounds for the Price of Fairness

Daniel Granot, Sauder School of Business, University of British Columbia, Vancouver, BC, Canada, Yifeng Cao, Yichuan Ding

A central decision maker (CDM), who seeks an efficient allocation of scarce resources among a finite number of players, often has to incorporate fairness criteria to avoid unfair outcomes. Indeed, the Price of Fairness (POF), a term coined in Bertsimas et al. (2011), refers to the efficiency loss due to the incorporation of fairness criteria into the allocation method. Quantifying the POF would help the CDM strike an appropriate balance between efficiency and fairness. In this paper we improve upon existing results in the literature, by providing tight bounds for the POF for the proportional fairness criterion for any n, when the maximum achievable utilities of the players are equal or are not equal. Further, while Bertsimas et al. (2011) have already derived a tight bound for the max-min fairness criterion for the case that all players have equal maximum achievable utilities, we also provide a tight bound in scenarios where these utilities are not equal. Finally, we investigate the sensitivity of our bounds and the bounds of Bertsimas et al. (2011) for the POF to the variability of the maximum achievable utilities.

3 - Not All Lines are Skipped Equally: An Experimental Investigation of Line-Sitting and Express Lines

Sezer Ulku, Georgetown University, Washington, DC, United States, Abdullah Althenayyan, Shiliang Cui, Luyi Yang

In this paper, we investigate how line-sitting and express lines affect customers' satisfaction and fairness perception about queues. In three experiments, we show that customers who encounter a line-sitting instance report higher satisfaction with their overall queueing experience than those who encounter an express-line customer, despite the actual wait time being held constant across the conditions.

4 - Timing Matters: Sourcing Workers in on-Demand Freight Matching Platforms

Ziqi Dong, Temple University, Philadelphia, PA, United States, Jingxuan Geng, Guangwen Kong, Qiuping Yu

We focus on the flourishing freight-matching businesses that rely on crowdsourced drivers for long-haul trucking. In particular, although the practice suggests that shippers' ordering behaviors of freight-matching services may remarkably impact crowdsourced drivers' bidding behaviors, the literature has yet to examine this issue formally. Therefore, we collect industrial data and construct a strict empirical schema for understanding the association between shippers' order timing and the freight-matching performance. Besides, by deliberately building a theoretical modeling framework and using a data-driven estimation of model parameters, we are able to simulate the freight-matching performance of adopting our empirical findings and evaluate the practical value of our study.

5 - Fairness and Efficiency Trade-offs in Multi-Class Service Systems

Hamid Arzani, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Ming Hu, Hossein Abouee Mehrizi

In service systems, the pursuit of efficiency by prioritizing certain groups often raises concerns about fairness toward those who are being prioritized. In this paper, we study a single-server queueing system with multiple classes of customers, distinguished by their base utility, urgency level, and arrival rate. We examine two policies: the efficient (i.e., utilitarian) policy, which maximizes the system's total expected utility by prioritizing the urgent class, and the fair (i.e., egalitarian) policy, which employs a randomized priority rule to maximize the minimum expected utility of individual customers across classes. We show that the fair policy may agree or disagree with the efficient policy depending on system utilization. We then explore the efficiency-fairness trade-off by analyzing the relative efficiency loss associated with the fair policy, namely the price of fairness (POF), and the relative fairness loss associated with the efficient policy, namely the price of efficiency (POE). We illustrate that even a slight increase in service capacity can lead to significant improvements in POF and POE. We further characterize the conditions under which POF or POE is the most significant. Our results emphasize that the connection between fairness and efficiency in our model is not dichotomous; instead, it often manifests as a continuum: Substantial gain in one might be achieved with only marginal loss in the other. This implies that in situations where alternative options are limited, such as immigration or healthcare systems, a slight adjustment in service allocation can promote fairness significantly while maintaining efficiency to a large extent.

Summit - 444

Data Analytics and Technology in Operations Management

Invited Session

MSOM: Service Operations

Chair: Kenneth Moon, University of Pennsylvania, The Wharton School, Philadelphia, PA, United States

1 - Capturing Cannibalization and Complementarity Effects with Transformers

Manuel Moran-Pelaez, MIT Operations Research Center, Cambridge, MA, United States, Georgia Perakis

We present a novel approach based on Transformers for capturing cannibalization and complementarity effects within the retail sector. Traditional demand methods often assume independence between items and hence struggle to capture the intricate interplay between products. In response, we propose a framework that combines product information (textual, visual, and numerical features), and the Transformer architecture to capture product interactions. The model is validated using real-world retail data, demonstrating its ability to predict and quantify the impact of cross-item effects accurately. The findings derived from this approach enhance our understanding of cannibalization and complementarity dynamics and offer valuable insights into retail operations, such as assortment optimization, pricing, and inventory management.

2 - Structural Forecasting of Customer Arrivals to Scheduled Services

Fernando Bernstein, Duke University, Durham, NC, United States, Bora Keskin, Adam Mersereau, Morgan Wood, Serhan Ziya

Motivated by the RDU International Airport, we develop methods to forecast future arrivals to a system where arrivals are tied to scheduled events. In our scenario, passengers arrive for their scheduled flights. We consider a setting in which the historical number of passenger arrivals is known, but it is unknown for which flight each passenger arrived. Assuming each passenger arrives early for their respective flight according to some distribution, we develop methods capable of learning the arrival structure of individual passengers to their respective flights using both a parametric model and a non-parametric approach of passenger arrival earliness. Earliness distribution estimates, along with future flight schedules, are used to forecast the total number of future passenger arrivals. We explore the benefit of allowing the earliness distribution estimate to vary depending on time of day, day of week, flight-type, and holiday occurrence. We compare the performance of these passenger arrival estimates to estimates derived from machine learning methods using real-world data.

3 - High-Flying Analytics: Harnessing Wearable Sensors and AI to Safeguard Military Aviators

Xufei Liu, Wharton, University of Pennsylvania, Philadelphia, PA, United States, Gad Allon, Kenneth Moon

For military aviators, functioning without fail within a high-stress work environment is a necessity. In order to complete critical missions, they make split-second decisions while piloting 44,000 lbs of hurtling machinery accelerating at up to 9G's in high-altitude conditions. For less experienced pilots, managing the associated physical and mental fatigue is an integral and challenging component of executing flights safely and well.

Yet, currently, few measures are in place to monitor and track fatigue for pilots. The US Air Force (USAF) primarily forecasts future states of fatigue using a general-purpose biomathematical model created decades ago - we aim to bring modern data science and analytics to the problem of live fatigue management for military pilots. We collaborate with a pioneering company that innovatively outfits aviators at 22 USAF bases with wearable sensors that record both the physical stresses of sorties (flights) and the biophysical states and reactions of pilots in real-time. Then, we develop analytical methods to make timely and accurate use of such novel wearable sensor data to benefit and safeguard pilots.

Our research focuses on maximizing high-stakes, learning-dependent performance in the field of operations management. Whereas the use of sensors and testing to manage performance is far from new to the field of operations, its use in expediting expert human experience and performance in complex settings, with the aid of artificial intelligence, is still nascent. We create a data-driven solution to identify critical intervention points based on highly complex data on dynamic human performance.

4 - Designing Recommendation Algorithms to Improve Equity in Access on VolunteerMatch

Akshaya Suresh, Yale University, New Haven, CT, United States, Vahideh Manshadi, Scott Rodilitz, Daniela Saban

In collaboration with VolunteerMatch (VM)---the world's largest online platform for connecting volunteers with volunteering opportunities---we designed and implemented a new display ranking algorithm. VM's original ranking algorithm intended to maximize efficiency (i.e., the total number of connections), but as a consequence it repeatedly displayed the same few opportunities atop its ranking, effectively limiting access to volunteers for the other opportunities. To incorporate VM's desire for equity (defined as the weekly number of opportunities with at least one connection) along with efficiency, we propose a modeling framework for online display ranking in settings where it is important to manage the trade-off between the total number of connections and the equitable allocation of these connections. Taking an adversarial approach in evaluating the performance of online algorithms, we show that a class of algorithms that applies a *penalty* to opportunities after each connection provides a strong (and, in certain regimes, optimal) performance guarantee. Based on our theoretical development, we propose *SmartSort*, a simple online display ranking algorithm with a penalty term that we calibrated using VM's data and simulation. We implemented SmartSort in experiments covering Dallas-Fort Worth and all of Southern California. Using a difference-in-differences analysis, we find that the implementation of SmartSort led to an estimated 8% increase in equity (consistent across both experiments) without any significant decrease in efficiency. If SmartSort has a similar distributional effect on a national scale, an additional 30,000 connections every year will go to opportunities that would have otherwise lacked access to volunteers.

Innovative Approaches to Sustainable Transportation and Workforce Diversity

Invited Session

MSOM: Sustainable Operations

Chair: Jingwei Zhang, Cornell University, Ithaca, United States

Co-Chair: Nagarajan Sethuraman, University of Kansas, Lawrence, KS, United States

1 - The Role of Driver Behavior and Interpretability in The Vehicle-to-Grid Market

Leann Thayaparan, Massachusetts Institute of Technology, Cambridge, MA, United States, Georgia Perakis

As renewable energy production increases, energy storage becomes a significant challenge. Electric Vehicles (EVs) could act as distributed storage. However policies for EVs to charge from and discharge to the electric grid must account for complex driver behavior. In this work, we introduce a driver-focused dynamic optimization model that incorporates the EV driving behavior. The optimization incorporates multiple aspects of driver concerns including earning a dollar profit, minimizing their carbon footprint and reducing range anxiety. A concern is this setting is that drivers will not participate in discharging markets due to distrust of blackbox charging/discharging policies. We characterize charging/discharging policies that are interpretable to drivers and analytically guarantee that these policies are optimal under certain parameter regimes of the optimization. The parameter regimes translate to intuitive weightings between the multiple objectives of the optimization. We also establish that the dynamic program can be solved in closed form, addressing tractability concerns. We collaborate with an American EV manufacturer to size the potential of the discharging market. Over a twelve day test set, we find that the average driver earns $95 from engaging in the vehicle to grid market and has a carbon benefit of 0.81 tons of CO_2. This is a carbon benefit equivalent to 2,076 miles driven by the average gas powered car, 91.1 gallons of gasoline consumed, 0.102 of a home’s annual energy usage or 13.4 tree samplings grown for 10 years.

2 - Income-Based Public Transit Design: Optimizing Service and Pricing for Equitable Access

Jingwei Zhang, Cornell University, Ithaca, NY, United States, Owen Wu

With the Infrastructure Investment and Jobs Act, many public transit agencies are improving the transit system by either increasing the service level or lowering the ticket price with earmarked budget. It's unclear yet which lever is more efficient in boosting social welfare. This paper studies the transit design problem by considering different income groups' sensitivity in travel time and price. Our findings offer cost-effective prescriptions for improving urban mobility.

3 - Impact of Women in the Invention Team on Product Realization in the Pharmaceutical Industry

Nagarajan Sethuraman, University of Kansas, Lawrence, KS, United States, Deepak Jena, Rachna Shah

Does having additional women participate in research and product development teams result in more successful products downstream? We examine this question in the context of the pharmaceutical industry which has suffered from historically low women participation in the patent invention teams.

4 - Going the Distance: the Impact of Commute on Gender Diversity in Public Service

Vanitha Virudachalam, Gies College of Business, UIUC, Champaign, IL, United States, Dawson Kaaua

We analyze the extent to which longer commute distances deter female political participation and whether this effect varies according to the degree of flexibility and commensurate compensation provided by the position. Furthermore, we investigate policies that can lower the barrier to entry for women in politics. Leveraging differences in distance to the state capitol among state house districts, we show that state house districts located further from the state capitol have a lower percentage of female candidates, up to 3 to 4% with the effect plateauing at 120 miles. This effect is driven by states that provide neither a high degree of flexibility (i.e., part-time work) nor a high level of compensation (i.e., full-time work). In such states, the decrease in female participation is up to 4 to 5% with the effect also leveling off at around 120 miles. Based on two conjoint survey experiments, we find that paid parental leave might motivate women at the beginning of their political careers with longer commutes to run for office while a remote work/proxy voting policy could help to sustain the political careers of these types of women.

Summit - 446

Sustainability through Supply Chain Innovations

Invited Session

MSOM: Sustainable Operations

Chair: Luyi Gui, The Paul Merage School of Business, UC Irvine, Irvine, CA, United States

Co-Chair: Xi Lin, UC Irvine, Paul Merage School of Business, Irvine, CA, United States

1 - Sustainable Sourcing of Agricultural Products: Fixed vs. Flexible Premiums

Vishal Agrawal, Georgetown University, Washington, DC, United States, Can Zhang

Sustainability certifications have gained increasing popularity for agricultural product sourcing. To help smallholder farmers achieve a living income, these certifications set a premium that firms must pay to farmers for certified crops in addition to the market price. A popular premium approach adopted by several major certifications is called fixed premium, under which farmers receive a fixed level of premium independent of the market price. This approach has been criticized for not protecting farmers from low market prices. An alternative approach called flexible premium, under which farmers receive a higher level of premium when the market price is lower, has been promoted by farmer advocacy groups and implemented recently by some certifications. We analyze and compare the effectiveness of these two premium approaches. Our analysis reveals several insights. First, contrary to expectation, we show that flexible premium can lead to a lower expected farmer income than fixed premium. Furthermore, even when flexible premium improves farmer income, it can lead to a lower expected sustainable sourcing quantity and firm profit. Second, we nevertheless identify that flexible premium can lead to a ``win-win-win" outcome for farmer income, sustainable sourcing quantity, and firm profit, but only in ample-supply, demand-constrained settings. Finally, motivated by the trend of firms creating their own sustainability labels, we show that such self-labeling can lead to a higher sustainable sourcing quantity but still lower farmer income as compared to under NGO labeling.

2 - Labor, Skills, and Product Recovery

Cerag Pince, Quinlan School of Business, Loyola University Chicago, Chicago, IL, United States, Atalay Atasu

Motivated by a third-party remanufacturer of consumer products, we study the workforce capacity investment problem in product recovery operations. We analyze how a remanufacturing firm should determine its workforce's quantity and type when the returned product volume and complexity are random. We characterize the optimal solutions for different workforce strategies and identify the conditions when one strategy dominates the other.

3 - The Value of Advice: Evidence from Thousands of Smallholder Farms in The Philippines

Canberk Ucel, Bilkent University, Ankara, Turkey, Diwas KC

Increasing the productivity of Philippine coconut farms that are well below world standards could improve the livelihoods of 3.4 million farming families, most suffering poverty. Government and supporting organizations have long promoted Good Agricultural Practices (GAPs), which decades of public research suggests would double farm productivity with little capital investment, but have failed to achieve widespread adoption and productivity gains. We study the role of change agents in facilitating GAP adoption and effective implementation using proprietary data on the productivity, granular farming practices, and characteristics of 1,998 smallholders. Our quantitative analysis leverages the pseudo-exogenous variation in agricultural extension office locations to find that having an extension office within 8 kilometers is associated with greater awareness of central recommendations for 7 of 8 GAPs, increased adoption rates for the three most effective GAPs, and 36% higher productivity, on average, on otherwise comparable farms. Our post-hoc analysis further finds suggestive evidence that physical interactions enable agents to support complex practice adoption and implementation decisions. Moreover, we find significant heterogeneity in the effects of agent access and offer facility reallocation and visit schedules to improve service coverage and effectiveness with existing capacity. Our results suggest that supporting organizations should integrate change agent support or otherwise focus on integrating customized advice, farmer feedback, and assistance with finer details of implementation. Evidence-based provision of advisory services, extended beyond the Philippine context, could potentially benefit two billion people worldwide dependent on smallholder farms, and benefit small heterogenous firms that dominate vital functions in other industries.

Applications of Operations Research and Analytics in Elections

Invited Session

Public Sector OR

Chair: Charles Thraves, University of Chile, Santiago, Chile

1 - Monotone Randomized Apportionment

Jose Correa, Universidad de Chile, Santiago, Chile, Paul Goelz, Ulrike Schmidt-Kraepelin, Jamie Tucker-Foltz, Victor Verdugo

Apportionment is the act of distributing the seats of a legislature among political parties (or states) in proportion to their vote shares (or populations). A famous impossibility by Balinski and Young (2001) shows that no apportionment method can be proportional up to one seat (quota) while also responding monotonically to changes in the votes (population monotonicity). Grimmett (2004) proposed to overcome this impossibility by randomizing the apportionment, which can achieve quota as well as perfect proportionality and monotonicity — at least in terms of the expected numberof seats awarded to each party. Still, the correlations between the seats awarded to different parties may exhibit bizarre non-monotonicities. When parties or voters care about joint events, such as whether a coalition of parties reaches a majority, these non-monotonicities can cause paradoxes, including incentives for strategic voting. In this paper, we propose monotonicity axioms ruling out these paradoxes, and study which of them can be satisfied jointly with Grimmett's axioms. Essentially, we require that, if a set of parties all receive more votes, the probability of those parties jointly receiving more seats should increase. Our work draws on a rich literature on unequal probability sampling in statistics (studied as dependent randomized rounding in computer science). Our main result shows that a sampling scheme due to Sampford (1967) satisfies Grimmett's axioms and a notion of higher-order correlation monotonicity.

2 - Maximizing Proportionality in Districting Plans

Brendan Ruskey, Lehigh Unversity Department of Industrial Engineering, Bethlehem, PA, United States, Larry Snyder

We present optimization models for generating fair redistricting plans. Every ten years in the United States, lawmakers sort the citizens of each state into groups of roughly equal population in what is called a "redistricting plan”. In the context of fairness between political parties, we define proportionality as the difference between a party's statewide share of individual votes and the share of districts in which the party has a majority of voters. In practice, disproportionate plans are seen as unfair. Therefore, we present multiple mixed-integer programming (MIP) models for the problem of maximizing proportionality within a redistricting plan. Our model differs from existing approaches, in that we present the first optimization model for maximizing proportionality assuming fractional seat shares. We also propose and implement a linear programming (LP) relaxation heuristic for the problem. We share computational results from applying our heuristic to actual US state redistricting problem instances, and compare these generated plans to existing US redistricting plans.

3 - Optimal Strategies in Ranked-Choice Voting

Sanyukta Deshpande, University of Illinois at Urbana Champaign, Champaign, IL, United States, Nikhil Garg, Sheldon Jacobson

Ranked Choice Voting and Single Transferable Voting are widely used. An open question is how candidates should strategize, forming coalitions or lending support to other candidates. Calculating optimal strategies is exponentially complex because of intricate per-round vote transfers, with minor changes in the voter rankings potentially leading to bigger ripple effects -- for example, lending support to a losing candidate can prevent their votes from transferring to a more competitive opponent. We study optimal strategies -- *persuading* voters to change their ballots or *adding* new voters -- both theoretically and algorithmically. Theoretically, we study the types of strategies that are effective under both perfect and imperfect polling information. Algorithmically, we develop efficient algorithms to reduce the election instance while maintaining optimization optimality, practically circumventing the computational complexity barrier. Finally, we apply our algorithmic approach to ranked-choice polling data on the US 2024 Republican Primary, finding, for example, that several candidates would have been optimally served by boosting another candidate instead of themselves.

4 - The *FastMap* Redistricting Algorithm: An AI Milestone for a Better American Democracy

Matthew Petering, UW-Milwaukee, Milwaukee, WI, United States

On January 12, 2024 seven proposals for Wisconsin's legislative districts were submitted to the Wisconsin Supreme Court in the case *Clarke v. Wisconsin Elections Commission*. One was generated by a computer algorithm, and six were created by expert human mapmakers. In this presentation, we examine a major development from the case: the map proposal generated by the *FastMap* algorithm significantly outperformed the other proposals. Relevant background information, an algorithm summary, and map visualizations/comparisons are provided. The case likely marks the moment when computer algorithms surpassed humans in overall mapmaking ability. Going forward, algorithmic mapmaking will enhance American democracy by ensuring that congressional, state legislative, and local election districts better reflect constitutional requirements, the will of the voters, and other criteria specified by courts and legal teams.

Advanced Optimization and Modeling Techniques in Operations Research

Contributed Session

Chair: Rick Willemsen, Erasmus University Rotterdam, Rotterdam, Netherlands

1 - Random Preference Models: Estimation and Identification

Moha Ghaderi, Pompeu Fabra University, Barcelona, Spain, Milosz Kadzinski, Kamel Jedidi

Random Preference Models (RPMs) provide analytical tools to describe and predict choices directly based on preference orderings. The linear relationship between RPMs and aggregated demand, their intuitive appeal in explaining choices without relying on utility mediums, and their flexibility to capture various types of context-dependency without needing random-utility-like specification assumptions make RPMs powerful tools. On the downside, estimating RPMs requires projecting choices onto the discrete space of preference ordering with a dimensionality that grows exponentially to the number of choice options. This causes computational hurdles in estimating RPMs in a reasonable time and identification issues in pinning down the RPM parameters. We provide a unimodal representation of RPMs and explore the properties of this subclass of RPMs. We proceed by developing efficient estimation procedures that iteratively construct a restricted support for the unimodal-RPM. Moreover, we explore identification of unimodal-RPM using the standard (menu, choice) input data and provide insights into their computational and predictive performances using a simulation analysis.

2 - A fast metaheuristic for the alpha-neighbor p-center problem

Roger Rios, Universidad Autonoma de Nuevo Leon, San Nicolas de los Garza, Mexico, Ernesto Ortiz, Diana Huerta

The alpha-neighbor p-center problem (ANPCP) is a location problem in which the goal is to select p centers such that the maximum distance of a user to its alpha-th closest open facility is minimized. This problem arises when the aim is to have a minimum guaranteed response time between a demand point and its center by providing backup centers in case one of them fails to respond to an emergency. We propose a GRASP for this NP-hard problem. The construction phase evaluates the objective function of the p-dispersion problem to provide a feasible solution. We enhanced the time complexity of this heuristic by using tailored-made data structures, called Greedy Dispersion , and adapted it to use a value-based restricted candidate list within GRASP. The constructed solution is then improved, in the next phase, by a local search whose move is a vertex substitution or interchange. We adapted the concept of fast interchange specifically for the ANPCP and called it Alpha Fast Vertex Substitution. This local search is significantly faster by exploiting the structure of the objective function, allowing to reuse several expensive computations, and led to outstanding computational speed-up times for all the test cases. Empirical evidence over a wide set of instances shows the effectiveness of the proposed procedure.

3 - Variable aggregation in a Benders decomposition for the p-median problem

Rick Willemsen, Erasmus University Rotterdam, Rotterdam, Netherlands, Daniel Aloise, Raf Jans

The p-median problem is a classical discrete location problem and is equivalent to the well-known k-medoids problem in the unsupervised clustering literature. The aim is to select p centers while minimizing the sum of distances from each customer to its nearest center. Recent advancements in solving the p-median and related problems have successfully leveraged Benders decomposition methods. In order to reduce the number of variables and possibly the number of Benders cuts in these models, it is possible to aggregate distance variables corresponding to customers. We propose to partially aggregate the distance variables based on an initial solution: aggregation occurs only when the corresponding customers are assigned to the same center in the initial solution. In addition, we propose a set of tailored valid inequalities for these aggregated variables. Initial experiments indicate that our model, post-initialization, provides a stronger lower bound, thereby accelerating the resolution of the root node. Furthermore, this approach seems to positively impact the branching procedure, leading to an overall faster Benders decomposition method.

4 - Workflow Scheduling in Cloud Environments using Graph Neural Networks

Vivek Anand Rajopanth, University of Illinois Urbana-Champaign, Urbana, IL, United States, Rakesh Nagi, Asser Tantawi, Chen Wang

Workflow Scheduling is a combinatorial optimization problem that focuses on efficiently allocating user-submitted jobs to cloud processing clusters. Traditional methods predominantly employ heuristics that are swift to deploy but often deviate from achieving optimal outcomes. In contrast, Mixed Integer Programming (MIP) provides a rigorous model of the system, capable of delivering optimal solutions for any problem instance, but at the expense of more computational time. A key observation in cloud computing systems is the similarity in job types received within specific time frames. Our research capitalizes on this similarity by using a Graph Neural Network (GNN) to predict a part of the schedule (heatmap) based on historical data of successful schedules. We then use these predictions to aid a heuristic to build a feasible schedule with minimal deviations from optimality. By integrating the precision of MIP with the predictive power of the GNN, our approach significantly enhances workflow management efficiency in cloud environments.

System Medicine and AI: Transforming Healthcare Landscapes

Invited Session

Health Applications Society

Chair: Dimitris Bertsimas, Massachusetts Institute of Technology, Cambridge, MA, United States

Co-Chair: Yu Ma, MIT, Cambridge, MA, United States

1 - M3h: Multimodal Multitask Machine Learning for Healthcare

Yu Ma, MIT, Cambridge, MA, United States, Dimitris Bertsimas

Recent breakthroughs in AI are poised to fundamentally enhance our existing study and understanding of healthcare. Specifically, the development of an integrated many-to-many framework that leverages multiple data modality inputs for the analytical modeling of multiple medical tasks, is critical for a unified understanding of modern medicine. In this work, we introduce M3H, an explainable Multimodal Multitask Machine Learning for Healthcare framework that consolidates learning from diverse multimodal inputs across a broad spectrum of medical task categories and machine learning problem classes. We evaluate the M3H framework by validating models trained from four modalities (tabular, time-series, language, and vision) on 41 medical tasks across 4 machine learning problem classes. Our results demonstrate that M3H consistently produces multitask models that outperform canonical single-task models (by 1.1- 37.2%) across 37 disease diagnoses from 16 medical departments, three hospital operation forecast, and one patient phenotyping tasks: spanning machine learning problem classes of supervised binary classification, multiclass classification, regression, and clustering. Additionally, the framework introduces a novel attention mechanism to balance self-exploitation (focus on learning source task), and cross-exploration (encourage learning from other tasks). Furthermore, M3H provides explainability insights on how joint learning of additional tasks impacts the learning of source task using a proposed TIM score, shedding light into the dynamics of task interdependencies. Its adaptable architecture facilitates the easy customization and integration of new tasks and data modalities, establishing it as a robust, scalable candidate solution for advancing AI-driven healthcare systems.

2 - Precision Medicine in Cardiology: Enhancing Valve Prescription for Improved Outcomes

Vasiliki Stoumpou, Massachusetts Instiute of Technology, Cambridge, MA, United States, Phevos Paschalidis, Lisa Everest, Yu Ma

As a minimally invasive procedure, Transcatheter Aortic Valve Replacement (TAVR) has played an increasingly vital role to help fight the prevalent aortic stenosis condition. However, the choice of valve type has remained a much-debated question without clear guidance from either the literature or clinicians. This study leverages artificial intelligence-based techniques to tackle this debate and minimize postoperative complications, specifically permanent pacemaker implantation (PPI). We propose an interpretable, personalizable, machine-learning-based Optimal Policy Tree (OPT) approach to optimally prescribe the preferred transcatheter heart valve (THV), the Medtronic Evolut Pro Plus or Edwards Sapien 3, to minimize postoperative risks. We train our OPT model on a retrospective dataset of patients who received a first-time Edwards Sapien or Medtronic Evolut Pro TAVR procedure between January 2011 and September 2022 at a large hospital system in the US. We perform external validation of our model on a retrospective patient dataset with the same criteria, between January 2011 and December 2021 at Hygeia Hospital, Greece. On historical data from a large US hospital program, we predict a reduction of observed PPI by as much as 26%. On an external validation dataset, we predict a 16% improvement, confirming our model's generalizability on unseen data.

3 - Efficient Infection Detection: Predictive Analytics in Hospital Operations

Phevos Paschalidis, Harvard University, Cambridge, MA, United States, Dimitris Bertsimas, Carol Gao, Konstantina Rasvani

Inappropriate and excessive diagnostic testing for urinary tract infections (UTI) and bloodstream infections (BSI) presents a significant cost burden to hospitals and can result in false positives that mislead physicians and encourage overuse of antibiotics, potentially leading to adverse drug events. Optimizing the process of ordering, performing, and reporting tests such as urinalysis and blood cultures is therefore critical to ensuring high quality care upon patient admission. In collaboration with Hartford HealthCare — the largest hospital system in Connecticut — we develop two clinical support tools that estimate the risk of UTI and BSI for admitted patients. Responding to recent advancements in large-scale multimodal machine learning, we leverage both tabular and language data using the Holistic AI in Medicine (HAIM) framework. Our models achieve high AUC of 0.85 and 0.75 for UTI and BSI prediction corresponding to a 25% reduction in ordered urinalyses and 10% decrease in ordered blood cultures. Given the more than 400,000 urinalyses and 50,000 blood cultures collected annually at Hartford HealthCare, these models promise to save hundreds of thousands of dollars while accurately identifying more than 98% of infected patients.

4 - Brainsage: Learning Meaningful Representations from 3D Brain Scans For Neurological Disease Prediction

Matthew Peroni, MIT, Cambridge, MA, United States

Early detection of neurological disease is a challenging and crucial task in modern healthcare. Given the increasing availability of MRIs, especially T1-weighted (T1w) scans, there has been an effort to use brain scans for early detection and diagnosis of neurological disease. In this work, we develop deep learning models for neurological disorder classification and brain age prediction using T1w MRI scans, leveraging a large data set of scans from a major hospital network in the United States. We develop a 3D vision transformer (Vit) encoder, pre-trained as a masked autoencoder, to project the brain scans into a latent feature space that can be used for various downstream supervised prediction tasks and unsupervised tasks. We demonstrate the potential of using masked autoencoders as a pre-training technique for learning representations of the human brain, leveraging their contextual nature. The downstream models trained on the masked autoencoder representations are extremely light-weight, providing an improvement in parameter and compute efficiency compared to creating task-specific deep-learning models.

Co-Chair: Minmin Zhang, University of Texas at Dallas, Richardson, TX, United States

1 - Improving Access for Underserved Communities: Network Implications of Opening Rural Healthcare Clinics

Masoud Kamalahmadi, University of Miami, Coral Gables, FL, United States, Kurt Bretthauer, Jonathan Helm, Rodney Parker

We study the impact of new rural clinics established by the Department of Veterans Affairs on rural veterans' healthcare access and service utilization patterns. Using a difference-in-difference analysis, we find that the new clinics attracted a significant number of new patients and also increased healthcare usage among current patients, especially in rural areas. We also investigate the network effects of the new clinics on patient demand in other facilities. We find that while the new clinics partially substituted for certain services in a larger medical center, they also generated additional referrals for specialist services not available in them. Conversely, we find a decline in hospitalizations, indicating that the expansion of outpatient services may facilitate earlier diagnoses and interventions, ultimately improving health outcomes.

2 - When Less is More: An Analytical Analysis and Empirical Evidence of Control Limit Strategies in a Telemedicine Platform

Guangwen Kong, Temple University, Philadelphia, PA, United States, Jingxuan Geng, Marco Qin

We consider a telemedicine platform that allows patients to seek multiple medical diagnoses from doctors online. We find that using a commission-based pricing mechanism alone may yield a downward distortion on price to prevent the over-participation of doctors compared to a centralized benchmark. By imposing a control limit on the number of diagnoses received per inquiry, the platform can charge a higher price while maintaining the appropriate number of responses from doctors. When patients are sensitive to delays in receiving diagnoses, interestingly, a platform may benefit from a patient's increased delay sensitivity because it plays a similar role as the control limit by discouraging later arriving doctors from participating. As a result, the profit improvement from imposing a control limit mechanism may decrease with delay sensitivity. When doctors are heterogeneous in their service quality, the undesirable outcome of low-quality doctors driving out all high-quality doctors may occur. A control limit could increase high-quality doctors' participation by increasing their chances of being rewarded by patients. We empirically test the predictions using data from a large telemedicine platform and find that it supports the results from the model analysis.

3 - A Multi-Treatment Forest Approach for Analyzing the Heterogeneous Effects of Team Familiarity

Minmin Zhang, University of Texas at Dallas, Richardson, TX, United States, Guihua Wang, Wallace Hopp, Michael Mathis

This study investigates the impact of team familiarity on surgery duration, exploring whether this effect varies among patients. Introducing and applying the "MT forest" approach to orthopedic surgeries, we show that increased team familiarity, particularly between anesthesiologists and nurses, and surgeons and anesthesiologists, significantly reduces surgery duration. Moreover, the effect of team familiarity varies across patients with different characteristics. By developing an optimization model, the study suggests that leveraging these variable effects enhances hospital operational efficiency by better aligning surgical teams with patients.

4 - The Impact of Inspection Backlogs on Nursing Home Quality: State Agencies&Rsquo; Lax Oversight and Staffing Shortage

Wilson Lin, Santa Clara University, Santa Clara, CA, United States, Susan Lu, Lauren Lu

This study examines the impact of inspection delays on nursing home operations. Using nursing home data from 2013 to 2023 from the Centers for Medicare & Medicaid Services, we find that inspection backlogs are associated with increased nursing home deficiency citations. These effects become stronger as these inspection delays beyond the statutory 15 months between standard health inspections. Furthermore, we find that the effects of these delays are heterogeneous. These findings facilitate us to design a new inspection mechanism under insufficient staffing supply.

1 - Harnessing AI for Holistic Emissions Monitoring and Management in Nature-Based Climate Solutions

Seyed Shahabeddin Mousavi, Stanford University, Stanford, CA, United States, Olamide Oladeji

Amidst the recent rapid advances in the domain of artificial intelligence (AI) and the exploration of possibilities for how AI can change industries, AI has been proposed as an important tool to support an array of efforts related to nature-based climate solutions, including but not limited to the forecasting and detection of wildfires that affect forests and vegetation-based offsets. While this application and others provide important demonstrative value for the extent to which AI can impact climate change mitigation efforts, such efforts have typically been undertaken in disjointed silos, lacking sufficient awareness of the integrative nature of real-world climate policy-making. We propose a novel overarching framework for AI-powered integrated and comprehensive decision support for the various aspects of nature-based climate decision-making. With a focus on vegetation-based solutions such as forests, we demonstrate how different AI-aided decision support models such as AI-powered wildfire detection, vegetation carbon stock assessment, reversal risk mitigation, and disaster response planning can be integrated into a comprehensive framework. Rather than viewing these models as disparate elements working independently, we posit that the exchange of data and analytical results across elements of the framework as they function in tandem and careful mitigation of uncertainty propagation provide tremendous value and significant improvements relative to the status quo for real-world climate policy-making. This comprehensive framework is meant to be utilized by decision-makers to provide comprehensive computational decision support for nature-based climate solutions, enabling steadfast advancement in the domain through scientific backing for climate targets and proposed policies.

2 - Equipping Engineering and Science Students for the Modern Age of Artificial Intelligence

Stephany Coffman-Wolph, Ohio Northern University, Ada, OH, United States

We are currently in an era of unprecedented advancement of artificial intelligence (AI) and the integration of AI into various facets of everyday life. A comprehensive understanding of AI fundamentals is essential to equip the next generation of engineers and scientists with the necessary skills to navigate this ever-changing field. This presentation will cover the curriculum for a course that provides students with a holistic overview of AI and AI fundamentals. By empowering students with AI literacy, we aim to cultivate a generation of innovators equipped to leverage AI technologies responsibly and ethically. Ultimately, we aim to inspire and prepare tomorrow's leaders to harness AI's power for society's betterment.

3 - A bi-level programming approach to climate policy design in liberalized power systems under risk

Emil Dimanchev, Norwegian University of Science and Technology, Trondheim, Norway, Steven Gabriel, Stein-Erik Fleten, Filippo Pecci, Magnus Korpas

Climate policy makers must incentivize risk-averse firms to deploy large amounts of capital toward clean energy. In liberalized electricity markets, firms can face considerable risks due to the incompleteness of long-term markets, which is also known as the missing market problem. We consider how popular climate policies should be optimally designed in such markets. Our focus is specifically on investment tax credits, such as those in the U.S. Inflation Reduction Act, and carbon taxes. We introduce a new analytical framework for modeling a government's optimal policy decisions in anticipation of electricity market behavior under risk. Our model uses bi-level programming to endogenize subsidy choice, unlike traditional models which treat such policies as exogenous. A simple case study demonstrates our approach for an abstract power system with a traditional gas technology, variable renewables, storage, and a clean firm technology, under demand and gas price uncertainty. In illustrative experiments, we observe that optimal investment tax credits and the optimal carbon tax are both higher when long-term markets are missing than when markets are complete. In some of our cases, investment tax credits are more cost-effective than a carbon tax. This occurs because, by increasing investment in renewables, subsidies can mitigate unhedged societal risk from gas price uncertainty.

4 - Dynamic ESG Scoring Modelling in Asset Management

ziru tao, University of Manchester, manchester, United Kingdom, paul baguley, clara cheung, obuks ejohwomu

In the pursuit of a better world and the United Nations Sustainable Development goals, smarter decisions are now critical in the realm of engineering project management. The integration of Environmental, Social, and Governance (ESG) factors into project cost estimation is now critical and timely, and Artificial Intelligence (AI) presents a transformative tool for this task. This research **Aims** to develop an AI-assisted methodology to estimate ESG-related project costs for facilities management of fleets of buildings, disrupting traditional cost management approaches and enhancing decision-making for a more sustainable future.

The **Research Methodology** includes a state-of-art review of 108 journal papers used to synthesise an initial conceptual framework. It includes Estimating Requirements, Data Integration, ESG Costs and Cost Drivers, AI Architecture, and the critical aspect of AI Explainability. The objective of the framework is to guide smarter decisions by providing a clear, accountable, and data-driven approach to ESG cost estimation, thereby contributing to a better world through responsible project management.

The **Findings** are an analysis of a global facilities management company's estimating requirements, and a dynamic ESG scoring model using Recurrent Neural Networks (RNN) to evaluate the ESG performance of fleets of buildings during the use stage of the full life cycle.

The prediction results are favourable in that a chosen ESG metric has been reasonably predicted for the buildings in the data set. However, **Limitations** exist in the scope of the data set analysed, the subjectivity in the ESG metric developed, and the lack of synthesis with private cost data.

5 - Integrating Battery Energy Storage Systems for Renewable Energy Deployment

Carlos Olivos, Universidad Católica del Norte, Antofagasta, Chile, Javier Flores

The Unit Commitment Problem (UCP) is a classical problem in the Operations Research and Power Systems field. During recent years, there has been a significant interest in phasing out fossil fuel-based energy and transitioning towards renewable sources. However, the intermittency of renewables yields to fluctuations, resulting in infeasible pre-dispatch schedules. Battery Energy Storage Systems (BESS) is a technology that could ease the energy transition by storing the surplus of renewable energy and discharging it when energy from renewable sources is not available. In this study, we integrate BESS into the UCP to address renewable energy variability. We evaluate various BESS materials and their impact on the feasibility and cost of energy schedules. Results, conclusions, and algorithms will be presented.

Summit - Ballroom 2

Resilient and Equitable Power Grid Management

Contributed Session

Chair: Juliette Ugirumurera, National Renewable Energy Laboratory, Golden, CO, United States

1 - Envisioning the Future of Power System Operations: An Energyshed Framework

Dakota Hamilton, University of Vermont, Burlington, VT, United States, Samuel Chevalier, Amritanshu Pandey, Mads Almassalkhi

In an effort to enable green energy transition and increase energy resilience, local and regional governments around the world have begun to incentivize the creation of local energy communities through public policy decisions. In this work, we explore the concept of energysheds, which are contiguous energy communities in which a minimum percentage of local energy demand is met by local energy generation over a given window of time, and investigate the impact of energysheds on future power systems operations. We introduce a mathematical framework for studying such energyshed operations and formulate energyshed policy design as an optimization problem which enables communities to achieve their energy transition goals by managing operational flexibility in an equitable and cost-effective manner. The non-linearity of such local energyshed policy requirements and the underlying power system physics results in non-convex optimization problems. Despite this, we demonstrate how the problem structure can be exploited by leveraging techniques from quasi-convex optimization and parametric optimization in order to find globally optimal solutions within arbitrary precision. Through this framework, we study how physical power system infrastructure and public policy requirements can enable or hinder the ability of local energy communities to achieve their energy goals. Finally, we demonstrate the importance of cooperation and coordination across energysheds, which are interconnected by electrical networks, as a critical step in green transition.

2 - Power grid reliability during future extreme heat and wildfire events

Hannah Burroughs, Lawrence Livermore National Laboratory, Livermore, CA, United States, Juliette Franzman, Jhi-Young Joo, Jean-Paul Watson, Andrew Mastin

Heat waves can have significant human and economic impacts including strain on the power grid. In addition, if wildfires happen concurrently with heat waves, they can further strain the power grid due to requirements to de-energize power lines near active fires or electrical infrastructure damaged within wildfire perimeters. As the probability and severity of concurrent heat waves and wildfires increases due to global climate change it is insufficient to use historical data to understand the potential impacts of these extreme events.

We develop a methodology to study the power reliability impacts of future concurrent extreme heat and wildfires. First, we identify plausible future heat wave events using temperature data from a high-resolution global climate model. The temperature data set is then used to predict increase in electrical load. In parallel, we identify future high risk wildfire areas using global climate model projections. To determine the power grid impact of plausible future wildfire events we use a bi-level optimization method. The objective is to find the set of power grid components which, if damaged by wildfire, will lead to the largest loss of load, with an understanding of how the grid operator will adjust the system in the event of outages. Finally, we use the hourly electrical load data and wildfire contingency set (electrical components disable during fire) to study the reliability impacts on the power grid (using a steady state AC power flow) from these concurrent events.

3 - Equitably Allocating Wildfire Resilience Investments for Power Grids: The Curse of Aggregation and Vulnerability Indices

Madeleine Pollack, Massachusetts Institute of Technology, Cambridge, MA, United States, Ryan Piansky, Swati Gupta, Alyssa Kody, Daniel Molzahn

Wildfires from power lines are devastating, with recent fires like the Camp Fire in California and the Smokehouse Creek Fire illustrating the need for effective, long-term solutions to fires ignited from power infrastructure. Emergency power shutoffs reduce wildfire risk from power lines; however, network, geographic, and demographic factors can lead to disproportionate power lost by vulnerable groups. Hence, power line undergrounding is an attractive, if costly, alternative. In this study, we model and evaluate Biden-Harris Justice40 policies for equitable power shutoff and undergrounding decisions on a high-fidelity synthetic transmission network in Texas using a Mixed Integer Program. We find that vulnerability indices suffer from “the curse of aggregation,” preventing targeted intervention to at-risk groups. Therefore, we recommend coupling vulnerability indices with percentage-based “min max fairness” objectives to prioritize relief to these groups.

4 - New integer programming formulations for parallel power system restoration

Hatice Çalık, KU Leuven, ELECTA, Department of Electrical Engineering, Leuven, Belgium, Dirk Van Hertem

Blackouts are emergency situations with tremendous economic and societal impacts. To minimize these impacts, efficient restoration of power systems after a blackout is of extreme importance. We investigate novel methods for restoring power systems as quickly as possible after a total blackout. Particularly, we introduce new integer programming formulations for the NP-Hard generator start-up sequencing (GSS) and parallel power system restoration (PPSR) problems. A blackout refers to a complete loss of power in the grid. Only a subset of generators has the capability to restart themselves to quickly reach their maximum capacity and energize other generators and critical loads. Such generators are referred to as ‘black start’ (BS) generators. BS capacity is often not sufficient to energize the entire network directly.

Energizing one or more non-BS generators of higher capacity gradually increases the power capacity and step-by-step restores the entire network. The GSS is challenging since each non-BS generator requires an initial cranking power for a certain period. Once the cranking period is over, the power output of the generator increases at a certain rate until it reaches the maximum capacity. The PPSR combines network design decisions with the GSS to enable partitioning the network into connected components for safer restoration. Our models provide tight bounds for both problems and they outperform the state-of-the-art formulations in terms of speed on several IEEE network instances. We also discuss model extensions for tackling uncertainty due to high penetration of renewable energy resources.

5 - Enhancing Power Grid Resilience: a Stochastic Programming Approach for Infrastructure Hardening

Minhang Zhou, University of Arizona, Tucson, AZ, United States, Pavlo Krokhmal

Climate hazards such as hurricanes pose significant threats to overhead power distribution systems, demanding improved resilience under extreme weather conditions. To address this, we propose a two-stage stochastic programming model aimed at optimally hardening power grid infrastructure. In the first stage, the model determines the hardening degrees for each transmission line, while in the second stage, it seeks to minimize total load shedding and assign optimal power flows across the lines. A novel aspect of our model is its handling of decision-dependent uncertainty, specifically the survival probabilities of distribution lines, which vary based on first-stage hardening decisions. We employ sample average approximation (SAA) to manage problem size and a modified Benders decomposition algorithm to enhance computational efficiency. The validity and effectiveness of our approach are demonstrated through application to the IEEE 33-bus distribution system under typical and extreme scenarios. This study provides a strategic framework for resource allocation in power systems facing increasing risks from climate-related events.

6 - Energy Justice Constrained Power System Dispatch and Planning

Juliette Ugirumurera, National Renewable Energy Laboratory, Golden, CO, United States, Sarah Awara, Devon Sigler, Vikram Ravi, Yun Li, Sarah Inskeep

Power plants are a major contributor to air pollution, and our current grid modeling systems lack the ability to integrate air pollution and health impact considerations from the electricity industry into their optimization processes. To address this gap, we propose a novel approach that connects a power system model (Sienna) with a high-fidelity air quality model (SCICHEM) and a human health impact assessment tool (BenMAP). This integrated system evaluates the health and damage costs associated with operating power plants and can identify environmental justice impacts on different demographic groups, especially vulnerable communities.This approach will also guide better decisions in capacity expansion models to avoid disproportionately affecting certain communities in future energy systems. A case study will demonstrate the modeling capabilities and provide example analyses for regions with at-risk populations. This new system can be utilized by system operators, researchers, and other stakeholders to improve energy planning and operations that ensure equity and understand the effects of our current power system on specific communities.

Summit - Ballroom 3

OR in the Utilities Industry

Invited Session

The Practice Section of INFORMS

Chair: Kathryn Walter, Avista Corporation, Spokane, WA, United States

1 - Implementing Optimization at Avista

Kathryn Walter, Avista Corporation, Spokane, WA, United States

Over the past dozen years, Avista has gone from not using mathematical modeling to having customized optimization models embedded within the organization to help with both short term and long term decisions. This presentation will discuss how the team grew the Avista Decision Support System (ADSS) from one person’s idea to a highly used and highly impactful tool. The audience will learn what optimization for the utilities industry looks like in practice.

2 - *Optimization-Based Framework for Enhancing Photovoltaic Hosting Capacity with Battery Energy Storage under Uncertain PV Adoption*

Khash Mahani, Quanta Technology, Brooklyn, NY, United States

Determining photovoltaic (PV) hosting capacity and enhancing it while considering uncertainties surrounding PV adoption is essential for renewable promotion and robust grid planning and operations. Existing methods for determining PV hosting capacity under uncertain PV adoption have limitations in terms of computational efficiency, accurate representation of probabilistic PV adoption, and applicability for designing solutions to increase hosting capacity beyond current limits. This presentation focuses on an optimization-based probabilistic integrated planning framework for distribution grids. It assesses feeder hosting capacity while assuming uncertain locations and amounts of PV adoption and optimizes battery deployment to increase hosting capacity limits to desired targets under those probabilistic scenarios. The framework is then applied to a distribution feeder, validating the methodology and demonstrating the benefits of batteries in maximizing PV penetration. The proposed framework can provide guidance to planners in making informed decisions regarding PV deployment strategies and effective utilization of batteries for renewable integration.

3 - Representing future hydrogen markets in the National Energy Modeling System

Stephen York, U.S. Energy Information Administration, Washington, DC, United States, Kathryn Dyl

The U.S. Energy Information Administration (EIA) will discuss our efforts to develop and integrate a representation of future hydrogen markets within our National Energy Modeling System (NEMS).

The NEMS model produces multi-decadal, long-term projections of energy systems for the United States as published in the Annual Energy Outlook (AEO). NEMS produces a general equilibrium solution for U.S. energy markets on an annual basis and includes detailed representation of energy demand, transformation, and supply projections.

A new Hydrogen Market Module (HMM) will represent the domestic hydrogen market in AEO2025. Representing an integrated hydrogen market in the NEMS allows us to analyze the potential growth in hydrogen use as a clean energy source and to reflect current laws and regulations. It also allows us to evaluate the mid- to long-term impacts of these regulations, such as the Section 45V hydrogen production tax credits in the Inflation Reduction Act, and to evaluate the possible roles of hydrogen in deep decarbonization scenarios.

The HMM projects hydrogen production by technology, connecting supply to consumers. HMM demands electricity and natural gas, transforms fuels into hydrogen, and delivers it to consumers. For AEO2025, HMM focuses on representing a simplified, integrated U.S. hydrogen market reflecting key dynamics. We are simultaneously modifying existing NEMS consumption representation for ammonia plants and refineries and adding new potential sources of hydrogen demand for the industrial, transportation, and electric power sectors.

The EIA is a U.S. statistical agency that collects, analyzes, and disseminates independent and impartial energy information.

Summit - Signature Room

Role of Influencers in Social Media

Contributed Session

Chair: Yigit Ege Bayiz, 2207 Leon Street, 78705

1 - Recommendation Agents: Transformer-Based Personalized Recommendation Systems

Landon Butler, University of California, Berkeley, Berkeley, CA, United States, Yigit Efe Erginbas, Andrew Qin, Kannan Ramchandran

The recommendation systems employed in large online marketplaces such as Amazon and Alibaba are typically designed in-house, resulting in recommendations that are geared towards maximizing the platform's profits rather than prioritizing consumer welfare. Third-party services such as Google Shopping exist to aggregate products from various online retailers, but generate revenue through paid product promotions. All in all, by using recommendation services whose goals are not fully aligned with their own, a consumer may encounter difficulties in finding the product that best meets their preferences. Furthermore, it offers little incentive for the consumer to offer feedback that improves the recommendation services for themselves and others.

Building on the recent emergence of powerful AI personal assistants, we introduce recommendation agents: interactive, cross-domain recommendation algorithms seeking to maximize the welfare of a particular consumer. Our agent comprises three sub-modules: a sequential recommendation transformer, which learns the consumer's evolving preferences from historical purchase sequences; a personalized recommendation constructor, which accounts for the consumer's idiosyncrasies such as price and risk sensitivities; and an Augmented Language Model, designed to explain recommendations and integrate consumer feedback. Through testing on a large-scale Amazon dataset, we demonstrate empirically that our agents can accurately learn consumer preferences and offer strong predictive power. We conclude with discussion on the construction of markets over many recommendation agents, allowing for efficient price discovery in large online marketplaces.

2 - Who Are the Favorites of Multi-Channel Networks? Influencer Selection with Product Collaboration

Xiongfei Guo, University of Science and Technology of China, Hefei, China, People's Republic of, Yangyang XIE, Jie Wu

We consider a brand cooperating with a Multi-Channel Network (MCN) to sell product on sales events. The brand may provide standard product, or utilize MCN’s IP into its product, called collaboration product. The MCN works with multiple heterogeneous influencers differing in performance and type. We investigate the brand’s product policy, MCN’s influencer selection strategy, and influencers’ pricing decisions with standard and collaboration products. We find that product collaboration achieves better utilization of influencers’ performance and better coverage of market, which always benefits the brand and may hurts the MCN. We obtain the MCN’s optimal influencer selection strategy, which trades off between matching influencers’ type with consumers’ taste and avoiding intensified influencer competition, and provide a quick judgement for adopting the multiple-influencer strategy. We also reveal that with standard product, a higher commission rate is always preferred by the MCN, whereas with collaboration product, making a concession to the brand in the commission rate may benefit the MCN. Additionally, higher-performance influencers may hurt brands providing standard product, while always benefit brands with collaboration product. Meanwhile, higher-performance influencers may be non-favorable for an MCN with both products. Technically, we develop a framework dealing with game involved optimization problems where infinite equilibria exist.

3 - Impact of Average Rating and Number of Reviews on Business Performance on Digital Platform

Samayita Guha, Florida International University, Miami, FL, United States, Naveen Kumar, Subodha Kumar, Joydeep Srivastava

Consumers increasingly use social media contents to make their purchase decision. A significant number of consumers study online reviews about products or services before purchasing. Online review platforms, such as Yelp and TripAdvisor, provide consumers with reviews and ratings of businesses and service providers. Hence, all types of businesses maintain their presence on online review platforms to improve their performance. To make their presence felt strongly among so many other competitors on online review platforms, the businesses need to understand which review characteristic (such as volume, rating value, reviewer identity, texts, etc.) has more influence on consumer purchase decision and in what ways. In this context, it becomes important to understand the interplay between both review rating and review number. To study this interplay empirically, we are using a data set about restaurants that are present on Yelp platform. The answer to our research question will help restaurants in allocating their resources more effectively to improve the number of reviews and improve their rating, depending on whether they have high or low average ratings.

4 - A Dynamic Model of Influencers' Organic and Sponsored Content Creation

Michael Yang, University of Texas at Dallas, Dallas, TX, United States, Xingchen Xu, Yong Tan

In online video platforms, influencers draw their audience by consistently generating high-quality content. Concurrently, they engage in the production of sponsored content, which provides direct economic benefits. This approach, however, incurs potential costs as followers may respond negatively to overt commercialization, impacting the influencers' long-term earning potential. Influencers must therefore strategically balance immediate financial returns with the dynamics of follower engagement to sustain future gains. Additionally, the manner in which sponsored content is presented—including its placement and duration—significantly influences viewership metrics and follower behavior. In light of these dynamics, we have developed the first dynamic model that accounts for forward-looking and strategic content creation decisions among influencers. This model has been calibrated using data from a prominent Chinese video platform. We also propose a counterfactual policy designed to optimize content delivery efficiency.

5 - Ranking Refinement for Increasing Credibility in Social Media Recommendations

Yigit Ege Bayiz, The University of Texas at Austin, Austin, TX, United States, Arash Amini, Ufuk Topcu

Social media often includes content derived from news sources. However, these sources are not always credible, which negatively impacts the credibility of the social media content. We present an optimization-based method designed to improve the source credibility of news content on social media platforms by refining existing content feed rankings to include source credibility scores. Our proposed solution uses a dual-objective optimization approach that minimizes the Kendall tau distance to the original ordering to approximately maintain the original content order while incorporating a linear cost function tailored to elevate the credibility of sources. We showcase our approach through an experimental setup using Reddit posts, where our algorithm doubles the credibility of ranked content compared to Reddit's hot ranking algorithm. Additionally, the algorithm allows for the incorporation of arbitrary scores other than source credibility, making it applicable across various platforms and capable of refining any arbitrary ranking of items with an additional linear cost objective.

AI for Social Good

Invited Session

Information Systems

Chair: Aaron Cheng, London School of Economics, London, United Kingdom

1 - Roleplaying of AI: the Effect of Authoritative and Altruistic Ai on Promoting Prosocial Behaviors

Haoze Wu, University of Rochester, Rochester, NY, United States, Junyuan Ke, Weiguang Wang

In the implementation of AI, identity plays a critical factor, with human and AI identities exhibiting varied effects. However, existing literature on AI identity typically discloses the tool’s nature as AI rather than portraying it as human. Within this framework, different AI roles can be assigned, but their effects remain unclear. This study explores how varying AI roles impact effectiveness due to their assigned identities. We conducted a field experiment at a business hotel to investigate the effect of AI systems fulfilling different roles on environmental sustainability, specifically water consumption reduction. Based on our AI’s personalized prediction on water usage for different customers, messages were generated with varying degrees of authority and altruism to reducing water usage. Based on our randomized field experiment of the four study groups, no AI, neutral AI, authoritative AI, and altruistic AI, the findings reveal that authoritative AI messaging significantly reduces water consumption among guests. In contrast, no significant reduction is observed for neutral and altruistic AI, compared with no AI. The study underscores that AI’s persuasive capabilities vary with the different perceived roles. Overall, this research contributes to the broader discourse on AI’s role in human-AI collaboration and resource management.

2 - The Impact of Artificial Intelligence (AI) Powered Micro-gym on Public Health Welfare

Siliang Tong, Nanyang Technological University, Singapore, Singapore, Mingjie Ma, Kimhuat Goh, Yixing Chen

The rise of AI empowers the prevalence of micro-gym, a compact gym center well connected through AI technology for exercise booking and movement monitor and feasible for single person private exercises. The emergence of AI-powered micro-gym not only facilitates exerciser with better understanding of their exercise progress with AI data tracking and analysis, but also complement the discrepancy between commercial gym center and public gym facilities in local neighborhood with the flexibility and accessibility. In this study, we investigate the social impact of AI micro-gym rollout on public health welfare improvement. Leveraging a granular doctor visit record database across subzones in Singapore, we gauge how the introduction of the micro-gym affects the likelihood of doctor visits of local residents. Our empirical analyses with a stagger Difference-in-Differences framework demonstrate that the introduction of micro-gym significantly reduces the likelihood of doctor visits for local residences, indicating an improvement of the public health welfare. Further analyses across different types of diseases suggest that the introduction of micro-gym in local subzones reduces the likelihood of doctor visits for chronic diseases, cancer, digestive diseases, endocrine, musculoskeletal, mental diseases, stroke, and physical injury.

3 - Safety on Autopilot: An Empirical Investigation of Autonomous Driving and Traffic Safety

Jiyong Park, University of Georgia, Athens, GA, United States, Miyeon Jung, Min-Seok Pang

While autonomous driving holds the promise to confer economic and societal benefits, there has been a persistent concern on the safety of vehicles on autopilot. This study investigates the impact of automated driving systems on traffic safety. We design a natural experiment by combining Tesla’s rollout of ‘Navigate on Autopilot’ (NoA) in the U.S., an advanced autopilot feature that enables semi-autonomous driving on the highway, with regional variations in the intensity of Tesla vehicles. Using granular-level data on traffic accidents and electric car registrations in the Washington state during the period 2011–2022, our findings show that the intensity of Tesla vehicles is significantly associated with the reduction in the number of traffic accidents after the rollout of NoA, especially for non-fatal accidents. Additionally, it has proven more effective in preventing single-car accidents involving pedestrians or collisions between Tesla and non-Tesla vehicles, further substantiating the safety advantages of this technology. Moreover, we reveal the circumstances and conditions under which vehicles on autopilot can enhance traffic safety. Specifically, the semi-autonomous driving feature of Tesla demonstrates its effectiveness in preventing non-fatal accidents, especially under circumstances with limited visibility, less familiar routes, and less uncertainties on the roads. Taken together, our findings imply that the safety implications of autonomous driving are shaped by situational factors, encompassing not only the constraints of human capabilities but also the technological capabilities that can overcome these challenges. This study sheds new light on the potential of automated systems to prevent human errors and enhance safety.

Machine Learning and Game Theory in Policy and Sports

Contributed Session

Chair: William Melville, Brigham Young University, Brigham Young University, Provo, UT, 84602, United States

1 - Integrating Machine Learning with System Dynamics: A Pioneering Approach to Addressing Policy Leakage and Enhancing Environmental Governance <cib-overlay></cib-overlay>

Satwinder Singh, Indian Institute of Management Amritsar, Amritsar, India, Aarushi Jain

In the realm of Public Policy research, the mitigation of policy leakage is a critical concern. This study introduces an innovative methodology that amalgamates machine learning with System Dynamics, thereby augmenting the analytical prowess. By harnessing the insights derived from machine learning, System Dynamics is able to employ optimal feature selection, thereby streamlining the analysis of voluminous datasets. This hybrid model significantly bolsters analytical accuracy and efficiency, which in turn enhances decision-making processes across a multitude of domains. The integration of machine learning techniques enables System Dynamics to adeptly navigate the intricacies of large datasets, thereby facilitating more profound insights and informed analyses. Furthermore, the employment of optimal feature selection methodologies ensures the procurement of relevant data, thereby amplifying the capacity of System Dynamics to provide meaningful insights. This approach ultimately provides an efficacious solution for the analysis of extensive datasets, obviating the need for manual intervention and economizing resources. Consequently, this advances decision-making processes across a diverse array of domain of policy leakage research.

2 - Analysis on relationship between language models and data quality through personality type prediction

Sungmin Lim, Ewha Woman's University, Seoul, Korea, Republic of, Juheon Kwak, Dongil Kim

In social media data analysis, the Myers–Briggs Type Indicator (MBTI) is used as a label for data analysis and artificial intelligence model training. Although the format and interests of posts may vary depending on the platform, there is research showing that an individual's text input style and speaking style revealed in the context of the post is related to MBTI. In this study, we evaluate the performance of several transformer-based language models using a low-capacity, high-quality Kaggle dataset. Then, we conducted the same experiment with high-volume, low-quality Twitter MBTI data and Reddit MBTI data to analyze which model using the data had better performance and even the performance when cross-verified.

3 - A Game Theoretical Approach to Baseball Managerial Decisions

William Melville, Brigham Young University, Provo, UT, United States, Tristan Mott, David Grimsman, Christopher Archibald

During baseball games, managers are tasked with making important strategical decisions such as when to replace a starting pitcher with a reliever, when (and with whom) to pinch hit for a batter, and when to make a defensive substitution. An optimally-strategic manager must consider how the opposing manager might react to their decisions. For instance, a manager may hesitate to bring in a relief pitcher to face an opposing hitter if they know that their opponent is likely to replace that hitter with a pinch hitter. In this work we model these baseball matchup decisions as an extensive-form zero-sum game played between two baseball managers. The goal of each manager is to take the sequence of actions that leads their team to a win with the highest probability. As part of our game model we present a novel approach to calculating the probability of plate appearance outcomes between a batter and a pitcher. This model considers the skill of the fielders and the effect of pitch count, which helps identify when a pitcher is too fatigued to continue pitching. We conclude that a Nash equilibrium strategy in this game identifies a baseball management strategy that is robust to opposing counterstrategies.

Co-Chair: Cristian Roman, Western University, London, ON, Canada

1 - The Impact of Supply Chain Networks on Correlated Default for SMEs

Sahab Zandi, Western University, London, ON, Canada, Kamesh Korangi, María Óskarsdóttir, Christophe Mues, Cristián Bravo

In the domain of financial risk assessment, some recent research has focused on understanding how credit risk spreads among Small and Medium-sized Enterprises (SMEs). SMEs often form complex networks through mutual dependencies and financial interactions, which dynamically evolve. This study utilizes multilayer network data from SMEs, provided by a prominent financial institution, to estimate credit risk. Our approach leverages graph neural networks to predict SME default, using multilayer network data where connections are based on company ownerships and financial transactions between them. We demonstrate that combining this information with traditional structured data enhances application credit scoring performance, and explicitly models contagion risk across companies. Moreover, the study explores how the directionality and intensity of these connections influence risk propagation, offering a more profound understanding of the underlying processes. Our findings, validated against multiple baseline models, reveal the significance of incorporating network data and underscore the critical role of supply chain networks in the correlated default risks faced by SMEs.

2 - Breaking Barriers: Unveiling Gender Disparities in Corporate Board Career Paths using Deep Learning

Yuhao (Jet) Zhou, Western University, London, ON, Canada, Collins Ntim, María Óskarsdóttir, Matt Davison, Cristian Bravo

This study delves into the interplay between gender, professional networking, career-path trajectory, and board director appointments in Canadian publicly traded companies. At the core of our inquiry lies a uniquely constructed dataset, meticulously derived from BoardEx. This dataset (consisting of over 700 Canadian firms covering more than 19,000 senior managers and board members between 2000-2022), presents detailed network connections of both senior managers and board members across five key dimensions: education, current and prior employment, and current and prior social engagement. By matching senior managers of both genders based on their career trajectories and backgrounds, and applying Long Short-Term Memory (LSTM) deep learning alongside network analysis, we uncovered the distinct network influences impacting the board appointment prospects of women versus men. The findings causally demonstrate a "glass ceiling", suggesting that women necessitate more substantial networking credentials than men to secure equivalent corporate board positions.

3 - Self-explainable Nowcasting with Large Language Models

Daniel Abib, University of Western Ontario, London, ON, Canada, Cristian Bravo, Sanghyun Jung

We build a novel multimodal learning model with the capability of generating self-explanatory documentation.

Using separate blocks for forecasting economic time series and generating text, we use a Large Language Model (LLM) to fine tune the desired combined output to be a forecasting report with both the input numbers and a comment resembling an expert forecaster. The complexity of the document can then be tweaked according to necessity.

The model being built in blocks allows for using the preferred forecasting method, as well as for updating the LLM model when a superior one becomes available by simply switching the blocks.

4 - Score2Text: a Large Language Model Designed for Interpretable Credit Scoring

Huan Yu, University of Southampton, Southampton, United Kingdom

The widespread adoption of predictive modelling in finance institutions has significantly improved credit risk assessments. Traditional credit scoring models has been criticized of lack the transparency and interpretability for stakeholders to understand the rationale behind credit decisions. This study explores the innovative use of large language models (LLMs) to generate natural language explanations for credit scoring. By leveraging the advanced nature language processing capability model of LLMs, we aim to produce clear, human-readable interpretations of credit risk predictions. Our methodology integrates fine-tuned Llama with established interpretability technique of SHAP (SHapley Additive exPlanations) to elucidate the factors influencing credit predictions. Experimental results on diverse credit scoring datasets demonstrate that our approach not only significantly enhance interpretability of credit scores but also makes it possible to automate credit analysis reports. This study highlights the potential of LLMs to provide transparent and comprehensible explanations, fostering greater trust and enabling more informed decision-making in financial institutions.

5 - Finding paths to financial wellness: comparing investment decisions through time

Sanghyun Jung, Western University, London, ON, Canada, Cristian Bravo

The financial decision-making process of individuals is highly complex, influenced by a myriad of factors including demographics, income, macroeconomic conditions, and previous decisions. Traditional research often models this process by focusing on a limited number of these factors, which falls short of capturing the complexity of reality and fails to predict counterfactual outcomes of decision-making pathways accurately. With the rapid advancement of deep learning, there is now potential to leverage extensive datasets to more accurately model complex investment decision-making processes. However, deep learning models often struggle with discerning potential outcomes along specific decision paths. In response, our study introduces a novel causal deep learning model that leverages a Causal Transformer architecture, enhanced by incorporating time-fixed transformer blocks. These blocks compute attention scores for time-fixed variables that universally affect observations but not vice versa. This model is designed to estimate and interpret the causal impact of investment decisions. Utilizing data such as Know Your Client (KYC) profiles, account transactions, and macroeconomic indicators, we analyze which factors significantly influence decision-making paths. Moreover, by exploring counterfactual scenarios, we determine which decision paths could lead to desired financial wellness outcomes for individuals. This approach enhances our understanding of complex decision dynamics and aids in the practical application of achieving targeted financial objectives.

Adoption and Applications of AI Agents Featuring ML Algorithms

Invited Session

Artificial Intelligence

Chair: Xiaoyan (Amber) Liu, Santa Clara University, Santa Clara

1 - Algorithmic Bidding in Procurement Auctions

Jingyi Tian, University of Houston, Houston, TX, United States

As online auction platforms evolve rapidly, they amass vast data from repeated interactions, prompting bidders to harness AI technology for strategic advantage. This paper explores the intriguing role of AI bidders in online procurement auctions, driven by this technological shift. Through a novel analytical model, we demonstrate how the Deep Q-Network (DQN), a widely used reinforcement learning algorithm, achieves a stable auction equilibrium. Our findings reveal a fascinating twist: the algorithm, operating with incomplete information, learns a correlated objective that leads to overbidding. We further investigate market conditions that enable collusive algorithmic overbidding through the DQN updating process. Complementing our analytical insights, we also conduct experiments with AI bidders to empirically confirm stationary convergence on algorithmic overbidding and assess measures to mitigate this inefficiency. Our results highlight the peril of misspecified correlated objectives in AI-driven multi-agent environments, showing stark contrasts in decision-making and equilibrium outcomes compared to rational human bidders. In light of this discrepancy, we offer strategic recommendations for refining procurement processes in auctions to minimize algorithmic overbidding. Additionally, we discuss broader implications for market design on digital platforms, advocating for human-centered approaches amid the rapid surge in AI adoption. Our work underscores the critical need for thoughtful AI integration in auction markets, balancing technological advancements with effective governance.

2 - Target Collection using Efficient Reinforcement Learning Algorithms via Posterior Sampling for Distributionally Environments

M. Amin Rahimian, University of Pittsburgh, Pittsburgh, PA, United States, CARLOS HURTADO, Lei Fang, Ze-Xu Li

Consider a soldier/robot(Agent) that is searching for targets in a bounded region (Environment). The agent does not have information on the exact location of the targets, but that their locations are sampled from a given distribution. Target locations are sampled from a hierarchical normal model with two levels. The first level uses an overall mean and overall variance-covariance matrix to sample centers of patches. Therefore, we use each center of the patch as a mean parameter to sample targets per patch. We want to find a set of movement directions, also known as policy, such that we maximize the number of targets collected and minimize the total distance traveled. This optimization problem is equivalent to maximizing the search efficiency which is the ratio between targets collected and distance traveled. We take advantage of the structure of the target distribution to design a policy while the agent interacts with the environment and collects more information. Thus, we use the following key ideas to implement a policy as a solution to our problem. If the targets' locations are known, this problem can be stated as a shortest path problem. Which is easy to solve, where each target location is a node to visit in the shortest path problem. Either if the target is found or not, we can update the overall hierarchical distribution model. We show that this approach learns the optimal path between nodes, and we provide convergence rates as a function of the parameters of the hierarchical distribution.

3 - AI Spillover Impact on Real Estate Employment

lingyu li, Virginia Commonwealth University, Richmond, VA, United States, Yeongin Kim, Xiaojin Liu

This study explores the AI technology spillover effects. This study investigates the spillover impact of AI on employment in the real estate industry. We model AI technology using the upgrades of Zestimate in Zillow. We explore how the upgrade of Zestimate in Zillow spillover to affect the employment of real estate agents. In this paper, we apply a difference-in-difference and propensity score matching method. We find a significant negative spillover impact of AI technology application on employment in the real estate industry. These impacts are more pronounced in poorer areas and high technology penetration areas. Our work has practical implications for policymakers in formulating AI technology-related policies. Furthermore, our study supports the argument that AI technology helps alleviate the imbalance between the poor and the rich, thereby improving overall social welfare.

4 - AI Driven Software Development: An Empirical Analysis

Karthik Babu Nattamai Kannan, Southern Methodist University, Dallas, TX, United States, Narayan Ramasubbu

Generative AI is significantly transforming the landscape of software development. By leveraging advanced machine learning algorithms, GenAI automates various aspects of the development process, thereby increasing efficiency, reducing errors, and fostering innovation. These tools help developers generate code, summarize their changes, test and debug the code. Prior research points to an increase in developer productivity due to GenAI tools. In this paper, we examine how the introduction of GenAI tools impacts the software development. We exploit a quasi-experimental setting in which GenAI tools were introduced during certain time periods of the development process. Using a difference-in-differences framework, empirically examine how the adoption of these GenAI tools impacts the different aspects of the software development process.

AI Innovations: Text Interaction to Trustworthy Decisions

Contributed Session

Chair: Petros Xanthopoulos, Stetson University, DeLand, FL, United States

1 - Committee Configuration Optimization for Parallel Consensus

Yifei Xie, University of Edinburgh, Edinburgh, United Kingdom

Current blockchain applications encounter significant scalability challenges. A practical solution to this issue involves partitioning the consensus network into multiple committees and executing consensus processes in parallel, a technique known as sharding. However, achieving optimal partitioning in distributed environments is complex due to potential node failures and network communication delays.

To address this problem, we propose a stochastic programming method designed to enhance the performance of parallel consensus in sharded blockchain networks. Our primary objective is to develop an optimal partition configuration that maximizes performance in the sharded blockchain network, accounting for uncertain network conditions and dynamic system states. This approach integrates the strengths of traditional methods, random configuration, and mathematical programming. We applied stochastic programming to optimize both the replication protocol during normal operations and the view change protocol in the event of a leader node failure.

To evaluate the effectiveness of our method, we conducted experiments in a realistic testing environment using Microsoft Azure cloud virtual machines. Our results demonstrate a consistent performance improvement of approximately 24% in parallel consensus, thereby validating the efficacy of our proposed method.

2 - A text similarity based tool against AI-assisted paraphrasing

Petros Xanthopoulos, Stetson University, DeLand, FL, United States, Konstantinos Xylogiannopoulos, Panagiotis Karampelas, Georgios Bakamitsos

Large Language models (LLMs) can be used to paraphrase human text that in turn can be used in a number of malicious AI-assisted plagiarism applications. Unlike conventional AI text detection, paraphrased text can fly under the radar of commercial AI detection classification tools. In this presentation we demonstrate certain similarity based patterns that can be used for the successful detection of AI plagiarized text generated by ChatGPT. We demonstrate the application of this feature into a number of application such as fake online review detection and fake news articles detection.

3 - Impacts of Resource Sharing in Smart Manufacturing on Operations Strategy: A Text Mining Approach

Ai-Hsuan Chiang, Ming Chuan University, Taipei, Taiwan

With the advent of Industry 4.0, smart manufacturing has become a trend in the manufacturing industry. Smart manufacturing enhances production flexibility to create customized products and reduces the need for labor, enabling enterprises to lower various costs. This article focuses on the relationship between smart manufacturing and operations strategies. Previous research indicates that sharing and utilizing resources can bring greater benefits to enterprises. Therefore, this study explores the impact on competitive priorities when enterprises implement knowledge sharing and physical resource sharing under smart manufacturing. This research employs text mining methods, using corporate annual reports and data from the Taiwan Economic Journal to analyze research model from 281 electronic manufacturing companies. The results show that smart manufacturing significantly influences both cost-first competitive priority and customization-first competitive priority. Knowledge sharing positively affects the choice of a cost-first competitive priority for enterprises. If an enterprise opts for a customization-first competitive priority, it needs to implement both physical resource sharing and knowledge sharing. The findings illustrate that under smart manufacturing, the benefits can only be maximized when the chosen strategies and resource-sharing behaviors of an enterprise are aligned.

4 - Do Not Let the Lexicons and Their Components Drive Your Results

Eduardo Villacis-Calderon, University of Texas at El Paso, El Paso, TX, United States, Sergio Grove, Yoonsun Jeong

Given the popularity and widespread application of computer-aided text analysis (CATA) approaches in lexicon-based text analysis, we present a novel issue that researchers usually overlook. Our research examines the implications of improper use of difference scores in sentiment analysis paired with whimsical lexicon selection criteria. We replicate prior research on perceived review usefulness that used difference scores to measure overall sentiment (positive minus negative sentiment) as the sole sentiment construct. Our study demonstrates that inadequate approaches to using overall sentiment scores may result in empirical bias that can lead to opposite effects depending on the lexicon employed. We raise awareness of substantial methodology weaknesses that affect researchers in their theorization and testing. Using a sample of 21,016 consumer reviews from Amazon.com, our findings call for changes in methodology when using the overall sentiment score and selecting lexicons. Accordingly, we provide practical recommendations and minimum testing standards for CATA lexicon-driven models in business research.

Innovative Approaches in AI, Supply Chains, and Multi-Agent Systems

Contributed Session

Chair: Kyeonghyeon Park, KAIST, 291, Daehak-ro, Yuseong-gu, Daejeon, 34141, Korea, Republic of

1 - Hypernetwork-based approach for optimal composition design in partially controlled multi-agent systems

Kyeonghyeon Park, KAIST, Daejeon, Korea, Republic of, David Molina Concha, Hyun-Rok Lee, Chi-Guhn Lee, Taesik Lee

A Partially Controlled Multi-Agent System (PCMAS) is comprised of two types of agents: those that are controllable, directly managed by a system designer, and those that are uncontrollable, operating autonomously. In scenarios where agents' autonomy must be preserved, effectively managing controllable agents is essential for steering the system towards desired outcomes. In this study, we investigate a new approach to the composition design problem faced by the system designer in PCMAS, wherein the optimal number of controllable agents within a budget constraint should be found. Besides determining the optimal number of controllable agents, this problem also involves crafting cooperative policies for the controllable agents and identifying the best response policies for the uncontrollable agents. Obtaining the solution to this problem requires repeatedly solving multi-agent reinforcement learning (MARL) for various configurations, which is computationally demanding. To overcome these obstacles, we introduce a hypernetwork-based method that optimizes system composition and cooperative policies. Instead of training independent policy networks for each composition, we utilize a hypernetwork architecture that generates the weights of another neural network, enabling unified training across all system compositions. Through this approach, we generate policies for both controllable and uncontrollable agents across various system compositions, mitigating computational burden and lack of information sharing in similar compositions. We assess how closely the generated policies approximate equilibrium policies and demonstrate performance improvements resulting from optimized system composition facilitated by the trained hypernetwork.

2 - Modeling human behavior with incomplete data; a hybrid approach integrating agent-based modeling and machine learning

Ali Mahdavi Adeli, University of Memphis, Memphis, TN, United States

To create simulation models of socioeconomic phenomena (e.g., human behavior in financial markets), we can think of two extremes on a continuum. On one extreme, we have an established theory or full understanding of the phenomena (and/or its domain) and can therefore hardcode (stochastic or deterministic) decision rules to create, for example, agent-based models, or specify analytical models with certain simplifications and assumption about the domain (e.g., Cobb-Douglas production function in economics). On the other end, we might not have an understanding or theory of the phenomena but have large amounts of data, which allow us to use data-hungry machine learning (ML) or deep learning approaches to create models that replicate the observed phenomena or predict outcomes of interest. In between these two extremes, we have situations where there is partial understanding about the phenomena and partially observed data (on outcomes and variables of interest), but not enough to successfully utilize purely ML based approaches. We propose a hybrid approach integrating ML techniques with agent-based modeling to model human behaviors in such scenarios, i.e., where there is partial understanding and partially observed data available. We provide a guideline to determine the suitability of our proposed approach given a problem scenario and demonstrate its effectiveness by creating a simulation model of human decision making in the complex decision environment of combinatorial auctions. We show how our approach provides, otherwise unfeasible, insights on auction outcomes and participants' strategies under all plausible scenarios.

3 - The Limits of Static Decision Rules in Supply Chain Games

el ouardighi fouad, essec business school, cergy, France

This talk suggests examples of supply chain game models, each associated with specific scenarios involving one manufacturer and either one supplier or one retailer. Both shortsighted and farsighted decision rules are derived from the models. Our analysis exposes the underlying mechanisms contributing to the suboptimality of static policies compared to their dynamic counterparts.

4 - Achieving Sustainable Supply Chains through Artificial Intelligence: Systematic Literature Review

Abdullah Albizri, Montclair State University, Montclair, NJ, United States, Marina Evy Johnson, Antoine Harfouche

The sustainability and supply chain management research studies have become more theoretically rich and methodologically rigorous. Similarly, there have been many significant advances in Artificial intelligence (AI) and an increase in its adoption that AI-based technologies drive many industry functions and operations. Therefore, there is an increasing demand for investigating the ways to create and manage sustainable supply chains, particularly through AI. To this extent, this paper provides a systematic, rigorous, and methodologically valid review of sustainable supply chain management and AI literature to extract insights and identify AI-related key factors to create and manage sustainable supply chains. This study also determines the most recent trends and gaps to develop a new research agenda to guide future sustainable supply chain management studies.

1 - Game Theory and Sports Analytics with Applications to Baseball

David Grimsman, Brigham Young University, Provo, UT, United States, Christopher Archibald, William Melville

Game theory is a mathematical tool used to analyze strategic decision-making in complex environments. Its application to sports is a natural fit, given the recent abundance of data and well-defined rules and outcomes. In this talk we will give a brief overview of game theory and sports analytics, including problem formulation and the fundamental tradeoff between optimization and robustness. We will discuss a recent line of work in baseball: an analysis of the batter-defense interaction as a zero-sum game. The work presents a methodology for choosing an optimal pitch sequence and fielder positioning by solving for a game equilibrium that is a generalization of Nash equilibrium and Stackelberg equilibrium. The presentation will conclude with some possible game-theoretic problem formulations and expected challenges in other major sports.

2 - Teaching and Engaging Students with Sports Data: SCORE National Network

Andrew Lee, US Military Academy, West Point, NY, United States

Many students are athletes and/or avid sports fans who appreciate and find motivation in applications of statistics to issues that arise in sports. Where can instructors (or students) find relevant and accessible sports data? What are some sports questions that map well to typical course objectives? How can we structure sports-based examples to be accessible and interesting to non-fans? How can instructors publish their own instructional modules? I will share information about the SCORE network, which is a national network for developing and disseminating Sports Content for Outreach, Research, and Education in data science, funded through the NSF. The mission of SCORE is to create a sustainable national network of academics, industry and government partners that will build the SCORE platform through which we will develop and ensure the sustainability of our efforts in elevating statistics and data science education, particularly in underrepresented populations and minorities.

3 - Who is the GOAT? Sports Rankings and Random Walks on the Symmetric Group

Juan Martinez Mori, Georgia Institute of Technology, Atlanta, GA, United States, Gian-Gabriel Garcia

Given a collection of historical sports rankings, can one determine which athlete is the greatest of all time (i.e., the GOAT)? In this work, we introduce a data-driven random walk on the symmetric group to obtain a stationary distribution over athlete rankings, spanning across different time periods in sports history. We combine this distribution with a notion of stochastic dominance to obtain a partial order over the athletes. We implement our methods using publicly available data from the Association of Tennis Professionals (ATP) and the Women's Tennis Association (WTA) to find the GOATs in the respective categories.

4 - Personalized Endurance Training: Leveraging Data for Runner Optimization

Marc De Reu, University Ghent (Belgium), Gent, Belgium, Dirk Van den Poel

In recent years, training theory for endurance sports has emphasized optimizing training loads. Not only elite runners but also recreational marathon runners rely on personalized training plans to improve their performance and prevent injuries. Previously, only experienced human coaches could design such plans. However, we develop algorithms that use detailed training and racing data to generate customized training plans for each runner.

Our model uses a comprehensive dataset with specific details of training sessions and race performance to tailor each training session to the runner's unique profile, time available to train and performance goals. Our machine-learning model analyses large amounts of data to adjust training variables such as intensity and volume, minimizing the training load for each runner, and providing feedback to both the runner and the coach.

Our approach has shown promising results, such as an improvement in performance by approximately 2% - 3% and a decrease in injuries by more than 50% compared to traditional training methods. While these initial results are promising, we believe that including additional lifestyle factors such as sleep patterns, stress levels and dietary habits could further refine the accuracy of our training algorithms. Our goal is to develop even more personalized and effective training plans that take these broader personal lifestyle variables into account.

Our new approach demonstrates the potential of using detailed data in sports training and paves the way for more advanced adaptations in personalized coaching in endurance sports.

5 - Nfl Referee Bias Based on Perceived Differences in Quality and Score Difference

Timothy Kaskela, Oregon State University, Corvallis, OR, United States

Research has consistently found that referees are affected by bias in numerous contexts. Prior research has focused on how bias occurs against each team, finding bias based on factors such as home team and distance of fans to the playing area. This research examines how penalties are called based on a different context: how penalties are called on the winning team. As both teams could be winning at different times during the game, the examination of penalties does not solely focus on one team or the other. Instead, I examine how penalties are called on the winning team at that specific point in the game. This examination is conducted through play-by-play data for every NFL game from 2016-2022. As I focused on plays in which a penalty was called, the dataset was narrowed down to only those plays that resulted in a penalty, for a final total dataset of 21,473 observations. Moderating factors such as the difference in perceived quality of each team, score differential, and subjectivity of a penalty are taken into account. I find that there is an inverse u-shaped relationship between score differential and probability of a penalty being called on the winning team and the difference in perceived quality of the teams has a significant effect on said relationship. In addition, while prior research has found that the number of penalties called on each team tends to be fairly balanced, I find that penalties when split between when a team is winning or losing is unbalanced.

Latest Practices of Stochastic and Robust Optimization for Renewable Energy

Invited Session

ENRE: Electricity

Chair: Guangchun (Grant) Ruan, MIT, Boston, MA, United States

1 - Planning and Investment in Electricity Markets with Abundant Penetration of Offshore Wind Using Quantile Fourier Regressions and Markov Decision Processes

Golbon Zakeri, University of Massachusetts - Amherst, Amherst, MA, United States, Geoffrey Pritchard, Arash Khojaste

We will present a model for daily operation of electricity markets with abundant penetration of renewable resources of electricity generation, e.g. offshore wind. Our model captures the underlying uncertainty based on inhomogeneous Markov models whose states are determined from quantiles of the underlying data. To incorporate seasonal and diurnal variations smoothly and have a simple parametric form, we appeal to Fourier basis functions.

2 - Designing Renewable Power Purchase Agreements: Impact on Green Energy Investment

Zuguang Gao, University of California, Irvine, Irvine, CA, United States, Nur Sunar, John Birge

We study a firm that aims to sign a power purchase agreement (PPA) with a renewable energy producer. Using a stochastic control framework, we identify the optimal renewable PPA for the firm. Our analysis generates various valuable insights for both managers and policy makers.

3 - Optimization for Data-Driven Modeling and Control of Inverter-Based Resources

Javad Khazaei, Lehigh University, Bethlehem, PA, United States

A complex physics-based modeling procedure and the uncertainty and confidentiality of internal parameters of cyber-physical systems motivate data-driven system identification tools. With the availability of high-fidelity measurements and historical data, model-free identification of nonlinear dynamical systems can facilitate the control design without tedious physics-based modeling procedures. An application domain that can benefit from such exploration is the electricity grid with many inverter-dominated cyber-physical systems such as renewables, energy storage, electric vehicles, and various nonlinear loads, which is complex to model using conventional approaches. This presentation introduces statistical learning and sequential optimization techniques for data-driven nonlinear modeling and control of distributed energy resources (DERs) in smart grids using sparse identification. Using the proposed data-driven model identification tool for closed-loop control of DERs, we demonstrate the effectiveness of a model-free design in successful control and stability analysis of nonlinear DERs in smart grids. Compared with existing physics-based designs that heavily rely on knowing the detailed system dynamics or uninterpretable data-driven designs that rely on large historical data, the proposed model-free DER identification and control frameworks can accurately capture the dynamics of the DERs based on available measurements and provide guaranteed performance for black-start, weak AC grid integration, microgrid integration, and stability analysis.

4 - Distributionally Robust Chance-Constrained Optimal Building HVAC Control for Renewable Integration

Jin Dong, Oak Ridge National Laboratory, Oak Ridge, TN, United States, Yiling Zhang

Aggregation of heating, ventilation, and air conditioning (HVAC) loads can provide reserves to absorb volatile renewable energy, especially solar photo-voltaic (PV) generation. Given the uncertain and time-varying nature of solar PV generation, its probability distribution is difficult to be estimated perfectly, which poses a challenging problem of how to optimally schedule a fleet of HVAC loads to consume as much as local PV generation. We formulate a distributionally robust chance-constrained (DRCC) model to ensure that PV generation is consumed with a desired probability for a family of probability distributions under two typical ambiguity sets: the moment-based and Wasserstein ambiguity sets. We derive mixed integer linear programming (MILP) reformulations for DRCC problems under both sets.

AI and Data Science for Smart Systems

Invited Session

Data Mining

Chair: Jihoon Chung, Pusan National University, Busan

Co-Chair: Emmanuel Yangue, Oklahoma State University, Stillwater, OK, United States

1 - Physics Informed Neural Network Using Sparse Identification of Differential Equation with Application to Additive Manufacturing

Jihoon Chung, Pusan National University, Korea, Korea, Republic of, Raghav Gnanasambandam, Bo Shen

Differential equations are fundamental in modeling numerous physical systems, including thermal, manufacturing, and meteorological systems. Due to the development of deep learning, Physics-informed Neural Networks (PINN) are evolving as a new paradigm for solving differential equations. However, most previous work assumes that differential equations are given, which is an unrealistic assumption in practice. Therefore, we develop the framework to determine the accurate differential equations for PINN. Specifically, we focus on the sparsity of possible functions of the differential equation to derive accurate equations according to data. The actual additive manufacturing data is utilized to validate the proposed method's effectiveness.

2 - Noise Conditioned Diffusion Denoising Implicit Model (Ddim) with Mixed Sampling Distribution and Adversarial Discrimination

Emmanuel Yangue, Oklahoma State University, Stillwater, OK, United States, Chenang Liu, Wenmeng Tian, Feng Yu

Given the rapid progress in deep learning, numerous studies have employed its capacity to tackle diverse challenges within specific fields. Within engineering applications (e.g. additive manufacturing (AM) and disease treatment using medical imaging), the analysis and interpretation of images are pivotal for advancing system capabilities and expanding their utility. This study introduces an advanced diffusion-based generative model with adversarial capability. In this novel approach, the diffusion model employed, a denoising diffusion implicit model (DDIM), serves as the generator in the adversarial framework to produce high-quality synthetic images. Within this model, a variational encoder conditions the diffused noise injected into input images with prior information from the training images. Afterward, the generated images go through a timestep discriminator to assess their realism. The noise distribution is based on a hybrid sampling technique that combines gamma and Gaussian distributions. The proposed model underwent testing across various case studies, including layer-wise AM images and tumor ultrasound medical images. Current findings demonstrate the substantial potential of this approach to provide solutions to real-world engineering applications.

3 - Multi-Objective Bayesian Optimization Framework for Extreme Value Analysis

Shehzaib Irfan, Auburn University, Auburn, AL, United States, Jia Liu

Extreme value theory (EVT) can model and predict extreme events, such as floods, heatwaves, and financial crises. The block maxima (BM) sampling is usually used to divide the region of interest (e.g., years) into blocks and extract the maximal values from each block for EVT analysis. However, BM lacks a mechanism to propose an optimal block size for extracting the maximal values. This work proposes a Bayesian optimization framework for finding the optimal block size for modeling the extremes. The framework defines two objective functions that balance goodness-of-fit for distribution of maximal values and prediction accuracy for extreme values. The optimal block size is found from a Pareto frontier by using Multi-Objective Bayesian Optimization. In the case study, using the optimal block size from the proposed framework for EVT analysis has achieved an improvement of about 50% in prediction accuracy. Such framework can be extended to different applications when using EVT to analyze extreme events.

4 - Personalized Federated Learning for Enhanced Predictive Modeling in Additive Manufacturing

Rong Lei, Rutgers University-New Brunswick, Piscataway, NJ, United States, Yuebin Guo, Weihong Guo

Additive Manufacturing (AM) processes can significantly benefit from process monitoring, anomaly detection, and defect prediction. Current AM processes are characterized by significant variability and complexity, often leading to instability and defects. Averaging-based federated learning (FL) approaches, designed for collaborative learning without data sharing, struggle with the inherent heterogeneity of AM data. This paper introduces a novel knowledge-distillation based FL framework tailored for the AM industry, particularly addressing small- to medium-sized enterprises (SMEs) that crowdsource shared resources. The proposed framework incorporates personalized models that leverage local knowledge and dynamic distillation techniques to improve predictive accuracy and robustness across diverse AM scenarios. Our approach enhances data preprocessing to reduce heterogeneity and accelerates model convergence. We design a dynamic evaluation of knowledge transfer to balance global model accuracy with local personalization. Additionally, the framework incorporates customized aggregation indices to guide the selection of local training models and hyperparameters.

Advances in Quantitative Methods for Business Analytics

Invited Session

Data Mining

Chair: Jessica Leung, Monash University, Melbourne, 3145, Australia

1 - High-Dimensional Visualisation via Projection Pursuit: Performance of the jellyfish optimizer

Jessica Leung, Department of Econometrics and Business Statistics, Monash University, Melbourne, Australia, Sherry Zhang, Nicolas Langrené, Di Cook

This study explores the integration of the jellyfish algorithm, a metaheuristic optimizer, in enhancing high-dimensional visualization through the projection pursuit guided tour. The jellyfish algorithm, inspired by the natural foraging behavior of jellyfish, is utilized for its efficiency in navigating the complex search spaces typical of high-dimensional datasets. Through extensive simulations, our approach demonstrates improved efficacy in uncovering underlying data structures that are not readily apparent. Our findings suggest that using the jellyfish algorithm markedly enhances the discovery of insightful projections, facilitating a deeper understanding of multidimensional data landscapes.

2 - Market Timing with Bi-objective Cost-sensitive Machine Learning

Robert James, The University of Sydney, Sydney, Australia, Jessica Leung, Artem Prokhorov

This paper develops a framework for cost-sensitive training of machine learning models that predict the direction of aggregate stock returns. We design a bi-objective loss function that augments the traditional log-loss objective with an objective that minimizes the cost of individual false-positive and false-negative classification errors. We argue that the option implied tail conditional value-at-risk is a natural measure of misclassification costs. Our bi-objective optimization framework permits us to isolate the effect of cost-sensitivity from log-loss minimization, and integrate forward-looking information from options markets directly into the model training process. We study changes in the classification behavior of elastic-net logistic regression and gradient boosted decision trees trained using our bi-objective loss function. These new models improve the risk-adjusted returns of market timing strategies and substantially reduce downside risk.

3 - TBA

4 - Enhancing cyber resilience of crown jewels in cyber supply chains

Kam-Fung Cheung, University of New South Wales Business School, Sydney, Australia, Chung-Li Tseng, Michael Bell

The COVID-19 pandemic has accelerated the digitisation of businesses, while its associated cyber threats affect various industries such as logistics and shipping. The unavailable crown jewels, i.e., critical assets, due to successful cyberattacks undermine the focal organisation's and its partners' profits, thus there is an urgency in enhancing cybersecurity and cyber resilience of critical assets in supply chains. This work proposes a novel integer programming model based on eigenvector centrality to identify (hidden) critical assets in a cyber supply chain network and improve their security by implementing effective cybersecurity measures. Managerial insights for enhancing cybersecurity and cyber resilience for critical assets are provided to help develop defensive strategies.

5 - On Improved Semi-parametric Bounds for Tail Probability and Expected Loss

Artem Prokhorov, University of Sydney Business School, CEBA, CIREQ, Sydney, Australia, Erick Li

We revisit the fundamental issue of tail behavior of accumulated random realizations when individual realizations are independent, and we develop new sharper bounds on the tail probability and expected linear loss. The underlying distribution is semi-parametric in the sense that it remains unrestricted other than the assumed mean and variance. Our sharp bounds complement well-established results in the literature, including those based on aggregation, which often fail to take full account of independence and use less elegant proofs. New insights include a proof that in the non-identical case, the distributions attaining the bounds have the equal range property, and that the impact of each random variable on the expected value of the sum can be isolated using an extension of the Korkine identity. We show that the new bounds not only complement the extant results but also open up abundant practical applications, including improved pricing of product bundles, more precise option pricing, more efficient insurance design, and better inventory management.

Data Analytics and Machine Learning in Healthcare

Invited Session

Data Mining

Chair: Tianshu Feng, George Mason University, Fairfax, VA, United States

1 - Variational and Explanatory Neural Networks for Encoding Cancer Profiles and Predicting Drug Responses

Tianshu Feng, George Mason University, Fairfax, VA, United States, Rohan Gnanaolivu, Yuanhang Liu, Jun Jiang, Alexander Partin, Priyanka Vasanthakumari, Yitan Zhu, Chen Wang

Human cancers present a significant public health challenge, necessitating novel drug discoveries through translational research. Transcriptomics profiling data, detailing molecular activities in tumors and cancer cell lines, are widely utilized for predicting anti-cancer drug responses. De-spite previous efforts to develop data-driven AI/neural network (NN) models for cancer studies, their effectiveness is impeded by a lack of robust encoders to account for noise in continuously measured transcriptomics data and difficulty achieving biological interpretability in sophisti-cated learning tasks, such as drug response predictions. To address these limitations, we intro-duce a novel neural network framework, VETE (Variational and Explanatory Transcriptomics Encoder), which incorporates a variational component to combat noise effects and integrates traceable gene ontology into NN architecture to encode cancer transcriptomics data. Key innova-tions include a local interpretability-guided method for identifying connected ontology terms as an interpretable path for explaining predictions and an interactive visualization tool to elucidate likely biological mechanisms for different anti-cancer drug responses. The VETE framework demonstrated robust classification accuracies in patient tumors and cancer cell lines. Moreover, we investigated the interpretability of VETE in classifying human cancer cell-lines according to tissue of origins and predicting drug responses, providing traceable biological explanations. VETE represents a promising advancement in the field, bridging the gap between AI-driven pre-dictions and biologically meaningful insights in cancer research.

2 - Artificial Intelligence for Nano Particle Folding Prediction of Rna

You Zhou, Arizona State University, Tempe, AZ, United States

The approaches to predict the RNA secondary structure were mainly realized by minimizing the free energy previously. Due to the large success of utilizing Deep Learning to predict the protein structure, utilizing Deep Learning becomes a new direction to handle RNA structure prediction. In this study, we propose a novel Deep Learning approach (Transformerfold) to predict the RNA secondary structure. The Transformerfold is based on Transformer whose predictions are reinforced by our previously proposed RNA sequence-secondary structure pair evaluation models, NU-ResNet and NUMO-ResNet. The Transformerfold with its open-source software would be beneficial to RNA folding field.

3 - SAM-Driven Explainable and Uncertainty-Aware Automatic Measurement Model in Echocardiography

Beom Gyo Shin, Yonsei University, Seoul, Korea, Republic of, Jaeik Jeon, Hyunsoo Yoon

In echocardiography, an estimation of left ventricular (LV) volume plays a key role in assessing cardiac diseases, yet it poses challenges. Previous research has relied on segmentation-based approaches, which incur significant costs and time for labeling. Additionally, in quantitative medical image analysis, there exists inter-intra observer variability. This study introduces a novel probabilistic deep learning framework for measuring the LV volume and quantifying associated uncertainty, without relying on segmentation labels. Furthermore, the proposed method maintains the explainability of the model by generating LV boundary using weak supervision techniques and Segment Anything Model (SAM). Experimental results demonstrate competitive performance in predicting both LV volume and boundaries and estimating uncertainty.

4 - Inferring Drug-Induced Plasticity via Drug Screen Data

chenyu wu, University of Minnesota - Industrial and Systems Engineering, MINNEAPOLIS, MN, United States, Kevin Leder, Jasmine Foo

Resistance to drugs remains a significant challenge in cancer treatment, often attributed to the presence of a cancerous stem-like subpopulation that drives tumor recurrence post-treatment. Compounding this issue, many drugs targeting cancer cells inadvertently induce plasticity, reverting differentiated cancer cells to a stem-like state. Addressing this phenomenon is crucial for advancing cancer therapeutics. In this study, we introduce a robust statistical framework founded in multi-type branching processes to dissect both drug effects and tumor dynamics using high throughput screening data. Through comprehensive *in silico* experiments, we demonstrate the efficacy of our framework in accurately estimating parameters governing population dynamics and drug responses. Moreover, our framework is applied to recent *in vitro* data, spotlighting the drug-induced plasticity of ciclopirox olamine in gastric cancer cells. Leveraging established model selection criteria, our analysis yields consistent insights into the impact of ciclopirox olamine on gastric cancer cell behavior.

5 - Modelling hospital bed and ventilator capacity during COVID-19

Ozlem Cosgun, Montclair State University, Montclair, NJ, United States, Eyyub Kibis

During the COVID-19 outbreak, all countries faced a critical shortage of beds and ventilators that caused a dramatical increase in mortality rates. In this study, we addressed the optimization problem of allocating bed and ventilator capacities by explicitly incorporating Non-Pharmaceutical Interventions (NPIs) into an extensive SIR model to minimize the number of deaths in New York City during COVID-19. A mixed integer programming model was developed to decide on the optimal bed and ventilator expansion amounts that minimize the number of deaths over time.

Heat Decarbonization

Invited Session

ENRE: Energy-Climate

Chair: Jacqueline Dowling, Carnegie Science, 260 Panama St., Providence, 94305, United States

Co-Chair: Henry Ssembatya, NC State University, RALEIGH, NC, United States

Co-Chair: Aleksander Grochowicz, University of Oslo, Oslo, Norway

1 - The Role of Policy and Module Manufacturing Learning in Industrial Decarbonization by Small Modular Reactors

Max Vanatta, University of Michigan, Ann Arbor, MI, United States, Michael Craig, William Stewart

Small nuclear modular reactors (SMRs) offer a unique solution to the challenge of decarbonizing mid- and high-temperature industrial processes. We develop deployment pathways for four SMR designs serving industrial heat processes at 925 facilities across the United States under diverse policy and factory and onsite learning conditions. We find that widespread SMR deployment in industry requires natural gas prices above $6/MMBtu or aggressive carbon taxes. At natural gas prices of $6 to $10/MMBtu, 7 to 55 GWt of SMRs could be economically deployed by 2050, reducing annual emissions by up to 59 million mt CO2e. Widespread deployment potential hinges on avoiding substantial cost escalation for early investments. Policy levers like direct subsidies are not effective at incentivizing sustainable deployment, but aggressive carbon taxes and investment tax credits provide effective support for SMR success. Large-scale SMR deployment hinges on factory, not onsite, learning.

2 - Evaluating Tradeoffs of Residential HVAC Electrification in a Changing Climate

Parth Vaishnav, University of Michigan, Ann Arbor, MI, United States, Shuhaib Nawawi, Michael Craig, Ming Yi

Decarbonizing the residential sector requires the electrification of the heating, ventilation, and air conditioning (HVAC) systems, with air source heat pumps (ASHP) emerging as a promising technology. To plan for this transition, analysts must evaluate the effect of widespread ASHP adoption at an appropriate temporal resolution, focusing on both household and power grid. In response, we develop a reduced complexity building energy model (RC-BEM) to predict the hourly energy demand of over 17k statistically representative single-family homes across 54 U.S. cities. Using RC-BEM, we co-optimize occupant- and grid-related objectives using historical and future climates. Our trade-off analysis reveals three key findings: i) energy cost dominates the optimization and is the most sensitive to different comfort levels, followed by monetized human health and environmental damages from electricity consumption, and peak demand cost, ii) conventional HVAC sizing strategies based on historical climate may be inadequate for ensuring thermal comfort in a warmer climate, and iii) using the price of electricity as a proxy for thermal discomfort is likely to underestimate the true disutility experienced.

3 - A Comparison of Integrated Power System and Natural Gas Planning under Building Sector Decarbonization Policies

Stephanie Wilcox, Johns Hopkins University, Baltimore, MD, United States, Ben Hobbs, Ozge Kaplan

Policies aimed at decarbonizing the building sector seek to mitigate greenhouse gas (GHG) by promoting the use of cleaner technologies, restricting access to GHG-intensive fuels, or transitioning electricity generation towards lower carbon-sources, for example. However, the economic implications, operational effects, and investment impacts of these policies are often understudied. Our research, using a generation and expansion planning model and natural gas distribution system steady-state flow model, indicates that power system decarbonization goals result in minimal building sector GHG reductions. Our findings also suggest that the most cost-effective GHG-reducing solutions consider homogeneity of building archetypes and local natural gas and power system network characteristics, such as capacity and age.

4 - Stochastic Power-Gas Infrastructure Planning to Meet the Challenges of Heating Electrification

Rahman Khorramfar, MIT, Cambridge, MA, United States, Dharik Mallapragada, Saurabh Amin

Central to economy-wide decarbonization efforts is building heat electrification which directly impacts power-gas infrastructure through replacing gas with electric power. Here, we develop a modeling framework to quantify the end-use demand for both power and gas in the residential building sector under various electrification pathways. We then evaluate their impact on the joint power-gas investment and operational planning under uncertainty to ensure that the future grid is resilient to interannual weather variations. This modeling framework is motivated by the uncertain impacts of climate change on renewable energy potential and shifting demand patterns in many socio-economically vulnerable regions. We propose two mathematical paradigms, namely stochastic programming (SP) and distributionally robust optimization (DRO), to characterize the underlying uncertainty in power-gas demand as well as generation potential of renewables. We develop a computational approach that exploits the spatial correlation between electric power and natural gas demands both within and across load zones, resulting in a mixed-integer programming (MILP) formulation. We compare the resulting uncertainty-aware designs with the certainty equivalent problem for a realistic power-gas system in the U.S. New England region and highlight the importance of systematic modeling of inter-annual variability in demand and renewable energy supply.

Operational and Data-Centric Perspectives on Sustainability

Invited Session

ENRE: Environment and Sustainability

Chair: Ilgin Dogan, INSEAD, Fontainebleau, 94707, France

Co-Chair: Ho-Yin Mak, Georgetown University, Washington, DC, United States

1 - Data-Driven, Large-Scale Inventory Routing for Energy Solutions at the Bottom of the Pyramid

Dan Iancu, Stanford University, Stanford, CA, United States, Sergio Camelo, Maximilian Schiffer, Simon Thoma

We propose a large-scale inventory routing problem in the context of distributing clean cooking stoves in East Africa. Using a comprehensive dataset from an industry partner, we develop a stochastic model that accounts for significant supply and demand fluctuations, censored and incomplete data, and propose a data-driven approach to solve the resulting problem at scale. Our numerical results demonstrate that the proposed method yields significant improvements over the status quo, leading to significant cost savings and improved accessibility to clean cooking solutions.

2 - Exploring the Distribution Dynamics of Clean Cooking Solutions

Banu Tiryaki, Stanford University, Stanford, CA, United States, Dan Iancu, Omer Karaduman

This study examines the role of third-party service providers in the distribution and adoption of clean cooking solutions in Kenya. The emergence of new clean cooking solutions has created job opportunities that not only facilitate the adoption of these innovations but also potentially support the businesses providing them. Our research models the operations of intermediaries connecting users with businesses and examines individual participation in these third-party services. By exploring the dynamics of these intermediaries, we aim to understand their impact on the market and the businesses supplying clean cooking solutions.

3 - Planning Stormwater Retention for Resilience Against Extreme Rainfalls

Aiqi Zhang, Wilfrid Laurier University, Waterloo, ON, Canada, Sheng Liu, Wei Qi

Climate changes inflict prolonged and intensified rainfalls on cities around the world. Unfortunately, existing efforts hardly meet the urgent need for climate-adaptive stormwater management. Urban stormwater infrastructure is typically planned based on empirically predetermined rainfall scenarios on the intensity-duration-frequency (IDF) curve, which fails to capture the worst-case scenarios that should be planned against. This paper identifies the worst-case rainfall scenarios that cause the most severe flooding loss through robust optimization, which constructs a new type of uncertainty set that builds upon IDF curves. Our analysis reveals that not all rainfalls on the same IDF curve are equal in terms of the incurred flooding loss. If the planners fail to account for the city's intrinsic infrastructure capabilities, they may pick a wrong 50-year rainfall to target and end up barely surviving a 2-year rainfall. Hence, we construct cost-indifferent isocurves that classify rainfall events according to the severity of the flooding loss, providing city planners with interpretable flooding risk mitigation guidelines. We demonstrate that cities should be savvy in achieving a balance between investments in stormwater retention flow rate and investments in stormwater retention capacity, as reflected in the composition of green and grey infrastructures. Under a budget constraint, green infrastructures should give way to grey ones, exchanging flow rates for a larger retention capacity to withstand severe rainfalls that have a longer duration and larger volume. Finally, we show that flooding loss ramps up quickly as the climate change risks are exacerbated, underscoring the urgency of taking the proposed integrated measures.

4 - Optimal Management of Renewable Energy Certificates (REC): A Reinforcement Learning Approach

Michael Lim, Seoul National University, Seoul, Korea, Republic of, Daeho Kim, Dong Gu Choi

Renewable Portfolio Standards (RPS), which require electricity suppliers to purchase Renewable Energy Certificates (RECs) from renewable energy generators to meet the standard levels, have led to the emergence of a brokerage service for renewable generators. Our research focuses on optimizing REC management for brokerage service providers. We use a Markov Decision Process framework to formulate the problem and identify key structural properties of the optimal policy. We then develop a deep reinforcement learning (DRL) algorithm and verify its performance based on real market data. Finally, we employ eXplainable AI techniques to understand the logic behind our black-box DRL algorithm

5 - Estimating the Impact of Climate Change: An Empirical Analysis of Smart Thermostat Data

Michael Blair, Wilfrid Laurier University, Waterloo, ON, Canada, Saed Alizamir, Shouqiang Wang

Using a rich micro-level dataset, we empirically analyze smart thermostat data to understand the relationship between households' thermostat settings and their ambient environment. Within this data we observe two key decision levers that households use to manage their home heating and cooling. Combining a variety of methodological tools including Dynamic Linear Models, random effects, and Bayesian Statistics, we develop models for these behavior levers and study how households are impacted by varying weather conditions. A critical insight from these models is that households typically react to the weather in a comfort-seeking manner, leading to increased energy usage. We also find that this behavior is more prevalent in households that routinely override the settings they have pre-programmed into the thermostat. With these insights in mind, we leverage well-established models to create realistic estimates of future weather conditions under a variety of climate change scenarios and combine these scenarios with our statistical models to estimate the impact of climate change on how households use their thermostats. Specifically, we predict future household behavior and investigate the resulting changes in energy usage for heating and cooling. These changes have a profound impact on the operations of the energy grid specifically relating to operating costs, grid capacity, and reliance on intermittent renewable energy sources. The insights derived from our research provide a valuable framework to evaluate and design interventions such as smart nudging or demand response management programs.

Power Systems Operations and Planning V: Recent Advances

Invited Session

ENRE: Other Energy

Chair: Mengyi Sha, Tsinghua University, Beijing, N/A

Co-Chair: Wei Qi, Tsinghua University, Beijing, N/A, China, People's Republic of

1 - First-in-first-out (FIFO) or highest-energy-first-out (HEFO)? A tale of two electric vehicle (EV) battery swapping policies

Mengyi Sha, Tsinghua University, Beijing, China, People's Republic of, Wei Qi, Yuli Zhang

Battery swapping is gaining traction in cities and spurs wider EV adoption, as the business mode can alleviate range anxiety efficiently. In this paper, considering random service requests and random status of incoming batteries, we focus on the operations management of an individual battery swapping station, and propose mean-variance distributionally robust optimization (DRO) models to compare FIFO and HEFO swapping policies analytically. The results demonstrate that HEFO policy is superior to FIFO policy in most scenarios, except when all EVs wait for the recharged batteries to reach a target state-of-charge (SOC). We also verify the conclusions via numerical experiments using real-world data sets.

2 - Robust Grid-Vehicle Integration: A Machine Learning-Driven Optimization Approach

Ziliang Jin, The Hong Kong Polytechnic University, Hong Kong, China, People's Republic of, Jianqiang Cheng, Kai Pan, Zuo-Jun Shen, Yulan Wang

We examine a grid-vehicle integration system that uses vehicle-to-grid (V2G) technology to connect the grid and the electrical vehicle sharing system. Our focus is on the operation of this integration system under uncertainties. We formulate a two-stage robust mixed-integer program. We propose a machine learning-driven optimization approach that incorporates alternating direction method of multipliers (ADMM), machine learning, and strong valid inequalities. This approach significantly outperforms a commercial solver in both computational time and solution quality based on real data. Our findings suggest that in addition to enhancing the operation efficiency of the grid, V2G also promotes sustainability by reducing carbon emissions. However, the extent of this contribution varies under different power load patterns.

3 - Virtual Trading in Multi-Settlement Electricity Markets

Bo Yang, Columbia University, New York, NY, United States, Agostino Capponi, Garud Iyengar, Daniel Bienstock

In the electricity market, suppliers and load-serving entities (LSEs) enter into contracts to secure energy in the Day-Ahead (DA) market and later adjust for any discrepancy between contracted quantities and actual deliveries in the Real-Time (RT) market. This two settlement structure offers hedging benefits for both suppliers and LSEs but may lead to market inefficiencies. We develop a supply function equilibrium model to explore how virtual trading — a financial strategy that allows participants to speculate on price differences between the DA and RT markets without physical transactions — can mitigate these inefficiencies. Our analysis reveals that without virtual trading, LSEs often bid below their actual demand in the DA market, leading to DA prices that are lower than the expected RT prices. We show that introducing virtual trading narrows this price disparity and, with an increasing number of virtual traders, potentially eliminates it. Nonetheless, this mechanism prompts LSEs to further reduce their bids in the DA market, deviating from their true demand forecasts. Our analysis indicates that the presence of renewable energy suppliers leads LSEs to submit higher bids in the DA market, compared to scenarios with traditional energy suppliers only. We provide empirical support to our main model implications using data from the California and New York Independent System Operators.

Chair: Rohit Kannan, Virginia Tech, Blacksburg, VA, United States

1 - A Generalizable Learning Approach to Accelerate Global Optimization of Quadratically-Constrained Quadratic Programs

Harsha Nagarajan, Los Alamos National Laboratory, Los Alamos, NM, United States, Erin George, Rohit Kannan, Deepjyoti Deka

Quadratically-constrained quadratic programs (QCQPs) are a broad class of non-convex optimization problems which occur in applications such as energy infrastructure networks and the pooling problem, but are often slow to solve in practice. Leveraging efficient MIP relaxations, and the sensitivity of partitioning choices, we propose the novel problem of "strong partitioning" to optimally partition variable domains "without" sacrificing global optimality guarantees. We propose to replace this expensive "ideal policy" with a machine learning (ML) approximation for homogeneous families of non-convex QCQPs. Further, we construct a novel end-to-end loss function so that the desired attributes of an output partitioning scheme can be learned directly, without reference to a pre-selected policy. Additionally, we introduce a graph-based method to produce a single ML model which works on a variety of different sizes. Numerical results demonstrate the ML model's ability to learn partitioning policies which generalize well, even to unseen problem sizes, significantly reducing the run times of partitioning-based iterative algorithms.

2 - Learning to Generate Cutting Planes with Miplearn

Alinson Santos Xavier, Argonne National Laboratory, Lemont, IL, United States

While many classes of cutting planes described in the literature have been effective in terms of gap closure, they are often computationally demanding to generate and offer only modest improvements in running times. Taking into account that many discrete optimization problems are solved repeatedly with only slight variations in input data, in this talk we investigate the usage of machine learning (ML) methods to accelerate the selection and generation of such cuts. We start by introducing MIPLearn, an extensible open-source framework which uses machine learning (ML) to enhance the performance of state-of-the-art MIP solvers. The framework is compatible with multiple MIP solvers (e.g. Gurobi, CPLEX, SCIP, HiGHS), multiple modeling languages (JuMP, Pyomo, gurobipy) and supports user-provided ML models. We then present computational experiments on using ML to accelerate the generation of rank-1 Gomory mixed-integer (GMI) cuts from multiple tableau bases.

3 - Power Systems Optimization Under Uncertainty

Rahul Gupta, Georgia Institute of Technology, Atlanta, GA, United States

The uncertainties within the power system's operation and planning can be broadly classified into two categories. The first refers to cases where uncertainty lies in power injections, such as demand or generation, which cause stochastic fluctuations in the power system's state, such as nodal voltages. The second kind refers to cases where uncertainty exists in the power system models themselves, for example, inaccurate network parameters such as line impedance or topology. Such uncertainties lead to inaccuracies in estimating or predicting power system states. Overall, both kinds of uncertainty lead to challenges in power system operation. These challenges are particularly linked to the regulation of network states, such as nodal voltages that must be kept within statutory limits, as well as managing power flows along lines and transformers within rated capacities. Such challenges prompts the important question of how to make optimal decisions amidst uncertainty. This talk will present different methods to tackle the above two kinds of uncertainties using stochastic and robust optimization algorithms. Additionally, the talk will also present two different power system applications for addressing these uncertainties.

4 - A Computational Study of Cutting-plane Methods for Multi-stage Stochastic Integer Programs

Akul Bansal, Northwestern University, Evanston, IL, United States, Simge Kucukyavuz

We report a computational study of cutting plane algorithms for multi-stage stochastic mixed-integer programming models with the following cuts: (i) Benders', (ii) Integer L-shaped, and (iii) Lagrangian cuts. We first show that Integer L-shaped cuts correspond to one of the optimal solutions of the Lagrangian dual problem, and, therefore, belong to the class of Lagrangian cuts. To efficiently generate these cuts, we present an enhancement strategy to reduce time-consuming exact evaluations of integer subproblems by alternating between cuts derived from the relaxed and exact computation. Exact evaluations are only employed when Benders' cut from the relaxation fails to cut off the incumbent solution. Our preliminary computational results show the merit of this approach on multiple classes of real-world problems.

1 - Exploring Fairness, Efficiency, and Incentives in Federated Learning through Game Theory and Social Choice

Aniket Murhekar, University of Illinois, Urbana-Champaign, Urbana, IL, United States

Federated learning (FL) has emerged as a powerful scheme to facilitate the collaborative learning of models amongst agents holding their own private data. While agents benefit from sharing data through as it results in accurate models, they also incur costs associated with data sharing such as communication or privacy costs. This can lead to agents being strategic about their contribution to achieve an optimal tradeoff between their learning payoff and data sharing cost, and can lead to free-riding.

To study such issues of incentives arising in FL, we consider the existence of Nash equilibrium (NE) in a simple collaborative learning model. We show the existence of Nash equilibrium (NE) under mild assumptions on agents' payoff and costs. However, some of the NE may be bad in terms of overall welfare for the agents, implying little incentive for some fraction of the agents to participate in the learning. To remedy this, we design a budget-balanced mechanism involving payments to the agents, that ensures that any p-mean welfare function of the agents' utilities is maximized at NE. In addition, we introduce a FL protocol FedBR-BG that incorporates our budget-balanced mechanism, utilizing best response dynamics. Our empirical validation on MNIST and CIFAR-10 substantiates our theoretical analysis. We show that FedBR-BG outperforms the basic best-response-based protocol without additional incentivization, the standard federated learning protocol FedAvg, as well as a recent baseline MWFed in terms of achieving superior p-mean welfare.

2 - Distributed Randomized Zeroth-Order Gradient Tracking Methods for Stochastic MPECs

Mohammadjavad Ebrahimi, Rutgers University, Piscataway, NJ, United States, Uday Shanbhag, Farzad Yousefian

We consider a class of hierarchical multi-agent optimization problems over networks where agents seek to compute an approximate solution to a single-stage stochastic mathematical program with equilibrium constraints (MPEC). MPECs subsume several important problem classes including Stackelberg games, bilevel programs, and traffic equilibrium problems, to name a few. Our goal in this work is to provably resolve stochastic MPECs in distributed regimes where the agents only have access to their local objectives and an inexact best response to the lower-level equilibrium problem. To this end, we devise a new method called randomized smoothed distributed zeroth-order gradient tracking (rs-DZGT). This is a novel gradient tracking scheme where agents employ a zeroth-order implicit scheme to approximate their (unavailable) local gradients. Leveraging the properties of a randomized smoothing technique, we establish the convergence of the method and derive complexity guarantees for computing a stationary point of an optimization problem with a smoothed implicit global objective. We also provide preliminary numerical experiments where we compare the performance of rs-DZGT on networks under different settings with that of its centralized counterpart.

3 - Federated Convex Bilevel Optimization: A Universal Regularized Scheme with Guarantees

Farzad Yousefian, Rutgers University, Piscataway, NJ, United States, Mohammadjavad Ebrahimi, Yuyang Qiu, Shisheng Cui

We study a bilevel federated learning (FL) problem, where clients cooperatively seek to find among multiple optimal solutions of a primary distributed learning problem, a solution that minimizes a secondary distributed global loss function. This problem has attracted increasing attention in machine learning, in particular, in over-parameterized learning and hyperparameter optimization. Despite some recent progress, communication-efficient FL methods equipped with complexity guarantees for resolving this problem are primarily absent. Motivated by this lacuna, we propose a universal regularized scheme and derive promising error bounds in terms of both the lower-level and upper-level loss functions. Leveraging this unifying theory, we then enable existing FL methods, including FedAvg and SCAFFOLD, to solve the corresponding bilevel FL problem, and derive novel communication complexity guarantees for each method. Intriguingly, the universal scheme can be employed to provably enable many other state-of-the-art optimization methods to address the bilevel problem. We present numerical experiments for over-parameterized convex neural networks on MNIST and CIFAR-10 datasets.

4 - Scalable Privacy-Preserving Federated Learning for Electric Load Forecasting

Shourya Bose, University of California Santa Cruz, Santa Cruz, CA, United States, Yu Zhang, Kibaek Kim

Federated learning (FL) has emerged as a powerful approach for training models using data distributed across numerous devices. In this study, we address the application of privacy-preserving federated learning (PPFL) to train electric load forecasting models across a vast network of smart meters, with enhanced privacy assurances compared to conventional FL methods. Our approach leverages differential privacy and personalized layers (PLs) to effectively manage data heterogeneity while safeguarding against potential data leakage from model weights.

Edelman Reprise: Molslinjen

Plenary/Keynote Session

Keynote

Chair: Rajesh Tyagi, GE Global Research, Plainsboro, NJ, United States

1 - Molslinjen – Passenger Ferry Operations in the Digital Era: Forecasting & Revenue Management at Molslinjen

Pierre Pinson, Halfspace / Imperial College London, Copenhagen, Denmark

Halfspace and Molslinjen have partnered to develop and operate a successful forecasting and revenue management toolbox for data-driven operation of ferries in Denmark, rolled out operationally since 2020. This has resulted in $2.6-3.2M yearly savings and been a significant contributor to a 3% reduction in fuel costs and emissions. This toolbox relies on the latest advances in machine learning for forecasting and ORMS approaches to revenue management. The potential for generalizing to the global ferry industry is significant, with an impact on both revenues and ESG criteria.

OR/AI Applications in the (Bio)Pharmaceutical Industry: A Vision and Future Research Directions

Plenary/Keynote Session

Keynote

Chair: Muge Capan, University of Massachusetts Amherst, Amherst, MA, United States

1 - OR/AI Applications in the (Bio)Pharmaceutical Industry: A Vision and Future Research Directions

Tugce Martagan, Eindhoven University of Technology, Eindhoven, Netherlands

The application of Operations Research and Artificial Intelligence (OR/AI) methodologies has successfully helped transform several industries. However, there is still a significant need for more OR/AI research in the (bio)pharmaceutical industry. Until recently, competitive advantage in the (bio)pharmaceutical industry has been driven primarily by advances in life sciences. However, with increasing demand and competition, the industry is becoming more sensitive to cost efficiency, supply chain resilience, and equitable patient access to medicines.

In this presentation, we will reflect on how OR/AI applications can help advance the (bio)pharmaceutical industry. We will begin with an overview of current industry trends, needs and challenges. We will also discuss some examples from manufacturing and supply chain applications, based on our work presented in the 2022 Franz Edelman competition. Finally, we will propose a research roadmap and a portfolio of future research directions for OR/AI applications in (bio)pharmaceutical manufacturing.

1 - How Matching Algorithm Innovations Impact Platform Economy Ecosystem: Empirical Evidence from Ridesharing Platforms

Mengwei Qu, University of Connecticut, Storrs, CT, United States, Bowen Lou, Chen Liang

Matching algorithms serve as the backbone of ridesharing platforms, facilitating efficient and timely connections between passengers and drivers. These sophisticated algorithms meticulously optimize various factors, including geolocation, supply and demand dynamics, driver allocation strategies, and routing and traffic conditions, to facilitate successful matches. However, the pursuit of optimization often entails imposing extensive algorithmic control, potentially leading to inefficiencies in matching processes. Our research delves into the realm of matching algorithm innovation, particularly through the development of a reduced control approach that operates at an aggregate level rather than micromanaging individual parameters. Leveraging a Triple Difference-in-Differences model, we evaluate the effects of these innovations. Our findings reveal a notable decrease in riders' wait times, signifying a tangible enhancement in service efficiency. Additionally, we uncover significant improvements in drivers' earnings, earnings efficiency, and overall rider satisfaction metrics. Furthermore, innovative matching algorithms also influence drivers' pick-up location decisions, suggesting a positive impact on drivers' preference for the matching algorithm. Our study provides valuable empirical evidence elucidating the profound impact of matching algorithm innovations on the ridesharing platform ecosystem. Beyond insights, it furnishes actionable managerial recommendations for online platforms, highlighting the efficacy of tailored matching algorithms in elevating service quality, fostering efficiency, and potentially reducing operational costs. These findings pave the way for future advancements in ridesharing technology and algorithmic optimization strategies.

2 - Strategic Value of Firm-Specific Knowledge in Big Data Analytics: Insights from S&P 500 Firms

Yuhan Su, Tianjin University, Tianjin, China, People's Republic of, Yuanyang Liu, Kejia Hu, Xiande Zhao

In the era of big data, firms increasingly value Big Data Analytics (BDA) for its potential to enhance efficiency and drive superior performance. While previous research has emphasized the value of Big Data Analytics Capabilities (BDAC), this study addresses the gap in understanding the impact of firm-specific knowledge within BDA human capital. We employ a comprehensive dataset for S&P 500 firms, comprising workforce data on data scientists, financial data, and job advertisement data from 2011 to 2019, to analyze firm-specific knowledge, inflow, and outflow of data scientists alongside firm performance metrics.

Our findings indicate that data scientists' firm-specific knowledge significantly improves Return on Assets (ROA), whereas IT workers' firm-specific knowledge has a negligible effect. Additionally, we categorize companies based on their level of data analytics and integration capabilities (High, Centralized Analytical, Decentralized Analytical, Low) and identify that the positive impact of data scientists' firm-specific knowledge and inflow is maximized during the Centralized Analytical stage of data integration strategies. This suggests that firms can enhance the benefits derived from data scientists' tenure and inflow by focusing on their business integration capabilities. Our study provides empirical evidence supporting the strategic value of firm-specific human capital in the context of BDA, offering insights for firms to optimize their data integration strategies and achieve a competitive advantage.

Complex System Modeling, Monitoring, and Decision-making

Invited Session

Quality, Statistics and Reliability

Chair: Dongmin Li, Georgia Institute of Technology, Atlanta, GA, United States

Co-Chair: Xiaochen Xian, University of Florida, Gainesville, FL, United States

1 - A Bayesian Jump Model-Based Pathwise Sampling Approach for Online Anomaly Detection

Dongmin Li, University of Florida, Gainesville, FL, United States, Miao Bai, Di Wang, Xiaochen Xian

Moving vehicle-based sensors (MVSs) have received growing attention for real-time anomaly detection in various applications such as wildfire and oil spill detection. To tackle challenges due to the spatial covariance structure among observations, uncertainties under partial observations, as well as the physical MVS movements, we propose a Bayesian jump model-based pathwise sampling approach to detect abrupt changes in an area of interest in real time using MVSs. Specifically, we integrate a jump-model based Bayesian scheme, the upper confidence bound algorithm, and mathematical optimization in a unified manner to exploit spatial correlation and real-time partial observations, to handle uncertainties of noisy observations, limited observability, and anomaly occurrences, and to adaptively coordinate the routes of multiple MVSs for quick anomaly detection. We perform theoretical investigations and conduct simulations to confirm the exceptional effectiveness of the method we propose. A case study for early wildfire detection demonstrates that our proposed method outperforms benchmark methods, which contributes to the reduction of the area of affected land and wildfire-related costs.

2 - Reinforced Scan: a Reinforcement Learning Enabled Scanning Strategy in Pbf Additive Manufacturing

Chaoran Dou, Virginia Tech, Blacksburg, VA, United States, Jihoon Chung, Raghav Gnanasambandan, Yuhao Wu, Zhenyu Kong

Additive Manufacturing (AM) is an innovative technology that fabricates parts layer by layer. However, in powder bed fusion (PBF), printed metal parts often exhibit residual stresses, deformations, and other defects due to uneven temperature distribution during the printing process. To address this, an optimized scanning sequence within each layer can help mitigate temperature inconsistencies. Traditional optimization methods are based on domain knowledge, employing try-and-error or heuristic methods. Nonetheless, these methods are not universal and cannot achieve the optimal. The challenge of improving the scanning strategy is the large search space for optimizing the scanning sequence for the scanning tracks within the layer. To fill this gap, this work proposes an innovative scan strategy aiming to optimize scanning sequences for achieving uniform temperature distribution in PBF. The proposed Reinforced Scan approach uses reinforcement learning methods to determine the scanning sequence with a customized reward function intelligently. This reward function not only considers the temperature variance but also the spatial uniformity of temperature distribution. This method can significantly reduce the computational burden involved in scanning sequence optimization. The effectiveness of the proposed Reinforced Scan is validated through Netfabb Local Simulation involving laser scanning on a Ti64 thin plate, where its performance is compared with existing heuristic scan sequences. The simulation results demonstrate that Reinforced Scan yields superior outcomes, achieving reduced residual stress compared to conventional heuristic methods.

3 - Boundary Quality Characterization and Modeling for Printed 2D Products Using Printing Primitives

Minghao Gu, University of Southern California, Los Angeles, CA, United States

Surface quality characterization is essential for design, manufacturing and product functionality. Although a wealth of literature has been developed for surface quality characterization in mass production, it faces unique challenges in additive manufacturing (AM) due to one-off fabrication of a large variety of products with complex geometries. Surface quality of AM products side surfaces can be viewed as the stacking-up and combination of boundary quality for each fabricated layer. Boundary quality characteristics can vary with built geometries and covariates such as size, built location and orientation, which makes existing methods not adaptable to frequent design changes in AM. To address these challenges, we proposed a novel boundary surface quality characterization and modeling approach based on printing primitives. We partition a 2D design into a finite amount of printing primitives. The in-plane boundary quality patterns on each type of primitives are characterized through tensor-product modeling with integration of domain knowledge to reflect the impact of individual covariates. Simulation studies demonstrate the capability of the proposed model for learning the stochastic process governing the boundary quality distribution. We also illustrate the application of the proposed model for analyzing real printed samples produced by an AM process.

4 - Conformal Spatiotemporal Forecasting and Application in Energy Load Prediction

Shiyuan Piao, The Hongkong University of Science and Technology (Guangzhou), Guangzhou, China, People's Republic of, Fugee Tsung

Conformal prediction is a statistical framework that provides valid probabilistic predictions with well-calibrated confidence sets. This approach is particularly useful in spatial-temporal forecasting, where the goal is to predict future values of a variable based on its past values and spatial relationships with other variables. In the context of energy load forecasting, conformal prediction can offer significant advantages over traditional statistical and machine learning methods.

Spatial-temporal data in energy load forecasting is characterized by complex patterns and dependencies that evolve over time and space. Conventional forecasting methods often struggle to capture these intricate dynamics, leading to suboptimal predictions. However, conformal prediction, with its non-parametric nature, can adaptively learn from the data without making strong assumptions about the underlying distribution. This flexibility allows conformal methods to better model the spatial-temporal dependencies and provide more accurate and reliable forecasts.

The use of conformal prediction in energy load forecasting has several benefits. It provides a principled way to quantify uncertainty, which is crucial for risk management and decision-making in the energy sector. Additionally, conformal methods can handle non-stationarity and changing patterns in energy consumption, making them robust to shifts in demand that might be caused by economic, social, or technological factors.

In conclusion, conformal prediction offers a powerful and flexible approach to spatial-temporal forecasting, with promising applications in energy load forecasting. By leveraging the inherent structure of spatial-temporal data, conformal methods can deliver more accurate and reliable predictions, supporting the efficient and sustainable management of energy resources.

Theoretical Perspectives and Statistical Approaches to Robust Inference

Invited Session

Quality, Statistics and Reliability

Chair: Liyan Xie, University of Minnesota, Shenzhen

Co-Chair: Taposh Banerjee, University of Pittsburgh, Pittsburgh, PA, United States

1 - Distributionally Robust Multi-Hypothesis Testing with Moment Constrained Uncertainty Sets

Akshayaa Magesh, UIUC, Urbana, IL, United States, Venugopal Veeravalli, Zhongchang Sun, Shaofeng Zou

The problem of robust multi-hypothesis testing in the Bayesian setting is studied in this paper. Under the m hypotheses, the data-generating distributions are assumed to belong to uncertainty sets constructed through some moment functions, i.e., the sets contain distributions whose moments are centered around empirical moments obtained from some training data sequences. The goal is to design a test that performs well under all distributions in the uncertainty sets, i.e., a test that minimizes the worst-case probability of error over the uncertainty sets. Insights on the need for optimization-based approaches to solve the robust testing problem with moment constrained uncertainty sets are provided. The optimal (robust) test based on the optimization approach is derived for the case where the observations belong to a finite-alphabet. When the size of the alphabet is infinite, the optimization problem is infinite-dimensional and intractable, and therefore a tractable finite-dimensional approximation is proposed, whose optimal value converges to the optimal value of the original problem as the size of the dimension of the approximation goes to infinity. A robust test is constructed from the solution to the approximate problem, and guarantees on its worst-case error probability over the uncertainty sets are provided. Numerical results are provided to demonstrate the performance of the proposed robust test.

2 - Non-Asymptotic Convergence of Discrete-TIME Diffusion Models: New Approach and Improved Rate

Yuchen Liang, The Ohio State University, Columbus, OH, United States, Peizhong Ju, Yingbin Liang, Ness Shroff

The denoising diffusion model has recently emerged as a powerful generative technique that converts noise into data. While theoretical convergence guarantee has been extensively studied by discretizing some continuous-time diffusion processes, many generative samplers in real applications directly employ a discrete-time diffusion process. However, existing techniques for analyzing discretized continuous-time processes are not applicable to discrete-time processes, and for such discrete-time processes a convergence result has only been obtained for distributions with bounded support. In this paper, we establish the convergence guarantee for substantially larger classes of distributions under such discrete-time diffusion processes and further improve the convergence rate for distributions with bounded support. In particular, we first establish the convergence rates for both smooth and general (possibly non-smooth) distributions having finite second moment. We then specialize our results to a number of interesting classes of distributions with explicit parameter dependencies, including distributions with Lipschitz scores, Gaussian mixture distributions, and any distributions with Gaussian perturbation. We further propose a novel accelerated sampler and show that it improves the convergence rates of the corresponding regular sampler by orders of magnitude with respect to all system parameters. For distributions with bounded support, our result improves the dimensional dependence of the previous convergence rate by orders of magnitude. Our study features a novel analytical technique that constructs a tilting factor representation of the convergence error and exploits Tweedie's formula for handling Taylor expansion power terms.

3 - Revisit the Trade-off Between Accuracy and Robustness in Adversarial Training

Qunzhi Xu, Georgia Institute of Technology, Atlanta, GA, United States

The ability of generalizing to unseen, adversarially perturbed data is an important metric for evaluating the effectiveness of methods in improving the robustness of machine learning models. In this paper, we study the generalization properties of adversarial training (AT) and adversarial regularization (AR) in linear regression. Specifically, we consider a standard linear regression model and a perturbed linear regression model whose coefficient might change. By studying the asymptotic performance of AR and AT in these two models, we show that AR can generalize better in the sense of achieving a lower adversarial risk as compared to AT. Extensive simulation studies and real-world data analysis on different machine learning models are conducted to validate our theoretical results.

4 - Score-based approach to robust quickest change detection

Taposh Banerjee, University of Pittsburgh, Pittsburgh, PA, United States, Sean Moushegian, Vahid Tarokh

Score-based algorithms are proposed for the quickest detection of changes in unnormalized statistical models. These are models where the densities are known within a normalizing constant. These algorithms can also be applied to score-based models where the score, i.e., the gradient of log density, is known to the decision-maker. Performance analysis is provided for these algorithms and compared with their classical counterparts. It is shown that strong performance guarantees can be provided for these score-based algorithms where the Kullback-Leibeler divergence between pre- and post-change densities is replaced by their Fisher divergence. Robust solutions are also obtained and analyzed.

Summit - 323

Innovative Optimization Techniques and Applications

Contributed Session

Chair: Iris Forma, Tel-Aviv Afeka Academic College of Engineering, School of Industrial Engineering and Management, Tel Aviv - Yafo, Israel

1 - Hybrid classical-quantum approaches based on the column-generation framework for hard combinatorial problems: Examples and Benchmarks

Victor Drouin-Touchette, Université de Sherbrooke, Sherbrooke, QC, Canada

In this talk I will present an overview of various hybrid classical-quantum algorithms that are inspired by classical column-generation procedures developed in the field of operations research. In addition to leveraging fast classical solvers of linear programs, we use a quantum sampler based on neutral-atom platforms to heuristically propose new columns to add to a given combinatorial optimization problem. Benchmarks on the minimum vertex coloring problem and the traveling salesman problem will be presented, which together show that these hybrid algorithms can deliver good solutions in few iterations. I will also present a comparison with different state-of-the-art classical and quantum approaches and comment on the potential benefits of a quantum-enhanced solution workflow.

2 - Heuristic Emphasis in FICO Xpress

Leona Gottwald, FICO, Berlin, Germany

This talk will dive into primal heuristics for mixed-integer models in the FICO Xpress Solver.

We will highlight recent advances, new MIP heuristics, and take a closer look on the heuristic emphasis mode of Xpress. The heuristic emphasis mode aims at finding feasible solutions early during the search.

3 - Complexity-Optimal and Parameter-Free First-Order Methods for Finding Stationary Points of Composite Optimization Problems

Weiwei Kong, Google, New York, NY, United States

This talk presents a "parameter-free" and "complexity-optimal" accelerated proximal descent method for finding stationary points of nonconvex composite optimization problems. The main advantages of this method are that (i) it does not require knowledge of the global topological properties of its objective function and (ii) it obtains optimal iteration complexity bounds for nonconvex problems and nearly optimal bounds (up to logarithmic terms) for convex problems, without any parameter tuning. To the author's knowledge, this is the first method in the literature to obtain (i) and (ii) simultaneously. Another point of interest is the new set of inexact proximal termination conditions used in developing the method's outermost iterations.

This talk also describes how the proposed method can be leveraged in other optimization frameworks, such as min-max smoothing and penalty frameworks for constrained programming, to create more specialized parameter-free methods. Finally, we present several numerical experiments to support the method's practical viability.

4 - Application of federated optimization on generating stochastic scenarios

Mehrdad Mohammadi, Auburn University, Auburn, AL, United States, Alexander Vinel

This presentation introduces a new stochastic optimization approach using federated learning. This decentralized machine learning approach enables model training across multiple devices or locations while keeping data local, which is being utilized to generate different scenarios based on predicted values.

Data is distributed between clients, and the federated learning approach will optimize each client's model and aggregate them into the main model.

This approach leverages the power of federated learning, enabling optimization techniques tailored for stochastic scenario generation. This method optimizes decision-making processes in complex, dynamic environments by seamlessly integrating distributed data sources.

5 - Optimize Shading Planning in Cities

Iris Forma, Tel-Aviv Afeka Academic College of Engineering, School of Industrial Engineering and Management, Tel-Aviv, Israel

This research introduces an optimization approach for planning shading in cities, addressing the significant challenges posed by heat waves and Urban Heat Islands in the coming decades. Recognizing the imperative need to cool cities, there is a growing awareness of the need for solutions. While reforestation stands out as an efficient strategy due to the unique benefits of trees for the environment and human health, it may not be feasible in all urban areas. Consequently, providing shade becomes crucial even in areas where tree planting is impractical. Decision-makers in such locations can deploy artificial shadings tailored to urban environments, such as shade sails and pergolas.

This research presents an innovative optimization model that integrates both natural and artificial shading. It considers climatic, geographic, economic, and demographic parameters. The primary objective is to maximize climatic comfort by optimizing decisions regarding the placement and surface area of both natural and artificial shading in open and urban spaces.

Comparing our mathematical model with conventional decision-making in 10 scenarios, real data from the Mapping and Geospatial Information Unit of the Tel Aviv municipality revealed a 33% improvement in shaded areas and a 68% increase in the number of shaded locations, on average. Additionally, we provide a budget sensitivity analysis and discuss ongoing research.

Resource Management in Services

Contributed Session

Chair: Cong Wang, Peking University, Beijing, N/A, China, People's Republic of

1 - Balancing Privacy Preservation and Data Value in Smart Meters: A Correlation-Aware Differential Privacy Approach

Cong Wang, Peking University, Beijing, China, People's Republic of

The wide-scale deployment of smart grids has revolutionized data-driven power management, but the collection of fine-grained and correlated electricity consumption data recorded by smart meters poses a potential threat to user privacy. To address this, we propose a Correlation-Aware Differential Privacy (CaDP) method to balance user privacy with data utility in smart meter data. CaDP addresses privacy concerns by considering data correlation, which allows for more efficient use of the privacy budget. It presents a bi-objective optimization to balance privacy and data value, providing a practical framework for selecting privacy parameters. Real-world data evaluation shows CaDP's effectiveness in preserving privacy while maintaining data utility for tasks like load forecasting, outperforming other methods. The work contributes to the theory and practice of cybersecurity by offering both theoretical insights and practical guidelines for managing the privacy-data value tradeoff in smart grids.

2 - Using Bio-Inspired Reconfigurations to Enhance the Resilience of Electric Power Systems: A Decentralized Approach

Tianye Wang, George Washington University, Washington, DC, United States

This study introduces a robust decentralized control algorithm designed to significantly enhance the resilience of electrical power systems. The innovation integrates key characteristics of biological cell development, notably environmental awareness, decentralization, and redundancy. By mimicking the adaptive and autonomous features of cellular systems, the algorithm empowers a networked microgrid, to autonomously detect, respond to, and recover from localized disruptions without centralized oversight. To validate its efficacy, a stochastic cost-minimization model is employed to demonstrate improved resilience metrics, such as shorter recovery time and lower economic loss, under a range of failure scenarios, including extreme weather events. Preliminary results indicate a significant enhancement in the system's ability to adapt to and recover from adverse conditions, with potential implications for the design of future resilient power infrastructure. The algorithm's scalability and adaptability to different grid configurations are also discussed, highlighting its broad applicability and potential for real-world implementation.

3 - Regularized Benders Decomposition for High Performance Capacity Expansion Models

Filippo Pecci, Princeton University, Princeton, NJ, United States, Jesse Jenkins

We consider electricity capacity expansion models, which optimize investment and retirement decisions by minimizing both investment and operation costs. In order to provide credible support for planning and policy decisions, these models need to include detailed operations and time-coupling constraints, and allow modeling of discrete planning decisions. Such requirements result in large-scale mixed integer optimization problems that are intractable with off-the-shelf solvers. Hence, practical solution approaches often rely on carefully designed abstraction techniques to find the best compromise between reduced temporal and spatial resolutions and model accuracy. Benders decomposition methods offer scalable approaches to leverage distributed computing resources and enable models with both high resolution and computational performance. Unfortunately, such algorithms are known to suffer from instabilities, resulting in oscillations between extreme planning decisions that slows convergence. In this study, we implement and evaluate several level-set regularization schemes to avoid the selection of extreme planning decisions. Using a large capacity expansion model of the Continental United States with over 70 million variables as a case study, we find that a regularization scheme that selects planning decisions in the interior of the feasible set shows superior performance compared to previously published methods, enabling high-resolution, mixed-integer planning problems with unprecedented computational performance.

4 - Empowering Privacy Policy Understanding and Accessibility in Smart Home Devices

HILAL PATACI, University of Texas at San Antonio, San Antonio, TX, United States, Ke Yang, Anthony Rios

Despite nearly 70 million U.S. households using smart home technology, significant gaps in the clarity and accessibility of privacy policies hinder informed data use decisions. Alarmingly, recent studies indicate that almost 50% of devices in the U.S. market lack a privacy policy. This lack of transparency, combined with the complexity of existing policies, poses serious privacy and security concerns. Our research seeks to address these issues by enhancing the interpretability of these legal documents, ensuring they are accessible and understandable to a diverse range of users, including vulnerable populations.

We introduce a novel QA system specifically tailored for privacy policies associated with smart home technologies. The research is structured around three main objectives: enhancing data collection by creating a comprehensive smart-home device-specific QA dataset; evaluating the performance of existing QA systems; and developing robust, inclusive QA models that address the nuances of privacy policy queries. The novel QA system includes the integration of privacy policies with user-generated questions and vulnerability information from NIST's National Vulnerability Database, employing novel data curation techniques to enrich the QA dataset. By leveraging state-of-the-art NLP technologies and innovative algorithmic frameworks, we aim to improve the accuracy and fairness of QA systems, making privacy information more accessible and understandable for diverse users.

The broader impact of this work extends beyond technological advancements, fostering trust and compliance with privacy regulations among users. By empowering individuals to make informed decisions about their data, this research contributes to the fields of data privacy, algorithmic fairness, and smart home technology.

5 - The Value of Flexible Resources

shilei niu, Department of Economics, Faculty of Arts, University of Waterloo, Waterloo, ON, Canada, Tony Wirjanto

Flexible resources are critical for the power system reliability due to the high penetrations of variable renewable energy (VRE) during the decarbonization of the electricity industry. Using a real options approach, this paper develops a general model to value a class of assets with the power generation, storage and ramp capability. Within the non-market valuation framework, we adopt the no-arbitrage principle to measure the marginal value of flexible ramping through the shadow price which is the fair value implied from the electricity markets. To evaluate the incentives to invest in flexible resources and provide flexible ramping products (FRPs) in the power markets, we conduct extensive elasticity and sensitivity analyses to understand how the scarcity and cost of resources for power production and the electricity price signals affect the asset value and shadow price. Our numerical results show that the plant value decreases, but the shadow price increases exponentially as the ramping constraints become more restrictive. Both the flexible ramping up (FRU) and flexible ramping down (FRD) are valued, while the FRU has much higher value to the power generator. The scarcity and cost of resources and the electricity price characteristics have significant impacts on the asset value and shadow price; however, the magnitudes and directions of the impacts vary among these parameters. This research will facilitate the investment decisions to the flexible resources, development on the FRPs market and implementation of ramping regulations designed to promote the integrity of the ecosystem and climate while meeting the power system reliability.

Advances in Machine Learning Applications

Contributed Session

Chair: Keli Xiao, Stony Brook University, Stony Brook, NY, United States

1 - A Newly Designed Data Envelopment Analysis Approach that Ranks a Set of Mutual Funds and Mutual Fund Companies

Richard Muszynski III, Wilkes University, Wilkes-Barre, PA, United States

One of the many great investment choices for investors has been the plethora of mutual funds. The popularity of mutual funds arises from their diverse selection of stocks, bonds and other securities that reduces an investors overall risk of losing capital. Since there exists an abundance of mutual fund choices, the investors' goal of selecting mutual funds that match with their beliefs or expectations becomes an ever-daunting task. We provide analysis regarding which mutual funds an investor should invest in by using a nonparametric linear-programming approach called data development analysis (DEA). The goal of the present paper is to analyze and rank a set of mutual funds across several mutual fund companies by solving the input-oriented DEA model (Banker et al., 1984) and the output-oriented DEA model (Banker et al., 1984). After solving both models, we obtain distance measures and compute the magnitude distance for each country across multiple dimensions in order to calculate efficiency scores for each respective mutual fund. Rankings are determined by sorting the efficiency scores for each respective mutual fund. After ranking the set of mutual funds for each mutual fund company, we then rank mutual fund companies by taking averages, medians, and standard deviations of the efficiency scores of individual mutual funds of each company to determine overall and consistent mutual fund company performance. We also demonstrate why standardizing data is crucial in order to create equal weighted factors that may rank mutual funds.

2 - Does Size Matter? Short-Term Momentum versus Long-Term Reversal Returns in Investment Strategies

Nafise Aalipour, University of Rhode Island, Kingston, RI, United States, Georges Tsafack

Stock market direction is challenging to predict. However, it has been well documented that well-performing stocks tend to keep up in the short-term while some reversal is observed in the long run. We separately investigate those phenomena and their relation to the market size of stocks. Interestingly, our research indicates that long-term reversal is predominantly driven by small market cap stocks, whereas momentum is more commonly observed in medium and large size stocks. Moreover, our findings hold true whether we apply traditional measures of momentum and reversal or utilize risk-adjusted metrics such as the Sharpe ratio or alpha for the asset allocation process. Our analysis of data spanning from 1927 to 2022 reveals that these trends have become more pronounced post-1966, coinciding with advancements in financial research tools such as CAPM-alpha and the Sharpe ratio.

3 - Enhancing Long-Term Decision-Making for Social Welfare: A Multi-Agent Reinforcement Learning Approach

Keli Xiao, Stony Brook University, Stony Brook, NY, United States, PENGZHAN GUO, Jingyuan Yang

Sequential decision-making with a long-term perspective is important in various domains, but existing decision support systems often prioritize short-term, individual solutions. This research explores the potential of AI techniques, specifically reinforcement learning, to enhance long-term decision-making by maximizing social benefit. We address the challenge of multi-user scenarios with limited social resources by formulating a generalized problem and translating it into a multi-agent reinforcement learning framework. Our approach emulates a social decision system, balancing individual objectives with collective welfare. To manage the computational complexity of multi-user decision-making, we propose a deep learning-guided, performance-weighted search algorithm. This algorithm leverages deep neural networks and performance-based weightings to enhance computational efficiency and adaptability, dynamically adjusting the search strategy to different path requirements, such as talent mobility and mobile route recommendations. We provide evidence from multi-agent reinforcement learning simulations to demonstrate the effectiveness and efficiency of our method. The simulations, using real-world data in tasks like sequential route recommendation and long-term career planning, show that our approach outperforms state-of-the-art techniques. Robustness tests using synthetic data confirm the stability and reliability of our method.

Advancements in Supply Chain Resilience and Performance

Contributed Session

Chair: Wenxin Zhang, syracuse university, 721 University Ave, syracuse, 13244

1 - Supply Chain Mapping with Synthetic Data Powered by Large Language Models

Jaewon Kim, Korea University, Seoul, Korea, Republic of, Eunbi Kim, Dongsu Kim, Yoojoong Kim, Taesu Cheong

Supply chain mapping is crucial for global companies to identify and assess potential risks in their supply chains. While previous research has explored the use of Natural Language Processing (NLP) techniques for automated supply chain mapping, these methods face challenges due to data scarcity and the high cost of data annotation. This study proposes a novel approach to enhance the accuracy and efficiency of supply chain mapping using synthetic data generated by large language models (LLMs). The proposed methodology involves a two-part process. First, a multi-turn prompt guides LLMs to generate relation triples of company-relation-company. The prompt includes a structured output template to ensure the generated text, including corresponding synthetic sentences, adheres to a predefined schema for automated parsing. Second, these synthetic sentences and their corresponding relation triples are used to fine-tune a BERT-based relationship classifier. The results show that the BERT classifier surpasses previous state-of-the-art results in NLP-based supply chain mapping, and an innovative method using special tokens at the position of company names further improves performance. Augmenting the training dataset with LLM-generated synthetic examples proves to be a viable approach, especially when manually annotated data is limited. An additional case study with mining-related articles reveals insights into the supply chain network, demonstrating the practical use of this method.

2 - Enhancing Supply Chain Resilience and Equitable Access: A Strategic Approach to the Infant Formula Shortage

Chun-Miin Chen, Bucknell University, Lewisburg, PA, United States

The 2022 infant formula shortage in the United States exposed significant vulnerabilities in the nation's supply chain, revealing the challenges of concentrated production among a limited number of manufacturers and a fragile distribution network. This crisis emphasized the pressing need for strategies to bolster supply chain resilience and ensure equitable access to essential products. This study leverages established approaches to address these challenges, focusing on distribution frameworks that tackle current weaknesses. The research explores various inventory management strategies and identifies key product availability factors, particularly in underserved regions. These strategies aim to enhance expected consumer surplus, improving overall consumer welfare. The findings highlight the importance of implementing targeted adjustments to distribution systems to strengthen supply chain resilience. This study contributes to the conversation on how best to redesign supply chains to enhance resilience and prioritize the needs of the most vulnerable populations.

3 - Resilience in the Semiconductor Supply Chain - A Systematic Literature Review

Zachary Ramirez, Purdue University, West Lafayette, IN, United States, Tho Le

Resilience has been a growing area of interest within supply chain research. This has been driven by the increasing frequency of disruptive events within the globalized supply chain such as pandemics, geopolitical conflicts, and extreme weather events. Furthermore, rising demand for advanced electronics places semiconductors in a critical position for ensuring global security and promoting innovation. This study seeks to assess current resilience levels in the semiconductor supply chain by analyzing historical disruptions and their impacts, identifying critical vulnerabilities and bottlenecks in the supply chain, and developing a comprehensive understanding of the factors contributing to supply chain disruptions through literature review of research on supply chain resilience in the semiconductor industry.

The review was conducted systematically following the PRISMA approach with papers related to semiconductor supply chain resilience and risk management sourced from Web of Science and Connectedpapers.com. The final selection included 45 papers spanning September 2001 to February 2024. The papers were then analyzed to determine sources of risk and mitigation strategies. This analysis concluded that the most discussed sources of risk in the semiconductor industry were hardware security and shortage effects. Following the analysis, a framework was proposed to model resilience in the semiconductor supply chain and assess the effectiveness of risk management options.

4 - The Interplay between Supplier’s Demand Forecast Sharing and Channel Encroachment

Wenxin Zhang, Syracuse University, Syracuse, NY, United States, Zhengping Wu

Motivated by the observation that many suppliers have their own private demand forecasts, we study the strategic interplay between encroachment and information sharing decisions using the signaling game framework, where the strategic interplay refers to different decision sequences: whether the supplier makes the encroachment decision *before or after* deciding whether to share his private information with the retailer. In addition, three information-sharing formats are examined, including no information sharing, voluntary information sharing, and mandatory information sharing. We characterize the equilibrium outcomes of the different scenarios, which yield the following managerial insights: First, when the supplier decides whether to encroach *before* sharing information, the results are consistent with the simultaneous decision-making situation. Specifically, whether the supplier chooses to encroach or not, information sharing always benefits both firms. Second, when the supplier decides whether to encroach *after* sharing information, the sharing formats will strategically impact the encroachment decision, which is imperfect information for the retailer. Specifically, in the voluntary-sharing format, when the supplier chooses not to share information and encroaches into retailing, the upward distortion of wholesale prices will intensify downstream competition and then lead to a win-lose outcome. However, if the supplier opts not to encroach, it will lead to a win-win outcome, and the supplier can earn the highest profit.

Accelerated Computing for Mathematical Programming

Invited Session

OPT: Computational Optimization and Software

Chair: Sungho Shin, Argonne National Laboratory, Lemont, IL, United States

Co-Chair: François Pacaud, Mines Paris - PSL, Paris, France

Co-Chair: Mihai Anitescu, Argonne National Laboratory, Lemont, IL, 60439, United States

1 - Nonlinear programming on GPU with MadNLP

François Pacaud, Mines Paris - PSL, Paris, France, Sungho Shin

In this talk, we explore an interior-point method for solving large-scale constrained nonlinear programs with the aid of graphics processing units (GPUs). The interior-point method involves resolving a sequence of symmetric indefinite linear systems, or Karush-Kuhn-Tucker (KKT) systems, which become increasingly ill-conditioned as we approach to the solution. Solving the KKT systems with traditional sparse factorization methods involve numerical pivoting that makes parallelization difficult. Instead, we reformulate the KKT systems into symmetric positive-definite systems using a condensed space approach. As a result, we can solve the KKT systems efficiently on the GPU using sparse Cholesky factorization. We implement the method on GPUs with MadNLP.jl, a solver interfaced both with the NVIDIA library cuDSS for solving sparse positive definite systems and ExaModels.jl for evaluating models on GPUs. We assess the performance on large-scale problems from the PGLIB and COPS benchmarks, revealing that GPUs can achieve up to a tenfold speed increase compared to CPUs.

2 - HiOp: An HPC Optimization Suite with Exa-Scale Computing Capability

Nai-Yuan Chiang, Lawrence Livermore National Laboratory, Livermore, CA, United States, Cosmin Petra, Jingyi Wang

HiOp is an optimization suite designed for tackling large-scale mathematical programming challenges efficiently. This lightweight High-Performance Computing (HPC) solver takes advantage of an application's existing data parallelism to parallelize optimization iterations using specialized parallel linear algebra kernels. Acceleration can be achieved through OpenMP, CUDA, or HIP, thanks to the RAJA portability abstraction and various execution policies. HiOp has demonstrated its capabilities in solving large-scale optimization problems on parallel machines equipped with AMD or NVIDIA accelerators. Notably, it has been successfully applied to solve Security-Constrained AC Optimal Power Flow problems for networks featuring 10,000 buses, 10 renewable energy forecast scenarios, and a staggering 100,000 contingencies on the Frontier platform, all achieved within an impressive 20-minute timeframe.

3 - Acceleration of (Nonlinear) Optimization for Robotics through Co-Design: from MCUs to GPUs

Brian Plancher, Barnard College, Columbia University, New York, NY, United States

Model predictive control (MPC) is a powerful tool for controlling highly dynamic robotic systems subject to complex constraints. However, MPC, and its underlying (nonlinear) optimization algorithms, are often too computationally demanding to meet real-time rates for robotic platforms, both large and small. By leveraging a combination of parallelism, approximation, and structure exploitation, we have co-designed accelerated (nonlinear) trajectory optimization solvers for real-time performance on non-standard computational hardware, ranging from microcontrollers (MCUs) to graphical processing units (GPUs). These results have enabled us to run MPC onboard an MCU powered 27g quadrotor, as well as to run whole-body nonlinear MPC at kHz rates for a GPU powered manipulator, demonstrating high-speed trajectory tracking and dynamic obstacle avoidance.

4 - Advances in direct linear solvers for enhancing interior methods on GPU

Alexis Montoison, GERAD, Montréal, QC, Canada, Iain Duff

The solution of sparse linear systems has been the major technical challenge for implementing continuous optimization solvers on GPUs. Due to this challenge, GPU implementations of optimization algorithms have been primarily based on algorithms that do not require the use of matrix factorization, such as first-order methods or iterative linear solvers.
However, recently there has been significant progress in utilizing sparse direct linear solvers within optimization solvers running on GPUs. This presentation discusses some of the recent progress in the direct sparse linear solver capabilities on GPUs.
First, we highlight some of the impressive capabilities of NVIDIA's cuDSS library when applied to optimization solvers.
In particular, the recent NVIDIA cuDSS toolbox offers LU, LDL', and LL' decompositions, significantly enhancing the computational efficiency of interior methods.
We introduce the Julia interface CUDSS.jl and demonstrate its integration with the nonlinear optimizer MadNLP.jl.
Second, we discuss developing a new GPU-accelerated linear solver, based on the mature implementation of MA57, to deliver scalable solutions for symmetric indefinite linear systems.
We will discuss the distinct challenges posed by the nature of GPUs and discuss the strategies to exploit the BLAS-like routines on GPUs to maximally utilize the parallel computing capabilities of GPUs.
We also discuss the efforts to ensure portability across different GPU architectures, including NVIDIA, AMD, and Intel.

5 - OSQP with GPUs & FPGAs: Accelerating quadratic programming on heterogeneous systems

Ian McInerney, Imperial College London, London, United Kingdom, Maolin Wang, Bartolomeo Stellato, Vineet Bansal, Amit Solomon

The rise of machine learning has led to increased availability of accelerators, including GPUs in workstations and cloud services like AWS offering GPUs and FPGAs. However, traditional optimization solvers have largely not leveraged this computational power. In this talk, we present our recent work in the OSQP (Operator Splitting Quadratic Programming) 1.0 release, which implements end-to-end solver acceleration on both GPU and FPGA platforms. At the core of this acceleration is a linear algebra abstraction layer that decouples the core optimization steps from numerical operations, enabling a unified OSQP solver API regardless of the computational backend. This layer allows for seamless backend selection at build-time, including CPU backends with sparse operations or Intel MKL, a GPU backend using cuSPARSE, and an FPGA backend using RSQP. OSQP libraries with these backends are packaged with high-level interfaces, such as the OSQP Julia and Python packages, enabling users to easily solve quadratic optimization problems on GPUs.

Operations and Revenue Management for AI Development

Invited Session

Revenue Management and Pricing

Chair: Ningyuan Chen, Rotman School of Management, Toronto, ON, Canada

Co-Chair: Rafid Mahmood, University of Ottawa + NVIDIA, Ottawa, ON, Canada

1 - R&D Data Sharing in New Product Development

Jussi Keppo, National University of Singapore, Singapore, Singapore, Zhi Chen

Many innovations today are data-driven such as self-driving cars. To improve the algorithms of these products, firms make substantial investments in data collection. However, the data is limited for an individual firm. This paper studies whether data collected by individual firms should be shared in order to promote innovation.

2 - Operations for New ML Products by Optimally Stopping Data Collection

Rafid Mahmood, Telfer School of Management, Ottawa, ON, Canada, Yufeng Zheng, Ningyuan Chen

The proliferation of machine learning (ML) models as software products is limited by the escalating costs of model development. These costs lie primarily in the collection of training data, since more training data leads to better models and thus, better products. In this work, we explore the problem of optimizing the development and deployment of the ML software from a revenue management perspective. Here. a firm must forecast when the diminishing value of marginal improvements to their ML product with respect to user demand is outweighed by the costs of collecting the additional data needed to obtain these improvements. We estimate the neural data scaling laws associated with the model and apply a stopping policy that achieves bounded regret with respect to revenue obtained from user demand. Simultaneously, we explore the effect of this forecast on the prices that the firm can set for the ML product. Numerical evaluation on several ML tasks reveal that, rather than the current trends of perpetually chasing bigger datasets and better models, firms can significantly reduce their development costs by learning to stop early and deploying a “just good enough” ML model that meets user demand.

3 - When Emotion AI Meets Strategic Users

Yifan Yu, University of Texas at Austin, Austin, TX, United States, Wendao Xue, Lin Jia, Yong Tan

When organizations adopt artificial intelligence (AI) to recognize individuals' negative emotions and accordingly allocate limited resources, strategic users are incentivized to game the system by misrepresenting their emotions. The value of AI in automating such emotion-driven allocation may be undermined by gaming behavior, algorithmic noise in emotion detection, and the spillover effect of negative emotions. We develop a game-theoretical model to understand emotion AI adoption, particularly in customer care, and analyze the design of the associated allocation policies. We find that adopting emotion AI is valuable if the spillover effect of negative emotions is negligible compared to resource misallocation loss, regardless of algorithmic noise and gaming behavior. We also quantify the welfare impacts of emotion AI on the users, organization, and society. Notably, a stronger AI is not always socially desirable and regulation on emotion-driven allocation is needed. Finally, we characterize conditions under which leveraging the AI system is preferred to hiring human employees in emotion-driven allocation. We also explore the alternative application of using emotion AI to monitor strategic employees and compare it with hiring a human manager for monitoring. Intriguingly, algorithmic noise may increase the profit of AI monitoring. Our work provides implications for designing, adopting, and regulating emotion AI.

Innovative Approaches to Inventory Management and Sustainable Sourcing

Contributed Session

Chair: Seongwon Park, Michigan State University, East Lansing, 48824

1 - Retailer Matching for the Environment in a Supply Chain

Ji Young You, National Taiwan University, Taipei, Taiwan, Chialin Chen

In recent years, there has been a significant reevaluation of the role of retailers in promoting environmental sustainability within supply chains. This shift is exemplified by initiatives from major players like Walmart and Alibaba, who actively collaborate with green manufacturers and consumers. Contrary to traditional views associating retailers with negative impacts on supply chain sustainability, contemporary evidence suggests otherwise. This study delves into how retailers can influence green supply chains, considering two scenarios: direct competition between traditional and green manufacturers, and a retailer-facilitated "matching" model.

In direct competition, eco-friendly options may be limited, but in the matching model, retailers connect consumers with the best-suited green products from various manufacturers, making green options readily available. This challenges the conventional perception of retailers hindering sustainability and highlights their potential to promote environmentally friendly products.

Our findings emphasize the pivotal role retailers can play in advancing environmental responsibility by enhancing the accessibility of green products through effective consumer-product matching. This underscores the necessity to reconsider the role of retailers in supply chain sustainability and underscores the potential benefits of collaborative efforts between retailers, manufacturers, and consumers in driving positive environmental outcomes.

Our research provides valuable insights into how retailers can leverage their influence to drive sustainability initiatives and contribute to a more environmentally conscious marketplace. By redefining their role and embracing collaboration, retailers can become key drivers of positive change in the pursuit of a greener future.

2 - The Role of Retail Competition in Store Brand Introduction Decisions

Alexander Maslov, University of Kentucky, Lexington, KY, United States, Yasin Alan, Mumin Kurtulus, Chunlin Wang

We study a supply chain with a single national brand manufacturer that sells to consumers through two competing retailers who have an option to introduce a store brand. We explore the role of competitive interactions between the two retailers and the national brand manufacturer on the store brand introduction decisions. We find that existing studies overestimate the marginal benefit of store brand introduction. In addition, we characterize conditions under which one retailer may benefit from the other retailer introducing a store brand. Finally, we show that competition may force retailers to introduce store brands even though it results in lower profits for both retailers.

3 - Dynamics of Environmental Management in Multi-tier Supply Chains: Focusing on Aggregate Effects

Seongwon Park, Michigan State University, East Lansing, MI, United States, Srinivas Talluri, Seetharama Chandrasekhar Manchiraju, Gyusuk Lee

To reduce adverse environmental impact in supply chains, multinational corporations not only manage their own operations internally but also collaborate externally with other members of their supply chains. Although firms are increasingly sharing their environmental performance with external stakeholders, empirical studies assessing the environmental impact of cross-tier interactions between member firms in multi-tier supply chains are scant. The primary goal of this study is to address the differential environmental impacts of downstream firms on the upstream partners in multi-tier supply chains. To achieve this, we draw upon supply chain relationships data provided by FactSet Revere and Trucost environmental performance data and create firm-level environmental efficiency scores, across the supply chains of 6 different manufacturing industries, using network data envelopment analysis. We use a 5-year panel data from 2014 to 2018 based on 259 open triadic relationships. Our empirical analysis demonstrates that a focal firm's environmental efficiency positively influences its first-tier supplier's environmental efficiency. We also find that this influence increases with the financial dependence of the first-tier supplier on the focal firm. Moreover, while the first-tier supplier's environmental efficiency positively influences the second-tier supplier's environmental efficiency, focal firms may not directly impact the environmental efficiency of second-tier suppliers.

4 - Location based omnichannel assortment planning

Qingwei Jin, Zhejiang University, Hangzhou, China, People's Republic of, Zhi Pei

We consider a location based omnichannel assortment planning problem. The retailer is running several offline and online stores in an area. Each online store order is fulfilled by nearby offline stores through delivery service. The assortment in each offline store is serving both offline and online stores and the service relation forms a network. The retailer needs to determine the optimal assortment in each offline store and each online store. We design a partition rule to divide the network and propose a 1/2-approximation scheme when the network is a long chain and 1/3-approximation scheme when the network is induced from a 2-dimensional plane.

5 - A framework for retailers and manufacturers to maximize their profits through the utilization of food shelf-life extension technology

Yue Yao, University of Tennessee, Knoxville, Knoxville, TN, United States, Mingzhou Jin

We are going to build a framework for retailers and manufacturers to maximize their profits through the utilization of food shelf-life extension technology. The retailer needs to decide inventory cycle length, selling price, and order quantity for given extended shelf-life and wholesale price to maximize the total profit after considering the loss caused by expiry. The manufacturer needs to decide the length of the extended shelf-life and wholesale price to maximize his profit.

WA14

Summit - 334

New Topics in Grocery Retailing

Contributed Session

Chair: Yasamin Salmani, Bryant University, Smithfield, RI, United States

1 - Strategic Prediction and Decision Model for Operational Plan in Multichannel Food and Grocery Retailing

Jingran Zhang, Marshall University, Huntington, WV, United States

The Online Food and Grocery retailing is an increasingly growing market of Grocery Delivery and Meal Delivery. Customers turned to e-commerce for all their daily needs during and post pandemic, including food and groceries. Retailers provide different ways to process and fulfill customer orders from both online and offline channels, but one of the biggest challenges is last mile delivery stage. As a result, they need to make strategic operational decisions on channel switch and maintain. In this study, an integrated strategic decision model is established with demand prediction and expense estimation of delivery, and quick response to consumer orders to optimize cost-cutting of retailers and order fulfillment performance.

2 - Learning Commissions and Subscription Fees under Uncertainty in Two-Sided Marketplaces

Christina Liepold, School of Management, Technical University of Munich, Munich, Germany, Maximilian Schiffer

Two-sided marketplaces are online platforms that facilitate exchanges between suppliers and buyers as they reduce search costs, for example, in the context of vacation rentals, freelancing, or salon bookings. These platforms charge marketplace fees, typically through commissions or subscription fees, which are crucial for revenue generation and long-term economic success of the marketplace.
Existing research approaches focus on deterministic settings, analytically evaluate optimal marketplace fees, and discuss how to optimally fix commissions and subscription fees a priori to maximize marketplace operator revenue or overall marketplace welfare. In practice, however, marketplace operators may face multiple uncertainties regarding the market setup that complicate the fee-setting procedure, such as suppliers' and buyers' stochastic arrivals, pricing expectations, and maximum waiting times. In this context, we study an adaptive design of marketplace fees based on deep reinforcement learning (DRL), enhancing the operator's ability to navigate inherent market uncertainties. Exploring the intersection of DRL and the platform economy, this approach allows for non-myopic fee-setting in marketplaces by considering the impact of these fees on the overall welfare of all marketplace participants and the operator's revenue.

3 - Batching of Grocery Orders with Attribute Selection in an Island Layout

Zijia Wang, New Jersey Institute of Technology, Newark, NJ, United States

The order picking literature focuses exclusively on specific or unique items. Grocery item order picking includes a class of items that are characterized by attributes associated with customer preferences. Fresh produce such as fruits and vegetables have natural variations, and each unit of the same item is different. Picking three apples from a pile of gala apples has multiple outcomes in terms of weight, color, and ripeness. Grocery stores want to provide BOPS customers with item-specific attributes that are then transmitted to the pickers. Attribute-based order picking can be challenging, and this is the first research to address the problem. Item pick times are no longer fixed but a function of the number and complexity of the attributes. We develop non-linear functional models to describe the picking times and develop correlations across multiple orders. These items are typically stocked in an island layout with perimeter access. We present both MIP and heuristic solutions to the order picklist problem. The objective is to create order batches that minimize the combined travel and picking times. Experimental results show that the heuristics provide high-quality solutions in negligible time.

4 - Analysis of Factors Influencing Waiting Time for Unloading Trucks at Fresh Produce Wholesale Markets

Hiroki Iizuka, Waseda University, Tokyo, Japan, Kotomichi Matsuno, Shunichi Ohmori, Shintaro Nishibe, Takahiro Ohno

Wholesale markets serve as crucial infrastructures in the supply of fresh food products. Specifically, in the distribution channels for fresh produce, there is a flow between individual farmers, agricultural cooperatives, wholesale markets (wholesalers/intermediaries), and retailers. Information dissemination is one of the key functions of wholesale markets, enabling smooth transactions through information sharing among these entities. However, the uncertainty of shipping information until the last moment makes it difficult to implement effective strategies through information sharing. As a result, there is a concentration of truck arrivals at wholesale markets during late-night hours, exceeding the market's capacity, which leads to long waiting times for market entry. This issue directly impacts the working conditions of drivers and market staff, highlighting the urgency for a solution.

Current efforts focus on developing cargo reservation systems and improving unloading procedures to reduce overall waiting time. However, the magnitude of the impact of these initiatives remains unclear and has not been connected to significant decision-making processes. Therefore, it is necessary to validate the waiting time reduction effects generated by each proposed improvement.

In this study, we aim to simulate the entire process from truck transportation to unloading at the wholesale market in order to quantitatively demonstrate the effects of each proposal on reducing waiting time. This will enable us to determine the optimal allocation of resources and encourage the implementation of improvement measures.

5 - Strategic Sales Channel Management in Times of Crisis

Yasamin Salmani, Bryant University, Smithfield, RI, United States, Yuyun Zhong, Yang Li

In light of pandemic-induced disruptions, this study investigates the impact of sales channel mixes on the revenue of 84 U.S. manufacturing companies. Analyzing data from the last quarters of 2019 and 2020 with association rule mining, the research highlights how different sales strategies and product types interrelate within these channels. The results demonstrate that third-party retailers contribute positively to revenue, whereas company-owned physical stores often result in losses. Online channels prove most effective when aligned with experiential products. The study discerns that while multiple channels may decrease revenue, focused channel approaches—single or dual—tend to increase it. These insights aid in refining sales channel management during crises and suggest areas for further research.

Dynamic Models in Revenue Management

Invited Session

Revenue Management and Pricing

Chair: WEIYUAN LI, Cornell Tech, New York, NY, 10044, United States

1 - Prophet Inequalities with Cancellation Costs

Rad Niazadeh, Chicago Booth School of Business, Chicago, IL, United States, Farbod Ekbatani, Pranav Nuti, Jan Vondrak

Most of the literature on online algorithms and sequential decision-making focuses on settings with "irrevocable decisions" where the algorithm's decision upon arrival of the new input is set in stone and can never change in the future. One canonical example is the classic prophet inequality problem, where realizations of a sequence of independent random variables X_1, X_2, ... with known distributions are drawn one by one and a decision maker decides when to stop and accept the arriving random variable, with the goal of maximizing the expected value of their pick. We consider "prophet inequalities with cancellation costs" in the linear cost setting, where after accepting a variable X_i, we can still discard X_i later and accept another variable X_j, at a cost of f times X_i. The goal is to maximize the expected net reward, which is the value of the final accepted variable minus the total buyback cost. Our main result is a full characterization of the optimal competitive ratio as a function of parameter f everywhere. In particular, when f>1, we show an optimal competitive ratio of (1+f)/(1+2f). Our upper-bound result is obtained by (i) a sequence of reductions to identify worst-case instances, (ii) using combinatorial optimization techniques involving LP duality, flows, and cuts, and (iii) finally reducing the characterization of the optimal competitive ratio to solving a particular differential equation and showing how to solve that differential equation. We complement this upper-bound by a matching lower-bound

2 - Approximation Schemes for Dynamic Pricing with Opaque Products

Jacob Feldman, Olin Business School, Clayton, MO, United States, Yukai Huang, Danny Segev, Levi DeValve

In this paper, we consider a multi-period, multi-product dynamic pricing problem in which each product is endowed with an exogenous starting inventory level, and there is the added complexity of an opaque selling option. That is, alongside traditional (transparent) products, the retailer or platform also has the option to create and price an opaque product, which corresponds to a dummy product comprised potentially of any subset of the displayed transparent products. In the event that a customer selects the opaque product, the platform has the freedom to choose any of the opaque product's constituents to satisfy this demand. All-in-all, we are left with a classical dynamic pricing problem with a twist, since the addition of the opaque selling option gives the platform an extra lever of flexibility to balance supply and demand. For this novel pricing setting, we develop a nuanced constant factor approximation scheme.

3 - Prophet Inequalities for Product Recommendation Under the Bounded Last-Choice Model

Pin Gao, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Guillermo Gallego, Shaoyu Wang

This paper introduces a novel regular choice model that merely imposes an upper bound on each product's last-choice probability (i.e., the purchase probability of being exclusively recommended). Notable instances of this model include the Multinomial Logit (MNL), click-based MNL, sequential click-based MNL, and the general attraction model. For the static cardinality-constrained revenue-maximizing recommendation problem, despite its NP-hardness even under specific model instances, we propose a polynomial-time solvable constant-factor approximation heuristic for the general case, leveraging solely the last-choice probabilities. Additionally, we investigate an online recommendation scenario inspired by the burgeoning practice of live-streaming e-commerce. In this context, product-specific parameters are sequentially revealed as random and independent variables, compelling decision-makers to make immediate and irreversible decisions regarding whether to recommend a product upon receiving its information. We offer constant-factor approximations for cases where the information arrival order is adversarial or adheres to specific distributional patterns. Our comparative performance analysis underscores the importance of information in the online setting and establishes a novel connection between the online recommendation problem and the classical multiple-unit prophet inequality.

4 - Revenue Management with Calendar-Aware and Dependent Demands: Asymptotically Tight Fluid Approximations

Weiyuan Li, Cornell University, New York, NY, United States, Paat Rusmevichientong, Huseyin Topaloglu

When modeling the demand in revenue management systems, a natural approach is to focus on a canonical interval of time, such as a week, so that we forecast the demand over each week in the selling horizon. Ideally, we would like to use random variables with general distributions to model the demand over each week. The current demand can give a signal for the future demand, so we also would like to capture the dependence between the demands over different weeks. Prevalent demand models in the literature, which are based on a discrete-time approximation to a Poisson process, are not compatible with these needs. In this talk, we focus on revenue management models that are compatible with a natural approach for forecasting the demand. Building such models through dynamic programming is not difficult. We divide the selling horizon into multiple stages, each stage being a canonical interval of time on the calendar. We have random number of customer arrivals in each stage, whose distribution is arbitrary and depends on the number of arrivals in the previous stage. The question we seek to answer is the form of the corresponding fluid approximation. We give the correct fluid approximation in the sense that it yields asymptotically optimal policies. The form of our fluid approximation is surprising as its constraints use conditional expected capacity consumption. As the resource capacities and number of stages increase with the same rate, our performance guarantee converges to one.

Network Design/Revenue Management and Platform Operations

Invited Session

Revenue Management and Pricing

Chair: Victor Araman, American University of Beirut, Beirut, Lebanon

Co-Chair: Heng Zhang, Arizona State University, Tempe, AZ, United States

Co-Chair: Yunduan Lin, The Chinese University of Hong Kong, Santa Clara

1 - Expectation vs. Certainty: The Influence of Discount Announcements on Purchasing Behavior

Frederico Zimmerman, Harvard Business School, Cambridge, MA, United States, Gustavo Vulcano, Joaquín Navajas

We conducted a study to examine whether pre-announcing discounts affects consumers' decisions to wait or buy in a simulated retail scenario. Contrary to rational models, we hypothesized that preannounced discounts would lead more individuals to wait for markdowns. Participants were placed in conditions with varying stock quantities and discount information, including scenarios with no discount preannouncements and specific preannounced discounts of 20%, 50%, and 80%. Our results consistently showed that preannounced discounts led to more participants waiting for markdowns. We also observed that participants in the non pre-announced condition who imagined larger discounts were also more likely to wait. Remarkably, even participants in the non-preannounced condition who expected a 20% discount were significantly more likely to wait for the markdown than those who were certain about a 20% discount in the preannounced condition. Overall, these findings suggest that not preannouncing discounts can increase consumer uncertainty and elicit more impulsive purchasing, which may be more beneficial for retailers.

2 - Analysis of a Competitive Distributed Supply Chain

Victor Araman, American University of Beirut, Beirut, Lebanon

We consider a two-tier supply chain model constituted of a retailer facing end-consumers' demand and supplied by a large number of small suppliers. The retailer selects an adequate base-stock policy while suppliers decide, each independently, on their capacity levels. We adopt a queueing theoretic-approach for the supply function and reduce the dynamics complexity through the use of mean field equilibrium. We show the existence of such equilibrium and obtain a full characterization of the solution. We suggest a mechanism design that guarantees full coordination of the supply chain.

3 - Diversified Learning: Bayesian Control with Multiple Biased Information Sources

Xinyuan Zhang, Sauder School of Business, University of British Columbia, Vancouver, BC, Canada, Jussi Keppo, Michael Jong Kim

We consider a decision-maker (DM) who can acquire signals from multiple biased information sources to learn about a hidden state prior to making an earning decision. Unbiased signals are also available, but the acquisition cost is high. The DM jointly optimizes his learning (acquisition) and earning decisions to maximize the expected payoffs. This is particularly relevant in healthcare and revenue management, where decisions rely on data from different sources (e.g., combining diagnosis results, aggregating demand forecasts). We develop a Bayesian control framework for such problems, where multi-source learning is modelled by a hierarchical Bayesian network. Focusing on the budget-constrained scenario, we identify an optimal acquisition policy that promotes diversification across biased sources to mitigate misinformation risks. To support our theoretical findings, we also perform empirical and simulation studies on disease prevalence and consumer demand datasets. These studies underscore the vital importance of a diversified information acquisition strategy in complex decision-making scenarios.

4 - Information Disclosure and Consumer Search on the Online Experience Goods Platform: Theory and Empirical Evidence

Yushu Zeng, Hong Kong University of Science and Technology, Hong Kong, China, People's Republic of, Ying-Ju Chen, Xin Wang, Hu Huang

This paper explores the vertical and horizontal quality information disclosure strategies in a scenario where firms sell experience goods to consumers through an online platform. In the theoretical part, We develop a stylized game-theoretical model to capture the equilibrium patterns. We then test our predictions using data from a web novel platform and find supporting real-life evidence in the empirical part. Our findings indicate that when the search cost is negligible and vertical quality information is private, firms are less inclined to disclose horizontal attribute information. Additionally, we observe that firms with lower vertical quality are more likely to disclose fit information compared to high-type firms. Furthermore, platforms exhibit a lack of incentive to provide consumers with vertical quality information when the search cost is low.

5 - E-Commerce Subset Selection Problems and Approximate Submodularity

Levi DeValve, University of Chicago, Chicago, IL, United States, Duygu Soylemez

Many challenging problems in managing e-commerce fulfillment networks can be posed as subset selection problems: which fulfillment arcs to select during the network design phase, where to place each SKU in the network during the inventory planning phase, and where to fulfill orders from during the execution phase. These impactful problems are computationally challenging due to their combinatorial structure, and both the academic and practitioner communities have recognized the need to develop effective heuristics. The academic literature has long understood submodularity to be an invaluable structural property for analyzing subset selection problems, for the intuitive reason that local changes in the objective can be used to bound global changes. Unfortunately, most subset selection problems arising in the e-commerce setting lack submodularity, due to the inherent “two-sided” nature of the supply and demand networks under consideration. We overcome this technical challenge using a novel form of approximate submodularity to analyze local search heuristics for these problems, proposing a general framework that provides new constant factor approximation guarantees.

New Applications and Methodology in Pricing and Inventory Management

Invited Session

Revenue Management and Pricing

Chair: Meichun Lin, Singapore Management University, Singapore, Singapore

1 - Combatting Food Waste via Joint Pricing and Perishable Inventory Optimization

ZICHUN LIU, McGill University, Montreal, QC, Canada, Sentao Miao, Wei Qi

We address the simultaneous determination of pricing and inventory control for perishable food. The optimal policy is computationally intractable due to the curse of dimensionality. We then develop heuristic policy and prove asymptotic optimality under several parameter regimes, and show theoretical and numerical performance of the policy.

2 - Mostly Beneficial Clustering: Aggregating Data for Operational Decision Making

Chengzhang Li, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Zhenkang Peng, Ying Rong

With increasingly volatile market conditions and rapid product innovations, operational decision-making for large-scale systems entails solving thousands of problems with limited data. Data aggregation is proposed to combine the data across problems to improve the decisions obtained by solving those problems individually. We propose a novel cluster-based Shrunken-SAA approach that can exploit the cluster structure among problems when implementing the data aggregation approaches. We prove that, as the number of problems grows, leveraging the given cluster structure among problems yields additional benefits over the data aggregation approaches that neglect such structure. When the cluster structure is unknown, we show that unveiling the cluster structure, even at the cost of a few data points, can be beneficial, especially when the distance between clusters of problems is substantial. Our proposed approach can be extended to general cost functions under mild conditions. When the number of problems gets large, the optimality gap of our proposed approach decreases exponentially in the distance between the clusters. We explore the performance of the proposed approach through the application of managing newsvendor systems via numerical experiments. We investigate the impacts of distance metrics between problem instances on the performance of the cluster-based Shrunken-SAA approach with synthetic data. We further validate our proposed approach with real data and highlight the advantages of cluster-based data aggregation, especially in the small-data large-scale regime, compared to the existing approaches.

3 - Online Learning for Dynamic Pricing in Consumer Electronics Trade-in Program

Sean Zhou, Chinese University of Hong Kong, New Territories, Hong Kong, Zhuoluo Zhang, Wenhao Li

We consider joint learning and pricing for an electronics trade-in platform which buys and sells multiple used electronics. The platform offers both trade-in-for-cash and trade-in-for-upgrade options and sets the corresponding prices to acquire the used products and their reselling prices after simple cleaning and refurbishing. Both supply and demand models are parametric. We propose two heuristics and analyze their regret bounds.

4 - Balancing Between Sustainability and Profitability on Online Food Platforms

Yeqing Zhou, Eindhoven University of Technology, Eindhoven, Netherlands, Salma Abououkal, Nourhan Sakr

In an era where food waste is a growing concern, we model an online platform that matches unsold surplus food from various outlets with customers willing to order 'surprise boxes.' The inherent unpredictability of leftover inventory and customer choices often results in either excess waste or unmet demand, impacting both sustainability and profitability. To address this challenge, we propose dynamic algorithms that recommend a subset of stores to customers based on sales data. This targeted approach not only promotes a more equitable distribution of surplus food but also enhances the platform’s operational efficiency. Preliminary results demonstrate a significant reduction in food waste along with relative revenue stability. Our paper details the proposed algorithmic solutions, evaluates their effectiveness through simulation, and discusses the implications for both food sustainability and business performance.

1 - Coins, Cards, OR Apps: Impact of Payment Methods on Street Parking Occupancy and Search TIMES

Sena Onen Oz, McGill University, Montreal, QC, Canada, Mehmet Gumus, Wei Qi

City dwellers often struggle with on-street parking. In most cities, once finally finding a curbside spot, drivers must pay in advance, but estimating the exact parking duration needed can be challenging. However, mobile payment applications enable drivers to adjust their parking duration remotely, if necessary, unlike traditional payment methods such as cash and credit cards. This paper examines how different payment methods and hourly parking prices affect drivers’ parking behavior, street parking occupancy, and search time. We investigate the influence of payment methods by conducting an online survey wherein participants make payment decisions under various conditions. Additionally, in collaboration with a municipal agency from a densely populated North American city, we examine high-resolution, multi-year records of street parking payments to evaluate the effect of pricing on payments. Our findings indicate that drivers' payment amounts vary significantly depending on their preferred payment methods and prices. Specifically, drivers tend to pay less using mobile applications than credit cards and cash, and decreasing hourly prices increases street parking payments. To provide further guidance to municipalities, we simulate parking scenarios to examine the effects of these factors on occupancy and search times. Our findings revealed that decreasing prices significantly increases the search time and street occupancy. We also found that the progressively increasing pricing policy significantly impacts both operational metrics compared to constant pricing. Lastly, we showed that mobile payment adoption could reduce search times and occupancy thanks to the reduced overpayment of mobile payers.

2 - (Machine) Learning Consumption Preferences in Service Networks

Kenneth Moon, University of Pennsylvania, The Wharton School, Philadelphia, PA, United States

The shopping paths that time-conscious customers take through service networks (e.g., supermarkets and shopping centers) reveal their choices over multiple stations with different offerings (e.g., a supermarket's sections for distinct categories), yet data on such paths present unique challenges for empiricists. Customers often realize value by visiting specific groups of complementary stations, and they navigate between the combinatorially many possible network paths to reach their destinations most conveniently and quickly. When using such data to recover customers' underlying consumption preferences and patience for time spent shopping, existing empirical methods exhibit surprising limitations, including intractability or inconsistency. We develop new estimators to address several major issues and apply them to an empirical case study utilizing customer mobile location data from a hypermarket serving over 1M shoppers annually. Despite the combinatorial complexity of network choice sets, we show that making a small set of utility comparisons against ``local'' alternatives suffices to validate that a customer is visiting her optimal set of stations and, for empirical researchers, to maximally learn customers' underlying preferences from observing their chosen paths in data. Neural networks capably exploit such hidden low-dimensional structure, which motivates us to develop estimators that use them to discriminate between and thus identify different customer types from shopping paths data.Our empirical methods enable analyses of service network management and customer targeting that account for station complementarities and customer patience. For a simple network staffing problem at the hypermarket, we find

3 - Points Plus Money: Uncovering the Impact of Mixed Currency Payments

Freddy Lim, INSEAD, -, Singapore, So Yeon CHUN

We explore the impact of implementing a mixed currency payment method, which allows consumers to use a combination of points and money for payments, on consumer behaviors and firm revenues. We develop a two stage self-selection model with instruments to empirically investigate the adoption of this payment method and its post-adoption outcomes within a large scale coalition loyalty program. After controlling for self-selection, the findings reveal that mixed currency payments increase consumers' point earning, point spending, and monetary spending. This change in consumer behavior boosts firm revenue, and we identify that a consumer segment often overlooked in marketing efforts contributed significantly to this revenue increase. Finally, we discuss the potential mechanisms behind this effect.

4 - Repair OR Replace: An Empirical Analysis of the Impact of Diagnostic Decisions on Product Returns in a Bike-Sharing Platform

Jingxuan Geng, Temple University, Philadelphia, PA, United States, Hailong Cui, Guangwen Kong, Guo Li

Bike-sharing has emerged as an effective solution for consumers in recent years. However, the growing consumer adoption of bike-sharing has led to an increase in the susceptibility of shared bikes to frequent damages, resulting in escalated operational costs. Our study focuses on the maintenance practices employed by bike-sharing platforms to address this challenge. We have gathered a comprehensive operational dataset from a prominent bike-sharing platform in Asia. In our reduced-form analysis, we first establish that decisions regarding the repair or replacement of defective bike components significantly influence the likelihood of the bike being returned for maintenance in a short timeframe. Subsequently, we delve into the development of a structural estimation model to examine how repair workers make diagnostic decisions and how these decisions impact the overall maintenance expenses for the platform.

Pricing and Market effects

Contributed Session

Chair: Vicente Ahumada, Universidad Adolfo Ibáñez, Viña del Mar, 2540050, Chile

1 - Fairness-aware Contextual Dynamic Pricing with Strategic Buyers

Pangpang Liu, Purdue University, West Lafayette, IN, United States, Wei Sun

Contextual pricing strategies are prevalent in online retailing, where the seller adjusts prices based on products' attributes and buyers' characteristics. While such strategies can enhance seller's profits, they raise concerns about fairness when significant price disparities emerge among specific groups, such as gender or race. These disparities can lead to adverse perceptions of fairness among buyers and may even violate the regulation and law. Conversely, price differentials can incentivize disadvantaged buyers to strategically manipulate their group identity to pursue a lower price. In this paper, we investigate the contextual dynamic pricing with fairness constraints, taking into account buyers' strategic behaviors when their group status is private and unobservable from the seller. We propose a dynamic pricing policy that simultaneously achieves price fairness and discourages strategic behaviors. Our policy achieves an upper bound of $O(\sqrt{T})$ regret over T time horizons. We also prove an $\Omega(\sqrt{T})$ regret lower bound of any pricing policy under our problem setting. We support our findings with extensive experimental evidence, showcasing our policy's effectiveness. In our real data analysis, we observe the existence of price discrimination against race in the loan application even after accounting for other contextual information. Our proposed pricing policy demonstrates a significant improvement, achieving 34.75% reduction in regret compared to the benchmark policy.

2 - Bundling vs Two-part Pricing under Heterogeneity in Demand Uncertainty

Sreya Kolay, University at Albany, SUNY, Albany, NY, United States, Rajeev Tyagi

Two-part pricing and bundling are two commonly observed price discrimination strategies used by firms. For example, sellers such as Costco use two-part pricing through annual club membership fees in addition to per-unit prices. On the other hand, sellers such as Sling TV offer programing through bundles of different sizes. Prior academic literature has shown that bundling yields a higher profit compared to two-part pricing for a monopolist firm selling to consumers with heterogeneous valuations. This paper extends that research by introducing consumer uncertainty about their future demand needs. We show that under certain conditions on degree of consumer uncertainty and degree of consumer heterogeneity, two-part pricing can yield the seller a higher profit than under bundling. We also examine the implications of these pricing schemes on consumer welfare under consumer demand uncertainty.

3 - Data-driven advertising and pricing policy with budget constraint on e-commerce platform

Yunzhi Cao, City University of Hong Kong, Hong Kong, Hong Kong, Houmin Yan

Advertising and pricing are crucial tools for retailers on the e-commerce platform for promotion, such as Amazon. This study focuses on the joint bidding and pricing policy for retailers subject to budget limitation under multiple periods. The bidding is for the impression on the sponsored advertising list. The click-through rate and conversion rate functions with respect to bid and price are learned and estimated based on historical data. We formulate a stochastic model and construct a dynamic programming formulation. We prove the existence of the unique optimal solution and characterize the structure of an optimized bidding and pricing policy. Through theoretical analysis and a case study, we investigate the relationships among the optimal policy, value function, and key factors, and demonstrate the effectiveness of the optimal policy and the proposed dynamic model.

4 - Constraint learning: design and comparison of methods for the construction of constraints in multiproduct pricing

Vicente Ahumada, Universidad Adolfo Ibáñez, Viña del Mar, Chile, Luis Aburto

Optimizing multiproduct pricing is a challenging process. Demand models calibrated with transactional data tend to exhibit bias in cross elasticity effects, mainly due to endogeneity issues, leading to nonsensical or extreme outcomes during optimization. We examine different supervised and unsupervised methods to extract constraints from the data to formulate a robust feasible space for the pricing optimization process. These constraints, or pricing rules, reveal latent business rules that show the relationships between product prices. Moreover, they help to identify price solutions correlated with strong product category performance. We apply our methodology to an orange juice dataset from different supermarket stores, achieving significant and robust improvements in expected category profit, ranging from a 15% to 40% gain in profits. The methods used to create constraints for an improved optimization included an exhaustive parameter iteration, skope rules classifiers, robust optimization, definition of ellipsoidal feasible regions, support vector machines and tree classifiers.

5 - An Interpretable Auto-ML Pipeline for B2B Pricing Decisions

Zijian Zeng, PROS, Houston, TX, United States, Jonas Rauch, Manu Chaudhary, Mohit Mahajan, Chih-Hsien Wu, Royce Kallesen

In business-to-business pricing, organizations aim to maximize profits over time by developing optimized pricing strategies based on historical transactions involving a wide variety of customers, products, and other characteristics. Each customer receives a unique price for the product determined through negotiation, which makes it essential to consider both customer-specific prices (CSP) and market prices (MP) in pricing decisions. This task has become increasingly challenging in the era of big data due to the presence of millions of transaction records and countless possible combinations of transaction features, making it difficult for humans to analyze and optimize pricing effectively.

Current pricing solutions often require segmenting transactions to reduce dimensionality and define market boundaries. However, this approach limits cross-segment information sharing. To leverage all available data, we propose an automated machine learning (Auto-ML) pipeline for making smart pricing decisions. Our pipeline infers CSP and MP directly from transactions data without requiring segmentation, sacrificing interpretability, or requiring extensive manual tuning. It employs a deep-and-wide neural network to comprehensively explores feature information and cross-effects. Time-dependent bases can be added to identify linear and seasonal patterns at both market and transaction levels, if present. The pipeline uses a specialized hyperparameter search space to narrow down tunable parameters, enabling efficient Bayesian optimization for automatic tuning. At the end of training, Shapley values explain feature importance and identify the price changes attributable to each feature.

This Auto-ML pipeline has been used for daily pricing decisions in practice, delivering high credibility and strong results.

Emerging Topics in Decision Analysis

Invited Session

Decision Analysis Society

Chair: Xiao Xiao, California State University, Stanislaus, Turlock, CA, United States

1 - Loyalty programs: when are they profitable for franchisees in hotel industry

Yunke Li, Tongji University, Shanghai, China, People's Republic of, Harihara Natarajan, Nan Yang

To scrutinize the impacts of loyalty programs, in this study, we develop a stylized game model featuring two firms with vertical product differentiation and a limited supply of products. Considering the fact that capacity commitment can soften price competition, and given the fixed number of rooms in hotels, our model's unique feature is that while it assumes that hotels cannot directly alter capacity, it does permit hotels to commit to a new room capacity by allocating a portion of rooms for reward redemption. Implementing reward redemption through loyalty program channel necessitates specific pricing and capacity constraints. We find that the hotel can enhance its profitability under specific conditions related to the proportion of loyal customers and redemption point requirements.

2 - Future of Healthcare: A New Perspective on Emerging Technology Adoption and Organizational Performance

Heng (John) Xie, California State University, Sacramento, Sacramento, CA, United States, Xinyu Wei, Richard Peng, Victor Prybutok

Rapid technological advancements provide healthcare organizations with increasing opportunities to enhance organizational performance. However, healthcare organizations face challenges in effectively understanding and leveraging these technologies. Previous studies have outlined the process through which users understand, accept, and utilize emerging technology, yet few have explored the combined effects of emerging technology adoption on hospital organizational performance. This research proposes a comprehensive model to study the impact of emerging technology adoption and integration on organizational performance in the healthcare industry. It specifically aims to integrate both upstream factors influencing technology adoption and downstream factors involved in measuring performance resulting from the utilization of these technologies. The results illustrate how emerging technology adoption can be effectively connected to hospital organizational performance. Additionally, this study discusses various factors influencing the adoption of emerging technologies by healthcare organizations and offers robust empirical evidence that can guide future research and inform decision-making processes within healthcare management.

3 - Managing Long-Term Supply Risks: Incentives for Smooth Production Flow

Xiao Xiao, California State University, Stanislaus, Turlock, CA, United States, Dawei Jian, Mohsen Elhafsi

Smooth production flow, a key aspect of lean manufacturing, is essential for firms to ensure continuous supply, stabilize prices, and maintain customer satisfaction. However, it is vulnerable due to dynamic supply risks. How should the firm incentivize a smooth production flow through procurement? We study a new class of long-term procurement contracting problem within a two-echelon supply chain, where a risk-averse buyer with market pricing power replenishes from a supplier whose private state of production is subject to random shocks and evolves dynamically over time. We derive the optimal procurement contract; it distorts order quantity in the initial period for screening purpose and subsequently intensifies quantities to align with production needs. We demonstrate that smooth production flow concern can reduce quantity distortion, addressing the agency problem and promoting a more stable supply chain. This work advances our understanding of addressing dynamic supply risks to foster smooth production flow.

4 - Invalid Extra Online Shopping for Free Shipping Policy

Si Liu, Kent State University, Kent, OH, United States

Delivery activity costs have become a significant concern for e-commerce retailers (ECRs). To strategically mitigate these costs, many ECRs impose criteria such as minimum purchase values or a specific number of items for customers to qualify for free forward shipping. However, these criteria are often absent for free returns (backward shipping), provided returns occur within a designated timeframe. This discrepancy in shipping policies can give rise to a phenomenon we term 'Invalid Extra Shopping' (IES), where customers purchase additional items with the intent to return them, solely to benefit from the free shipping policy that they would not otherwise qualify for. IES leads to revenue losses for ECRs and exacerbates delivery-related impacts such as congestion and pollution.

This paper addresses the IES phenomenon through a threefold approach. First, we develop a model to capture customer behavior associated with IES. Second, we analyze the influence of customer characteristics, purchase item classification, and ECRs' return windows on their revenues, identifying which ECRs are most susceptible to IES. Third, we evaluate the effects of various shipping and return policies on IES and propose optimal policies that benefit all stakeholders. Our findings offer critical insights for ECRs aiming to balance cost-effective operations with customer satisfaction.

Stochastic Analysis of Energy Power Systems

Contributed Session

Chair: Joonho Bae, University of Michigan Ross School of Business, 2301 Stone Rd, Ann Arbor, MI, 48105, United States

1 - Assessing the Resilience of Integrated Energy Systems under Capacity Expansion Risks

Weijie Pan, The George Washington University, Washington, DC, United States, Ekundayo Shittu

Within the framework of sustainable development, the decarbonization of electricity generating systems plays a pivotal role in climate change mitigation strategies. Energy policies have led to increases in the integration of renewable energy (REN) especially in capacity expansions. However, the enactment of these policies involves multiple considerations such as technical performance, economic effectiveness, and resource accessibility, all accompanied by significant uncertainties. While past literature extensively explores various expansion portfolios of REN technologies through qualitative discussions and quantitative modeling, few studies verify the feasibility of these policies in terms of physical system operations. Moreover, contemporary energy systems face high-impact, low-probability (HILP) threats from extreme environmental incidents and malicious human activities, necessitating enhancements in resilience. Consequently, the extent to which increased REN technology penetration affects system operations and resilience remains unclear. This study uses Modelica modeling language to capture the physics of energy systems in the presence of both HILP events and heightened REN generation technology penetration. Preliminary results illustrate the effectiveness of expanded REN capacities in recovering post-disaster system performance, contingent upon an assessment of the generation mix in the presence of the intermittency introduced by REN resources. By assessing the impact of energy policies on capacity expansion, this study contributes to informing how decision-making for system resilience enhancement is influenced by the physics of technologies.

2 - The influence of additionality and time-matching requirements on the emissions from grid-connected hydrogen production

Dharik Mallapragada, Chemical and Biomolecular Engineering, Tandon School of Engineering, New York University, New York, NY, United States, Michael Giovanniello

Decarbonization policies emphasize electrifying end-uses while growing low-carbon electric power supply. This approach raises the question of the induced emissions attributable to a specific load connected to the grid that also contracts variable renewable energy (VRE) power supply. The answer is not obvious because instantaneous power flows from a particular producer cannot be directly associated with a particular user. Nonetheless, such assessments are necessary and in the case of electrolytic hydrogen (H_2) production, have billion-dollar ramifications due to the emission-indexed H_2 production tax credit (PTC) in the U.S.. There has been a vigorous debate on the qualifying requirements for grid-connected H_2 production to receive the PTC, with the focus on: a) requirements on “time-matching”, i.e. the period over which electricity use must match production from contracted generators, and b) “additionality”, which require contracting newly built VRE plants. Here, we use an open-source macro-energy system model, DOLPHYN, to show that the emissions and cost impact of alternative time-matching requirements are conditional upon the way additionality is modeled. Significantly lower emissions are achievable under annual time-matching in the additionality framework that presumes VRE for non-H_2 electricity demand does not compete with VRE for H_2 (“non-compete” framework), as opposed to the framework where all VRE resources are in direct competition (“compete”). In practice, the “non-compete” framework can be realized with binding and stringent grid decarbonization targets. This implies that for regions with such policies, less stringent (and therefore less costly) time-matching requirements are sufficient to avoid system-level emissions increases due electrolytic hydrogen deployment.

3 - Assessing the Vulnerability of Power Systems in Decarbonized Power Grids: A Network Interdiction Study

Veronica Veronica Diaz, North Carolina State University, Raleigh, NC, United States, Jordan Kern

Decarbonizing electric power systems will likely involve greater reliance on variable renewable energy, especially wind, and solar, which provide lower electricity output per land area than fossil fuel and nuclear-based power. As a result, a distinct feature of future bulk power systems may be more numerous, lower-capacity generators spread more evenly throughout the network. The impacts of this new configuration on the vulnerability of system operations are still unclear. Motivated by recent physical attacks on grid infrastructure, this study examines how decarbonization through variable renewables could alter the vulnerability of the power system to intentional attacks. We explore this question as a network interdiction problem, a two-player sequential game model where an adversary aims to maximally damage a cost-minimizing system operator by destroying grid components (generators, transmission lines, substations, etc.). While network interdiction has previously been used to assess the vulnerability of power systems, its application in the context of system-wide decarbonization is novel. We use a clustering procedure on annual load and renewable generation data from a real-world 662-bus regional transmission system to generate representative operating scenarios. We then evaluate how an attacker's optimal strategies change throughout a typical operating year, contrasting the vulnerabilities of the current and future (decarbonized) grid configuration, including the capacity mix and its distribution throughout the regional transmission network.

4 - Navigating Challenges arising from Large-scale Renewable Energy Integration and Solutions to Address Them

Elnaz Kabir, Texas A&M University, College Station, TX, United States

The global priority to combat climate change has led to a focus on decarbonizing power systems. However, the variability and intermittency of renewable energy sources pose several challenges for power systems operations, including energy curtailment, load shedding, and electricity price volatility. In this presentation, we analyze these challenges and propose solutions to address them using a real world case study.

5 - Cost-Saving Synergy: Energy Stacking in Battery Energy Storage Systems

Joonho Bae, University of Michigan Ross School of Business, Ann Arbor, MI, United States, Roman Kapuscinski, John Silberholz

Despite the great potential benefits of battery energy storage systems (BESS) to electrical grids, most standalone uses of BESS are not economical due to batteries' high upfront costs and limited lifespans. Energy stacking, a strategy of providing two or more services with a single BESS, has been of great interest to improve profitability. However, some key questions, e.g., the underlying mechanism by which stacking works, or why and how much it may improve profitability, remain unanswered in the literature. Using two popular battery services, we analytically show that there often exists cost-saving synergy -- the cost of performing both services at the same time (simultaneous stacking) is smaller than the sum of individual costs if we had performed each service alone -- which allows for bigger profits. Furthermore, we perform comparative statics on the optimal mix of the services to systemically characterize grid/market conditions that maximize/minimize this synergy. We also derive a theoretical upper bound on simultaneous stacking's benefits, showing that it can approximately double the profit of the best standalone service. Several generalizations of the base model not only show that the main lessons continue to hold but also that stacking's benefits may become even stronger.

6 - Optimizing Energy Consumption in AI Training: A Reinforcement Learning Approach

Viveka Saraiya, Independent Researcher, Seattle, WA, United States, Mayuree Binjolkar

With artificial intelligence (AI) developing at a rapid pace, and with its growth potential increasing by the day, the question arises of what amount of energy is required to support this growth. The energy efficiency of an AI model is an emerging research area that needs to be explored further in order to understand any potential implications of this growth. Based on this motivation, the purpose of the study is to examine opportunities to more efficiently utilize the energy required to train an AI model. We develop a dynamic predictive model that uses reinforcement learning to continuously adjust optimization strategies to reduce its energy consumption. The primary constraints are to minimize gains in training time and to maintain the original range of model accuracy.The model evaluates making changes to hardware setups, software settings, and training methods based on continuous model performance feedback. The results show that with the optimized combinations of rewards and robust model formulation, energy efficiency of AI can be maintained while making incremental changes to the different setups.

AI and Technology for Humanitarian Logistics and Supply Chain Resilience

Contributed Session

Chair: Ahana Malhotra, McMaster University, Hamilton, ON, L8P1C3, Canada

1 - Using Machine Learning to Predict Late Deliveries in International Healthcare Logistics

Nima Molavi, California State University, San Bernardino, San Bernardino, CA, United States, Jeevan Sai Gali

The global healthcare supply chain encounters numerous challenges, ranging from natural disasters to logistical inefficiencies, which can lead to disruptions in the delivery of essential medical commodities. Machine learning models can be applied to the healthcare big data to predict and mitigate late deliveries, and consequently ensure timely access to healthcare resources. This research aims to contribute to the body of knowledge by (1) Identifying influential factors in late deliveries in international healthcare logistics, and (2) Developing Machine Learning models based on the identified factors to predict late deliveries in international healthcare logistics.

The identified factors in this paper can be listed under three major categories: Transportation Characteristics, Shipment Characteristics, and Country Capabilities. To study the impact of these factors on late deliveries, the USAID Health Commodity Delivery Dataset is modified and complemented by the Logistics Performance Index (LPI) to generate a more holistic view of the problem. Next, to predict the delay in shipments, several Machine Learning models such as Neural Networks, Random Forests, and Support Vector Machines, are developed based on the identified influential factors. The performance of these models have been assessed and compared to provide additional insights. To sum it up, by understanding the factors contributing to disruptions, exploiting advanced analytics to predict late deliveries, and developing proactive strategies for the industry, this research strives to improve the efficiency and reliability of healthcare commodity logistics worldwide.

2 - Technology Trends in Human Trafficking

Wojtek Wolfe, Rutgers University, Camden, NJ, United States, Srinivasa Puranam

Modern slavery and human trafficking are very prevalent in supply chains. Advancements in technology have yielded new methods and opportunities for identifying and impeding human trafficking. For example, data mining techniques and machine learning algorithms can detect patterns and trends within extensive data sets, making it possible to uncover potential trafficking networks and high-risk areas. This project aims to understand how technology simultaneously facilitates and obstructs human trafficking within a geopolitical understanding.

In focusing on the intersection of geopolitics, the use of technology, and modern slavery, the first objective aims to lay a solid groundwork for the research through a detailed literature review and environmental scan. This crucial step will help pinpoint the existing knowledge, gaps, and potential opportunities in the field. Delving into the business models, supply chain intricacies, and the interplay of political, legal, and regulatory systems highlights the necessity of grasping the wider context where technology and human trafficking converge by looking at human trafficking through the lens of the supply chain – where human trafficking begins, who are the key players, and how it gets to its final consumers.

3 - Adoption of innovative technology in the last-mile delivery of non-profit food rescue organizations

Ahana Malhotra, McMaster University, Hamilton, ON, Canada, Elkafi Hassini

We investigate an innovative direct-to-client last mile delivery for non-profit food rescue organizations that we call Crowdfeeding. Capitalizing on the existing successful ride sharing platforms, a driver collects surplus food from retail outlets and delivers it to food bank clients that are located on the route of their regular customer deliveries. Interviews with employees of food rescue organizations in Canada have been conducted and analyzed. Empirically grounded analytics is used to gain insights and data analysis is conducted by the Technological Acceptance Model (TAM) for analyzing cases. In the second part, empirical analysis highlighting the performance of the implementation of crowdfeeding. Our findings suggest that crowdfeeding is an effective strategy for organizations that care about minimizing their impact on the environment, maximizing the availability of nutritious meals, and decreasing food waste. In addition to our theoretical contributions to the food rescue literature, we offer an empirical account of our theoretical framework, proposals for future research and practical suggestions to managers handling food rescue operations.

Keywords: last-mile delivery, non-profit organization, food rescue, Technological Acceptance Model, case study research

Port Operations and Freight Logistics

Contributed Session

Chair: Pirmin Fontaine, KU Eichstaett-Ingolstadt, Ingolstadt School of Management, Ingolstadt, Germany

1 - A Cost Focused Machine Learning framework for replenishment decisions under transportation cost uncertainty

Pirmin Fontaine, KU Eichstaett-Ingolstadt, Ingolstadt School of Management, Ingolstadt, Germany, Daniel Müllerklein, Janosch Ortmann

Companies worldwide seek a balance between risks and cost-efficiency in their supply chains. Due to the increase in extreme weather events, global inland waterway transport disruptions gained growing attention as shipment carriers enforce contractual surcharges to account for capacity losses. To improve efficiency and resilience, one open question is, therefore, when and how much to transport from which of the multiple suppliers considering their lead time differences and account for the transportation cost uncertainty driven by the enforced surcharges.

We formulate this problem as a stochastic Inventory Routing Problem with Direct Deliveries and introducing a new Cost Focused Machine Learning (CFML) framework. Compared to existing approaches, we perform a hyperparameter tuning where the costs of applying the resulting transportation decisions are optimized instead of the prediction score of the individual decisions of the machine learning model.

We evaluate our CFML in a case study, based on a chemical company at the border of the river Rhine. Relevant features for our CFML include the inventory position, historical water level, their trends, and predictions. While traditional learning approaches result in inefficient policies, we show that our CFML can reduce costs by 18% compared to classical machine learning frameworks and more than 20% compared to a standard (s,Q)-reorder policy representing industry standard.

2 - Optimal Capacity Decisions for Competing Forwarders under Transshipment

Jiyong Kim, Seoul National University, Seoul, Korea, Republic of, Byeongkwon Lee, Kunsoo Park, Kwanghun Chung

Carriers and forwarders are major players in the air cargo industry, typically entering into contracts for the carriers' capacity. Forwarders serving the same routes compete for this capacity. At the same time, to better align with demand, they may choose to transship with each other. To better understand these dynamics, we model the forwarder's problem of finding the optimal reservation quantity under capacity substitution and transshipment, along with the optimal transshipment price. Furthermore, we incorporate the carrier's problem and identify a contract that can coordinate the entire supply chain.

3 - Equilibrium Analysis of Shipping Market Priority Competition with Multiple Stakeholders

Xinyue Pu, Tsinghua University, Beijing, China, People's Republic of, Xi Lin, Xiwen Bai

With the rapid growth in trade volume and the expansion of port service regions, port competition has intensified, prompting ports to adopt strategic measures such as berthing priority. This paper investigates the impact of berthing priority on port congestion, stakeholder competition, and social welfare by developing an analytical tri-level game-theoretical model to explore the maritime equilibrium in a port-carrier-cargo-owner system. Specifically, cargo owners, operating under perfect competition, make cargo assignment decisions to minimize their costs. At the carrier level, a Cournot-Nash game is modeled where carriers decide on fleet allocation to balance the revenue from cargo transportation with the costs induced by port congestion. Ports determine the provision of priority to enhance their throughput. Through this intricate game-theoretical framework, we derive market equilibrium using numerical experiments. Our research reveals the potential impact of berthing priority on the entire system, considering carriers' complex decision motivations, and offers decision support from a managerial perspective.

4 - A Stochastic Optimization Model for Tramp Scheduling with Many-to-many Matching and Speed Optimization

Liangqi Cheng, Tsinghua University, Beijing, China, People's Republic of, Xi Lin, Xiwen Bai

The tramp shipping industry involves large volumes of homogeneous cargoes transported around the world. Tramp companies route vessels to pick-up and deliver these cargoes in order to minimize total costs, but the scheduling process becomes increasingly challenging due to the uncertainties and risks in the tramp market. In addition, long transportation time and dispersed pick-up and delivery regions cause delayed responses to market volatilities and exacerbate the complexity of short-term decision-making. This study introduces a tramp scheduling model considering stochastic future revenues to enhance short-term decisions. The model employs “many-to-many” matching in the tramp market, where each vessel can transport multiple cargoes simultaneously, and a single cargo can be split and delivered by multiple vessels. Initially, a two-stage stochastic arc flow formulation is presented within a space-time network, enabling vessel speed optimization during arc selection. Subsequently, Dantzig-Wolfe Decomposition is utilized to manage the extensive set of variables, resulting in a path flow master problem and pricing subproblems, each solved for a specific vessel and scenario. A branch & price solution method is devised, incorporating a label-setting algorithm for the subproblem in each column generation iteration that can determine the cargo quantity decisions brought by split deliveries. This label-setting algorithm is developed through an in-depth analysis of the extreme structure of delivery quantities on a specific route. Extensive numerical experiments are conducted to demonstrate the efficiency of the proposed algorithms. The computational results also uncover the temporary idle and repositioning behaviors of vessels across different tramp markets.

5 - Dynamic Berth Allocation Policies in Deep-Sea Terminals

Orkun Tunay, Rotterdam School of Management, Rotterdam, Netherlands, Pieter van den Berg, Rob Zuidwijk, DEBJIT ROY

While deep-sea vessels play an important role for the revenue streams of container terminals, barges and feeders play an important role in ensuring the functioning of the transshipment and hinterland transportation operations. Besides, the roles of feeders and barges are further leveraged as a cost and emission-efficient alternative to long-haul trucking. These different classes of vessels compete for the same berth space in container terminals. The terminal operators conventionally have the tendency to fully prioritize deep-sea vessels. However, with the increasing incentives and regulatory pressure for the increase of barge and feeder throughput, some terminal operators started to allocate dedicated berths for barges and feeders.
In this paper we will study the berth allocation problem in order to find a pareto-optimality frontier that balances barge throughput and deep-sea vessel waiting times. Barges and feeders which are of smaller volume, occupy a smaller space and have a shorter expected handling time. By using analytical methods from Queuing Theory, we will first demonstrate the pareto-efficiency of different heuristics of berth allocation policies, i.e. dedicated terminal spaces, barge limits, motivated by the current industry practices. Based on the insights that we receive from analytically tractable systems, we will design a Markov Decision Process to propose a better pareto-optimality frontier with dynamic policies.

Embracing Uncertainty: Digital Workspaces and Resilience Strategies

Contributed Session

Chair: Siyi Yang, Fudan University, Shanghai, N/A

1 - Visualization of Ideation Process Considering Thinking Styles in Discussion

Mayato Hattori, Waseda University, Tokyo, Japan, Kotomichi Matsuno, Terumasa Mastuyuki, Kenta Nakagawa, Yoshikuni Edagawa, Takahiro Ohno

In contemporary society, where the generation of innovation is an urgent issue, balancing "knowledge exploration" and "knowledge exploitation" are indispensable. In the field of ideation, where ideas are generated, it is necessary to repeatedly cycle through divergent and convergent thinking and discuss objectives and means bidirectionally to produce effective ideas. Although the thought patterns of Causation and Effectuation have been systematized, the application of these methods remains highly subjective, often relying on the experience and intuition of facilitators. Proficient facilitation contributes significantly to the generation of innovative ideas and to the efficiency of discussions. Therefore, there is a need for a reproducible and effective facilitation methodology. This research aims to establish an engineering-based ideation method that focuses on the interaction between divergent and convergent discussions and the interplay between objectives and means. Methodologies are proposed to infer thought patterns and discussion states.

In workshops aimed at creating new businesses in Japan, surveys on thought patterns were conducted before and after ideation, and discussion audio and brainwaves were measured. Bayesian network analysis revealed that thought patterns change due to brain activity. Additionally, using audio data, discussion states were classified into four types: "divergent," "convergent," "goal-driven," and "means-driven," and their relationships with thought patterns were analyzed. This study contributes academically by providing a structured framework for understanding and analyzing ideation processes, and practically by offering tools and methods that can enhance the effectiveness and reproducibility of innovation activities in real-world settings.

2 - Using Disruption Intensity to Measure System Resilience

Daniel Romero, SUNY Polytechnic Institute, Utica, NY, United States, Alex Savachkin, Weimar Ardila, Jose Navarro

Measuring the resilience of a system is essential in evaluating its ability to withstand disruptive events. We present a resilience metric that explicitly incorporates the intensity of a disruptive event to provide a more accurate estimation of system resilience. A comparative analysis between the proposed metric and average performance resilience metrics for linear and nonlinear loss and recovery functions is presented. The new metric is evaluated using a testbed of a community affected by a pandemic influenza outbreak, where nonlinear relationships between resilience capacities and disruption intensity are captured and used for pandemic control.

3 - Overcoming Data Contribution Uncertainty: Relational Contracts for Effective Data Market

Siyi Yang, Fudan University, Shanghai, China, People's Republic of, Jinzhao Wang, Yifan Dou, Lihua Huang

The rapid growth of data-driven industries like Artificial Intelligence has sparked a demand for data circulation and transactions, leading to the emergence of data markets. A major challenge in data market is achieving consensus between buyers and sellers regarding the price of data. This primarily stems from that the value buyers can ultimately derive from the data depends on the collaborative efforts of both parties in the data transactions, which, however, is inherently difficult to measure. Such uncertainty underscores the necessity for developing sophisticated contract forms capable of accommodating the unique characteristics of data transactions. This paper introduces the relational contract as a potential solution to the above challenge, which is a well-established informal contract form that relies on self-enforcement by both parties through repeated interaction. Our analytical results indicate that a transaction is only viable when the reference price is relatively low. Upon a data transaction, the contract form choice depends on the expected data contribution. If it is relatively high, relational contract is optimal; otherwise, only a formal contract can be used. Notably, utilizing relational contracts leads to a higher performance and profits of both the buyer and seller than formal contracts. Thus, to build long-term and efficient trading relationships, market planners can encourage both transaction parties to adopt relational contracts by offering several reasonable reference prices. This not only alleviates the dilemma of pre-selecting the optimal price but also effectively incentivizes both parties to invest in the transaction process and unlock the value of data.

Workplace Behavior and Organizational Dynamics

Contributed Session

Chair: Yuan Li, University of Tennessee, Knoxville, TN, United States

1 - Investigating Impact of Personality Traits, Workplace Ostracism and Perceived Organizational Justice on Work Procrastination Among Professors: Mediating Role of Cyberloafing

Marwah Rafiq, University of science and technology beijing, beijing, China, People's Republic of, Jianhua Yang, Sahafiul Bashar

This study investigates the effects of workplace ostracism, perceived organizational justice, and personality factors on workplace procrastination. This study additionally investigates into the mediating function of cyberloafing in these interactions. This study examines at the relationships between workplace ostracism, personality traits, perceived organizational justice, cyberloafing, and work procrastination. When conducting the empirical component, this study used the partial least squares structural equation modeling approach using a sample of 251 academics from Pakistani and German institutions. The findings show that personality traits have a significant impact on employee cyber-loafing. Employees who face workplace ostracism and poor perceived organizational justice are less productive and more likely to procrastinate at work. Furthermore, this study provides useful information for investigating cyberloafing's mediation function in the relationship between these variables and work procrastination. Likewise, when interacting with educational institutes, it was found that professors might be treated unfair at times and receive less support from their supervisors which leads them to face workplace ostracism and perceived organizational justice, causing deviant behavior in them. This study adds to the “Theory of Organizational justice” by working on perceived organizational justice faced by professors. Furthermore, this research adds to the “theory of interpersonal behavior” and the “theory of planned behavior” by exploring the relationships of workplace ostracism and personality traits with cyberloafing and eventually work procrastination.

2 - A recommender system for employee retention based on a new feature selection strategy

Gulser Koksal, TED University, Ankara, Turkey, Nagihan Taskiran

This study addresses the critical issue of employee retention in organizations, emphasizing the importance of personalized strategies over generic approaches. Traditional retention strategies may not effectively cater to individual employee needs and priorities. To tackle this, the study proposes an enhanced recommendation system utilizing a combination of clustering and ensemble learning techniques. By identifying "precious" employees through Fuzzy C-Means clustering, the study selects the most influential attributes affecting churn using a novel feature selection method. Various classification algorithms are then employed to predict potential churners, including Random Forest and Gradient Boosting. Moreover, a unique recommendation approach is introduced, comparing similar non-churner and potential churner profiles to suggest personalized retention strategies. The study ultimately provides HR departments with a set of attributes tailored to each potential churner employee, categorized by experience level, aiding in proactive retention efforts.

3 - Negative Feedback in Corporate Communication: a Social Sensitivity Perspective

Yang Jiao, ShanghaiTech University, Shanghai, China, People's Republic of, Ruijie Zhang, Lifeng Yang

Effective communication within corporate management is crucial for operational excellence. Often, project managers may overlook existing issues that are apparent to their subordinates, leading to dissatisfaction and negative feedback from employees. This discrepancy can result in substantial losses for the firm if not addressed. The reluctance of employees to provide high-quality feedback can be attributed to psychological barriers related to social sensitivity, a factor not extensively explored in operations management literature. This study introduces a behavioral perspective that incorporates social sensitivity into the analysis of corporate communication dynamics. We employ stylized models under various scenarios to simulate the decision-making processes of employees when considering (1) whether to provide negative feedback to project managers, and (2) the extent of the provision. Initially, a simplified model shows the basic relationship between project completion and firm returns. Incorporating social sensitivity reveals its importance in enhancing feedback quality and optimizing effort, thus improving profitability. Additionally, we finds that cooperation among employees leads to higher feedback quality and project returns by leveraging diverse perspectives, and different social sensitivity degrees affect employees' contribution. This paper concludes by highlighting the need for effectively leveraging social sensitivity and promoting cooperation to enhance project performance and profitability, offering practical insights for managerial decision-making.

4 - Employees’ affects and beliefs as antecedents of OCB towards change implementation

Bernardo Quiroga, West Virginia University, Chambers College of Business, Morgantown, WV, United States, Andrés Raineri Bernaín

This paper uses an attitude theory framework to analyze the simultaneous contribution of employees’ Change Readiness and Change Cynicism beliefs, as well as their positive and negative affects towards change, as antecedents of employees’ Organizational Citizenship Behaviors directed Towards Change (OCBTC) implementation. Using a time-lagged methodology, this study examines, in a sample of 402 employees, the additional contribution that different cognitive and emotional components of employees’ attitudes towards change have in explaining employees’ OCBTC. Relative Weight Analysis results indicate that core affects explain variance of OCBTC beyond that explained by Change Readiness and Change Cynicism. As well, Change Readiness and Change Cynicism beliefs do add to each other’s contribution in predicting the criterion variables. These results support the use of an attitude theoretical framework for researchers to study employee reactions to change, where both cognitive and affective components are considered as antecedents of employee behaviors. Furthermore, results suggest that managers should foster among their employees' both the cognitive and affective components of appropriate attitudes towards change, to help them engage in behaviors aiming to facilitate organizational change implementation.

5 - The Impact of Psychological Need Satisfaction and Frustration on Security-related Stress and ISP Violations

Yuan Li, University of Tennessee, Knoxville, TN, United States

Security-related stress (SRS) causes employees' violations of information security policies (ISPs). Its antecedents have not been adequately analyzed, as past research assumed its existence but focused on the coping responses to SRS. We suggest that the causes of SRS are more complex, as employees' perceptions about the motivations and basic psychological needs play vital roles in determining SRS.

Building on the recent literature on psychological need satisfaction and frustration, we develop a model to examine the antecedents to SRS. We argue that the intrinsic and extrinsic motivation factors, such as perceived legitimacy of ISP, perceived value congruence, perceived punishment, and perceived reward, influence psychological need satisfaction and frustration. Psychological need satisfaction and frustration then influence SRS, which in turn affects ISP violations.

A survey on 271 employees in the United States was conducted to empirically test the research model. The results show that perceived legitimacy and perceived value congruence increase need satisfaction and decrease need frustration. While punishment decreases need satisfaction, it does not affect need frustration. Reward increases both need satisfaction and frustration, exhibiting a punitive side effect. On the other hand, need frustration is a primary cause of SRS whereas the effect of need satisfaction on SRS is partialed out. As expected, SRS increases ISP violations.

This study highlights the mediating roles of psychological need frustration in determining SRS and ISP violations. Due to the difference between need frustration and satisfaction, the study emphasizes the value of analyzing the causes and consequences of need frustration in ISP requirements.

1 - Service Systems with on-Demand and Reserved Servers

Zhichao Feng, Hong Kong Polytechnic University, Hung Hom, Hong Kong, Milind Dawande, Ganesh Janakiraman, Anyan Qi

Many modern queueing-based service systems have a choice of using either long-term reserved capacity or short-term on-demand capacity; examples include the use of cloud-computing resources by firms, healthcare professionals by post-acute-care services, and customer-service agents by call centers. We study a canonical M/M/s queueing system that employs both reserved and on-demand servers – the number of reserved servers is decided at the beginning of the time horizon while the number of on-demand servers is decided dynamically as needed, in real time. We study two problems: minimizing the infinite-horizon discounted cost incurred in the hiring of servers and in the waiting of the jobs in the queue, and minimizing the long-run average cost. Using a sample-path analysis and a vanishing-discount approach, we show that the optimal on-demand capacity control in both problems is a threshold-based bang-bang policy: If the number of jobs in the system is below a threshold, then no on-demand servers are employed. Otherwise, the number of on-demand servers is chosen such that no jobs wait (i.e., the number of servers in use equals the number of jobs). Significantly, we obtain a closed-form expression for the cost of any such policy for a given number of reserved servers and derive an algorithm for obtaining the optimal number of reserved servers and the threshold. Our analysis provides practical rules-of-thumb for managing capacity and waiting costs in queueing systems that have access to both long-term and short-term server capacity.

2 - Combating Overbilling in Outsourced Projects: A Dynamic Auditing Mechanism

Like Bu, The University of Texas at Dallas, Richardson, TX, United States, Shivam Gupta, Milind Dawande, Ganesh Janakiraman

The practice of overbilling, where an external agent charges a firm more than what is deemed reasonable for the outsourced service, has been well-acknowledged as a notorious and long-standing problem across major industries. We consider a repeated-interaction principal-agent setting and develop a non-monetary dynamic auditing mechanism to mitigate overbilling.

3 - Pay with Your Data: Optimal Data-Sharing Mechanisms for AI Services

Seetharama Chandrasekhar Manchiraju, Eli Broad College of Business, Michigan State University, East Lansing, MI, United States, Sameer Mehta, Milind Dawande, Ganesh Janakiraman

Rapid advances in Machine Learning (ML) have led to a proliferation of Artificial Intelligence~(AI) services offered by firms. To develop a valuable AI service, a firm must build an accurate ML model which, in turn, requires a large amount of training data. Present-day firms usually obtain this data by offering incentives to consumers to share their data during the initial development phase of the AI service, and then use that data to re-train the ML models to improve the quality of the service. Consumers, on the other hand, incur privacy costs for sharing their data. Inspired by AI services such as speech-to-text conversion offered by Google, and ChatGPT and DALL-E offered by OpenAI, we analyze two popular data-sharing mechanisms that firms employ in practice: manual data-sharing and algorithmic data-sharing. In the former approach, consumers decide the amount of data to share with the firm, whereas in the latter, the firm uses algorithmic data-redaction — an established approach used by technology firms such as Amazon, IBM, and Oracle — to identify and censor sensitive segments of data, and determine the amount of data collected from consumers. For both the data-sharing approaches, we obtain revenue-maximizing mechanisms for the firm and analyze the fundamental differences between the two approaches in terms of the revenue accrued by the firm, the consumer surplus, and the volume of data collected. Our analysis uncovers several interesting economic effects.

4 - Combating Overbilling in Outsourced Projects: A Dynamic Auditing Mechanism

The practice of overbilling, where an external agent charges a firm more than what is deemed reasonable for the outsourced service, has been well-acknowledged as a notorious and long-standing problem across major industries. We consider a repeated-interaction principal-agent setting and develop a non-monetary dynamic auditing mechanism to mitigate overbilling.

Innovative Operations for Social Goods and Sustainability

Contributed Session

Chair: Qianqian WANG, N/A

1 - is Innovation Competition vs. Innovation Cooperation Strategic Choice of Platform Considering Complementors Innovation

Qianqian WANG, The Hong Kong Polytechnic University, Hong Kong, China, People's Republic of, Sai-Ho Chung, Qiang Chen

The level of innovation among complementors, i.e., third-party firms providing products, technologies, or services on digital platforms, plays a crucial role in sustaining the competitive advantage of these platforms. To encourage complementors to innovate, digital platforms have employed either innovation competition or innovation cooperation strategies. However, the effectiveness of these strategies in incentivizing complementors to innovate remains a topic of extensive debate, leading to practical ambiguity between complementors and digital platform firms. To address this issue and compare the innovation incentive effects of the two strategies, we develop a Stackelberg game model. Considering innovation spillover effects and innovation synergy costs, we investigate the innovation decisions and benefits of strong and weak complementors under the two digital platform strategies. Our preliminary findings suggest that strong and weak complementors respond differently to the innovation incentive strategies of digital platforms. The innovation competition strategy provides better incentives for weak complementors to innovate, while the innovation cooperation strategy is more effective in incentivizing innovation among strong complementors. We observe that higher competition intensity leads to increased innovation efforts by complementors, but the innovation spillover rate hampers their innovation incentives. Digital platforms sharing complementors' innovation costs can effectively enhance their motivation to innovate, but co-innovation with complementors does not necessarily increase their innovation efforts, as it is influenced by co-innovation costs. These findings offer valuable insights for complementors in determining their innovation efforts and for digital platform firms in optimizing their innovation incentive strategies.

2 - Partial Vertical Ownership, Specific Investment, and Control in a Platform Supply Chain

Chenchen Hua, School of Economics and Management, Southeast University, Nanjing, China, People's Republic of, Lindu Zhao

The acceleration of digital and intelligent technology development and the growth of customers' individual needs promote transformation and upgrading in manufacturing industry. Researchers have devoted great efforts to working on centralized and decentralized supply chains, making contributions to operation and management area. However, much less attention has been focused on supply chains with financial interconnectedness, such as partial vertical ownership, which is also a common business phenomenon between firms in manufacturing area.

This paper studies the impact of partial vertical ownership (PVO) in a supply chain consisting of a upstream manufacturer and a downstream industrial internet platform. The industrial internet platform holds non-controlling partial vertical interests of the manufacturer in order to establish a specific relationship between them. The platform is able to acquire superior information about the future market demand and place an order with the manufacturer who is capable of fulfilling the order. Passive partial vertical ownership may encourage the manufacturer to make specific investments for the satisfaction of diversified requirements in the market. We work on the impact of PVO on manufacturer's specific investment level and the platform's operational cost reduction level with game theory model.

This research may possibly contribute to the theory and practice of firms with financial interconnectedness in a supply chain to some extent, though limitation remains. Further studies are needed to broaden the applicable scope of this research, and to figure out the influence of PVO in a supply chain in more complicated scenarios.

3 - Capacity sharing strategies for competing manufacturers: component-sharing or technology-sharing?

Xuzheng Li, School of Economics and Management, Southeast University, Nanjing, China, People's Republic of, Lindu Zhao

Shared manufacturing is an important part of service-oriented manufacturing and introduces an innovative business model for allocating manufacturing resources in the sharing economy era. This business model includes a component-sharing mode, which uses shared production lines, and a technology-sharing mode, which involves sharing product design capabilities. Within this framework, manufacturers with different capacity can not only design and produce a complete product family independently, but also cooperate with competitors to produce some products in a product family. Specifically, manufacturers with limited capacity can produce non-core components independently, purchase core components at a lower cost from leading manufacturers through a component-sharing mode, and subsequently assemble the product with additional processing. Alternatively, through the technology-sharing mode, manufacturers with limited capacity can acquire technologies for core components at a reduced cost by paying fixed license fees and royalties to leading manufacturers. They can then innovate and enhance these technologies to develop new products. This study adopts an oligopolistic competition modeling framework to construct game-theoretic models of manufacturers under different modes and derive the corresponding equilibrium solutions. Based on profit analysis, we identify the optimal mode selection strategies for manufacturers with different capacity. This research broadens the scope of studies in shared manufacturing and has significant implications for the operational decisions of manufacturers.

4 - Pricing and Operations Planning for New Product Launch: Introducing Adopters' Variant Willingness to Pay

Alejandro Lamas, NEOMA Business School, Mont-Saint-Aignan, France, Sara Jahanmir

For sustainable profit growth and competitiveness, firms dedicate significant resources to development and launch of new technologies. Setting the right price for these innovations is an enormous challenge, which requires (i) a clear understanding of the social interaction influencing adopters' purchasing decisions, and (ii) coordinating marketing and operations so that products are available and affordable for adopters, especially for those who are more resistant to higher prices as the innovation moves through its life cycle. Building on this, we study the joint pricing and operations planning of firms when launching a new product in a market where the adopters' willingness to pay decreases over time. We combine and extend the traditional Bass model for diffusion and lot-sizing problems to price-sensitive demand settings. As the resulting formulation suffers from non-linearity, we propose an efficient linear approximations-based methodology for price/diffusion relationships. We show that both optimistic and pessimistic biases due to ignoring adopters' heterogeneous willingness to pay can result in losses of more than 20% relative to our modeling. We also show that ignoring such heterogeneity can blur the financial returns from launching new products and thus affect the commercial success of innovations.

5 - Coordination of Product-Service Supply Chain in a Framework of Profound Integration of Manufacturing and Service Industries

Yanling Feng, Beijing university of posts and telecommunications, Beijing, China, People's Republic of

The continuous evolution of the integration between manufacturing and service industries is paving the way for new opportunities for economic development. The quality of service provided by sales service integrator has become a critical determinant of product demand in the ensuing product-service supply chain. However, there exists an information asymmetry concerning service levels among the parties involved in the supply chain. Since the integrator has direct access to the consumer market, it possesses the informational advantage regarding the actual service level it provides.

This study examines a two-echelon supply chain composed of a manufacturer and a sales service integrator. The service cost sharing contract is developed with the understanding that integrator is under a lot of pressure to cover the service cost alone, which results in a lack of motivation to raise the service level. The integration of blockchain technology, with its inherent information traceability, into the product-service supply chain management is a strategic move aimed at mitigating service level information asymmetry. This approach ensures the seamless execution of contracts, even when information is incomplete.

The results reveal that service cost-sharing contracts can serve as effective incentives for integrator to augment service quality, adjust product pricing, and achieve supply chain coordination and optimization. It provides theoretical proof that blockchain technology can effectively alleviate the issue of information asymmetry, thereby boosting the overall profit margin of the entire supply chain system.

Computational Integer Optimization

Invited Session

OPT: Integer and Discrete Optimization

Chair: Daniel Bienstock, Columbia University, New York, NY, United States

Co-Chair: Daniel Bienstock, Columbia University, New York, NY, United States

1 - Polynomial TIME Algorithms for Mixed-Integer Inference Problems

Andres Gomez, University of Southern California, Los Angeles, CA, United States, Shaoning Han

We discuss classes of nonlinear mixed-integer optimization problems arising in statistical inference that admit polynomial time algorithms. The problems in question include outlier detection, sparse inference and data imputation, and have in common an underlying submodular structure. We develop polynomial time algorithms relying on a parametric algorithm to solve related convex optimization problems and exploiting de Lovasz extension of the underlying submodular functions.

2 - A Two-Stage Stochastic Integer Programming Approach for Open-Pit Mine Scheduling Under Geological Uncertainty

Patricio Lamas, AlicantoLabs, La Reina, Chile, Marcos Goycoolea, Eduardo Moreno

In open-pit mine scheduling, it is assumed that a mine corresponds to a discrete set of material blocks. Each block is characterized by a set of attributes such as weight, volume, grade of mineral, etc. Thus, the scheduling problem consists of answering three questions: WHICH blocks to extract; WHEH to extract those blocks; and WHERE to send the extracted blocks. The goal is to maximize the net present value of the mine project. Traditionally, the open-pit mine scheduling problem has been solved assuming that the attributes of each block are perfectly known before the project starts. Such an assumption does not necessarily hold, given that, in practice, the blocks attributes are only approximately known through geostatistical methods using drill-hole information.

We propose a two-stage stochastic programming approach for solving the problem under geological uncertainty. In a first stage, the WHICH and WHEN questions are answered, while, in a second stage, when the uncertain geological attributes are realized, the WHERE question is answered.

We show that our proposed two-stage stochastic programming problem can be efficiently solved with the Bienstock-Zuckerberg decomposition algorithm. This decomposition algorithm has been extensively used for solving traditional, deterministic open-pit mine scheduling problems.

Moreover, we provide Mak et al. Monte Carlo bounds for determining the quality of the solution obtained by solving our two-stage stochastic programming problem.

Our computational results suggest that our approach provides schedules with significantly larger expected net present values than those provided by the traditional deterministic approaches.

3 - Cardinality-Constrained Convex Quadratic Programming Problems Under Sparsity Conditions

Tongtong Chen, Columbia University, New York, NY, United States

We present results on cardinality-constrained convex quadratic programming problems under sparsity conditions. In the problems, we consider continuous variables partitioned into a family of subsets; only a constrained count of such subsets are allowed in the feasible solutions. Motivated by problems from two sources, (1) an instance in QPLIB and (2) the cardinality-constrained portfolio optimization problem, we introduce a new metric for sparsity, namely, the treewidth of the intersection graph for the transpose of our constraint matrix. We provide complexity results and approximation algorithms for those types of problems.

4 - Parallelized Conflict Graph Cut Generation

Yongzheng Dai, The Ohio State University, Columbus, OH, United States, Chen Chen

A conflict graph represents logical relations between binary variables, and effective use of the graph can significantly accelerate branch-and-cut solvers for mixed-integer programming (MIP). In this paper we develop efficient parallel conflict graph management: conflict detection; maximal clique generation; clique extension; and clique merging. We leverage parallel computing in order to intensify computational effort on the conflict graph, thereby generating a much larger pool of cutting planes than what can be practically achieved in serial. Computational experiments demonstrate that the expanded pool of cuts enabled by parallel computing lead to substantial reductions in total MIP solve time, especially for more challenging cases.

5 - Incorporating Service Reliability in Multi-depot Vehicle Scheduling: A Chance-Constrained Approach

Merve Bodur, University of Edinburgh, Edinburgh, United Kingdom

The multi-depot vehicle scheduling problem (MDVSP) is a principal planning challenge for transit agencies. We introduce a novel approach to MDVSP by incorporating service reliability through chance-constrained programming (CCP), targeting the pivotal issue of travel time uncertainty and its impact on transit service quality. We propose an exact branch-and-cut scheme to solve our CCP model. We present several cut-generation procedures that exploit the underlying problem structure and analyze the relationship between the obtained cut families. Additionally, we design a Lagrangian-based heuristic to handle large-scale instances reflective of real-world transit operations. Our empirical evaluation demonstrates the superiority of our stochastic variant as well as the computational benefits of our methodologies.

Invited Session

OPT: Computational Optimization and Software

Chair: Hande Benson, Drexel University, Philadelphia, PA, United States

1 - A quantum-inspired quadratic programming solver with large-scale GPU implementations

Yuxiang Peng, University of Maryland, College Park, MD, United States, Jinglei Cheng, Samuel Kushnir, Pengyu Liu, Jiaqi Leng, Hanrui Wang, Xiaodi Wu

Quantum and quantum-inspired algorithms have demonstrated significant advantages for numerous non-convex optimization problems. Compared with conventional quantum algorithms, quantum-inspired algorithms do not require access to quantum computers yet still exhibit advantageous performance against classical methods. Specifically, quantum-inspired algorithms offer a more flexible design space, enabling the use of cutting-edge computational hardware like GPUs. In this talk, we introduce a new solver based on a recently proposed quantum-inspired algorithm for quadratic programming. Our implementation is optimized for large-scale GPU deployment, providing substantial computational speedups at low costs. We benchmark our solvers on both public and synthetic datasets and demonstrate that our solutions are superior in runtime and solution quality compared to other solvers on large problem instances.

2 - Multi-Objective Optimization-Based Anonymization of Structured Healthcare Data for Machine Learning Applications

Yusi Wei, Drexel University, Philadelphia, PA, United States

Healthcare data plays a crucial role in machine learning (ML) for clinical research; however, the risk of multiple types of privacy attacks still remains when sharing such data. Techniques have been proposed to further protect data privacy, but there is still a need for models that can simultaneously achieve protection against attacks while maintaining the information value of healthcare data to ensure the usefulness of ML models. In this paper, we propose and solve a multi-objective optimization model for minimizing information loss and enhancing protection against attacks on healthcare data for the diagnosis of sepsis. We compare our model with existing algorithms to assess information loss and the number of patients subject to linkage or homogeneity attacks. The results indicate that our proposed model achieves the lowest information loss and effectively mitigates the risk of attacks by reducing more number of patients susceptible to these attacks in healthcare data compared to the alternative algorithms. We also leverage our anonymized quasi-identifiers along with other variables present in healthcare data for the prediction of sepsis. The findings demonstrate that our model does not adversely affect the prediction of sepsis using ML models when utilizing small values of k for k-anonymity, such as k=5, 10, 15, and 20. This study affirms that our model provides a viable solution for maintaining patient privacy while still allowing for effective ML prediction. Future studies can be built upon our work to develop models that can preserve patient privacy while maintaining the high performance of ML models.

Data-Driven Robust Optimization Applications

Invited Session

OPT: Optimization Under Uncertainty

Chair: Zhi Chen, The Chinese University of Hong Kong, Shatin, Hong Kong

1 - Prescriptive Analytics for Queue Optimization - An Optimization-Based Paradigm for Modelling Queues

Peng Wang, School of Business, Singapore University of Social Sciences, Singapore, Singapore, Chaithanya Bandi, Gar Goei Loke, Taozeng Zhu

Queueing networks occur in many contexts, leading to the need to control and optimize aspects of the network, such as routing of jobs and capacity control. Queueing theory, as it stands, focuses on the analysis of the stochastic properties of a network, leveraging upon them to perform optimization. These methods of analysis, bespoke for the network, rapidly increase in theoretical complexity with network size, making the researchers indispensable in the process. These factors impede the wider use of its techniques in the automation-driven business world. In this paper, we present a fundamentally novel approach to queueing, with the goal of creating a unified framework to solve optimization problems in queueing networks for a large class of queueing problems, that would lend itself to a tractable package that is accessible to business users, untrained in queueing theory. We do so by proposing a novel set of primitives for modelling queues, founded on optimization principles, leaving the correlated stochastics of queues to be resolved as a constrained problem. We also introduce a new state variable, which we call as "present delay" that tracks waiting time at each node. This allows much of the dynamics to decompose into a linear form, which improves tractability. Finally, we handle the stochastics by leveraging emergent techniques in robust optimization that achieves tractable solutions in stochastic optimization formulations. This also hints at good out-of-sample performance. Our final model is one that can solve any connected network of general queues in polynomial time.

2 - Distributionally Robust Optimal Open-Loop Policy in Backlog Inventory Models with Stochastic Lead Times

Jingjun Men, Chinese University of Hong Kong, Hong Kong, Hong Kong, Xin Chen, Daniel Zhuoyu Long

In this paper, we address an inventory management problem characterized by random demand and lead times. Recognizing the inherent uncertainty and potential ambiguity in their distributions, we assume only the marginal distributions of demand and lead times are known. Our objective is to minimize the worst-case expected cost under these conditions, a challenge compounded by uncertain lead times. We approach this by optimizing across all open-loop control policies. Initially, we demonstrate that our inventory model can be formulated as a Mixed Integer Linear Programming (MILP) problem. To streamline the process further, we establish a necessary and sufficient condition for 'no order crossover' in the worst-case distribution. This condition allows the problem to be transformed into a shortest path problem on a directed acyclic network, which can be solved efficiently. We discover that the optimal open-loop policy can be effectively achieved by considering the order quantities as the cumulative sum of consecutive incoming orders over several days. Numerical examples are provided to demonstrate the practical effectiveness of our approach.

3 - Service Oriented Considerate Routing: Data, Predictions and Robust Decisions

yue zhao, Institute of Operations Research and Analytics, National University of Singapore, Singapore, Singapore, Zhixing Luo, Stanley Lim, Caihua Chen, Melvyn Sim

This paper focuses on improving service oriented routing by addressing the nuanced challenge of punctuality through the consideration of couriers' ability to ensure on-time deliveries. We utilize a comprehensive real-world dataset from a cold chain logistics firm for analysis. Our empirical investigation indicates that relying solely on travel distance is inadequate for accurate delivery time prediction. We highlight critical elements, including couriers' fixed effects and workload, as key covariates to improve prediction performance. Distinguishing our work from existing literature, we integrate couriers' workload and location familiarity into our Service Oriented Routing model to enhance predictions of delivery times. We introduce the Courier Assigned Location Mismatch (CALM) metric as a less intrusive approach to incorporating couriers' location familiarity into their delivery efficiency. We propose the novel Service Oriented Considerate Routing (SOCR) model; by minimizing the CALM metric, couriers are assigned routes within familiar territories to the extent possible within the total routing distance constraint. The considerate routing strategies could potentially reduce the stress couriers face when delivering in unfamiliar areas. Additionally, we develop the connection of the SOCR model with a robust satisficing approach. This strategy guarantees timely deliveries by effectively mitigating the effects of predictive inaccuracies and potential model misspecifications. To solve the SOCR model, we apply Benders decomposition for an exact solution and Tabu Search for a heuristic approach, demonstrating their effectiveness and superior out-of-sample performance. Notably, our heuristic solutions significantly outperform exact solutions of classical vehicle routing problems with deadlines, resulting in substantial improvements in timely delivery performance.

4 - Optimize-via-Estimate: Realizing out-of-sample optimality in data-driven optimization

Gar Goei Loke, Durham University Business School, Durham, United Kingdom, Taozeng Zhu, Ruiting Zuo

We propose a novel methodology that achieves almost zero regret in data-driven optimization, wherein the uncertainty lies in a parametric family, when one restricts to generalizing over a given region of possible truths. We prove that there are no solutions that are unconditionally optimal over all possible true parameters. When restricted over a neighbourhood of parameters, we prove sufficient conditions for optimality - functions of the sufficient statistic of the parameter. We present an optimization problem that yields such an optimal solution, which can be solved efficiently. We also state sufficient conditions for the existence and uniqueness of this solution. Next, we illustrate specificity-sensitivity trade-off in terms of the size of the neighbourhood considered on the specific example of a one-dimension parameter. Finally, we illustrate our model on the newsvendor model to find strong performance when compared against alternatives in the literature.

Recent Advances in First-Order Methods and ADMM.

Invited Session

OPT: Global Optimization

Chair: Leandro Maia, Texas A&M, College Station, TX, United States

Co-Chair: Leandro Maia, Texas A&M University, College Station, TX, United States

1 - An Adaptive Block Proximal ADMM for Weakly Convex, Linearly-Constrained Composite Functions

Leandro Maia, Texas A&M University, College Station, TX, United States, David Gutman, Renato Monteiro, Gilson Silva

This work presents an adaptive, cyclic block proximal version of the alternating direction method of multipliers (AP-ADMM) for solving linearly-constrained, weakly convex, composite optimization problems. This method is adaptive to all problem parameters including smoothness and weak convexity constants. We assume that the smooth component of the objective is weakly convex and possibly nonseparable, while the non-smooth component is convex, block-separable, and has easily computable block proximal maps. Each iteration of AP-ADMM consists of: (1) sequentially solving the sequence of all block proximal subproblems, and (2) performing full Lagrange multiplier and/or penalty parameter updates based on a novel update criterion. Without any rank assumptions on the constraint matrices, it is shown that AP-ADMM obtains an approximate first-order stationary point of the constrained problem in $\boldsymbol{O}(\varepsilon^{-3})$ iterations.

2 - Efficiency of a restarted parameter-free FISTA method for strongly convex/convex optimization with provable complexity guarantees

Arnesh Sujanani, University of Waterloo, Waterloo, ON, Canada, Renato Monteiro

This talk presents an efficient restarted parameter-free FISTA (RPF-FISTA) method for solving strongly convex and convex composite optimization problems. RPF-FISTA adapts to the local geometry underlying the problem and checks novel conditions to determine when to restart. The complexity of the method is established and its computational efficiency is demonstrated on numerous vector and matrix problems.

3 - Last iterate convergence for convex function constrained optimization problem.

Digvijay Boob, Southern Methodist University, Dallas, TX, United States, Mohammad Khalafi

In recent times, various works have explored algorithms for convex function-constrained optimization problem. Most of these works provide convergence guarantees for the average-iterate. Such solutions degrade various desirable properties of the algorithmic output such as sparsity requirements or differential privacy guarantees. Moreover, it is common practice to output the last-iterate. Even then, last-iterate convergence guarantees are uncommon in function-constrained optimization problems. In this talk, we present primal-dual type algorithms that converge for nonsmooth and stochastic convex function-constrained optimization problems in the last iterate. In particular, our algorithms do not need to search for the Lagrange multiplier, nor do we need explicit descent in some potential function to get a bound on the dual iterate. Our designs are simple to implement and the gradient complexity of our proposed methods matches the existing state-of-the-art for the average iterate in both nonsmooth and stochastic cases.

4 - A Riemannian ADMM

Jiaxiang Li, University of Minnesota, Minneapolis, MN, United States, Shiqian Ma, Tejes Srivastava

We consider a class of Riemannian optimization problems where the objective is the sum of a smooth function and a nonsmooth function, considered in the ambient space. This class of problems finds important applications in machine learning and statistics such as the sparse principal component analysis, sparse spectral clustering, and orthogonal dictionary learning. We propose a Riemannian alternating direction method of multipliers (ADMM) to solve this class of problems. Our algorithm adopts easily computable steps in each iteration. The iteration complexity of the proposed algorithm for obtaining an ϵ-stationary point is analyzed under mild assumptions. Existing ADMM for solving nonconvex problems either does not allow nonconvex constraint set, or does not allow nonsmooth objective function. In contrast, our complexity result is established for problems with simultaneous nonsmooth objective and manifold constraint. Numerical experiments are conducted to demonstrate the advantage of the proposed method.

Learning and Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Qiran Dong, University of California, Berkeley, Berkeley, CA, 94720, United States

Co-Chair: Paul Grigas, UC Berkeley, Berkeley, CA, United States

1 - Beyond Discretization: Learning the Optimal Solution Path

Qiran Dong, University of California, Berkeley, Berkeley, CA, United States, Paul Grigas, Vishal Gupta

Many machine learning methods require minimizing a family of parametrized optimization problems across some hyperparameter space (e.g. weighted binary classification and fair learning). Traditional approaches discretize this space into a grid and solve problems independently, which does not necessarily exploit the solution path structure. We propose a novel and flexible first-order approach, which prescribes a set of basis functions and uses stochastic gradient descent (SGD) with randomized hyperparameters to solve for the *entire* solution path in a single optimization problem. Our method accommodates a variety of basis functions and offers substantial complexity improvements over traditional methods. Specifically, when the solution path is fully interpolable by the prescribed basis, our method requires O(log(1/ε)) and O(1/ε) gradient calls for exact and noisy gradient oracle models respectively, compared to the best-known grid search schemes which require ~O(ε-1/2) and O(ε-3/2) gradient calls. We demonstrate our method's effectiveness on a weighted logistic regression problem with an imbalanced dataset.

2 - Fusing learning and optimization for sustainable power system analytics

Linwei Sang, Tsinghua University, Shenzhen, China, People's Republic of

3 - Route `em and Count `em: A Two-Stage Stochastic Programming Model in Undersea Warfare

Vanessa Sawkmie, University of Wisconsin-Madison, Madison, WI, United States, Jeff Linderoth

The detection of targets in undersea warfare requires successful detection by an active search asset. Maximizing detection likelihood requires strategic placement and routing of the search assets, each of which has unique search capabilities, in the decision theatre over the planning horizon. We develop a two-stage integer stochastic programming model designed to maximize the expected number of targets detected, considering both the stochastic nature of target movements and the probabilistic detection capabilities of the assets. Leveraging the problem structure, we develop a closed-form solution for the second stage of the stochastic program, which allows for large-scale instances of the model to be solved efficiently via Benders decomposition. We conduct computational experiments to demonstrate the efficacy of the approach.

4 - On Solution Structure and Stability of Optimality-Based Clustering

Soroush Akbarijokar, University of Pittsburgh, Pittsburgh, PA, United States, Taewoo Lee

We study a new clustering problem where data points are decisions made by solving some optimization problem and are clustered based on their latent decision-making preferences. We model this problem as a large-size mixed-integer program, which we then reformulate as a more efficient combinatorial problem. We then propose a stability-driven variant of the clustering model to mitigate the impact of data noise and uncertainty on the clusterings. We discuss practical implications of this problem in healthcare applications including eliciting group diet preferences and clustering clinical pathways based on underlying clinical preferences.

Lagrangian Methods and Optimization Techniques

Contributed Session

Chair: David Gay, AMPL Optimization, Inc., 900 Sierra Place SE, Albuquerque, NM, 87108-3379, United States

1 - Evaluating Hessians in Parallel

David Gay, AMPL Optimization, Inc., Albuquerque, NM, United States

When solving nonlinear optimization problems, sometimes it is helpful to use the Hessian matrix (of second partial derivatives of the Lagrangian function). Many nonlinear problems exhibit partially separable structure, which can be found automatically, as in the AMPL/solver interface library. This structure invites parallel evaluation. This talk reviews Hessian structure and discusses exploiting it in parallel.

I may not get to Seattle until late Sunday. Please schedule this talk for Monday or later.

2 - Exact Augmented Lagrangian Duality for Mixed Integer Convex Optimization

Avinash Bhardwaj, Indian Institute of Technology Bombay, Mumbai, India, Vishnu Narayanan, Abhishek Pathapati

Augmented Lagrangian dual augments the classical Lagrangian dual with a nonnegative nonlinear penalty function of the violation of the relaxed/dualized constraints in order to reduce the duality gap. We investigate the cases in which mixed integer convex optimization problems have an exact penalty representation using sharp augmenting functions (norms as augmenting penalty functions). We present a generalizable constructive proof technique for proving existence of exact penalty representations for mixed integer convex programs under specific conditions using the associated value functions. This generalizes the recent results for mixed integer linear programming [M. J. Feizollahi, S. Ahmed, and A. Sun, *Math. Program.*, 161 (2017), pp. 365–387] and mixed integer quadratic progamming [X. Gu, S. Ahmed, and S. S. Dey, *SIAM J. Optim.*, 30 (2020), pp. 781–797] while also providing an alternative proof for the aforementioned along with quantification of the finite penalty parameter in these cases.

Modeling and Techno-economic Analysis for Vehicle Grid Integration and Vehicle-to-Everything (V2X)

Invited Session

TSL: Intelligent Transportation Systems

Chair: Zhaocai Liu, National Renewable Energy Laboratory, Golden, CO, United States

Co-Chair: Yili Tang, University of California, Berkeley, Hong Kong, ON

1 - Valuing V2x for Customer and Grid Resilience

Zhaocai Liu, National Renewable Energy Laboratory, Golden, CO, United States

Vehicle grid integration (VGI) will bring disruptive and revolutionary impact on grid reliability, efficiency, and resilience. EVs with bidirectional charging capability can be used to power a home and feed energy back into the electricity grid, and thus are able to provide support to enhance system resilience. This presentation will show our modeling and analysis for quantifying the potential resilience benefit of vehicle-to-home and vehicle-to-grid.

2 - Leveraging Electric Vehicles as a Resiliency Solution for Residential Backup Power During Outages

Shanshan Liu, University of Illinois Urbana-Champaign, Urbana, IL, United States, Alex Vlachokostas, Eleftheria Kontou

Climate change exacerbates power outage events that pose significant risks to local economies and can even endanger citizens' lives. An electric vehicle (EV) equipped with bidirectional energy exchange capability and vehicle-to-home (V2H) technology can serve as a battery resource and provide backup power to meet residential energy needs during an outage, aiming to curb health hazards caused by overheating or cold temperatures. We simulate the electric V2H system in nine US climate regions, over four seasons, and during short-term, long-term, and extremely severe outage events. We propose new resilience metrics to evaluate EV-enabled household energy resilience that measures the duration of time that EVs can serve household energy needs during outages, and mobility resilience, which represents the remaining driving range of EVs after the outage. Our findings indicate that contemporary EV models, even when their state of charge is 50%, can meet residential energy needs during a 12-hour outage in mild seasons (i.e., spring and autumn), except for communities in the Central, West North Central, and East North Central regions due to lower temperatures and higher household energy needs. The resilience of the household energy system during long-term outages is affected by the start time of the outage, heating and cooling power requirements, and daily travel needs. During extremely severe power outages, EVs can protect residents from cold stress over multiple days. Our methods and findings contribute to the coupled management of the integrated residential and EV energy system.We propose strategies for mitigating the adverse impacts of extreme weather events.

3 - Evs&Rsquo; Potential for Smoothing Daily Load Profile Considering Mobility Needs and Solar Output

Nima Rashgi Shishvan, University of Central Florida, Orlando, FL, United States, Zhaomiao Guo

The growth of electric vehicle (EV) adoption and renewable energy sources presents challenges to the power system. Therefore, this study aims to leverage the spatio-temporal charging flexibility of EVs to smooth daily power load and provide ancillary services using vehicle-to-grid (V2G) features. To achieve this objective, we mathematically formulate the aforementioned flexibility based on daily trip chain data and develop a convex optimization model to optimize the smoothness of the regional net load profile, subject to flexibility constraints. We test our approach on real data derived from the Chicago Metropolitan Agency for Planning (CMAP) travel survey and solar generation, as well as net power load data in the area of interest. Our findings indicate that a centralized management system employing the proposed control methodology can significantly smooth the overall power load, considering various levels of charging schemes, EV penetration levels, and infrastructure availability. This study provides an upper bound for future mechanism design to guide the charging behavior of EVs.

Modeling and Optimizing Infrastructure for Freight Transportation Operations

Invited Session

TSL: Freight Transportation

Chair: Hyeong Suk Na, University of Missouri, Columbia, MO, 65211, United States

1 - Enhancing Public Transport Evacuation Efficiency: A Round-Trip Bus Evacuation Model

Mina Samiei nasab, University at Buffalo, Buffalo, NY, United States, Rajan Batta

As emergencies such as natural disasters and industrial accidents occur with increasing frequency, the need for effective evacuation planning has become more pressing. Buses, with their large capacity and manageability, are often employed to evacuate individuals without personal vehicles. To enhance the efficiency and practicality of public transport evacuation plans, this study introduces a round-trip bus evacuation model. The model optimizes bus scheduling and routing planning, with constraints including bus capacity, evacuee demand at pick-up points, time windows, and flow balance. The aim is to maximize the total number of evacuees. Additionally, this study emphasizes equity in evacuation planning, ensuring fair attention to all affected populations. To demonstrate the effectiveness of the proposed model and solution, a case study is conducted.

2 - Simulation and Optimization for the Restaurant Food Delivery Problem in Dublin

Luis Cadarso, Rey Juan Carlos University, Fuenlabrada, Spain, Adrian Serrano, Peter Keenan, Javier Faulin

The Restaurant Food Delivery Problem consists of the logistical challenges faced by restaurants in efficiently delivering food orders to customers. This involves optimizing the delivery process to ensure timely and accurate delivery while minimizing costs and maximizing customer satisfaction. Traditionally, restaurants with delivery services rely on their fleet of vehicles, typically motorbikes, which can be costly and troublesome. However, more recently, new delivery systems such as crowdshipping have emerged, offering all restaurants an easy and cost-effective way to handle deliveries. This work aims to assess how a crowd-based bike food delivery system would perform in the city of Dublin (Ireland). To achieve this, an agent-based simulation model is built featuring population, bikers, and restaurants characteristics. Additionally, several optimization problems are integrated into the simulation to guide agents behavior. This also includes a biased-randomization savings heuristic for the Vehicle Routing Problems derived from the traditional own-fleet-based restaurant deliveries. Promising results are obtained for KPI related to economic and customer satisfaction for a set of scenarios based on delivery system, demand rates, and bikers adoption, among other factors.

3 - A Stacked Machine-Learning Method for Predicting Global Supply Chain Restructuring Under Changing Environmental Conditions

Hadi Ghayoomi, George Mason University, Fairfax, VA, United States, Elise Miller-hooks

This talk introduces a stacked ML approach for modeling global supply chains with limited information. Through the identification of the most important features, prediction of how a supply chain might restructure in response to changing logistical opportunities can be made. Such prediction is illustrated on a case study of lithium-ion batteries for possible future scenarios related to changing environmental conditions.

Summit - 429

Innovations in Urban Transportation

Contributed Session

Chair: Yihan Wang, Tianjin University, Tianjin

1 - A supervised machine learning framework to predict the request fit for dynamic dial-a-ride problems

Simon Mader, KU Eichstätt-Ingolstadt, Ingolstadt, Germany, Pirmin Fontaine, Stefan Voigt

Efficient public transport is key to the sustainable mobility transformation, especially in rural areas where traditional line-based bus services struggle due to the sparse demand. Therefore, innovative on-demand buses, with flexible routes and schedules, present a practical solution for improving rural mobility. Public transport providers aim to maximize the number of served passengers with these on-demand buses but operate within limited resources, leading to challenging decisions on accepting or rejecting passenger requests. Moreover, the dynamic booking process requires an immediate decision without knowing the impact of the request on potential future requests. Therefore, the problem of predicting the request fit for dynamic passenger-maximizing dial-a-ride problems (PM-DARPs) emerges.

To address this problem, we introduce the request fit predictor (RFP) framework. Within this framework, we model the request fit as a binary classification task and learn the fit with supervised machine learning models, having perfect information about historical requests. The RFP combines the request fit learned from static PM-DARPs with dynamic components of the cheapest insertion to guarantee feasibility, integrate request prescience, and facilitate an immediate acceptance/rejection decision.

The RFP is tested on real-life data from a German public transport provider and serves 26.19% more passengers than the current business practice. Compared to the cheapest insertion, the RFP not only serves 7.48% more passengers but also covers 6.68% less distance. In the presentation, we will discuss the trade-offs of the RFP's performance KPIs and give further insights into the framework's fairness and adaptability.

2 - A Nuanced Approach to Project Bus Headway Variations

Xiaotong Ding, MBTA, Boston, MA, United States, John Maleyeff

The presentation describes an approach used by the Massachusetts Bay Transportation Authority (MBTA) to evaluate bus headway performance using a queue modeling approach. Bus headway refers to the interval of time between buses on the same route; its control is crucial for efficient public transit operation. The approach aims to identify patterns that cause headway problems so that strategies can be developed to achieve effective headway performance that minimizes occurrences of long waits for passengers and avoids bus bunching, where multiple buses arrive at a stop simultaneously. The problem was studied by projecting headway variations in consecutive buses' departures based on historical Automatic Vehicle Location (AVL) event based data. The distribution of variations across route lengths, route designs, street types, times of the day and bus schedules will be studied. Various forms of queueing methodologies are used to create projections of headway performance. Based on this work, decisions such as holding the bus at stations, modifying schedules, and controlling traffic signals can be evaluated.

3 - Research on the Emergence and Evolution of Social Stability Risks in Urban Renewal Projects Based on ABM

Yihan Wang, Tianjin University, Tianjin, China, People's Republic of, Hui Sun, Yiyue Zhang, Yuxin Huang, Jidong Chen

Urban development in various countries has entered a stage predominantly focused on upgrading existing assets through urban renewal projects. The key to judging the success of such projects lies in whether residents find their living conditions improved. Significant dissatisfaction among residents can lead to considerable social stability risks. This study delves into the emergence and evolution of social stability risks in urban renewal projects, guided by the theory of risk perception. It posits that public assessment of risks in urban renewal projects is subjectively perceived and characterized by various attributes such as ambiguity. Intuitive fuzzy sets are suggested as a tool to measure this risk perception, with the collective risk perceptions of all individuals forming social stability risks at the project level. The study fully considers the human characteristics of public risk perception, suggesting that significant differences in project characteristics exist. Attributes of the public, complex network features, and modes of perception interaction can influence the transmission and evolution of risk perception. Employing Agent-Based Modeling (ABM) within a simulation research framework, the study simulates various factors and establishes a model for the evolution of social stability risks in urban renewal projects, summarizing patterns observed from multiple projects. This research provides a microscopic research perspective on the emergence and evolution of social stability risks in urban renewal projects, uncovering several evolutionary mechanisms. The findings contribute to the effective management and control of social stability risks in urban renewal projects.

4 - Continuous Approximation for Bipartite Matching with Rideshare Dispatch Application

Bo Jones, United States Naval Academy, Annapolis, MD, United States, Illya Hicks, John Carlsson

We consider matching rideshare drivers and passengers sampled from some continuous distribution in a service region. A pair can be matched if they are within a specified radius of one another. Employing continuous approximation analysis, we provide formulas which predict the number of matches that can be made and characterize this matching cardinality's dependence on the radius. We test our prediction using a simulation on a real road network.

5 - Dual Effects of Ex-Post Regulation in the Gig Economy: A Field Experiment of Gig vs. Traditional Agents in a Call Center

Qiaowen Guo, Washington University in St. Louis, Saint Louis, MO, United States, Fuqiang Zhang, Tianjun Feng

As the gig economy continues to thrive, the shift from ex-ante screening of traditional workforces to ex-post regulation of gig workforces has gained increasing attention. While recent research has highlighted the positive effects of this shift in ride-hailing platforms, its impact on interactive service settings like call centers remains understudied. The interactive nature of call centers requires robust ex-post regulations to control performance and mitigate misconduct among gig workers; however, stringent regulations can have unintended consequences on customers' follow-up actions. Through a 14-day field experiment in a call center partnered with a large e-commerce platform, we study the dual effects of regulations on gig workers' service compared to traditional agents. Our findings reveal that gig workers outperform traditional agents in FCR rate, service duration, and first response time, with increases of 3.49% and decreases of 8.72% and 26.42%, respectively. However, gig workers' risk-averse behaviors resulting from robust regulations, such as transferring cases more frequently, can negatively affect customer repurchase intention. Additionally, we highlight the positive effect of the platform's daily-updated reputation system on enhancing gig workers' service efficiency and confirm the positive impact of consistent schedules on first contact resolution rates for gig workers. We also find that female gig workers exhibit more risk-averse behaviors when faced with a competitive incentive scheme. To help the platform better understand the trade-offs in managing a blended workforce, we propose a two-stage analytical staffing model based on a queueing network. Our case study provides practical insights into optimizing workforce composition for the platform.

Aerospace Design, Ethics and Operations with AI/ML

Invited Session

Aviation Applications

Chair: Xin Peng, GE Aerospace, Niskayuna, NY, United States

Co-Chair: Vishwanath Bulusu, Crown Consulting, Inc., Mountview, CA, United States

1 - Machine Learning Application in Aircraft Engine Conceptual Design

Michael Tong, NASA Glenn Research Center, Cleveland, OH, United States

In today's competitive landscape, the effective development and utilization of machine-learning (ML) applications have become imperative across various sectors. This study presents an outline of the procedure involved in creating and implementing ML models for conceptualizing and evaluating aircraft engines. These models leverage supervised deep-learning algorithms to analyze patterns within an open-source repository containing data on both production and research conventional turbofan engines. The main areas of focus encompass crucial engine parameters like thrust-specific fuel consumption (TSFC), engine weight, engine diameter, and turbomachinery stage counts. While the creation of ML models is fundamental for their utilization, ensuring their seamless deployment holds equal significance. To address this aspect, a conversational AI (artificial intelligence) chatbot is constructed, utilizing natural language processing (NLP) techniques, to facilitate the deployment of these ML models. The comprehensive workflow encompasses several key stages: gathering and enhancing engine data, training and cross validating the ML models, testing and evaluating their performance, and finally, deploying, monitoring, and updating the ML models. By following this systematic approach, the aim is to streamline the development and deployment process of ML models tailored for aircraft engine conceptual design.

2 - Engineering the Ethical Use of AI in Aerospace

Paul Ardis, GE Aerospace, Niskayuna, NY, United States

The ethical use of artificial intelligence requires that a system exhibit one key aspect of human behavior: rational, ethically-consistent self restraint. Research turns now to the ability to determine how to establish ethical self-restraint for systems of arbitrary complexity, particularly in the aerospace sector where lives hang in the balance.

3 - Autonomous AAM Operations: Considerations, Challenges, and Opportunities

Pavan Yedavalli, Wisk Aero, Mountain View, CA, United States

In this talk, Dr. Yedavalli will introduce Wisk Aero and the company's position in the Advanced Air Mobility (AAM) landscape, highlighting its plan to deliver the first autonomous eVTOL aircraft to market. He will explain how Wisk models its aviation operations and evaluates market opportunities, introducing their advanced microsimulation platform, called SCOPE. The SCOPE simulation model determines and evaluates a variety of insights, including optimal vertiport locations using unsupervised machine learning, specific air taxi ridership across varying global markets, and detailed autonomous AAM operations to understand highly-trafficked routes, vertiport throughputs, fleet sizes, personnel requirements, and required supporting autonomy infrastructure.

There are also many autonomy considerations at the vertiports, such as precision landing and navigation, that will enable aircraft to safely arrive at the final approach and takeoff (FATO) area on the ground, and command and control (C2) links to enable safe communication across the aircraft, air traffic control, and the multi-vehicle supervisor. Finally, the airspace remains both an enormous opportunity as well as a challenge, as dedicated IFR corridors are expected over time, but will require specific spatial separations in early procedures. The integration of these parameters into the broader SCOPE simulation platform will also be discussed.

Dr. Yedavalli will end the discussion with areas of future exploration and research that can help advance the autonomous AAM industry further.

4 - A UAM Benefit Case Study: the San Francisco Bay Area

Xin Peng, University of California Berkeley, Berkeley, CA, United States

Urbanization and population growth have led to an increase in traffic congestion in many cities worldwide, prompting the exploration of potential solutions such as Urban Air Mobility (UAM). By transporting passengers through the air, UAM can bypass ground-level congestion and reduce the number of vehicles on the roads. This presentation provides a framework for evaluating the value of UAM in alleviating congestion, which includes a UAM vertiport design module for determining vertiport placement and passenger assignment, a GPU-based microstimulator for capturing vehicle movements, and a UAM allocator. The results of a case study conducted in the San Francisco Bay Area demonstrate the potential of multi-modal UAM systems in relieving ground congestion like increasing average travel speeds for some roads, reducing total Vehicle Miles Traveled (VMT) and decreasing travel times for certain ground users. However, the required vertiport infrastructure can be substantial.

Summit - 431

Advanced Computational and Algorithmic Approaches for Optimization

Contributed Session

Chair: Keyju Lee, Seoul,, Korea, Republic of

1 - GPU Accelerated Branch and Bound through Best First Search

Samiran Kawtikwar, University of Illinois at Urbana Champaign, Urbana, IL, United States, Rakesh Nagi

Branch and Bound has emerged as a fundamental technique for solving optimization problems across various domains due to its ability to systematically explore the solution space to find an optimal solution. Among its many variants, Best First Search stands out for its efficiency in guiding the search towards promising regions. However, the computational demand of exploring such large solution spaces remains a challenge with significant performance and scalability issues. In recent years GPU-accelerated solutions for Branch and Bound have surfaced, but they predominantly rely on less efficient search strategies like Depth First Search or Breadth First Search, due to their ease of parallelization. This work presents the first GPU-accelerated implementation of Branch and Bound employing Best First Search. This couples the computational power of the GPU with the efficiency of Best First Search. Our approach utilizes a GPU resident multi-producer multi-consumer queue design within a single kernel to mitigate communication overheads, yielding a high-performance solution. Testing moderate sized instances of the Resource Constrained Assignment Problem (RCAP) demonstrates a staggering ~20x speedup over CPU. Furthermore, we also show that our parallel implementation mirrors the exploration pattern of Best First Search, approximately matching the number of nodes explored in single threaded implementations.

2 - Results of Fuzzy Re-Sorting in Dynamic Bin Packing

Gene Coffman, Retired - Ford Motor Company, Plymouth, MI, United States, Stephany Coffman-Wolph

Many algorithms for dynamic sequencing leverage bin packing like heuristics that rely on fast and efficient sort algorithms executed multiple times (to reorder jobs by new criteria or because additional items have been added to the queue). The authors will apply a fuzzy sort to a sequencing algorithm and will extend the fuzzy concept to the “fuzzify” the bin backing algorithms.

3 - Analysis of Decoding Logic for the Multiple Yard Crane Scheduling Problem

Keyju Lee, Korea Aerospace University, Goyang-City, Korea, Republic of, Dongjin Jeong, Jungyong Seo, Junjae Chae

The encoding and decoding processes for the solution representation (e.g., chromosome for a genetic algorithm) are crucial for efficiently solving scheduling problems. In this research, a chromosome is encoded with the allocation of tasks to cranes and the task sequence within each crane. Since multiple yard cranes, specifically more than three yard cranes, are in use and certain safety distances must be maintained, cranes can become obstacles to each other during operation. An idling crane sometimes has to give way to another crane to ensure a task can be reached without breaching safety distances. A crane may also have to wait before proceeding to a task location until the other crane completes its task and moves away. A decoding logic capable of creating meticulous evading maneuvers to minimize task waiting time is required. This research focuses on designing and comparing different decoding logics for efficiency.

4 - Stochastic Two-stage Assembly Lot Streaming Problem

Daniel Neira, Virginia Tech, Blacksburg, VA, United States, Subhash Sarin, Manish Bansal

In this paper, we address a stochastic two-stage assembly problem of processing multiple batches of jobs (lots) on the machines in Stage 1 and then assembling the jobs on the machines in Stage 2, under lot streaming. The problem is to determine the sequence in which to process the lots and the equal-sized sublots to use for transferring the jobs from the subassembly machines in Stage 1 to the assembly machines in Stage 2 in order to minimize the makespan. The uncertainty arises in the subassembly times in Stage 1 while the assembly times in Stage 2 are known a priori. The problem is formulated as a two-stage stochastic mixed-integer program with recourse. We propose valid inequalities and also present a polyhedral analysis to study their geometric properties. We also use a multicut L-shaped method in conjunction with a progressive-hedging (PH) based heuristic to solve the problem. Results of a computational investigation are presented that reveal the effectiveness of using the inequalities along with the proposed solution methodologies over the use of Gurobi and SCIP solvers

5 - Precise Bayes Regression

Amin Vahedian Khezerlou, Northern Illinois University, DeKalb, IL, United States

Interpretability in Machine Learning has been the focus of ethical conversations in the research and practitioner communities. Given the black box nature of the Deep Learning methods, today's dominant solution, researchers have proposed interpretable predictive models to compete with the level of accuracy of Deep Learning. The recently proposed Precise Bayes Classifier is an estimation of Bayes Optimal Classifier that provides us with a promising route towards optimal accuracy, while remaining interpretable. Continuing on this path, we propose Precise Bayes Regression. We propose a non-parametric method to directly estimate a probability distribution for the output value, conditioned on the observation of a test point. In cases where evidence is sparse, the model builds a local linear model using the estimations from nearby, non-sparse points. Precise Bayes Regression assumes no functional form for the target function. Moreover, we make no assumptions on the independence of the input variables and no assumptions on their distributions. Through theoretical analysis, we show that with increasing number of samples learned, our error value approaches the irreducible error. Experiments on synthetic data confirm our theoretical findings.

Hospital Operations

Contributed Session

Chair: Yuanxin Zhu, Carnegie Mellon University, 927 Maryland Ave, Pittsburgh, 15232

1 - Data-driven decision-making support for health care delivery in the Trauma Center and Emergency Department

Jianing Man, Beijing Institute of Technology, Beijing, China, People's Republic of, Kal Pasupathy

Uncontrolled hemorrhage is one of the leading causes of preventable death among trauma patients, and the early detection of hemorrhage could support rapid decision-making to save lives. Recent use of non-invasive and continuous hemoglobin (SpHb) concentration monitoring tools attracted abundant attention, which could provide real-time hemoglobin measurement compared to delayed laboratory analysis. However, the accuracy is still a concern in healthcare settings. We proposed to use Kernel regression and LOESS models to improve the measurement accuracy by considering its trends and behaviors. Gaussian process and functional regression models are considered to handle the missing values among the continuous measurements and improve the prediction accuracy of lab values. The impact of patient demographics is also discussed.

Besides the physiological indicator and its monitoring, the patient service system also needs close monitoring and analytical support to improve service efficiency and quality. Research opportunities and insights related to the decision-making support of the Emergency Department healthcare service will be shared and discussed, which includes the service system status monitoring and flexible staffing design based on system performance or system status indicators. However, due to the complexity and high uncertainties in the healthcare service system, especially for the ED, it is quite challenging to provide accurate predictions on patient behavior as well as the system status. Challenges and research opportunities will be further discussed as well.

2 - Data-Driven Resource Allocation for Healthcare Facility Optimization Under Uncertainty with SIR Dynamics

Seyedreza Abazari, FAMU-FSU College of Engineering, Tallahassee, FL, United States, Arda Vanli

This paper tackles the formidable challenge of allocating COVID-19 resources in regions with constrained healthcare facilities through a nonlinear mathematical model comprising two key components. Initially, hospital capacities were assessed, and using time series modeling, patient-to-bed ratios were estimated. Subsequently, a Susceptible, Infected, Removed (SIR) model was incorporated to examine disease dynamics, taking into account the dampening effect of allocated resources. The model aimed to minimize unmet demand for beds and transfer costs while managing disease spread within a stochastic framework that captures uncertainties in disease spread and recovery rates. Employing this model to allocate resources across regions, this study leverages data from Florida's 67 counties during the COVID-19 pandemic to enhance our understanding of disease transmission and resource allocation dynamics, particularly focusing on efficient resource distribution in settings limited by uncertainty and scarce resources.

3 - Early prediction of patient admission likelihood in emergency departments

Farzad Zeinali, Clemson University, Clemson, SC, United States, Kevin Taaffe, Chris Gaafary, Ronald Pirrallo, William Jackson, Michael Ramsay, Jessica Hobbs

Efficiently transitioning patients from the emergency department (ED) to inpatient units is a critical challenge in the US, often contributing to ED overcrowding. Early prediction of patients' admission likelihood and the demand for inpatient units enables hospital managers to apply proper strategies before real changes in demand happen. Our developed prediction model incorporates clinical and demographic information, vital signs, triage notes, and external factors like weather conditions and local events. This model serves as a decision support tool to provide hospital managers with near real-time predictions of their unit's demand. The study proves that predicting the likelihood of admitting patients to inpatient units in real-time will help identify the system's changing status and make proactive decisions before any surge in demand happens. Such a responsive decision-making approach can improve healthcare systems' operational efficiency and capacities.

4 - Continuous Remote Patient Monitoring (CRPM) for Post-Discharge Patient Management: A Discrete Event Simulation Approach for Workflow Modeling and Operational Analysis

Yuanxin Zhu, Carnegie Mellon University, Pittsburgh, PA, United States, Rema Padman, Holly Wiberg, Mariana Escallon Barrios, Nirav Shah

Remote patient monitoring (RPM) has gained considerable significance in recent years, especially after the COVID-19 pandemic and Medicare coverage expansion in 2019. However, there has been limited investigation of the workflow integration and operational challenges associated with the deployment of this technology for remote patient management. This study addresses the operational challenge of optimizing resource allocation for patient care in multi-provider workflow planning of continuous remote patient monitoring (CRPM) systems. We use discrete event simulation (DES) modeling within Cascade-HF, a pilot CRPM deployment at a major health system in the US to reduce Heart Failure (HF)-related hospitalizations and readmissions. Physiological data is collected from patients using wearable biosensors over a 30-day period, to determine decompensation risk among HF patients. This is combined with electronic health record (EHR) data and patient-reported symptoms. This limited data is used to create a large synthetic dataset that reasonably mirrors the characteristics of the real dataset. We conduct extensive simulation experiments using the synthetic data to balance resource utilization with differing staffing configurations, operational efficiency metrics and cost with varying patient arrival rates and patient characteristics. The results provide several insights into how a simulation-based approach may be used to support operational decision-making with hospital CRPM systems for optimal staffing and resource allocation strategies based on multiple criteria which depend on the patient arrival rate and the hospital's financial constraints.

Stochastic Processing and Matching Networks: Recent Developments

Invited Session

Applied Probability Society

Chair: Sushil Mahavir Varma, Georgia Tech, Atlanta, GA, United States

1 - State-Dependent and State-Independent Assignments in Matching Models with Exchangeable Compatibilities

Rhonda Righter, University of California-Berkeley, Berkeley, CA, United States, Elene Anton, Kristen Gardner, Esa Hyytia, Runhan Xie

We consider a matching system with N classes of drivers (or jobs, etc.) that arrive according to Poisson processes with a common rate and wait to be matched to riders (or service completions, etc.). Riders arrive according to a Poisson process and an arriving rider has a compatibility vector for the N driver classes that is exchangeable across the driver classes. We show that the optimal (response-time minimizing) state-dependent assignment policy is to “assign to the longest compatible queue” (LCQ). This extends classical results with full compatibility. We also show, for the smallest exchangeable matching model with two driver classes and three rider classes (the “M” model), that for state-independent policies, first-come-first-matched (FCFM) performs better than ROM (random order of matching).

2 - The Cost of Impatience in Dynamic Matching

Itai Gurvich, Northwestern University, Kellogg School of Management, Evanston,, IL, United States, Angela Kohlenberg

We study matching queues with abandonment. The simplest of these is the two-sided queue with servers on one side and customers on the other, both arriving dynamically over time and abandoning if not matched by the time their patience elapses. We identify universal, non-asymptotic scaling laws for the matching loss due to abandonment, which we refer to as the “cost-of-impatience.” The scaling laws characterize the way in which this cost depends on the arrival rates and the (possibly different) mean patience of servers and customers. Our characterization reveals four operating regimes identified by an operational measure of patience that brings together mean patience and utilization. The four regimes subsume the regimes that arise in asymptotic (heavy-traffic) approximations. The scaling laws, specialized to each regime, reveal the fundamental structure of the cost-of-impatience and show that its order-of-magnitude is fully determined by (i) a “winner-take-all” competition between customer impatience and utilization, and (ii) the ability to accumulate inventory on the server side. Practically important is that when servers are impatient, the cost-of-impatience is, up to an order-of-magnitude, given by an insightful expression where only the minimum of the two patience rates appears. Considering the trade-off between abandonment and capacity costs, we characterize the scaling of the optimal safety capacity as a function of costs, arrival rates, and patience parameters. We prove that the ability to hold inventory of servers means that the optimal safety capacity grows logarithmically in abandonment cost and, in turn, slower than the square-root growth in the single-sided queue.

3 - Asymptotically Optimal Energy Consumption and Inventory Control in A Make-to-Stock Manufacturing System

Erhun Ozkan, Koç University, Istanbul, Turkey, Barış Tan

We study energy consumption and inventory control in a make-to-stock manufacturing system. We consider a Markovian system with a single server. The server consumes energy, and the associated energy cost depends on the server state: a busy server consumes more power than an idle server does, and an idle server consumes more power than a turned-off server does. However, when a turned-off server is turned on, it must complete a set-up process which is costly and lasts for a while. The objective of the system controller is to minimize the long-run average inventory holding, backorder, and energy consumption costs by deciding when to produce, when to idle or turn-off the server, and when to turn on a turned-off server. We consider the asymptotic regime in which the server is in the conventional heavy-traffic regime. We formulate a Brownian control problem (BCP) which has both impulse and singular controls. Depending on the system parameters, the optimal BCP solution is of either control-band or barrier type. From the optimal BCP solution, we propose a simple heuristic control policy and prove its asymptotic optimality. Finally, we demonstrate the close-to-optimal performance of the heuristic control policy by numerical experiments.

4 - Dynamic Scheduling of a Multiclass Queue in the Halfin-Whitt Regime: a Computational Approach for High-Dimensional Problems

Ebru Kasikaralar, University of Chicago, Booth School of Business, Chicago, IL, United States, Baris Ata

We consider a multi-class queueing model of a telephone call center, in which a system manager dynamically allocates available servers to customer calls. Calls can terminate through either service completion or customer abandonment, and the manager strives to minimize the expected total of holding costs plus abandonment costs over a finite horizon. Focusing on the Halfin-Whitt heavy traffic regime, we derive an approximating diffusion control problem, and building on earlier work by Han et al. (2018), develop a simulation-based computational method for solution of such problems, one that relies heavily on deep neural network technology. Using this computational method, we propose a policy for the original (pre-limit) call center scheduling problem. Finally, the performance of this policy is assessed using test problems based on publicly available call center data. For the test problems considered so far, our policy does as well as the best benchmark we could find. Moreover, our method is computationally feasible at least up to dimension 100, that is, for call centers with 100 or more distinct customer classes.

1 - Posterior Sampling via Autoregressive Generation

Kelly Zhang, Columbia University, New York, NY, United States, Tiffany Cai, Hongseok Namkoong, Daniel Russo

Real-world decision-making requires grappling with a perpetual lack of data as environments change; intelligent agents must comprehend uncertainty and actively gather information to resolve it. We propose a new framework for learning active exploration algorithms from massive historical data, which we demonstrate in a cold-start content recommendation bandit setting. First, we pretrain an autoregressive model to predict a sequence of repeated feedback/outcomes (e.g., responses to news articles shown to different users over time). In learning to make accurate predictions, the model implicitly learns an informed prior based on rich features (e.g., article headlines) and how to sharpen beliefs as more outcomes are gathered (e.g., clicks as article is recommended). At decision-time, we autoregressively sample an imagined sequence of outcomes for each action, and choose the action with the largest average imagined reward. Far from a heuristic, our approach is an implementation of Thompson sampling (with a learned prior), a prominent active exploration algorithm. We prove our pretraining loss directly controls online decision-making performance, and we demonstrate our framework on a news recommendation task where incorporating language model text features is crucial for best performance.

2 - More Effective Reward Modeling via Indexed Temporal Difference Learning

Shi Dong, Google DeepMind, Mountainview, CA, United States

Reward modeling in reinforcement learning from human feedback (RLHF) remains an evolving field with open challenges. This talk addresses several limitations with a novel reward model training algorithm that coherently synthesizes information from both pre-trained language models and human-labeled preference datasets. Our approach, which we call indexed temporal difference learning (ITDL), trains an ensemble of reward models to capture complex human preferences and leverages ideas from temporal difference learning, one of the central pillars of reinforcement learning. We use results on simple experiments to demonstrate the algorithm's potential, and leave large-scale empirical studies on real-world language models for future work.

3 - Pre-training and In-Context Learning *IS* Bayesian Inference *a la* De Finetti

Naimeng Ye, Columbia University, New York, NY, United States, Hanming Yang, Andrew Siah, Hongseok Namkoong

In-context learning (ICL) has emerged as a powerful learning paradigm, and a line of work has analyzed this phenomenon through the lens of classical bayesian implicit latent factors/parameters learning. On the other hand, multiple works have studied the importance of quantifying uncertainty in prediction models. In this paper, we aim to address both lines of work by re-interpreting uncertainty-aware-ICL as *explicit* Bayesian inference *a la* De Finetti. From this view, pre-training of ICL optimizing the marginal likelihood of observed sequences *automatically* provides the *correct notion* of uncertainty; compared to fitting priors in conventional empirical Bayes, pre-training fits posterior predictives using transformers. Our observation highlights previously under-explored capabilities of ICL: statistical inference and uncertainty quantification. We theoretically prove that under exchangeability, the usual pre-training loss (perplexity) exactly captures the model's ability to do bayesian inference. We also empirically study the effect of imbuing exchangeability into model design on facilitating uncertainty quantification. On length generalization and coverage, we observe that the imbuing inductive bias improves performance of the model significantly. Finally, we address potential considerations in applying this framework to real-world applications such as language modeling. In particular, choosing the unit of which the data becomes exchangeable is a key consideration in the design of the model.

1 - CLT for Two-Timescale Stochastic Approximation with Controlled Markov Noise – Theory and Application to Distributed Stochastic Optimization

Vishwaraj Doshi, NCSU, Charlotte, NC, United States

Two-timescale stochastic approximation (TTSA) is among the most general frameworks for iterative stochastic algorithms. This includes well-known stochastic optimization methods such as SGD variants and those designed for bilevel or minimax problems, as well as reinforcement learning. In this work, we conduct an in-depth asymptotic analysis of TTSA under controlled Markovian noise via central limit theorem (CLT), uncovering the coupled dynamics of TTSA influenced by the underlying Markov chain. This goes beyond previous CLT results of TTSA which only consider Martingale difference noise. We use the TTSA framework to study token algorithms - a family of distributed stochastic optimization algorithms where gradients are sampled by a token traversing a network of agents in random-walk fashion. Typically, these are chosen to be Markov chains that asymptotically sample from a desired distribution. We take a novel approach by replacing the vanilla Markovian token by one which follows a controlled Markov chain - namely the Self-Repellent Radom Walk (SRRW). Defined for any given 'base' Markov chain, the SRRW, parameterized by a positive scalar α, is less likely to transition to states that were highly visited in the past. We prove that the optimization iterate errors of the resulting algorithm converge to zero almost surely, and also prove second-order convergence by applying the TTSA CLT. By deriving the explicit form of the resulting asymptotic covariance matrix corresponding to iterate errors, we show it is always smaller than that of an algorithm driven by the base Markov chain and decreases at rate $O(1/\alpha2)$.

2 - MaxMin-RLHF: Alignment with Diverse Human Preferences

Reinforcement Learning from Human Feedback (RLHF) aligns language models to human preferences by employing a singular reward model derived from preference data. However, the single reward model overlooks the rich diversity of human preferences inherent in data collected from multiple users. In this work, we first derive an impossibility result of alignment with single reward RLHF, thereby highlighting its insufficiency in representing diverse human preferences. Next, we propose to learn a mixture of reward models via an expectation-maximization algorithm and solve a MaxMin alignment objective inspired by the Egalitarian principle in social choice theory to better honor diverse human preferences. We present comprehensive experimental results on small-scale (GPT-2) and large-scale language (with Tulu2-7B)) and show the efficacy of the proposed approach in the presence of diversity among human preferences. We remark that our findings in this work are not only limited to language models but also extend to reinforcement learning in general.

3 - Localized spectral representations for networked reinforcement learning

Zhaolin Ren, Harvard University, Cambridge, MA, United States, Na Li

Networked Markov Decision Processes (MDPs) pose a significant challenge to efficient learning due to the exponential growth of the overall state-action space with the number of agents. Recent works have attempted to address this by leveraging the locally decaying structure of the dynamics to develop localized policies that depend only on a truncated portion of the state-action graph. However, these approaches are limited to finite state-action spaces, leaving the more realistic and challenging scenario of large or continuous state-action spaces in networked MDPs as an open problem. In this work, we leverage recent advances in spectral representation of Q-value functions, which have enabled efficient learning for single-agent MDPs, to derive a networked version of a localized spectral representation for the Q-function of each agent, utilizing the exponential decay structure of network dynamics. Building on these local spectral representations, we design efficient algorithms for continuous state-action networked MDPs. We illustrate the efficacy of our approach with a series of representative experiments.

4 - A Single-Loop Finite-Time Convergent Policy Optimization Algorithm for Mean Field Games

Sujay Bhatt, JPMorgan AI Research, New York City, NY, United States, Sihan Zeng

We study the problem of finding the equilibrium of a mean field game (MFG) -- a policy optimal with respect to the mean field induced by itself. Existing works on this subject take a fixed-point-iteration approach. Due to the lack of strong structure and the non-uniqueness of the equilibrium, they settle for solving a regularized version of the problem, with the regularization weight so large that the equilibrium is the unique fixed point of a contractive mapping. This leads to a regularized solution that can deviate arbitrarily away from the original equilibrium. In this work, we take an innovative approach, based on gradient-based policy optimization rather than fixed-point iteration, to solve the original infinite-horizon average-reward MFG. Besides removing the need to regularize, our algorithm is superior in that it is completely data-driven, single-loop, and single-sample-path. Our first main contribution is to characterize the finite-time convergence of the algorithm to a mean field equilibrium, through a novel multi-time-scale analysis. We support the theoretical results with numerical simulations that illustrate the superior convergence of the algorithm over the prior art.

An MFG reduces to an average-reward Markov decision process (MDP) in the degenerate case where the transition kernel and reward are independent of the mean field. As a byproduct of our analysis for MFGs, we get an actor-critic algorithm for finding the optimal policy in average-reward MDPs with a convergence guarantee matching the state-of-the-art. The prior bound is derived under an unrealistic assumption on the Bellman operator. Our analysis removes the assumption.

Appointment Scheduling in Healthcare: From Patients to Physicians

Contributed Session

Chair: Dyutimoy Das, Penn State University, 950 W Aaron Drive, State College, PA, 16803, United States

1 - Fair Appointment Scheduling using Deep Reinforcement Learning

Dyutimoy Das, The Pennsylvania State University, University Park, PA, United States, Soundar Kumara, Paul Griffin

In outpatient settings, an incoming patient often requires multiple sequential appointments to treat their ailments successfully. These appointments may include diagnostic and lab visits or further physician consultation sessions. Though these services are provided within a single healthcare provider network, it is common for the scheduling process to be decentralized with multiple groups given access to the same capacity. This can lead to a lack of communication between different departments and preplanning, which can result in long waiting times for patients and/or an inefficient use of provider resources including equipment and staff. To improve provider efficiency, we propose a centralized appointment scheduling algorithm that keeps track of possible future appointments and considers patient cancellations and no-shows, and ensures that the scheduling process is fair across all patient groups. The sequential appointment scheduling process is modeled as a Markov Decision Process and optimized using an intrinsically motivated reinforcement learning algorithm. The approach is demonstrated for a large provider network in the Midwest.

2 - On the Deterministic Equivalent Formulation of the Appointment Scheduling Problem

Yong-Hong Kuo, The University of Hong Kong, Pokfulam Road, Hong Kong, Mengchuan Zou, Janny LEUNG

In this study, we investigate the appointment scheduling problem (ASP), which involves determining the optimal schedule of appointment intervals for outpatients. We came across a stochastic linear program (SLP) formulated in the literature, which claimed to be equivalent to ASP and was used in subsequent research. However, we demonstrate that this equivalence does not hold in general by presenting a counterexample. To address this issue, we establish a necessary and sufficient condition under which the SLP is equivalent to ASP. Furthermore, we discuss the conditions for equivalence in variations of ASP, such as considering no-show patients and unpunctual patients. To solve the ASP with general cost vectors, we propose a stochastic mixed integer linear program. Additionally, we provide analytical and experimental results for ASP in various settings to further understand the problem and evaluate the effectiveness of our approach.

3 - Improving Stroke Prevention through Enhanced Capacity Planning and Patient Appointment Scheduling

Antoine Sauré, Telfer School of Management, University of Ottawa, Ottawa, ON, Canada, Shahryar Moradi, Jonathan Patrick

Motivated by a problem faced by The Ottawa Hospital (TOH) in Canada, this presentation focuses on the study of patient appointment scheduling practices at a Stroke Prevention Clinic (SPC). A patient who is referred to a SPC is typically scheduled for an initial consult with a neurologist; prior to the initial consult, several tests, depending on the patient's condition, need to be performed. Some SPCs face several challenges in reducing patient wait times for consults and in having all test results available before consultation. To address these challenges, we propose a dynamic multi-priority, multi-resource appointment scheduling model which we approximately solve using Approximate Dynamic Programming (ADP) techniques. The main purpose of this model is to identify policies for allocating available testing and consultation capacity to incoming patients, while reducing patient wait times and increasing the number of test results available before consultation in a cost-efficient manner. The potential benefits from the proposed approach are evaluated by simulating the performance of the resulting policy for a practical example based on data provided by TOH. We also investigate the quality and practical implications of the resulting appointment scheduling policy by comparing its performance to that of other heuristic policies derived from the existing literature on appointment scheduling. We believe the booking guidelines resulting from this research could be used in practice by SPCs to significantly improve stroke prevention and thus decrease the impact of unnecessary delays and incomplete test results on patients' health.

4 - A Comparative Analysis of Queueing Model Accuracy for Healthcare Resource Planning under Epidemic Demand

Alexander Rutherford, Simon Fraser University, Burnaby, BC, Canada, Samantha Zimmerman, Alexa van der Waall, Monica Norena, Peter Dodek

Queueing theory and discrete event simulation models can be used to determine capacity requirements to meet access-to-care targets in acute and critical care resource planning. However, simulation optimization can be computationally intensive in scenarios with heavy demand, and queueing theory approximations may be less accurate when demand is changing rapidly with time—as was the case during the COVID-19 pandemic. To address these challenges, we developed a hybrid optimization approach that combines a simulation-based search procedure with a queuing theory approximation, that was chosen based on a comparative analysis of three different approximation methods. Our analysis compares the pointwise stationary approximation, the modified offered load approximation, and the fixed point approximation under epidemic growth in demand. These methods were evaluated in a case study of mechanical ventilator access in British Columbia, Canada, during the first wave of the COVID-19 pandemic. The case study uses COVID-19 case projections from the British Columbia Centre for Disease Control and critical care data from the British Columbia ICU Database. In the case study results, the fixed point approximation achieved the most accuracy under rapidly growing demand. Our modelling analysis was able to efficiently compute the mechanical ventilator capacity required for 95% of patients to access a ventilator immediately, during the peak of the first wave of the COVID-19 pandemic.

1 - Brand-Name Versus Generic Drugs: An Empirical Study on Health Outcomes of Generic Atorvastatin Usage

Xinyu Liang, University of Michigan, Ann Arbor, MI, United States

Generic drugs represent over 90% of prescriptions and have saved the US healthcare system over 2.4 trillion dollars over the past decade. The full potential of cost-saving benefits, however, can only be unlocked when the drug's effectiveness is ensured. In this paper, we focus on atorvastatin, the world's best-selling statin designed to alleviate cardiovascular risks, as an example to study its effectiveness by estimating the effect of generic drug usage on health outcomes compared to the brand-name counterpart. We leverage the market entry of generic atorvastatin and address the potential endogeneity using instrumental variables. We find that the usage of generic atorvastatin significantly increases healthcare service utilization with heterogeneous treatment effect cross patient populations, particularly leading to more outpatient visits, emergency department visits, and inpatient admissions. Clinically, despite no significant association with increases in major adverse events and side effects, the generic version leads to higher LDL-C levels and is less effective in mitigating cardiovascular symptoms. Furthermore, we show variations in generic drug effectiveness across manufacturers, particularly between authorized generic manufacturers and regular manufacturers. Our findings corroborate the FDA inspection and recall records that manufacturers identified as producing the least effective drugs also had more quality violations and subsequent product recalls. Our paper highlights the impact of generic drug usage on healthcare outcomes and differential effects based on patient and manufacturer heterogeneity with implications for the FDA, payers, and medical practitioners.

2 - Decoding Patient Trust in AI Gatekeeper Healthcare Systems

Shujing Sun, University of Texas at Dallas, Richardson, TX, United States, Wei Gu, Lauren Lu, Susan Lu

This study investigates the dynamics between humans and algorithms in healthcare, focusing on patient-AI gatekeeper interactions where the AI recommends doctors based on patient-provided symptoms. Through a large field experiment in a healthcare organization, we find a general lack of trust in AI recommendations among patients. Despite this, a positive correlation emerges between patient acceptance and the presence of information on prediction accuracy and peer acceptance. More interestingly, in the presence of both information, patients willingly embrace recommendations with high peer acceptance, even with lower accuracy, suggesting human inclination towards conformity to peer choices more than relying on algorithmic precision.

3 - Understanding the Causes and Costs of Staff Attrition in ICU Nursing

Blair Liu, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Diwas KC, Bradley Staats

This study delves into staff attrition among nurses in Cardiovascular Intensive Care Units (CICUs), with a particular focus on operational factors influencing their decisions to resign. Utilizing a detailed dataset from a comprehensive CICU, we empirically identify the principal drivers of nurse turnover and quantify the subsequent impacts on patient care quality and hospital operations. Our analysis reveals that nurse scheduling, support systems, and burnout prevention influence turnover intentions. The findings advocate for managerial interventions that sustain nursing staff and improve patient outcomes.

1 - Mitigating Shortages of Generic Drugs: The Role of Reliability Certification

Xiaoyu Wu, Fuqua Business School, Duke University, Durham, NC, United States, Robert Swinney, Can Zhang

Generic drugs play a vital role in keeping costs down in the U.S. healthcare system. However, generic drugs have experienced severe shortages due to supply disruptions, caused by a number of factors, including low profit margins that lead manufacturers to underinvest in supply reliability. Shortages result in numerous negative consequences for patients as well as institutional buyers of generic drugs, such as hospital systems, who may be forced to use more expensive alternative drugs when a shortage occurs. The U.S. Food and Drug Administration has recently sought to address generic drug shortages caused by supply disruptions, and one proposal is to implement a certification system that assesses and discloses the reliability of generic drug manufacturers. In this paper, we investigate the effectiveness of such a certification system. We propose a game theoretic model that captures the effects of generic drug manufacturer reliability certification on manufacturers, buyers, a group purchasing organization, and patients. We find that certification may motivate manufacturers to improve their reliability; however, this may increase patients’ shortage cost once the manufacturers adjust their wholesale prices and the buyers adjust their sourcing strategies in response. Nevertheless, we also identify conditions under which certification can benefit all stakeholders compared to the status quo with no certification. Finally, we find that combining certification with subsidies—where certified reliable manufacturers are subsidized by the government—can further reduce the shortage cost when the subsidy level is sufficiently high, but it may backfire if the subsidy level is too low.

2 - Reimbursement Policy and Drug Shortages

Xuejun Zhao, UNC Charlotte, Charlotte, NC, United States, Justin Jia, Hui Zhao

Drug shortages have posed a significant challenge for the U.S. pharmaceutical industry and the government in recent years, causing severe consequences and drawing widespread attention. Substantial efforts have been devoted to identifying the causes, with one debate linking the shortages to Medicare's adoption of the Average Sales Price (ASP) policy for hospital drug reimbursement. Few studies have captured the main tradeoffs and nuances in drug wholesale pricing decisions and subsequent shortages under the reimbursement policy, leaving the exact link between the policy and drug shortages unclear. Recognizing that the reimbursement policy influences shortages through affecting supply chain parties' decisions and given the scarcity of data on GPOs, who are pivotal in these decisions, we analyze a drug supply model that captures the essential elements and tradeoffs in drug wholesale price decisions under the reimbursement policy. We find that under the ASP policy, the interplay of two opposing effects, the free-ride effect and the coordination effect, guides wholesale pricing decisions and affects shortage outcomes. We capture key factors influencing these effects and show that the ASP policy actually possesses resistance to shortages of the drugs that have experienced shortages. We further conduct numerical analysis incorporating real pharmaceutical data (with the aid of machine learning) to gain additional insights. The numerical analysis confirms the ASP policy's resistance to drug shortages and shows that overemphasis on lowering wholesale prices through GPOs can exacerbate drug shortages. Finally, we provide a thorough discussion of policy implications based on our findings.

3 - Impacts of a Non-Profit Intermediary on Reliability of Drug Supply

Junghee Lee, University of Notre Dame, Notre Dame, IN, United States, Jennifer Ryan, Hyoduk Shin, Daewon Sun

Generic drug shortages have become increasingly common and costly in the U.S. Recently, non-profit organizations dedicated to enhancing the reliability of the drug supply have begun to enter the pharmaceutical supply chain, alongside traditional for-profit intermediaries, such as group purchasing organizations. In this paper, we study the impact of a non-profit intermediary on the reliability of supply in the context of a single drug that is vulnerable to shortages. We develop an economic model tailored to long-off-patent generic drugs, produced by a limited number of suppliers. We find that the non-profit intermediary's entry will improve supply reliability for its members but will not necessarily improve the overall supply chain reliability. However, in a long-term setting, in which both suppliers can adjust their wholesale prices, for some cases, more providers will see improved reliability of supply. Surprisingly, we also discover that an increase in the reimbursement rate for the vulnerable drug may not lead to more reliable supply. Our results provide critical insights to government officials and policy makers given that increased reimbursement rates for generic drugs are often suggested as one possible solution to the drug shortage crisis. Our results also provide useful guidance for non-profit organizations who actively seek to mitigate drug shortages. We find that such efforts may have limited impact on the reliability of the drug supply if not properly implemented and that decisions such as the degree of vertical integration can have a significant effect.

4 - Optimal Conditional Drug Approval

Chenxi Xu, Duke University, Durham, NC, United States, Giuseppe Lopomo, David Ridley, Peng Sun

New prescription drugs require regulatory approval before drug makers can sell them. In some countries, regulators may conditionally approve a drug, which allows sales to begin before the developer has proven the drug's efficacy. After further testing, the regulator may either grant final approval or reject the drug. We show that conditional approval not only speeds access to drugs but also encourages the development of drugs that would not have been pursued otherwise. Using mechanism design principles, we show that regulators should conditionally approve a drug even if it is ex-ante less likely to prove efficacious, under certain conditions. The regulator should approve the drug to encourage investment, especially when only the firm knows the testing cost. However, drugs that are less likely to prove efficacious should only be conditionally approved for a portion of the patient population if that is enough to motivate testing. Additionally, the impact of conditional approval is greater when the firm's revenue increases over time. Finally, a regulator should sometimes commit that in the future it will grant final approval for a drug that narrowly misses the efficacy threshold in return for the firm testing an otherwise unprofitable drug.

Summit - 439

Healthcare Operations

Invited Session

Health Applications Society

Chair: Sindhoora Prakash, University of Massachusetts Amherst, Amherst, MA

Co-Chair: Hari Balasubramanian, University of Massachusetts, Amherst, Amherst, MA, United States

1 - Scheduling Interventions for Individuals in Complex Care Programs

Sindhoora Prakash, University of Massachusetts Amherst, Amherst, MA, United States, Hari Balasubramanian

Patients with multiple chronic conditions, as well as unmet social needs, have significantly higher healthcare costs and utilization. Holistic, person-centered care interventions, often led by a multidisciplinary team consisting of nurses, community health workers, and social workers, have emerged as a strategy to engage with and help improve the health and well-being of such patients. The objective of these interventions is to reduce the occurrence of unnecessary hospitalizations and overall healthcare costs. In this talk, we highlight the potential benefits of using simulation and mixed integer programming to estimate and optimize the allocation of health and social care services to patients, such that their waiting times are limited while minimizing the variance of the number of staff hours required per week.

2 - Outpatient Appointment Scheduling in the Multi-Physician Setting

Haolin Feng, Sun Yat-sen University, Guangzhou, China, People's Republic of, Zitian Li

We study outpatient appointment scheduling in a multi-physician setting with stochastic service times. The decisions are the appointment times for the set of patients given. The objective is to optimize the weighted expected value of patient waits, physician idling, and overtime. We derive expressions for the performance measures and provide theoretical results of the optimization problem. Numerical studies are included to shed light on the managerial implications.

3 - Novel absence forecasting for nursing resource team sizing using nurse-specific absence probabilities

Taylor Martin, University of Toronto, Toronto, ON, Canada, Michael Santorelli, Michael Carter

This study introduces a novel approach to predict nurse absenteeism in an acute care setting. Results are used to plan optimal replacement staffing, such as a Nursing Resource Team. The method, unique in its use of individual staff characteristics, offers improved accuracy compared to traditional average-based approaches. Using historical attendance data to train a machine learning model, individual likelihoods of absence are predicted for each upcoming shift and an expected value across all staff is computed as the forecast for each shift. The novelty of this approach is that for each shift the predicted number of absent nurses is influenced by the individuals scheduled to work. Forecast absence data are used in an optimization model to determine levels of pre-booked and ad-hoc staffing under operationally relevant constraints. Testing over 244 weeks of real data from an acute hospital indicated that the optimized machine learning model produced total staffing costs that were 5% lower, with 15% less regret, than baseline. Testing revealed superior performance when i) nurse-specific identifiers were included (‘nurse-aware’ models) and ii) more training data were used. This research demonstrates the potential for nurse-aware approaches to forecasting and optimization in an applied setting. Optimization results demonstrated that an ML approach yields lower numbers of pre-scheduled staff and higher values of ad-hoc straight time shifts. What does mean for the workforce? In the current global nursing shortage lower staffing requirements are attractive, and optimization leads to fewer nurses being better utilized.

4 - Maintaining Fairness in Chemotherapy Scheduling Under Uncertainty

Batuhan Celik, Rennselaer Polytechnic Institute, Troy, NY, United States, Serhat Gul, Ozlem Karsu

Chemotherapy scheduling is hard to manage under uncertainty in infusion durations, and focusing on expected performance measure values may lead to unfavorable outcomes for some patients. In this talk, we aim to design daily patient appointment schedules considering a fair environment regarding patient waiting times. We propose using a metric that encourages fairness and efficiency in waiting time allocations. To optimize this metric, we formulate a two-stage stochastic mixed-integer nonlinear programming model. We employ a binary search algorithm to identify the optimal schedule, and then propose a modified binary search algorithm (MBSA) to enhance computational capability. Moreover, to address stochastic feasibility problems at each MBSA iteration, we introduce a novel reduce-and-augment algorithm that utilizes scenario set reduction and augmentation methods. We use real data from a major oncology hospital to show the efficacy of MBSA. We compare the schedules identified by MBSA with both the baseline schedules from the oncology hospital and those generated by commonly employed scheduling heuristics. Finally, we highlight the significance of considering uncertainty in infusion durations to maintain fairness while creating appointment schedules.

EVs -- Adoption, Operations and Interface with the Utility Grid

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Siddharth Singh, University College London, London, United Kingdom

1 - Utilities' Managed Home-Charging Programs for Electric Vehicles

Ali Fattahi, Johns Hopkins University, Baltimore, MD, United States

Experts estimate 20 million electric vehicles (EVs) will be on U.S. roads by 2030, and the majority (around 80%) of EV drivers will use home charging. Many utilities are designing managed home charging (MH) programs to centrally manage EV drivers' home charging to reduce cost, avoid new and aggravated peaks and blackouts, and ensure grid stability. An MH program is either an active program (AMH), in which the utility continuously controls the EV charging while the vehicle is plugged in, or a passive program (PMH), in which the participating EV drivers decide when to charge, based on pre-announced low-rate episodes. We present a program-design model (PD) and a load-management model (LM) for jointly designing and executing MH programs. PD designs a menu of MH programs, tailored for each driver type, and LM dynamically manages the load supply to each individual participant. LM consists of a large number of non-homogeneous participants, and it is a large-scale mixed-integer nonlinear stochastic problem. We present an effective approximation method, conduct thorough theoretical and numerical analyses of our approximation, and provide worst-case bounds for its error components. Our methodology provides detailed insights on the amount and timing of the improvements achievable in cost and demand variability by offering AMH, PMH, and both, and by customizing PMH. It also offers detailed insights on the significance of the trade-off between cost and demand variability. We find promoting a culture of charging EVs every night may significantly increase utilities' total cost if PMH has a high participation level.

2 - Optimal Megawatt Charging Station Investment and Design: Mitigating Peak Demand

Ridvan Aksu, The University of Alabama, Tuscaloosa, AL, United States, Mesut Yavuz

Medium and Heavy Duty (MDHD) trucks contributes the 6% of the greenhouse gas emissions of the US while accounting for the 29% of the transportation fuel use. In order to adapt Electric MDHD, an established fast charging network is required, given their high energy demand, current limitations of battery and charging technologies, and the time sensitive nature of land freight transportation. Existing plans for Megawatt Charging Systems (MCS) and zero-emission freight charging corridors to expedite this transformation requires a heavy load on grid networks, given the power demand of each megawatt charging port being the size of a small to medium size manufacturing plant. In this work, we investigate utilizing on-site renewable energy generation and energy storage systems to mitigate the peak load on the grid and providing a quick turnaround time for MDHD vehicles while having a profitable business plan, given the high investment cost of charging, storage, and energy generation systems. We also analyze charging policies that balances the tradeoff of the grid load and customer satisfaction with respect to customer arrival density and energy pricing.

3 - Watt's Next: Navigating the Surge in Electric Vehicle Adoption and its Implications for Grid Operations

Siddharth Singh, University College London, London, United Kingdom, Karthik Murali, Owen Wu, Mesut Yavuz

As policy decisions pave the way for more Electric Vehicles (EVs) on the road, there is expected to be a tremendous strain on the utility grid. Managing this strain requires careful planning for (and possibly control of) EV charging operations by the utility firm. This may include the utility firm managing intra-day demand variations using grid-scale batteries, and taking over charging operations of some fraction of EVs (via a managed charging program), including the possible use of Vehicle-to-Grid (V2G) technologies. A managed charging program must be carefully designed, accounting for EV users' driving patterns and range anxieties. Using a stylized analytical model that considers two periods per day (peak and off-peak), we derive optimal grid operations in the presence of a fraction of EV owners who sign up to a managed charging program. We find the optimal operating policy and show that both V2G and grid-scale battery usage are only useful when the fraction of managed EVs is low. We demonstrate the validity of all our findings numerically using a higher fidelity hour-to-hour model calibrated to real data. Our results suggest that a long-term outlook on navigating EV adoption should focus on managing more EV charging, rather than installing stationary battery capacity or promoting V2G. Our results also carry useful implications for policy-makers on the optimal target level of EV adoption under various objectives that weigh environmental factors differently.

4 - Economic Potential and Benefits of PV-Integrated Vehicle-to-Grid (V2G) Technology in the Rent-a-Car Industry: A Case Study of Jeju Island

Yoonmo Koo, Seoul National University, Seoul, Korea, Republic of, Wonjong Lee, Jonghyeok Han

Vehicle-to-grid (V2G) technology, enabling bidirectional power transactions between the power grid and electric vehicles (EVs), is recognized as a promising solution for the deep integration of EVs with renewable energy (RE). While substantial research has been conducted on V2G applications for private EVs and car-sharing businesses, the exploration of V2G within the rent-a-car industry remains limited. This study investigates the economic potential and advantages of a PV-integrated EV rent-a-car business in tourist destinations, with a particular focus on Jeju Island, a leading tourist spot in South Korea.

Utilizing 105,473 rental and return data points from 2023, this research employs bilevel programming to simulate the decision-making and interaction between the rent-a-car business and the system operator. The upper level models the V2G/G2V bidding strategies of the rent-a-car business, while the lower level addresses the market-clearing decisions of the system operator. By applying the Karush-Kuhn-Tucker conditions and the strong duality theorem, the model is transformed into a single-level mixed integer linear programming problem.

The findings indicate that an optimal configuration—15 MW of solar PV, 10 MW of unidirectional chargers, and 30 MW of bidirectional chargers—can generate an annual revenue of USD 3,205,580, accounting for investment and battery degradation costs. Additionally, the power system's operation costs were reduced by up to 6.8% through the alleviation of RE curtailments by 5.5%. These results highlight a novel revenue stream and co-benefits for V2G in the EV rent-a-car business in tourist areas, suggesting a feasible decarbonization strategy to mitigate carbon emissions in such locales.

Summit - 441

Collaboration in Supply Chains with Channel Partners and Competitors

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Abhishek Roy, Temple University Fox School of Business, Philadelphia, PA, 19122, United States

1 - The First-Mile Problem in the Reverse Supply Chain of Used Electronics

Yunke Mai, University of Kentucky, Lexington, KY, United States, Haoying Sun

In this paper, we study how to incentivize consumers to send their end-of-life electronics for reuse and recycling under current reverse supply chain structures. We show that utilizing existing retail channels could be an effective approach and establish the optimal subsidy policies that increase the recycling rate.

2 - A Random Model of Supply Chain Networks

Philippe Blaettchen, Bayes Business School (formerly Cass), London, United Kingdom, Andre Calmon, Georgina Hall

Many optimization problems in supply chain management are formulated over graphs representing networks of interlinked supply chains. Solution approaches to these problems are often studied and tested on small, stylized supply chain networks, or on some of the few publicly available supply chain network dataset. This paucity of data means that fundamental questions about the relationship between the network structure and the properties of the problem solution such as quality and complexity are not addressed systematically.

Our paper fills this gap by introducing a random generative model of supply chain networks, in line with the computer science and social sciences literature, where random graph models are a popular tool for studying properties of “typical” networks. We show that our model, based on simple micro-foundations, generates network structures similar to those observed in practice. We propose that it supports (i) analyzing how network structure affects computational complexity, (ii) identifying new managerial insights, and (iii) benchmarking heuristics. We illustrate these benefits with a case study on safety stock optimization.

3 - Progressive referral fee on online retail platforms

Aadhaar Chaturvedi, University of Auckland, Auckland, New Zealand, Aditya Jain

To boost product variety, online retailers have adopted agency selling model wherein the supplier determines prices and retailer charges a fraction of price as referral fee. This paper tackles the important question of how should a retail platform design progressive referral fees facing heterogenous suppliers differing in demand and cost.

4 - Impact of cocreation under supply chain encroachment

Abhishek Roy, Temple University Fox School of Business, Philadelphia, PA, United States, PIYAL SARKAR

The increasing complexity of supply chains has led firms to redesign supply chain strategies based on the collaborative value created through co-creation with other supply chain members. Co-creation is an economic strategy that binds supply chain members to jointly improve the output. Our research investigates how co-creation can add value under supplier encroachment environment. Encroachment refers to the scenario when a manufacturer establishes a direct sales channel (especially via an online platform). Supplier encroachment mitigates double marginalization and secures Pareto-improvements for both parties. Companies such as Apple, Nike, Adidas practice cocreation as well as encroachment strategies. Previous literature has investigated the impact of cocreation under different settings, but the impact of cocreation under supply chain encroachment environment has received little attention. This study addresses this gap and tries to draw managerial insights by integrating the co-creation and encroachment strategies. The study aims to provide the following insights: a) co-creation strategies given quality is the main differentiator of the product under supply chain encroachment environment and b) encroachment strategies given co-creation exists between the manufacturer and retailer.

Summit - 442

Care Access and Delivery

Invited Session

MSOM: Healthcare

Chair: Anita Carson, Boston University, Boston, MA, United States

Co-Chair: Ruozhu (Savannah) Wang, Boston university, Boston, MA, 02215, United States

1 - Work Design and Scheduling for Dialysis Clinics

Vincent Slaugh, Cornell University, Ithaca, NY, United States, Andre Cire

Based on work with a large network of dialysis clinics, we show potential improvements for labor costs and work design by switching from a "push" schedule to an "interlaced" schedule. We analyze closed-form expressions of day length and consider tandem work models. We also share insights from implementation.

2 - When Is Standardization Most Beneficial for Improving Healthcare Service Quality? The Moderating Role of Operational Failures

Qi Wang, Boston University, Boston, MA, United States

Research finds a mixed result on clinical outcomes from standardizing medical procedures. Under some conditions, standardization improves performance, while under other conditions, it hurts. We investigate a condition we term “operational failures” – influences the relationship between standardized procedures and clinical outcomes. We conduct two separate studies to test whether operational failures moderate the relationship between standardized procedures and clinical outcomes. Study 1 uses survey data from nurses in medical and surgical units across 56 U.S. hospitals to gather measures of operational failures and standardization and matches them with data on pressure injuries. Study 2 triangulates Study 1 by using objective clinical data from over 17,000 patient visits at a major U.S. medical center. Through both studies, we find strong support that standardization enhances clinical outcomes in units that suffer from frequent operational failures. We suspect that standardization is most beneficial when it provides structure in a chaotic work environment. Conversely, in units that experience few operational failures, standardization provides little benefit for clinical outcomes. This surprising result may be because of the downsides of standardization: it limits clinicians’ flexibility to respond to patients’ unique needs. In a reliable work environment, there is less need to impose the rigidity that comes from highly standardized procedures. We provide insight to healthcare managers by explaining that standardization’s positive impact peaks in environments with frequent operational failures but offers little benefit when operational failures are rare.

3 - Seeing is Believing - Surgery Video Sharing Improves Trust , Adherence and Health Outcomes

yueran Hou, Southwestern University of Finance and Economics, Chengdu, China, People's Republic of, Lin Zhao, Meng Li

In the realm of healthcare, the significance of trust cannot be understated. It serves to mitigate feelings of vulnerability in patients and enhances the efficacy perceived by clinicians. The patient-physician relationship is often presupposed to be underpinned by trust due to its fundamental nature. However, with the evolution of healthcare systems and societal shifts, trust is increasingly understood to be at risk and in need of attention, medical disputes arising from mistrust are becoming more common. In this paper, We have proposed a method to bolster the trust between physicians and patients - sharing surgical videos with patients. We have conducted research on the impact of this approach on the psychological, physiological, and behavioral aspects of patients.

4 - The Effect of Must-Access Prescription Drug Monitoring Programs on Opioid Prescriber Rates

Behrooz Pourghannad, Lundquist College of Business, University of Oregon, Eugene, OR, United States, Beyza Celik, Guihua Wang

We examine the effect of must-access Prescription Drug Monitoring Programs (PDMPs) on opioid prescriber rates. We first use the difference-in-differences approach to analyze the average effect of PDMPs. We then use an empirical machine learning approach to analyze the treatment effect heterogeneity across healthcare providers. Our analysis sheds light on the effects of must-access PDMPs, informing policymakers and stakeholders about their implications in addressing the opioid crisis and optimizing patient care.

Summit - 443

Data-Driven Methods to Human - Artificial Intelligence Interactions

Invited Session

MSOM: Service Operations

Chair: Agni Orfanoudaki, Oxford University, Oxford, OX26SQ, United Kingdom

1 - Generative AI at Work: Hallucination, Moral Hazard, and Contracting

Tinglong Dai, Johns Hopkins University, Baltimore, MD, United States, Terry Taylor

We examine how generative AI can affect workplace dynamics, with a particular focus on how the phenomenon of hallucination can complicate the incentive design problem. We show that moral hazard may be either exacerbated or mitigated by the hallucination of generative AI outputs. Our findings point to the need to rethink incentive design to facilitate effective human-AI interaction in the workplace.

2 - Algorithm-in-the-Loop: Towards Better Human Decision Making

Michael Lingzhi Li, Harvard Business School, Boston, MA, United States, Agni Orfanoudaki

As data availability continues to expand, the deployment of data-driven algorithms to assist human decision-making is becoming increasingly prevalent across a wide range of industries. However, the effectiveness of these algorithms can vary significantly depending on how human decision-makers are influenced by the algorithmic advice. This paper establishes a comprehensive framework for measuring and optimizing the positive impact of algorithms on human decision-making.

We introduce the concept of an influence function, which is central to understanding human performance when algorithmic advice is available. Different behavioral assumptions can be naturally encoded within the influence function, allowing us to capture various modalities of algorithmic benefits, ranging from harmful and contradictory to complementary and beneficial.

To demonstrate the practical applicability of our framework, we conducted a randomized study in a large academic hospital. This study involved doctors and focused on the impact of algorithmic advice on the prescription of antibiotic prophylaxis. Our results showcase the framework's ability to accurately measure the heterogeneity of influence functions across different doctors and personalize algorithmic outputs to optimize human performance.

3 - Towards Stable Machine Learning Model Retraining via Slowly Varying Sequences

Vassilis Digalakis, HEC Paris, Jouy-en-Josas, France

Stability is important for both ensuring consistent performance and enhancing interpretability: significant changes in a model’s structure or the resulting analytical insights can lead to skepticism and hesitation for adoption. In this talk, I will present my research in the area of stable and “slowly varying” ML through the lens of healthcare applications and collaborations with major US hospitals. First, I will introduce the framework of slowly varying regression under sparsity, allowing sparse regression models to exhibit controlled, slow and sparse variations. Next, I will propose a decision tree stabilization methodology relying on a new distance metric for decision trees, which is used to determine a tree's level of stability. Lastly, I will discuss a general, model-agnostic framework aimed at stabilizing ML model structures (including black-box models such as boosted trees) upon retraining with new data. We have tested the proposed methodologies on a variety of real-world case studies and have shown, empirically and theoretically, that, with a small, controlled decrease in predictive power, we often gain a significant improvement in the models' stability.

Summit - 444

Empirical Research on Marketplaces

Invited Session

MSOM: Service Operations

Chair: Rakesh Allu, Cornell University, Ithaca, NY, United States

Co-Chair: Vishal Gaur, Cornell University, Ithaca, NY, 14850, United States

1 - Causal Product Networks: Discovery and Applications for Basket Shopping

Ziwei Zhu, Cornell University, Ithaca, NY, United States, Vishal Gaur, Nur Kaynar

Modeling the purchase decisions of basket-shopping consumers is a hard problem. In this paper, we employ a novel causal structure learning technique to uncover the causal relationships among product purchases and study two main research questions: (1) How do causal product networks perform in describing the relationships among product purchases when compared to various other network structures that represent hypothetical consumer behavior? (2) Given the empirical evidence for network structures, how can we construct the optimal assortment strategy based on the causal relationships among product purchases, and to what extent does it outperform a benchmark within-category assortment strategy based on Multinomial Logit (MNL) models? Our empirical evidence shows that across all five themes, the model based on the causal structure among products consistently provides the best fit. Besides, we compare the performance of causal product networks and MNL models in both brick-and-mortar and online channels, and find that the assortment strategies derived from the former significantly outperform those from the latter, achieving objective values that are two to three times higher. Thus, our study yields insights into consumer behavior as well as provides a parsimonious model for estimating basket-shopping behavior from historical data and thereby optimizing assortments across product categories in an integrated model.

2 - The Role of Algorithmic Housing Market Intermediary in Attenuating Racial Price Differentials - Evidence from iBuyers

Yuan Cheng, Cornell University, Jersey City, NJ, United States

Algorithms powered digital technologies are playing an increasingly important role in automating home buying process, offering efficiency and convenience for home buyers. However, it also raises the fairness concerns, as algorithms not designed to discriminate can also discriminate due to bias in the data. In this paper, we examine whether a new type of housing market intermediary -- iBuyers, which rely heavily on algorithms to compute housing valuations -- exacerbate or attenuate racial price differentials in the US housing market. Using millions of housing transactions and mortgage data and a repeat-sales framework that ensures comparable housing, we find strong evidence that iBuyers attenuate existing racial price differentials in markets with the most iBuyer presence. Our findings are robust to the potential unobserved changes in housing characteristics, which are achieved by using coarsened exact matching. For comparison, we further investigate the traditional housing market intermediary, known as flippers, but find no evidence of similar function as iBuyers in addressing racial disparities. Finally, our heterogeneity analyses shed light on the mechanism of iBuyers' role in attenuating racial price differentials.

3 - Do Online Marketplaces Democratize Market Access? Evidence from a B2B Platform.

Vishal Gaur, Cornell University, Ithaca, NY, United States

TBD

4 - Shift Commitment in the Gig Economy: A Study with a Food Delivery Platform

Yao Cui, Cornell University , Ithaca, NY, United States

Online delivery platforms often rely on gig workers to serve as delivery drivers. While there are certain purported benefits to utilizing gig workers for this role, it often leads to a challenge in maintaining an adequate supply of drivers to meet the fluctuating customer demand throughout the day. Hence, to address this issue, platforms have been designing new incentives schemes to encourage greater commitment in the availability of the gig workers at the crucial hours. In this study, we are interested in how platforms can resolve the demand and supply imbalances through incentivizing the gig workers to commit to certain shifts. Using a comprehensive dataset from a major food delivery platform in Asia, we empirically study the impact of shift commitment on gig workers' behavior, and provide guidance for platforms seeking to enhance the reliability of gig worker availability.

1 - Reducing Food Waste: The Impact of Online Grocery Shopping

Jimin Park, Massachusetts Institute of Technology, Cambridge, MA, United States, Yanchong Zheng

The use of online grocery shopping has been rapidly increasing in recent years. With food waste reduction becoming a global priority, it is critical to understand the impact of online grocery shopping on food waste. This paper examines how the advent of online grocery shopping influences household and retail-level decisions and analyzes its role in reducing food waste along the supply chain system. We develop a game-theoretic model to characterize a two-level grocery supply chain, comprised of the household and the retail-level, under the base scenario of no online shopping. We examine how product and consumer characteristics impact the decisions and the waste outcomes. We then analyze and contrast the model with the adoption of online shopping with the base scenario to uncover its differential impacts on the equilibrium. Finally, we use actual transaction data from the US to empirically validate our modeling insights and quantify the impact of online grocery shopping on food waste. Our findings reveal that online grocery shopping has the potential to decrease food waste at both the household and retail-levels, but its effectiveness depends on being adopted by the "right" households and product lines. Specifically, online shopping successfully reduces food waste at the household-level when utilized by households who are distant from the retailer on products that are less perishable and are consumed at a slower rate. Analytical and empirical results further demonstrate that retail-level food waste always decreases under the same conditions due to the increased power in managing inventory.

2 - Variability Propagation in Perishable Product Supply Chains

Xiaoyue Yan, University of Oregon, Eugene, OR, United States, Elena Belavina

Demand variability and its propagation in the supply chain have played a key role in recent shortages, inflation and turmoil. Managing demand variability is essential to minimizing costs and delivering reliable supply. In perishable-product supply chains it is also key to reducing food waste and carbon emissions. This study provides the analysis of variability propagation in perishable-product supply chains. We build and calibrate a two-echelon perishable-inventory model, showing that the nature of variability propagation in perishable-product supply chains is strikingly different from that in well-studied durable-product supply chains. In particular, we find that (i) product perishability is a novel, hitherto unknown driver of the much-examined bullwhip effect (upstream variability amplification), (ii) surprisingly, perishability can also lead to upstream variability attenuation, an *anti*-bullwhip effect. Our data-driven model calibration reveals a great variation in the degree of variability amplification across different products resulting from more/less favorable combinations of the product and market characteristics. Products with more extreme (high or low) purchasing price, replenishment cost, mean of product expiration time, and standard deviation of buyer demand exhibit higher variability amplification. High mean of buyer demand and standard deviation of product expiration time also yield higher amplification. Finally, we show that the buyer's order quantity modulates the extent of the upstream variability amplification, and as a result, the supply chain partners could attempt to identify contracts that coordinate on buyer's order quantities to limit variability amplification. This could lead to overall less food waste (3-6%) and higher profits (2-10%) for the supply chain.

3 - Farm Equipment Sharing in Emerging Economies

Priyank Arora, University of South Carolina, Columbia, SC, United States, Olufunke Adebola, Can Zhang

In emerging economies, there is a growing number of farm equipment sharing platforms that connect smallholder farmers with tractor owners who are willing to fulfill farmers' requests for mechanization services. Due to the small farm sizes and the low digital literacy in rural areas of emerging economies, these platforms often rely on the so-called "booking agents" to collect demand from individual farmers and submit the aggregated demand on the platform (rather than having individual farmers submit their service requests). This paper studies how the presence of such booking agents affects the platform's optimal pricing and wage decisions and the equilibrium outcomes. Our analysis reveals several insights with managerial implications. First, in contrast to conventional sharing settings, we show that in the presence of booking agents, an increase in the number of service providers (i.e., tractors) may lead to a lower optimal platform commission. Second, while supply-side interventions, such as increasing the number of tractors on the platform, generally lead to a decrease in price and an increase in total farmer surplus, we find that reducing booking agents' demand aggregation cost can lead to an increase in price and a decrease in total farmer surplus. Finally, although the platform needs to pay booking agents when it relies on these agents to collect demand, we show that the presence of these agents leads to a "win-win-win" outcome for farmers, tractor owners, and the platform when booking agents' demand aggregation cost is moderate or the number of tractors exceeds a certain threshold.

4 - Enhancing Agri-Food Supply Chain Resilience: Implications for Wholesale Prices and Inventory Management

Goutham Takasi, University of Alabama, Tuscaloosa, AL, United States, Stanley Lim, Monireh Mahmoudi

This study examines the operational challenges local food distributors encounter, particularly when sourcing from small and medium-sized farms (SMFs), which significantly impact the supply chain's resilience. The inconsistency in supply from SMFs, attributed to factors such as limited capacity and inadequate infrastructure, poses a risk of supply chain disruptions and potential retail shortages. To address these issues, we collaborate with Tamarack Holdings (TH), a Michigan-based agri-food distributor, with the aim of enhancing supply chain resilience through improved demand estimation and strategic inventory management. Our research is twofold: firstly, we develop a choice-based analytical framework to accurately estimate product demand, considering the multifaceted nature of customer orders in terms of the variety and quantity of stock-keeping units (SKUs). This model facilitates the identification of critical SKUs, enabling TH to prioritize resources and design effective farmer incentive schemes, potentially through adjustments in wholesale pricing. Utilizing a unique dataset comprising 3,292 SKUs over a 12-month period in 2022, which includes daily inventory data, replenishment orders, and customer transactions, we employ the multiple discrete-continuous extreme value (MDCEV) choice model to capture customer purchasing behaviors accurately. Our approach aims to provide insights into product consumption and substitution patterns, thereby contributing to the literature on supply chain management and inventory control in agri-food distribution.

Co-Chair: Somya Singhvi, USC Marshall School of Business, Los Angeles, CA, United States

1 - Labeling the Supply Chain: Signaling Supply Chain Transparency to Consumers Through Eco-Labels

Katelyn Thompson, University of South Carolina, Columbia, SC, United States, Priyank Arora, Blair Flicker

Increasingly, consumers' buying decisions are influenced by the perceived sustainability of *how products are made*—especially firm efforts to pay workers fair wages and reduce their CO_2 emissions. As such, many firms want to make their supply chains more transparent. Though firms engage in a wide array of sustainability practices, a primary mechanism to disclose this information to consumers, particularly during the buying process, is through a sticker – i.e., an eco-label – printed on product packaging (e.g., Fair Trade, Carbon Reduction). Mapping the complexity of production practices onto a small set of labels, which are often binary, results in information loss and contributes to "label confusion". Several recent studies find that consumers are unclear about the standards that must be met to earn each label and the amount of scrutiny involved in verifying compliance.

Given the widespread use of eco-labels in practice, we undertake a behavioral study to evaluate firms' sustainability practices and labeling strategies, in tandem. We ask: Do firms need separate eco-labels for societal and environmental impact dimensions? Or does information from one dimension spill over onto the other? We consider the following three labeling strategies: (i) augment a single eco-label with precise, quantitative information about firm performance; (ii) complement the existing eco-label with a second eco-label related to the other dimension or; (iii) complement the existing eco-label with a textual self-disclosed claim related to the other dimension. These choices help test the extent of transferability of trust gained via firm's disclosure on one dimension to the other.

2 - Are Chief Sustainability Officers Guardians of Environmental Justice? An Empirical Evaluation

Finn Petersen, University of Minnesota, Carlson School of Management, Minneapolis, MN, United States, Vibhuti Dhingra, Rachna Shah

Environmentally hazardous manufacturing facilities are disproportionately located in underserved communities, which exposes low-income and non-white populations to significantly higher toxic releases and adverse health risks. We study whether a firm governance reform—specifically, the appointment of a Chief Sustainability Officer (CSO)—can mitigate this environmental injustice. Using data on the toxic releases of U.S. manufacturing facilities from 2000 to 2020, we find that appointing a CSO decreases toxic releases by up to 19% and that the effect is particularly pronounced for facilities in underserved communities. We show that this effect is driven, at least in part, by increased implementation of source reduction activities by the treated facilities. Our work sheds new light on how corporate governance reforms act as a control mechanism for addressing environmental injustice, an issue that has proven challenging to regulate effectively.

3 - State Mandated Employment Certificate for Minors Reduces Child Labor Violations in the US

Ashish Kabra, University of Maryland-College Park, College Park, MD, United States, Jiacong Bao

As several states in the US debate loosening child labor laws, we assess the efficacy of existing work permit regulations for child labors. Our analysis reveals that mandating work permits lowers child labor violations, yet their influence is heterogeneous across different industries

4 - Turning a Blind Eye: Buyer-Supplier Relationships and Drug Diversion in the Prescription Opioid Supply Chain

Iman Attari, Indiana University Bloomington, Bloomington, IN, United States, Jonathan Helm, Robert Wiedmer

The opioid crisis has caused severe public health impacts across the United States, leading to approximately 69,000 fatalities in 2020 alone. Academic evidence suggests that the crisis, particularly in its early stages, was fueled by the pharmaceutical industry, with pharmacies playing a significant role through the excessive dispensing of prescription opioid drugs, despite clear indicators of drugs being diverted to non-medical channels. The prevalence of illicit behavior across the supply chain suggests that the current Drug Enforcement Administration (DEA) monitoring strategies, which mandate suppliers to monitor their customers and report suspicious activities, are not effectively curbing the diversion of drugs. Utilizing a comprehensive dataset that captures all opioid drug shipments in the US from 2006 to 2014 and employing a novel approach to detect drug diversion across the supply chain, this study examines how the dynamics of supplier-pharmacy relationships facilitate illicit behavior within the supply network. Our findings reveal the complex mechanisms underlying drug diversion and provide insights that can help governmental agencies, including the DEA, in developing more targeted regulatory measures that address the root causes of illicit behavior more effectively.

Summit - 447

Power Systems Planning and Operation II: Cutting Edge Strategies

Invited Session

ENRE: Other Energy

Chair: Patricia Hidalgo-Gonzalez, University of California, San Diego, La Jolla, CA, United States

1 - Climate Change and Its Influence on Water Systems Increases the Cost of Electricity System Decarbonization

Patricia Hidalgo-Gonzalez, University of California, San Diego, La Jolla, CA, United States, Julia Szinai, David Yates, Pedro Sánchez-Pérez, Martin Staadecker, Daniel Kammen, Andrew Jones

The electricity sector faces a dual challenge: decarbonization and adaptation to climate change. In many regions, this challenge is complicated by interdependence of electricity and water systems, through hydropower and energy-intensive water resources. By coupling detailed water and electricity system models, we evaluate how climate change alters pathways to carbon-free generation across the Western Interconnect, emphasizing water interactions. We find that grid planning ignoring climate and water linkages misestimates the magnitude, type, and location of capacity needed for decarbonization. By 2050, electricity use could grow by up to 2% annually but up to 8% in July from cooling and water-related electricity demand, while hydropower generation could decrease annually by 23%. Here, we show that to adapt, the region would need to build up to 139 GW of capacity between 2030 and 2050, equivalent to nearly thrice California's peak demand, and could incur up to $150 billion (+7%) in extra costs.

2 - Quantifying the Impact of Energy System Model Resolution on Siting, Cost, Reliability, and Emissions

Anna Jacobson, Princeton University, Princeton, NJ, United States, Denise Mauzerall, Jesse Jenkins

Energy systems models are critical for power sector decision support and decarbonization. Because they are typically written using formulations whose computational requirements increase non-linearly with resolution, large and detailed models are generally intractable even on modern hardware. Scaling dynamics require modelers to omit information for the sake of runtime, affecting siting, cost, and emission results to an unknown degree. We explore the interplay between resolution and results in order to afford decisionmakers greater confidence in recommendation quality. In order to better quantify the impact of coarseness on results, we rely on recent algorithmic innovations via Benders Decomposition to model at higher resolution, and use newly tractable highly granular systems as baselines in comparison with more efficient, low resolution simulations. We find high resolution energy systems models recommend investments with more realistic siting, lower emissions, greater reliability, and less scarcity pricing than analogous models at coarse resolution. We find spatial resolution to be more impactful than temporal, but that errors in model outputs are introduced by the lowest between the two. We see no diminishing returns in model accuracy for several key metrics when increasing resolution. We recommend that modelers use modern mathematical techniques to maximize system granularity and subsequently allocate resources without neglecting any aspect (spatial, temporal, operational) of resolution.

3 - Offshore Wind and Wave Energy Can Reduce Total Installed Capacity Required in Zero Emissions Grids

Natalia Gonzalez, University of California San Diego, La Jolla, CA, United States, Paul Serna-Torre, Pedro Sánchez-Pérez, Ryan Davidson, Bryan Murray, Martin Staadecker, Julia Szinai, Rachel Wei, Daniel Kammen, Deborah Sunter, Patricia Hidalgo-Gonzalez

As the world races to decarbonize power systems to mitigate climate change, the body of research analyzing paths to zero emissions electricity grids has substantially grown. Although studies typically include commercially available technologies, few of them consider offshore wind and wave energy as contenders in future zero-emissions grids. Here, we model with high geographic resolution both offshore wind and wave energy as independent technologies with the possibility of collocation in a power system capacity expansion model of the Western Interconnection with zero emissions by 2050. In this work, we identify cost targets for offshore wind and wave energy to become cost effective, calculate a 17\% reduction in total installed capacity by 2050 when offshore wind and wave energy are fully deployed, and show how curtailment, generation, and transmission change as offshore wind and wave energy deployment increase.

4 - A Nodal Capacity Expansion Model and Data for California Climate Impacts Analyses

Jean-Paul Watson, Lawrence Livermore National Laboratory, Livermore, CA, United States

We consider a power grid capacity expansion optimization model that co-optimizes generation, transmission, and storage given a set of representative weather days. Leveraging the recently introduced CATS synthetic-but-realistic power flow model, we introduce a capacity expansion data set for the state of California in the US, which includes: renewables and load time-series, land use constraints, and requisite unit performance and cost characteristics. We consider both present-day climatology (as represented by the US National Weather Service HRRR data set) and future climatology (as represented by a high-resolution variant of the US Department of Energy's E3SM climate model). Instances for the time periods 2015-2019 and 2040-2045 are analyzed, with solutions obtained in tractable run times via use of advanced progressive hedging decomposition strategies and high-performance computing platforms. Identified expansion plans will be compared and contrast, focusing on impacts of climate change on solution structure.

5 - Hydrological Price Formation in High Renewable Production Cost Modeling Scenarios

Kaleb Smith, Cornell University, Ithaca, NY, United States, Brent Eldridge, Konstantinos Oikonomou

The Western Interconnection system for electricity in the western half of the United States is in a period of market transition given the rapid integration of new variable renewable energy (VRE) capacity and that a large fraction of the region remains vertically integrated. Of particular interest to planners are market systems dominated by zero-marginal cost (ZMC) resources, because current planning scale production cost models (PCMs) may not adequately model the interactions of long-term storage, flexible demand, and high penetration of VRE in the price formation process. Due to the link between the value of storage and potential price volatility shown in these PCMs, accurately modeling the value of hydropower storage in the Columbia River Basin will be important in reliability studies in the Western Interconnection. This work develops a series of operational models for hydropower operation in a simplified grid network representing the Western Interconnection with simulations of four different cases of VRE penetration and demand flexibility. The operational model formulations include an energy budget proxy model, storage equivalent model, fixed head reservoir model, and a convex envelope model. A number of non-linearities are relaxed to reduce computational complexity. Additionally, we simulate on both annual and weekly time-scales, fitting storage values and state of charge values from the annual model as targets of the weekly model.

Recent Advances in Stochastic Optimization

Contributed Session

Chair: Yu Zhao, Tokyo University of Science, 1-3 Kagurazaka, Shinjuku-ku, 162-0801, Japan

1 - Cognitive Analysis of multiple wind turbine faults using Vision Transformer on Augmented SCADA data

Chufan Wu, City University of Hong Kong, Hong Kong, Hong Kong, Zijun Zhang

This talk presents a novel cognitive-based method for detecting wind turbine component faults, attempting to approach fault detection from a new perspective by leveraging visual clues. In the proposed method, we first transform the SCADA data of target turbine components into images of size 128*128, gathering numerical data of multiple timestamps into informative visual patterns. As the gathering of numerical data decreases the number of trainable faulty samples, we further propose a color adaptation algorithm to integrate with deep convolutional generative adversarial networks (DCGAN) for generating a set of augmented images that show realistic faulty operation patterns. Based on both real-world and augmented SCADA images, a vision transformer is applied to classify images with faulty turbine operation patterns from the normal ones, realizing a high-precision, generalizable, and real-time identification of wind turbine faults. Compared with classic SOTA fault detection methods, we show that, in detecting blade breakage, loosening bolt, and gearbox overheat faults, the proposed cognitive fault detection method achieves a significant reduction in false alarm rates by at least 61.3% while maintaining a correct alarm rate of nearly 100%, serving as a practical solution to AI-assisted wind turbine fault detection.

2 - Automating ML Workflow Orchestration: Strategies for Autonomous Post-Deployment Model Updates

SeongHyun Seo, Sungkyunkwan University, Seoul, Korea, Republic of, Dong-Joon Lim

This presentation is focused on autonomous model update strategies aimed at improving the performance and stability of machine learning (ML) models after deployment. Unlike traditional approaches that often involve periodic retraining or retraining triggered by performance falling below predetermined thresholds, these autonomous strategies make informed decisions regarding the optimal timing and procedures for iterative model training, ensuring long-term sustainability. We propose an adaptive framework to facilitate concept drift detection and adaptation, leveraging data/feature extraction, model management, hyperparameter adjustments, and artifacts versioning. An empirical case study from the Korean steel industry highlights the necessity of autonomous retraining strategies after model deployment and the importance of considering these strategies during model development.

3 - Multi-stage stochastic hub and spoke location-allocation problem

KAZI WAHADUL HASAN, Arizona State University, Tempe, AZ, United States, Pitu Mirchandani

Multi-stage network optimization is a particular area of operations research that frequently emerges in problems related to location-allocation, telecommunication, scheduling, and production systems. In this talk, we will present a multi-stage hub-and-spoke recycling network that considers the single allocation of the spokes. We incorporate two different waste streams, named single stream and source-separated stream, as origins while end markets are destinations. The hub serves as the consolidation point between the origin and destination. Materials from single waste streams remain unsorted and need to go through a material recovery facility (MRF). Our study views the recyclable wastes recovered by the MRF as uncertain due to contamination. We develop a two-stage stochastic mixed integer programming (MIP) model and apply a decomposition approach to solve it. Our decomposition approach is strengthened with some cuts as valid inequalities. We conduct numerical experiments and present our findings to demonstrate the effectiveness of the decomposition approach.

4 - Optimal Control Using Time-series Forecasting Models and Integer Programming

Vinicius Lima, IBM Research, Yorktown Heights, NY, United States, Dzung Phan, Sumanta Mukherjee, Pankaj Dayama, Jayant Kalagnanam

Our talk addresses process control for physical systems with generic forecasting models. We introduce a multi-step set point recommendation framework for industrial process optimization. This method employs multivariate time-series forecasting models to predict long-term trajectories for target variables that must remain within desired operating ranges. We construct a state-based action-response model by simulating various action trajectories and using the response from a global complex forecasting model as the target trajectory. To solve the optimal control problem efficiently, we reformulate it as a mixed-integer linear program (MILP), leveraging MILP representations for action response models. Through experimental evaluations, we demonstrate the efficacy of our proposed techniques.

5 - Evaluating Efficiency in DEA with Consideration of Probabilistic Variations in Data

Yu Zhao, Tokyo University of Science, Shinjuku-ku, Tokyo, Japan

In Data Envelopment Analysis (DEA), both input-oriented and output-oriented models are widely used in practical analysis. Previous studies have applied a bootstrap method to enhance statistical analysis in DEA. In this study, we consider the probabilistic variations present in input-output vectors and propose a tree-based sampling procedure with different orientations for handling the statistical properties of efficiencies. To obtain possible probability distributions of the data, we classify the observed decision-making units into several different clusters and maximize the information gain of each cluster using a Gaussian-based entropy function. The proposed approach shares several characteristics with the bootstrap DEA method. An illustrative example and numerical simulations will be presented.

Summit - Terrace Suite 1

Advanced Analytics for Healthcare Operations

Invited Session

Health Applications Society

Chair: Gabriel Zayas-Caban, University of Wisconsin Madison, Madison, WI, United States

Co-Chair: Fernando Acosta-Perez, University of Wisconsin-Madison, Madison, WI, United States

1 - Hospital Discharge Prediction Models in Multisite Healthcare Systems

Fernando Acosta-Perez, University of Wisconsin-Madison, Madison, WI, United States, Justin Boutilier, Gabriel Zayas-Caban, Sabrina Adelaine, Frank Liao, Brian Patterson

Care coordination and planning is a complex task for hospital systems, best illustrated by the emergency department (ED) admission process. When deciding where to admit a patient from the ED into the inpatient units, the decision maker needs to balance multiple competing objectives such as the patient waiting time, level of care or specialty fit, and bed blocking of incoming patients. Coordination has become an increasingly complicated task as the result of the increase in hospital mergers and acquisitions, where patients may now have the option of being admitted or transferred to a hospital different from the one that they initially arrived. The use of discharge prediction models has been proposed before as a tool to enhance decision making in the admission process. In multisite healthcare systems, hospitals within the network may interact with each other, and in this case models to predict discharges in one location may benefit from using features/data from other hospitals in the system. In the study we present in this talk, we used more than 170,000 discharge records from two facilities in our partner health system to develop models to dynamically (i.e., near real-time) predict the number of discharges in the next one to four hours in the general care units and explore different strategies to account for the interactions between the different hospitals in the network.

2 - Hospital Occupancy Levels and Inpatient Falls

Jared Chiu, University of Toronto, Toronto, ON, Canada, Vahid Sarhangian, Sarah Tosoni, Laura Pozzobon, Lucas Chartier

Inpatient falls are the highest reported safety events in hospitals. In order to prevent falls, patients typically receive fall risk assessments soon after admission, followed by appropriate interventions. We present semi-Markov models of hospital stay to examine the impact of unit occupancy levels on (1) time-to-fall before receiving an intervention or discharge; and (2) time-to-assessment before fall or discharge. We estimate our models using data from a network of hospitals in Toronto, Ontario and identify a tipping point in unit occupancy level which results in significant reduction in time-to-assessment and increase in risk of fall.

3 - Predicting Long-Term Opioid use via Interpretable Machine Learning

Jingyuan Hu, UCLA Anderson School of Management, Los Angeles, CA, United States, Fernanda Bravo, Elisa Long

Long-term opioid use is associated with increased risks of misuse, addiction, overdose, and death. Early identification of patients at risk provides an opportunity for intervention. This work introduces the Long-Term Opioid Use Risk (LTOUR) model, a simple and interpretable risk-scoring tool developed using an optimization-based machine learning approach. Trained on California's prescription monitoring data, LTOUR performs comparably to state-of-the-art machine learning models while offering greater simplicity and ease of use for healthcare providers, making it a practical tool for real-world applications.

4 - Extended Cna Training Hours and Its Impact on Nursing Homes

Catherine Wang, Wisconsin School of Business, UW-Madison, Madison, WI, United States, Bob Batt, Hessam Bavafa

The study investigates the impact of extended Certified Nurse Aide (CNA) training hours on nursing home quality and staffing. CNAs play a critical role in providing care for residents in nursing homes, yet concerns persist regarding the adequacy of their training. While federal regulations mandate a minimum of 75 training hours, composed of clinical and didactic components, several states have opted to increase this requirement. However, the causal relationship between extended training hours and nursing home outcomes remains unclear. By analyzing changes in training requirements between 2009 and 2019, this study employs a Diff-in-Diff analysis to evaluate the effects on nursing home quality and staffing. The findings address challenges in quality improvement and staffing shortages faced by nursing homes, thereby enhancing resident care and ensuring workforce sustainability within the healthcare system.

5 - Operating theater planning and scheduling for cardiac surgery

Christopher Sun, University of Ottawa, Ottawa, AB, Canada, Thierry Mesana, Amirhossein Moosavi, Bahar Motamedivafa, Jonathan Patrick

Operating theaters are vital yet expensive assets in healthcare facilities, comprising crucial resources like operating rooms, surgeons, intensive care unit beds, and ward beds. Managing these resources efficiently is essential and intricate. This ongoing research investigates the operating theater planning and scheduling at the Ottawa Heart Institute, Canada. We aim to develop a methodology to construct a master surgical schedule and optimize the allocation of elective and emergency patients. The objective functions may include patient wait time, resource utilization and surgery cancellation costs. In this talk, we delve into our problem and solution approach, and share our initial findings.

Summit - Terrace Suite 2

OR Applications in Healthcare Delivery Systems

Invited Session

Health Applications Society

Chair: Esma Gel, University of Nebraska-Lincoln, Lincoln, NE, 68507, United States

Co-Chair: Thomas Kingsley, Mayo Clinic, Rochester, MN, United States

1 - Predicative Versus Prescriptive Analytics: a 30 Day Hospital Census Forecast for Resource Optimization of Hospital Practice as a Case Study

Thomas Kingsley, Mayo Clinic, Rochester, MN, United States

Our team developed a predictive model that could forecast hospital census across hospital service lines at a large academic hospital. The goal was resource optimization. However, our team discovered resource optimization could not occur in practice with predictive analytics alone. A prescriptive analytics approach was needed to achieve resource optimization goals.

2 - Rationing by Waiting TIME for Outpatient Clinical Appointment Workflows via Novel Patient Access Workflows

Esma Gel, University of Nebraska-Lincoln, Lincoln, NE, United States, Derya Kilinc, Mustafa Sir, Kalyan Pasupathy

Increasing demand for healthcare has necessitated the need to ration care resources by prioritization. We present the use of time windows for rationing by waiting time in outpatient settings. We demonstrate effectiveness for different rationing schemes using real-life transactional data from a leading academic medical center.

3 - Results from Randomized Controlled Trial of an AI Tool for ED and Hospital Operational Efficiency

Alex Ryu, Mayo Clinic, Rochester, MN, United States, Shant Ayanian

Hospital and ED overcrowding remains a significant concern. We designed and implemented an AI model that predicts ED patients' need for hospital admission, with the goal of improving hospital and emergency department efficiency. We discuss the results of a randomized, controlled trial of the AI tool to evaluate performance.

WA59

Summit - Ballroom 1

Strategies for Climate Mitigation and Sustainability

Contributed Session

Chair: Cara Marcy, EIA, Washington, DC, United States

1 - Charting the Climate: Estimating and forecasting greenhouse gas emissions in New Haven county in Connecticut

Peiyao Zhao, University of Massachusetts Amherst, Amherst, MA, United States, Jimi Oke

Climate change has been a pressing issue in society, leading to phenomena such as wildfires, rising sea level, and habitat loss. This is fueled by increasing concentrations of Greenhouse gases (GHG) in the atmosphere. To understand the sources of these emissions and devise effective mitigation strategies, analyzing current emissions pattern and predicting future emissions trends and shifts are paramount. While the development of a nationwide emissions inventory is essential, a regional-level emissions database is significant for local government to design tailored strategies for emissions mitigation. The study presents a greenhouse gas inventory estimation and projection framework specifically tailored for the local area, using New Haven county, Connecticut as a case study. We found that emissions in New Haven totaled 6.97 million metric tons of carbon dioxide in 2021. Among all the emissions from seven sectors (transportation, electricity consumption, solid waste, stationary combustion, agriculture and wastewater), fossil fuel related activities, such as on-road transportation and residential heating, were the primary source of emissions. Due to the fact that we have the most granular data in transportation sector and this sector was the highest emitting contributor, we utilized Gaussian process regression to forecast future vehicle miles traveled (VMT) based on historical trends. Subsequently, we estimated emissions under various VMT scenarios and evaluated the impact of different kernel functions on model performance. Besides, we discover the influence of external factors population, GDP to the model performance. Finally, the policy implication about the carbon dioxide reduction will be provided.

2 - The next generation of long-term energy modeling at EIA

Cara Marcy, EIA, Washington, DC, United States

This presentation will discuss updates related to Project BlueSky. Project BlueSky is an initiative out of the U.S. Energy Information Administration (EIA) to develop a next generation energy systems model, which will eventually be used to produce the Annual Energy Outlook (AEO) and International Energy Outlook (IEO). The new model will be designed to address the complexity and interconnectivity of the modern world and the uncertainty associated with markets, technologies, and international trade.

The EIA is a U.S. statistical agency that collects, analyzes, and disseminates independent and impartial energy information. A core aspect of our mission is to develop multi-decadal, long-term projections of the energy system. Because the energy system is moving at a faster rate than available data, the next generation model will account for future uncertainty in our long-term projections. It will also be nimble so that it can be updated quickly and flexible to handle rapid changes and emerging issues. Our next generation model will be made open source and accessible to the public.

3 - Flexibility-aware co-optimization of integrated low-carbon energy systems for enhancing networks' resilience in extreme events

Yu Weng, MIT, Cambridge, MA, United States, Ruaridh Macdonald

Global climate change induces more frequent extreme events worldwide. Events such as heatwaves, droughts, wildfires, storms, and higher temperatures have posed significant threats to infrastructure safety and the reliable supply of essential services like electricity. According to government data analysis, the occurrence of extreme weather-induced power blackouts has doubled in the past two decades, leading to substantial economic losses and endangering lives, especially during summer and winter. Facing potential disorder, a preventive scheme emphasizing regional self-sufficiency and flexibility analysis is indispensable to ensure the basic service of energy networks under possible stress scenarios. However, there lack of a joint decision-making model that plans for the future where extreme events occur more often. Thus, we propose to a Dolphyn-based framework to optimize the multiple energy carriers for a self-sufficient scheme planning. This planning maintains the basic service inside each region only requiring minimum or affordable extra support by making the most of distributed energy resources. Dolphyn is a decision optimization model enabling long-term low-carbon planning for multiple energy systems, i.e., power, hydrogen, biofuels, liquid fuels, and natural gas. It is an effective toolbox facilitating the network expansion co-optimization planning in the next decades and it can be extended easily. The availability of energy resources is quantified by the flexibility of energy carriers inside each zone. Embedding such flexibility with Dolphyn, the temporal and spatial shifting capability from resources in different energy domains can be utilized to enhance networks' resilience in extreme events.

4 - The Environmental and Economic Impacts of Carbon Tax Policies: A Case Study of GHG Emissions in South Asian Region Countries

Muhammad Suleman, Xi'an Jiaotong University, Xi'an, China, People's Republic of

Climate change is growing as an important issue worldwide, having the potential to have far reaching and irreversible environmental, social, and economic implications. One of the main causes of climate change is emissions of anthropogenic greenhouse gases (GHG). Specifically, CO2 emissions from numerous industrial processes and the combustion of fossil fuels. The power sector contributes significantly to Green House Gas emissions in Pakistan, India, Bangladesh, and other South Asian region countries. The corresponding eliminated for SAR countries would be 11%. If a carbon tax is implemented on SAR countries with higher rates of GHG emissions, hydropower and other renewable energy resources will be used to replace fossil fuels. As a result, power sector GHG emissions in Bangladesh, India, Pakistan, and other South Asia Region countries will be reduced by 55%, 20%, 26%, and 25% from baseline in 2050, respectively. Integrated Energy Model (IEM) in this paper was created using The Integrated Markal-Efom System (TIMES) modeling framework. The TIMES model is a strong tool for analyzing energy scenarios and assessing the impact of prospective policy changes.These findings highlight the significance of reducing GHG emissions through the imposition of a carbon tax.

Key words: Environment, GHG emission, carbon tax, SAR, Hydropower, power sector, IEM, TIMES

Innovative Approaches for Dynamic Data Analysis and Control

Contributed Session

Chair: James Bailey, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States

1 - Uncertainty Quantification by Set Membership: Convergence Rate Analysis for Control Dynamical Systems

Yingying Li, UIUC, Urbana, IL, United States, Jing Yu, Lauren Conger, Taylan Kargin, Adam Wierman

This paper studies uncertainty set estimation for unknown linear systems. Uncertainty sets are crucial for the quality of robust control since they directly influence the conservativeness of the control design. Departing from the confidence region analysis of least squares estimation, this paper focuses on set membership estimation (SME). Though good numerical performances have attracted applications of SME in the control literature, the non-asymptotic convergence rate of SME for linear systems remains an open question. This paper provides the first convergence rate bounds for SME and discusses variations of SME under relaxed assumptions. We also provide numerical results demonstrating SME's practical promise.

2 - Adaptive Online Learning with LSTM Networks for Energy Price Prediction

Salih Salihoglu, University of Miami, Coral Gables, FL, United States, Ramin Moghaddass

Accurate prediction of electricity prices is crucial for stakeholders in the energy market, particularly for grid operators, energy producers, and consumers. This study focuses on developing a predictive model leveraging Long Short-Term Memory (LSTM) networks to forecast day-ahead electricity prices in the California energy market. The model incorporates a variety of features, including historical price data, weather conditions, and the energy generation mix. A novel custom loss function that integrates Mean Absolute Error (MAE), Jensen-Shannon Divergence (JSD), and a smoothness penalty is introduced to enhance the prediction accuracy and interpretability. Additionally, an online learning approach is implemented to allow the model to adapt to new data incrementally, ensuring continuous relevance and accuracy. The results demonstrate that the custom loss function can improve the model's performance, aligning predicted prices more closely with actual values, particularly during peak intervals. Also, the online learning model outperforms other models by effectively incorporating real-time data, resulting in lower prediction error and variability. The inclusion of the energy generation mix further enhances the model's predictive capabilities, highlighting the importance of comprehensive feature integration. This research provides a robust framework for electricity price forecasting, offering valuable insights and tools for better decision-making in dynamic electricity markets.

3 - Disrupting Labor Exploitation

James Bailey, Rensselaer Polytechnic Institute, Troy, NY, United States, Bahar Cavdar, Yanling Chang

In work settings dominated by short-term contracts and high worker turnover, there is a heightened risk of wage exploitation. In this paper, we introduce a game-theoretical model to study wage theft in such settings. We use the principal-agent framework, categorizing the employer as the principal and the worker as the agent. We analyze the problem when the worker has no awareness of wage theft, and the only deterrence for exploitation is through external inspection and penalties. We show that the problem can be reduced to a single-decision variable and partially characterize the optimal solution to the principal-agent problem to understand the structure of verbal contracts and the resulting wage theft as a function of system parameters. Our analysis extends to different system factors, such as worker skill level, reservation utility, the frequency of inspections, and penalties. This analysis highlights the factors that amplify worker vulnerability, offering strategic insights to mitigate wage theft.

4 - Don't Leave Me on Read! How Avoidance-Based vs. Busyness-Based Attribution of Read Receipts Influences Relationship Outcomes

Yige Wan, Boston University, McKinney, TX, United States, David Fang

In 2012 instant messaging (IM) services such as Facebook Messenger and Whatsapp released the read receipt feature, allowing users to see when someone has read their message. Through a series of 4 online studies (N = 1421) this paper investigated whether individuals would provide a “desire to avoid” attribution or “too busy to respond” attribution when they send a message that was read without reply (RWR) or when they received a message that they RWR and how interpersonal relationships (e.g.trust, closeness, and reliability) become affected by RWR messages. Studies 1 and 2 found that both senders and receivers were more likely to attribute RWR messages to busyness (vs. desire to avoid). Study 3 posited that perceptions of interpersonal factors such as trust, reliability and closeness all dropped for both senders and receivers of RWR messages and that the drop was moderated by an individual’s desire to avoid attribution level. Study 4 further examined this effect in three relationship scenarios of varying closeness levels (parents, friends, and strangers) and found that strangers who sent a message that was RWR tended to underestimate the other party’s desire to avoid them whilst experiencing greater decreases in trust, closeness, and reliability. Additionally, a survey on layman beliefs showed that most participants favor the read receipt function, with nearly 30% being indifferent. When considering reasons why people might not reply after reading a message, the majority believed justifiable reasons such as busyness or forgetfulness, with only a small percentage thinking that they were intentionally ignored.

Summit - Ballroom 3

AI and Game Theory Applications

Contributed Session

Chair: Guoqing Zhang, University of Windsor, 401 Sunset Avenue, Windsor, ON, N9B 3P4, Canada

1 - A Machine Learning Based on Row Generation Algorithm to Solve the Cooperative Game

Miao Chang, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, China, People's Republic of, Lixin Tang, Shengnan Zhao

Cooperative game theory constitutes a significant category within the field of game theory. It has demonstrated considerable practical value across various domains due to its facilitation of cooperative endeavors among participants, leading to cost savings. In practical applications, while pure optimization-based solution methods, such as the row generation algorithm, can yield optimal solutions within a sufficient timeframe, they often require a substantial amount of time. Additionally, an important characteristic in real-world scenarios is that the intervals between successive problem-solving instances of cooperative games may be short, and the variations in the input data are typically minor. In this study, we introduce a machine learning-based technique that leverages the solution information from previously solved cooperative game problems to significantly enhance computational performance in solving similar problems in the future. The integration of machine learning technology with mathematical optimization accelerates the speed of traditional row generation algorithms in solving cooperative game problems while still ensuring optimality. As a versatile algorithm, the proposed method is applicable to almost all cooperative game problem. We have tested the performance of the proposed algorithm on several classic and significant cooperative game problems. The experimental results show that the proposed algorithm has a conspicuous performance improvement.

2 - Best of Both Worlds Guarantees for Smoothed Online Convex Optimization

Neelkamal Bhuyan, Georgia Institute of Technology, Atlanta, GA, United States, Debankur Mukherjee, Adam Wierman

We study the smoothed online convex optimization (SOCO) problem where, at each round t, a player plays an action x_t in response to a convex hitting cost and an additional l_2-norm cost for switching actions. This problem class has strong connections to a wide range of application domains including smart grid management, adaptive control, and data center management, where switching-efficient algorithms are highly sought after. Historically, these problems have been studied only from a worst-case viewpoint. We study the SOCO problem in both adversarial and stochastic settings, and in this process, perform the first stochastic analysis of this class of problems. We provide the online optimal algorithm when the minimizers of the hitting cost function evolve as a general stochastic process, which, for the case of martingale process, takes the form of a *distribution-agnostic dynamic interpolation algorithm*, which we call Lazy Adaptive Interpolation (LAI). In this setting, that is stochastic, we prove an $\Omega(T)$ expected regret for the adversarial optimal algorithm in the literature (ROBD). Further, we prove the poor worst-case performance of the stochastic optimal LAI through its sub-optimal competitive ratio. This reveals a trade-off between the stochastic and the adversarial worlds. Finally, we present a best-of-both-worlds algorithm that obtains the *optimal competitive ratio* while simultaneously achieving a *constant regret*.

3 - Configuring a distributed manufacturing supply network with an AI based integrated method

Guoqing Zhang, University of Windsor, Windsor, ON, Canada, Behrang Bootaki

In this talk, we present a supply network problem designed for a distributed manufacturing platform, where the manufacturing facilities are distributed across various locations with the support of Additive Manufacturing (AM) technologies. The proposed problem includes three different types of decisions: location-allocation, production planning, and product delivery routing, named the Location-Production-Routing (LPR) problem. To solve this complex problem, we develop a novel solution method that integrates machine learning surrogate models with a genetic algorithm. Our numerical experiments show that the proposed method can achieve near-optimal solutions. We also provide a lower bound analysis.

Co-Chair: Keegan Harris, CMU, Pittsburgh, PA, United States

1 - User Strategization and Trustworthy Algorithms

Sarah Cen, Massachusetts Institute of Technology, Cambridge, MA, United States, Andrew Ilyas, Aleksander Madry

Many human-facing algorithms---including those that power recommender systems or hiring decision tools---are trained on data provided by their users. The developers of these algorithms commonly adopt the assumption that the data generating process is exogenous: that is, how a user reacts to a given prompt (e.g., a recommendation or hiring suggestion) depends on the prompt and not on the algorithm that generated it. For example, the assumption that a person's behavior follows a ground-truth distribution is an exogeneity assumption. In practice, when algorithms interact with humans, this assumption rarely holds because users can be strategic. Recent studies document, for example, TikTok users changing their scrolling behavior after learning that TikTok uses it to curate their feed, and Uber drivers changing how they accept and cancel rides in response to changes in Uber's algorithm. Our work studies the implications of this strategic behavior by modeling the interactions between a user and their data-driven platform as a repeated, two-player game. We first find that user strategization can actually help platforms in the short term. We then show that it corrupts platforms' data and ultimately hurts their ability to make counterfactual decisions. We connect this phenomenon to user trust, and show that designing trustworthy algorithms can go hand in hand with accurate estimation. Finally, we provide a formalization of trustworthiness that inspires potential interventions.

2 - Matching of Users and Creators in Two-Sided Markets with Departures

Liang Lyu, Massachusetts Institute of Technology, Cambridge, MA, United States, Daniel Huttenlocher, Hannah Li, Asuman Ozdaglar, James Siderius

Many online platforms of today, including social media sites, are two-sided markets bridging content creators and users. Most of the existing literature on platform recommendation algorithms largely focuses on user preferences and decisions, and does not simultaneously address creator incentives. We propose a model of content recommendation that explicitly focuses on the dynamics of user-content matching, with the novel property that both users and creators may leave the platform permanently if they do not experience sufficient engagement. In our model, each player decides to participate at each time step based on utilities derived from the current match: users based on alignment of the recommended content with their preferences, and creators based on their audience size. We show that a user-centric greedy algorithm that does not consider creator departures can result in arbitrarily poor total engagement, relative to an algorithm that maximizes total engagement while accounting for two-sided departures. Moreover, in stark contrast to the case where only users or only creators leave the platform, we prove that with two-sided departures, approximating maximum total engagement within any constant factor is NP-hard. We present two practical algorithms, one with performance guarantees under mild assumptions on user preferences, and another that tends to outperform algorithms that ignore two-sided departures in practice.

3 - [Incentivize Mechanism and Communication Protocol for Federated Bandit Learning] Chuanhao Li

CHUANHAO LI, Yale University, New Haven, CT, United States, Zhepei Wei, Haifeng Xu, Hongning Wang

Federated bandit learning is an extension of the traditional multi-armed bandit problem applied to a distributed setting where multiple agents collaboratively explore a shared environment while preserving data privacy. This approach is critical in scenarios where communication between agents is costly, i.e., a communication protocol balancing regret and communication efficiency becomes essential.

However, most existing works take it for granted that all clients are altruistic about sharing their data with the server for the collective good whenever needed. Despite their compelling theoretical guarantee on regret and communication efficiency, this assumption is overly idealistic and oftentimes violated in practice, especially when the algorithm is operated over self-interested clients, who are reluctant to share data without explicit benefits, or even untruthfully report their cost to get higher payment from the platform. Negligence of such self-interested behaviors can significantly affect the learning efficiency and even the practical operability of federated bandit learning. In light of this, we aim to spark new insights into this under-explored research area by formally introducing an incentivized communication problem for federated bandits, where the server shall motivate clients to share their local data and truthfully report their associated costs. The proposed approach still guarantees the sub-linear regret and communication cost as prior works that forbid agents' strategic behaviors without any overhead, which demonstrates the possibility of simultaneously achieving incentive compatibility and nearly optimal regret in federated bandit learning.

4 - Online Strategic Classification

Saba Ahmadi, TTIC, Chicago, IL, United States, Avrim Blum, Kunhe Yang

In this talk, I discuss an online learning problem in the presence of strategic behavior. In this setting, a sequence of agents arrive one by one and must be classified as positive or negative just like in classic online learning. However, there is a twist: the agents wish to be classified as positive (e.g., consider loan applicants or college applicants) and have the ability to modify their features to a limited extent or at some cost. In particular, agents observe the current prediction rule and will manipulate their features to get classified as positive if they can do so for a cost less than their value for being classified as positive. Agents can manipulate their features in predefined ways, modeled by a manipulation graph. We show how to achieve a bounded number of mistakes when the target function belongs to a known hypothesis set and give upper and lower bounds showing how the graph structure impacts the achievable mistake bounds.

5 - Exploiting Observation Bias to Improve Matrix Completion

Yassir Jedra, MIT, Cambridge, MA, United States

We consider a variant of matrix completion where entries are revealed in a biased manner, adopting a model akin to that introduced by Ma & Chen (2019). Instead of treating this observation bias as a disadvantage, as is typically the case, the goal is to exploit the shared information between the bias and the outcome of interest to improve predictions. To that aim, we consider a natural and simple model where the observation pattern and outcome of interest are driven by the same set of underlying latent or unobserved factors. Under such setting, we propose Mask Nearest Neighbor (MNN), a matrix completion algorithm proceeding in two stages: first, recover (distances between) the latent factors by utilizing matrix estimation for the fully observed noisy binary matrix, corresponding to the observation pattern; second, utilize the recovered latent factors as features and sparsely observed noisy outcomes as labels to perform non-parametric supervised learning. The proposed approach is shown to enjoy entry-wise finite-sample error rates that are competitive with corresponding supervised learning parametric rates. Despite not having access to the latent factors, MNN enjoys such competitive performance by only exploiting the shared information between the bias and outcomes. Finally, through empirical evaluation using a real-world dataset, we find that with MNN, the estimates have 28x smaller mean squared error compared to traditional matrix completion methods, suggesting the utility of the model and the method proposed in this work.

Invited Session

Information Systems

Chair: Yue (Katherine) Feng, Hong Kong Polytechnic University, Hong Kong

1 - The Impact of AI Summaries on Video Consumption: Insights from a Randomized Field Experiment

Rui QIN, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Yue Feng, Dai Yao

Generative artificial intelligence (AI) technology has been increasingly adopted for content generation in online platforms. A prominent application of this technology is to generate condensed and synthetic summaries of content, which is originally of greater lengths and complexity. To understand the impact of AI summaries on the consumption of original content, we conduct a randomized field experiment on a major video content platform in China. We insert AI summaries to the comments of videos in the treatment group covering a broader range of life cycles, and track various user consumption behaviors of these videos and comparable control videos. Our results demonstrate that the inclusion of AI summaries effectively facilitates video consumption behaviors in diverse aspects, including views, likes, shares, and comments. Further analyses reveal the mechanisms behind these effects, which are contingent on the characteristics of video content, as well as the informativeness and credibility of the summary content. Our findings provide valuable insights into the role played by AI-generated content in online platforms and contribute to the growing body of knowledge surrounding the utilization of AI in content consumption. These insights carry significant implications for marketers, content creators, and platform providers.

2 - Bike-Sharing Systems&Rsquo; Spillover Effects in Local Communities: An Analysis of Business Foot Traffic

Zenan Zhou, Arizona State University, Tempe, AZ, United States, Tian Lu, Elliot Rabinovich

Bike-sharing systems have become an important micro-mobility alternative for many individuals, promoting both local transportation and healthy travel options. As operators strive to maximize user adoption and ensure a broad availability of bikes during station location planning, the establishment of new bike stations may also influence the local economy by affecting foot traffic to nearby businesses. This study seeks to empirically assess the impact of new bike stations on local business footfall. Given that a bike station functions both as a point of departure and a destination, and users may travel to other destinations or return to their starting stations, the effects on nearby business visits are not clearly understood. Addressing these questions could unveil broader benefits of bike-sharing systems and provide valuable insights for operators, local regulators, and business owners. Through an empirical analysis in the Los Angeles metro area, we estimate the effects on local businesses attributed to expansions in the city's bike sharing system and the trips these expansions generate. Based on this estimation, we also offer policy recommendations to help operators, local communities, and city governments maximize the benefits of bike-sharing systems.

3 - Does a Face Matter when It Comes to User Voice? Evidence from a Music Social Media Platform

Jordan He, Lehigh University, Bethlehem, PA, United States, Jia Gao, Jinqi Men, Oliver Yao

AI beauty filters have been increasingly become a standard add-on feature in social media applications, especially with photos and videos. While beauty filters are widely used across various applications and by users of all age groups, there are few studies that explore the effect of the beauty filter on the user-generated content (UGC). Drawing on the self-presentation and social exchange theory, we develop econometric models to fill this literature gap by empirically studying the effect of beauty filters adoption on user engagement such as video likes. We also examine whether the user face matters on a vocal-dominant social media platform that focuses on music entertainment. Interestingly, we find that beauty filters significantly enhance video likes more than singing quality, suggesting that facial appearance is more influential even on this vocal-dominant platform. We further explore interaction effects of singing quality and real facial features (e.g., smiling, eye contact) on the effectiveness of beauty filters. Results show that while beauty filters boost likes, their impact is moderated by both the quality of singing and genuine facial expressions. In contrast, accessories like glasses and headwear amplify the beauty filter effect, despite their general negative association with video likes. Implications for theory and practice are discussed.

Graphs and Algorithms in Social Media: Theories and Applications

Invited Session

Social Media Analytics

Chair: Pantelis Loupos, University of California, Davis, Davis, CA, United States

1 - Network Formation and Dynamics among Multi-LLMs

Marios Papachristou, Cornell University, Ithaca, NY, United States, Yuan Yuan

Social networks shape opinions, behaviors, and information dissemination in human societies. As large language models (LLMs) increasingly integrate into social and professional environments, understanding their behavior within the context of social interactions and networks becomes essential. Our study analyzes LLMs' network formation behavior to examine whether the dynamics of multiple LLMs are similar to or different from human social dynamics. We observe that LLMs exhibit key social network principles, including preferential attachment, triadic closure, homophily, community structure, and the small-world phenomenon when asked about their preferences in network formation. We also investigate LLMs' decision-making based on real-world networks, revealing that triadic closure and homophily have a stronger influence than preferential attachment and that LLMs perform well in network formation predictions. Overall, our study opens up new possibilities for using LLMs in network science research and helps develop socially aware LLMs by shedding light on their network formation behaviors and exploring their impacts on social dynamics.

2 - Graph Neural Networks for Causal Inference Under Network Confounding

Pantelis Loupos, University of California, Davis, Davis, CA, United States

This paper studies causal inference with observational network data. A challenging aspect of this setting is the possibility of interference in both potential outcomes and selection into treatment, for example due to peer effects in either stage. We therefore consider a nonparametric setup in which both stages are reduced forms of simultaneous equations models. This results in high-dimensional network confounding, where the network and covariates of all units constitute sources of selection bias. The literature predominantly assumes that confounding can be summarized by a known, low-dimensional function of these objects, and it is unclear what selection models justify common choices of functions. We show that graph neural networks (GNNs) are well suited to adjust for high-dimensional network confounding. We establish a network analog of approximate sparsity under primitive conditions on interference. This demonstrates that the model has low-dimensional structure that makes estimation feasible and justifies the use of shallow GNN architectures.

Applying Artificial Intelligence Models to Text Mining for Leveraging Business Value

Invited Session

Artificial Intelligence

Chair: Nohel Zaman, University of Alabama at Birmingham, Birmingham, AL, United States

1 - Discovering Unintended Consequences of App Usability from Online Reviews of AR/VR-integrated Apps using Text Mining Technique

Nohel Zaman, University of Alabama at Birmingham, Birmingham, AL, United States

This study focuses on applying the supervised text mining approach to extract the key terms specific to unintended consequences of AR-VR app usability. The results may help app developers and product designers improve the feature concerns of AR/VR-integrated apps and develop strategies to address feature suggestions to improve the app usability.

2 - Combining NLP and Data Visualization to Analyze Voluminous Narrative Text: Applications for Journalism, Law, Philosophy, and Research

Michel Mitri, James Madison University, HARRISONBURG, VA, United States

This presentation pertains to a software application called Story Analyzer (SA), which combines natural language processing (NLP) and interactive data visualizations to produce dashboards that help users navigate complex text documents. SA uses Stanford's CoreNLP as its NLP engine, which provides these services: sentence splitting, tokenization, parts-of-speech tagging, lemmatization, named entity recognition, dependency parsing, coreference resolution, and temporal tagging. Story Analyzer uses all these services for its information extraction. After information extraction, SA generates interactive dashboards depicting people, groups, their interactions, places and times of the interactions, and key themes from a story narrative. During my talk, I intend to discuss the CoreNLP's services, how they are used by SA to analyze narrative and discursive text, applications of these to current political and legal issues in the news, merging NLP results with interactive data visualization technology, and technical issues with implementing meaningful text-analytic dashboards for enlightening readers of complex text. I will demo some SA dashboards to illustrate the user experience. I also encourage you to view this video to get an idea of a typical SA dashboard: https://youtu.be/mnnF2md_Lh8.

3 - Detecting ICO Scams with Explainable AI

Ruilin Wang, UMass Lowell, Lowell, MA, United States, Xiaobai Li

Initial coin offerings (ICOs) are an increasingly popular method for startups to raise funds for business development. In this process, companies sell new digital tokens or cryptocurrencies to investors in exchange for capital. These tokens can be traded with other investors or used to purchase the company's goods or services. However, ICO projects are not bound by specific disclosure or audit requirements, leading to an unregulated environment that raises concerns about ICO-related fraud. Prior works have explored features that could indicate potential ICO fraud and developed methods to predict ICO scams. Machine learning and AI techniques have been used to predict ICO scams, but there is often a trade-off between accuracy and explainability. While complex models may offer greater prediction accuracy, they typically lack transparency and are harder to understand. This paper aims to improve the accuracy of ICO fraud prediction by using machine learning and AI techniques to extract features from ICO white papers. At the same time, it also adapts Large Language Models (LLMs) to enhance the interpretability of the results. This research will support legislative and regulatory efforts in the ICO market, help potential investors to identify ICO scams, and contribute to the application of LLMs.

Data Integration for Learning and Decision-Making

Invited Session

Artificial Intelligence

Chair: Kaizheng Wang, Columbia University, New York, NY, United States

1 - Non-Stationary Bandits with Auto-Regressive Temporal Dependency

Djallel Bouneffouf, IBM, Poughkeepsie, NY, United States

Traditional multi-armed bandit (MAB) frameworks, predominantly examined under stochastic or adversarial settings, often overlook the temporal dynamics inherent in many real-world applications such as recommendation systems and online advertising. This paper introduces a novel non-stationary MAB framework that captures the temporal structure of these real-world dynamics through an auto-regressive (AR) reward structure. We propose an algorithm that integrates two key mechanisms: (i) an alternation mechanism adept at leveraging temporal dependencies to dynamically balance exploration and exploitation, and (ii) a restarting mechanism designed to discard out-of-date information. Our algorithm achieves a regret upper bound that nearly matches the lower bound, with regret measured against a robust dynamic benchmark. Finally, via a real-world case study on tourism demand prediction, we demonstrate both the efficacy of our algorithm and the broader applicability of our techniques to more complex, rapidly evolving time series.

2 - Transfer learning for contextual multi-armed bandits

Changxiao Cai, University of Michigan, Ann Arbor, MI, United States

We study the problem of transfer learning for nonparametric contextual multi-armed bandits, where we have access to data pre-collected from source bandits to assist decision-making in the target bandit. We explore two cases: (1) the source dataset consists of expert demonstrations in which arm assignments predominantly reflect optimal choices; (2) it is produced by an exploratory policy in which suboptimal arms are uniformly randomly explored. The minimax rates of convergence for the regret are established and novel transfer learning algorithms that provably attain these minimax regrets are proposed. The results quantify the contribution of the data from the source domains for learning in the target domain in the context of nonparametric contextual multi-armed bandits, providing a precise characterization of the dependence on the distribution shift and behavior policy.

3 - Speeding up Policy Simulation in Supply Chain Reinforcement Learning

Tianyi Peng, Columbia University, New York, NY, United States, Vivek Farias, Joren Gijsbrechts, Aryan Khojandi, Andrew Zheng

Simulating a single trajectory of a dynamical system under some state-dependent policy is a core bottleneck in policy optimization algorithms. The many inherently serial policy evaluations that must be performed in a single simulation constitute the bulk of this bottleneck. To wit, in applying policy optimization to supply chain optimization (SCO) problems, simulating a single month of a supply chain can take several hours.

We present an iterative algorithm for policy simulation, which we dub Picard Iteration. This scheme carefully assigns policy evaluation tasks to independent processes. Within an iteration, a single process evaluates the policy only on its assigned tasks while assuming a certain 'cached' evaluation for other tasks; the cache is updated at the end of the iteration. Implemented on GPUs, this scheme admits batched evaluation of the policy on a single trajectory. We prove that the structure afforded by many SCO problems allows convergence in a small number of iterations, independent of the horizon. We demonstrate practical speedups of 400x on large-scale SCO problems even with a single GPU, and also demonstrate practical efficacy in other RL environments.

4 - Sequential Decision Making with Expert Demonstrations under Unobserved Heterogeneity

Keertana Chidambaram, Stanford University, Standford, CA, United States, Vahid Balazadeh, Vasilis Syrgkanis, Viet Nguyen, Rahul Krishnan

We study the problem of online sequential decision-making given auxiliary demonstrations from experts who made their decisions based on unobserved contextual information. These demonstrations can be viewed as solving related but slightly different tasks than what the learner faces. This setting arises in many application domains, such as self-driving cars, healthcare, and finance, where expert demonstrations are made using contextual information, which is not recorded in the data available to the learning agent. We model the problem as a zero-shot meta-reinforcement learning setting with an unknown task distribution and a Bayesian regret minimization objective, where the unobserved tasks are encoded as parameters with an unknown prior. We propose the Experts-as-Priors algorithm (ExPerior), an empirical Bayes approach that utilizes expert data to establish an informative prior distribution over the learner's decision-making problem. This prior enables the application of any Bayesian approach for online decision-making, such as posterior sampling. We demonstrate that our strategy surpasses existing behaviour cloning and online algorithms, as well as online-offline baselines for multi-armed bandits, Markov decision processes (MDPs), and partially observable MDPs, showcasing the broad reach and utility of ExPerior in using expert demonstrations across different decision-making setups.

5 - An Adaptive Neuron Reset Threshold for Maintaining Plasticity in Continual Learning

Adam Jozefiak, Massachusetts Institute of Technology, Cambridge, MA, United States, Vivek Farias

Recent literature has demonstrated that a neural network's ability to adapt to new data progressively deteriorates, commonly referred to as the loss of plasticity. Empirically, we find that many existing techniques for addressing plasticity loss are sensitive to the choice of their corresponding hyperparameter(s) where a single log-scale deviation often results in a substantial degradation of performance.
Therefore, these existing continual learning methods necessitate an exponentially larger hyperparameter search space, creating an additional computational cost to their deployment. To remedy this, we propose the adaptive neuron-reset threshold algorithm (ART) that addresses plasticity loss by selectively resetting neurons according to an adaptive threshold. ART has the flexibility to specify a single network-specific threshold, layer-specific thresholds, or neuron-specific thresholds, tailoring reset-threshold parameters to both the order and architecture of each layer. We verify through extensive experiments, on common continual learning variants of the MNIST and ImageNet datasets, that ART outperforms existing continual learning techniques while simultaneously being robust to its choice of hyperparameters. While ART still retains hyperparameters, they are naturally interpretable and our experiments demonstrate that any "reasonable" choice results in a performant algorithm. We additionally perform an ablation study with a fixed reset-threshold variant of ART, demonstrating that ART's adaptive layer-specific reset-thresholds

contribute to a more performant intervention, beyond simply alleviating the need for an exhaustive hyperparameter search.

Innovative Applications in Healthcare and Wellness

Contributed Session

1 - Optimizing Home Care Worker Assignments: A case study in British Columbia

Kibele Sebnem YILDIRIM, The University of British Columbia, Kelowna, BC, Canada, Mohammadsadra Nejati, Amir Ardestani-Jaafari, Hamidreza Eslami

The vital role of home care workers underscores the significance of efficiently managing their assignments, especially in regions where the availability of such workers is limited. The challenge lies in optimizing their schedules and routes to serve a diverse client base spread across various locations. Our aim is to cluster clients effectively, ensuring that each nurse is assigned a manageable workload within a close geographic proximity. By minimizing the driving distance between clients assigned to the same nurse, we strive to enhance operational efficiency and timely service delivery. To achieve this objective, we propose two methods. Firstly, leveraging regression techniques, we generate closed-form predictions of driving distances between clients using data from the Google Maps API. Subsequently, we explore the application of deep learning algorithms to refine these predictions further. Finally, we employ optimization techniques to allocate clients to nurses, considering both the predicted distances and the predetermined threshold for maximum travel distance. We validate our proposed methods through a case study conducted in the province of British Columbia, Canada.

2 - What kind of physicians do patients prefer, live streaming or not? Empirical evidence from online health communities

Binhua Ye, Tongji University, Shanghai, China, People's Republic of, Jiantong Zhang

The emergence of live streaming has given rise to a new economic paradigm, blending with the medical services, resulting in a novel modality known as physician live streaming (PLS). However, there is a dearth of evidence regarding the impact of PLS on physicians' online consultation performance. Drawing on the Interaction Ritual Chain (IRC) theory, this paper aims to address the existing research gap, with a primary focus on the influencing factors of live streaming characteristics, consultation characteristics, and the mediating role of Parasocial Relationship (PSR) between physicians and patients. We extract datasets from online health communities in China, which encompass live streaming and online consultation information of 951 physicians, and construct an quarterly-level unbalanced panel dataset. Employing the fixed effects model and difference-in-differences with propensity score matching (PSM-DID), the results reveal a significant positive effect of PLS on physicians' online consultation performance, with PSR mediating the relationship significantly. Moreover, the Emotional Energy (EE) between the physician and patient emerges as a salient moderating factor in the nexus between the physician's live-streaming service and their online consultation performance.

3 - Dynamic Linear Modeling of Social Determinants of Health During the Covid Pandemic

Rasim Musal, Texas State University, Austin, TX, United States, Tevfik Aktekin, Tahir Ekin

The Covid-19 pandemic has affected every aspect of society. We discuss the changes in the effects of social determinants of health for the duration of 77 biweeks on Covid-19 Mortality in the 58 counties of California. We specifically focus on the changes in the effect of median household income and poverty levels while controlling for other variables, including but not limited to vaccination rates, median age, population size and density as well as spatial effects within the counties. In investigating random and spatial effects we use Besag York Mollie model and utilize STAN platform for the application of the Bayesian framework.

4 - Machine learning for optimal test admission in the presence of resource constraints

Dmitry Krass, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Ramy Elitzur, Eyal Zimlichman

Developing rapid tools for early detection of viral infection is crucial for pandemic containment. This is particularly crucial when testing resources are constrained and/or there are significant delays until the test results are available – as was quite common in the early days of Covid-19 pandemic. We show how predictive analytics methods using machine learning algorithms can be combined with optimal pre-test screening mechanisms, greatly increasing test efficiency (i.e., rate of true positives identified per test), as well as to allow doctors to initiate treatment before the test results are available. Our optimal test admission policies account for imperfect accuracy of both the medical test and the model prediction mechanism. We derive the accuracy required for the optimized admission policies to be effective. We also show how our policies can be extended to re-testing high-risk patients, as well as combined with pool testing approaches. We illustrate our techniques by applying them to a large data reported by the Israeli Ministry of Health for RT-PCR tests from March to September 2020. Our results demonstrate that in the context of the Covid-19 pandemic a pre-test probability screening tool with conventional RT-PCR testing could have potentially increased efficiency by several times, compared to random admission control.

AI and Analytics in Operations and Logistics

Contributed Session

Chair: Christian Truden, University of Klagenfurt - Department of Operations, Energy, and Environmental Management, Klagenfurt, 9020, Austria

1 - Artificial Intelligence (AI) Security for Logistic Disruption Mitigation in Distributed Uav Swarms and Other Autonomous Cyber-Physical Systems

Lida Hagh, Old Dominion University, Norfolk, VA, United States, Mohammad Ghasemigol

New cyber-physical systems (CPSs) that integrate the physical and digital (cyber) spaces must be protected on critical infrastructures such as the Port of Virginia. Among new CPSs to support port operations, Unmanned Aerial Vehicles (UAV) are increasingly used in monitoring and communications for remote reconnaissance missions, surveillance operations, and supporting command and control. Many of these applications are distributed in nature, requiring coordination, planning, and often runtime reconfiguration to conduct operations. Traditionally, human decision-making controls UAV operations' movement and task completion. However, the literature is extensive indicating the limitations of this approach. Artificial Intelligence (AI) has emerged as a critical tool to overcome these limitations. We propose that methods would make risk mitigation and informed decision-making challenging. Unlike traditional intrusion detection systems, ML-based systems require less human intervention and are more effective in detecting new attacks.

2 - Apache Spark-Based Approach for Automated Polygon Generation in Maritime Operation Areas

Gabriel Fuentes, Norwegian School of Economics, Bergen, Norway, Justin McGurk, InKyung Choi, Kristoffer Overholdt Solberg, Eric Glenjen

Statistics generation from Automatic Identification System (AIS) data has been beneficial for maritime research. The process from raw data to statistics generation usually involves finding vessel port visits with AIS data and polygons outlining berths and anchorage areas. However, manual production of detailed polygons restricts such studies to local or regional contexts. To mitigate this, we present an automated approach for generating polygons that can identify critical maritime operational areas, including berths, anchorage zones, and Single Buoy Mooring areas. While current methods offer general approximations of port areas based on serial algorithms with limited AIS data, our technique extends this work by enabling recognition of specific berths and anchorages. This method, designed to leverage the power of parallel computing, can process worldwide AIS data within a big data architecture, such as Apache Spark.

3 - Disasters, Infrastructure, and Supply Chains

Seth Guikema, University of Michigan, Ann Arbor, MI, United States

Natural hazards regularly impact infrastructure systems, and both infrastructure outages and the hazard itself impacts supply chains. The dependence of supply chains on interdependent infrastructure poses significant analysis challenges for supply chain operators. This talk presents new approaches for estimating (1) loss of interdependent infrastructure services during natural hazards and (2) loss of functionality of supply chains due to both direct hazard impacts and loss of infrastructure services. The modeling approach is a combination of stochastic simulation and network theory and uses only publicly-available information to estimate infrastructure loss of service and supply chain impacts.

4 - ML-Based Prediction of Vehicle Fleet Performance in Routing Applications

Christian Truden, University of Klagenfurt - Department of Operations, Energy, and Environmental Management, Klagenfurt, Austria, Mike Hewitt

We present a method to perform a comprehensive analysis of the fleet composition problem that is suitable for most variants of the vehicle routing problem. Its basic principle is to estimate a fleet's performance by using the company's delivery planning tools in a black-box fashion. In a case study, we analyze the fleet size and mix for a fictional grocery home delivery service. A fleet comprising multi-compartment vehicles is employed, where each compartment is designated for storing groceries at specific temperature zones tailored to their storage requirements. In general, the stakeholders are interested in finding a fleet configuration that enables good performance regarding defined key performance indicators (KPIs). Seasonal demand changes occur in nearly all types of routing applications. Therefore, we aim to identify fleet configurations that ensure consistent and satisfactory performance across all seasons. We do not propose a methodology for choosing a fleet. This is because stakeholders may consider multiple KPIs when making fleet composition decisions, and these KPIs may be conflicting and vary by scenario. Thus, we focus on a method for predicting the values of multiple KPIs for a given fleet.

AI-Driven Cybersecurity

Invited Session

Artificial Intelligence

Chair: Tung Cu, Northeastern Illinois University, Chicago, IL, United States

1 - AI-Enabled Search Engines: Ethics, Privacy and Security

Tung Cu, Northeastern Illinois University, Chicago, IL, United States

The study conducted a systematic review of the social and technical challenges of AI-enabled Search Engines related to ethics, privacy, and cybersecurity. Firstly, the ethical dimensions of AI search engines are profound, as these tools shape our perception of the world but are often manipulated by commercial interests. The ethical challenges include issues like the distribution of knowledge, global dominance, and decision-making processes in displaying results. Secondly, privacy concerns are a central theme in the discourse surrounding AI. The use of AI for user profiling and data manipulation has raised alarms about the need for stringent data protection measures. Past research reflects public apprehension about the use of personal data by AI systems, especially in sensitive areas like education. They emphasize the importance of user awareness and acceptance of data tracking and profiling by AI systems. Finally, cybersecurity is intricately linked with AI advancements. Others address the security implications of AI, noting that ethical AI utilization in cybersecurity and hacking requires transparency, accountability, and fairness. The rapid advancement of Generative AI models like ChatGPT and Google Bard further complicates this landscape, as these tools can be used both defensively and offensively, raising new security and privacy concerns. Inclusion, we proposed a list of recommendations and policies to tackle the challenges. The body of research underscores the need for an interdisciplinary approach to address the ethical, privacy, and security challenges posed by AI search engines. This approach must balance technological innovation with the protection of individual rights and societal values.

2 - Exploratory Study on Factors Affecting Believability of Video-Based Misinformation

Calvin Cheng, Hong Kong Polytechnic University, Hong Kong , Hong Kong, Vanessa Liu

User-generated videos are made easy and quick by Generative AI image-to-video and text-to-video technologies. The extant literature on misinformation focuses primarily on texts or images. This study aims to fill this gap by adopting multiple theoretical perspectives to examine the factors affecting believability of video-based misinformation on social media. Drawing on the concepts of Autonomous Sensory Meridian Response, we test the effect of video-specific artifacts such as sound quality in shaping believability. While prior studies show that believability leads to viral behavior such as reposting, we investigate the reciprocal effect of virality on believability based on the social influence notion. Leveraging the social presence theory, we compare believability in AI generated videos vis-à-vis regular videos. An experiment will be conducted with 700 participants to empirically verify our hypotheses. The findings should be of theoretical and practical contributions to both the domains of social media and cyberlaw.

Electric Reliability and Resilience

Invited Session

ENRE: Electricity

Chair: Benjamin Leibowicz, The University of Texas at Austin, Austin, TX, 78712, United States

1 - The Value of Coordination for Restoring Power and Wireless Networks

Rachel Moglen, The University of Texas at Austin, Austin, TX, United States, Benjamin Leibowicz, Alexis Kwasinksi

In the aftermath of natural disasters, the rapid restoration of critical infrastructures—in this paper we focus specifically on power and wireless cellular networks—is imperative, yet challenging due to the complexities of their interactions. Cellular networks rely on the power network for electricity to operate, meaning their restoration processes cannot be siloed from power restoration. To support optimal power and cellular network restoration, we develop a framework that prescribes actions that maximize demand served by both networks. We analyze coordination dynamics between power network decision makers and wireless carriers, ranging from perfect coordination—where both power and cellular restoration efforts are optimized simultaneously—to zero coordination—where decision makers make restoration plans and execute independently and without knowledge of the other decision makers' restoration plans. We apply this framework to a case study in Guayama, Puerto Rico following a 50-year design storm hurricane and thereby explore how coordination can impact restoration outcomes in practice. We find that perfect restoration coordination can significantly improve cellular restoration outcomes at a limited cost to power restoration outcomes, relative to zero coordination. We also explore the impacts of partial coordination, where wireless carriers identify a limited number of critical assets that are prioritized in the power network's restoration problem. We find that this partial coordination can capture some of the benefits of perfect coordination relative to zero coordination, when carefully executed. Finally, we find that information sharing without modification to power restoration has limited ability to improve cellular restoration outcomes over the zero coordination case.

2 - The Short-Term Strategic Response of Residential Customers to Long-Duration Power Interruptions

Juan Pablo Carvallo, Lawrence Berkeley National Laboratory, Berkeley, CA, United States

Climate change is driving more frequent and intense extreme weather events, which in turn are producing longer and widespread electric service interruptions. These interruptions can have substantial economic impacts, but quantifying this impact remains elusive and understudied. This paper studies the response of residential customers to long duration power interruptions by identifying their actions after the event and the economic costs of both these actions and the interruption. We develop a novel survey instrument and apply it to over 1000 residential customers in the ComEd Illinois service territory for fictional summer and winter 1-, 3-, and 14-day long interruptions. Analyzing the response using probit regression, we find that customers are significantly more likely to relocate if they do not own a generator, if they live in multi-family buildings, and if they are poor. Rural customers, in contrast, are 27% less likely to relocate compared to their urban counterparts, revealing better adaptation to the hardship brought by lack of electricity service. We estimate that, overall, residential customers are 12% more likely to relocate for each additional day interrupted. Economic survey responses reveal that relocation is substantially more expensive than staying home, even when accounting for the direct impacts of the interruption, but over 80% of customers would relocate. Analyzing relocation costs by income bracket reveals that poor customers would spend, on average, their entire monthly income during a 14-day interruption, revealing substantial inequality concerns about resilience response. These results have important implications for the equality of electric interruption impacts, and for

3 - Anticipating Uncertain Infrastructure Interdependencies: A Case Study of Coupled Power-Transportation Networks

Alireza Rangrazjeddi, Vanderbilt , Nashville, TN, United States

Infrastructure systems consist of interdependent relationships, where various components interact through physical, functional, or logical connections. A disruption in one component can have a cascading effect, impacting the functionality of other components. Similarly, resilience planning in one network may impact the overall resilience of the system of coupled infrastructure networks.

Infrastructure interdependencies are often driven by physical connections between these networks represented by connected facilities and equipment. However, under uncertain conditions, such as climate-driven disasters, these interdependencies can become uncertain and change dynamically as the disaster is evolving. For example, in the case of power and transportation networks, power outages can impact traffic conditions due to failure in traffic signals. Consequently, blocked or congested roads can hinder the restoration of power outages due to significant delays and reduced accessibility of repair crews dispatched to restore the power grid. As such, understanding and evaluating the stochastic nature of infrastructure interdependencies is important to better prepare for and respond to disasters.

This study aims to develop a framework for understanding these complex interdependencies between components of infrastructure networks. We propose to use stochastic block models, a class of statistical network models, to evaluate the probability of such interdependencies evolving over the course of a disaster and as failures cascading across multiple network components. The study will specifically focus on the interdependencies between power and transportation networks. This probabilistic approach seeks to enhance the resilience and robustness of critical infrastructure networks against various disruptions.

4 - Resilient Capacity Expansion Planning for Power Grids in a Changing Climate

Berk Sahin, University of Texas-Austin, Austin, TX, United States, Erhan Kutanoglu, Andrea Staid

Extreme weather events have a significant impact on the power grid, affecting the operation of lines, substations, and generators, causing outages and disrupting service to populations that increasingly rely on power. Scientists believe that climate change will exacerbate these events. Therefore, integrating climate change and long-term resilience needs into the grid planning processes is essential for future power grid performance. In this research, we analyze ways to make optimal capacity expansion planning decisions, aiming to meet the future resilience, supply and demand needs of the grid while considering the nature and uncertainty of extreme events and climate change. We use realistic test cases based on actual power grids to compare the benefits of the proposed approaches considering the projected growth in various aspects of the grid including population, renewables, and electrification.

Data Analytics in Manufacturing Industry

Invited Session

Data Mining

Chair: Dohyun Kim, Myongji University, Yongin-si, N/A

Co-Chair: Jason Shin, Mississippi State University, 230 Brook Avenue, Starkville, MS, 39759, United States

1 - Development of a Graph Generation Model for Linking Heterogeneous Domain Graphs

SuA Yoon, Myongji University, Yong-In, Korea, Republic of, Dohyun (Norman) Kim

Analyzing heterogeneous data provides comprehensive and innovative insights that cannot be obtained from a single data type, making it essential for the advancement of knowledge and applications. This study develops a deep learning-based algorithm to generate graphs that connect heterogeneous data sources. Specifically, we present a model that integrates expert and corporate graphs to create a new graph linking experts and companies. This approach is expected to enhance connections and collaboration between experts and companies, thereby fostering innovation and improving decision-making processes.

2 - Llm-Based Recommendation System Between Manufacturing Enterprises and Experts

Ki Jeong Choi, Myongji University, Yong-in, Korea, Republic of, Dohyun (Norman) Kim

The increasing complexity of industrial processes and the rising demand for specialized knowledge have underscored the need for recommending experts to address challenges faced by manufacturing enterprises. Traditional recommendation systems struggle with this due to the textual nature of existing data on enterprise information, including challenges and expert profiles. Recent advancements in Large Language Model (LLM) technology have shown promise in overcoming these difficulties. We propose a recommendation system that utilizes LLMs to analyze textual data from manufacturing enterprise information and expert profiles, providing suitable expert recommendations to resolve specific enterprise challenges.

3 - Designing Electric Power Grid Investment Plans for Economic Growth and Energy Security

Kwon Gi Mun, California State Polytechnic University - Pomona, Irvine, CA, United States, Sungyong Choi, Mark Rodgers, Wenbo (Selina) Cai, Gül Çulhan Kumcu

This study presents a Generation Expansion Planning (GEP) model that determines the optimal capacity expansion investment plan while considering economic growth, energy security, and renewable energy considerations. Specifically, the motivation of this study is to leverage the power grid capacity expansion decisions in developing countries to facilitate sustainable economic development. To accomplish this, first, a relationship between energy generation and Gross Domestic Product (GDP) is established with an econometric model. Then, this linear relationship is integrated into the GEP model to support the expansion planning process. According to an exhaustive search of the energy literature, this is the first comprehensive study that endogenously integrates the GDP econometric function into the constraints of the GEP model. This study aims to provide policy development and analysis insights, especially for resource-rich, energy-poor countries. Further, this study presents a roadmap that developing countries can follow to increase GDP while reducing fossil fuel dependency and avoiding CO2 emissions from these sources.

4 - How Does the "Golden Screw" Problem Affect New Order Dynamics

Jason Shin, Mississippi State University, Mississippi State, MS, United States, Jason Miller, Judy Whipple

Industry practitioners and policy makers have a strong interest in understanding dynamics associated with manufacturing firms' new orders. In the United States, many organizations including the Institute for the Supply Management (ISM®), multiple branches of the Federal Reserve Banking System, and the Census Bureau each publish data on new orders to inform practitioners and policy makers. This research explores how the impact of shifts in manufacturing firms' new orders impacts their production, recruitment of workers, and their suppliers' lead times. We draw on economic theory regarding how economic activity behaves during periods of chronic shortage to explain why increases in new orders will have a less pronounced effect on production and employment but a greater impact on supplier lead times during periods of pronounced shortage. To test our theory, we assemble a unique archival dataset that melds ISM's Purchasing Manager Index (PMI) data with the Census Bureau's Quarterly Survey of Plant Capacity Utilization to obtain measures of shortages. We test our hypotheses using time series techniques. We find results consistent with our predictions, which have important implications for theory, practice, and public policy.

Applications on Data Analytics

Invited Session

Data Mining

Chair: Jiao Wu, Northern Illinois University, DeKalb, IL, United States

1 - Exploring the Impact of Virtual Instructor Design and Study Activities on Student Engagement and Emotional Responses

Jiao Wu, Northern Illinois University, DeKalb, IL, United States

This work explores students' emotional responses and study engagement with different types of virtual instructors (human-like versus stylized). We propose that the design of virtual instructors and the nature of study activities (lecture-based versus interaction-based) influence students' engagement and emotional responses. Utilizing Emotional Design Theory, we will analyze patterns and correlations in student interactions and feedback to draw meaningful insights. This research could contribute to the design of educational information technology and teaching strategies. The findings may enhance educational outcomes and support student well-being in technology-mediated learning environments.

2 - Enhancing Influencer Marketing: The Impact of Visual Attributes and Influencer–Product Gender Congruence on Consumer Engagement

Ying Wang, Northern Illinois University, DeKalb, IL, United States, Jaeki Song

This study examines the dynamics of influencer marketing, specifically the impact of visual attributes and gender congruence between influencers and products on consumer engagement. Utilizing framing theory and gender congruence literature, we suggest that visual elements like colorfulness, brightness, and vividness play crucial roles in driving active consumer engagement. Our analysis of 2,000 YouTube videos in feminine and masculine product categories indicates that colorfulness and vividness enhance engagement, whereas brightness may decrease it. Gender congruence between influencer and product significantly intensifies the influence of visual attributes on engagement. The findings provide a comprehensive understanding of how visual attributes and gender congruence interact in influencer marketing, offering theoretical insights and practical guidance for optimizing marketing strategies and enhancing the effectiveness of influencer marketing.

3 - Analyzing Key Factors Influencing Online Reviews of Historically Black Colleges and Universities (HBCUs) through Text Mining

Jiaxi Luo, Midwestern State University, Wichita Falls, TX, United States

This study employs text mining techniques to identify key factors influencing online reviews of Historically Black Colleges and Universities (HBCUs) using data from niche college rankings. Sentiment analysis, topic modeling, and keyword extraction algorithms are applied to uncover prevalent themes and sentiments in the reviews. The identified factors are analyzed to determine their impact on the perception of HBCUs. Additionally, a comparative analysis between HBCUs and other universities is conducted to highlight any distinct differences. The findings contribute to a better understanding of the unique challenges and strengths of HBCUs, providing insights for administrators, policymakers, and researchers to enhance the educational experience and support the growth of these vital institutions. The comparative analysis emphasizes the significance of HBCUs in the higher education landscape.

4 - Digital Transformation and Carbon Emissions: a Deep Neural Network Based Latent Dirichlet Allocation Approach

Jiang Hu, Texas A&M University San Antonio, San Antonio, TX, United States, Ying Teng

This study investigates the impact of digital transformation on firms' carbon emission intensity (CEI). Employing a deep neural network (DNN)-based Latent Dirichlet Allocation (LDA) to assess the level of digital transformation and Economic Input-Output Life Cycle Assessment (EIO-LCA) to quantify CEI, we analyzed data based on 1958 firm-year observations from 673 Chinese listed companies between 2010 and 2020. Our findings reveal an inverse U-shaped relationship between digital transformation and CEI. This relationship varies by firm type, specifically between firms operating in environmentally sensitive industries (ESF) and those operating in non-environmentally sensitive industries (NESF). While digital transformation has no significant impact on ESFs' CEI, it has a notable inverse U-shaped relationship with NESFs' CEI. Moreover, certain board characteristics, such as independence, gender diversity, and age diversity, negatively moderate the relationship between digital transformation and CEI. In addition to enrich the existing literature, our study provides valuable insights for government and industry practitioners.

3 - Triple Component Matrix Factorization: Untangling Global, Local, and Noisy Components

Naichen Shi, University of Michigan, Ann Arbor, MI, United States

In this work, we study the problem of common and unique feature extraction from noisy data. When we have N observation matrices from N different and associated sources corrupted by sparse and potentially gross noise, can we recover the common and unique components from these noisy observations? This is a challenging task as the number of parameters to estimate is approximately thrice the number of observations. Despite the difficulty, we propose an intuitive alternating minimization algorithm called triple component matrix factorization (TCMF) to recover the three components exactly. TCMF is distinguished from existing works in literature thanks to two salient features. First, TCMF is a principled method to separate the three components given noisy observations provably. Second, the bulk of the computation in TCMF can be distributed. On the technical side, we formulate the problem as a constrained nonconvex nonsmooth optimization problem. Despite the intricate nature of the problem, we provide a Taylor series characterization of its solution by solving the corresponding Karush–Kuhn–Tucker conditions. Using this characterization, we can show that the alternating minimization algorithm makes significant progress at each iteration and converges into the ground truth at a linear rate. Numerical experiments in video segmentation and anomaly detection highlight the superior feature extraction abilities of TCMF.

Decision Support for the Path to Net-Zero Emissions

Invited Session

ENRE: Energy-Climate

Chair: Jesse Jenkins, ZERO Lab, Princeton University, Princeton, NJ, United States

Co-Chair: Edgar Virgüez, Carnegie Science, Stanford, CA, United States

Co-Chair: Jacqueline Dowling, Carnegie Science, 260 Panama St., Providence, 94305, United States

1 - MACRO: A holistic planning tool for net-zero emissions energy and industrial systems

Jesse Jenkins, Princeton University, Princeton, NJ, United States, Filippo Pecci, A.D.T Perera, Luca Bonaldo, Sambuddha Chakrabarti, Ruaridh Macdonald, Jun Wen Law, Dharik Mallapragada

In a transition to net-zero emissions, energy and industrial systems will become increasingly coupled, as complex flows of electricity, hydrogen, bioenergy, and CO2 create strong interconnectedness across multiple energy vectors and industrial supply chains. Ideally, energy and industrial system planning models should be able to co-optimize multiple interconnected energy and industrial supply chains. Discrete planning decisions are also important, in order to capture the significant economies of unit scale that characterize many assets in energy networks and industrial facilities. And with electrification expanding the role of electricity across the economy and weather-dependent renewable resources moving to the center of the energy supply mix, such models should retain the high temporal and spatial resolution found to be critical in prior power systems planning research while considering uncertainty across multiple weather years.

These challenges motivate the development of MACRO, a next-generation holistic planning tool for net-zero emissions energy and industrial systems. This talk will discuss the computational advances necessary to enable capacity expansion models for integrated energy and industrial system planning with expansive scope, granular spatial resolution, high temporal resolution, and discrete planning decisions. That includes harnessing both temporal and spatial decomposition strategies to break apart these large-scale problems and take full advantage of parallel computing capabilities.

2 - Net-zero emissions energy systems

Steven Davis, Stanford University, Stanford, CA, United States

Net emissions of CO_2 by human activities—including not only energy services and industrial production but also land use and agriculture—must approach zero in order to stabilize global mean temperature. A review paper published in 2018 described the technological and economic challenges to deliver all modern energy services with net-zero CO_2 emissions. I will briefly recap the main takeaways of that work, discuss important technological and research progress during the past 6 years, and highlight current research frontiers. As the review paper did, the presentation will address four areas in particular: aviation, long-distance transportation and shipping; structural materials; reliable electricity; and carbon management.

3 - Integrated Energy Systems Perspective on Blue and Green Hydrogen in Net-Zero Energy Systems

Jun Wen Law, MIT Energy Initiative, Massachusetts Institute of Technology, Cambridge, MA, United States, Bryan Mignone, Dharik Mallapragada

The versatility of Hydrogen (H2), with multiple production technologies and potential end use applications, is one factor driving its growing appeal. However, this versatility leads to multiple potential pathways and cross-sectoral interactions that complicate its assessment. Here, we apply an open-source, multi-sector capacity expansion model (MACRO) to investigate the drivers of green and blue H2 deployment in a cost-optimized, net-zero energy system. MACRO represents the spatial and temporal coupling between the power grid, H2 infrastructure (production, storage, and transmission), and spatially resolved CO2 storage and biomass resources. In a case study of the contiguous U.S., we find that H2 deployment is primarily affected by H2 infrastructure such as H2 storage and pipelines. When such resources are unconstrained, green H2 accounts for the largest share of H2 supply, as it exploits the H2 infrastructure to maximize electrolytic H2 production at locations and times of low electricity prices and vice versa. In contrast, blue H2, which requires additional investments in negative emissions technologies and CO2 transport and storage, accounts for the largest share of H2 supply when H2 infrastructure is limited. Counterintuitively, increasing blue H2 operating flexibility with limited H2 storage and pipeline deployment increases green H2 deployment, as it also enables operational flexibility of green H2. Our analysis also sheds light on the value of grid-connected vs. islanded H2 systems under cost-optimized net-zero constraints. We find that grid-connected systems meet a greater share of H2 demand using electrolyzers, highlighting potential synergies of co-optimized electricity and H2 production in decarbonized energy systems.

4 - Improving the Performance of Risk-Adjusted Stochastic Unit Commitment for Clean Electricity

Dimitrios Floros, Duke University, Durham, NC, United States, Mauricio Hernandez, Kyle Bradbury, Dalia Patino-Echeverri

The increased likelihood of extreme weather events and the expansion of variable renewable energy (VRE) sources underscore the need for improved uncertainty characterization in electric power systems. Traditional real-time operation decisions for power generators and storage are predicated on single-point forecasts of electricity demand and energy supply for the planning horizon. Cognizant of the error in such forecasts, electricity system operators schedule assets so that the system has enough operating reserves to account for real-time deviations in demand and renewable energy production, which may lead to elevated reserve targets and system costs under higher uncertainty. A promising alternative that reduces system costs and enhances reliability is the stochastic unit commitment (SUC) methodology. Rather than using a single-point forecast, SUC utilizes an ensemble of plausible forecasts to inform operational decisions by pre-positioning all power-generating and storage assets to satisfy demand under each scenario. The applicability of SUC, however, is contingent upon the quality of the probabilistic forecast ensembles and the ability to solve the problem within the required time constraints. To this end, we introduce the solution learning approach (SLA) that identifies patterns in past SUC solutions and utilizes these patterns to solve future SUC problems promptly. We benchmark our framework in stochastic unit commitment within the Duke Energy system—the largest vertically integrated utility in the United States—showcasing the SLA's potential as a practical and scalable solution for enhancing SUC processes.

Energy Justice II: Equity in Energy Systems

Invited Session

ENRE: Other Energy

Chair: Weihang Ren, University of Florida, Gainesville, FL, United States

Co-Chair: Yongpei Guan, University of Florida, Gainesville, FL, United States

1 - Transmission Capacity Planning Through the Lens of Energy Justice

Weihang Ren, University of Florida, Gainesville, FL, United States, Yongpei Guan

In this paper, we present a novel transmission capacity planning framework that integrates energy justice principles and constraints. The transmission capacity directly influences the binding constraints within an ISO's economic dispatch model, ultimately determining energy prices. The proposed model incorporates various energy justice metrics to inform transmission capacity planning, introducing complementary constraints into the economic dispatch model. Our framework identifies optimal transmission capacity investments, prioritizing disadvantaged communities for enhanced energy access and equity.

2 - Distribution Grid Planning With Equity Objectives

Luis Rodriguez-Garcia, Lawrence Berkeley National Laboratory, Berkeley, CA, United States, Miguel Heleno

This talk presents an optimization model for an equity-informed deployment of distributed energy resources in power distribution grids. More specifically, this model decides on the location of solar generation and battery energy storage to enhance the resilience of power distribution systems to heat waves, while ensuring that the distribution energy resource installation is equitably distributed based on community vulnerability to extreme heat. The model considers a metric that captures the impact of power outages during extreme heat as an objective, initially analyzed on individual buildings and then aggregated for a system-level overheating inequity assessment. Through this implementation, state and local authorities can support decisions to foster equitable and resilient energy infrastructure development.

3 - Understanding Energy Burden in New England Households

Jie Xu, George Mason University, Fairfax, VA, United States, Siwei Li, Saba Siddiki, Feng Qiu

We analyzed the distribution of energy burden among households living in New England states using 5-year American Community Survey data. We trained machine learning models to identify major factors associated with energy burden.

Industrial Decarbonization II: Optimizing Hydrogen Use to Decarbonize the Transportation and Industrial Sectors

Invited Session

ENRE: Other Energy

Chair: Ahmed Abdulla, Carleton University, Ottawa, ON, K1S 5B6, Canada

Co-Chair: Ahmed Abdulla, Carleton University, Ottawa, ON, Canada

1 - Hydrogen Microgrids Could Facilitate Diesel Exit in Remote and Northern Communities

Ahmed Abdulla, Carleton University, Ottawa, ON, Canada, Ian Maynard

Most remote and northern communities in the Arctic continue to rely on diesel for their electrical and thermal needs, including to serve their industries and livelihoods. Communities and governments are working toward diesel exit strategies, but the role of hydrogen technologies has not been explored. These could serve both electrical and thermal loads, reduce emissions, and enhance energy security and self-determination. Here, we present results from energy optimization models that compare the cost, emissions, and resource requirements of both diesel and hydrogen microgrids across a large sample of varied communities. These models optimize the buildout of each microgrid and track how hydrogen is stored and used to serve both electrical and thermal loads over the course of the year. Our model shows that hydrogen microgrids remain less costly over their lifetimes than diesel systems across the majority of communities studied, though they require large overbuilding of electric power generation capacity to meet both electrical and thermal needs.

2 - Using Direct Air Capture Waste Heat for Hydrogen Production

Kieran Graham, Carleton University, Ottawa, ON, Canada, Kristen Schell, Erick Arwa

Direct air capture (DAC) of carbon dioxide is a promising technology to enable climate change mitigation. The liquid solvent DAC (LSDAC) process is one of the leading technologies being piloted. However, LSDAC uses a high-temperature regeneration process which requires a lot of thermal energy. Although current LSDAC designs incorporate pre-heat cyclones and a heat recovery steam generator to enable heat recovery, these do not maximize the use of the heat in the products of calcination. In this work, a process model is designed to maximize the use of waste heat from the LSDAC process to drive water electrolysis to produce hydrogen. Water use and net energy production from this new process are analyzed. Further examination identifies the price at which hydrogen production is prioritized.

3 - Optimizing Hydrogen Delivery to Heavy Duty Trucks in a Decarbonized Electricity Supply System

Andrew Moffat, Carleton University, Ottawa, ON, Canada

Heavy road freight transportation annually produces 66 million tonnes of greenhouse gas emissions in Canada, representing 9% of the country's total emissions—on par with its entire electricity system. To date, little progress has been made in decarbonizing this subsector. Current efforts in the field of freight decarbonization center around interventions in truck operations. These measures include platooning, autonomous operation, aerodynamic improvements, and electrification. Moreover, this research rarely considers the impacts of freight decarbonization on other sectors of the energy system, including the electricity system. Meanwhile, electricity system models often ignore the technological richness and uncertainties associated with freight decarbonization pathways. This research aims to bridge the gap by analyzing how freight decarbonization pathways affect the electricity system. The integrated assessment model includes: 1) a physics-based model to calculate truck energy use on road segments; 2) an uncertainty-informed demand load projection to 2050 that considers freight technology, electrification of light duty transport, climate, and population growth; and 3) a generation expansion planning model of the Alberta power system that determines where capacity should be built to serve the high demands of freight decarbonization. Results demonstrate that a switch to battery-electric traction could reduce total energy use to 15 PJ, while a transition to hydrogen would result in total energy consumption of 35 PJ (compared to 55 PJ of diesel), with substantial benefits to downstream emissions as both hydrogen and batteries have zero tailpipe emissions.

4 - The Impact of Uncertainty in Low-Carbon Industrial Demand on The Decarbonization of a Canadian Province: Results of a Generation Expansion Planning Model

Caleb Stairs, Carleton University, Ottawa, ON, Canada

As the world deals with the increasingly frequent and severe effects of climate change, it has become imperative that collaboration and proactive measures be taken at local, national, and international levels to reduce greenhouse gas emissions. Actions are required to shift energy use to low carbon and renewable sources. Forecasting models are needed to predict future energy needs and analyze the cost of meeting those needs.

This research analyzes the uncertainty in future energy demand in the small eastern Canadian province of New Brunswick and explores the effect of that uncertainty on generation expansion planning across the province. To date, provincial energy forecasting has been limited and mainly done by industry and government with little transparency. Such efforts often use scenario analysis rather than fully examining the uncertainties inherent in this activity. This research uses Monte Carlo simulation to develop predictions of energy needs integrating population growth, effects of climate, increased electric vehicle use and electrification of industry. A generation expansion planning model reveals the effect of uncertainty in this future demand on the cost and mix of resources required to achieve net-zero emissions by 2050.

Simulation & Analytics for Sustainable and Resilient Urban Networks - Session 1

Invited Session

Computing Society

Chair: Pavithra Sripathanallur Murali, George Mason University, Fairfax, VA

1 - On Local Topological Measures and Network Vulnerability Patterns: a Comparative Analysis

Nazanin Tajik, Mississippi State University, Mississippi State, MS, United States, Saviz Saei

This study examines how complex systems are vulnerable to the increasing impacts of climate change and extreme weather events. The focus is on the transportation infrastructure in the United States. The research measures the susceptibility of external events to random, targeted, and localized disruptions. Recent findings on local topological measures are synthesized to illustrate network vulnerability under various conditions. The research utilizes the 35 most commonly used local measures in critical infrastructures to quantify connectivity, accessibility, and criticality levels of (i) 15 popular topologies in social and physical network studies, (ii) the Nguyen and Dupuis network, and (iii) Sioux Falls Network. The results from topological and non-topological analysis demonstrate the effectiveness of local measures in explaining real-world critical infrastructure performance under different disruption scenarios.

2 - Decentralized Scheduling in Network-of-Networks Post-Disruption to Enhance Resilience: a Multi-Agent Reinforcement Learning Study

Pavithra Sripathanallur Murali, George Mason University, Fairfax, VA, United States, Shima Mohebbi

Optimizing task scheduling in interdependent systems characterized as network-of-networks post-disruption is crucial for enhancing resilience. Traditional centralized scheduling models fail to capture the dynamic complexities of these networks governed by interconnected nodes. This study proposes a decentralized scheduling approach using multi-agent reinforcement learning (MARL). The methodology leverages a hybrid simulation model that captures organizational and network evolution dynamics, enabling agents to autonomously carry out scheduling policies via MARL. A novel reward shaping method is incorporated into the reinforcement learning framework, allowing agents to learn from past experiences and schedule actions based on previous scheduling decisions. The increasing frequency of natural disasters underscores the importance of optimal scheduling for restoration efforts in critical infrastructures (CIs). By combining decentralized decision-making with a holistic view of the system, the proposed approach offers a solution that is both comprehensive and adaptable to the intricate nature of network-of-networks. The proposed model is applied to water distribution and mobility networks in Tampa, FL, demonstrating the efficacy of the decentralized approach in restoring components post-disruption and improving network resilience.

3 - Discrete Event Simulation Model for Capturing the Impacts of Virtual Health Adoption Rates for Outpatient Mental Health Clinics

Aaron Sporrer, US Air Force, Wright-Patterson AFB, OH, United States, Robert Curry, Anna Svirsko

The Defense Health Agency (DHA) is in the early stages of a historical advancement in the way healthcare is delivered to its 9.5 million beneficiaries world-wide. With an aim to improve access to care and patient experience with a reduction in resourcing, the agency has introduced a new “digital first” methodology to the Family Practice and Behavioral Health service lines at five venture sites with the intent of expanding to its remaining 703 Military Treatment Facilities in Fiscal Year 2025 and forward. The objective of this study is to assess how various adoption rates for virtual care may impact the resourcing requirements for the Behavioral Health Clinic at one of the venture sites (Wright Patterson Medical Center) and gain insights on how these advances may impact Military Healthcare at-large. To meet this objective, we use a discrete event simulation to model the implementation of virtual care within the Behavioral Health Clinic at Wright Patterson Medical Center. In particular, we study how an increase in virtual care appointments will affect provider utilization rates. Our analysis finds that while the transition to a “digital first” model has a modest impact on the resourcing requirements within the Behavioral Health Clinic, it has a substantial impact on workplace availability for Active Duty patients across the force.

4 - Integrated Intermodal Freight Models and Tools for Efficiency and Resiliency – Use of POLARIS agent-based simulation tool

Jesus Osorio, University of Illinois Urbana-Champaign, Urbana, IL, United States, Natalia Zuniga

The U.S. freight transportation industry is responsible for a significant portion of the nation’s greenhouse gas (GHG) emissions, and its under-capacitated infrastructure has exacerbated its vulnerability to disruptions. One of the primary barriers to the enhancement of freight network decarbonization and resiliency is the lack of an integrated, overarching, and data-driven modeling framework that can be used to predict, optimize, and provide decision-support for intermodal freight logistics operations.

This presentation introduces the proposal for the development of a series of integrated data and computational models, as well as associated executable computer programs, that would enable modeling and decision making on the nation’s intermodal freight logistics systems across water, roadway, and railway modes. System dynamics analysis under disruption scenarios will also be used to assess the system resilience. All these data and model capabilities will be integrated into POLARIS, a high-performance, computationally efficient tool that implements advanced travel and freight demand modeling, dynamic traffic assignment, and transportation simulation into an integrated modeling platform.

Optimization and Robust Linear Models

Contributed Session

Chair: Bo Tang, University of Toronto

1 - Uncertainty quantification for iterative algorithms in linear models with application to early stopping

Kai Tan, Rutgers University, Piscataway, NJ, United States, Pierre C Bellec

This paper investigates the iterates $\hbb^1,\dots,\hbb^T$ obtained from iterative algorithms in high-dimensional linear regression problems, in the regime where the feature dimension p is comparable with the sample size n, i.e., $p \asymp n$. The analysis and proposed estimators are applicable to Gradient Descent (GD), proximal GD and their accelerated variants such as Fast Iterative Soft-Thresholding (FISTA). The paper proposes novel estimators for the generalization error of the iterate $\hbb^t$ for any fixed iteration t along the trajectory. These estimators are proved to be $\sqrt n$-consistent under Gaussian designs. Applications to early-stopping are provided: when the generalization error of the iterates is a U-shape function of the iteration t, the estimates allow to select from the data an iteration $\hat t$ that achieves the smallest generalization error along the trajectory. Additionally, we provide a technique for developing debiasing corrections and valid confidence intervals for the components of the true coefficient vector from the iterate $\hbb^t$ at any finite iteration t. Extensive simulations on synthetic data illustrate the theoretical results.

2 - A Learning Based Large Neighborhood Search Framework for Mixed-Integer Linear Programming

Yu Sun, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, 110819, China, People's Republic of, Ying Meng, Lixin Tang

Mixed-Integer Linear Programming (MILP) is one of the most crucial modeling approaches in the field of combinatorial optimization. Since most combinatorial optimization problems are NP-hard, solving large-scale MILP models is time-consuming. In this paper, we propose a learning-based large neighborhood search framework to effectively solve the general MILPs. In the proposed framework, we first adopt the hypergraph partitioning technique to decompose the model into an arrow corner block structure, and then employ Graph Neural Networks (GNN) to identify integer variables in the model that are likely to appear in the optimal solution. Based on the obtained corner block structure and the information provided by the GNN, a construction heuristic algorithm named Decomposition Kernel Search (DKS) and an improved heuristic algorithm named Decomposition Graph Neighborhood Search (DGNS) are designed. Experiments on the MIPLIB2017 dataset demonstrate that our framework substantially improves the solving efficiency of MILP solvers.

3 - Sensitivity analysis for linear change of the constraint matrix of an LP

Quentin Louveaux, University of Liège, Liège, Belgium, Bardhyl Miftari, Damien Ernst, Guillaume Derval

Understanding the variation of an optimal value with respect to change in the data is an old problem of linear optimization. In this paper, we focus on a linear problem in which a matrix D modifies linearly the coefficients of the constraint matrix A. It can be used to analyze the impact of multiple linear changes in the constraint matrix. As a new approach to the problem, we derive five bounds which allow us to avoid recomputing the problem for numerous changes in the matrix A and provide guarantees on the objective function’s behavior. We discuss an iterative algorithm that use these bounds to compute an approximation to the original function within a given error threshold. We analyze the performance of the bounds on toy and real-world problems and demonstrate the effectiveness of the approach.

4 - Data-Driven Distributionally Robust Chance-Constrained Linear Matrix Inequalities

Fengjie Liang, The Hong Kong Polytechnic University, Hung Hom, Hong Kong, Jianqiang Cheng, Kai Pan

This paper presents approximation and reformulation techniques for Distributionally Robust Chance-Constrained Linear Matrix Inequalities (DRCCLMIs) to overcome the computational challenges arising from multidimensional integration and non-convexity of feasible sets. DRCCLMIs seek a robust solution which ensures the satisfaction of chance constraints across a wide range of possible distributions within an ambiguity set. In particular, we consider a data-driven ambiguity set which contains all potential distributions that share the same moment information. We first derive an inner approximation for the general form of DRCCLMIs to cope with common constraint structures encountered in the real world. The key method we use is the Conditional Value-at-Risk (CVaR) approach, which allows us to approximate DRCCLMIs in a way that ensures a certain solution quality while maintaining robustness. In addition, we also derive exact reformulations for a special case, i.e., DRCCLMIs with block matrix structure embedded in the linear matrix inequalities. Notably, our approximation and reformulation techniques help transform the original DRCCLMIs into more tractable semidefinite programming (SDP) problems, thereby simplifying the computational process and improving the accuracy of the solution. The effectiveness of these techniques are demonstrated through numerical studies on two real-world applications: truss topology design problem and calibration problem.

5 - CaVE: A Cone-Aligned Approach for Fast Predict-then-optimize with Binary Linear Programs

Bo Tang, University of Toronto, Toronto, ON, Canada, Elias Khalil

The end-to-end predict-then-optimize framework, also known as decision-focused learning, has gained popularity for its ability to integrate optimization into the training procedure of machine learning models that predict the unknown cost (objective function) coefficients of optimization problems from contextual instance information. Naturally, most of the problems of interest in this space can be cast as integer linear programs. In this work, we focus on binary linear programs (BLPs) and propose a new end-to-end training method to predict-then-optimize. Our method, Cone-aligned Vector Estimation (CaVE), aligns the predicted cost vectors with the normal cone corresponding to the true optimal solution of a training instance. When the predicted cost vector lies inside the cone, the optimal solution to the linear relaxation of the binary problem is optimal. This alignment not only produces decision-aware learning models, but also dramatically reduces training time as it circumvents the need to solve BLPs to compute a loss function with its gradients. Experiments across multiple datasets show that our method exhibits a favorable trade-off between training time and solution quality, particularly with large-scale optimization problems such as vehicle routing, a hard BLP that has yet to benefit from predict-then-optimize methods in the literature due to its difficulty.

Integrating AI in Healthcare Operations to Enhance Service Delivery

Invited Session

Service Science

Chair: Zhenzhen Jia, Xi'an Jiaotong University, Xi'an, N/A

1 - AI's Assistance in Disease Diagnosis: When Patients Cannot Access Advanced Tests

Zhenzhen Jia, Xi'an Jiaotong University, Shaanxi, China, People's Republic of, Jianqiang Hu, Kejia Hu, Sriram Venkataraman, Qingchen Wang, Ning Zhang

The accuracy of diagnostic processes significantly influences patient outcomes and carries considerable implications for service efficiency and quality within healthcare systems. However, this accuracy can often be compromised by financial, psychological, or physical barriers that restrict access to advanced diagnostic tests, especially among rural patients. In response to these constraints, our study explores the deployment of artificial intelligence to maintain high diagnostic accuracy, regardless of the availability of advanced test results. This paper introduces SIP-HD, a novel deep learning model that performs simultaneous imputation and prediction on high-dimensional data. Notably, our model utilizes the imputation process to enhance the accuracy of predictions. When benchmarked against various two-step models, one-step models, and doctors' preliminary diagnoses, SIP-HD exhibited superior performance in terms of accuracy, area under the curve, and F1 score. The proposed model offers significant potential to enhance diagnostic decision-making in real-world scenarios, particularly when advanced tests are inaccessible. Its adaptability amplifies its value, allowing it to serve as both a supportive diagnostic tool and a telemedicine aid, with a potential extension to an online self-diagnosis platform. These applications hold promise for improving service efficiency and quality within healthcare while also offering substantial cost savings.

2 - Nonparametric Data-Driven Algorithms with Inventory Competition and Demand Correlation

Lei Lei, Chongqing University, Chongqing, China, People's Republic of

We study stochastic inventory planning of two competitive firms with lost sales and instantaneous replenishment under inventory competition, i.e., a proportion of consumers will switch to another retailer in the case of stockout. The primary demands are allowed to be correlated, but the knowledge of the joint distribution of the primary demands is not available. At the same time, we observe only the sales quantity in each period without knowing the lost sales. Furthermore, it is impossible to distinguish the primary and spillover demands for each firm. We develop an algorithm to make the ordering decision in each period based only on historical sales data, and conduct numerical experiments to demonstrate the effectiveness of our proposed algorithm.

3 - Signaling quality with return policies: a social learning perspective

Huiwen Guo, Chongqing University, Chongqing, China, People's Republic of, Bingsheng Liu, Yinghua Shen, Yuan Chen

Amid the increasingly prevalent online shopping, consumers often exhibit considerable uncertainty in their product valuation. In response, firms may provide lenient return policies (e.g., partial returns or full returns) to encourage consumers to make purchase because these policies not only stimulate demand but may also signal quality. Yet, benefits derived from lenient return policies to firms may not be that straightforward, considering the increasing returned products and the signaling cost (as a high refund). Situation becomes more complicated when consumers can utilize online reviews, which often serve as a free channel for quality disclosure, to update their belief of product valuation. Through a two-period stylized model, this research analyzes the informational roles of return policies when product quality (either low or high) is the firm’s private information, as well as the strategic interaction between the firm and social learning consumers. We especially focus on the effectiveness of return policies as the signal of product quality, and how online reviews interact with it. Our analysis yields three main findings. First, the optimal partial-return policies serve as an effective signal of high quality for products with small salvage value or high exogenous price, where separating equilibrium exists. Second, for most of the firms, offering partial-return policies is more advantageous for them than no-return or full-return policies considering the increased firm profit. Third, the synergy between return policies and online reviews can better reveal the quality of products. Intuitively, by being distinguished from low-quality firms easily, high-quality firms benefit more from online reviews.

4 - Rethinking Appointment Scheduling: Addressing Counselor Burnout and Improving Patient Outcomes

Yuchen Liang, National University of Singapore, Singapore, Singapore

Since the growing demand for mental health services has placed significant strain on psychological counsellors, posing unique challenges for counselling clinic operations, we study the impact of mental stress on counsellor performance and clinic operations within the appointment scheduling setting. Utilizing a data-set from a counselling clinic in a Singaporean university, we examine the effects of workload and task complexity on counsellor behaviour. To improve clinic operations, we propose a scheduling heuristic that integrates workload and task complexity considerations, and develop a discrete-event simulation model to compare the results.

Modeling and Online Monitoring Techniques with Health Applications

Invited Session

Quality, Statistics and Reliability

Chair: Lu You, University of South Florida, Lutz, FL, 33620, United States

1 - Reduced-Rank Cox Regression for Analyzing High-Dimensional Multi-Response Survival Data with Hidden Confounders

Kai Yang, Medical College of Wisconsin, Milwaukee, WI, United States

In this talk, we present a low-rank Cox model that correlates multiple survival responses with high-dimensional mixed-type covariates in the presence of unmeasured confounders. In confounded regression, recent advancements focus on generalized or multivariate linear models, typically estimating latent components through linear factor models and drawing inference based on debiased Lasso. In many applications, however, the existence of discrete covariates makes linear factor models unsuitable. To overcome this limitation, we quantify the association between covariates and confounders using a generalized linear factor model and propose an efficient parallel algorithm for recovery of hidden confounders. Moreover, we design an effective estimation scheme to consistently determine ranks of coefficient matrices and compute estimators of regression parameters in the multi-response Cox model, employing the proposed adaptive nuclear norm and sparse-group Lasso penalty. To facilitate inference, we develop an innovative approach named hidden conditional independence regression, which transforms high-dimensional inference into low-dimensional regression problems. This idea is general and potentially can be extended to other high-dimensional inference problems involving unmeasured confounders. Our method outperforms existing approaches such as the debiased Lasso. It accommodates rare-event responses and between-response correlations. Theoretical and numerical studies demonstrate its effectiveness in practice.

2 - Online Risk Monitoring of Multiple Diseases by a Dynamic Screening System

Zibo Tian, University of Florida - Department of Biostatistics, Gainesville, FL, United States, Peihua Qiu

Disease early detection and prevention (DEDP) is an important topic in medical and public health research. Because disease risk factors are usually observed sequentially over time, DEDP is a sequential decision-making problem and statistical process control (SPC) charts turn out to be a powerful tool after the major complexities of the observed data (e.g., time-varying distributions and serial correlation) are properly addressed. In the literature, several SPC charts have been developed for solving the DEDP problem, but they are designed for detecting a single disease. In practice, however, we are often concerned about multiple diseases (e.g., different cardiovascular diseases), and there are no existing SPC methods designed for detecting multiple diseases yet due to its complexity. In this paper, a new dynamic screening system (DySS) is proposed for detecting multiple diseases. The new method first quantifies a patient's risk to each disease in concern at the current observation time, and then compares the quantified risk pattern with the regular risk pattern of non-diseased people that is estimated from a training dataset by a flexible longitudinal data modelling approach. The cumulative difference between the two risk patterns by the current observation time is used for determining whether a given patient has any of the multiple diseases in concern. Numerical studies show that the proposed method works well in different scenarios.

3 - Online Monitoring and Early Detection of Influenza Incidence Rates Using Exponentially Weighted Spatial Lasso: A Case Study in China During 2015-2020

Yuhang Zhou, University of Florida - Department of Biostatistics, Gainesville, FL, United States, Shoumi Sarkar, Yang Yang, Peihua Qiu

The People's Republic of China, since 2000, has developed an extensive nationwide surveillance network, focusing on various diseases, including influenza. This network's data is characterized by significant spatial and temporal variations, presenting a complex challenge in the real-time detection of deviations in the spatio-temporal (ST) process, such as outbreaks. The data structure in this network is intricate, encompassing complex ST variations and correlations. One notable aspect is that process shifts, often signaling the onset of outbreaks, typically start in small, clustered regions. However, existing literature in this domain is limited by fails to justify rigid distributional assumptions, other covariate effects, and ST data correlation. Addressing these limitations, the Exponentially Weighted Spatial LASSO (EWSL) approach has been developed. This method begins with establishing a baseline model using historical data, such as from 2014-2015, to describe the in-control ST pattern. The current observed data, like that of 2016, is then standardized and decorrelated for real-time monitoring. The EWSL model signals alerts when it detects deviations, demonstrating its effectiveness in accommodating the complexities of ST data, evidenced by small residuals and its success in identifying upward shifts in process mean, which would generally indicate disease outbreaks. This approach has significantly impacted disease surveillance and outbreak detection. Notably, it has reclarified the spread date of H7N9, suggesting an earlier spread than documented in existing literature, and detected early signals that may indicate the emergence of COVID-19. Furthermore, the model observed an increasing trend in influenza from 2014 to 2020.

4 - Joint Modeling of Multistate and Nonparametric Multivariate Longitudinal Data

Lu You, University of South Florida, Tampa, FL, United States, Falastin Salami, Carina Törn, Åke Lernmark, Roy Tamura

It is oftentimes the case in studies of disease progression that subjects can move into one of several disease states of interest. Multistate models are an indispensable tool to analyze such data. In this presentation, a joint model for simultaneous inference of multistate and multivariate nonparametric longitudinal data is proposed to analyze data and answer the research questions brought up in The Environmental Determinants of Diabetes in the Young (TEDDY) study, which is an observational study of at-risk children from birth to the onset of type-1 diabetes. The proposed method allows us to make statistical inferences, test hypotheses, and monitor future disease progression. The performance of the proposed method is evaluated by simulation studies. The proposed method is applied to the motivating example to demonstrate the capabilities of the method.

Point Cloud Analytics for Advanced Manufacturing Applications

Invited Session

Quality, Statistics and Reliability

Chair: Yujing Yang, The University of Texas at Arlington, Arlington, TX, United States

Co-Chair: Chen Kan, The University of Texas at Arlington, Arlington, TX, United States

1 - Point Cloud Representation Learning via Graph Signal Processing for Quality Assurance of Additive Manufacturing

Yujing Yang, The University of Texas at Arlington, Arlington, TX, United States

Recent advancements in 3D scanning technologies enable the capture of high-resolution 3D point cloud data, which provides a great opportunity for the detection of geometric defects and surface anomalies in additive manufacturing (AM) products. However, it is challenging to process layer-wisely scanned point clouds and extract defect-pertinent information, due to 1) the layer-to-layer geometric variations and 2) the sparsity of surface defects. To address these challenges, this study develops a novel point cloud representation learning approach based on graph signal processing. By representing point clouds as graphs and the adaptive learning of graph filters, this approach effectively detects both surface and geometric defects in the AM process. The effectiveness of the developed methodology has been demonstrated by both simulation and real-world case studies.

2 - Extracting Features from 3D Point Cloud for Design-Process Knowledge Discovery in Advanced Manufacturing

Zhaohui Geng, Ohio University, Athens, OH, United States

With the advancement of Industrial 4.0, three-dimensional (3D) point clouds have become ubiquitous in many applications, especially those related to the modern manufacturing industries. However, the lower quality of the models generated by 3D scanning or AM constrains the broader adoption of both technologies by the manufacturing industry. Moreover, it is critical to understand the relationship between geometric features, described by the point clouds, and the manufacturability of the advanced manufacturing techniques. The major bottleneck is the lack of suitable analytical methodologies to both fit their unique process characteristics and process the 3D point clouds to extract intricate design-process knowledge from the models produced by both processes. The objective of this presentation is to develop a novel machine learning-driven framework that can extract the process patterns, both global and local, concealed in the point cloud and, combined with the field knowledge, unmask and understand the intricate relationship between geometric design and advanced manufacturing processes. Case studies in additive manufacturing are presented to demonstrate and validate the proposed method.

3 - Pointsgrade: Sparse Learning with Graph Representation for Anomaly Detection by Using Unstructured 3D Point Cloud Data

Juan Du, The Hong Kong University of Science and Technology (Guangzhou), Guangzhou, China, People's Republic of

Surface anomaly detection by using 3D point cloud data has recently received significant attention. To completely measure the common free-form surfaces without loss of details, advanced 3D scanning technologies, such as 3D laser scanners, can be applied and will produce an unstructured point cloud. However, this irregular data structure poses challenges to anomaly detection, in that the existing methods based on regular data, e.g., 2D image, cannot be directly applied. This article proposes a sparse learning framework with a graph representation of the unstructured point cloud for anomaly detection (PointSGRADE). Specifically, the free-form surface is assumed to be smooth. Then, the associated point cloud can be represented as a graph. Subsequently, considering the sparse anomalies, we propose a sparse learning framework and formulate the anomaly
detection problem as a penalized optimization problem, which is further solved by a computationally efficient majorization-minimization framework. Case studies demonstrate the accuracy and robustness of the proposed method. This article proposes a novel methodology for sparse anomaly detection on smooth free-form surfaces represented by unstructured point cloud, which is critical for quality inspection in manufacturing and other application areas.

4 - Filtered Kriging: Improve Kriging Interpolation for Periodic Manufacturing Surfaces with a Pre-filter

Zhiqiao Dong, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Sixian Jia, Chenhui Shao

In modern manufacturing, high-resolution characterization of surfaces is essential in various quality control tasks, including surface quality inspection and tooling maintenance. However, direct high-resolution surface measurements are often prohibitively expensive and/or time-consuming. Interpolation methods are commonly used to obtain denser estimations from more affordable, low-resolution measurements. When 3-D point cloud data is collected over a surface area, it generally corresponds to 2.5-D measurements taken from non-uniformly distributed sites. To interpolate these scattered measurements, methods based on spatial process models, especially kriging-type techniques, are frequently employed. Periodic spatial correlations, which are common in manufacturing applications, cannot be adequately captured by conventional spatial models, thereby causing potential performance degradation or numerical issues. To address these challenges, we introduce a procedure termed filtered kriging (FK), which separates the periodic component using a bandpass pre-filter, allowing the residual to be well fitted with standard models. Drawing on signal processing theories, frequency-domain analyses are conducted to establish effective criteria and devise a practical bandpass filter design strategy. The effectiveness of FK is validated through case studies involving real-world periodic surfaces from two-photon lithography and ultrasonic metal welding. FK has been shown to capture spatial correlation more adequately than conventional methods, and achieves better interpolation accuracy.

Data-Driven Urban and Social Analysis

Contributed Session

Chair: Jin Fang, Clark University

1 - Unraveling Seattle's Travel Patterns Through Data Science Exploration

Yangyang Wang, University of Michigan, Ann Arbor, MI, United States, Tayo Fabusuyi, Yifei Sun

This study explores Seattle's travel patterns through a data-driven approach. We analyze social demographic factors, origin-destination pairs, and transportation modes to predict travel behaviors. Employing machine learning models and network analysis techniques, we uncover insights into travel behavior and network structures. Additionally, we develop a real-time user interface for interactive exploration. Validation with real-world data and population synthesis further enhances the robustness of our findings. Our study contributes to understanding travel dynamics and informs policy-making for transportation infrastructure in urban areas.

2 - Enhancing Road Safety: A Data-Driven Spatial Typology of Crashes in New England

Mohammed Abdalazeem, University of Massachusetts Amherst, Amherst, MA, United States, Jimi Oke

This research seeks to address the urgent need for a deeper understanding of roadway crash patterns to improve multimodal safety in New England. We are developing a data-driven spatial typology of crashes at the census tract level, drawing on a comprehensive dataset that integrates crash records, network topology, socioeconomic indicators, and travel behavior metrics from all six New England states. Using dimensionality reduction and clustering techniques, we identify distinct crash characteristic patterns, and reveal geographically-specific variations in crash types. Our analysis uncovers key differentiating factors, such as crash severity, contributing factors (e.g., speeding, weather conditions, roadway design), and modal involvement (e.g., pedestrian, cyclist, passenger vehicle). This research will ultimately produce a predictive model for classifying crash typologies and a publicly accessible database and interactive dashboard. These tools will facilitate data exploration and evidence-based decision-making for transportation safety practitioners, allowing for the development of targeted, data-driven strategies to mitigate crashes and improve safety outcomes.

3 - Analyzing Factors Influencing U.S. City Rankings Over Two Decades: A SEDEA and MRA Approach

Jin Fang, Clark University, Worcester, MA, United States, Yasamin Salmani, Fariborz Partovi

In this study, we analyzed the impact of various social, economic, and environmental factors on the evolution of city rankings over time. We collected data on major U.S. cities over a 20-year period and utilized the super-efficiency data envelopment analysis (SEDEA) model to determine the city rankings for 2000, 2005, 2010, 2015, and 2020. By examining the shifts in these rankings, and conducting a sensitivity analysis through multiple regression analysis (MRA), we identified the most impactful factors, such as cost of living, education, and income. The results significantly inform decisions for individuals choosing where to live and assist policymakers in enhancing urban socio-economic attributes. Additionally, the study provides businesses with essential insights for strategic planning and sustainable growth by identifying key contributors to the city livability index.

Optimization and Reliability in Engineering Systems

Contributed Session

Chair: Akshay Mutha, University of Vermont, Burlington, VT, United States

1 - The Price of Complexity in Experimentation

Yudi Huang, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Sebastien Martin, Tony Qin

Tech companies rely on continuous and frequent experimentation to enable rapid system updates. The goal is to implement changes that improve the system, as measured by the experiments' treatment effect. However, these changes may also increase the complexity of the system. For example, experimentation can be harder in the future due to increased potential interferences, or innovation can be slowed down due to technical debt, hurting the company in the long run. The issue is that this effect is hard to model and often overlooked in practice and literature. We use a Markov Decision Process (MDP) to model the development of a tech company as a sequence of experiments and system update decisions. Some changes may be very profitable in the short term but costly in the long term because of increased complexity, which makes the company's decision not trivial. Analyzing optimal policies, we uncover potential traps that lead to significant innovation slowdown, even if firms are aware of complexity issues and even if they can roll back problematic changes. We also show that measuring and anticipating complexity effects, even in a very imperfect way, can significantly help in the long run.

2 - Learning parametric valid inequalities for mixed-integer linear optimization

Shivi Dixit, University of Minnesota Twin Cities, Minneapolis, MN, United States, Qi Zhang

Efficient and safe process operations require decision-making in real-time. Many online decision-making frameworks involve solving discrete optimization problems, many of which present themselves as mixed-integer linear programs (MILPs). However, often the computational complexity of these MILPs presents a major challenge such that the long solution times render them ineffective in time-critical applications. To tackle this challenge, we previously proposed a data-driven surrogate modeling approach, where surrogate models for the MILPs were trained offline in a decision-focused fashion. These surrogate models are linear programs (LPs) and can be solved more efficiently online. While these LP surrogate models prove to be very efficient in providing near-optimal solutions, they are not guaranteed to preserve the true optimal solutions or to even directly predict feasible solutions.

In this work, we build upon our previous work and propose a method for learning effective valid inequalities offline. This is inspired by the cutting-plane method commonly used to solve MILPs, where adding valid inequalities (or cuts) results in tighter MILP formulations. In state-of-the-art MILP solvers, these cuts are added "on the fly" and need to be generated from scratch for every new instance. In contrast, the learned inequalities in our proposed framework are parametric in the input parameters such that they get automatically updated with every new instance. The resulting tighter MILP formulation can then be employed online where it is expected to solve more efficiently while obtaining the same optimal solution as the original MILP.

3 - Surrogate-Assisted Non-linear Economic Model Predictive Control (MPC) for Large-Scale Complex Industrial Semi-Batch Process

You Peng, The Dow Chemical Company, Columbus, OH, United States, Ivan Castillo, Ricardo Rendall

Semi-batch processes have been widely used in industry to produce high-value products. Economic model predictive control (MPC) can be implemented to maximize profits in real-time. However, MPC requires process models which can be difficult to obtain for semi-batch systems due to their non-linear and time-varying dynamics. Often times, we end up with a large system of nonlinear differential-algebraic equation (DAE) that are computationally challenging to solve. Therefore, having simpler but also accurate models can be extremely helpful.

Historically, linear state space models were used as the simplest form of approximation to non-linear process dynamics. However, this requires periodic updates on the controller around the linearized operating points and are only suitable for non-stiff systems. With the emerging of machine-learning based data-driven approaches in the past decade, neural networks (NN) especially structures like LSTM and Transformers that are designed for sequential data modeling, has become the most popular approach for developing dynamic surrogate models.

In this work, we compared a non-linear economic MPC implementation for a large-scale complex semi-batch chemical process at the Dow Chemical Company using 3 types of process models: a DAE based fundamental model with estimated kinetic parameters from process data, a linear state space model fitted from process data and a neural network based dynamic surrogate model trained using both process and simulation data generated from the fundamental model. The result indicates by using an effective surrogate such as NN, similar controller performance when complex DAE model is used can be achieved with much less computational resources.

4 - Product Acquisition for Remanufacturing

Akshay Mutha, University of Vermont, Burlington, VT, United States, Zhaolin Li, Daewon Sun, Jennifer Ryan

We develop models to analyze the acquisition of used products for remanufacturing operations. We perform numerical analyses to show the applicability of our models.

Advancements in Edge Computing and Networks

Contributed Session

Chair: Junghyun Kim, Ajou University, Suwon-si, N/A

1 - Deep Network Compression using Kernel Machines

Junghyun Kim, Ajou University, Suwon, Korea, Republic of, Hyunjung Shin

Recently, there has been a surge of interest in On-device AI, which enables Deep Neural Network (DNN) to operate efficiently on small devices (edge devices). For this, it is essential to compress the DNN into a lightweight model while maintaining performance comparable to the original model. One of the leading methods is pruning, which is used to compress models by removing less useful hidden nodes from the network. However, identifying redundant or irrelevant hidden nodes is still ambiguous. In this study, we propose a novel DNN compression method. First, the hidden nodes are transformed to transitional vectors and fed to the kernel machine. Second, a kernel machine plays a role of discerning critical nodes by checking node variability, which measures how sensitive the output values of the node changes depending on the samples. The experiments on benchmark datasets show that the proposed method maintains performance even when the original DNN model is reduced in size by more than 80%.

2 - Deployment Algorithm for End-to-End Time-Constrained Microservices on Geographically Distributed Post-5G Infrastructure

Hirotaka Kasahara, SoftBank Corp., Tokyo, Japan, Ryuichi Kitajima, Jun Towada, Osamu Sato, Takahiro Hirofuchi

This research proposes an efficient deployment algorithm for end-to-end (E2E) time-constrained microservices in the context of edge computing. Edge computing enables real-time data processing by performing computations near the data source, reducing network congestion and latency. The optimal placement of latency-sensitive microservice-based applications poses a challenge in edge computing environments. Such applications, including autonomous driving technology and sensor networks, require strict Quality of Service (QoS) requirements for processing speed and latency. To meet these requirements, it is crucial to minimize data transfer time from IoT devices to edge nodes and ensure responsive communication. To address this challenge, we propose a deployment algorithm that considers the unique characteristics of post-5G infrastructure. This infrastructure includes geographically distributed data centers, Multi-access Edge Computing (MEC), and a highly connected, low-latency, and reliable network. This paper focuses on defining a graph abstraction representation for microservices-based applications with E2E time constraints and formulating the deployment problem as an integer linear optimization problem. We propose a novel deployment technique called “sequential sub-path graph mapping”, which partitions the application graph to accelerate microservices placement calculations. The proposed approach’s effectiveness is demonstrated by comparing it with mixed-integer linear solvers, genetic algorithms, and heuristic methods. The proposed algorithm efficiently produces the application deployment solution that meets resource and E2E time constraints. The proposed algorithm exhibits superior performance in terms of resource utilization costs and minimizing the number of hops between microservices, outperforming existing heuristic methods and metaheuristic techniques.

3 - Decentralized Scheduling in Edge Computing Paradigms: End-to-End Decision Analytics and the Price of Anarchy

Jiayi Zeng, The University of Hong Kong, Hong Kong, China, People's Republic of, Wenjuan Hou, Qiao-Chu He, Zuo-Jun Shen

In this article, we design an edge computing system wherein a platform leverages incentive instruments to coordinate request-heterogeneous computing tasks and resource-heterogeneous edge servers. We propose an integrated optimization model in which the platform decides rewards and scheduling policy, and edge servers individually decide on service capacities, while each computing task minimizes its aggregate cost by selfish routing via available edge servers. We focus on system efficiency evaluation by measuring the Price of Anarchy of the entire system (PoAw), while the efficiency loss due to selfish routing is measured by the Price of Anarchy (PoA). At a strategic level, we decompose the PoAw by analyzing the double marginalization between the platform, edge servers, and computing tasks, which is significantly magnified by PoA. At an operational level, we propose a local-first, local-increasing-costs-and-nonlocal-decreasing-efficiency (LFID) scheduling policy to reduce PoA, with an interesting feature of reversed priorities between local and non-local tasks. In particular, we demonstrate the optimality of the LFID policy for general communication network topologies. The integrated optimization model is solved via reformulations based on SAA. To derive the equilibrium of the selfish routing game, two end-to-end (E2E) computational frameworks are proposed based on neural networks, which produce load data and facilitate solving the integrated optimization model. Case studies are conducted by combining both simulations and real data, and our results advise platform and service providers on scheduling policy design in the edge computing paradigm.

Summit - 330

Insights into Food Supply Chain and Food Insecurity

Contributed Session

Chair: Suzan Alaswad, Zayed University, Abu Dhabi, United Arab Emirates

1 - Optimizing Store Order Demand Forecasting for Distribution Centers through Data Aggregation Techniques for Store Prepared Items

Sara Branson, Afresh, Mead, CO, United States

Grocery stores rely on distribution centers to supply them with food, and these distribution centers, in turn, source their products directly from farms and food vendors. We use store order forecasts to determine the expected orders that will come into the distribution centers. This enables us to maintain only needed inventory at distribution centers, extending shelf lives and reducing food waste. In the process of forecasting store order demand for distribution centers, we faced difficulties in predicting the demand for products that are ordered in one form and sold in another. While some items are sold both in their original form and in a different form, others are exclusively sold in different forms. For instance, pineapple is sold both as a whole fruit and in sliced pineapple bowls. Another example is meat, where the store orders a sub-primal and sells it in various cuts but very rarely as it is. Current state of the art forecasting techniques fail to consider the contributions from store prepared components. To address this issue, we conducted experiments by using various data aggregation techniques to identify the one that yielded the highest forecast accuracy. We will discuss our approach and the results of our experiments, which improved the forecast accuracy of store order demand for distribution centers.

2 - Developing Data-Driven Market Intelligence Systems for Food Supply Chains

Xaimarie Hernandez Cruz, Arizona State University, Tempe, AZ, United States, J. Rene Villalobos, George Runger

In recent years, the traditional food supply chain has been scrutinized for various reasons, including its high food waste and lack of flexibility in reacting to disruptions in a timely manner. This work discusses an innovative, intelligent machine learning-based system that analyzes the fresh produce market in the United States (US). This system can collect and process relevant fresh produce data, monitor it to identify disruptions, verify the signals, and forecast market prices for any location within the US. Statistical monitoring methods, machine learning pattern recognition techniques, and transformer-based spatial forecasting and interpolation methods were developed to achieve the system's goals. By utilizing this system, supply chain participants will receive timely alerts about market disruptions, enhancing the flexibility of the supply chain and reducing food waste significantly. In this presentation, we discuss the developed market intelligence system and illustrate its components through case studies.

3 - Food distribution improvement via market design approach with optimization-based choice rule

Hou-An Chen, North Carolina State University, Raleigh, NC, United States, Umut Dur, Osman Ozaltin

In this study, we utilize market design tools, particularly matching theory, to offer a market-oriented approach to food distribution through food banks. We examine a market where a single agency can obtain goods from several distribution centers. Our formulation differs from previous studies as we elicit the actual preferences of the agencies for food bundles and incorporate accounts from multiple distribution centers. Based on the renowned Gale Shapley algorithm, our proposed mechanism includes choice rules for distribution centers. In particular, these choice rules are developed using optimization methods that consider three objectives: efficiency, equity, and effectiveness.

4 - When Does Food Become Surplus? A Game Theoretical Model for Partnerships in Food Supply Chains

Suzan Alaswad, Zayed University, Abu Dhabi, United Arab Emirates, Sinan Salman

Our paper presents a game theoretical model designed to examine the dynamics of business partnerships between commercial food supply chains and charitable organizations engaged in food redistribution. The primary objective of this model is to provide decision support and analytical tools for managing food effectively, by maximizing profitability for commercial organizations, minimizing costs for charitable organizations, and facilitating surplus recovery and redistribution within food supply chains. We explore the impact of uncertainties related to food freshness and consumer demand, as well as the effects of cost and operational parameters. Our model's solution, coupled with experimental results, sheds light on the intricate interplay between these factors and the decisions made by the involved parties. Our findings reveal a freshness threshold for the optimal decision-making process as food ages within the supply chain. Furthermore, we demonstrate that food age variance plays a pivotal role in the decision-making process. Higher variance in food age leads to a reduced value of the food for both commercial and charitable organization. These insights highlight the need for improved food age estimation technology and enhanced production, transportation, and storage conditions to minimize food age variance. By quantifying the benefits of such investments, our results provide valuable guidance for practitioners in the food supply chain industry, enabling them to optimize their operations while minimizing food waste. The implications of our research extend to various stakeholders, including government, semi-governmental, and commercial entities.

Assortment Planning

Contributed Session

Chair: Sang Won Kim, KAIST College of Business, Seoul, Korea, Republic of

1 - Platform Promotion and Sellers' Price Competition in e-Markets

Sang Won Kim, KAIST College of Business, Seoul, Korea, Republic of, yiying zhang, Youngsok Bang, bosung kim

We consider an e-commerce platform where both the platform and individual sellers provide promotions. We examine how platform-level promotions reshape the buyer structure on the platform, the price competition between individual sellers, and the inequality in sellers' sales. We build an analytical model that considers buyers' heterogeneity in price sensitivity and searching behaviors, as well as sellers' heterogeneity in attractiveness. Our results indicate that as platform promotions decrease the ratio of directly-purchasing consumers to price-comparing consumers on the platform, larger sellers increase their discount amounts faster than smaller sellers. Consequently, platform promotions exacerbate market inequality. We also conduct empirical investigations that provide evidence supporting our analytical findings.

2 - When to Push Ads: Optimal Mobile Ad Campaign Strategy under Markov Customer Dynamics

Guokai Li, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Pin Gao, Zizhuo Wang

We investigate a seller's optimal advertising campaign strategy targeting customers who interact with the seller over time. We model customers' engagement as a continuous-time Markov chain with two states, active and inactive. While in the active state, customers make purchases according to a Poisson process, with each purchase yielding a specific reward; in contrast, customers in the inactive state make no purchases. The seller can use advertisements to activate customers and the activation probabilities may be affected by customers' fatigue to promotion. The objective of the seller is to maximize the long-term expected average profit by designing an optimal ad campaign strategy based on customers' purchase histories.
For a single customer without budget constraints, we demonstrate the optimality of a triple-threshold policy based on the elapsed time since the last purchase or ad campaign. Moreover, we find that the seller tends to push ads earlier to customers with high purchase rates and low recapture rates (i.e., low transition rates from an inactive state to an active state). Surprisingly, we also find that the seller should push ads earlier to customers with intermediate churn rates (i.e., intermediate transition rates from an active state to an inactive state) compared to those with small or large churn rates.
When confronted with a budget constraint on the overall ad cost, we provide an asymptotically optimal poilcy that first solves a relaxed problem and then implements a separate threshold policy for each customer with a specified budget.

3 - Dynamic Assortment Selection and Pricing with Contextual Learning

Yigit Efe Erginbas, UC Berkeley, Berkeley, CA, United States, Thomas Courtade, Kannan Ramchandran

We consider a dynamic assortment selection and pricing problem in which a seller has N different items available for sale. In each round, the seller observes a d-dimensional contextual preference information vector for the user, and offers to the user an assortment of K items at prices chosen by the seller. The user selects at most one of the products from the offered assortment according to a multinomial logit choice model whose parameters are unknown. The seller observes which, if any, item is chosen at the end of each round, with the goal of maximizing cumulative revenue over a selling horizon of length T. To the best of our knowledge, we are the first to address the problem of dynamic simultaneous contextual assortment selection and pricing. For this problem, we propose an algorithm that learns from user feedback and achieves a revenue regret of order $\wt{\mathcal{O}}(d \sqrt{K T} / L_0)$ where L_0 is the minimum price sensitivity parameter. We also obtain a lower bound of order \smash{$\Omega(d \sqrt{T}/ L_0)$} for the regret achievable by any algorithm, showing that our regret rate is optimal up to logarithmic factors.

4 - Manufacturer-C2M or Platform-C2M: Comparative Analysis of an Innovative E-Commerce Model

Tonghuan Shi, School of Management, Fudan University, Shanghai, China, People's Republic of, Lin Tian, Yifan Xu

In e-commerce, manufacturers frequently launch new products but repeatedly fail due to mismatches with the market. Taking advantage of big data, platforms begin to mine consumer insights and incorporate them into the development process to drive product success, which is known as the customer-to-manufacturer (C2M) model. In this paper, we consider a setting in which a manufacturer distributes products through an online retail platform. We examine two typical C2M modes: one is that the platform sells data to the manufacturer, who then engages in C2M cooperation and develops new products (i.e., Manufacturer-C2M mode); the other is that the platform retains data and takes charge of all decisions related to C2M innovation (i.e., Platform-C2M mode). Our analysis shows that product prices in Platform-C2M mode are generally lower than those in Manufacturer-C2M mode when both firms succeed in their respective innovation. Besides, when the platform demonstrates a higher relative efficiency than the manufacturer, it will invest more to develop C2M products and thus have a higher success rate and vice versa. Furthermore, the preferences of the platform, the manufacturer, and consumers for the two C2M modes are largely determined by the data volume and moderated by the two firms' efficiency in developing products. Unexpectedly, the manufacturer is more likely to prefer the Platform-C2M mode as his efficiency improves relatively. And the platform's entry is not necessarily beneficial to consumers. Additionally, firms and consumers can only align with each other under the Manufacturer-C2M mode, and markets fitting this profile are common in practice.

5 - Dynamic Assortment with Demand Learning under Nonparametric Choice Model

Yifan Li, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of, Lei Xie, Chaonan Zheng

We consider a dynamic assortment selection problem. During each period, a customer arrives with a deterministic purchase pattern randomly according to a nonparametric choice model. The company offers a subset of n substitutable products with capacity constraint at K, from which the customer purchases according to the specific purchase pattern. All the potential types of purchase pattern are assumed to be known to the company, while the arrival probabilities of each pattern are unknown, and only the purchase information, rather than customers' type, is observable to the company. The company's objective is to optimize total expected revenue over T periods while learning the arrival probabilities by incomplete information. We design a policy that constructs a linear confidential space for the probability vector, and selects the assortment with highest potential revenue within the confidential space, reaching expected regret of order at O(√(κKT logκT)), where κ is the maximum number of how many combinations of arrival probabilities appear in the data set. In some cases mentioned in literature, κ can be proved not to be too large. In order to improve the solvability, we adopt the LP-relaxation on the assortment to solve the assortment optimization problem on [0,1]^n rather than on {0,1}^n and randomize the relaxed assortment back to {0,1}^n. Although it sacrifices the regret performance at O(√nKT+√(κKT logκT)+√nK T), where the O(√nK T) term is the penalty of relaxation, a boundary condition with relaxed assortment falling on {0,1}^n allows to drop the O(√nK T) term and ensures a sublinear regret.

6 - Causal Inference for Pricing of Airline Seats: Evidence from a Large Online Field Experiment

Ravi Kumar, PROS Inc, Houston, TX, United States, Shahin Boluki

We consider the problem of dynamic pricing of a product in the presence of feature-dependent price sensitivity. Developing practical algorithms for robustly estimating price elasticities, especially when information about no purchases (losses) is not available, is a challenge faced by many industries. Based on the Poisson semi-parametric approach, we construct a flexible yet interpretable demand model where the price related part is parametric while the remaining (nuisance) part of the model is non-parametric and can be modeled via machine learning (ML) techniques. We apply the double/debiased ML estimation methodology which makes the estimation of the price-sensitivity parameters robust to biases in the estimators of the nuisance parameters of the model and show the performance of the proposed estimation schemes on simulated and real data from the Airline industry. We also present results from a large scale comprehensive A/B test, which demonstrates that this methodology can substantially improve airline revenues through data-driven price optimization.

Assortment Planning with Multiple Warehouses

Contributed Session

Chair: Jayendran Venkateswaran, Indian Institute of Technology Bombay, Mumbai, India

1 - Warehouse Slotting Optimization

Jayendran Venkateswaran, Indian Institute of Technology Bombay, Mumbai, India, Meet Joshi

Efficient warehouse operations are critical in today's consumer goods supply chains, spurred by the tremendous growth in e-commerce. The key warehouse decisions explored in this study include slotting and routing. Slotting refers to the identification of dedicated bins/rack positions for a product or family of products. Order routing refers to the movement of personal/machines within the warehouse to pick-up multiple products of an order. A generic single warehouse consisting of five shelves, each with 25 columns and four levels, is considered. This study explores various algorithms to optimize slotting and routing processes of a warehouse, in response to dynamic customer demands.

The slotting phase employs clustering techniques such as KMeans, HAC, and Pairwise Clustering to identify groups of products frequently ordered together and is applied over single level slotting. For multilevel slotting, the Golden Section slotting strategy is used to predefine slots for stock keeping units (SKUs), and Genetic algorithm for finding optimal slotting.

Effectiveness of slotting strategies is further studied by comparing the total distance travelled and total time required for order picking using various routing options including S-shape routing, Return routing, Mid-point routing, and Travelling Salesman Problem (TSP). Additionally, Simulated Annealing meta-heuristics over TSP is used to optimize travel distance for multiple order picking. Computational experiments, with multiple replications, for slotting of 500 SKUs and with approximately 100 orders for pickups, varying in size from 2 to 50 SKUs per order, have been conducted. Insights into improving warehouse operations through improved slotting and routing are presented.

2 - Inventory Management with Actual Palletized Transportation Costs and Lost Sales

Willow Yang, Sam Houston Sate University, Huntsville, TX, United States, Kanglin Liu, Juan Zhang, Pamela Zelbst

Pallets are widely used for bulk shipping. In response to the call for more comprehensive research on inventory management that incorporates practical freight rates, this study investigates optimal inventory replenishment decisions by explicitly considering palletized shipping rates and lost sales in multi-product multi-period inventory system facing stochastic demand. We first introduce a stepwise transportation cost function that accurately captures real-world palletized less-than-truckload (LTL) and truckload (TL) shipment costs by accounting for both pallet quantity and truck capacity. We then formulate two novel inventory models that consider palletized freight costs and the coexistence of LTL and TL shipments, with one model excluding lost sales and the other specifically incorporating lost sales. We apply both models to a wholesaler in the U.S. and analyze the effects of varying shipping rates and lost sales on inventory decisions. Results show the inclusion of lost sales in the inventory replenishment model can potentially reduce total costs for the company. Interestingly, our findings contradict prevailing industry practices of maximizing truck capacity, revealing that filling up the "free" space on a truck may increase total logistics costs. This holds true even when shipping rates are relatively high and lost sales are considered. Furthermore, our results suggest that joint optimization of transportation and inventory decisions may not be necessary when shipping costs are small relative to inventory costs and lost sales are not considered. However, as shipping rates increase and lost sales are factored in, a joint optimization that accounts for all factors can yield much greater savings.

3 - Multiple-stage solution of the joint order batching and routing problem considering picker blocking for a mixed-shelves warehouse.

Jean-Raymond Fontin, National Taiwan University of Science and Technology, Taipei, Taiwan

Mixed-shelves storage strategy (or scattered storage strategy) has gained a lot of attention in the last 5 years in the literature due to shorter lead times of orders in e-commerce. Shops are forced to considerably decrease the picking time of items to fulfill orders on time. One of the solutions consists of placing Stock-Keeping-Units in multiple locations around the warehouse for greater accessibility. The strategy is called the mixed-shelves storage strategy. Solving the routing problem in a mixed-shelves warehouse is more complex than in other warehouses. When multiple pickers are involved simultaneously the problem becomes even more complex. In this work we present a multiple-stage solution of the joint order batching and routing considering real-life factors such as picker blocking for a mixed-shelves warehouse.

4 - Beyond Traditional Transshipment: A Flexible Mechanism for Multi-Echelon Logistics System

Zheng Tan, University of Science and Technology of China, Hefei, China, People's Republic of, Lindong Liu, Hanzhang Qin, Yugang Yu

Multi-echelon warehousing and logistics systems often incur high costs, particularly for heavy cargo that is inconvenient to store separately. Data from a home appliance logistics company shows that over 54% of orders require transshipment between warehouses, leading to significant operational costs. To address these challenges, we propose a Flexible Transshipment Vehicle (FTV) mechanism. The FTV unloads goods from the mainline fleet at multiple transshipment points, enabling flexible delivery and reducing overall transshipment costs. While static scheduling for FTVs has been studied with pseudo-polynomial algorithms, addressing this in a dynamic scenario remains challenging. We apply a distributionally robust stochastic dual dynamic programming (DR-SDDP) framework, which demonstrates promising out-of-sample performance. Numerical results show that introducing a single FTV can significantly reduce operation costs, with dynamic decisions outperforming greedy strategies without considering long-term effects.

Chair: Narendra Singh, Nazarbayev University, Astana, Kazakhstan

1 - Learning Cannibalization and Complementarity for Omnichannel Next-Basket Recommendation: A Novel Graph Neural Network Approach

Jiawei Chen, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of, Zufan Liu, Yue Qian, Yinghui Yang

Omnichannel retailing is a strategy that fully integrates all existing channels to offer customers a seamless experience. A core challenge in omnichannel retailing is recommending the next basket of products to customers in different channels to enhance their experience. To address this, we propose a novel graph neural network approach for omnichannel next-basket recommendation. Our modeling framework effectively captures and infers cannibalization and complementarity relationships between products both within and across channels. We evaluate our approach through comprehensive experiments with real-world data from an omnichannel retailer. Our proposed approach significantly outperforms other alternatives in next-basket recommendation performance for each channel. We also analyze the learned item relationships and provide practical insights.

2 - Buy Online and Return in Store via Partnership

Tao Xu, Drexel University, Philadelphia, PA, United States, Wenjing Shen, Joshua Ignatius

Online retailers are facing more challenges than offline retailers when it comes to dealing with customer returns. We study a BORS (Buy Online and Return in Store) model wherein the online retailers propose an agreement with the local offline retailers to offer offline returns to the customers instead of mailing them back through delivery services. Our goal is to seek what kind of return partnership agreements can benefit customers and both retailers. We find out that for the customers, even though they are offered with better return experience, the prices for the products when implementing BORS partnership will be higher than the prices without such policy. We show that the profits for both online and offline retailers may be higher when they implement the BORS partnership compared to the case when the online retailer provides dropbox to collect returns. BORS partnership policy benefits the online retailer by attracting more customers and when return happens, customers who choose to return in the offline store tend to purchase the substitute products which also benefits the profits of the offline retailers. Finally, we show that the per unit price agreement, in which for every returned product in offline store, the online retailers will pay a certain amount of money to the offline store, is only profitable when there are more high value customers. We provide the management insights to online retailers and help them make the decision on whether to adopt the BORS partnership to the offline retailers.

3 - Omnichannel Product Selection and Shelf Space Planning Optimization

Yajing Chen, Shanghai Jiao Tong University, shanghai, China, People's Republic of

As the retail industry is evolving toward an omnichannel paradigm, we study a product selection and shelf space planning problem faced by omnichannel retailers. We aim to maximize aggregated profits across channels by determining the optimal product offerings for the offline and online channels while optimizing the allocation of limited shelf space to these products in brick-and-mortar stores. Furthermore, the showroom effect of physical stores on online sales is also taken into account. We propose a corresponding model that jointly optimizes these decisions. To solve the nonlinear nonconvex model of practical scale, we first reformulate it into a mixed integer quadratic programming by exploring the structural properties. Next, we use the reformulation linearization technique to further improve the computational speed. Our numerical studies validate the efficiency of the proposed solution approach. In addition, we derive some managerial insights, including that retailers should adopt joint optimization and consider how the involved effects and parameters may influence their profits and decisions.

4 - Store brand interaction on e-tailer's showroom strategy

Yitong LIU, Shanghai Jiao Tong University, Shanghai, China, People's Republic of

Numerous e-tailers have implemented their own store brands in an effort to increase their supply chain competitiveness. And to cope with customers information uncertainty due to purchasing online, many e-tailers choose to open offline showrooms where customers can visit the store to try and inspect products. Our research aims to explore how the store brand interacts with the e-tailer's showroom strategy, including the market coverage investment and contract of sharing with other national brands. We consider a game-theoretic model with an e-tailer, with options to introduce its store brand and showrooms, and a national brand manufacturer (NBM), who sells its product through this e-tailer and could choose to display its product in the e-tailer's showroom with e-tailer's cost-sharing contract. We find that the e-tailer would enlarge the showrooms' market coverage if store brand exists when the operation cost of the showroom is reasonably low and the national brand is relatively less familiar to customers. Additionally, the e-tailer would have additional motivation to open showrooms following the introduction of the store brand. Interestingly, the e-tailer would even have increased profit on customers' disutility of online purchasing by carefully designing the cost-sharing contract. When the national brand is well-known, the e-tailer may refuse the NBM's participation. And when its fame is moderate, the NBM can be better-off from joining in the showroom, leading to a win-win outcome. However the e-tailer will exploit all additional profit of the NBM through manipulating the cost-sharing fraction of showroom if the national brand is rarely acknowledged.

5 - Remanufacturing of Consumer Returns by a Retailer: Implications for Supply Chains

Narendra Singh, Nazarbayev University, Astana, Kazakhstan

I analyze a supply chain where a manufacturer sells new products to consumers through a retailer and the retailer also offers remanufactured products from consumer returns. I examine how strategic interactions among the manufacturer, the retailer, and consumers affect the supply chain profits in the presence of remanufacturing of consumer returns.

1 - Diversification of Definitions of Latent Attirtion by Customer Segment in Non-Contractual Settings for Multi-Channel, Multi-Brand Firms

Giwon Son, Korea Advanced Institute of Science and Techonology, Seoul, Korea, Republic of, Sungho Park

Although prior studies have addressed definitions of customers' latent attrition in non-contractual settings through customer base analysis, there are few discussions on how it can be defined at firm-wide level in multi-channel, multi-brand firms. Since their customers enjoy unique experiences that each brand and channel offers, along with firm-wide benefits, these customers may exhibit highly diverse purchasing and exploring behaviors. Therefore, applying the same fixed time-window across all customers, on which attrition is defined as non-purchases in existing studies, may be inappropriate for our setting. Survival analysis may be an alternative approach, but it could require considerable computational time and costs if the number of observations and/or variables is large. In this study, leveraging transaction, exploration, and experiential data from a beauty and personal care firm, we propose a methodology to define latent attrition, aiming to optimize profitability of the anti-churn marketing campaign by examining customer segments derived from various methods, including the RFM criterion and a machine learning clustering algorithm such as BIFGS. We also provide key factors crucial for predicting attrition in our setting.

2 - Competitive Persuasion with Biased Disclosure

Yue Feng, Tianjin University, Tianjin, China, People's Republic of

Companies often induce consumers to buy by disclosing product information, such as advertisements, audits, and survey reports. Despite the importance of information disclosure, it is crucial to recognize that firms' self-disclosed information is often tainted with bias. Firms tend to exhibit positive bias when presenting information about their own products, aiming to downplay any negative aspects and emphasize the positive attributes. On the contrary, when disclosing information about competitors' products, firms may adopt a negative bias, exaggerating the flaws and concealing the strengths of rival products.

In this paper, we investigate a competitive-information-design variant where two rival firms employ biased information disclosure in a sequential Bayesian persuasion game to influence consumer purchase decisions towards their respective products. The primary contributions of this article are twofold. Firstly, it delves into the endogenous decision-making process of the competing firms, specifically focusing on the critical determination of whether to disclose their own information or that of their competitor. Secondly, the paper presents tailored information design strategies for competitive scenarios, particularly addressing situations where consumers' prior beliefs about the two products differ.

3 - Exploring the Current State and Future Prospects of Servitization in Small and Medium-sized Enterprises: A Follow-up Study

Chulok Ahn, Kunsan National University, Gunsan-si, Jeollabuk-do, Korea, Republic of, Sungyong Choi

Servitization has emerged as a crucial strategy for manufacturers, particularly for gaining a competitive edge in the market. While numerous success stories have been reported, most of the existing studies focus on large enterprises, leaving a gap in understanding its applicability to Small and Medium-sized Enterprises (SMEs). In this follow-up study, we delve into the current state and future prospects of servitization specifically within SMEs. Our focus industries are electrical equipment manufacturing and basic metal parts production, chosen due to their relevance across manufacturing sectors.

Employing a qualitative research approach, we conducted in-depth interviews with CEOs, managers, and employees from selected companies in these industries. The analysis aimed to assess the current level of servitization and identify potential opportunities for further integration of services into their business models. Our findings reveal that the level of servitization in these industries remains relatively low among SMEs, with limited prospects for significant changes. Challenges such as capital constraints and limited human resources hinder the adoption of servitization practices.

However, despite these challenges, companies acknowledge the importance of servitization for long-term sustainability and express willingness to embrace opportunities for growth in the future. By revisiting these companies and observing any evolving trends or shifts in attitudes towards servitization, our study seeks to contribute to a deeper understanding of servitization dynamics within SMEs and provide insights for enhancing their competitiveness in the evolving market landscape.

4 - Optimizing Reusable Packaging Production Decisions and Return Logistics in E-commerce

Bartu Arslan, Eindhoven University of Technology, Eindhoven, Netherlands, Albert Schrotenboer, Zumbul Atan

Increasing environmental concerns and the growth of e-commerce necessitate sustainable practices in the retail industry. In collaboration with an industry partner, we introduce an optimal control framework for managing reusable packaging logistics in online retail. From the perspective of a reusable package producer, we consider a dynamic system integrating multiple packaging sizes, production decisions, online retailers, and delivery services. We focus on balancing the number of reusable packages within the system with the cost of intervening in the return process. The flow starts with the initial production of reusable packages, followed by allocation to retailers, and then delivery to customers. Subcontracted delivery services facilitate the delivery and retrieval of packages, forming a semi-open supply chain network due to potential losses during transportation. The core of our study is the collection decision of packages from delivery depots to the producer's warehouse, incurring large fixed costs for truck dispatches and variable costs for each visited depot. This resembles a stochastic Joint Replenishment Problem (JRP). We model this as a Markov Decision Process, considering sequential production, fulfillment, and replenishment decisions to minimize overall costs, including production, logistics, and inventory costs. To solve this complex problem, we employ Deep Reinforcement Learning and heuristic methods to manage the system's high-dimensional state space. Our solutions aim to outperform traditional approaches, providing near-optimal strategies for reusable package management and offering insights into sustainable practices in online retail logistics.

1 - Online Facility Location: Running Stores on Wheels with Spatial Demand Learning

Yan Zhang, McGill University, Montreal, QC, Canada, Junyu Cao, Wei Qi

A shift toward shopping at (autonomous) wheeled vending stores is redefining urban retail. Compared with traditional brick-and-mortar stores, such mobile stores are cost-efficient to deploy and adaptive to fast-evolving business environments. However, mobile stores are confronted with unknown demand and limited capacity. Store mobility enables demand learning and profit maximization, yet an optimal dynamic store location policy remains unclear. We model this "learning-and-earning" problem by taking optimistic actions under parameter uncertainty. The joint optimization over parameter and action set is complicated by the combinatorial nature and infinite choices within the action set. We overcome these challenges by leveraging continuous approximation methods, and then propose a continuous-approximation optimistic (CA-O) learning framework under some special problem structures. Nevertheless, for more general scenarios, the problem remains intricate due to the nonconvexity in unknown parameters. We alternatively propose a CA-O faster learning algorithm by utilizing first-order approximation techniques and further proving a closed-form gradient to guarantee computational efficiency. We theoretically analyze and numerically validate the regret for the proposed algorithms. In a Toronto case study, our algorithm significantly outperforms baselines. Mobile stores earn higher profits than brick-and-mortar stores through demand learning and store mobility. More broadly, this paper envisions the future landscape of urban retail enhanced by omnipresent mobile facilities.

2 - Bulk vs. Sequential Product Returns: Algorithms and Insights for Assortment Planning

Sahika Sahan Konur, Texas State University, McCoy College of Business, San Marcos, TX, San Marcos, TX, United States, Jacob Feldman

The convenience of online shopping has transformed it into a retail powerhouse. However, this shift has significantly increased the frequency of product returns, imposing additional costs on retailers, including refurbishing and restocking. Our paper tackles these challenges by comparing the Sequential Returns model by Wagner and Martínez-de Albéniz (2020) with our newly proposed Bulk Returns model. The Sequential Returns model assumes customers purchase one item at a time, while the Bulk Returns model caters to consumers who order multiple products simultaneously. Each model integrates a returns disutility parameter to quantify the inconvenience of returning items.

In this paper, we focus on the assortment optimization problem under both returns models. The goal is to select a subset of products to offer to maximize expected profits. We show that even without return costs, the assortment problem under the Bulk Returns model is NP-Hard. Moreover, we show that there exists an optimal polynomial-time algorithm for the Sequential Returns model when return costs are homogeneous. Our theoretical analysis indicates the Sequential Returns model generally yields higher expected profits and market share. Numerical experiments using real-world data measure the profit improvement afforded by the Sequential Returns model. We also analyze how this profit improvement compensates for the potentially increased number of return trips in Sequential Returns model, which is capped at one under the Bulk Returns model.

This study provides key insights for optimizing product recommendations and managing return behaviors, offering strategies for retailers to enhance profitability and customer satisfaction amidst return costs and inconveniences.

3 - Impact of Market Thickness and Heterogeneity on Matches in Online Marketplaces with Active Providers

Jayashankar Swaminathan, University of North Carolina Chapel Hill, Chapel Hill, NC, United States, Nur Sunar, Rahul Roy

In online service marketplaces, supply-side thickness (the number of providers) is widely believed to be crucial for facilitating matches, i.e., transactions between providers and customers. The empirical literature generally supports this view, providing evidence for the hypothesis that market thickness increases matches, albeit at varying rates. This support is typically obtained in contexts with a passive seller listing where all sellers are readily listed for customers. Distinctively, our study empirically examines an online marketplace where providers are active, meaning they must extend a proposal to be listed. For our study, we collaborated with a leading U.S. online solar marketplace that connects solar panel installers with potential adopters. We use an instrumental variable approach and advanced clustering algorithm to investigate how supply-side thickness affects transactions in such marketplaces. Our analysis of an online marketplace with active providers reveals results that challenge the conventional understanding: We find a significant, inverted U-shaped relationship between market transactions and supply-side thickness. This indicates that transactions initially increase with thickness up to a certain thickness threshold, after which they begin to decline. This finding diverges from the general understanding in the literature, suggesting the need for new marketplace design strategies. We show that increased market heterogeneity negatively impacts transactions, and this effect is exacerbated in thicker markets. To our knowledge, this is the first empirical study that explores the effect of market heterogeneity on marketplace transactions with active providers. Our findings highlight the complex effects of increased thickness and heterogeneity, offering valuable managerial insights.

4 - Dynamic Decision Making with Operational Data Analytics (ODA)

Revenue Management: Sustainable and Fair Approaches

Invited Session

Revenue Management and Pricing

Chair: Mina Iravani Mohammadabadi, Hong Kong, Hong Kong

Co-Chair: Ozge Sahin, Johns Hopkins Carey Business School, Baltimore, MD, United States

1 - Fairness-Aware Assortment and Pricing Optimization under Inventory Constraints

Yanzhi Li, City University of Hong Kong, Hong Kong, China, People's Republic of, Hongbin Zhang, Yu Yang

We study a retail platform that sells products from multiple suppliers with inventory constraints. The platform aims to maximize the minimum expected revenue of all suppliers by personalizing assortments and prices to customers, whose purchase behavior is unknown. Assuming customer choices follow a sequential multinomial logit (SMNL) model, we develop online learning algorithms for various scenarios, considering different planning horizons and inventory bounds. Our algorithms achieve sub-linear regrets in all cases, ensuring fair treatment of brands and improved engagement in the e-commerce environment.

2 - Transparency and Power Dynamics: A Game Theoretic Analysis of the Supply Chain Due Diligence Regulations

Ali Shantia, HEC Paris, Paris, France, Sara Rezaee Vessal, Sam Aflaki

We explore the impact of supply chain sustainability policies, focusing particularly on the roles of asymmetric bargaining power and transparency. Utilizing a game-theoretic model within a two-tier supply chain framework, the study uncovers that the asymmetric power distribution between buyers and suppliers crucially influences sustainability compliance levels. Key findings suggest that a strategic balance between high sustainability standards and corresponding non-compliance penalties is essential for enhancing policy effectiveness. However, the effectiveness of these standards and penalties is contingent upon the relative bargaining power of supply chain actors and the degree of transparency within the chain. Limited transparency typically results in only partial compliance with sustainability policies. Consequently, the optimal formulation of these standards and penalties must be tailored to the specific power dynamics and transparency levels present in the supply chain. For managers, the study emphasizes the necessity of comprehending supply chain dynamics to foster effective sustainability compliance. Moreover, policymakers are advised to consider these dynamics when designing sustainability policies, thereby potentially increasing the sustainability and ethical responsibility of supply chain operations.

3 - Default or Dare: The Impact of Defaults on Consumer Choice, Assortment, Pricing, and Estimation

Jing Peng, University of Science and Technology of China, Hefei, China, People's Republic of, Ming Hu, Ruxian Wang

The default effect, the tendency of individuals naturally to pay more attention to the default option than alternatives. We incorporate the default effect into the classic multinomial logit choice model and study the associated problems. We characterize the default effect by multiplying an enhancement factor with the attractiveness of a selected product. Interestingly, setting a default option is unnecessary to benefit the total expected profit, while optimally setting the default option guarantees an improvement of the total expected profit. We find that the optimal selection of the default option depends on the product markup and attractiveness, as well as the magnitude of the default effect. Moreover, jointly optimizing the default option and assortment shrinks the size of the optimal assortment while jointly optimizing the default option and prices improves the markups of all products. In the extensions, we first consider selecting multiple default options with different enhancement factors and characterize the optimal selection of the default options to maximize the total expected profit. Second, we identify the conditions under which the optimal sequence of default selections is the same for both the firm and consumers. Third, we incorporate product fairness into the default optimization problem and develop an algorithm to find the optimal default option efficiently. Fourth, we characterize the default effect by additive enhancement and show the optimal default option and pricing policy. Finally, we develop a maximum likelihood estimation method and use synthetic data to validate the proposed model and illustrate how to mitigate estimation bias.

4 - Size Substitution and Fairness in Assortment Optimization

Alireza Alavi, McGill University, Montreal, QC, Canada, Mehmet Gumus, Javad Nasiry

In retail settings, customers facing size stockouts may opt to substitute with neighboring sizes. Stockouts also raise fairness concerns, especially among marginalized size groups. We develop static assortment optimization algorithms to find profitable yet fair assortments in the presence of size substitution and fairness concerns.

5 - The Impact of Multi-unit Promotions on Sustainability and Fairness: Waste and Fair Allocation

Mina M Iravani , Hong Kong University of Science and Technology (HKUST), Hong Kong, Hong Kong, Ozge Sahin, Ying-Ju Chen

Sustainability has emerged as a paramount concern in today's world, as urgent environmental challenges like climate change, deforestation, and ocean pollution loom large. Excessive consumption and the resulting waste generation are major contributors to these issues. Unfortunately, common marketing strategies often employed by sellers to incentivize consumers to purchase more mostly exacerbate this problem. While these strategies may enhance equity by increasing consumer access to products, they also pose a threat to the environment. Consequently, striking a balance between sustainability and consumer access becomes a crucial and challenging task. We focus on pricing bundles and analyze its impact on sustainability and equity. We propose a novel strategy that not only decreases the waste and increases consumers' access but also improves the seller's profit. We compare the proposed strategy with take back legislation, analyzing their impact on waste, seller profit, and product accessibility, and outlining the specific conditions under which each approach can be most effective.

Advances in (Network) Revenue Management

Invited Session

Revenue Management and Pricing

Chair: Rui Zhang, University of Colorado Boulder, Boulder, CO, 80309, United States

1 - Probabilistic Approximations for Network Revenue Management

Rui Zhang, University of Colorado Boulder, Boulder, CO, United States

We propose probabilistic approximations to capture the interactions among resources for network revenue management. The probabilistic approximations are stronger than SPL approximation in the sense that they lead to tighter upper bounds. Our numerical results also suggest that the probabilistic approximations lead to better control policies than the SPL approximation.

2 - Gradient Descent Method in Network Revenue Management: Improved Results

Sichen Guo, Shanghai University of Finance and Ecnomic, Shanghai, China, People's Republic of, Cong Shi

We address a standard online network revenue management problem, where a firm aims to maximize revenue over a finite selling season without knowing the precise relationship between price and demand rate. A major challenge is the high dimensionality of pricing decisions and the interdependencies between products. To the best of our knowledge, this problem has not been fully resolved. We assume that the revenue function is strongly concave in the price-controlled demand rate, while the decision maker can only adjust prices. Leveraging the idea of online inverse batch gradient descent (IGD) algorithm, we overcome several significant challenges stemming from inverse estimation and the lack of first-order information. Our algorithm and analysis framework can be further extended to limited inventory cases and concave problems.

3 - Network Revenue Management Problem: A Computational Method

Hongzhang Shao, University of Chicago Booth School of Business, Chicago, IL, United States, Baris Ata

We consider a high-dimensional network revenue management problem and develop a simulation-based computational method that relies heavily on deep neural network technology. The effectiveness of our policy is demonstrated through problem instances derived from the airline revenue management dataset provided by Topaloglu (2009).

Summit - 338

Optimization of Electric Power Systems Under Decision-Dependent Uncertainty

Invited Session

OPT: Optimization Under Uncertainty

Chair: Alexandre Moreira, Lawrence Berkeley National Laboratory, Berkeley, CA, United States

1 - Dynamic Transmission Line Switching Amidst Decision-Dependent Wildfire-Prone Conditions

Juan-Alberto Estrada-Garcia, University of Michigan, Ann Arbor, MI, United States, Ruiwei Jiang, Alexandre Moreira

Power grids are vulnerable to wildfire and its propagation over time. Wildfire-related transmission line failures can trigger extended power in regions of the system. During dry seasons, environmental conditions increase the risk of wildfires and their propagation, exposing power grids to cascading failure conditions. Simultaneously, transmission line operations beyond normal limits, as a response to compensate for failed lines, can cause failures and subsequent fire ignition. In this work, we propose a multi-stage optimization model to dynamically switch transmission lines to adapt the network structure to respond to the wildfire while considering the trade-off between operational performance and wildfire propagation. The proposed formulation is a multi-stage model with decision-dependent probabilities of line failure and fire propagation. We developed a stochastic nested decomposition algorithm to solve this model and present a case study using a 120-bus transmission system.

2 - Leveraging Mdps and Decision-Dependent Uncertainty Sets for Effective Distribution System Operation in Wildfire-Prone Areas

Prasanna Raut, University of Washington, Seattle, WA, United States

Wildfires pose a significant threat to electricity grids, often resulting in prolonged power outages. With climate change increasing the frequency of dry conditions, this threat is expected to escalate. It's crucial to prevent human-induced wildfires, including those triggered by power system operations, especially in areas prone to wildfires. In this work, we propose a Markov Decision Process (MDP) model to capture the relationship between the availability of lines and the line-flow decisions made by a System operator. As the transition probabilities are only known through sample estimates, we need a method that takes into account the ambiguity of these probability distributions. To this end, we employ Distributionally Robust Bellman's equations for obtaining optimal policies for operation of the distribution system. This method ensures that the chosen policy remains robust across various probability distributions within a decision-dependent ambiguity set, thus enhancing the system's resilience to uncertainties in wildfire-prone environments.

3 - Mitigating the Risk of Wildfire Ignitions from Electric Grid Infrastructure

Line Roald, University of Wisconsin - Madison, Madison, WI, United States

The electric grid is known to cause the ignition of highly destructive and deadly wildfires. Our research has considered different methods for managing this risk, most notably de-energization or undergrounding. We will discuss these and other mitigation measures in the context of optimization under decision-dependent uncertainty, as well as challenges (and solutions) for modeling and solving the resulting optimization problems.

4 - Decision-Dependent Uncertainty-Aware Distribution System Planning Under Wildfire Risk

Alexandre Moreira, Lawrence Berkeley National Laboratory, Berkeley, CA, United States

The interaction between power systems and wildfires can be dangerous and costly. Damaged structures, load shedding, and high operational costs are potential consequences when the grid is not properly prepared. In fact, the operation of distribution grids can be liable for the outbreak of wildfires when extreme weather conditions arise. Within this context, investment planning decisions should consider the impact of operational actions on the uncertainty related to wildfires that can directly affect line failure likelihood. By not properly recognizing this aspect, the evaluation of the trade-off between cost and benefit when planning system investments to deal with wildfire risk can be compromised. In this paper, we propose a decision-dependent uncertainty (DDU) aware methodology that provides the optimal portfolio of investments for distribution systems while considering that high power-flow levels through line segments in high-threat areas can ignite wildfires and therefore increase the probability of line failures. Thus, our methodology identifies the best combination of system upgrades (considering the installation of new lines, hardening existing lines, and placement of switching devices) to provide the necessary leeway to operate the distribution system under wildfire-prone conditions. Our case study demonstrates that the load shedding and associated operational costs can be substantially decreased by adequately modeling the DDU relationship between power flow prescriptions and line failures in locations where wildfires can take place.

5 - Assessing Traffic Patterns in Egress Modeling: Identifying Challenges in Evacuation Route Accessibility during Wildfire Events

Fatemeh Aarabi, San Diego Gas and Electric, San Diego, CA, United States

Given the increasing frequency and intensity of wildfires, the development of an effective evacuation model is paramount for ensuring public safety and reducing casualties. This presentation introduces a wildfire evacuation model that integrates fire spread shape with traffic patterns and human behavior during evacuation scenarios. Key parameters, such as wind direction and gusts, are employed to determine the progression of the fire, while the characteristics of the underlying road network facilitate the prediction of evacuation behavior. Additional factors, including demographic variables such as age, are incorporated to refine travel time estimations across the network. The model ultimately identifies critical bottlenecks and high-risk locations, providing projections of the affected population. A real-world case study of San Diego County will be utilized to demonstrate the model's applicability and effectiveness.

Energy Systems Planning

Contributed Session

Chair: Kristen Schell, Carleton University, Ottawa, ON, Canada

1 - A sample robust optimal bidding model for a virtual power plant

Seokwoo Kim, Pohang University of Science and Technology (POSTECH), Pohang, Korea, Republic of, Dong Gu Choi

This study explores one operational challenge for a virtual power plant—the optimal bidding for highly uncertain distributed energy resources in a day-ahead electricity market. The optimal bidding problem can be formulated as a scenario-based multi-stage stochastic program. However, the scenario-tree approach raises two consequent issues—scenario overfitting and massive computation cost. This study addresses the issues by deploying a sample robust optimization approach with linear decision rules. A tractable robust counterpart is derived from the incentive-based market structure, a unique feature of the South Korean market. The original model is then reduced to a two-stage stochastic mixed-integer linear program and then efficiently solved by adopting a dual decomposition method combined with heuristics. Computational studies were conducted using real-world business data with several benchmark models.

2 - Convergence Guarantees of a Distributed Network Equivalence Algorithm for Distribution-OPF

Yunqi Luo, University of Science and Technology of China, Hefei, China, People's Republic of, Rebayet Sadnan, Bala Krishnamoorthy, Anamika Dubey

Optimization-based approaches have been proposed to handle the integration of distributed energy resources into the electric power distribution system. The added computational complexities of the resulting optimal power flow (OPF) problem have been managed by approximated or relaxed models, which may lead to infeasible or inaccurate solutions. Other approaches based on decomposition-based methods require several message-passing rounds for relatively small systems, causing significant delays in decision-making. We propose a provably convergent distributed algorithm called ENDiCo-OPF for nonlinear OPF. Our method is based on a previously developed decomposition-based optimization method that employs network equivalence. We derive a sufficient condition under which ENDiCo-OPF is guaranteed to converge for a single iteration step on a local subsystem. We then derive conditions that guarantee convergence of a local subsystem over time. Finally, we derive conditions under a suitable assumption that when satisfied in a time sequential manner guarantee global convergence of a line network in a sequential manner. We also present simulations using the IEEE-123 bus test system to demonstrate the algorithm's effectiveness and provide additional insights into theoretical results.

3 - Optimization of Integrated Energy System Operation under the Virtual Power Plant V2G Model

Yuping Huang, Guangzhou Institute of Energy Conversion, Guangzhou, China, People's Republic of, Tong Ye

The study explores the optimization of integrated energy system operations in industrial parks under the VPP model. A multi-objective optimization model is built to enhance the coordinated operation of power users, load aggregators, power storage units, PV power generation, and electric vehicle charging-discharging and swapping systems. Based on a two-stage scheduling framework with a dual settlement mechanism, the Non-dominated Sorting Genetic Algorithm II (NSGA-II) is employed to solve this complex optimization problem. This method provides IES operators with an effective decision-making tool to enhance energy efficiency and reduce operational costs, thereby addressing the volatility and uncertainties of the electric power market.

4 - Integrating thermal and electrical dependencies into optimal community energy planning

Kristen Schell, Carleton University, Ottawa, ON, Canada, Laura Catalina Jaramillo Villarreal

Most energy system optimization models focus only on electrical supply and demand. However, many northern communities have thermal energy needs that are twice those of the electrical side of the energy system. Research indicates that addressing thermal energy solutions is crucial for the sustainability and energy independence of cold climate communities. By prioritizing heating while maintaining electrical supply, energy systems can be adapted to ensure a more balanced and effective energy strategy for these regions. This study develops an energy system optimization model that combines both the electrical and thermal energy demands, as well as their points of interdependency. The optimization model is applied to a case study of an Arctic Canadian community, Aklavik in the Northwest Territories. Results show how incorporating thermal and electrical interdependencies affect optimal investment decisions and community energy plans. In discussing these challenges, recommendations are made for how the model can inform energy policy and decision-making in community energy planning.

Incentive Design for Multi-agent Agent Systems

Invited Session

Decision Analysis Society

Chair: Sukanya Kudva, UC Berkeley, Berkeley, CA, United States

Co-Chair: Anil Aswani, UC Berkeley, Berkeley, CA, United States

1 - Optimal Interventions in Coupled-Activity Network Games: Application to Sustainable Forestry

Rohit Parasnis, Massachusetts Institute of Technology, Cambridge, MA, United States, Saurabh Amin

We consider the problem of promoting sustainability in production forests wherein a given number of strategic entities are authorized to manage concession regions. These entities harvest commodities and sell them in a market. Concession owners (agents) engage in producing a commodity that does not interfere with protected forest resources (sustainable activity) but are also inclined to infringe into protected regions to expand their agricultural footprint (unsustainable activity). Current sustainability certification programs aim to incentivize agents to reduce their individual levels of unsustainable activity by providing them pricing incentives to compensate for sustainability certification costs. However, such incentives ignore the coupling between the sustainable and unsustainable activities and the impact of interactions between agents that share concession boundaries and/or production resources. Importantly, they do not guarantee any aggregate reduction in the unsustainable activity. To design optimal pricing policies that address these limitations, we adopt a coupled-activity network game model and characterize two types of policies in a budget-constrained setting: one that maximally suppresses the aggregate unsustainable activity and another that maximizes social welfare while constraining the aggregate unsustainable activity to remain below a predefined tolerance. Our analysis provides new insights on the agents' equilibrium effort levels resulting from intra-activity and cross-activity network effects. We also develop an algorithm that solves our non-convex welfare maximization problem for an important class of pricing policies and real-world concession networks. Besides, we identify a measure of node centrality that helps us determine pricing incentives that can lead to effective suppression of the aggregate unsustainable activity.

2 - Market Mechanisms for Advanced Air Mobility

Victoria Tuck, UC Berkeley, Berkeley, CA, United States

Advanced Air Mobility (AAM) is poised to be a multibillion dollar industry and has the ability to transform mobility by providing new means for urban transportation, cargo delivery, and more. Due to the expected scale and heterogeneity of such operations, the Federal Aviation Administration (FAA) is advocating for market-based mechanisms for strategic management of airspace, to be facilitated by Providers of Services for UAM (PSUs). Leveraging insights from economic theory, we will discuss two mechanisms to be deployed by PSUs which encourage fair and efficient operations while safely allocating limited resources in infrastructure (eg. vertiports). First, we propose an incentive-compatible and individually rational vertiport reservation mechanism that uses the monetary bids from operators to maximize the overall valuations of all operators while improving the congestion at vertiports. Additionally, we improve the computational tractability of designing the reservation mechanism by proposing a mixed binary linear programming approach that is based on constructing a network flow graph corresponding to the underlying problem. Second, we propose an iterative market mechanism, inspired from recent advances in Fisher markets that is based on revealed preferences of operators in the form of congestion on the infrastructure and does not require them to reveal bidding information for their desired paths. Finally, we discuss open challenges and opportunities.

3 - Dynamic Contract Design with Learning

Yong Liang, Tsinghua University, Beijing, China, People's Republic of, Shiyuan Wang, Peng Sun

We investigate a dynamic moral hazard problem in which the agent's capability is unknown to both the principal and the agent in the beginning and can be learned over time. Specifically, the agent can exert effort in order to generate random arrivals that are beneficial to the principal. The probability of arrival, however, is determined by the agent's capability. Not knowing the agent's type as well as whether the agent exerts effort or not makes it extremely hard to identify the optimal dynamic contract. Therefore, we focus on designing dynamic contracts that achieve the best regret rate. In a discrete-time setting with two possible agent's capability types, we propose two types of contracts, both of which achieve the regret rate of $O(\ln T)$ for a time horizon T. Our contracts are ``history-independent,'' and therefore easy to implement for the principal. They motivate the agent to always exert effort before termination, and therefore are easy for the agent to respond to. We also establish a regret lower bound, which is $\Omega (\ln T)$ among all contracts, including the ones that do allow the agent to shirk. This implies that our regret rate is the best possible. We further extend these results to continuous-time settings.

4 - Trilevel Optimization for Hierarchical Decision Making

Sukanya Kudva, UC Berkeley, Berkeley, CA, United States, Anil Aswani

Multi-level optimization problems can help the industry and the government in making decisions that involve a hierarchy of players or a chronology of events in time. The first player in a hierarchy or the first chronological event takes the first action, followed by the next in hierarchy/ chronology, and so on. And at each level, the action optimizes an objective subject to the actions previously taken and is dependent on future actions that could be taken. In this work, we propose an algorithm for a trilevel optimization problem, when there are three such levels. We discuss our model assumptions, algorithm, convergence proof and experimental results.

5 - Designing Service Menus for Bipartite Queueing Systems with Strategic Customers

Lisa Hillas, University of Auckland, Auckland, New Zealand, Rene Caldentey, Varun Gupta

We consider a multiclass, multiserver queueing system, in which customers of different types have heterogeneous preferences over the many servers available. The goal of the service provider is to design a menu of service classes that balances two competing objectives: (1) maximize customers’ average matching reward and (2) minimize customers’ average waiting time. A service class corresponds to a single queue served by a subset of servers under a first come, first served–assign longest idle server service discipline. Customers act as rational self-interested utility-maximizing agents when choosing which service class to join. In particular, they join the class that maximizes their expected ex ante net utility, which is given by the difference between the server-dependent service reward they receive and a disutility based on the mean steady-state waiting time of the service class they join. We study the problem under (conventional) heavy-traffic conditions: that is, in the limit as the traffic intensity of the system approaches one from below. We prove that there are simple service menus that will optimise each of the two service provider objectives separately, and provide three mixed-integer linear programmes that identify a range of service menus that will trade off-the two objectives.

Summit - 341

Advancements in Healthcare and Service Analytics

Contributed Session

Chair: George Miller, Altarum Institute, 3100 E Delhi, Ann Arbor, MI 48103, Ann Arbor, MI, 48103, United States

1 - Usage Analysis of the Southeast Wisconsin Paratransit System

WILKISTAR OTIENO, University of Wisconsin-Milwaukee, Milwaukee, WI, United States

To protect the rights of seniors and Persons with Disabilities (PWDs), the United States government, through Congress, enacted the Americans with Disabilities Act (ADA) in 1990. The Act ensures that there is equity for persons with disabilities in all aspects of public services including employment, education, transportation, accommodation, commercial facilities and businesses and communication (Federal Register, 2010). In this study, we focus on the problem of transportation of PWDs, specifically in Milwaukee County Transit System (MCTS). The research first explores the effect that increased ADA bus ridership would have on the paratransit system performance such as bus utilization by PWDs, PWD average waiting time as well as the average time in system. Per the results, the average utilization was found to be 6.5%. This percentage is an indicator of that MCTS has potential to increase fixed bus route ridership by persons with disabilities, especially if challenging issues such as low bus frequency, less geographical coverage of the bus network (to cover areas where most Casino ADA visitors reside), public transport awareness, bus driver training and most of all, increased accessibility at the destination.

2 - Bayesian Analysis of Hospital Service Quality:Pre- and Post-COVID

Ling Hu, University of South Florida, TAMPA, FL, United States, Sajeev Varki, Daniel Zantedeschi

The hospital sector is the largest revenue-generating industry in the United States. Its service quality profoundly influences societal welfare. The Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS), administrated by the CMS (Centers for Medicare &

Medicaid Services), serves as a cornerstone in fostering patient-centered care, enhancing informed decision-making, and optimizing healthcare resource allocation.

Departing from the conventional methodologies using linear or multilevel linear regression models with Maximum Likelihood Estimation (MLE) to analyze cross-sectional rating score data, this research employs a novel approach. Leveraging a multilevel Item Response Theory (MLIRT) model, it delves into the hierarchical structure of HCAHPS data through Bayesian estimation. By separately estimating the latent hospital service quality and item parameters of threshold and discrimination, the MLIRT model effectively addresses measurement error, enabling more precise estimation. Bayesian estimation is favored over MLE due to its superior ability to incorporate prior knowledge or beliefs about these parameters and handle heterogeneity issues.

Our study provides insights for hospitals to optimize resource allocation to improve service quality. Our findings offer actionable recommendations by identifying 'Care Transition,' 'Nurse Communication,' and 'Doctor Communication' as the foremost service attributes reflecting latent service quality. Furthermore, our investigation into the service quality change before and after COVID-19 provides hospitals and policymakers with a more comprehensive understanding of the pandemic's impact, which may help develop appropriate strategies when facing similar crises. Lastly, our research introduces an alternative framework for evaluating hospital service quality, offering policymakers a fresh perspective on assessment methodologies.

3 - Nursing Home Staffing Shortages and the New Federal Nursing Home Standards

George Miller, Altarum Institute, Ann Arbor, MI, United States

Nursing homes in the U.S have major staffing shortages that can lead to poor quality of care for residents. New minimum staffing standards mandated by the U.S. Centers for Medicare and Medicaid Services are intended to address this problem. The standards include requirements for a daily minimum of 2.45 hours of nurse aide (NA) time per resident (referred to as hours per resident day, or HPRD) and 0.55 daily hours of time by registered nurses (RNs) per resident. Most nursing homes in the U.S. do not currently meet these new standards, but there is significant variation among nursing homes around these overall HPRD levels. This has led us to investigate the following question: What characteristics of nursing homes are associated with a higher probability of meeting the newly proposed standards? Using logistic regression and national datasets, we investigate the association between whether a nursing home meets the standards and the following characteristics of the home:

- Whether the home is in a rural rather than non-rural county
- Whether the home is operated by a for-profit rather than nonprofit provider
- The percent of residents in the home who are persons of color
- The percent of residents in the home whose primary funding is Medicaid, as opposed to higher funding levels from Medicare or private payers

We also examine variation among states in the extent to which the above four characteristics affect the percent of nursing homes meeting the standards.

Summit - 342

Solutions for Low-Carbon Energy Transition

Contributed Session

Chair: Honghong Kou, Simon Fraser University, No. 266, Burnaby, BC, 710126, Canada

1 - Low-Carbon Optimization of User-Side Shared Energy Storage Based on Deep Reinforcement Learning

Tong Ye, Guangzhou Institute of Energy Conversion, Guangzhou, China, People's Republic of, Yuping Huang

Facing the challenges of global climate change and the need for improved energy efficiency, it is crucial to explore optimization strategies that reduce distribution network costs and carbon emissions. This study proposes a joint low-carbon optimization model for shared energy storage operators and distribution networks, considering tiered carbon trading. The model employs the Deep Deterministic Policy Gradient (DDPG) algorithm to achieve both economic benefits and environmental sustainability. Given the current constraints on carbon emissions and the instability of renewable energy supplies, the study first introduces an optimization framework that minimizes operational costs and carbon emissions through shared energy storage and all-day carbon trading. The scheduling problem is then formulated as a Markov Decision Process, defining the system's observation states, scheduling actions, and reward functions. Finally, the DDPG algorithm is applied for low-carbon economic dispatch.

2 - Coordinating TSOs, DSOs, and DERs Through a Tri-Level Decentralized Transactive Energy Market Framework

Tolga Karabas, Middle East Technical University, Ankara, Turkey, Meltem Peker Sarhan, Mustafa Kemal Tural

The increasing presence of Distributed Energy Resources (DERs) in power grids challenges the traditional unidirectional energy systems as they transition to bidirectional power flow. The inherent uncertainty of renewable DERs further complicates energy management. Despite these challenges, DERs provide valuable energy and flexibility services to power grids. This study introduces a novel tri-level decentralized transactive energy market framework to address these complexities. Within this framework, Distribution System Operators (DSOs) play a pivotal role as coordinators of local energy markets at the distribution level, serving as intermediaries to facilitate communication between Transmission System Operators (TSOs) and DERs using network-aware pricing and transactive control mechanisms. By enabling DER participation through optimized bidding strategies in local energy markets (and indirectly in wholesale markets via DSOs), the framework aims to optimize system operations while considering uncertainty through distributionally robust optimization methods. This approach offers a promising pathway to enhance grid security and reliability by addressing distributionally robust unit commitment and optimal power flow problems. By accounting for the dynamic interactions among TSOs, DSOs, and DERs, the proposed coordination approach seeks to establish a more resilient and efficient energy system management with optimized grid operations.

3 - Market Or Government Regulation: Impact On Operational Decarbonization

Eyup Emre Berk, Bilkent University, Ankara, Turkey

Operational decarbonization is the optimization of operational decisions in supply networks in the presence of carbon emissions penalties. We re-visit the stylized single location deterministic demand model with exogeneous carbon prices. In particular, we study the impact of carbon taxes imposed through government regulations and carbon pricing by consumers in the market on operational decisions when decision makers have objectives other than the traditional profit maximization motive. Our findings focus on the efficacy of carbon pricing mechanisms in reducing carbon footprints and have societal as well as potential regulatory implications.

4 - Asymmetric risk spillover network between energy stock index and China sector stock index based on energy transition perspective

Honghong Kou, Xidian university, Xi'an, China, People's Republic of

In the context of energy transition, elucidating the dynamic interactions and risk spillovers between energy markets and various industry stock indices is crucial for effective risk management and investment decisions. This paper employs the asymmetric TVP-VAR-DY model and MS-VAR model to construct an asymmetric time-varying energy-financial cross-market risk spillover network framework. This framework aims to describe asymmetric risk spillover relationships among 11 industry stock indices including traditional energy, clean energy, and Chinese energy, finance, and real estate. The research findings indicate: 1. Strong linkages exist between energy and Chinese industry stock index markets, with materials, industrial, and consumer discretionary sectors being the main sources of market risk, with the energy market primarily acting as a net receiver. 2. During bull markets, industry indices exhibit stronger predictability within the systemic network, while during bear markets, the energy market demonstrates greater predictability. 3. Further validation is provided on the association between extreme risk spillovers and significant economic events, policy interventions, investor sentiment, and global events. 4. Risk from Brent crude oil transmits to natural gas and coal, with Brent crude oil being more susceptible to contamination from clean energy than traditional energy. 5. With the advancement of energy transition policies, the spillover relationships exhibit a distinct three-stage transition, with risk gradually shifting towards new energy assets. Our research provides empirical evidence for the asymmetric interdependence and risk transmission mechanisms between energy and industry stock markets, revealing the impact of China's energy transition policies on the energy financial system.

5 - Understanding Sustainable Aviation Fuel Incentives with Low Carbon Fuel Policies: Market Designs in California

Adam Christensen, GAMS Development Corp, Fairfax, VA, United States, Colin Murphy, Julie Witcover

The US Environmental Protection Agency estimates that carbon emissions from the aviation sector was 8% of US transportation emissions and 2% of total US emissions in 2021; demand for these fuels is projected to increase dramatically. Decarbonizing the aviation sector is a grand challenge because commercial flight will be reliant on liquid fuels for the foreseeable future. Aviation fuel can be produced by hydrotreating lipids from agricultural/waste sources; other chemical pathways are also being explored. These fuels are often referred to as sustainable aviation fuels, or SAFs. SAFs have emerged as an attractive jet fuel alternative due to their lower embedded carbon content. However, the production of these fuels is limited; US aviation fuel consumption was ~23 billion gallons in 2021, but only 5 million gallons of SAF were consumed. California’s Low Carbon Fuel Standard (CA-LCFS) incentivizes these fuels by allowing producers to mint carbon credits and trade them in a marketplace. A wide variety of fuels can generate compliance credits making it difficult to model future credit market behavior. California is considering amendments to the LCFS that would incentivize SAFs although the exact incentive mechanism has not been determined. In this work we present our analysis of different market structures for integrating aviation fuels into the LCFS using a multi-agent partial equilibrium model of the California transport fuel sector and offer some policy-focused insights. This model is capable of resolving the different compliance strategies and endogenously determining the value of critical market incentives – specifically the carbon price.

Advancements in Neural Network Applications

Contributed Session

Chair: Bingyi Su, North Carolina State University, Raleigh, NC, United States

1 - Optimization of Artificial Neural Networks in the Recognition of User Trust in Automation Utilizing Gaze Data Metrics

John Coughlin, Louisiana Tech University, Ruston, LA, United States, Mary Fendley

The prevalence of automated systems in man-machine systems necessitates the ability to effectively monitor user trust in those systems. The objective of this study was to create an Artificial Neural Network that can recognize the trust of an individual through the input of eye gaze data. Three models of Artificial Neural Networks were trained and tested on datasets gathered from previous studies. The procedure consisted of training an Artificial Neural Network with gaze data metrics as inputs and trust as output, utilizing the testing set as it is being trained to verify it is learning, and finally, utilizing the evaluation set to verify that it is applicable to unknown data. First, statistics regarding the best performances on the testing set were gathered. Second, with the best number of nodes in the hidden layer for each model now known, the best performance on both the training and testing sets were found for each of them. Finally, each model was evaluated on unknown data. Ultimately, the hybrid model ended up performing the best on known data, but the ReLU model ended up doing better overall on both known and unknown data.

2 - Convolutional Propagation on Graph Neural Networks for Hierarchical Network

Hyunjung Shin, Ajou University, Suwon, Korea, Republic of, yoonshin kwak, Junwoo Choi

Recently, Graph Convolutional Networks(GCN) have achieved success in various domains such as gene networks in bioinformatics, community detection in SNS, drug design in the pharmaceutical industry, and intrusion detection in the security field, etc. However, its application is limited only for a plane network or graph. If a network has hierarchical or multi-layered structure, it cannot be applicable to those networks, for instance, the omics networks layered by genome, proteome, diseasome, the financial networks layered by individual stocks, financial derivatives, global economical indicators, and the genealogy networks stratified by ancestor-descendant relationships. Another limitation of GCN is that its convolution process of sharing information with neighboring nodes is not flexible and tightly bounded with the GCN structure. Including more neighboring nodes requires more convolutional layers, which requires expensive computational resources. To cope with these limitations, we propose Graph Convolutional Smoothing Networks. In the proposed method, the GCN is redesigned to be expandable to hierarchical networks, and the convolution process employes the propagation process that adjusts the range of neighboring nodes through the smoothness parameter. Experiments show that the proposed method outperforms the comparison methods by taking advantage of its applicability to hierarchical networks and its flexibility of convolutional propagation.

3 - Enhancing Representation Ability of CNN via Color Inversion Channel

Dohyun Bu, Sungkyunkwan University, Suwon, Korea, Republic of, Bonyoung Koo, Chanho Kim, Gaeun Kim, Minjun Jeong, Yulim So, Jong-Seok Lee

Convolutional Neural Networks (CNNs) have proven to be potent tools for extracting features in various image processing tasks. However, traditional convolutional operations struggle to extract meaningful information from zero-valued pixels, limiting their utility in domains such as medical image analysis where such pixels are important. To address this challenge, we introduce a novel architecture based on dual-channel CNNs. We integrate both original channel and color-inversion channel CNNs, trained jointly to capture the distinct characteristics of each channel. Moreover, our approach exploits the orthogonality between extracted features, facilitating the learning of unique information from each channel. We demonstrate the effectiveness of our method in classifying medical images. Experimental results indicate that our approach can seamlessly integrate with pre-trained CNNs and surpass the state-of-the-art models in classification performance.

4 - Model-agnostic post-hoc explanation for image anomaly detection

Yulim So, Sungkyunkwan University, Suwon, Korea, Republic of, Seokho Kang

Image anomaly detection is a task of training anomaly detectors on normal images to identify whether a new image is anomalous. There have been significant research efforts focused on improving the accuracy of anomaly detectors. However, most of these anomaly detectors do not provide explanations for why certain images are identified as anomalous due to their “black-box” nature. In this study, we propose a surrogate explainer to provide explanations for the decisions made by any anomaly detector. When a query image is identified as an anomaly by a certain anomaly detector, the surrogate explainer is constructed using both normal images and the anomalous query image. Specifically, a convolutional neural network (CNN) is trained with a learning objective consisting of (1) classification loss to distinguish the query image from the normal images; (2) equivariant regularization loss to ensure equivariance between the query image and its attention map under affine transformations; and (3) complementary guided attention loss to expand the attention on the query image while suppressing the attention on the normal images. After training, the visual explanation of which pixels in the query image contribute to the anomaly is derived by applying gradient-weighted class activation map (Grad-CAM) to the CNN. Through experiments using the MVTec-AD benchmark, we demonstrate that our method provides explanations comparable to those of existing explainable anomaly detectors.

5 - Privacy-preserving federated learning using CNN-LSTM for activity recognition in manual material handling

Bingyi Su, North Carolina State University, Raleigh, NC, United States, Lu Lu, Liwei Qing, Sehee Jung, Xu Xu

Work-related musculoskeletal disorders (MSDs) are a major public health issue, affecting around 1.71 billion people worldwide. These conditions are often caused by manual material handling (MMH) tasks, making activity recognition in MMH crucial for preventing MSDs. However, centralized methods for training activity classifiers pose data privacy risks due to the sensitive nature of human data. Therefore, this study introduces a privacy-preserving federated learning framework using CNN-LSTM for activity recognition in MMH. Specifically, CNNs are utilized for their ability to extract spatial information, while LSTMs are employed for their effectiveness with time sequence data. Human motion data for training and test were collected using a motion tracking system from 11 participants. The body motions include commonly seen activities at the workplace, such as walking, lifting, lowering, stepping up, and reaching. The data was down-sampled to 15 Hz, simplified to 17 coordinates, normalized, and segmented into 2.67-second sequences. The sequences were then randomly split into training and test sets with an 8:2 ratio. For comparison purposes, both centralized and federated learning setup were applied. The centralized model achieved a precision of 0.984, recall of 0.983, and F1-score of 0.983. The federated model achieved a precision of 0.965, recall of 0.954, and F1-score of 0.958. These results show that federated learning offers comparable accuracy to centralized methods while ensuring data privacy, making it valuable for decision management in industrial settings to enhance workplace well-being.

Advancements in Transportation and Logistics Optimization

Contributed Session

Chair: Rong Cheng, Eindhoven University of Technology, Eindhoven, 5612HZ, Netherlands

1 - Optimization of schedule-based barge timetable for a bi-modal urban logistics network

Rong Cheng, Eindhoven University of Technology, Eindhoven, Netherlands, Layla Martin, Claudia Archetti

Large facilities in city centers have high transport demands but operate in restricted space, resulting in low loading capacity and, consequently, long waiting times during peak hours, and negatively impacting traffic congestion and the environment. Some cities, such as Hamburg, can shift transportation to waterways thanks to an extensive network of canals. The barge timetable becomes crucial for freight owners' delivery decisions. This study develops a bi-level programming model for the barge timetabling problem in a bi-modal (truck delivery and truck-barge delivery) transport context, aiming to understand levers to incentivize freight owners to choose waterways using a game-theoretic analysis. The upper-level problem determines the barge timetable to maximize the share of truck-barge delivery. The lower-level problem describes freight owners' choice behavior by the user equilibrium, in which each freight owner chooses its delivery mode that minimizes its generalized cost according to the barge timetable of the upper-level model. The congestion effect at the facility's dock is modeled based on queueing theory. An iterative method is developed to solve the bi-level programming model. The iterative method includes: 1) an equilibrium assignment method to decide the delivery mode assignment. The equilibrium assignment method is embedded with a pointwise stationary fluid approximation method to evaluate the queueing system. 2) a branch-and-bound algorithm for the barge timetable design. Experiments are conducted to illustrate the model's properties and the performance of the solution method.

2 - Two-echelon multi-trip vehicle routing problems with synchronization under delays

Cigdem Karademir, Delft University of Technology, Delft, Netherlands, Breno Beirigo, Bilge Atasoy

Meeting the increasing demand in cities has become challenging under the regulations limiting freight vehicles to improve mobility and reduce carbon footprints. By effectively coordinating with larger vehicles, new electric vehicle technologies can overcome restrictions in driving range and storage capacity. This study proposes integrated water- and land-based transportation systems using light electric freight vehicles and autonomous vessels as mobile depots to enhance the efficiency of city logistics. However, such systems introduce dependency between different vehicles at the transshipment locations and face potential delays that can impact the reliability of the entire service network.

Dedicating storage at these locations might mitigate the impact of delays but limit the reliability to location and capacity decisions at the strategic level. On the other hand, public spaces such as parking spots or transportation stops can be used as on-demand transshipment points, enabling revisiting these decisions at the operational level. However, this flexibility requires spatio-temporal synchronization between interacting vehicles and might propagate the delays in the system.

This study provides comparative analyses of the impact of delays on integrated service designs with and without storage, 2-echelon-S and 2-echelon-F, respectively. We model these systems as two-echelon multi-trip vehicle routing problems with synchronization, addressing delays through a two-stage stochastic program with simple recourse. Preliminary experiments on small networks show that 2-echelon-F is better at reducing expected lateness and offers greater flexibility in logistics re-organization to minimize delays' impact. To further analyze the reliability of such sustainable logistics solutions in cities, different delay sources will be studied.

3 - Wattage vs. Mileage: Unpacking the Dilemma of Electric Long-Haul Trucking

David Menachof, Florida Atlantic University, Boca Raton, FL, United States, Nihat Ahmed

Electric long-haul semi-trucks are feasible for about 72% of origin-destination (O-D) pair combinations using existing truck stops (if enhanced with charging stations). Just because they are feasible, does not mean they are practical. While current charging infrastructure lacks the number of mega-chargers required to make the long-haul electric trucking practical, even if the charging network is expanded by a factor of 10, it would still not be enough to make it a viable alternative to the diesel tractor unit. Examination of the Freight Analysis Framework will show that realistic volumes of electric semi-truck units on any O-D combination will be a small percentage of total volume on each route.

Using QGIS, the US major highway network will be used to show the total volume over any segment of road. In some cases, multiple OD combinations will use a specific segment. Combining existing charging station locations along with projected locations, we will project potential daily volumes that can be supported. Using actual data over a segment compared to projected charging volumes, we will determine projected shortfall of charging capacity. We will examine maximum volumes over an OD route pair based on the distance and charging stops required. Charging capacity available at each stop will be calculated. The overall capacity constraint for the entire route will be determined by the lowest charging capacity among all stops along a route.

If the charging infrastructure capacity problem cannot be solved, then where does that leave the future of electric long haul semi-trucks?

4 - Enhancing Human Planning Decisions with AI: An Experimental Investigation and Evidence

Lijia Tan, Eindhoven University of Technology, Eindhoven, Netherlands, Eirini Spiliotopoulou, Willem van Jaarsveld

We experimentally investigate the impact of AI plans on human planning decisions in supply chains. The AI plans are based on a neural network and reinforcement learning algorithm, which provide recommendations for all decisions that humans need to make. We conducted two experiments. The first experiment examines the impact of AI plans on inexperienced and experienced planners, respectively. The first experiment shows that the presence of AI plans effectively improves the performance of inexperienced planners but barely affects experienced planners. Specifically, such AI plans assist inexperienced planners in performing as well as experienced planners, but they do not improve experienced planners' performance. The second experiment examines the impact of AI plans under a time-pressure environment. The results show that the presence of AI is more effective regardless of human experience when time pressure is present. In this study, our discussion on the interactive effects between AI plans and human experience, and between AI plans and time pressure, provides insights into the applications of AI in future supply chains.

Emerging Topics for Electric Vehicles

Contributed Session

Chair: Yamil Essus, North Carolina State University, Raleigh, NC, United States

1 - Estimating Access Risk Due to Vehicle Electrification During Blackouts in North Carolina

Yamil Essus, North Carolina State University, Raleigh, NC, United States, Benjamin Rachunok

Vehicle electrification is a key component of sustainable development goals, yet the mass adoption of electric vehicles can lead to unintended consequences for community mobility during natural hazards. Electric vehicles pose a challenge to owners during natural hazards that lead to power outages, as a lack of home charging limits the mobility of EV owners. Due to the direct relation between driving distance to essential services and vehicle battery consumption, changes in mobility will be impacted by geographic and technological factors. Geography determines the driving distance to essential services, which will be translated to electricity consumption devoted to transportation, and technology determines the size of electric vehicle batteries and vehicle efficiency. The linkage between mobility, electric power availability and quality of life has broad implications for community resilience as equitable access to essential services has been identified as the most important aspect of community resilience. We present the results of a computational framework for estimating the risk of losing access to essential services during a prolonged blackout in North Carolina, assuming complete adoption of electric vehicles. We leverage an open-source routing engine to compute driving distance to services, census data to identify driving requirements (such as school enrollment and commuting by private car) and a database of previous blackouts to estimate county-level blackout risk. Additionally, we incorporate a heuristic to approximate distance driven on commuting using isochrone curves. Finally, we explore the sensitivity of our results to vehicle battery capacity, which is tightly linked to vehicle affordability.

2 - Optimization of electric truck charging infrastructure considering GHG emissions

WEILIANG DENG, University of Arizona, Tucson, AZ, United States

Compared with widely adopted passenger Electric Vehicles (EVs), electric trucks (e-trucks) have high requirement for charging infrastructure and low operational efficiency (such as long charging time and frequent charging stops), which hinders market adoption. A reliable and easily accessible charging infrastructure network can facilitate this transformation from traditional truck fleets to electric alternatives. This paper proposes a charging infrastructure location optimization strategy to develop such charging stations network for e-trucks. Candidate charging station locations of e-trucks are identified using ArcGIS and evaluated based on various factors such as accessibility, grid network, power supply, and corridors priority. Besides, the source of electricity used to refill e-trucks' batteries will impact the overall GHG emissions during the operation stage of e-trucks. To ensure the lowest overall GHG emissions of e-trucks, energy mix of power supplier is incorporated to evaluate the overall environmental impact. A mixed integer programming model is formulated to minimize the total economic investment and GHG emissions. The model is then applied to investigate operation of commercial e-truck fleet in Arizona. Other managerial insights are further discussed.

3 - Optimizing Perimeter Control for Mixed Traffic of Conventional and Electric Vehicles in Large-Scale Transportation Networks

Ehsan Kamjoo, Michigan State University, East Lansing, MI, United States, Fatemeh Fakhrmoosavi, Ali Zockaie

Electric Vehicle (EV) technology offers an effective solution to mitigate traffic-induced air pollution in urban areas. However, the slow projected increase in EV market share leads to a prolonged period of mixed traffic of EVs and Conventional Vehicles (CVs). Given the non-uniform distribution of congestion and its related environmental issues across the network, there is a need for innovative traffic management strategies that prioritize EVs in areas experiencing high levels of congestion and pollution, such as Central Business Districts. This study introduces an innovative control strategy that dedicates specific links on the periphery of network regions to EVs to minimize both total travel time of vehicles as well as vehicular emissions over the network. Unlike existing studies that do not differentiate between CVs and EVs in perimeter control, this approach manages the accumulations of each vehicle type in each region by adjusting the traffic signals at the boundaries. A Model Predictive Control (MPC) method is employed to solve the optimization problem, coupled with a mesoscopic traffic simulation tool, DYNASMART-P, to simulate the movement of vehicles throughout the large-scale network. The proposed framework is successfully applied to the Chicago network, evaluating congestion and emissions under scenarios with and without perimeter control, including scenarios that do not differentiate between CVs and EVs. Different scenarios for the market share of EVs are also considered to evaluate their impact on the performance of perimeter control. The results provide valuable insights for policymakers on the effective implementation of this strategy in presence of EVs.

4 - Decarbonization Strategies: Balancing Investments in Renewables, Electric Vehicles, and Carbon Capture

Daniel Fontecha, KAUST, Thuwal, Saudi Arabia, Ricardo M. Lima, Omar Knio, Omar Knio

To which extent should governments invest in renewables and electric vehicles (EVs)? Renewables variability and significant investment costs in batteries and transmission hamper the decarbonization of the power sector and thus penetration of EVs.

EVs add extra load to the power sector, but can also support it through load-shifting and vehicle-to-grid (V2G), in addition to decreasing the carbon emissions of the transportation sector.

Therefore, given the interactions between power, transportation, and carbon emissions, it is crucial to quantify how long-term investments in renewables, EVs and carbon-capture technologies mutually affect each other to identify the most efficient path for decarbonizing our economies.

To address these questions, a capacity expansion problem is formulated as stochastic mixed-integer program, minimizing the total cost of a power system linked with the road transportation sector while adhering to annual emission limits. A two-stage decision framework is adopted to address uncertainty during the operational stage. The model is applied to Saudi Arabia, utilizing an extensive formulation and a parallelized solution strategy for multiple instances.

The study reveals a positive net effect of EVs on the power sector, with benefits magnifying as the share of renewable generation increases. For instance, an uncontrolled EV penetration of 10% reduces the total cost of a power sector under tight emission constraints by up to 17%. The optimal renewable share increased from 56% to 63%. However, the whole panorama changes when carbon capture technologies are incorporated in the model, demonstrating the importance of evaluating simultaneously all available technologies to trace decarbonization pathways.

5 - An Analysis of Capacity and Pricing Decisions for Renewable Energy-Powered EV Charging Stations on Highways

Zhuo Feng, Dalian University of Technology, Dalian, China, People's Republic of, Xin Chen, Ying Gao, Shuibo Zhang

The increasing adoption of electric vehicles (EVs) has led to the installation of solar panels to provide renewable energy to EV charging stations on highways, contributing to a decrease in carbon emissions associated with EV power consumption. This paper presents a game-theoretic model to study the capacity decisions (i.e., the capacities of solar panels and EV charging stations) and pricing decisions (i.e., tolls and charging prices) of a private firm. Additionally, we examine the government's necessary subsidy levels to meet predefined carbon emission reduction targets.

Innovative Approaches in Financial Market Analysis and Forecasting

Contributed Session

Chair: Grace Babalola, Binghamton University (SUNY), Johnson City, NY, United States

1 - A Network Approach for the Financial Market Regimes: A Study of Chinese Stock Market

Xiaodi Zhu, University of Wisconsin-La Crosse, La Crosse, WI, United States, Anqi Liu

In the investment world, identifying, measuring and modelling connections among different assets are important issues in risk management. Beyond portfolio management, when viewing the financial market as a complex system, connections among assets can not only reflect stability of the entire financial system, but also present the vulnerability, contributions, and spillovers of each asset. This study uses network method to study the Chinese stock market change in the past 10 years. Using a automatic regime detection method, this study detects four major financial regimes in the market, and visualize their structure change.

2 - Spatial Competition with Online Platforms: An Empirical Analysis of the Wealth Management Product Market

Shuoxun Zhang, Sichuan University, Chengdu, China, People's Republic of, Chao Ma

Previous empirical studies have analyzed multiple sectors and found that if different, most time online prices are lower than offline. We study the market of a financial product, the wealth management product (WMP), which is the largest component of China’s shadow banking sector. We find that prices of WMPs sold online is significantly higher than those sold at banks’ physical branches. The explanation is that customers need to pay travel costs for visiting physical branches and thus banks have to charge lower prices at physical branches to attract customers from online platforms.

The WMP market provides an ideal scenario to identify the effect of firms’ spatial competition that contributes to the gap between online and offline prices. The reason is that online and offline channels for WMP issuing are not differential in other dimensions that could affect prices, including delivery costs, search costs, convenience to inspect product qualities, and waiting costs.

We also find that a bank’s online-offline price gaps decrease with both the number of incumbent banks and the bank’s branch density in the city, although the former tends to decrease a bank’s market power whereas the latter tends to increase a bank’s market power. As the number of competitors increases, a bank can still maintain some local market power in the offline market over residents near its physical branches but cannot do so in the online market. In contrast, a bank’s branch density in a city directly increases the bank’s local market power only in the offline market.

3 - Dynamic Risk Budgeting Portfolio using Value-at-Risk and Expected Shortfall

Wen-Yi Lee, National Taipei University of Business, Taipei, Taiwan, Ya-Hsin Chou

Risk budgeting portfolio studies are a crucial aspect of asset allocation, aiming to incorporate different risk measurements. However, these studies need to pay more attention to the continuous nature of risk over time. We propose a risk budgeting portfolio that continuously detects Value-at-Risk (VaR) and expected shortfalls to address this issue. In this study, we present two models that consider different trading timings.

The first model is the portfolio model with static trading timing. This model involves rebalancing portfolios at fixed intervals, resulting in a predetermined rebalancing schedule with portfolios adjusted at predetermined intervals. While this approach offers a reliable method for risk budgeting, it may not account for market conditions that arise between these predetermined intervals. On the other hand, the second model utilizes dynamic trading timing. This approach involves trading portfolios when their VaR or expected shortfall exceeds critical values, allowing for a more nuanced and efficient response to real-time risk based on market conditions. This model offers more comprehensive risk budgeting portfolio studies that account for the continuous nature of risk and offer both static and dynamic trading strategies. Overall, our proposed models provide a more comprehensive approach to risk budgeting portfolio studies that accounts for the continuous nature of risk and offers both static and dynamic trading strategies.

4 - The Value of Historical Financial Statements in Predicting the Innovation Performance of Technology-Based SMEs: A Machine Learning Approach

bin ke, National University of Singapore, Singapore, Singapore, Xinjie Ma, Yanbo Wang

Utilizing a proprietary dataset of grant applications from technology-based SMEs to China's Innovation Fund for Small Technology-based Firms (Innofund), this study evaluates the utility of historical financial statements for assessing SMEs' innovation potential. Our findings demonstrate that an advanced XGBoost model, using 55 financial statement data items only, predicts innovation performance more effectively than an XGBoost model based on human experts' evaluation scores of the entire grant application. Additionally, merging financial data with expert scores does not improve prediction accuracy, indicating no incremental value from expert discretion. Analysis of Shapley values highlights distinct evaluation criteria differences between human experts and the XGBoost model. Our results demonstrate the promise of leveraging advanced machine learning with historical financial data in aiding government grant agencies to identify SMEs with high innovation potential.

5 - Analysis of Stock Market Performance During Election Year and Non-election Year Using Differential Entropy and Mutual Information

Grace Babalola, Binghamton University (SUNY), Binghamton, NY, United States, Ademola Adedoyin, Tejaswini Dinesh, Duxiao Hao, Uthman Kareem, Hamid Kolawole, Bukunmi Ofili, Simeon Ogunbunmi

Stock market volatility is one of the key factors in deciding the potential investment in the stock market. The volatility in the stock market in the months preceding an election has been observed for the past few decades. Several studies show that there has been a significant increase in the market value in the third year of a presidential term similarly to the year 2019 observation. However, the 'Presidential Election Theory' used in most of these studies is susceptible to other unpredictable factors which have been observed during the current year. Thus, this study attempts to evaluate a distinction in the performance of the stock market during election (X) and non-election (Y) years considering other susceptible factors not encountered in other studies, to give an overview of the distinction in the risks associated with investing. This study analyzed the Dow Jones Industrial Average Annual Stock Price using differential entropy and mutual information. The differential entropy calculated was 0.0848001 with $X\mu$:11,232.2 (X_{SD}: 7,625.58) and $Y\mu$:10,001(Y_{SD}:7,190.27), while the mutual information was calculated to validate the differential entropy value. Using the mutual information formula HX + HY – HXY, the output value is 5.3529. Invariably concluding based on the differential entropy that although the uncertainty in the information shared in the stock market performance during election and non-election year is approximately 5.35 bits of information, the stock market performance is independent of the year of election. Hence, one may ignore the condition of election year while deciding to invest in the stock market.

Advances in Sequential Decision-Making with E-Commerce Applications

Invited Session

Revenue Management and Pricing

Chair: Chamsi Hssaine, University of Southern California, Marshall School of Business, Los Angeles, CA, United States

1 - Primal-Dual Algorithm for Online Resource Allocation without Resolving

Yehua Wei, Duke University, Durham, NC, United States, Jiaming Xu, Sophie Yu

We present a simple primal-dual algorithm for online resource allocation problems with finite query types. We show that our algorithm achieves constant regret, i.e., a regret that is independent of T, when the fluid solution is non-degenerate. Unlike many other constant regret algorithms in the literature, our algorithm does not require the fluid problem to be resolved over time, making it more computationally efficient in large-scale resource allocation. In addition, we discuss our regret's dependency on system parameters outside of T, and how it compares with other algorithms in the literature.

2 - Liquid Welfare guarantees for No-Regret Learning in Sequential Budgeted Auctions

Giannis Fikioris, Cornell University, Ithaca, NY, United States, Eva Tardos

We study the liquid welfare in sequential first-price auctions with budgeted buyers. We use a behavioral model for the buyers, assuming a learning style guarantee: the utility of each buyer is within a γ factor ($\gamma\geq 1$) of the utility achievable by shading her value with the same factor at each iteration. We show a $\gamma+1/2+O(1/\gamma)$ price of anarchy for liquid welfare when valuations are additive. This is in stark contrast to sequential second-price auctions, where the resulting liquid welfare can be arbitrarily smaller than the maximum liquid welfare, even when $\gamma=1$. We prove a lower bound of γ on the liquid welfare loss under the above assumption in first-price auctions.
Our liquid welfare results extend when buyers have submodular valuations over the set of items they win across iterations with a slightly worse price of anarchy bound of $\gamma+1+O(1/\gamma)$ compared to the guarantee for the additive case.

3 - Optimizing Inventory Placement for a Downstream Online Matching Problem

Boris Epstein, Columbia University, New York, NY, United States, Will Ma

We study the inventory placement problem of splitting Q units of a single item across warehouses, in advance of a downstream online matching problem that represents the dynamic fulfillment decisions of an e-commerce retailer. This is a challenging problem both in theory, because the downstream matching problem itself is computationally hard, and in practice, because the fulfillment team is constantly updating its algorithm and the placement team cannot directly evaluate how a placement decision would perform.

We compare the performance of three placement procedures based on optimizing surrogate functions that have been studied and applied: Offline, Myopic, and Fluid placement. On the theory side, we show that optimizing inventory placement for the Offline surrogate leads to a $(1-(1-1/d)^d)/2$-approximation for the joint placement and fulfillment problem. We assume d is an upper bound on how many warehouses can serve any demand location and that stochastic arrivals satisfy either temporal or spatial independence. The crux of our theoretical contribution is to use randomized rounding to derive a tight $(1-(1-1/d)^d)$-approximation for the integer programming problem of optimizing the Offline surrogate. We use statistical learning to show that rounding after optimizing a sample-average Offline surrogate, which is necessary due to the exponentially-sized support, does indeed have vanishing loss.

On the experimental side, we extract real-world sequences of customer orders from publicly-available JD.com data and evaluate different combinations of placement and fulfillment procedures. Optimizing the Offline surrogate performs best overall, even compared to simulation procedures, corroborating our theory.

4 - Online Bin Packing with Load Balancing

Hanzhang Qin, National University of Singapore, Singapore, Singapore, Yan Chen, Zheng Tan, Yugang Yu

The balls-into-bins approach, extensively studied in Computer Science, can address load balancing against various uncertain environments. However, in real-world applications such as cloud resource allocation and last-mile delivery, constraints on bin capacity often necessitate more sophisticated approaches. In this paper, we present a novel framework centered on a level-based constrained optimization formulation aimed at simultaneously minimizing the surplus bins and mean-square deviation from the mean level in a lexicographically optimal manner. We introduce a new penalized Lagrangian function as the criterion for bin selection. Through theoretical analysis and numerical experiments, we establish the effectiveness of our proposed algorithm in achieving near-optimal solutions, particularly in sparse scenarios, when compared to offline optimal solutions.

Pricing and Other Considerations in Business Operations

Contributed Session

Chair: Ruibing Wang, University of Mannheim, Schwetzingen, Germany

1 - Detecting Forward-looking Statements Fraud in Earnings Conference Calls Using Graph Attention Network Approach

Elaheh Aghazadeh, University of Massachusetts Lowell, Lowell, MA, United States, Julie Zhang

The detection of forward-looking statement fraud in earnings conference calls is essential for maintaining the integrity of financial markets due to the inherent uncertainty of predictions about a company's future financial performance and strategic direction. These statements, which often include earnings forecasts and assessments of market potential, are particularly vulnerable to manipulation. Whether these manipulations are overly optimistic or pessimistic, they can significantly alter market perceptions, mislead investors, and detrimentally impact stock prices. Recognizing the critical need for robust detection mechanisms, this study employs a Graph Attention Network (GAT) approach. This method leverages advanced machine learning techniques to analyze complex relational data from earnings calls, aiming to identify deceptive patterns effectively. The objective is to enhance the capability of regulators and investors to verify the credibility of corporate disclosures, thereby ensuring market fairness and stability. The paper uses the GAT methodology and investigates its transformative potential in financial fraud detection, thus supporting more informed regulatory and investment decisions.

2 - Scoping due diligence process(es) in private equity transactions

Benoît Chevalier-Roignant, emlyon business school, Ecully, France

To make the right investment decisions, a private equity (PE) firm typically gathers critical information about the would-be acquiree (``target") as part of due diligence processes. Such information acquisition often requires the hiring of consultants who carry out various due diligence streams. This paper develops a simple mathematical model to study the optimal scope of one's due diligence process, first examining when to engage a consulting firm to conduct a particular due diligence stream (e.g., a financial or a commercial due diligence) and then exploring whether (and if so, how) the PE fund adjusts the project scopes if several consultants work on different streams in parallel. We identify key factors that drive the PE fund's decision and obtain useful managerial insights.

(Co-authored by Tiziano De Angelis, University of Torino)

3 - Assortment Planning and Pricing with Consumer Searching: The Role of Anticipated Regret

Ruibing Wang, University of Mannheim, Mannheim, Germany, Cornelia Schön, Oliver Vetter

Consumers often search for product information to resolve valuation uncertainties before purchasing. Since they cannot examine all alternatives because of their limited information-acquisition ability, they conduct a two-stage search, called consider-then-choose. In the first stage, they decide a consideration set which is a subset of all available alternatives. In the second stage, they resolve the uncertainty about all products in this consideration set and choose the one with the highest utility. We extend assortment optimization under consumer choice behavior by incorporating consumer anticipated regret into the consideration set formation. Specifically, after purchase, when consumers passively notice whether an unconsidered product is more suitable than the purchased one or not, they might regret having decided a small consideration set and not devoted enough effort to searching or regret having decided a large consideration set and devoted too much effort to searching. We show that if consumers anticipate the post-purchase regret when deciding a consideration set, in some conditions the firms should offer some products that consumers will not consider. Based on this finding, we develop fully-polynomial approximation schemes or exact conic formulation for a variety of assortment problems under the consider-then-choose models with anticipated regret. For the joint assortment planning and pricing problem with homogeneous consumers, we show that the intrinsic-utility ordered assortment and the price policy that charges the same price for the products except at most those outside the consideration set and one within it are optimal.

Approximation Algorithms

Invited Session

OPT: Integer and Discrete Optimization

Chair: Heather Newman, Carnegie Mellon University, Pittsburgh, PA, United States

Co-Chair: Rudy Zhou, Carnegie Mellon University, Pittsburgh, PA

1 - Identifying the minimum value under explorable stochastic uncertainty

Hessa Al-Thani, University of Michigan, Ann Arbor, MI, United States, Viswanath Nagarajan

Consider a set of bounded random variables, each of which can be probed to determine its realized value. We are interested in determining the minimum (or maximum) value of these random variables upto some precision, while minimizing the number of probes. This is an abstract model that has applications in hiring and bid-selection, where one wants to identify an option having the maximum/minimum value (upto some precision)
by evaluating the fewest number of available options. We provide a 4-approximate policy for this problem. Interestingly, our policy is "non adaptive",
that is it probes the random variables in an a-priori fixed order until a suitable stopping rule. We note that an optimal policy may be highly adaptive, choosing the next variable to probe based on all prior realizations.

2 - Bayesian Stochastic Probing

Rudy Zhou, Carnegie Mellon University, Pittsburgh, PA, United States

We introduce a new stochastic probing problem with correlations across items to be probed. This problem has applications in stochastic knapsack with correlations across items and Bayesian active search. We give non-adaptive and adaptive approximation algorithms for this problem.

3 - Simultaneously Approximating All lp-norms in Correlation Clustering

Heather Newman, Carnegie Mellon University, Pittsburgh, PA, United States, Sami Davies, Benjamin Moseley

This paper considers correlation clustering on unweighted complete graphs. We give a combinatorial algorithm that returns a single clustering solution that is simultaneously O(1)-approximate for all ℓ_p-norms of the disagreement vector; in other words, a combinatorial O(1)-approximation of the all-norms objective for correlation clustering. This is the first proof that minimal sacrifice is needed in order to optimize different norms of the disagreement vector. In addition, our algorithm is the first combinatorial approximation algorithm for the ℓ_2-norm objective, and more generally the first combinatorial algorithm for the ℓ_p-norm objective when $1<p<\infty$. It is also faster than all previous algorithms that minimize the ℓ_p-norm of the disagreement vector, with run-time $O(n^{\omega})$, where $O(n^{\omega})$ is the time for matrix multiplication on $n\times n$ matrices. When the maximum positive degree in the graph is at most Δ, this can be improved to a run-time of $O(n\Delta^2 \log n)$.

4 - Fast Combinatorial Algorithms for Efficient Sortation

Madison Van Dyk, Amazon, Seattle, WA, United States, Jochen Koenemann

Modern parcel logistic networks are designed to ship demand between given origin, destination pairs of nodes in an underlying directed network. Efficiency dictates that volume needs to be consolidated at intermediate nodes. In practice, such consolidation requires parcel-sortation. In this work, we propose a mathematical model for the physical requirements, and limitations of parcel sortation. We then show that, in the general model, it is NP-hard to determine whether a feasible sortation plan exists. We discuss several special settings, where (near-)feasibility of a given sortation instance can be determined efficiently. The algorithms we propose are fast and build on combinatorial witness set type lower bounds that are reminiscent and extend those used in earlier work on degree-bounded spanning trees and arborescences.

Verification of Decision-Making Algorithms

Invited Session

OPT: Linear and Conic Optimization

Chair: Vinit Ranjan, Princeton University, Princeton, NJ, United States

Co-Chair: Bartolomeo Stellato, Princeton University, Princeton, NJ, United States

1 - α,β-CROWN: A Linear Bound Propagation Framework for Formal Verification of Neural Networks

Huan Zhang, University of Illinois Urbana-Champaign, Urbana, IL, United States

Neural network (NN) verification seeks to rigorously guarantee some properties of neural networks, including safety, robustness, and correctness, which are essential for using NNs in mission-critical systems. It can be formulated as a large-scale non-convex optimization problem, but off-the-shelf solvers such as mixed integer programming (MIP) can hardly scale to NNs with practical sizes. To address this challenge, I will introduce a novel framework called “linear bound propagation methods”, which exploits the structure of this problem by efficiently propagating inequalities on neural networks. It is scalable to large neural networks with millions of neurons with GPU acceleration and achieves up to three orders of magnitude speedup compared to traditional algorithms. The series of successful bound propagation algorithms leads to the development of the award-winning α,β-CROWN toolbox (https://abcrown.org). Finally, I will introduce my recent work on applying α,β-CROWN to give formal stability and safety guarantees for neural network-enabled decision-making and nonlinear control problems.

2 - Computer-Assisted Design of Accelerated Composite Optimization Methods

Uijeong Jang, Seoul National University, Seoul, Korea, Republic of, Shuvomoy Das Gupta, Ernest Ryu

The accelerated composite optimization method FISTA (Beck, Teboulle 2009) is suboptimal, and we present a new method OptISTA that improves upon it by a factor of 2. The performance estimation problem (PEP) has recently been introduced as a new computer-assisted paradigm for designing optimal first-order methods, but the methodology was largely limited to unconstrained optimization with a single function. In this work, we present a novel double-function stepsize-optimization PEP methodology that poses the optimization over fixed-step first-order methods for composite optimization as a finite-dimensional nonconvex QCQP, which can be practically solved through spatial branch-and-bound algorithms, and use it to design the exact optimal method OptISTA for the composite optimization setup. We then establish the exact optimality of OptISTA with a novel lower-bound construction that extends the semi-interpolated zero-chain construction (Drori, Taylor 2022) to the double-function setup of composite optimization. By establishing exact optimality, our work concludes the search for the fastest first-order methods for the proximal, projected-gradient, and proximal-gradient setups.

3 - Verification of First-Order Methods for Parametric Quadratic Optimization

Vinit Ranjan, Princeton University, Princeton, NJ, United States, Bartolomeo Stellato

We introduce a numerical framework to verify the finite step convergence of first-order methods for parametric convex quadratic optimization. We formulate the verification problem as a mathematical optimization problem where we maximize a performance metric (e.g., fixed-point residual at the last iteration) subject to constraints representing proximal algorithm steps (e.g., linear system solutions, projections, or gradient steps). Our framework is highly modular because we encode a wide range of proximal algorithms as variations of two primitive steps: affine steps and element-wise maximum steps. Compared to standard convergence analysis and performance estimation techniques, we can explicitly quantify the effects of warm-starting by directly representing the sets where the initial iterates and parameters live. We show that the verification problem is NP-hard, and we construct strong semidefinite programming relaxations using various constraint tightening techniques. Numerical examples in nonnegative least squares, network utility maximization, Lasso, and optimal control show a significant reduction in pessimism of our framework compared to standard worst-case convergence analysis techniques.

4 - Data-Driven Performance Guarantees for Classical and Learned Optimizers

Bartolomeo Stellato, Princeton University, Princeton, NJ, United States, Rajiv Sambharya

We introduce a data-driven approach to analyze the performance of continuous optimization algorithms using generalization guarantees from statistical learning theory. We study classical and learned optimizers to solve families of parametric optimization problems. We build generalization guarantees for classical optimizers, using a sample convergence bound, and for learned optimizers, using the Probably Approximately Correct (PAC)-Bayes framework. To train learned optimizers, we use a gradient-based algorithm to directly minimize the PAC-Bayes upper bound. Numerical experiments in signal processing, control, and meta-learning showcase the ability of our framework to provide strong generalization guarantees for both classical and learned optimizers given a fixed budget of iterations. For classical optimizers, our bounds are much tighter than those that worst-case guarantees provide. For learned optimizers, our bounds outperform the empirical outcomes observed in their non-learned counterparts.

5 - Derivative-informed Abstraction of Neural Networks for Reachability Analysis

Mahyar Fazlyab, Johns Hopkins University, Baltimore, MD, United States

A current limitation of state-of-the-art verification methods for neural networks is their inability to efficiently handle continuously differentiable neural networks, as they are purposefully tailored to piece-wise-linear neural networks, and hence, become inherently inapplicable or at least highly inefficient for continuously differentiable neural networks. In this talk, I will discuss how we can leverage higher-order derivative information to drastically improve the scalability and computational efficiency of verifying neural networks for safety, robustness, or other desirable properties. More specifically, the proposed approach abstracts (i.e., over-approximates) the map of neural networks by higher-order Taylor series expansions and bounding the higher-order terms. In contrast to the existing verification methods, the resulting abstraction locally preserves the derivative information, thereby yielding accurate bounds for small uncertainties. We tailor this approach in adversarial robustness certification as well as reachability analysis.

Advances in Robust and Risk-Sensitive Markov Decision Processes

Invited Session

OPT: Optimization Under Uncertainty

Chair: Jefferson Huang, Naval Postgraduate School, Monterey, CA, United States

1 - Stationary Optimal Policies in Risk-averse MDPs with EVaR

Marek Petrik, University of New Hampshire, Durham, NH, United States

The infinite-horizon discounted objective is popular in reinforcement learning in part because it admits stationary policies and convenient analysis. Unfortunately, all common discounted risk-averse objectives require history-dependent policies that must be computed using complex state augmentation. In this paper, we show that the total reward objective (also known as a stochastic shortest path) under the Entropic Risk Measure (ERM) and Entropic Value at Risk (EVaR) can be optimized by a stationary policy. In addition, the optimal policy can be computed using value iteration, policy iteration, and even linear programming. We establish our results under the relatively mild condition of transient MDPs allowing for both positive and negative rewards, unlike prior work. Our analytical and numerical results suggest that the total reward criterion may be preferable to the discounted criterion in a broad range of risk-averse reinforcement learning problems.

2 - Risk-Sensitive Discounted MDPs with Monotone Utilities and Unbounded Costs and Rewards

Eugene Feinberg, Stony Brook University, Stony Brook, NY, United States

This talk deals with optimization of generalized risk-sensitive functions which are modelled using increasing functionals of the discounted sums of the per-stage cost or rewards. Such functionals are defined on the full paths of the underlying random dynamical system represented by a controlled Markov chain on general state and action spaces. For the cost minimization case with nonnegative and possibly unbounded-above per-stage costs, we prove the validity of optimality equations and existence of optimal policies with noncompact action spaces, both for the nite and in nite horizon setup. For the reward maximization case with nonnegative and possibly unbounded-above per-stage rewards, we prove the validity of optimality equations and existence of optimal policies under a mild assumption of asymptotic uniform integrability of the value function, again both for the nite and in nite horizon setup. For both cost and reward cases, we also prove the convergence of the nite-horizon optimal value function to the in nite horizon optimal one. For the reward case, we also provide some new results on the connection between Lyapunov stability of the underlying transition kernel and the asymptotic uniform integrability of the infnite-horizon value function.

3 - Dynamically Maintaining Infrastructure Networks

Jefferson Huang, Naval Postgraduate School, Monterey , CA, United States

This talk is about Markov decision models of sequential maintenance planning problems in infrastructure networks, such as fuel or water distribution networks. We focus on cases where the one-step cost associated with each feasible state-action pair is the optimal objective function value of an associated network flow problem. In general, optimal policies for these models are complicated, and can quickly become difficult to compute as the size of the network increases. Moreover, the possibility of climate or adversary-driven disruptions motivates the search for policies that are robust. We describe recent work addressing these issues that also draws connections to the network interdiction literature.

Recent Advances in Global Stochastic Optimization

Invited Session

OPT: Global Optimization

Chair: Burla Ondes, Purdue University, West Lafayette, IN, 47906, United States

1 - Rate-Optimal Budget Allocation for the Probability of Good Selection

David Eckman, Texas A&M University, College Station, TX, United States, Taeho Kim

This talk considers the allocation of simulation effort in a ranking-and-selection (R&S) problem with the goal of selecting a system whose performance is within a given tolerance of the best. We apply large-deviations theory to derive an optimal allocation for maximizing the rate at which the so-called probability of good selection (PGS) asymptotically approaches one, assuming that systems' output distributions are known. An interesting property of the optimal allocation is that some good systems may receive a sampling ratio of zero. We demonstrate through numerical experiments that this property leads to serious practical consequences, specifically when designing adaptive R&S algorithms. In particular, we observe that the convergence and even consistency of a simple plug-in algorithm designed for the PGS goal can be negatively impacted. We offer empirical evidence of these challenges and a preliminary exploration of a potential correction.

2 - Monte Carlo Partitioned Bayesian Optimization for Treed Black Box Functions

Mohit Malu, Arizona State University, Tempe, AZ, United States, Giulia Pedrielli, Gautam Dasarathy, Andreas Spanias

Bayesian Optimization (BO) frameworks typically assume the function to be optimized is stationary (homogeneous) over the domain. However, in many real-world applications, we often deal with functions that present a rate of variation across the input space. In this paper, we optimize heterogeneous functions where a finite set of homogeneous functions defined over sub-regions of the input space represent the heterogeneity. The disconnected sub-regions that can be characterized by the same function are said to be in the same class, and evaluating the function at input returns the minimum distance to a boundary of the contiguous class (sub-region).
The ClassGP modeling framework, previously developed to model for such heterogeneous functions along with a novel MCMC based tree sampling algorithm, is used to introduce a novel tree-based optimization framework dubbed as ClassBO (Class Bayesian Optimization). We present theoretical analysis of the algorithm and demonstrate the superior performance of ClassBO against other methods via empirical evaluations

3 - A Parametric Approach for Solving Convex Quadratic Optimization with Indicators Over Trees

Aaresh Bhathena, University of Michigan, Ann Arbor, MI, United States, Salar Fattahi, Andres Gomez, Simge Kucukyavuz

This paper investigates convex quadratic optimization problems involving n indicator variables, each associated with a continuous variable, particularly focusing on scenarios where the matrix Q defining the quadratic term is positive definite and its sparsity pattern corresponds to the adjacency matrix of a tree graph. We introduce a graph-based dynamic programming algorithm that solves this problem in time and memory complexity of $\mathcal{O}(n^2)$. Central to our algorithm is a precise parametric characterization of the cost function across various nodes of the graph corresponding to distinct variables. Our computational experiments conducted on both synthetic and real-world datasets demonstrate the superior performance of our proposed algorithm compared to existing algorithms and state-of-the-art mixed-integer optimization solvers. An important application of our algorithm is in the real-time inference of Gaussian hidden Markov models from data affected by outlier noise. Using a real on-body accelerometer dataset, we solve instances of this problem with over 30,000 variables in under a minute, and its online variant within milliseconds on a standard computer. A Python implementation of our algorithm is available at (https://github.com/aareshfb/Tree-Parametric-Algorithm.git).

4 - Global Multi-Objective Simulation Optimization with Low Dispersion Point Sets

Burla Ondes, Purdue University, West Lafayette, IN, United States, Susan Hunter

Consider the context of a Multi-Objective Simulation Optimization (MOSO) problem, that is, an optimization problem with multiple simultaneous and conflicting objectives that can only be observed with stochastic error through a Monte Carlo simulation oracle. The goal of solving a MOSO problem is to identify decision points that map to the global Pareto set. For such problems featuring continuous objectives on a compact feasible set, we determine how one should trade off the number of decision points to sample, m, with the number of simulation replications per sampled point, n, to ensure the estimated Pareto set converges to the true Pareto set under a novel performance measure called the modified coverage error. This performance measure enables us to quantify upper bounds on the deterministic and stochastic error as a function of the dispersion of the m points in the decision space and the number of simulation replications per point, n. The upper bounds and tradeoff analysis lead to efficient algorithms for solving global MOSO problems with probabilistic guarantees using low dispersion point sets.

5 - Optimizing Camera Placement in Critical Environments: A Simulation Optimization Approach

Yash Kumar, The University of Texas at Austin, Austin, TX, United States, Raghu Bollapragada, Benjamin Leibowicz

Camera placement optimization is critical for surveillance, environmental monitoring, and infrastructure inspection, yet even simplified versions are NP-hard due to high-dimensional camera configurations and challenges in accurate coverage calculation. This paper presents a novel simulation optimization framework for camera placement, combining discrete and continuous optimization methods for efficient free space coverage. Our approach employs mixed-integer programming and derivative-free optimization in an iterative structure, segmenting the free space into weighted voxels (3D pixels). By refining camera configurations based on visibility approximation and adaptive sampling, our method maximizes visibility coverage while considering resource constraints. Fine-tuning with a granular spatial grid improves accuracy, and utilizing derivative-free optimization methods improves the objective even further. Our research emphasizes intelligent strategies to enhance camera placement efficiency and robustness. Through case studies, we demonstrate the effectiveness of our approach in critical environments where efficient surveillance is crucial.

Stochastic Integer Programming with Applications

Invited Session

OPT: Optimization Under Uncertainty

Chair: Juan-Alberto Estrada-Garcia, University of Michigan, Ann Arbor, MI, 48109, United States

1 - Distributionally Robust Multimodal Generation Maintenance and Operations Scheduling with Storage and Wind Energy Uncertainty

Natalie Randall, University of Iowa, Iowa City, IA, United States, Beste Basciftci

This study focuses on a predictive generator maintenance and operations scheduling problem with storage units under multimodal wind energy uncertainty. We formulate this problem as a two-stage distributionally robust mixed-integer program under a multimodal moment-based ambiguity set, where the first-stage problem determines the maintenance and unit commitment related decisions of the generation units, whereas the second-stage problem determines the production related plans of the generators and storage units under the ambiguity of wind energy. We present a column-and-constraint generation algorithm to solve our large-scale problem. We provide a computational study over different IEEE bus instances, and analyze the impact of wind farms and storage units on the system while demonstrating the computational efficiency of the solution algorithm.

2 - Neural Approximate Dynamic Programming for the Ultra-Fast Order Dispatching Problem

Mucahit Cevik, Toronto Metropolitan University, Toronto, ON, Canada

Same-Day Delivery (SDD) services aim to optimize the speed of online order fulfillment while taking into account operational challenges such as fluctuations in order volumes and uncertainties in courier schedules. Our work enhances the effectiveness of SDD by concentrating on the ultra-fast Order Dispatching Problem (ODP), which entails the rapid assignment and dispatching of orders to couriers within a central warehouse environment, aiming to complete deliveries within tight deadlines (e.g., within minutes). We introduce improvements such as order grouping and specific courier allocations, offering a more accurate depiction of dispatch operations and boosting delivery performance. Our approach primarily employs NeurADP, a novel technique that merges Approximate Dynamic Programming with Deep Reinforcement Learning (DRL), marking its first application beyond ride-pool matching. NeurADP effectively handles the complex matching and routing challenges inherent in ultra-fast ODP through a neural network-based Value Function Approximation that adeptly manages high-dimensional problem complexities without the need for traditional manual feature engineering. We evaluate our method on four specialized datasets designed for ODP, assessing NeurADP's performance against standard myopic and DRL benchmarks and utilizing derived bounds to examine policy effectiveness. The numerical results show that incorporating order batching and courier queues significantly boosts delivery efficiency, with NeurADP outperforming alternative approaches.

3 - Stochastic Integer Programming with Decision-Dependent Uncertainty for Infrastructure Monitoring

Siqian Shen, U of Michigan/NSF, Ann Arbor/Alexandria, MI, United States, Juan-Alberto Estrada-Garcia

Infrastructure monitoring is critical for systems that are subject to uncertain failures. We consider the problem of dispatching multiple maintenance fleets (e.g., drones) to examine different parts of a system, whose failures are probabilistic and also depend on inspection schedules and fleets' arrival time. The goal is to balance the fleets' routing and operational cost with the uncertain cost of system failure and maintenance. We model a two-stage stochastic mixed-integer program with decision-dependent uncertainty and solve it via a stochastic decomposition algorithm. We speed up the computation of subproblems using column generation and random coloring algorithms. Furthermore, we consider dynamic system monitoring and real-time drone routing with updated system information after each arrival, and solve the problem using stochastic dual dynamic integer programming and reinforcement learning. We conduct numerical studies using networks with different sizes and topologies, as well as the IEEE 33-bus system, to demonstrate the efficiency and effectiveness of different approaches.

4 - Multi-stage stochastic programming models for long-term disaster housing planning

Sheng-Yin Chen, Clemson University, Central, SC, United States, Yongjia Song

In the long-term disaster housing logistics planning, our objective is to establish a housing logistics network for sustained disaster response and provide a long-term inventory strategic policy framework that decision-makers. We apply various types of multi-stage stochastic programming models to capture the life-cycle of disaster housing and aim to balance between long-term logistics cost and the quality-of-life of disaster victims.

Summit - 425

Advanced Scheduling and Optimization Techniques in Value Chains

Contributed Session

Chair: Payman Jula, Simon Fraser University, Vancouver, BC, Canada

1 - Scheduling parallel non-homogeneous machines in coordinated value chains.

Payman Jula, Simon Fraser University, Vancouver, BC, Canada

Motivated by scheduling challenges in complex manufacturing environments, we propose mathematical programming models and heuristic solutions to schedule parallel non-homogeneous machines that must be coordinated with other areas of the chain. We address selecting and scheduling jobs considering sequence-dependent setup times and strictly enforced time windows. The efficiency, effectiveness and robustness of the proposed methods are discussed.

2 - A Mixed-Integer Optimization Tool for System-Level Proactive Obsolescence Risk Management

Chad Uhles, University of Tennessee, Knoxville, Knoxville, TN, United States, Hugh Medal

Diminishing manufacturing sources and material shortages (DMSMS) pose a significant risk to the reliability and maintainability of many modern complex systems due to part obsolescence. Part obsolescence increases the risk of system failure or downtime, which is often not only undesirable, but non-negotiable. As such, it is imperative to anticipate events of part obsolescence and take proper actions to mitigate their effects. However, developing a detailed system-wide plan of mitigating events of obsolescence could necessitate the consideration of thousands, or even millions, of decisions before an optimal plan is derived. Thus, there exists a need for an automated tool that can produce a cost optimal obsolescence management plan. In this work, we propose a mixed-integer optimization tool that proactively manages and mitigates events of obsolescence at the system level. By considering the architecture of the bill of materials, part inventories, expected system demand, and forecasted obsolescence dates, our tool makes decisions of when and how to enact up to 8 unique short-term and long-term resolutions for every part within the system at every time until the anticipated system end of life. The parameters determine the structure of a mixed-integer optimization problem, where the objective is to minimize costs for the system over the entire time horizon. We present the findings of a case study that compares the obsolescence management plan of a reactive strategy to a plan produced by our mixed-integer programming optimization tool and derive insights based on the difference between the solutions produced by the two methods.

3 - Cooperation and competition in two-agent scheduling with parallel batching

Renjie Yu, The University of Sydney, Camperdown, Australia, Daniel Oron

We study single-machine scheduling problems involving two competing agents sharing a batching machine. This machine can handle at most one job from each agent simultaneously. Our focus is on two due date-related scheduling criteria: the number of late jobs and the total late work. We investigate two variations for each problem: minimizing the combined objectives of both agents, and minimizing the objective of one agent while imposing an upper bound on the other agent's objective. All four versions of the problem are demonstrated to be strongly NP-hard. To address this complexity, we devise efficient Mixed-Integer Linear Programming (MILP) formulations, and employ constructive algorithms and Tabu Search for approximate solutions. A comprehensive numerical analysis validates the effectiveness of the approximation algorithms.

4 - A restless bandit approach for capacitated condition-based maintenance scheduling

Ece Zeliha Demirci, TED University, Ankara, Turkey, Joachim Arts, Geert-Jan Van Houtum

We address the maintenance scheduling problem of multiple non-identical machines deteriorating over time. As the machines deteriorate, their efficiency diminishes, leading to reduced output quality and revenue losses. Maintenance costs increase as the machines' condition worsens, and the number of simultaneous maintenance tasks is restricted by the number of maintenance workers. We cast the problem as a restless bandit problem and propose an efficient index-based heuristic, namely Whittle’s index policy. Additionally, we establish a lower bound on the optimal solution using linear programming. Our numerical experiments demonstrate that Whittle’s policy outperforms both failure-based and threshold-based maintenance strategies.

Platforms Operation in Urban Transportation

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Sisi Jian, HKUST, Clear Water Bay, N/A

1 - Stackelberg Game in Mobility-as-a-Service Platforms with Stochastic Matching between Users and Operators

Bingqing Liu, New York University, Brooklyn, NY, United States, David Watling, Joseph Chow

This study proposes a stochastic Stackelberg game to model Mobility-as-a-Service (MaaS) systems, where the platform is the leader, users and operators are the followers. The platform set fares to maximize revenue. Users and operator react to the fares to form a stochastic many-to-many assignment game considering both fixed-route services and Mobility-on-Demand (MOD). There are two major contributions. First, the many-to-many assignment game is extended into a stochastic form while including the impact of fares. The stochastic assignment game captures the heterogeneity in both users and operators with a coalitional route-choice logit model. Second, the role of the platform is modeled as the leader of the platform who does pricing while fully anticipating the reaction of users and operators with the Stackelberg game. The Stackelberg game is written into a bilevel problem. The lower level is the stochastic many-to-many assignment game between users and operators, which is shown to yield a coalitional logit model. The upper level sets fares to maximize revenue. An iterative balancing algorithm is proposed to solve the lower-level problem. The bilevel problem is solved through an iterative fare adjusting heuristic with a Frank-Wolfe fare adjusting mechanism, whose solution is shown to be equivalent to the bilevel problem with an additional condition when it converges. Two case studies are conducted. The model could be applied to design MaaS fares maximizing income of the platform while anticipating the selfish behavior and heterogeneity of users and operators. Public agencies could also use the model to manage multimodal transportation systems.

2 - Preference-based matching mechanism tailored for ride-hailing platforms considering congestion effects

Yanyan Ding, Hong Kong Polytechnic University, Hong Kong, Hong Kong, Shixuan Tang, Sisi Jian

With the widespread and rapid growth of on-demand e-hailing service, how to effectively match passengers and drivers becomes one of the most significant operational problems for online platforms to realize their best revenues. This study therefore investigates the e-hailing matching problem from the perspective of platforms. Considering the passenger preference, a menu-based assignment mathematical model is formulated to maximize the expected operational revenue. For tractability, a deferred algorithm (DA) to effectively assign large-scale instances. Numerical experiments are conducted based on real data from Haikou, Hainan to validate the effectiveness and efficiency of the proposed method, followed by some practical insights and implication for the online matching platforms.

3 - The VCG Pricing Policy with Unit Reserve Prices for Ride-Sourcing is 3/4-Individual Compatibility

Xiaotong Sun, The Hong Kong University of Science and Technology (Guangzhou), Guangzhou, Hong Kong, Ruijie Li, Haiyuan chen, Kenan Zhang, Xiaobo Liu

We consider a customized pricing and matching strategy for ride-sourcing services in which drivers and riders disclose their willingness to pay (WTP) per unit distance and willingness to accept (WTA) per unit distance, respectively. The platform then matches drivers and riders based on their reports to maximize the total social welfare. While this strategy is motivated to promote transparency, fair pricing, and participant satisfaction, it faces a particular challenge to ensure riders and drivers truthfully report their valuations, which are considered private information. To encourage truthful reports, we implement the Vickrey-Clarke-Groves pricing policy augmented with unit reserve prices, referred to as VCG-URP. For the riders, the reserve price is set as the minimum WTP per unit distance, while for the drivers, it is the maximum WTA per unit distance. We demonstrate that VCG-URP ensures that riders provide truthful valuations. However, it does not guarantee the same level of honesty from drivers in reporting their valuations. While drivers cannot enhance their utility by overstating their unit WTA, they may benefit from understating it. These theoretical results are confirmed by numerical experiments with several additional findings: i) although the underreporting strategy of the drivers theoretically has an opportunity to achieve a higher utility, it always leads to a decrease in expected utility over randomly generated matching scenarios; ii) the introduction of reserve prices has larger impacts on riders than drivers and benefits the platform in excluding less profitable trips.

4 - eMaaS design that incorporates the three-sided matching among traveler, operator, and energy provider

Hai Yang, New York University, Brooklyn, NY, United States, Bingqing Liu, Joseph Chow

In the electric Mobility-as-a-Service (eMaaS) market, travelers interact with mobility providers, and the latter in turn interact with energy providers. This study proposes an electric-MaaS (eMaaS) assignment game capturing interdependencies between operators, travelers, and energy providers. The problem is formulated into a many-to-many 3-sided assignment game, using the supplier-firm-buyer structure. Matching is represented by two sets of disjoint path flows: flows of travelers along paths for ODs, and flows of vehicles to energy providers. The model captures steady state probabilistic flows. The matching problem can be represented by a tractable combination of a path-based multicommodity network design problem and a transportation problem. To capture probabilistic charging demand, we adopt a stochastic assignment game via a coalitional logit model where disjoint coalitions (travelers + mobility operators, mobility operators + energy providers) choose among a set of paths using a logit model. We propose to model the stability constraints corresponding to this problem as optimality conditions of the stochastic user equilibrium (SUE) problem, and the stochastic assignment game transforms into a Stackelberg game with platform pricing leaders (energy prices, mobility prices) and matching mobility operators, energy providers, and travelers as followers. The upper-level problem determines the pricing of service fares and charging costs, while the lower-level problem solves the assignment game between operators and travelers, as well as the assignment between operators and energy providers. By changing the upper-level objective function (max consumer surplus vs. max system profit), different pricing strategies of both operators and energy providers can be assessed.

Summit - 428

Modeling and Optimization in Transportation and Mobility Systems

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Wang Chen, The University of Hong Kong, Hong Kong, N/A

1 - Joint Pricing, Matching, and Repositioning for Dynamic High-Capacity Ride-Sharing Considering Future Opportunity Costs

Wang Chen, Department of Civil Engineering, The University of Hong Kong, Hong Kong SAR, China, People's Republic of, Jintao Ke

This research proposes a joint optimization framework for dynamic high-capacity ride-sharing, which simultaneously optimizes pricing, matching, and repositioning considering future opportunity costs that indicate the future expected revenue. This research considers passengers to be price-sensitive and have a choice to decline the upfront prices offered by the platform. The future opportunity costs and passengers' choice behavior are integrated into the optimization framework that maximizes the platform's expected revenue with given batches of passengers and drivers. This research models the framework as a two-stage stochastic optimization problem. This problem is relaxed to a one-stage problem with a convex objective function, achieving comparative accuracy while dramatically lower computational costs. Numerical studies show that the proposed optimization framework can create substantial economic benefits for the platform in different cities without adjusting hyperparameters, indicating the proposed optimization framework could be generally applied to other cities.

2 - Competition in the Intercity Passenger Transport Market with Ride-Pooling Services

Jinhua Si, Department of Industrial Engineering, Tsinghua University, beijing, China, People's Republic of

Ride-pooling services are increasingly promising for intercity travelers. These demand-responsive services are notably effective in promptly addressing intercity requests and reducing overall travel durations. However, planning for this emerging mode must also account for heightened competition from existing modes, such as conventional intercity buses and the expanding high-speed rail networks. In this study, we develop stylized game models to characterize the intercity passenger transportation market, which includes ride-pooling services and alternative intercity transportation modes. Through hierarchical passenger segmentation based on travel urgency and analysis of demand preferences across urban areas, we optimize fleet size and trip fares to achieve market equilibrium. By assessing competitive advantages across various market parameters and spatial conditions, we highlight the transformative impact of ride-pooling services on traditional modes and propose strategic entry points to leverage latecomer advantages. Our findings have implications for the deployment of intercity demand-responsive services, aiming to enhance benefits for both service providers and intercity travelers.

3 - Railway Disruption Management: Designing Shuttle Bus Services and Passenger Assignment with Subsidized Taxi Support

Hongzheng SHI, Department of Civil Engineering, The University of Hong Kong, Hong Kong, China, People's Republic of, jiguang Wang, Jintao Ke

Rail transit systems are playing an increasingly important role in major cities worldwide, leading to more frequent service disruptions. Shuttle bus service is a common coping strategy for these disruptions, but it suffers less flexible, which may lead to higher operating costs to serve all affected passengers. Giving subsidies to taxi drivers near the disruption location can attract them to provide flexible capacity for the shuttle bus service and thereforme reduce the total service cost while meeting passenger's demand. In this paper, we systematically investigate the problem of designing shuttle bus service with subsidized taxi support, which involves determining the taxi subsidy amount, shuttle bus route design, frequency determination, and passenger assignment. The problem is formulated as a mixed-integer programming (MIP) model with the objective of simultaneously minimizing route operating time, detour penalty, shuttle bus usage cost, and taxi subsidy cost. To address the model's nonlinearity, we propose a predict-then-optimize framework that first predicts the optimal subsidy and then optimizes the shuttle bus service design with the predicted subsidy. A column-generation-based algorithm is proposed to efficiently solve the model after the prediction process. Experiments demonstrate that our method can provide efficient response plans in advance for various disruptions.

4 - A Two-Stage Stochastic Programming Optimization for Multi-Type Chargers Deployment and Electricity Distribution

jiguang Wang, Department of Civil Engineering, the University of Hong Kong, Hong Kong, China, People's Republic of, Hongzheng SHI, Xinglu Liu, Kefan Lai, Jintao Ke

Electric vehicle systems have emerged as a promising and sustainable solution for urban mobility. This study proposes an integrated optimization problem that addresses the long-term deployment of multi-type charging facilities for electric taxi systems at the planning level. Additionally, it optimizes electricity distribution decisions from energy storage systems (ESS) and the power grid at the operational level, while considering the nonlinear operating costs of charging power supply. Charging demand is estimated from real taxi trajectory data, then to account for demand uncertainty, a two-stage stochastic integer program is formulated, and valid inequalities are designed to expedite the exact solution of the model. To handle a large number of scenarios in the stochastic program, the sample average approximation scheme is employed as the sampling strategy. The modeling and algorithm approach is rigorously tested through a comprehensive case study conducted in Hong Kong, China. The results of extensive experiments demonstrate that the deployment of multi-type charging infrastructure, along with the joint optimization of ESS and the power grid, can significantly enhance system profitability and improve operational performance. Sensitivity analysis is utilized to provide valuable management recommendations.

Advances in Delivery Service Operations

Contributed Session

Chair: Mouna Bamoumen, Tilburg University, Tilburg, N/A, Netherlands

1 - The Location-Routing Problem with Pickup Facilities and Heterogeneous Demand: Formulation and Heuristic Approach

Yida Xu, Tianjin University, Tianjin, China, People's Republic of, ZHAO ZHAO, Zhaofang Mao, Kan Fang

Nowadays, as more uncertain influential factors have emerged and customer demand becomes more heterogeneous and discrete, last-mile delivery has become a time-consuming and uncertain process. Unreasonable distribution network design would lead to higher delivery failure rates and lower vehicle utilization. As a result, courier companies have delpyed various innovative parcel storage facilities, including pick-up points and lockers.

In order to optimize the last-mile distribution network to adapt to the complex and ever-changing distribution environment, we focus on the introduction of self-pickup facilities in modern logistics and distribution scenarios under heterogeneous customer demands. We distinguish the demand into two categories: general goods and special goods (e.g., irregular package and refrigerated goods), as well as corresponding transportation vehicles. Subsequently, we address the location-routing problem with pickup facilities and heterogeneous demands (LRP-PFHD). To solve this challenging problem, we propose a mixed integer linear programming (MILP) model that aims to minimize the total cost. Due to the NP-hardness of the problem, we propose an adaptive large neighbourhood decomposition search algorithm to solve LRP-PFHD. We evaluate both the effectiveness and the efficiency of the proposed method using generated instances based on benchmark datasets. The results demonstrate the effectiveness of the proposed method compared to commercial MILP solvers such as Gurobi for LRP-PFHD, especially for large-scale instances. In addition, we make a comprehensive analysis of certain parameters (e.g., facility opening cost, transportation cost) to explore their impacts on the results and provide helpful managerial insights for courier companies.

2 - Combining Gamification and Crowdsourcing to Improve Solutions for the Container Loading Problem Applied to Large Objects

Jorge Elias Garcia Zamalloa, Georgia Institute of Technology, Atlanta, GA, United States, julien Maurice, Benoit Montreuil, Ali Barenji

The last-mile delivery problem is one of the key hot topics that researchers around the world are studying. Its relevance is mainly triggered by the costs associated with it, the rapid increase of e-commerce, and customers who expect to receive their orders almost instantly. Under this setting, an alternative that is becoming more popular is the introduction of modular warehouses—semi-permanent engineered infrastructures that can be assembled in a few weeks and can be disassembled to install elsewhere. Additional benefits include reduction of setup costs and closing the distance between companies and the market.

However, the main drawbacks are the difficulty of transporting the structure, and the capacity of the trucks to carry it efficiently. An optimization approach can be used to generate the required loading plan, but it is a resource-consuming process since it is a combinatorial optimization problem. Moreover, since most objects involved tend to have irregular shapes, the heuristics needed to solve the problem usually incorporate simplified geometric constraints and tend to generate suboptimal solutions.

We propose to generate an initial non-optimal containerization plan and improve it by leveraging human factor, gamification, and crowdsourcing. The key idea is to create ludic and realistic scenarios where people perform the containerization of 3D irregularly shaped objects and compete to maximize the utilization of the vessel. Then, an agent can learn from the best proposed configurations and develop its own strategies for new settings. This approach creates new research directions for the container loading problem.

3 - A Hybrid Q-Learning Evolutionary Approach for Routing Planning in Mobile Store Services

Chieh-Ju Juan, Department of Aviation Management, Air Force Academy, Taiwan, Kaohsiung, Taiwan, Taiwan

In recent years, with the rapid development of technological advantages and the concept of sharing economy, the prevalence of online delivery platforms has surged, providing people with convenient and fast options for fulfilling their consumption preferences. In order to bolster the competitiveness in sales, traditional retailers have begun introducing mobile store services. These mobile vehicles utilize their flexibility to park at different locations, thereby leveraging their adaptability to cater to a wide range of areas, effectively meeting the needs of a larger customer demographic. In this study, we define the Mobile Store Vehicle Routing Problem (MSVRP) as a dynamic vehicle routing problem with time windows. The objective is to enhance the adaptability of routing planning for mobile store vehicles, enabling them to effectively navigate the increased complexity resulting from fluctuating environmental conditions. A hybrid Q-Learning evolutionary algorithm (HQEA) is developed to solve the MSVRP, where two objectives are simultaneously considered: total duration of vehicles, and operation profit. In HQEA, the nondominated sorting genetic algorithm II serves as the static optimizer in stable environments, while a continuous reoptimization procedure is devised to address dynamic conditions. Within this reoptimization framework, three strategies are introduced and incorporated into a Q-learning mechanism, functioning as an agent to guide transitions between strategies. This approach aims to enhance the algorithm's performance systematically. The experimental results obtained from testing on benchmark datasets demonstrate that the proposed algorithm is successful in generating promising routing plans.

4 - Dynamic pricing and routing for online food delivery

Mouna Bamoumen, Tilburg University, Tilburg, Netherlands, Haitao Liu, Jan Fransoo

We examine the case of dynamic pricing and routing for online food delivery, where a group of couriers transports goods from various restaurants to customers who place orders. This work is motivated from a direct observation on the potential delays caused by prolonged waiting times for elevators during peak hours. To incorporate this new aspect into the modelling, our objective is to decide on delivery alternatives' prices and to allocate orders to couriers in order to efficiently manage the fleet of drivers and meet customer deadlines with the least amount of delay. This problem is characterized by three main sources of uncertainty. First, customers' identities remain unknown until they initiate an order. Additionally, the choice of delivery option is not known until the customer confirms their order. Lastly, the service time is impacted by the waiting time for elevators, which is not observed until the courier reaches their destination. We model this integrated demand management with dynamic pricing and routing decision problem under stochastic service times for Same-Day Delivery as a Markov Decision Process. We propose a Value Approximation Function to find the optimal policy of pricing and routing that maximizes the total expected revenue.

1 - Auto-Development of AI Systems for Predicting Discard of Donated Organs Empowered by Deep Reinforcement Learning

Yuzhang Han, California State University San Marcos, San Diego, CA, United States, Zahra Gharibi, Mehmet Ayvaci

We develop an advanced Artificial Intelligence (AI) system to detect procured organs at a heightened risk of being discarded. The AI identifies these organs and investigates the underlying reasons for potential discards, categorizing them into five distinct groups based on donor clinical, behavioral, and social characteristics. This categorization provides critical insights into the primary factors contributing to organ discards, enabling the development of improved strategies for organ handling and allocation. The AI model aids decision-makers and policy designers in enhancing organ utilization and patient outcomes by facilitating strategic organ allocation to efficiently match viable organs with recipients, thus reducing unnecessary discards and improving the transplantation process.

2 - Medical Livestreaming as Pipes and Prisms on Online Medical Consultation Platforms

YIXUAN LIU, Hong Kong Polytechnic University, hongkong, China, People's Republic of, Xiaofei Zhang, Mike Lai

Medical live streaming, a utilization of live streaming technology in online medical consultation (OMC) platforms, can be a bridge to close the information gap and alleviate medical disparities. Many OMC platforms have introduced this feature allowing qualified physicians to conduct medical live streaming. However, the impact of medical live streaming on platform operations remains unclear. Specifically, medical live streaming may present a paradox: it may help clarify uncertainties, and encourage patient consultations and patient professionalism; or it could promote self-diagnosis, reducing the patients' desire to consult and reduce patient professionalism. From a theoretical standpoint, there is also limited understanding regarding how the role of medical live streaming diverges from that of conventional live streaming. Therefore, it is crucial to investigate how medical live streaming influences patient consultations and patient professionalism, as well as the underlying mechanisms. In this paper, we study these tradeoffs through a quasi-natural experimental setting. We show that medical live streaming has a significant, positive, and robust impact on platform operations, in terms of patient consultations and patient professionalism. We further explore the underlying mechanisms and find that the impact is exerted potentially match-up effect. We also conduct a series of analyses to unravel the heterogeneity associated with the characteristics of live streaming and physicians/patients. Our findings contribute to the understanding of the role of medical live streaming and provide insights to academics and practitioners.

3 - Towards a robust decision aid for personalized deceased-donor kidney offer evaluation

Fatemeh Gholizadeh, University at Buffalo, Buffalo, NY, United States, Prashant Sankaran, Robert Dell, Moises Sudit, Liise Kayler

Patients with end-stage kidney disease (ESKD) primarily have two options for survival: dialysis and kidney transplant. When patients with ESKD opt for a kidney transplant, they join the dynamic national transplant waiting list where they are assigned an allocation score based on their characteristics that updates with health changes. When a deceased donor organ becomes available for transplant, its viability is assessed, a matching algorithm is run to find compatible candidates from the waiting list, and the kidney offer is made to the highest-ranked candidate. This offer includes information about the kidney to help the patient and their physician in evaluation. If rejected, the offer proceeds to the next candidate. While assessing the kidney offer, the physician must inform the candidate about the tradeoff in accepting or rejecting the offer. Estimating the quality and waiting time of a future kidney offer are two critical pieces of the decision-making process. Physicians generally cannot provide quantitative estimates of expected wait times and the quality of future kidney offers. Further, the offers available to lower-ranked candidates are affected by the decisions made by the higher-ranked candidates, highlighting the interdependence among the patients on the waiting list. The existing literature on personalized estimation of waiting times and the quality of future offers has not considered the influence of ranking on waiting times. Our work addresses this gap by including estimates of a candidate's ranking to estimate their waiting time and the quality of future offers.

Advancements in Medical Technology and Healthcare

Contributed Session

Chair: Carolina Arroyo-Roldan, University of Puerto Rico - Mayaguez, Añasco, PR, 00610, United States

1 - Feature Subset Selection Framework for Endometriosis Diagnostics

Carolina Arroyo-Roldan, University of Puerto Rico - Mayaguez, Mayaguez, PR, United States, Wandaliz Torres-Garcia

Endometriosis is a gynecological disease characterized by the growth of endometrial tissue outside of the uterus. It is known to cause pelvic pain, dyspareunia, and dysmenorrhea, and has been linked to infertility. The diagnosis of endometriosis takes various years, partly because the gold standard for diagnosis is an invasive laparoscopic surgery which poses both a physical and financial burden on women. Previous research studies to identify potential molecular biomarkers face statistical and computational limitations due to small sample sizes with high dimensionality. Additionally, there is no standardization regarding factors that should be considered when analyzing the gene expression of endometrial tissue, such as disease severity and the phase of the menstrual cycle. Though experiments with large sample sizes are not available, many new and upcoming experiments are being generated to bridge the gap in understanding the biological mechanisms of this largely uncharacterized disease affecting many women worldwide. Therefore, we propose the development of a consensus framework to extract the best feature subsets to discriminate between endometriosis patients versus women without the disease using gene expression of endometrial tissue, as well as clinical information such as the stage of the menstrual cycle. This framework aims to identify and rank feature subsets using (1) optimization-based search algorithms coupled with classification methods and (2) queries of functional processes from gene-annotated databases across multiple publicly available experiments from the Gene Expression Omnibus repository to evaluate consensus.

2 - Deep Learning to Synthesize Dynamic Contrast-Enhanced Breast MRI for Breast Cancer Screening

Suleeporn Sujichantararat, Department of Radiology, University of Washington, Seattle, WA, United States, Debosmita Biswas, Anum Kazerouni, Michael Hirano, Habib Rahbar, Savannah Partridge

Breast magnetic resonance imaging (MRI) is the most sensitive tool for breast cancer detection. Conventional breast MRI relies on gadolinium-based contrast agents (GBCAs) to produce dynamic contrast-enhanced (DCE) images, which reflect abnormal tissue vascularity and aid physicians in identifying cancers. However, GBCAs may pose side effects to patients and repeated doses used in annual breast MRI screening pose unknown health risks. Furthermore, administration of GBCAs is costly and time consuming, which makes MRI exams overall less accessible for general breast screening. To eliminate the need for GBCAs and improve the safety and accessibility of breast MRI, prior work has successfully utilized Artificial Intelligence (AI), specifically deep learning models, to synthesize DCE images from unenhanced images. In this work, we aim to refine the existing models, which were primarily designed for demonstrating larger invasive breast cancers, to detect early cancers in a screening population of women with dense breasts. One approach is utilizing U-Net, a convolutional neural network developed for biomedical image segmentation. Another approach is utilizing a hierarchical fusion network with attention mechanism model. Inputs to these models include a variety of combinations of different unenhanced MR sequences: T1-weighted, T2-weighted, diffusion-weighted imaging (DWI) with different b-values, and apparent diffusion coefficient (ADC) map. We will train and evaluate models on a dataset of women with mammographically dense breast tissue undergoing MRI screening. Evaluation metrics will include quantitative assessment using Structural Similarity Index Measurement (SSIM) and Normalized Mean Squared Error (NMSE), and qualitative multireader radiologist assessment of synthetic DCE quality.

3 - Combating the Societal Grand Challenge of Ransomware: Impacts of Disclosed Organizational Responses from an Epidemiological Perspective

Shivan Bhatt, Clemson University, Clemson, SC, United States, He Li, William Kettinger

Ransomware is a form of malware that involves three, sequential events. Hackers access a system, attack the system by preventing access and/or encrypting data, and demand a ransom in return for providing access to the system or decrypting data i.e., digital extortion. Ransomware attacks inflict significant costs on organizations, such as financial, downtime, opportunity, and reputation costs, while hackers use the ransom to fund more attacks, underscoring the importance of understanding ransomware and developing managerial guidance. Ransomware exists as strains, indicating that the malware contains a shared codebase with other malware. Survival of a ransomware strain is influenced by how organizations respond to ransomware attacks e.g., paying a ransom or coordinating with security experts. Organizational responses to ransomware attacks affect hackers' decision-making calculus i.e., how hackers perceive costs and benefits of strains. Hackers select strains that offer the highest benefit and lowest cost. We examine organizational responses to ransomware attacks and their impact on strain survival. Using time-to-event analysis, we find that both the immediate and cumulative effect of paying a ransom is an increase in strain survival. This contrasts with the effect of coordination, defined as an organization either engaging with law enforcement or information security experts. The immediate effect of coordination does not impact strain survival; only the cumulative effect of coordination decreases strain survival. We also find that responses are not path dependent i.e., previous responses do not predict current responses. These findings provide important theoretical and practical insight for organizations responding to ransomware attacks.

4 - Patient Satisfaction in Healthcare: The Roles of Pre-defined Service Aspects and Unstructured Comments

Lin Lu, Fairfield University, Fairfield, CT, United States, Qiong Hu

Healthcare services have undergone transformative changes to adapt to new safety protocols and technological advancements in response to the COVID-19 pandemic. This study investigates whether pre-defined service dimensions continue to capture the full spectrum of patient experiences or if new, emergent needs are being highlighted by patients. By analyzing data from medical surveys that include both established service dimensions and unstructured comments, we aim to identify shifting paradigms in patient expectations and ensure continuity of care. Our findings will inform potential improvements in service design, enhancing patient safety and satisfaction in the post-pandemic era.

5 - Predicting Sepsis Mortality using Machine Learning

Ameera Ibrahim, Saint Mary's College of California, Moraga, CA, United States, Ahmed Ahmadein

Sepsis is defined as a life-threatening organ dysfunction caused by a dysregulated host response to infection. According to the World Health Organization (WHO), it is estimated that 27% of patients with sepsis in hospitals and 42% of sepsis patients in intensive care units will die. With such a high mortality rate, sepsis has gained its reputation as an important public health issue and motivated many researchers to work on improving the prevention, diagnosis and treatment of sepsis. In this work, we propose a novel methodology to predict mortality in patients with sepsis. Our main goal is to design a reliable tool that can assist clinicians in evaluating the probability of a patient's fatality and identifying the best treatment plan for patients with sepsis. We exploit the XGBoost algorithm, a leading machine learning technique, on data extracted from the MIMIC-III dataset, a large and freely-available database comprising de-identified health-related data associated with over forty thousand patients who stayed in critical care units.

6 - Modeling Single-Donor Organ Chain Exchange: Optimization Framework for Analyzing Transplant Success

Yunxia (Peter) Zhu, University of Nebraska-Lincoln, Lincoln, NE, United States, Rakesh Mallipeddi, Chelliah Sriskandarajah, Jon Stauffer

An optimal matching problem to maximize transplant success rate is investigated in the context of single-donor organ exchange, where one living donor's organ is transplanted to a single patient. In such exchanges, multiple medical compatibility criteria pose a serious challenge for matching a patient with compatible donor. The objective of our study is to increase matching donors with patients requiring organs with maximum transplant success rate. In order to facilitate this organ matching, we use chain mechanism to increase the number of patient-donor matches with a maximum success rate for patients receiving transplants. We formulate a general optimization framework for obtaining the chain that maximizes the success rate of patients receiving transplants taking into account multiple compatibility criteria.

Innovations in Healthcare Service Delivery

Contributed Session

Chair: ILGIN ACAR, Western Michigan University, Department of Industrial and Entrepreneurial Engineering and Engineering Managem, Kalamazoo, MI, 49008-5336, United States

1 - Optimal contract policies for improving access to child and youth public services: the case of the Ontario Autism Program

Saha Malaki, Western Ontario University, London, ON, Canada, Felipe Rodrigues, Salar Ghamat, Camila de Souza, Greg Zaric

Access to public services in Canada has declined significantly, with the Ontario Autism Program (OAP) as a prime example. This publicly funded program currently has more than 60,000 children registered and waiting up to two years for provincial funding to access decentralized private services and treatments for autism spectrum disorder (ASD). We focus on the strategic decisions that families, service providers, and governments make in a decentralized system characterized by conges:on, where competing interests have been introduced in asymmetric competition, providing a strategic queuing game behaviour among its players. We developed a general mathematical framework to explore the structure of optimal contractual agreements for the OAP in the presence of congestion and information asymmetry in offering public treatment services for autism. This preliminary framework can then be generalized to other decentralized congested healthcare services.

2 - Last-Mile Attended Home Healthcare Delivery: a Robust Strategy to Mitigate Cascading Delays and Ensure Punctual Services

Mingda Liu, Tsinghua University, Beijing, China, People's Republic of, Yanlu Zhao, Xiaolei Xie

The attended home healthcare (AHH) industry is witnessing rapid growth due to the rising demand from an aging population and the potential benefits of alleviating pressures on traditional healthcare resources. However, ensuring timely one-on-one AHH services for homebound patients remains a challenge because of cascading delays arising from uncertainties in travel and service times. To address this issue in the last-mile homecare delivery, we develop a systematic cascading delay mitigation strategy that ensures patients receive dependable homecare services. Specifically, we introduce a compound set reliability index (CSRI) that captures risk exposure by characterizing travel and service time uncertainties separately. The CSRI-based service-level constraints are integrated into both compact and set-partitioning models to mitigate the cascading effect. We further devise an exact branch-price-and-cut framework and employ a variable neighborhood search metaheuristic to achieve fast-effective solutions. Our numerical experiments with benchmark and real-world datasets validate the efficacy of our algorithms, underscore the superiority of adopting our systematic cascading delay mitigation strategy, and provide insights to AHH service providers about the topological structure and crucial tuning parameters. The CSRI and the dedicated solution methods can effectively support decision-making and enhance the punctuality of AHH services, leading to better service dependability and heightened stakeholder satisfaction.

3 - Emergency Department Overcrowding: Introducing an Innovative Virtual Triage System for Effective Demand Management

Mattia Cattaneo, University of Bergamo, Dalmine, Italy, Sebastian Birolini, Elisa Alessio, Filippo Manelli

The emergency department (ED) serves as a cornerstone of our society, offering around-the-clock emergency care. However, its effectiveness is hindered by issues like overcrowding, mainly fueled by a surge in "non-emergency" visits. Despite numerous attempts to tackle ED overcrowding, no single solution has fully resolved the issue. Yet, a promising solution is emerging: virtual triage. This technology allows remote assessment of patients, providing immediate triage recommendations to prevent overestimations, reduce unnecessary hospital admissions, and schedule healthcare demand.

Our focus lies in exploring how this cutting-edge remote solution can identify patients who, while not in urgent need, require specific ED investigations. By implementing an appointment-based service, we aim to enhance the overall patient experience, minimizing on-site wait times and optimizing resource utilization. To gauge the impact of this approach, we develop a simulation model mirroring current ED processes, assessing the new service's effect on ED performance. To this aim, we investigate patient acceptance through a stated preference analysis, where individuals express their preferences among three ED access alternatives: Traditional ED access, Scheduled ED access, Fee-scheduled ED access.

4 - Multi-Depot General Colored Traveling Salesman Problem in Home Healthcare System

ILGIN ACAR, Western Michigan University, Kalamazoo, MI, United States, Islam Altin

The home healthcare system is crucial especially for elderly, disabled people or those who are facing challenges in accessing healthcare services. Furthermore, extraordinary situations, such as pandemics, increase the importance of home healthcare services. Access to traditional healthcare is restricted as lockdowns make it impossible for people to leave their homes. Therefore, home healthcare system plays a critical role in facilitating access to healthcare services during these challenging times. Considering all these situations, this study focuses on the medication delivery problem in the home healthcare system. In this problem, multiple pharmacies situated in various locations can meet the medication demands of patients. In addition, while some patients' medication demands must be satisfied by specific pharmacies, others' medication demands can be met by any pharmacy. In this case, considering the service constraints, medication delivery must be completed within the specified time limit using the vehicles available at the pharmacies. Therefore, it is necessary to obtain optimal routes to minimize the total distance traveled by vehicles from different pharmacies. The problem encountered in medication delivery is addressed as the Multi-Depot General Colored Traveling Salesman Problem (MD-GCTSP). A mixed-integer mathematical model was developed to obtain an optimal solution for the MD-GCTSP. Furthermore, a metaheuristic algorithm was used to get quality solutions with short computing times for large-sized problems. The performance of the proposed methods is demonstrated on different-sized test problems. Computational results show that the proposed solution approaches are efficient and well-suited for solving the MD-GCTSP.

1 - Optimal Rate-Matrix Pruning for Large-Scale Heterogeneous Systems

Zhao Zhisheng, Georgia Institute of Technology, ATLANTA, GA, United States, Debankur Mukherjee

We present an analysis of large-scale load balancing systems, where the processing time distribution of tasks depends on both the task and server types. Our study focuses on the asymptotic regime, where the number of servers and task types tend to infinity in proportion. In heterogeneous environments, commonly used load balancing policies such as JFSQ/JFIQ exhibit poor performance and even shrink the stability region. Interestingly, prior to this work, finding a scalable policy with a provable performance guarantee in this setup remained an open question. To address this gap, we propose and analyze two asymptotically delay-optimal dynamic load balancing policies. The first policy efficiently reserves the processing capacity of each server for ``good'' tasks and routes tasks using the vanilla Join Idle Queue policy. The second policy, called the speed-priority policy, significantly increases the likelihood of assigning tasks to the respective ``good'' servers capable of processing them at high speeds. By leveraging a framework inspired by the graphon literature and employing the mean-field method and stochastic coupling arguments, we demonstrate that both policies achieve asymptotic zero queuing. Specifically, as the system scales, the probability of a typical task being assigned to an idle server approaches 1.

2 - Flocking: Stability, Chaos and Traveling Waves

Sayan Banerjee, University of North Carolina, Chapel Hill, Chapel Hill, NC, United States, Amarjit Budhiraja, Dilshad Imon

We study a model for flocking given by a n-particle system under which each particle jumps forward by a random amount, independently sampled from a given distribution, with rate given by a non-increasing function w of its signed distance from the system center of mass. This model was introduced in Balázs et. al. (2014) and some of its properties were studied for the case when w is bounded. We are interested in the setting where w is unbounded which results in a stochastic dynamical system for interacting particles with fast and large jumps. We characterize the large n limit (the so-called `fluid limit') of the empirical measure process associated with the system and prove a propagation of chaos result. Next, for the centered n-particle system, by constructing suitable Lyapunov functions, we establish existence and uniqueness of stationary distributions and study their tail properties. In the special case where w is an exponential function and θ is an exponential distribution, by establishing that all stationary solutions of the McKean-Vlasov equation must be the unique fixed point of the equation, we prove a propagation of chaos result at t=∞ and establish convergence of the particle system, starting from stationarity, in the large n limit, to a traveling wave solution of the McKean-Vlasov equation. Our work answers several open problems posed in Balázs et. al.

3 - Limit Theorems for Heterogeneous Graphon Jsq(D) Model

Yan-Han Chen, Iowa State University, Ames, IA, United States, Arka Ghosh, Ruoyu Wu

We consider a variation of the supermarket model in which a task arriving at a dispatcher is routed to one of its neighborhood servers based on the Join-the-Shortest-Queue(d) policy. We consider both heterogeneous dispatchers and servers whose neighborhood relationships are described by a deterministic bipartite graph. The evolution of the queue length process for each server is described in the form of stochastic differential equations in which the interaction between servers exist. The law of large number results, both locally and globally, are established as the size of the system grows and the underlying graphs converge to a graphon. The limiting system is given by independent but heterogeneous processes governed by the graphon.

4 - Deep Backward and Galerkin Methods for the Finite State Master Equation

Cohen Asaf, University of Michigan, Ann Arbor, MI, United States, Mathieu Lauriere, Ethan Zell

This work proposes and analyzes two neural network methods to solve the master equation for finite-state mean field games (MFGs). Solving MFGs provides approximate Nash equilibria for stochastic, differential games with finite but large populations of agents. The master equation is a partial differential equation (PDE) whose solution characterizes MFG equilibria for any possible initial distribution. The first method we propose relies on backward induction in a time component while the second method directly tackles the PDE without discretizing time. For both approaches, we prove two types of results: there exist neural networks that make the algorithms' loss functions arbitrarily small and conversely, if the losses are small, then the neural networks are good approximations of the master equation's solution. We conclude the presentation with numerical experiments on benchmark problems from the literature up to dimension 15, and a comparison with solutions computed by a classical method for fixed initial distributions.

1 - Inpatient Overflow Management with Proximal Policy Optimization

Jim Dai, Cornell University & CUHK-Shenzhen, Ithaca, NY, United States, Pengyi Shi, Jingjing SUN

Overflow patients to non-primary wards can effectively alleviate congestion in hospitals, while undesired overflow also leads to issues like mismatched service quality. Therefore, we need to trade-off between con gestion and undesired overflow. This overflow management problem is modeled as a discrete-time Markov Decision Process with large state and action space. To overcome the curse-of-dimensionality, we decompose the action at each time into a sequence of atomic actions and use an actor-critic algorithm, Proximal Policy Optimization (PPO), to update policy. Moreover, we tailor the design of neural network which represents policy to account for the daily periodic pattern of the system flows. Under hospital settings of different scales, the PPO policies consistently outperform some commonly used state-of-art policies significantly.

2 - Autodifferentiable Discrete Event Simulation for Queuing Network Control

Jing Dong, Columbia University, New York, NY, United States, Ethan Che, Hongseok Namkoong

Queuing network control is a ubiquitous task for managing congestion in job-processing systems, such as manufacturing processes, service systems, communication networks, healthcare delivery systems, etc. Recently, there has been a growing interest in applying reinforcement learning (RL) techniques to learn good control policies for general queueing networks. However, queuing network control poses some unique challenges, including (1) high stochasticity and non-stationarity, (2) large state and action spaces, and (3) lack of stability guarantees. In this work, we propose a scalable framework for policy optimization in general queuing networks based on auto-differentiable discrete-event simulation, which tackles the challenges listed above and substantially improves the sample efficiency over existing approaches. This framework is based on a novel approach for computing pathwise gradients for discrete event dynamical systems, where we address the non-differentiability of the dynamics through carefully designed smoothing. Our proposed method is easy to train (e.g., not sensitivity to hyper-parameter tuning), highly scalable (e.g., can solve large-scale problems), can handle more realistic instances outside the scope of previous RL methods, including systems operating in a non-stationary environment with non-exponential inputs (i.e., interarrival and service times).

3 - Stein's method for Markov processes: beyond exponentially distributed jump times

Anton Braverman, Northwestern University, Evanston, IL, United States, Ziv Scully

The generator comparison approach of Stein's method is well-known for being able to compare stationary distributions of Markov chains. To date, all applications of the generator comparison approach have been to continuous-time Markov chains where the jump times are driven by exponentially distributed clocks.

Using the virtual workload of the G/G/1 system as an example, I will showcase how the generator comparison approach can be applied to continuous-time Markov *processes* where inter-jump times need not have an exponential distribution, thereby expanding the scope of models where the approach can be applied.

4 - Statistical Inference for Markov Chains with Known Structure

Peter Glynn, Stanford University, Stanford, CA, United States, Lin Fan

In this talk, we will discuss nonparametric estimation for Markov chains that satisfy stochastic recursions of a known form, but in which the driving noise has an unknown distribution. We assume that we observe samples of the driving noise. We will argue that such Markov chains/data sets arise naturally within the setting of operations research and management science. We will discuss general statistical theory for such Markov chains, including consistency of “plug-in” estimators, the influence function, central limit theorems, and related computational issues. This work is joint with Lin Fan.

Scheduling and Decision-Making in Stochastic Systems

Invited Session

Applied Probability Society

Chair: Ziv Scully, Cornell University, Ithaca, NY, United States

1 - Strongly Tail-Optimal Scheduling in the Light-Tailed M/G/1

George Yu, Cornell University, Ithaca, NY, United States, Ziv Scully

We study the problem of scheduling jobs in a queueing system, specifically an M/G/1 with light-tailed job sizes, to asymptotically optimize the response time tail. This means scheduling to make P[T>t], the chance a job's response time exceeds t, decay as quickly as possible in the t→∞ limit. For some time, the best known policy was First-Come First-Served (FCFS), which has an asymptotically exponential tail: P[T>t]~Ce−γt. FCFS achieves the optimal *decay rate* γ, but its *tail constant* C is suboptimal. Only recently have policies that improve upon FCFS's tail constant been discovered. But it is unknown what the optimal tail constant is, let alone what policy might achieve it.

In this paper, we derive a closed-form expression for the optimal tail constant C, and we introduce *γ-Boost*, a new policy that achieves this optimal tail constant. Roughly speaking, γ-Boost operates similarly to FCFS, but it pretends that small jobs arrive earlier than their true arrival times. This significantly reduces the response time of small jobs without unduly delaying large jobs, improving upon FCFS's tail constant by up to 50% with only moderate job size variability, with even larger improvements for higher variability. While these results are for systems with full job size information, we also introduce and analyze a version of γ-Boost that works in settings with partial job size information, showing it too achieves significant gains over FCFS. Finally, we show via simulation that γ-Boost has excellent practical performance.

2 - A Gittins Policy for Optimizing Tail Latency

Amit Harlev, Cornell University, Ithaca, NY, United States, George Yu, Ziv Scully

We consider the problem of scheduling to minimize the (asymptotic) tail latency in an M/G/1 queue. When the job size distribution is heavy-tailed, numerous policies have long been known to be asymptotically optimal (e.g. processor sharing, least attained service, SRPT). In contrast, for light-tailed distributions, only in the last few years have policies been developed that outperform FCFS. However, these policies all require job size information.

In this paper we find the optimal scheduling policy for minimizing asymptotic tail latency in the light-tailed M/G/1 with unknown job sizes. Surprisingly, the optimal policy turns out to be a novel variant of the Gittins policy, but with an unusual feature: it uses a negative discount rate.

3 - Economies of operational hybridity in large-scale service systems

Yunfang Yang, Department of Industrial Systems Engineering & Management, National University of Singapore, Singapore, Singapore, Shuangchi He

Large-scale service systems often need to serve multiple classes of customers subject to distinctive delay requirements. For example, the inpatient department of a general hospital is usually required to make beds available within hours for patients transferred from the emergency department, whereas it may provide beds in days or weeks for elective patients. In this study, we consider a many-server queue with two classes of customers that are managed under two distinctive regimes: the waiting times of the first-class customers should be of a lower order of magnitude than those of the second-class customers (e.g., hours versus days). Besides servers dedicated to each class, there are cross-trained servers that can serve both classes. We first propose a sequencing policy for cross-trained servers to meet service-level requirements for the two classes with a minimal staffing level. Then, we identify the minimum number of cross-trained servers that is needed by the sequencing policy to minimize the overall staffing cost. We prove that under the proposed sequencing and cross-training scheme, the service system can achieve "economies of operational hybridity"—that is, the system can be dimensioned as if it operates under the more efficient regime that the second-class customers require, while a small fraction of cross-trained servers are sufficient to help fulfill the first-class customers' delay requirements.

4 - Cost-per-sample Bayesian optimization via the Pandora's box Gittins index

Qian Xie, Cornell University, Ithaca, NY, United States, Raul Astudillo, Peter Frazier, Ziv Scully, Alexander Terenin

Bayesian optimization is a technique for efficiently optimizing unknown functions in a black-box manner. To handle practical settings where gathering data requires use of finite resources, it is desirable to explicitly incorporate function evaluation costs into Bayesian optimization policies. This includes possibly stopping if the gains expected from gathering more data are insufficient to justify the cost of doing so. We introduce a new policy for cost-per-sample Bayesian optimization, using an unexplored connection with the Pandora's box problem, a well-studied problem from economics. The Pandora's box problem admits a Bayesian-optimal solution based on an expression called the Gittins index, which can be interpreted as an acquisition function. We demonstrate empirically that the same acquisition function performs well for Bayesian optimization, particularly in medium-high dimensions. The acquisition function is computationally efficient, and extends naturally from a uniform cost per sample to heterogeneous costs. Our work constitutes a first step towards integrating ideas from Gittins index theory into Bayesian optimization.

5 - Local hedging approximately solves Pandora's box problems with nonobligatory inspection

Ziv Scully, Cornell University, Ithaca, NY, United States, Laura Doval

We consider Pandora's box problems with nonobligatory inspection and single-item or combinatorial selection. A decision maker is presented with several items, each of which contains an unknown price, and can pay an inspection cost to observe an item's price before selecting it. Under single-item selection, the decision maker must select one item; under combinatorial selection, the decision maker must select a set of items that satisfies certain constraints. In our nonobligatory inspection setting, the decision maker can select items without first inspecting them. It is well-known that search with nonobligatory inspection is harder than the well-studied obligatory inspection case, for which the optimal policy for single-item selection (Weitzman, 1979) and approximation algorithms for combinatorial selection (Singla, 2018) are known.

We introduce a technique, *local hedging*, for constructing policies with good approximation ratios in the nonobligatory inspection setting. Specifically, local hedging takes as an input policies for the obligatory inspection setting and outputs policies for the nonobligatory inspection setting, at the cost of an extra factor in the approximation ratio. The factor is instance-dependent but is at most 4/3. We thus obtain the first approximation algorithms for a variety of combinatorial selection problems, including matroid basis, facility location, and prize-collecting Steiner tree.

Advances in Medical Decision Support

Contributed Session

Chair: Anna K. Stirner, University of Cologne / Department of Business Administration and Health Care Management, Cologne, Germany

1 - An experiment on decision support in medicine

Anna K. Stirner, University of Cologne / Department of Business Administration and Health Care Management, Cologne, Germany, Bernhard Roth, Daniel Wiesen

Our experiment investigates how capacity constraints affect physicians' use of decision support systems to improve therapy decisions. Conducted with 247 German pediatricians, we manipulate physicians' capacity levels and the availability of decision support to observe changes in decisions regarding the length of antibiotic therapy for pediatric cases. Initially, physicians make decisions on therapy lengths for each case. Depending on their assigned experimental condition, subjects then either (i) decide whether to use decision support before making the final therapy decision, (ii) automatically receive decision support, or (iii) have no access to decision support. We vary information gathering costs, representing the capacity fraction needed for decision support. Subjects who decide or receive support can modify their initial therapy decisions for each case.

Results evidence that as capacity constraints increase, physicians' willingness to seek additional information declines. However, constraints did not affect the extent to which the gathered information was utilized. Importantly, our findings demonstrate that capacity constraints have a statistically significant and clinically relevant impact on the appropriateness of therapeutic decisions, affecting the quality of care, especially among less experienced physicians. The likelihood of gathering additional information increases significantly with case severity. Utilizing additional information leads to improvements in the appropriateness of therapy decisions in cases of undertreatment, while overtreatment persists even with decision support.

In conclusion, reducing capacity constraints could enhance the use of decision support, thus improving the appropriateness of therapeutic decisions. These findings have significant implications for healthcare management, suggesting that decreasing capacity constraints could benefit healthcare quality.

2 - Multi-Objective Optimization of Multi-Agent Kidney Transplantation Considering Fairness

Shayan Sharifi, Wayne State University, Detroit, MI, United States, Evrim Dalkiran

Despite advancements in living donor transplantation and kidney exchange programs, the demand for kidney transplants far exceeds the available supply, leaving thousands on waiting lists. This study presents a comprehensive Multi-Agent Kidney Exchange Programs (MKEP) model aimed at optimizing transplant numbers and enhancing transplant quality within the U.S. healthcare system.
In this paper, we introduce a novel MKEP model designed not only to increase the number of transplants available to patients but also to improve the quality of these transplants, thereby enhancing patients' post-transplant quality of life. Furthermore, we classify existing patients into three groups: normal, sensitive, and urgent, enabling us to prioritize kidney transplants for emergency patients. We utilize a multi-objective model to balance transplant quality and delay time, establishing an acceptable lower bound for human leukocyte antigens (HLA). Our findings demonstrate that employing this approach enhances both the quantity and quality of transplantations compared to traditional methods.

3 - Improving Outcome Predictions in Chronic Disease Management: A Case Study on Chronic Kidney Disease Using Multi-Sourcing, Integrated Data

yubo li, Carnegie Mellon University, Pittsburgh, PA, United States, Rema Padman

This study presents a novel predictive framework that integrates clinical and administrative claims data, leveraging advanced machine learning and deep learning techniques to forecast Chronic Kidney Disease (CKD) progression to End-Stage Renal Disease (ESRD). Our multi-stage approach encompasses data preprocessing, model development, and comprehensive analysis, employing a diverse set of models including logistic regression, random forest, XGBoost, and deep learning architectures such as temporal convolutional networks (TCN) and long short-term memory (LSTM) networks. The results demonstrate the superiority of deep learning models, particularly LSTM, in capturing the temporal dynamics of CKD progression, with a 24-month observation window emerging as the most effective timeframe for ESRD prediction across all data types. The application of explainable AI techniques provides insights into the complex interplay of predictive features, while the incorporation of a revised, race-neutral eGFR equation addresses potential bias and improves predictive accuracy for African American patients. Despite certain limitations, this study establishes a robust foundation for early detection and personalized risk assessment of ESRD, highlighting the power of integrating diverse data sources, advanced modeling techniques, and explainable AI in predicting CKD progression to ESRD.

4 - Patient Pathways and Team-Based Care for Cancer Patients in Kuwait: Process Mining Approach

Abdullah Alibrahim, Kuwait University, Kuwait, Kuwait, Munirah Alateeqi, Abdulwahab Al-Tourah, Waddah Al-Refaie

Cancer care demands systems that support multidisciplinary team-based care. This study aims to analyze patient pathways and team-based care metrics by examining various specialties engagement and how processes are standardized. We utilized linked two datasets: national-level discharge data from Kuwait Ministry of Health (MOH) hospitals and patient records from Kuwait Cancer Control Center (KCC). For this analysis, 50 cancer patients were selected from the two most prevalent types: breast and colon cancer, capturing 2,182 and 2,507 patient activities at KCC and hospitalizations from MOH discharge data for each cancer type, respectively. Our analysis uncovered significant variability in treatment patterns across different care stages, including care initiation, therapy, and surveillance. The analysis indicates that colon cancer patients experience more per-patient events than breast cancer patients during a longer treatment journey length (51.4 months for colon cancer vs. 49.6 months for breast cancer patients). Breast cancer patients required balanced therapeutic modalities with systemic treatment, radiation, and surgery. In contrast, colon cancer patients primarily underwent outpatient visits and medical infusions. Furthermore, 24% of colon cancer patients' hospitalization episodes occurred in general hospitals outside of KCC, indicating an urgent need for coordination and medical information sharing with other treatment facilities. Breast cancer patients often started treatment after registration, with 68% initiating treatment this way and the rest through a rapid-screening pathway. In contrast, all colon cancer patients were registered before treatment at KCC. These findings emphasize the importance of departmental coordination and standardization with a focus on conformance and enhanced personalized journeys.

New Advances in Organ Transplantation Modeling

Invited Session

Health Applications Society

Chair: Amirhossein Moosavi

Co-Chair: Yili Wang, University of Michigan, Ann Arbor, MI, United States

1 - Optimizing Sequential Decisions in Marginal Kidney Acceptance

Yili Wang, University of Michigan, Ann Arbor, MI, United States, Amirhossein Moosavi, Mariel Lavieri, Danielle Haakinson, Yee Lu, Kate Giles

Chronic kidney disease affects over 37 million people in the United States, with more than 700,000 patients requiring renal replacement therapy, including dialysis or kidney transplantation. Despite nearly 100,000 patients on the US transplantation waitlist, about 20% of lower-quality (marginal) kidneys are discarded annually. This ongoing project aims to develop models that assist patients and clinicians in making informed decisions about accepting marginal kidneys while considering their risk aversion level. We will present our pilot model and explore potential future research directions.

2 - A Data-Driven Approach for Identifying Candidates for Xenotransplant Human Clinical Trials

NAZ YETIMOGLU, The University of Chicago Booth School of Business, Chicago, IL, United States, Baris Ata, Robert A. Montgomery, Jesse D. Schold

The demand for transplant organs surpasses supply, with xenotransplantation offering a potential solution to this shortage. The successful investigational transplants of genetically edited pig kidneys into brain-dead patients and two, single patient IND enabled xeno-heart transplants into living human recipients signal that the first human clinical trials are imminent. Using the 2-year survival of non-human primates with gene-edited pig kidneys in pre-clinical studies as a benchmark, we developed a tool that identifies patients predicted to have a shorter life expectancy in the current system than with a xenotransplant. Using DeepSurv, Random Survival Forest and Cox Proportional-Hazards models, we found that it is hard to reach clinical equipoise unless the expected xenograft survival exceeds two years. As such, it is difficult to identify many candidates who would benefit from trials and potential beneficiaries are spread across 200 transplant centers. However, several incentives could allow more patients to reach equipoise. Keeping patients inactive on the waitlist while they have a functioning xeno-kidney incentivizes them, slightly improving equipoise. Giving patients with failed xeno-kidneys the same priority as prior living donors moves the needle towards equipoise marginally. Lastly, giving highest priority when a xeno-kidney fails could achieve equipoise for substantial number of patients.

3 - Thousands Unused: The Problem of Lossy Allocation in Kidney Transplantation and Opportunities for Operations Research

Elijah Pivo, MIT, Cambridge, MA, United States, Maura Hegarty, Theodore Papalexopolous, Nikolaos Trichakis, Dimitris Bertsimas

While tens of thousands hope to receive a kidney transplant, thousands of donated kidneys go unused annually. The vast majority are not accepted by a transplant candidate during the allocation process. In recent years, the nonuse rate has grown to greater than 25% of donated kidneys. We discuss potential clinical and logistical drivers for this phenomenon, as well as opportunities for machine learning and optimization to improve the allocation process.

4 - Personalized Data-Driven Model for Organ Acceptance

Jiahui "Gary" Luo, Dartmouth College, Hanover, NH, United States, Wesley Marrero, Mariel Lavieri, David Hutton, Neehar Parikh, Lawrence An

Our method for creating a personalized data-driven model for organ acceptance incorporates machine learning, survival analysis, and mathematical optimization. In this work, we focus on liver transplants, which are the second most common transplant in the United States. We employ machine learning-based methods to predict liver quality and forecast patient survival rates. Based on these predictions, we develop a Markov decision process (MDP) framework to represent the decision-making process of accepting or declining organ offers tailored to an individual candidate on the liver transplantation waiting list.

Decision-Making in Healthcare Systems

Invited Session

Health Applications Society

Chair: Zeyu Liu, West Virginia University, Morgantown, WV, United States

1 - Personalized and Interpretable Screening Policy for Diabetic Eye Disease

Taewoo Lee, Seoul National University, Seoul, Korea, Republic of, Poria Dorali, Soroush Akbarijokar, Christina Weng

Diabetic retinopathy (DR) is the leading cause of blindness among working-age Americans. Currently only 30-60% of patients adhere to annual screening guidelines due to limited access to eye care, particularly impacting medically underserved populations. Teleretinal imaging

(TRI) is emerging as an affordable tool that has the potential to increase screening rates for those with limited access. We develop a partially-observable Markov decision process (POMDP) that uses various patient-specific characteristics and determines personalized screening policies for TRI-based screening. To promote clinical implementability we then convert the POMDP-driven policy into a more interpretable screening policy. Finally we analyze the cost-effectiveness of the proposed policies against current screening guidelines.

2 - Dynamic Medical Countermeasure Deployment Under Epidemic Outbreaks

Mohsen Mehrabiyan, West Virginia University, Morgantown, WV, United States, Zeyu Liu

In recent years, medical countermeasure (MCM) deployment has been increasingly investigated to mitigate the impact of infectious disease outbreaks and enhance the preparedness and readiness of the national healthcare system. To address the lack of robust health security and the insufficiency in emergency response capabilities, there's still a critical need for an effective method to optimize MCM deployment strategies facing the complex dynamics during epidemics. In this study, we utilize a multi-stage stochastic programming (MSP) model to optimize emergency supply planning, including resource allocation and facility location decisions that optimize the distribution of MCMs, as well as sequential decision-making in response to disruptive uncertainties. In our model, we prioritize actions that ensure fair access to healthcare resources during emergencies, with a particular focus on supporting marginalized groups. Because of the computational difficulties arising from the MSP tree structure, we design novel computational algorithms to produce high-quality solutions efficiently. We collect real-world data from literature and design agent-based simulations for scenario realizations that quantify uncertainties according to individual characteristics. Through carefully designed experiments, our model enables comprehensive analysis of disease transmission, healthcare delivery, and public sentiment during infectious disease outbreaks.

3 - Equitable Anesthesiologist Scheduling Under Demand Uncertainty Using Multi-Objective Programming

Kai Sun, University of Texas at San Antonio, San Antonio, TX, United States, Minghe Sun, Ronald Dravenstott, Frank Rosinia, Arkajyoti Roy

This work addresses a practical anesthesiologist scheduling (AS) problem under clinical demand uncertainty. The goal is to plan and deploy providers to meet clinical demand and institutional protocols. A data-driven two-step sequential AS framework is developed using mixed-integer multi-objective programs. Step 1 designs shifts to minimize excessive clinical time using conditional value-at-risk constraints to account for demand uncertainty. Step 2 assigns shifts to providers considering optimal and equitable workload distribution and the number of required providers. An ε-constraint solution method is applied for multi-objective optimization, and an iterative solution method is developed to improve workload equity in clinical applications. Two case studies, the budget and hiring planning and the monthly AS, are addressed in a large anesthesiology department via the AS framework. For budget and hiring, decision makers can make tradeoffs based on their preference using the nondominated frontiers obtained via the ε-constraint method. For monthly AS, the iterative solution method can capture institutional requirements, accommodate pre-assigned shifts when incorporating complex clinical and lifestyle preferences, and further improve workload equity. The workload variance has been substantially reduced by 52.3% after the implementation based on the historical schedule data. The provider schedule satisfaction has been improved from 3.13/5 to 3.47/5, and at least 82% of scheduling burdens on department leaders have been relieved. The developed framework has been deployed and has become the key component of operating room scheduling in the partner hospitals, including University Hospital and VA Hospital, in San Antonio.

4 - Interpretable Deep Learning for Diabetic Retinopathy Prediction Using Electronic Health Records

Jiahao Shao, University of Tennessee, Knoxville, Knoxville, TN, United States, Zekai Wang, Anahita Khojandi, Tieming Liu, Bing Yao

Diabetic Retinopathy (DR), a complication of diabetes affecting the small blood vessels, stands as the primary reason for vision impairment in adults of working age. This condition often advances to critical stages due to inadequate screening participation and the prohibitive costs of necessary diagnostic technology. However, the widespread availability of Electronic Health Records (EHR) offers a significant opportunity to overcome these challenges through the use of machine learning techniques. This study introduces an interpretable, non-image-based deep learning model designed for data-driven detection of DR. By leveraging the Attentive Interpretable Tabular Learning (TabNet) architecture, along with employing missing value masks and multi-branching technique, this model aims to tackle the prevalent issues of missing value and data imbalance issues in medical datasets for accurately DR detection. Additionally, unlike traditional deep neural networks, which suffer from a lack of interpretability, our model is capable of providing the importance of each medical variable, enhancing transparency and usability for healthcare providers. This innovative approach has the potential to enable confident recommendations for personalized ophthalmic exams and screening frequencies, particularly targeting at-risk patients.

Optimizing Patient Flow and Readmission Risk in Healthcare Systems

Contributed Session

Chair: Suman Mallik, University of Kansas

1 - An Interpretable Imbalance Ensemble Classification Method for Readmission Risk Assessment Incorporating Multi-view Perturbation and SHAP Analysis

Shaoze Cui, Beijing Institute of Technology, Beijing, China, People's Republic of, Ruize Gao, junwei kuang, Liang Yang, Huaxin Qiu

In the realm of medical services, patients may experience readmissions shortly after discharge due to unreasonable discharge arrangements or recurring illnesses. This not only wastes valuable medical resources but also diminishes patient satisfaction. To this end, we propose an interpretable imbalance ensemble classification method incorporating multi-view perturbation to assess the readmission risk of inpatients. Compared to existing research, this study designs a novel multi-view perturbation method to enhance the model's generalization performance. Moreover, a more fault-tolerant ensemble strategy based on evidential reasoning (ER) rules is proposed, which makes the fusion results of the ensemble learning model more stable. Meanwhile, considering that sensitive parameters can affect model performance, we propose a parameter optimization method based on the differential evolution algorithm, which integrates model predictive performance and computational efficiency when designing the fitness function. Experimental results using real-world medical data demonstrate that the proposed method effectively identifies patients with high readmission risk and outperforms existing state-of-the-art readmission risk assessment methods.

2 - Optimizing Early Discharge: Trade-Offs between Capacity and Readmissions

Zhiyuan Lou, Technical University of Munich, Heilbronn, Germany, Taozeng Zhu, Jingui Xie, Gar Goei Loke

In this work, we consider the ward capacity management problem with readmissions, where the decision-maker optimizes the elective schedule and early discharge policy, so as to minimize bed shortages. Existing research has shown that early discharge can lead to higher rates of readmission, and longer readmission length-of-stay. This sets up the need to balance the temporal trade-off between the immediate capacity freed up by early discharges and increased readmissions down the road. Such re-entry structure creates challenges when modelling via traditional methods. We appeal to the Pipeline Queues (Bandi and Loke 2018) framework, and propose an optimization model where the early discharge policy is expressed as a state-dependent decision rule. The model has a reformulation, which can be solved as a sequence of convex programs with asymptotically linear constraints. In our numerical study, we identify an intermediate region of the probability of readmissions where time-invariant policies can lead to as much as 77% more shortages. Ignoring the effects of early discharge on readmissions can lead to at least 75% and 150% more bed shortages in time-homogeneous and non-time-homogeneous settings respectively, even against un-optimized elective admissions. Using optimal early discharge strategies without jointly optimizing elective admissions will lead to 20% more shortages.

3 - Developing a decision support system to predict delayed discharge from hospitals using machine learning

Majid Taghavi, Saint Mary's University, Halifax, NS, Canada, Mahsa Pahlevani, Peter Vanberkel, Enayat Rajabi

The increasing demand for healthcare services poses significant challenges in effectively managing patient flow, particularly concerning patients classified as Alternative Level of Care (ALC). These patients, although no longer in need of acute care, often encounter obstacles to discharge and cause several issues, such as hospital overcrowding and compromised health outcomes. Using administrative health data from Canadian hospitals, this study develops machine learning models to identify potential ALC patients and estimate their hospital length of stay as early as their admission time. Our findings show the efficacy of the eXtreme Gradient Boosting algorithm in accurately predicting potential ALC patients, while the Random Forest regression model surpasses others in forecasting the length of stay for ALC patients. To understand how the predictions are made, an explainable machine learning approach (SHAP) was used to identify the most important features that impact machine learning outcomes. We developed two sets of user-friendly and easy-to-follow guidelines for hospital staff to identify ALC patients proactively, estimate their length of stay, and mitigate the patient flow challenges posed by the ALC patients. Hospitals can use such decision-making tools to optimize resource allocation, enhance operational efficiency, and ultimately improve patient care outcomes.

4 - The Interactions of Crowding, Patient Severity, and Queue Rank at a Hospital Emergency Department

Suman Mallik, University of Kansas, Lawrence, KS, United States, Lu Wang, Mazhar Arikan

This study empirically investigates the impacts of additional patient arrivals and changing queue rankings on patient processing in the emergency department (ED). Through causal mediation analysis, we demonstrate that changes in queue rank mediate the effect of additional arrivals of higher-severity patients on patient waiting time. However, additional arrivals of patients with the same or lower severity levels directly affect patient waiting time.

1 - Semi-Nonparametric Adaptive Bidding in Repeated First-Price Auctions Under Binary Feedback

Yongyi Guo, University of Wisconsin Madison, Madison, WI, United States, Danqi Luo, Hongyu Shan, Zhengyuan Zhou

In the past three years, a particularly important development in the digital advertising
industry is the shift from second-price auctions to first-price auctions for online display ads. This shift immediately motivated the intellectually challenging question of how to bid in first-price auctions, because unlike in second-price auctions, bidding one's private value truthfully is no longer optimal. In this paper, we study how to adaptively bid in repeated first-price auctions under binary feedback–currently used by almost all ad exchanges–where the bidder only sees whether he wins or loses the bid after each auction. We develop a semi-nonparametric adaptive bidding policy that achieves low regret. Our results reveal an interesting phenomenon: as the non-parametric uncertainty component becomes smoother,
the regret performance also improve. In the limit, when the component becomes infinitely smooth, we obtain minimax regret up to log factors.

2 - Learning User Behavior in a Social Network with Limited Data

yunduan lin, University of California, Berkeley, Berkeley, CA, United States, Haoting ZHANG, Zeyu Zheng, Zuo-Jun Shen

Learning user behavior in a social network involves the understanding of both individual characteristics and the network effects arising from interactions among individuals. There are primarily two challenges. Firstly, the network diffusion process is dynamic and governed by intricate network structures. This complexity often makes the outcomes of diffusion lack straightforward, closed-form expressions. Secondly, calibrating network diffusion models is complicated by limitations in available data, both temporally and spatially. From the temporal aspect, capturing its entire trajectory of network diffusion may require extensive efforts and thus is often not feasible. From the spatial aspect, network structures are typically specific and limited. While individual-level data might be abundant, sampling network-level structures as desired is usually not possible. In this work, we aim to present a comprehensive framework for learning user behavior in a social network based on one single observed instance. We first analyze the learning performance under different data availability using a specific diffusion model. Then, we employ simulation as a vital tool to establish the framework for a broad class of models. Specifically, simulation enables the modeling of complex systems and the observation of their behavior under various conditions. By constructing a simulation model of the network, we can generate output data corresponding to different parameter values. We compare this simulated data to the observed data in an attempt to identify the values that yield the closest match by the definition of an objective function, which quantifies the distance between the given data and the simulated data.

3 - Value of One Data Point: Active Label Acquisition in Personalized Assortment Optimization

Mo Liu, University of North Carolina - Chapel Hill, Chapel Hill, NC, United States, Junyu Cao, Zuo-Jun Shen

Predicting customers' preferences based on their features is crucial for personalized assortment optimization. When building this prediction model, using informative data can significantly increase the expected revenue from personalized assortments. This paper studies how to sequentially collect informative data to construct this prediction model. We introduce a novel concept, the 'value of one data point,' which evaluates the marginal contribution of acquiring a specific customer's preference to the expected revenue in personalized assortment optimization, given the existing training set. Notably, this value drops to zero once the optimal assortment for this specific customer is determined. To estimate this value and identify important customers for acquiring their preferences, we derive a feature-dependent upper bound. This bound provides significant insights into the importance of each data point for revenue growth. Based on this upper bound, we develop a personalized incentive policy for effectively collecting survey data from customers to obtain their preferences. We provide non-asymptotic guarantees for both the cumulative incentives and the revenue from the final prediction model. Theoretically, we show that our personalized incentive policy requires smaller cumulative incentives than any fixed incentive policy to achieve the same level of revenue. Additionally, our numerical experiments with real-world and synthetic datasets validate the effectiveness of our personalized incentive algorithms over fixed strategies.

4 - Sequential Decision-Making in Online Experimentation: When Safety Meets Efficiency

Feng Zhu, Massachusetts Institute of Technology, Cambridge, MA, United States, David Simchi-Levi

This talk explores the integration of safety into efficiency in sequential decision-making for online experimentation, specifically within a stochastic multi-armed bandit setting. While previous work mostly focuses on achieving efficiency by minimizing regret expectation, controlling the regret tail risk to ensure safety is essential in applications such as revenue management, clinical trials, and financial investment, but has not been well studied. This work provides a detailed characterization of regret distribution under the safety concern of managing tail risk. In Part I, we aim to design policies that enjoy both optimal regret expectation and light-tailed regret distribution. We first find that any policy that obtains the optimal instance-dependent regret expectation could incur a heavy-tailed regret distribution. We then design a novel policy that enjoys the optimal worst-case regret expectation and has the optimal worst-case regret tail risk with an exponential decaying rate. Our policy design also bears an interesting connection with Monte Carlo Tree Search (MCTS) used in AlphaGo. In Part II, we study the optimal trade-off between expectation and tail risk for regret distribution. Our results reveal several managerial insights on how to design policies that balance efficiency and safety. All our results can be extended to the stochastic linear bandit setting.

5 - Atlanta Police Zone Redesign for Neighborhood Integrity

Zheng Dong, Georgia Institute of Technology, Atlanta, GA, United States, Yao Xie

Atlanta, the capital of the U.S. state of Georgia, plays an important role as the cultural and economic center of the Atlanta metropolitan area, which is home to 6.3 million people and the sixth-largest metropolitan area in the United States. The police departments in Atlanta (APD) have long struggled with staffing shortages. Officers, facing longer shifts and broader coverage areas, must strategically allocate their efforts. Georgia Tech (GT) has worked with Atlanta Police in 2019 to redesign zones and balance workload. However, socioeconomic development since COVID-19 pandemic changes the crime landscape increase again the imbalance of the police workload across Atlanta city area, calling for new police zone design. In this work, we collect data during post-pandemic era and re-design the police zones in Atlanta considering neighborhood integrity. We also use new metrics to balance local workload of officers between zones when dealing with 911 calls.

1 - Impact of Franchise Car Laws on EV Adoption

Andrey Makhanov, UNC Kenan-Flagler Business School, Chapel Hill, NC, United States, Nur Sunar, Jay Swaminathan

We empirically study the effect of the auto franchise law on electric vehicle (EV) adoption.

2 - Regulatory Power in Automotive Product Recall Effectiveness: An Empirical Investigation

Ramin Sepehrirad, Washington State University, PULLMAN, WA, United States, Kevin Mayo, George Ball

While significant research has explored causes and consequences of product recalls, little is known about recall effectiveness: how well a recalling firm performs in repairing faulty products. Anecdotal reports indicate that firms are relatively ineffective in this endeavor, leading to millions of recalled products remaining in the market, unaddressed. We study how regulatory authority in automotive product recalls impacts firms' remedial performance. Drawing upon Ocasio's attention-based view (ABV) and extant recall literature, we develop competing hypotheses of how mandating a recall affects repair rates — the proportion of remedied to affected vehicles. Using a unique dataset containing more than 4200 recalls on passenger vehicles from 2009 to 2022, we surprisingly find that when the regulator mandates a recall, fewer vehicles are repaired eventually. Specifically, in a quasi-experimental setting, we show that mandating reduces repair rates at least by 5%, equivalent to 20,000 vehicles for a typical recall campaign. We further investigate two moderation mechanisms and find that mandating negative effects is stronger when the estimated repair time is longer, or when the recall campaign is more costly. Finally, we examine how potential hazards of the defective component in a recall campaign impact remedial procedure effectiveness. Theoretical contributions and practical implications are discussed.

3 - Shifting Attention and the Green Ripple Effect: Unveiling Green Innovation Diffusions in Supply Chain Networks

Nima Safaei, University of Illinois Urbana-Champaign, Champaign, IL, United States, Jafar Namdar, Gautam Pant, Shagun Pant

In addition to internal R&D motivators, peers' innovation is an important stimulus to the focal firm's innovation performance. While it is well-known that firms in vertical relationships within supply chain networks affect each other's strategic decisions, operations, and innovation, our study focuses on an unexplored area: the upstream diffusion of attention shift toward more green innovation in the global supply chain network. We investigate whether and how (i.e., the mechanism) customers' attention shifts toward more green innovations, captured through patents, diffuse to suppliers. We further study the relationship between such an attention shift and firms' environmental performance and evaluate the impacts on firms' financial performance. We leverage a comprehensive dataset of 418,219 global supply chain linkages, combined with patent information and performance metrics of the firms in the relationship, and employ a structural econometric model to identify the diffusion effect. We find that shifting to more green innovation by customers directly diffuses to suppliers; the peer influence channel (i.e., the direct impact of customers' green innovation ratio on the green innovation ratio of the focal firm) is by far the most significant source of diffusion. We also find a positive impact of increased green innovation ratio on firms' environmental and financial performance, highlighting the critical role of focusing on more green innovation in achieving sustainable business practices and economic benefits.

Emerging Topics in Healthcare Operations

Invited Session

MSOM: Healthcare

Chair: Fernanda Bravo, UCLA Anderson School of Management, Los Angeles, CA, United States

Co-Chair: Maria Ibanez, Kellogg School of Management at Northwestern University, Evanston, IL, United States

1 - Mo-dalities, mo problems: The hidden costs of hybrid work in primary care practices

Mitchell Tang, Harvard Business School, Boston, MA, United States, A Jay Holmgren, Robert Huckman, J Michael McWilliams, Maximilian Pany

Many workers today have hybrid work schedules with a mix of in-person and virtual meetings. While the ability to conduct meetings virtually undoubtably has benefits, when integrated into a still predominately in-person schedule, it also introduces new frictions. Transitions between in-person and virtual meetings within the same day can burden workers. On the other hand, while creating dedicated virtual work periods reduces the likelihood of these transitions, it can also reduce capacity utilization if there isn't sufficient demand for virtual meetings in that specific window.

We examine these new frictions in the context of hybrid primary care practices, which offer both in-person and telemedicine (virtual) visits. We observe large negative impacts specifically for transitions from in-person to telemedicine visits. Subsequent telemedicine visits saw a 19% lower likelihood of on time start and patients were 33% more likely to abandon the visit before being seen. These disruptions also manifested in fewer logged diagnoses, lower rates of timely note completion, and lower patient-reported provider ratings. However, when providers instead allocated dedicated appointment slots for telemedicine, those slots saw an 11% reduction in booking rate. The negative impacts of dedicated telemedicine appointment slots were lessened for time slots and weeks when patient telemedicine demand was higher.

Our findings demonstrate the subtle costs of hybrid work. They also demonstrate the tradeoffs of incorporating explicit structure in a hybrid schedule, the types of work that may be better suited for dedicated virtual blocks, and the value of synchronizing schedules to minimize loss from those blocks.

2 - Reducing Appointment Delays: The Impact of Standardized EHR Usage on Physician Timeliness

Bradley Staats, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Umit Celik, Sandeep Rath, Saravanan Kesavan

Problem Definition: This study explores the impact of standardized documentation tasks within Electronic Health Record (EHR) systems on physician timeliness. By analyzing data from physicians' schedules and detailed EHR timestamps, we assess how standardizing EHR tasks before and during appointments affects appointment lengths and delays.

Methodology/Results: Utilizing classical propensity score matching and machine learning for causal inference, our analysis reveals that standardizing EHR tasks either before or during appointments significantly reduces the likelihood of delays in subsequent appointments. The primary mechanism identified is the shortening of appointment durations through EHR standardization. While increased standardization generally leads to shorter appointments, it does come with trade-offs, notably longer subsequent appointments for the same patient due to unnecessarily prolonged notes generated by standardization tools.

Managerial Implications: The findings underscore the importance of EHR standardization in enhancing physician timeliness and patient satisfaction. By mitigating appointment delays, physicians can potentially increase patient throughput and improve the quality of medical services provided. This study provides key insights for healthcare administrators seeking to optimize operational efficiency and patient care through strategic EHR standardization.

3 - Incentivizing Drug Rediscovery: Patent Extension vs. Accelerated Regulatory Pathways for Repurposed Therapeutics

Fernanda Bravo, UCLA Anderson School of Management, Los Angeles, CA, United States, Elodie Adida

Drug repurposing, involving the use of an already approved drug for a newly identified treatment, is seen as a method to expedite access to new therapies at a reduced cost. Despite its advantages compared to de novo drug development, drug repurposing is believed to be underutilized. We examine strategies for encouraging drug repurposing. While providing financial incentives to drug manufacturers can facilitate this process, we must carefully weigh the potential impact on patient well-being. We explore two approaches: extending exclusivity and expediting reviews, preventing cross-labeling between indications, and prohibiting narrow labeling. We assess the optimal design of each approach and its effects on patient welfare.

4 - When life gives you lemons: Spillovers between pharmaceutical recalls and shortages

Hanu Tyagi, University of Illinois, Urbana-Champaign, IL, United States, Rachna Shah, Junghee Lee

Operational failures in the pharmaceutical industry occur frequently and prolong for a long time. Hence, there may be spillovers between failures, i.e., the onset or recovery of one type of failure could impact the occurrence and recovery time of other types of failures. We investigate such spillovers and ask: How does a firm's recall experience impact shortages? Using recalls and shortages data for 319 firms from 2010 to 2019, we show that completed recall experience reduces the likelihood of future shortages suggesting internalized learning, whereas ongoing recall experience prolongs the shortage duration and shortage likelihood indicating operational burden.

Co-Chair: Yuan Ma, Ross School of Business, University of Michigan, Ann Arbor, MI, United States

1 - Health on Loan: The Effect of Local Credit Availability on Hospital (Re)Admissions

Yuan Ma, Ross School of Business, University of Michigan, Ann Arbor, MI, United States

Bank loans are crucial sources of finance for hospitals. This paper assesses the effect of increases in local credit supply on healthcare outcomes. We show that the total admission drop when there are more credits available in local banks, and the decrease is driven by decreases in readmission.

2 - The Impact of Senior Living Facilities on Healthcare Utilization

Carri Chan, Columbia Business School, New York, NY, United States, Ann Bartel, Minje Park, Fanyin Zheng

The senior population in the U.S. has been rapidly growing. Consequently, enrollment and spending in Medicare, the federal health insurance program for individuals aged 65 and older, have skyrocketed. At the same time, senior living facilities (SLFs) -- assisted living facilities and independent living facilities -- have drastically expanded in the U.S. to serve the needs of the elderly. SLFs provide housing in a community environment that often includes personal care assistance services. Thus far, there has been no research studying the effects of SLFs on healthcare utilization. We utilize data of Medicare claims and SLF real estate development to shed light on this question. Although we have granular data, analyzing the causal relationship with a naive regression will likely yield a biased estimate due to endogeneities in the decision to build SLFs in certain areas. To address potential endogeneities, we use the instrumental variables approach with a novel instrument variable motivated by the real estate and economics literature. Our analysis finds that senior living facilities significantly reduce Medicare utilization (both the dollar spent and length of stay) for skilled nursing facilities, the short-term, post-acute care provider where patients go after getting discharged from a hospital to continue recovering after an illness, injury, or surgery.

Summit - 444

Optimization for Natural Resource Extraction and Processing

Invited Session

Energy: Natural Resources

Chair: Alexandra Newman, Colorado School of Mines, Golden, CO, 80401, United States

1 - Improving the Effectiveness of Large-Scale Data Analysis Through Multiple Regression

Edikan Udofia, Colorado School of MInes, Golden, CO, United States

This project explores predictive modeling of roll forces in hot rolling, crucial for steel manufacturing efficiency and product quality. Using a dataset from a steel mill, it applies multiple regression, variable transformations, and selection techniques to improve prediction accuracy. Incorporating strain rate effects and addressing variable conversion and collinearity, the study enhances both predictive modeling and the understanding of hot rolling dynamics.

2 - Optimizing Haul Truck Maintenance Scheduling in Open Pit Mines

Bart Maciszewski, Imperial Oil, Calgary, AB, Canada, Jose S Rodriguez, Anuraj Grewal, Christine Viljoen, Amber McKay, Ervin Balleza, Andrew Milne, Jacob Olafsen, Cathy Giang, Hussam Mansour, Pujit Jetley, Brendan Cumming

We present a problem of scheduling maintenance for heavy haul trucks in an oil sands mine. The trucks require periodic preventive maintenance based on operating hours and in addition to break-in work. There is a need to schedule close to due dates while grouping activities to minimize the number of truck visits to the shop. Activities need to be performed on compatible bays and need to respect the amount of available resources. We decompose the problem into a grouping and detailed scheduling stage. We model grouping as a general assignment problem and scheduling as a special case of the Dual Constrained Hybrid Flow Shop with Skipped Stages. We solve both stages using constraint programming with rolling horizon decomposition for the scheduling stage. We show how the model has uncovered important business insights and improves over current approaches.

3 - Optimization of Daily Casting Schedule in Steel Production Using Mixed-Integer Programming

Jenifer McClary, Colorado School of Mines, Golden, CO, United States, Hayden Archer, John Cox, Alexandra Newman, Brian Thomas

This study presents an advanced mixed-integer programming model tailored for optimizing the daily casting schedule within a steel mill. The model addresses the intricate processes involved in alloying, refining, casting, and rolling of molten steel with the primary objective of minimizing penalties incurred due to deviations from mill best practices while adhering strictly to safety and logical constraints. Leveraging cutting-edge software, we solve large instances containing hundreds of variables and thousands of constraints. Results indicate potential cost reductions of up to 40%, thereby enhancing operational efficiency and reducing manufacturing costs in the steel industry.

4 - Trade-Offs Between Equity and Revenue in Electric Vehicle Charging Station Siting and Sizing

Felix Ayaburi, Colorado School of Mines, Golden, CO, United States, Yongchen Wu

With the increase in electric vehicle purchase for private passenger use, we focus on optimizing electric vehicle charging infrastructure across the United States. Specifically, while developers possess the incentive to place public charging stations in urban locations that will garner them the most revenue, underserved communities and neighborhoods, both commercial and residential, will be left without the opportunities to charge their vehicles, thus hindering adoption and resulting in increased exposure to emissions and pollution relative to more affluent neighborhoods. In turn, this impedes progress towards sustainable transportation goals. We develop a mixed-integer programming optimization model, coded in AMPL and solved with standard software, to prescribe strategic siting and sizing decisions, and corresponding operational strategies, so as to strike a balance between equity considerations and revenue maximization. By carefully assigning weights to factors such as demand and equity, we provide valuable insights into serving diverse populations while ensuring the financial sustainability of the charging network.

WB53

Summit - 445

Capacity management under supply and demand uncertainty

Invited Session

MSOM: Supply Chain

Chair: Sammi Tang, University of Miami, Coral Gables, FL, United States

1 - Capacity Sharing Contracts and Subsidy Policies Under R&D Uncertainty

Shuyue Yi, Fudan University, Shanghai, China, People's Republic of, Xiaole Wu, Christopher Tang

Besides R&D uncertainty, firms in the semiconductor and pharmaceutical sectors face long lead times to set up production facilities. To reduce time to market, some firms make upfront capacity investment before the development of the new product is complete. To reduce capacity investment risk, capacity sharing enables a firm to recover some of its capacity investment by producing for its competitor should it fail and yet its competing firm succeed in product development. This raises several questions. Should competing firms share production capacity? Should firms establish a capacity-sharing contract before (ex-ante) or after (ex-post) R&D uncertainty is resolved? To entice firms to invest in capacity, should the government subsidize a firm's capacity investment cost or its production cost? First, we find relative to no capacity sharing, capacity sharing can entice firms to increase (decrease) their capacity when the capacity investment cost is relatively high (low). Second, ex-post capacity sharing benefits the laggard firm with a lower R&D success probability, but hurts the leading firm when it has a sufficiently high success probability. In contrast, ex-ante capacity sharing is mutually beneficial when the capacity investment cost is low. Third, without capacity sharing, capacity-based subsidy is more efficient than production-based subsidy. A caveat is that offering a higher subsidy can result in higher unmet demand (in expectation) because it entices the laggard firm to increase and the leading firm to decrease its capacity without increasing the total capacity. Fourth, under capacity sharing, capacity- and production-based subsidies are equally efficient.

2 - Optimal Reward Policies for Academic Publications

Nirmanyu Batra, The Univesity of Texas at Dallas, Richardson, TX, United States, Milind Dawande, Ganesh Janakiraman

We consider a principal and N heterogeneous agents, all of whom are risk neutral. Agents produce two goods, A and B; they exert effort over a fixed time period that results in an amount of output of A and an amount of output of B. For each unit of output that an agent produces (of A and B) the principal offers a base reward b, and for each unit of A that an agent produces the principal offers an additional reward a. The principal derives value v from each unit of A produced by an agent, and does not derive any value from units of B produced. The principal's goal is to design a reward policy that specifies base and additional reward amounts to incentivize the production of A. This problem, which we denote by P, is motivated by the prevalence of *cash-per-publication* rewards in universities, which are used to motivate faculty to publish in prestigious academic journals. When there is only a single agent (N=1), we show that it is optimal for the principal to either offer only a base reward, or only an additional reward. When there are multiple agents (N>1), we show that only-base and only-additional rewards are not optimal in general. Furthermore, we specify conditions under which it remains optimal for the principal to offer either only a base, or only an additional reward.

3 - Pricing Strategies and Capacity Constraints

Huaqing Wang, Palm Beach Atlantic University, West Palm Beach, FL, United States, Chunlin Wang, Haresh Gurnani, Saibal Ray

We consider a model in which a supplier sells a product to consumers while facing cost and demand uncertainties. We study the effect of three pricing strategies (single-pricing, demand-based, and cost-based) on supplier's profits, consumer surplus, and social welfare under unlimited capacity, limited capacity, and correlation between cost and demand.

4 - Flexibility Value of Reshoring Capacity under Policy Uncertainty

Xiao Tan, East China University of Science and Technology, Shanghai, China, People's Republic of, Panos Kouvelis, Sammi Tang

Companies that operate global supply chains are facing increasing uncertainty in the cost of imported goods—both finished products as well as raw materials. This has prompted companies to rethink the need for a diversified global supply chain, particularly by adding an onshore/nearshore production location to the current offshore location. This paper adopts a game-theoretic model to analyze a global firm's reshoring capacity, output quantity, and production decisions in the presence of domestic market competition. We account for uncertainties around market demand and import costs at both the raw-material(RM) and finished-goods(FG) level. We show that an increase in the average RM cost will reduce reshoring capacity investment, but the impact of the FG cost is ambiguous. We identify two opposite effects in the increase of FG cost: (1) an overflow demand effect—present when demand is high and exceeds an overflow threshold, and unsatisfied production must overflow to the offshore location; and (2) an output quantity effect that leads to a reduction of the reshoring investment due to a higher expected unit cost of production. The direction of change in the reshoring investment depends on the dominant effect among the above two. We also find that when the cost disadvantage of onshore relative to offshore sourcing is large (small), the presence of domestic competition can lead to more (less) reshoring. Although higher import costs hurt the global firm's profit, the domestic competitor can sometimes benefit.

Summit - 446

Food Waste

Invited Session

MSOM: Sustainable Operations

Chair: Iva Rashkova, Washington University in St Louis, St Louis, MO, United States

Co-Chair: Parisa Shahsavand, The University of Texas at Dallas, Richardson, TX, United States

1 - Reducing Food Waste in U.S. Food Banks: the Role of Distribution Strategies

Luv Sharma, University of South Carolina, Columbia, SC, United States

This study looks at different operational decisions that food banks can take to reduce food waste in their distribution operations. We utilize data from 200 food banks within the Feeding America network over a five-year horizon for this empirical investigation.

2 - The Introduction of Online Operations to Brick-and-Mortar Grocery Stores and Its Impact on Shrink

Fredrik Eng-Larsson, Stockholm University, Stockholm, Sweden, Pedro Amorim, Nicole DeHoratius, Antonio Salgado

Omnichannel grocery retailers often use stores to fulfill online orders for a variety of reasons (e.g., faster deliveries, labor availability). This strategy influences inventory management, particularly the shrink ratio (defined as the ratio of loss to sales) in two opposing ways. Fulfilling online orders has the potential to increase the sales-to-stock ratio thereby improving turnover and, consequently, the shrink ratio. However, the last-expired-first-out picking policies used by store employees to serve online customers may generate higher levels of shrink in the store. Using granular data from a grocery retailer, we study the impact that introducing online fulfillment to existing stores has on shrink. Our empirical methods include a staggered difference-in-difference approach to account for the way in which online fulfillment was adopted throughout the chain. We find the shrink ratio to increase, on average, with the introduction of online fulfillment at brick-and-mortar stores. However, substantial heterogeneity in this increase exists across product categories and stores. We exploit this heterogeneity to understand more about the dynamics of online order fulfillment and to caution retailers about several unforeseen performance impacts of online operations.

3 - Leveraging Innovative Online Platforms to Combat Food Waste

Zhangchen Hu, California State University, Fullerton, ANAHEIM, CA, United States, Wei Wei

Online platforms, such as Too Good to Go, offer an innovative approach to addressing food waste. Retailers participating in these platforms sell their surplus food in "surprise bags" at discounted prices. Considering customers' purchase decisions on such a platform and using game-theoretical models, we investigate the operational decisions of retailers and the platform. Furthermore, we analyze how factors specific to customers, the market, and the platform impact their decisions and resulting outcomes.

4 - Manufacturers' Food Expiry Dates and Waste Implications

Parisa Shahsavand, The University of Texas at Dallas, Richardson, TX, United States, Dorothee Honhon, Iva Rashkova

We study the implications of manufacturers' food expiry dates on food waste. We model a food manufacturer who sells directly to consumers and sets food expiry dates in order to maximize its revenue. Consumers shop periodically and their purchasing behavior can be either be oblivious (not paying attention to the expiry date) or aware (preference for a product with an expiry date aligned with their expectation). When consuming the product, consumers can similarly be oblivious (consumer until the product spoils) or aware (consume until the expiry date). For these four types of consumers, we compare the food waste implications as retailer and consumer waste. We further identify the extent of food wasted after expiry and before spoilage and show a non-trivial dynamic between consumer behavior and food waste.

Summit - 447

Food Waste Reduction in Supply Chains

Invited Session

MSOM: Sustainable Operations

Chair: Nicholas Petruzzi, University of Wisconsin-Madison, Madison, WI, United States

Co-Chair: Aditya Vedantam, State University of New York at Buffalo, Williamsville, NY, United States

1 - The effect of store characteristics on food waste in grocery retail: An empirical analysis using Double Machine Learning

Fabian Schäfer, Technical University of Munich, Straubing, Germany, Konstantin Wink, Santiago Gallino, Alexander Hübner

Despite the well-established influence of certain characteristics of brick-and-mortar retail stores, like shelf-space and assortment planning or the size of the aisles, influencing customer behavior, little is known about the effect of various store attributes on food waste. Additionally, food waste remains a severe sustainability issue for retailers since empirical evidence about its root causes is scarce, resulting in higher carbon emissions and increased costs due to expired products. Thus, our research uses proprietary transaction data and geo data from a European retail chain partner company to investigate the relationship between store-specific characteristics and in-store waste levels. The data covers 315 retail stores in urban and rural areas. By applying the Double Machine Learning algorithm XGBoost for causal inference, our findings indicate that store-specific characteristics, such as grocery store density, delivery time, and delivery frequency, significantly impact food waste levels relative to its revenues. Our study fills a gap in the literature on food waste in grocery retail by providing empirical evidence on the store characteristics that lead to higher food waste levels. Furthermore, this study creates awareness and offers novel managerial insights for practitioners considering food waste when planning strategic store locations.

2 - Information Disclosure for Perishables: Profit and Food Waste Implications

Fan Zhou, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, Ekaterina Astashkina, Ravi Anupindi

The freshness of food, as measured by its residual shelf life (RSL), is often variable and unseen by consumers in online grocery retailing. This study examines the impact of disclosing RSL information to consumers on profit and waste. To that end, we consider two information schemes: a visible freshness scheme, under which consumers observe the food's RSL sold by the retailer; and an invisible freshness scheme, under which RSL is unobservable. We build a discrete-time game theoretical model with two players: the retailer and the consumer. The retailer announces the food's price under a certain information scheme, and the consumer, based on the available information, decides on the purchase quantity that maximizes the expected utility. The utility calculation takes into account household waste, which is jointly influenced by the purchase quantity, the RSL of the food at the time of purchase, and the food type. We find that the visible freshness scheme results in higher profits compared to the invisible freshness scheme due to: (i) the presence of pricing flexibility, which leads to higher sales; and (ii) consumers' risk aversion towards uncertain freshness. However, disclosing RSL to consumers does not always result in lower waste and, in fact, depends on the food type. In particular, for food that is less prone to waste, disclosing the RSL actually increases household food waste. Conversely, for food that is more prone to waste, disclosing RSL delivers a win-win by boosting the profit and reducing waste simultaneously.

3 - Strategic Sell-By Dates: Implications for Retail Food Waste

Karthik Murali, Oregon State University, Corvallis, OR, United States, Aditya Vedantam, Nicholas Petruzzi

Grocery stores in the U.S. throw away 16 billion tons of food each year due to expiration. In this study, we develop a game-theoretic model to examine the strategic motivations behind a manufacturer's choice of sell-by dates and the corresponding implications for food waste at the retail level.

Summit - 448

Optimizing Aviation and Air Mobility

Contributed Session

Chair: Randy Grivel, Arizona State University, Tempe, AZ, United States

1 - Integrated Recovery of Passenger and CargoConsidering the Belly Space of Passenger Aircraft

Sirui Wang, Harbin Engineering University, Harbin, China, People's Republic of, Yuzhen Hu

Thanks to the recovery of the international passenger market this year, the cargo capacity of passenger aircraft has increased significantly. It is necessary to rearrange cargo itineraries and jointly consider the coordinated recovery of passenger itineraries under the situation of cargo carried in the belly hold of passenger aircraft. We establish an integrated passenger-cargo recovery model and apply time-space network models to depict the transfer networks of aircraft, passengers, and cargo respectively. Taking into account the characteristics of cargo transportation, such as no restriction on the number of transfers under the premise of coordinating costs, we propose three strategies for the cargo transfer network to improve computational efficiency. Then, we conduct a case study using real data from a large Chinese airline and simulated data on cargo transportation. By comparing with the currently used model of airline, we explore the solving performance of the two recovery models. It is found that an increase in the number of cargo transfers leads to a situation where "the solution results are better but the solving efficiency is reduced," thereby validating the two improvement strategies proposed in this paper. And the first strategy can effectively improve the solving efficiency of the integrated model, increase the generation time of the transfer network, but overall reduce the solving time; the second strategy can significantly improve the solving efficiency at the cost of a deviation of less than 5% from the target value; and the third strategy can largely balance solving results and computational efficiency.

2 - Optimization-Based Simulation of Target Time Over For Flights Within the Decentralized ASEAN Region

Darryl Teo, Singapore University of Technology and Design, Singapore, Singapore, Peter Jackson, daniel delahaye

Air Traffic Flow Management (ATFM) tactical measures such as the imposition of acceptance rates and calculated take-off times require information sharing and collaboration between Air Traffic Control sectors. In a decentralized system such as Southeast Asia this is a challenge. To evaluate the potential benefits of different measures under different information sharing regimes, it is useful to construct a rolling horizon simulation of the decentralized system. An essential component of such a simulation is a model of each Flight Information Region (FIR) as a separate decision-making entity. We formulate the FIR decision problem as an optimization problem, the Waypoint Flow Regulation Problem (WFRP), which is to be solved for each FIR at each time step of the simulation using the local information available to each FIR at that time. We propose two methods to solve the WFRP: Gradient Descent Ascent (GDA), and Simulated Annealing (SA). Both heuristics were applied within the integrated simulator to published flight schedules, under two capacity scenarios, for the Southeast Asia region. Both algorithms achieved near-feasible solutions. SA yielded better flight delay performance but GDA was an order of magnitude faster.

3 - HEAT: Hub Efficiency Analytics Tool

Majid Akhgar Farsani, American Airlines, Grapevine, TX, United States, Billy Wang, Duaa Serhan, SHREEJIT BANDYOPADHYAY

In this work, we will present a large-scale optimization model developed by the Operations Research and Advanced Analytics team at American Airlines that aims to optimize the flight delay and cancel decisions as potential responses to operational capacity reductions at the airline's major hub airports. Adverse weather conditions, such as severe thunderstorms in the summer, can pose challenges to the safe operation of flights, resulting in capacity reduction on the arrival side, or the departure side, or both. Historically, the airlines have two options to manage this critical operational problem: either canceling flights proactively or collaborating with the FAA to implement air traffic management initiatives. However, both options tend to have their respective drawbacks. The model we designed is to address some of these drawbacks by incorporating a rich dataset of airline internal data and optimizing the delay and cancel decision jointly. Since its initial deployment in April 2022, this new model has been used more than 100 times at the airline's largest hub airports and prevented thousands of flight cancellations across the network. The use of the model has contributed to American Airlines' record operational performance in 2023.

4 - Aircraft Line Maintenance Scheduling: Q-Learning Approach

Syed Shaukat, University of New South Wales, Sydney, Australia

Recent advances in optimal airline scheduling have seen a shift towards data-driven and AI-based learning approaches, indicating great potential to complement or even replace conventional optimization-based models. Conventional optimization methods encounter significant challenges when applied to real-world conditions, including the uncertainties and nonlinearities inherent in the airline environment. This paper delves into the application of Q-Learning, a prominent reinforcement learning (RL) method, within the dynamic and complex realm of aircraft line maintenance job scheduling. Employing the reward-centric properties of reinforcement learning, the proposed methodology adeptly navigates the operational intricacies of airline scheduling.

The results demonstrate that the Q-Learning approach is capable of generating solutions comparable to those of conventional optimization models when tested with industry-inspired datasets. This AI learning method adeptly balances maximizing aircraft availability with maintaining stringent maintenance schedules, potentially affording airlines the operational agility necessary for superior decision-making, cost savings, and increased flexibility. By advocating a standardized and uniform approach, this AI-based methodology paves the way for integrated solutions to aircraft maintenance job scheduling, aircraft maintenance check scheduling, and aircraft tail assignment problems.

5 - Scheduling Resources in an Airport Security Screening Process with Break, Overtime, and Skill Considerations

Randy Grivel, Arizona State University, Tempe, AZ, United States, Ron Askin, Jorge Sefair, Jian Jiao

Airport security services in the United States can be modeled using sequential heterogeneous servers with dynamic processing rates and pooled resources. We model this system as a mixed integer program with the objective of minimizing the combined expected cost of passengers' wait time and operational cost of staff overtime and idle time. Our model includes realistic operational rules such as the ramp up and down processing rates when opening and closing stations, staff movement across facilities, working shifts, skill set of officers, and design of breaks and overtime plans. A novel method is used for determining staffing requirements of a baggage screening area. We illustrate the performance of our models using a real-based instance from an US airport.

Summit - Terrace Suite 1

Incorporating AI into Healthcare Delivery

Invited Session

Health Applications Society

Chair: Sidian Lin, Harvard University, Cambridge, MA, United States

1 - Exploring the Effects of Retrospective Study Design on Non-Alcoholic Fatty Liver Disease Prediction

Mary Ogidigben, Pennsylvania State University, State College, PA, United States, Paul Griffin, Soundar Kumara

Non-alcoholic fatty liver disease (NAFLD) affects 25% of the U.S. adult population and is the most common chronic liver disease. The condition is asymptomatic in most individuals. Progression of the disease leads to liver cirrhosis and is a leading indication for liver transplant. Although universal screening is not recommended, early detection is beneficial since lifestyle changes can control or reverse the condition. Several NAFLD risk prediction models have been developed and often modeled with machine learning techniques. However, most previous methods have been developed for homogenous populations and there is no consensus on the best predictive factors to use. We explore how retrospective study design affects feature selection and accuracy to construct a framework researchers can use to develop fair algorithms for early chronic disease diagnosis across a variety of patient classes.

2 - Development and Validation of a Reinforcement Learning Algorithm for Personalized Treatment in Bipolar Disorder

Sidian Lin, Harvard University, Cambridge, MA, United States, Soroush Saghafian, Jessica Lipschitz, Katherine Burdick

This paper presents a novel application of offline Multi-Agent Reinforcement Learning (MARL) for optimizing bipolar disorder (BD) treatments. Using Fitbit data and biweekly self-reports from BD patients, we develop an approach integrating the Implicit Constrained Q-Learning (ICQ) algorithm with copula-based dependency modeling. The proposed MARL demonstrates robust performance in optimizing individualized treatment plans, reducing mood episode frequency and potential suicide rates.

3 - Sequential Decision Making with Sparsely Observed Rewards

Daiqi Gao, Harvard University, Cambridge, MA, United States, Hsin-Yu Lai, Susan Murphy

Cardiac rehabilitation (CR) is an outpatient risk-reduction program for patients with cardiovascular disease, involving supervised exercise, dietary counseling, and stress management. However, sustaining the heart-healthy lifestyle changes adopted during CR after patients return to the obligations of everyday life remains a significant challenge. Our aim is to improve users' commitment to physical activity (PA) immediately after they leave the CR program by providing effective ongoing support through Mobile health (mHealth). This will be achieved through notifications on mobile devices prompting short bouts of activity. However, information about commitment to PA is collected through weekly or monthly surveys, resulting in sparsely observed rewards. We employ reinforcement learning to determine when and whether to deliver notifications. Causal information provided by domain experts is leveraged to speed up learning. We will also discuss practical challenges in designing the learning algorithm and constructing a simulation testbed.

4 - Enhancing Fairness and Accuracy in Mammography Screening Using
a Custom Ensemble

Mehmet Ahsen, University of Illinois at Urbana-Champaign, Champaign, IL, United States, Mehmet Ayvaci, cetin ozeken

As AI algorithms become increasingly prevalent in healthcare, ensuring both accuracy and fairness in algorithmic decision-making poses a dual challenge for healthcare organizations. We tackle this challenge by leveraging ensemble methods to promote fairness while maintaining accuracy, specifically in the context of mammography screening. This setting is particularly vulnerable to disparities in algorithmic bias among diverse racial groups. Moreover, multiple commercially available AI algorithms for mammography demonstrate varying accuracy across distinct subpopulations. We first develop a statistical analytical model to establish conditions for constructing a fair ensemble algorithm, even when individual algorithms exhibit unfairness. Through structural analysis, we demonstrate the trade-off between fairness and performance optimization by comparing the fair ensemble with the optimal ensemble. Then, we demonstrate our approach using twelve algorithms from
the Digital Mammography Dialogue on Reverse Engineering Assessment and Methods (DREAM) Challenge, trained and validated on mammograms from Kaiser Permanente Washington (KPW). We applied those algorithms to a large, geographically diverse screening population at a different healthcare organization in West Coast. The fair ensemble aims to achieve equitable performance in, contributing to more equitable healthcare outcomes in breast cancer screening. Our empirical analysis showcases the effectiveness of ensemble methods in improving both generalization and fairness in mammography screening. In doing so, our approach considers practical implementation factors, leveraging algorithm diversity and appropriate weighting to optimize performance while promoting equity.

1 - Ai Assistant for Highly Personalized and Dynamic Causal Decision-Making in Cancer Treatments

sina Aghaei, Harvard University, Cambridge, MA, United States, Jacob Jameson, Giuseppe Tarantino, David Liu, Soroush Saghafian

Large language models (LLMs) have demonstrated impressive capabilities in various domains, including healthcare. Existing work on LLMs in the medical field has mainly evaluated general-purpose models on tasks like information retrieval, summarization, question answering, and diagnostics. Less effort has focused on enhancing LLMs for impactful clinical uses such as those that require complex causal reasoning. This paper bridges this gap by developing an AI system tailored to optimizing treatment regime recommendations and assisting providers in their complex causal reasoning and decision-making processes. In close collaboration with the Dana-Farber Cancer Institute, we harness detailed data on patients with melanoma, spanning clinical records, diagnostic imaging, pathology reports and gene sequencing information, among others. We develop a multi-modal LLM and fine-tune it to have causal reasoning capabilities using novel causal reinforcement learning techniques. This enables the AI system to provide highly personalized and dynamic (i.e., fully adaptive) treatment recommendations via causal reasoning.

2 - A Robust Approach to Locating Vaccination Centers During A Pandemic: A Problem Driven by Herd Immunity and Decision-Dependent Concave Utility

Shibshankar Dey, Northwestern University, Evanston, IL, IL, United States, Esma Gel, Sanjay Mehrotra

This study introduces an optimization model for determining the location of vaccination centers (VC) while accounting for distributionally-robust decision-dependent utility, herd immunity, equity and facilities' end-of-life value. We consider the herd-immunity function as a potentially useful surrogate to the epidemiological compartmental model. We explore both linear and concave utility functions which, besides evaluating the utility of VC location, also have the potential to be a measure of vaccine hesitancy. Addressing uncertainty in the parameters defining utility and the herd immunity function, we first reformulate the problems respectively as two-stage stochastic mixed-integer bilinear and mixed-integer biconvex programs. Considering the inability of GUROBI to handle resultant bi-convex problem, we develop a decomposition linearize-branch-union approach with an embedded exploration-based heuristic. Our proposed decomposition algorithm iteratively adds optimality cuts in x-space (first-stage variable space) by linearizing, branching, union of the leaf nodes of branch-and-bound tree and finally projecting the union set onto x-space. Novelty lies not only in ensuring global validity of those cuts but also the adaptive linearization scheme used for bi-convex problem linearization. Using the proposed solution framework, we then solve several instances and interpret how location decision changes with anticipated herd immunity levels, equity thresholds, robustness considerations. Furthermore, we examine how concave utility affects the location decision and increases vaccination level in comparison to linear utility and no utility at all. We finally discuss the potential and flexibility of our proposed decision-dependent utility-based model and algorithm to solve diverse assignment problems that dominantly arise in the healthcare domain.

3 - Applications of Non-Stationary Bandits in Personalized Healthcare

Yonatan Mintz, University of Wisconsin Madison, Madison, WI, United States, Katherine Adams, Qinyang He

Mobile interventions have become commonplace in many healthcare applications ranging from diabetes management, mental health, addiction management, and weight loss. With this level of data availability interventionists and clinicians are now able to provide personally tailored interventions to individual participants to improve overall efficacy and adherence. A key aspect of these treatments is that the decision makers must use online intervention information to both learn the effect of various treatments on individual participants as well as decide on the most effective treatment options. This setting can thus be modeled through the use of multi-armed bandit (MAB) models which are designed to effectively trade off exploration (learning the parameters of the system) and exploitation (finding the optimal treatment choice). In contrast to classical applications of MAB models where only a single action or time invariant set of actions may be optimal, in the context of personalized interventions data is often non-stationary requiring MAB approaches that can account for frequently changing optimal actions. Moreover, interventionists are often faced with resource constraints such as limited numbers of nutritionists for counseling in the case of weight loss interventions, or limited financial budgets for contingency management interventions in addiction management. In this talk, I will discuss some of the recent advances made by my group in adapting non-stationary MAB models to these resource constrained settings. I will discuss both new theoretical guarantees that we can obtain for such algorithms and discuss several computational case studies showing their practical performance.

4 - Patient Management in the Neuro-ICU: to Scan OR Not to Scan?

Agni Orfanoudaki, Oxford University, Oxford, United Kingdom, Panos Tsimpos, Ethan Phillips, Charlene Ong, Stelios Smirnakis

Stroke survivors in the neuro-intensive care unit are at an increased risk of rapid cerebral edema development. Diagnosis requires cranial radiology imaging. However, high operational costs, radiation exposure, and scanner scarcity render hyper-aggressive scanning detrimental. To address this problem, we propose a partially observable Markov decision process approach with a one-step memory that allows us to dynamically capture the patient trajectory and suggest medical screening at the onset of clinical deterioration. We analytically characterize the derived optimal policy and identify a critical threshold for medical intervention. Moreover, we demonstrate how supervised machine learning models could improve the proposed policy by estimating a personalized patient kernel. We validate our framework leveraging data from two academic medical centres, highlighting the value that our approach could bring to real-world settings.

5 - The Costs of Inaccurate Resupply Information During Drug Shortages

Jacqueline Griffin, Northeastern University, Boston, MA, United States, Noah Chicoine

During drug shortages, pharmaceutical manufacturers may communicate estimated release dates (ERDs), communicating when the next batch of a specific product should enter the supply chain. Hospital pharmacists use ERD information to inform their inventory management and sourcing decisions. However, ERD information tends to be inaccurate, which has the potential to cost hospitals additional time, labor, and money if they make decisions that fully rely on this information. We demonstrate this phenomenon using a stylized model of optimal drug sourcing strategies using ERD information. We show that inaccurate ERD information can cause hospitals to invoke costly last-minute practice changes. We also demonstrate that more explicit descriptions of uncertainty ERDs could reduce these costs. This work highlights a possible area for improvement in increasing the resiliency of pharmaceutical supply chains and improving patient care at hospitals.

Summit - Ballroom 1

Planning and Operations of Power Systems

Contributed Session

Chair: Hanieh Rastegar, University of Illinois at Chicago, 821 W Bradley Pl, Chicago, IL, 60613, United States

1 - Capturing the Role of Peaking Power Plants in a Decarbonized Electricity System

Wesley Cole, National Renewable Energy Laboratory, GOLDEN, CO, United States, Brian Sergi

Electricity systems rely on peaking power plants to maintain system resource adequacy. These plants typically operate for only a small number of hours each year when dispatchable generation needs are greatest. Modeling of decarbonized electricity systems shows a strong role for peaking power plants such as hydrogen fuel cells, hydrogen combustion turbines, or uncontrolled natural gas plants with carbon offsets. However, the representation of these power plants can have considerable impact on the specific role that these types of plants play. This work will showcase several approaches for capturing peaker plant behavior in a national-scale capacity expansion model of the U.S. electricity system. It will highlight how resource adequacy choices, power plant flexibility choices, and efficiency choices impact model outcomes. For example, the choice between including a simple-cycle hydrogen combustion turbine (which has a lower efficiency) and a combined-cycle hydrogen combustion system (which has a higher efficiency) can have substantial impacts on the cost of achieving a fully decarbonized electricity system. This work will highlight the importance of peaker plant design decisions for electricity system planning models that are being used to study decarbonization scenarios.

2 - Modeling peak electricity demands across distribution grid types

Christine Gschwendtner, Massachusetts Institute of Technology, Cambridge, MA, United States, Seth Blum, Lauren Aguilar, Jessika Trancik

The electrification of heating and transport can cause increased peaks in electricity demand, if left unmanaged. These peaks may strain electric grids and require a costly expansion of the electricity supply. The combined integration of heat pumps and electric vehicles, and potential compound peak effects, may be especially challenging and should be investigated. These effects can be particularly strong at small spatial scales, i.e., for distribution grids, requiring infrastructure upgrades. Here we investigate these potential changes in peak electricity demand in different distribution grid types considering various adoption scenarios for heat pumps and electric vehicles. We characterize distribution grid types in the US according to characteristics that include the share of residential and commercial buildings, urban and rural areas, and climate zones. We simulate hourly electricity demand profiles with a focus on the temporal and spatial variation of weather events over a multi-year timescale. Analyzing the magnitude, duration, frequency, regularity, and timing of the resulting peaks for each technology, and across residential and commercial applications, allows us to identify mitigation strategies for peak reduction, such as demand response. These insights can support the development of demand-side management schemes and can inform grid investment decisions.

3 - Effects of Storage Participation on Wholesale Electricity Markets

Zhenhua Zhang, University of California, San Diego, Mountain View, CA, United States, Michael Davidson

The strategic behaviors of storage systems that participate in wholesale electricity markets can influence market prices, system costs, and profit distributions among generation types. We develop a bi-level model to examine how these impacts vary across participation requirements in the Western Electricity Coordinating Council region. The upper level includes a storage profit maximization model and the lower level represents the market operator's economic dispatch problem. We find that strategic behaviors can significantly increase storage profit but increase system cost only by a small margin under various renewable penetration levels relative to the case when storage is ISO-controlled. Market prices decrease during charging events but remain similar during discharging events, subject to electricity demand conditions and discharge offer prices. For storage that also participates in resource adequacy programs with minimum state-of-charge requirements, a low non-compliance penalty can help recover storage investments without significantly increasing system costs. Future designs on wholesale participation models and resource adequacy programs should consider how ISO requirements and storage strategic behaviors interact and evaluate the trade-offs between generator profitability and system costs.

4 - Post Disaster Restoration of Electrical Distribution Networks: Introducing a new variant of the TSP

Ran Wei, University of Washington, Seattle, WA, United States, Arindam Das, Daniel S. Kirschen, Payman Arabshahi

The costs of severe weather events, both tangible and intangible, on the overall power grid (generation, transmission, and distribution systems) can be exorbitant, depending on the scale of the event. Optimal restoration of distribution networks following a major weather event is a multifaceted optimization problem which involves pre-event as well as post-event decision making under uncertainty. We concentrate on post-event activities, specifically, optimal repair scheduling such that the distribution network can be brought back online as quickly as possible, thereby minimizing the human, social, and economic costs after a major event. Since a major limitation to the restoration process is the lack of timely and accurate information about the scale and locations of damages, we adopt a rolling horizon restoration framework which is naturally conducive to periodic resequencing of restoration activities, if necessary, due to repair time overruns and/or uncertainty in damage information. Considering both repair times and travel times of crews, we show that the optimal restoration problem can be formulated as a combinatorial optimization problem which closely resembles an instance of a cost-constrained reward-maximizing multiple traveling salesman problem (TSP) on doubly weighted graphs (weights on both nodes and edges, modeling repair times and travel times respectively). This is a new variant of the TSP and can be viewed as a generalization of the Selective TSP. We propose a mixed integer linear programming model to solve the above problem and validate it on standard IEEE test distribution networks as well as randomly generated network instances.

5 - A Two-Stage Stochastic Model for Mixed-Fleet Pickup and Delivery Routing Problem with Temperature Considerations

Hanieh Rastegar, University of Illinois Chicago, Chicago, IL, United States, Amir Shafiee, Xi Cheng, Jane Lin

Transportation is a significant source of CO_2 emissions, with freight operations being especially impactful. This study explores sustainable alternatives in freight transportation by integrating Electric Vehicles (EVs), known for their zero tailpipe CO_2 emissions. The adoption of EVs in distribution networks poses challenges such as high initial costs, restricted range and payload capacities, and long recharging durations. To address these issues, we introduce the Pickup and Delivery Multi-Fleet Vehicle Routing Problem (PDMFVRP). This model aims to minimize total costs, encompassing vehicle acquisition, travel time, and energy usage, while also incorporating the effects of temperature on EV performance. We employ a two-stage stochastic programming approach to optimize the composition of diesel and electric fleets, considering the variable impact of temperature on EV efficiency and routing. This approach aims to minimize both total operational costs and CO_2 emissions. Utilizing the epsilon constraint method for multi-objective optimization, we seek an optimal trade-off between cost efficiency and emission reductions, factoring in the complexities of EV charging demands and constrained driver hours. Our analysis indicates that although the shift to EVs may lead to higher costs and increased vehicle miles due to frequent charging stops, it substantially lowers tailpipe emissions. This study presents a detailed and sustainable strategy for the modernization of goods distribution, aimed at reducing environmental impacts.

Optimizing Electric Vehicle Charging Infrastructure

Contributed Session

Chair: Jiangxue Han, N/A

1 - Enhancing electric vehicle charging demand prediction with graph neural networks

Yuanjie (Tukey) Tu, University of Washington, Seattle, WA, United States, Mayuree Binjolkar

As Electric Vehicles (EVs) become increasingly popular, predicting EV charging demand at public EV charging stations has been critical to help optimize operations and prevent grid overloading. In this study, we leverage graph neural network (GNN) to predict EV charging demand, incorporating both multivariate historical EV charging data and spatial-temporal interactions between EV charging stations. Our approach is compared with other statistic and deep learning models including autoregressive moving average (ARMA), multiple linear perceptrons (MLP), convolutional neural networks (CNNs), and long short term memory (LSTM). Moreover, we investigated the model explainability of GNN. As a result, our approach is conceptually advantageous to other methods, which do not consider the interactions between EV charging stations or model explainability. Empirical results on a time-series EV charging dataset of 47 charging stations show that CNN outperformed start-of-art methods. These findings provide actionable insights for city planners and engineers to anticipate peak usage periods, optimize operations, and help with power grid stability and sustainability.

2 - Optimal Placement of Electric Vehicle Charging Stations

Iason Liagkas, University of Michigan Ann Arbor, Ann Arbor, MI, United States, Neda Masoud

As the demand for electric vehicles (EVs) continues to surge, efficiently integrating EV charging stations within urban settings emerges as a critical challenge. This paper investigates the strategic placement of these stations to achieve three primary goals: reducing overall traffic congestion, minimizing government expenditure on infrastructure, and lowering the societal costs associated with conventional internal combustion engine vehicles. Our approach considers the availability of public transportation as an alternative to EV usage, ensuring a comprehensive analysis of urban mobility. Furthermore, Benders decomposition is adopted as a robust solution strategy, with its efficacy illustrated through detailed numerical examples. This study not only provides practical insights for urban planners but also contributes to the broader goal of making cities more sustainable and efficient in the face of rising EV adoption.

3 - Optimum Configuration of Fast Charging with Integrated Distributed Energy Resources during Fluctuating Demand and Extreme Weather Conditions

Hamid Mozafari, Michigan State University, East Lansing, MI, United States, Kunle Adeyemo, Chenyang Deng, Mehrnaz Ghamami, Annick Anctil, Ali Zockaie

The rapid transition towards electric vehicle (EV) necessitates a well-established network of direct current fast charging (DCFC) stations and a robust power distribution system. Recent battery technologies have mitigated range anxiety for urban EV users, though challenges persist for long-distance travel. This study aims to determine the optimum charging infrastructure for EVs incorporating second life batteries (SLBs) and photovoltaics (PVs) as distributed energy resources (DERs) under fluctuating travel demands and temperatures. The proposed framework consists of two optimization models: the first minimizes the total system cost, including investment (i.e., charger cost) and user (i.e., queueing and detour delay) costs, while the second, executed by Homer Pro, determines the optimal capacity of DERs at each charging station. DERs not only reduces the system costs and alleviates the strain on the electricity grid network during peak-demand seasons and hours but also DERs also mitigates the environmental impact by repurposing used EV batteries. The results demonstrate that incorporating SLBs and PVs into DCFC stations is not only cost-effective but also significantly alleviates the grid's load, besides the environmental benefits of reusing the EV batteries. Integrating the optimal capacity of SLBs and PVs into DCFC stations has the potential to diminish the required grid power by up to 70%, and decrease the total system costs by 59%, contingent upon the DERs acquisition scenarios and the charging schedule approach.

4 - A Pricing Model for Enhancing the Utilization of Public Electric Vehicle Facilities: A Case Study in Hong Kong

Jiangxue Han, The University of Hong Kong, Hong Kong, Hong Kong, Yong-Hong Kuo

With the wide acceptance of electric vehicles (EVs) and the significant increase in the number of EVs, greater attention has been paid to the development of public EV charging facilities. However, issues such as constrained charging spaces, EV overcharging, and inconvenient charging locations, might lead to difficulties in achieving a high utilization of public EV charging facilities. Existing research primarily focuses on enhancing the spatial planning of EV charging stations. In this research, we provide a pricing perspective as a more flexible and adaptive complement to optimize the utilization of the established EV charging infrastructure.

We focus on the case of Hong Kong in this work. While the Government has adopted an (almost) uniform pricing policy, we develop a more effective pricing scheme for the public EV charging services in the city. Based on the primary factors that may influence drivers' choice in EV charging facilities, we build a linear optimization model to explore the mutual influences between these factors, with the objectives to improve the utilization of public EV chargers and to satisfy the EV charging demands. Numerical experiments are conducted based on real data to examine the performance of the proposed pricing mechanism.

Application of Machine Learning Methods

Contributed Session

Chair: ekrem duman, Ozyegin University, Istanbul, Turkey

1 - Utilizing Large Language Models for Improved Missing Data Handling in Classification Tasks

Francis Kim, Sungkyunkwan University, Suwon, Korea, Republic of, Dohyun Bu, Chanho Kim, Jong-Seok Lee

In this research, we propose a novel method for handling missing values in tabular data by utilizing Large Language Models (LLMs) for classification tasks. Traditional approaches to handling missing values, such as imputation or deletion, often introduce bias and decrease prediction accuracy. Our method addresses these issues by systematically augmenting the complete training dataset with various combinations of missing values and converting each instance into a textual format. This enables the Large Language Model (LLM) to learn from the augmented data during fine-tuning. The process includes three main steps: data augmentation through the introduction of missing values, converting these augmented instances into text, and fine-tuning the LLM using this textual dataset. The LLM is also trained to predict the target class based on the available information, thereby effectively learning the marginal probabilities of the target variable given the observed data. Experimental results demonstrate the effectiveness of our method across different missing data mechanisms (MCAR, MAR, MNAR), showing improved performance over traditional imputation methods. Our approach ensures robust predictions and maintains high accuracy, even in situations where the data contains a significant number of missing values, making it a valuable tool for domains frequently encountering incomplete datasets.

2 - Better Generative AI, Better Prompts: The Ongoing Need for Prompt Engineering

Eaman Jahani, University of Maryland, Washington, DC, United States, Hong-Yi TuYe, Joe Zhang, Mohammed Alsobay, Benjamin Manning, Siddharth Suri, David Holtz

The extent to which generative AI can provide value in any context is highly contingent on the quality and efficacy of the textual instructions, “prompts”, that users provide to the model. The practice of creating prompts for generative AI has come to be known as “prompt engineering” and some firms have begun creating dedicated prompt engineer job positions. Although there are already a number of studies documenting the quality gains due the advances in generative AI models, there has been very little focus on how more powerful models influence the necessity for prompt engineering. Several scholars have argued that as generative AI models become more proficient in understanding human language, the need for meticulously crafted prompts will diminish. We investigate how advances in generative AI models interact with the importance of prompt engineering and show that at the very least over the short term, prompting techniques remain important in generating higher quality content as models become stronger. We show that the transition for DALL-E2 to DALL-E3 leads to significant improvements in the quality of user-requested images. We further decompose this gain to two sources: improvements directly resulting from the model enhancement and, improvements due to changes in prompting techniques indirectly induced by the stronger model. Each of the mediating sources contribute to about half of the overall performance gain. Our results suggest that as generative AI technology advances, both the inherent capacity of the models and the more sophisticated prompting strategies they enable are critical for generating high quality content.

3 - Generative AI in Recruitment: A Comparative Study of Llama2 and ChatGPT for Resume Screening

Wenyue Xi, New York University, New York, NY, United States, Oscar Wan, João Sedoc

Generative AI has the potential to enhance hiring efficiency at scale; however, the integration of Large Language Models (LLMs) into such processes requires examination of trade-offs. Thus, we study a popular open-source model, Llama 2-13B, and a close-source model, ChatGPT, in the context of the recruitment process. We focus on their lexical processing, explanation, and decision-making abilities. We aim to address critical concerns, such as enhancing the financial accessibility of open-source LLMs, addressing privacy concerns, improving explainability in hiring processes, and ensuring transparency and reproducibility in their outcomes. We use a resume dataset (Jiechieu & Tsopze, 2020) and a job description dataset from PromptCloud and DataStock. First, we assess the capability of Llama2 and ChatGPT to convert resumes into structured data and effectively align them with job descriptions. Next, we utilize methodologies such as word embedding, BERTopic, and LlamaIndex to determine how well these models match resumes with job descriptions based on their suitability. Additionally, we investigate the key input features that influence decision-making in Llama2 during the resume screening process and employ Integrated Gradients and Chain-of-Thought Prompting to explore the models’ explainability (Parasurama et al., 2022). This study emphasizes the necessity of evaluating Generative AI applications in recruitment to enhance efficiency and ensure fairness in the automated hiring process.

4 - Development of Collection and Churn Scorecards

ekrem duman, Ozyegin University, Istanbul, Turkey

This article addresses the challenges faced by banks in managing non-performing loans (NPLs) and optimizing collection strategies for delinquent customers. The study presents a systematic approach to optimize collection strategies, aiming to maximize the total probability of payment before litigation for each customer while minimizing the risk of customer churn. The study proposes the development of collection and churn scorecards framework to predict the effectiveness of various collection actions and their potential impact on customer churn. Using logistic regression models, the author analyze historical data to identify key predictors of payment and churn probabilities, incorporating action severity and capacity constraints into the modeling process.

Auctions and Market Design

Chair: Yunke Mai, University of Kentucky, Lexington, KY, United States

1 - Optimal incentive design for ongoing book writers with freemium-to-premium reading mode

Lang Fang, Dongbei University of Finance and Economics, Dalian, China, People's Republic of

The rise of online paid reading has resulted in an increase in publishing platforms offering ongoing books for sale online. Instead of releasing complete books, writers release several chapters for free and then utilize a pay-per-chapter option to continue releasing additional chapters based on reader engagement (freemium-to-premium reading mode). Writers adjust chapter quality based on reader feedback in this process. For platforms, how to set the chapter price and the profit sharing ratio of writers is a key decision. Our research introduces two principal-agent models to assist platforms in effectively implementing (i) myopic and (ii) forward-looking chapter pricing and profit sharing ratio-based contracts to maximize platform benefits. For the myopic contract design, which means that the platform only focuses on maximizing profit for one chapter. We develop a principal-agent model to determine the price of chapters and the profit sharing ratio of writers. The optimal solution is provided by model simplification and specific search algorithm respectively. For the forward-looking problem that the platform aims to maximize the total profit of an ongoing book, we develop an efficient solution procedure to simultaneously set the chapter price and decide the profit sharing ratio of writers over a planning horizon. Additionally, we also explore the impact of the number of free chapters on platform revenue optimization. We demonstrate the superiority of our solution strategies for both myopic and forward-looking problems against multiple benchmark methods used in practice. Finally, we present several valuable insights into writer and ongoing book management for these platforms.

2 - A Hybrid Solution to the Print-on-Demand Platforms: Can Less be More?

Pengyu Wang, University of Washington, Foster School of Business, Seattle, WA, United States, Yuankun Li, Masha Shunko, Yong-Pin Zhou

Print-on-Demand (POD) platforms are emerging as popular online marketplaces where individual content creators can upload unique graphic designs for customers to select, which are then printed on various blank products and shipped to the customers by the platform. The platform incurs all the costs and shares the revenue with the content creators based on a pre-determined schedule. Currently, POD platforms use a make-to-order (MTO) production model, which provides flexibility and minimizes inventory cost, but comes at a high production cost. We propose a novel hybrid production strategy that supplements the MTO model with the cost-effective make-to-stock (MTS) model. To make sure that the new system is incentive compatible, we propose three different implementation strategies that encourage content creators to focus on increasing demand for each design rather than flooding the market with excessively many designs. Our solution leads to substantial reductions in unit production costs and significant profit increases for both the platform and the content creators.

Co-Chair: Yinliang Tan, University of Houston, Houston, TX, United States

1 - Would AI Replace Friends? Examining the Impact of Ai Interaction Frequency on Social Relationships

Zenan Chen, The University of Texas at Dallas, Richardson, TX, United States, Teng Ye, Jason Chan

This study examines the potential of large language model (LLM)-based artificial intelligence (AI) companions to fulfill human socialization needs, an area of increasing interest as these digital entities become more integrated into daily life. With their ability to understand and respond in a human-like, empathetic manner, these AI companions have quickly attracted millions of users. This research aims to understand whether interactions with LLM-based chatbots could replace human relationships, a question with significant implications for our comprehension of digital companionship and the socio-psychological impacts of technology. Such insights are crucial for informing future public policy on LLM regulation and the design of socially responsible AI technologies.

To explore this, we design a randomized experiment using a cross-platform AI companion powered by a large language model featuring customizable 3D avatars. The study focuses on measuring changes in the depth and breadth of participants' social interactions with friends and family via social media messaging, before and after the introduction of the LLM-based companion. This ongoing work promises to shed light on the evolving dynamics of human-digital relationships and their broader societal and theoretical implications.

2 - Beyond Automation: the Impact of Robotaxi Services on Ride-Hailing Consumer Behavior

Chen Liang, University of Connecticut, Storrs, CT, United States, Tong Shen, Xinxin Li, Chunxiao Li, Shuliu Yuan

Robotaxi technology, an innovative development within ride-hailing services, is undergoing regional deployments across different countries, yet its influence on consumer demand remains largely unexamined. Our study employs a difference-in-differences (DiD) model to estimate the causal impact of robotaxi usage on consumers' ride-hailing demand by comparing the behavior or consumers experienced robotaxis services with those who are did not. Our identification strategy leveraging a unique identification strategy based on the algorithmic, quasi-random distribution of robotaxi services to consumers. Our identification strategy exploits the algorithm-driven, quasi-random allocation of robotaxi services to consumers when they requested robotaxi services, wherein some consumers experience them while others do not. Our findings reveal a significant 24.8% increase in overall weekly rides for users who had robotaxi rides. Our further analysis indicates a boost in demand for both robotaxi and regular ride-hailing services. This surge is particularly pronounced in robotaxi-accessible areas, whereas demand declines in inaccessible areas. Moreover, we find differential impacts on single-homing and multi-homing consumers, highlighting the nuanced implications for market competition. For single-homing consumers, robotaxi usage boosts demand in service-accessible areas, without significant changes elsewhere. Conversely, multi-homing consumers experience a more pronounced increase in demand in robotaxi-accessible areas (compared to single-homing consumers), whereas they significantly reduce their usage of the focal platform in inaccessible areas.

3 - Iv Estimation with Violated Exclusion Restrictions in Randomized Encouragement Designs

Cheng Lu, Washington University in St. Louis, St. Louis, MO, United States, Guangying Chen, Tat Chan, Zhengling Qi, Dennis Zhang

This paper examines the use of randomized encouragement designs as instrumental variables (IVs) for estimating treatment effects, despite potential violations of the exclusion restriction. Such violations occur when the encouragement design directly affects the outcome, beyond its indirect effect through the treatment. We demonstrate that, under conditions of heteroskedastic treatment intensity across groups, randomized encouragement designs can still yield unbiased estimations of treatment effects. Additionally, this approach allows for the isolation and measurement of the direct effect of the encouragement. Our simulation study illustrates that, in scenarios where the exclusion restriction is not met, our methodology recovers the true average treatment effects (ATEs) of both the endogenous treatment and the encouragement design, in contrast to the biased estimates produced by ordinary least squares (OLS) and two-stage least squares (2SLS). Furthermore, we introduce an adversarial min-max estimator to assess heterogeneous treatment effects (HTEs) of both the treatment and the encouragement design. We also propose a procedure for researchers to test the validity of the exclusion restriction in their encouragement designs by comparing the 2SLS estimates with those derived from our method. This procedure is demonstrated through an empirical study analyzing the impact of network size on the usage time of social media users, highlighting the practical importance of verifying the IV's exclusion restriction using our approach.

4 - Music Motion Synergy: a Multi-Modal Deep Learning Measure for Unveiling Engagement and Consumer Insights in Social Media Videos

Erya Ouyang, Temple University, Philadelphia, PA, United States, Wen Wang, Xueming Luo

Short-form videos are rapidly gaining popularity on social media as the leading format for entertainment and marketing. In this study, we propose a novel deep learning-based measure, referred to as Music Motion Synergy (MM Synergy), for assessing video quality on social media. We demonstrate that MM Synergy addresses three main challenges in video quality assessment: 1) leveraging core video content, 2) understanding interactions between multimodalities, and 3) integrating various engagement metrics that reflect management-relevant indicators. To derive this measure, we develop a new Multi-Task Multimodal Transformer model (MulT-MTL) and our extensive experimental results show that MulT-MTL achieves significantly lower forecast errors compared to various state-of-the-art deep learning models. More importantly, we show the practical value and superiority of MM Synergy as a general measure for assessing video quality and how MM Synergy can assist different influencers in creating better content. For example, we demonstrate that this measure not only informs about future multifaceted customer engagement but also predicts more nuanced psychometric consumer responses, providing valuable insights for stakeholders. This indicates that our measure can serve as quality check before publishing videos, or it can be embedded in recommendation systems or search engines to enhance the consumer experience. Furthermore, we investigate the mechanisms by quantifying the importance of capturing the key elements of MM Synergy. In summary, our methodology offers a decision-support measure to assist influencers, brands, and platforms in enhancing business outcomes and customer experiences of social media videos in this burgeoning entertainment market.

Persuasion and Opinion Dynamics

Invited Session

Social Media Analytics

Chair: Tauhid Zaman, Yale University, New Haven, CT, United States

1 - Multi-Agent Nudging in Social Networks

Yen-Shao Chen, Yale University, New Haven, CT, United States, Tauhid Zaman

Influence campaigns on online social networks, run by organizations, political parties, and nation states, aim to sway large audiences using agents that disseminate persuasive content. However, their effectiveness is often limited by the bounded confidence phenomenon, where individuals are only influenced by viewpoints within a narrow spectrum. Our research demonstrates that agents must employ a strategy of gradual opinion shifts, or 'nudging', to successfully persuade under these conditions. We utilize control theory principles to develop a nudging policy and target selection strategy for multiple agents in an influence campaign. Simulations using real Twitter data reveal that these multi-agent nudging policies can effectively shift mean opinion and modify levels of opinion polarization. Our findings indicate that nudging strategies surpass other common techniques that overlook bounded confidence effects. Nonetheless, these strategies raise significant ethical concerns and risks of malicious use, emphasizing the need for careful consideration in the implementation of influence campaigns.

2 - Opinion Dynamics and Bayesian Persuasion

Tauhid Zaman, Yale University, New Haven, CT, United States

In this work, we demonstrate how various opinion dynamics models can be unified under a common Bayesian persuasion framework. We start with the assumption that an individual holds a prior belief about a certain state and receives signals regarding this state, with the likelihood of these signals being state-dependent. Within this Bayesian framework, these opinion dynamics models track the evolution of the posterior mean based on the received signals. By selecting appropriate priors and likelihoods, we are able to replicate many classic opinion dynamics models. We provide Bayesian formulations for the classic DeGroot model, the bounded confidence model, over-reaction, bounded shift, and the backfire effect. Additionally, we show how the structure of each opinion dynamics model is determined by the score (also known as the informant) of the signal likelihood.

3 - Investigating the Cumulative and Curvilinear Impact of Politicians' Negative Expressions on Twitter

Lingshu Hu, Washington and Lee University, Lexington, VA, United States, Kennon Sheldon, Rui Sun

The capacity to capture attention on social media holds paramount importance for public figures, as these platforms serve as pivotal arenas for exerting societal influence and accruing social and economic advantages. Particularly in political spheres, the ability to garner attention on social media not only mirrors politicians' social capital, likability, and popularity, but also shapes the communicative landscape of public forums, wielding influence over public attention and opinions, thus impacting our deliberative democracy. While the utilization of different sentiments to attract public attention has been extensively explored across social media and traditional media, previous studies have predominantly treated sentiment effects as linear phenomena, focusing on individual message units and overlooking the cumulative and non-linear dynamics of information dissemination. To address this gap, our study endeavors to employ computational and deep learning models to investigate the cumulative and curvilinear impacts of politicians' negative expressions using a comprehensive dataset sourced from Twitter. Moreover, individuals with diverse political identities often harbor contrasting worldviews and attitudes towards one another. Our research seeks to delve into how political partisanship and intergroup communication— encompassing dialogues with members of one's own political faction and those of opposing parties—moderate the influence of sentiment.

4 - The Highest Subreddit in the Land: Studying the Supreme Court Watchers Community on Reddit

Li Zhang, University of Virginia, Charlottesvle, VA, United States

This paper examines the vibrant community of Supreme Court watchers on Reddit, specifically within the "supremecourt" subreddit. By collecting a novel dataset of posts and comments, we analyze the discourse, engagement patterns, and topical trends among users. This study offers insights to understand how Reddit serves as a platform for public legal discussion, the nature of the conversations surrounding Supreme Court decisions and its Justices, and the characteristics of these participants.

Causal Inference and Empirical Topics in (Digital) Markets

Invited Session

Information Systems

Chair: Dominik Molitor, Fordham University, New York, Germany

1 - The Impact of Uncertainty on Customer Satisfaction

Dominik Molitor, Fordham University, New York, Germany

This paper introduces a theoretical model of customer satisfaction that combines both a reference-dependent and a reference-independent component. Reference points are determined by expectations, which reflect the distribution of individual beliefs about performance outcomes. According to the model, uncertainty shifts subjective reference points, thereby increasing the level of performance at which customers start gaining satisfaction from reference dependence. The model further suggests that uncertainty mitigates the effect of both positive and negative deviations of actual performance from subjective reference points. Consequently, expected poor performance becomes less disappointing, while expected good performance becomes less gratifying compared to unexpected outcomes. The model's predictions are supported by findings from an experimental study on product delivery and a field study using data from an online retailer. Additionally, the paper features a web-based app that simulates the effect of uncertainty on customer satisfaction in a variety of customizable scenarios. The findings of the paper hold significant implications for firms' communication, customer valuation, and service strategies.

2 - Helping Small Businesses become more Data-Driven: A Field Experiment on eBay

Sagit Bar-Gill, Tel Aviv University, Tel Aviv, Israel, Erik Brynjolfsson, Nir Hak

As digitization sweeps across industries and markets, analytics and data-driven decision-making (DDD) are becoming increasingly important. The adoption of analytics and DDD has been slower in small-to-medium enterprises (SMEs) compared to large firms, and reliable causal estimates of the impacts of analytics tools for small businesses have been lacking. We derive experiment-based estimates of the impact of an analytics tool on SME outcomes, analyzing the randomized introduction of eBay's Seller Hub (SH), a data-rich seller dashboard. We find that SH adoption is associated with increased DDD, and that access to SH increases e-retailers' revenues by 3.6% on average, as more items are transacted and service quality increases, without increases in average prices. Our results suggest that analytics and DDD help SMEs establish a competitive advantage. Managerial practices play an important role in reaping the benefits from the analytics dashboard, as over a third of the SH impact is driven by active performance monitoring. Digital platforms should, therefore, embed analytics tools to support SMEs, to increase entry and revenues. Furthermore, policies to support small businesses' transition to the data era should address analytics and DDD gaps by ensuring access to both tools like SH and to appropriate managerial training.

3 - Analyzing Store Cannibalization Using Mobility Data

Shachar Reichman, Tel Aviv University, Coller School of Management, Tel Aviv, Israel, Peter Zubcsek, Tal Shoshani

Retailers commonly use mobile location data to improve marketing campaigns, while other uses of consumer location data in retail analytics are limited. For instance, although the literature has recognized the importance of mapping store cannibalization of brick-and-mortar outlets, prior work in this area has primarily attempted to quantify it based on consumers' distance from stores. This research presents a mobile location analytics application to model store cannibalization, using the specialty coffee retail market as a testbed. Specifically, we addressed: (1) How can mobile location data capture the externalities of store cannibalization? (2) What is the predictive power of urban mobility data regarding store performance? (3) How does the predictive performance of semi-supervised models using aggregate mobility data compare to supervised models with network features from individual mobility data? We answered these questions using two large sets of urban mobility data, focusing on co-visitations (when a consumer visits two stores within a week). We constructed a network of retail stores, linking nearby outlets with weights proportional to co-visitations and the inverse of the squared distance between stores. Using network analysis techniques and a graph transformer model, we extracted store-level features to predict store closures. Preliminary results indicate that analyzing store co-visitation networks improves model performance in assessing store health compared to using only census-based economic variables. Our research contributes to management and marketing literature by showing how consumer mobility data can help understand and predict store cannibalization dynamics.

4 - User Data and Brokers

Joy Wu, UBC Sauder School of Business, Vancouver, BC, Canada, Ananya Sen

Data brokers sell access to and usage of personal information they harvest about individuals and facilitate the exchange of personal data utilized throughout the digital economy. However, little is known about people's valuation, perceptions, and demand for their privacy from data brokers. We conducted a survey experiment of 4,000 U.S.-representative individuals and provisioned information about how brokers harvest user data from two broad categories of data transfers people participate in: those with government agencies and those with commercial entities. We gathered individuals' beliefs about data exposure and their revealed preferences for privacy from brokers. Perceptions about exposure to brokers shift in a direction that suggests Americans largely underestimate their data exposure—particularly the size of the broker market that harvests government records—and these beliefs are malleable to information interventions. Despite shifting their beliefs, individuals' willingness to pay to delete data from brokers is unaffected by our interventions on the aggregate level. However, we find significant variations in how effective information interventions are at influencing valuations for privacy based on characteristics of individuals, such as whether they conducted prior data deletion requests and whether they have applied for a change of address request with USPS. These results highlight the importance of how, even though individuals can be systematically underinformed about how much privacy they have, their privacy choices depend on their idiosyncratic, instrumental value of privacy.

Enhancement of Object Detection

Invited Session

Artificial Intelligence

Chair: Nicolas Bustos, University of South Florida, Plant City, FL, 33613, United States

1 - FT-Cyclegan: A Novel Frequency-Based Architecture for Visual-and-IR Image Translation to Enhance Multimodal Object Detection

Nicolas Bustos, University of South Florida, TAMPA, FL, United States

Multimodal architectures are being touted as the future of object detection. These architectures can overcome environmental challenges such as adverse lighting and weather conditions to deliver more accurate detection. The fusion of visual and infrared (IR) data has been shown in the literature to improve the detection under fog and poor lighting conditions. However, there is a lack of publicly available multimodal datasets that are paired and aligned for use in multimodal models and data fusion algorithms. In this work, we introduce FT-CycleGAN, a CycleGAN-based architecture that uses Fourier transform (FT) within the computation of its cycle consistency loss. We generate synthetic images using FT-CycleGAN that multimodal object detection algorithms can leverage to improve their performance. The FT component of the cycle consistency loss is computed by matching the frequency amplitude between the input and cycled images. FT-CycleGAN is used to generate visible-and-infrared translated images from the Teledyne FLIR dataset. Faster-RCNN is shown to perform better utilizing the generated image pairs.

2 - The Impact of using Data Fusion with Synthetic Images on Multimodal Object Detection

Mehrsa Mashhadi, University of South Florida, Tampa, FL, United States, Nicolas Bustos, Susana Lai-Yuen, Tapas Das

The performance of object detection models can be compromised under adverse weather conditions such as reduced visibility and altered lighting. Models trained on unimodal data struggle, as these conditions distort visual data. Specifically, models relying solely on visible imagery, while rich in texture details, are vulnerable to weather variations, compromising their effectiveness. Thermal images offer a robust alternative since they are less affected by lighting. Combining visible and thermal imagery enhances detection robustness by leveraging both modalities. Despite various fusion approaches, comprehensive evaluations of visible and thermal imagery for object detection on diverse weather conditions are limited due to a lack of standardized benchmarks and the publicly available datasets containing paired images with weather labels. We used data fusion with synthetic images utilizing the Teledyne FLIR dataset, which features unpaired visible and thermal images labeled with weather conditions. Synthetic pairs were generated using CycleGAN. Advanced fusion techniques, SeAFusion and GAN-FM, were applied, and models such as Faster R-CNN, YOLOv7, and Detection Transformers were assessed across different weather scenarios and object sizes.

Results indicate that training Faster R-CNN with thermal images provides the best results across different scenarios. The use of synthetic data with fusion techniques generally yields lower results compared to using unimodal images only. Comparing the data fusion techniques, our findings suggest that using fused images with SeAFusion improves detection performance compared to GAN-FM. These insights highlight the potential benefits of incorporating synthetic and multimodal data and offer valuable considerations for improving object detection models under diverse weather conditions.

3 - Zero-Shot Vision-Language Models: Advancing Multimodal Understanding

Raphael Caleb Yao, University of San Francisco, San Francisco, CA, United States

The emergence of zero-shot vision-language models has marked a pivotal development in the field of artificial intelligence, enabling models to comprehend and interpret visual data with minimal to no direct task-specific training. These models combine the strengths of natural language processing and computer vision, allowing for the understanding of images and text in tandem. CLIP (Contrastive Language-Image Pretraining) utilizes large-scale training on diverse image-text pairs to learn generalized representations. This approach allows it to recognize visual concepts based solely on textual descriptions, demonstrating remarkable zero-shot transfer capabilities. Similar models like DALL-E and ALIGN have shown that the integration of language and vision enables complex tasks such as image generation from text prompts. This paper explores architecture and training strategies behind a zero-shot vision-language model that it develops, examining its potential for applications like image classification, object detection, and multimodal search without task-specific fine-tuning. It analyzes the challenges involved in understanding visual concepts from textual descriptions, the models' generalization abilities across domains, and the implications for future research in multi-modal learning.

AI and Optimization in Manufacturing

Contributed Session

Chair: Zhaoguang Xu, Dalian University of Technology, Dalian City, 116024

1 - Evaluating Machine Learning and Multi-variate Empirical Models in Solder Joint Characteristic Life Prediction

Seyed Soroosh Alavi, Auburn University, Auburn, AL, United States, Dr. Daniel F. Silva

This research compares the application of machine learning (ML) vs. a newly developed multi-variate physics-based empirical model to predict the characteristic life of solder joints, previously estimated through single-variable empirical models. Both approaches utilize data from isothermal aging tests followed by thermal cycling tests conducted on solder joints. The ML approach seeks to create a universal prediction model that consolidates various test conditions. Concurrently, the empirical model incorporates and uses both aging duration and temperature as input variables to provide a robust alternative to traditional single-variable empirical models, which require separate models for each aging condition. Comparative analysis shows that both the ML and the two-variable empirical models achieve high and comparable accuracy to traditional single-variable empirical models. The ML approach offers significant cost and time efficiencies, while the two-variable empirical model demonstrates an ability to combine test conditions, reducing the number of necessary models and experiments. The final comparative study between both models discusses the advantages and disadvantages of each, highlighting their practical applications and performance merits in the field of solder joint characteristic life prediction.

2 - Defect Detection for OHT Wheels in Semiconductor Manufacturing Processes Using Generative AI-based Data Augmentation

Chang Hyun Lee, Department of Industrial Engineering, Sungkyunkwan University, Suwon, Korea, Republic of, JUHYUN KIM, Sungjun Hur, Dong Hee Lee

Monitoring the wheel condition of Overhead Hoist Transport (OHT) systems is crucial for maintaining production efficiency and safety in semiconductor manufacturing processes. However, collecting defect data in real manufacturing environments is challenging, and the defects often appear in very small regions within the images, limiting the performance of existing machine learning models. This study proposes a method to train robust defect detection models from limited real data by leveraging generative AI technology to augment OHT wheel defect images.

The proposed technique first generates various virtual defect patterns resembling real defects and seamlessly synthesizes them onto OHT wheel images using appropriate image processing techniques, creating realistic defective wheel images. Domain adaptation techniques are then applied to minimize the domain gap between the generated synthetic images and real images. The augmented dataset is utilized to train a convolutional neural network-based defect detection model, and its performance is evaluated in an actual manufacturing environment.

Experimental results demonstrate that the proposed method achieves higher accuracy compared to models trained solely on real data, highlighting the effectiveness of generative AI-based data augmentation in addressing the limited real data problem.

3 - A Heuristic Approach to the Problem of Min-Time Coverage in Constricted Environments with Arbitrary Guidepath Networks

Young In Kim, ISyE Georgia Tech, Atlanta, GA, United States, Spiridon Reveliotis

In a recent work, we investigated some min-time coverage problems that use networked robotic fleets for conducting routine inspections and other monitoring services in well-structured but constricted environments. That work provided a detailed description of these problems, their formal characterization in the form of a Mixed Integer Programming (MIP) formulation, and strong combinatorial relaxations that can significantly reduce the number of integer variables without compromising the correctness of the derived solutions with respect to the original formulations. The current work develops a heuristic approach to address larger problem instances that are not amenable to the aforementioned relaxations. Numerical studies demonstrate the efficacy and the computational gains achieved by the proposed heuristic.

4 - Optimization-Informed Supervised and Unsupervised Learning for Energy-Cost and Thermal Comfort-Aware Air Conditioning

Minseo Kim, Yonsei University, Seoul, Korea, Republic of, Soongeol Kwon

This study aims to develop an optimization method for scheduling AC operations to minimize energy costs while ensuring indoor thermal comfort. We propose an optimization-informed learning method that integrates unsupervised and supervised learning models with a mathematical optimization model. This integration allows the mathematical optimization model to interpret data from an optimization perspective, enhancing the understanding of uncertainties and variabilities. The method begins by clustering uncertain weather and time-variable price data to identify underlying patterns. A two-stage chance-constrained stochastic program then defines AC operation schedules for each cluster. Finally, the most appropriate schedule is selected through supervised learning, considering uncertainties and variabilities in the clustered data. This process enables the optimization model to provide the learning models with an informative form of data and criteria to ultimately determine proper AC operations in an energy-cost and thermal comfort-aware scheme.

5 - Optimization of Multi-Period Quality Costs Leveraging Predictive Analytics in Intelligent Manufacturing

Zhaoguang Xu, Dalian University of Technology, Dalian, China, People's Republic of, Stefan Minner

The trade-off between quality and cost is a key challenge faced by manufacturing enterprises. In the environment of intelligent manufacturing, predictive quality technology offers new opportunities for improving quality and reducing costs. However, it is difficult to use predictive results to optimize quality costs quantitatively. Thus, we propose a predict-then-optimize approach for quality cost optimization. In particular, we first leverage industrial big data and machine learning techniques to construct a deep learning-based quality prediction model to estimate the defect probabilities in products. These predictive insights are then incorporated into a multi-period knapsack problem model for the second stage to optimize the total quality costs, considering the tradeoff between inspection and external failure costs. Considering the false negative and false positive errors of the prediction models, we analyze the mechanism of impact of the predictive model on inspection decisions and quality costs.

AI in Action: Enhancing Decision-Making and Collaboration

Contributed Session

Chair: Michelle Vaccaro, MIT, Cambridge, MA, United States

1 - When Are Combinations of Humans and AI Useful?

Michelle Vaccaro, MIT, Cambridge, MA, United States, Abdullah Almaatouq, Thomas Malone

Inspired by the increasing use of AI to augment humans, researchers have studied human-AI systems involving different tasks, systems, and populations. Despite such a large body of work, we lack a broad conceptual understanding of when combinations of humans and AI are better than either alone. Here, we addressed this question by conducting a meta-analysis of over 100 recent experimental studies reporting over 300 effect sizes. First, we found that, on average, human-AI combinations performed significantly worse than the best of humans or AI alone. Second, we found performance losses in tasks that involved making decisions and significantly greater gains in tasks that involved creating content. Finally, when humans outperformed AI alone, we found performance gains in the combination, but when the AI outperformed humans alone we found losses. These findings highlight the heterogeneity of the effects of human-AI collaboration and point to promising avenues for improving human-AI systems.

2 - Evaluate AI or Evaluate Myself? Effects of AI Explanations on Appropriate Decision Adjustment

Mandie Liu, City University of Hong Kong, Hong Kong, Hong Kong, Weiling Ke, David Xu

To enhance interpretability and mitigate human resistance, AI-advised decision-making increasingly comes with explanations about why they make the predictions. However, the effects of AI explanations on appropriate decision adjustment have yielded mixed results. Therefore, it’s urgent to comprehensively understand how AI explanations influence human decision-making process. Drawing on dual process theory, our research addressed this question by examining the role of AI explanations in deliberate processing, specifically self-reflection, which is a pivotal aspect of effective decision-making. This approach differs from prior studies, which focused on heuristic processing, like perceived expertise in AI. Employing the context-specific framework, we also theorize how AI explanation, as a technology-related variable, interacts with other context aspects, including a user characteristic (cognitive bias) and usage context variable (advice distance). Through two online experiments (N=120 and N=366) conducted in the context of stock investment, we found that 1) AI explanations bolster both perceived expertise and self-reflection, but only when advice distance is far; 2) compared to perceived expertise, self-reflection had stronger effects on hit rates but weaker effects on false alarms, which indicates that evaluation for initial judgment, rather than evaluation for AI, more directs appropriate decision adjustment. 3) when users suffer from cognitive bias (specifically familiarity and herding biases in our study), AI explanations showed stronger effects on driving self-reflection when advice distance is far. Our study advances the understanding of the mechanisms underlying the relationship between AI explanations and appropriate decision adjustment. We also offer practical insights for AI providers to better support effective decision-making.

3 - An Empirical Study on the Methods for an Effective Collective-Interest AI Recommendation Systems

Yalda Hojjati, Auburn University, Auburn, AL, United States, Yuanyuan Chen, Uzma Raja

AI recommendation systems have become ubiquitous, shaping various facets of modern life. While much research has focused on improving the effectiveness of individual-centric AI recommendation systems, fewer studies have examined AI systems providing recommendations based on collective interests. Collective-interest recommendation systems hold promise in a wide range of domains, such as public health emergency management, climate change, transportation optimization, and community resource allocation. Unlike their individual-centric counterparts, collective-interest recommendation systems offer suggestions to benefit groups rather than serve personal interests. Advancing collective interests requires individuals to engage in cooperative and altruistic behaviors, often at a personal cost for the greater good. However, the success of these systems depends heavily on user adoption. Achieving collective interest will become a formidable challenge if users do not trust or adopt AI recommendations. Therefore, investigating methods to promote user trust and adoption of AI-recommended cooperative and altruistic behavior aiming for collective interest is theoretically and managerially important.

Our research examines the mechanisms for designing AI recommendation systems that foster trust in AI technology and encourage individuals to adopt collective interest recommendations. Specifically, we aim to evaluate the effectiveness of different modalities and explore the impact of elucidating the AI's underlying process on user trust and adoption of such recommendations. The study also has significant managerial implications, as it helps organizations design systems that promote collective interests while fostering user trust and engagement.

4 - How Forced Intervention Facilitates Long-term Algorithm Adoption

Jiankun Sun, Imperial College London, London, United Kingdom, Xinyu Cao, Chenshan Hu, Dennis Zhang

While artificial intelligence (AI) technologies increasingly become powerful and useful in daily operations, human workers often resist adopting algorithmic recommendations, a phenomenon known as algorithm aversion. This aversion can undermine the performance of algorithms in practical applications. In this paper, we investigate whether and why forced interventions can promote algorithm adoption and reduce algorithm aversion in the long term. Data from a leading online education company reveal that sales workers underutilize a new matching algorithm and often apply it to low-quality leads. A field experiment was conducted where sales workers were required to use or abstain from using the algorithm for three weeks. Experimental results show that forcing workers to use the algorithm during the experiment causally increases their algorithm usage one month after the experiment by 15.8 percentage points. We develop a theoretical model to explore the mechanisms behind this improvement. Our findings suggest that learning is the primary mechanism driving algorithm adoption among workers. Enforced usage allows workers to experience the algorithm's unbiased performance firsthand and positively adjust their beliefs about it. Consequently, after the experiment, the workers in the treatment group not only use the algorithm more frequently but are also more likely to apply it to high-quality leads. The study offers empirical evidence that forced intervention can effectively enhance long-term algorithm adoption among workers. It also suggests that firms could implement extrinsic interventions or educational programs to help workers recognize the benefits of algorithms and develop unbiased beliefs about their capabilities, thus promoting sustained algorithm usage.

5 - AI Testing as a Critical Milestone towards Effective AI Integration in Serious Games Test-Beds for Human-AI Collaboration

Amir Abdollahi, Northeastern University, Boston, MA, United States

As AI becomes more prevalent in our lives, effectively integrating it and determining the best conditions for human-AI collaboration is crucial, especially in critical areas like public policy and healthcare. We introduce a framework for complex policymaking, focusing on pandemic management to simulate real-world scenarios, deepening our understanding of AI integration in this essential context. By gamifying the policymaking process, we simulate real-world scenarios, aiming to validate AI's effectiveness before actual deployment in human-AI collaboration contexts.

Utilizing deep reinforcement learning (DRL), we train an agent on historical lockdown and travel restriction data from 186 countries during the COVID-19 pandemic. Comparing the DRL agent's performance with governmental actions, we evaluate AI-driven policies' potential impact on infection rates, fatalities, and recoveries. Results show the DRL agent's adeptness in understanding epidemic dynamics, often surpassing governments' performance by reducing fatalities and infections while increasing recovery rates. However, our initial study encountered limitations as it relied on historical data, hindering the construction of an entirely realistic counterfactual pandemic scenario.

Consequently, we created a more comprehensive simulated environment for better generalization. Our approach, incorporating the SEIRD model, demonstrates the DRL agent's effectiveness in pandemic management, improving recovery rates and reducing infection and mortality rates over time. This research emphasizes the importance of assessing AI performance before implementing human-AI collaboration in sensitive contexts. We propose future research to expand on this work by incorporating human-AI collaboration scenarios and considering financial constraints, providing a holistic perspective on efficient pandemic policymaking.

6 - Travel Demand Forecasting: A Fair AI Approach

Xiaojian Zhang, University of Florida, Gainesville, FL, United States, Qian Ke, Xilei Zhao

Artificial Intelligence (AI) and machine learning have been increasingly adopted for travel demand forecasting. While AI-based models offer precise predictions, they can also introduce biases and fairness concerns. Relying on these biased models for decision-making could worsen social inequalities in transportation policies. Therefore, in this study, we propose a novel methodology to develop fairness-aware, highly-accurate travel demand forecasting models. Particularly, the proposed methodology can enhance the fairness of AI models for multiple protected attributes (such as race and income) simultaneously. Specifically, we introduce a new fairness regularization term, which is explicitly designed to measure the correlation between prediction accuracy and multiple protected attributes, into the loss function of the travel demand forecasting model. We conduct two case studies to evaluate the performance of the proposed methodology using real-world ridesourcing-trip data in Chicago, IL and Austin, TX, respectively. Results highlight that our proposed methodology can effectively enhance fairness for multiple protected attributes while preserving prediction accuracy. Additionally, we have compared our methodology with three state-of-the-art methods that adopt the regularization term approach, and the results demonstrate that our approach significantly outperforms them in both preserving prediction accuracy and enhancing fairness. This study can provide transportation professionals with a new tool to achieve fair and accurate travel demand forecasting.

2 - Mathematically Based Global Optimization Algorithms and their Application to Computationally Expensive Environmental Pollution Problems

Christine Shoemaker, Cornell University, Singapore, Singapore

There are many environmental problems that could benefit from optimization analysis, but their solution is challenging because the problems are not convex and the evaluation of the objective function (usually an expensive multimodal numerical simulation model) allows only a modest number of objective function evaluations. Shoemaker's group have developed a series of mathematically based global optimization algorithms with radial basis function surrogates that can be efficiently used with costly simulation models to identify cost-effective pollution control and climate change predictions . These “PYSOT” algorithms are freely available online. Application to very expensive PDE models of lake pollution and of global climate change will be presented.

Harnessing Machine Learning and Advanced Optimization for Power System Planning in Developing Countries

Invited Session

ENRE: Electricity

Chair: Yifu Ding, MIT Energy Initiative, Cambridge, MA, United States

1 - Optimizing the least-cost decarbonization pathways for India's power system through data-driven coal plant retrofitting strategies

Yifu Ding, MIT Energy Initiative, Cambridge, MA, United States, Dharik Mallapragada, Serena Patel, Jansen Wong, Guiyan Zang, Robert Stoner

India set two Nationally Determined Contribution (NDC) targets by 2030 to achieve the net-zero carbon emission goal by 2070, which requires deep decarbonization of India’s power generation sector. Yet in India, coal-fired electricity contributes to more than 60% of power generation, and the government still permits new construction and life extension of coal plants. This study creates a dataset for the operating characteristics of 806 India's coal-fire power units using machine learning. Then we optimize the least-cost decarbonization pathways for India's power system considering two retrofitting technologies: carbon capture and storage (CCS) and biomass co-firing. Results show the optimal coal retrofitting strategy could lead to a more balanced distribution of generation capacity, decrease the unabated coal plant capacity, and lower the electricity generation and carbon abatement costs under a relatively stringent carbon cap of less than 1000 Mt CO_2 to meet India's NDC goals.

2 - Location-based regional power decarbonization planning for a just energy transition: exploring coal repurposing opportunities

Ziting Huang, Johns Hopkins University, Baltimore, MD, United States, Benjamin Hobbs, Debabrata Chattopadhyay, Qingyu Xu

Deep decarbonization of energy system may give rise to stranded asset risks for some regions where thermal power dominates the energy mix. Regarding coal power assets, we put forward five alternatives to assist with energy decarbonization: demolishing completely, mothballing for backup generation, retrofitting with CCS, repurposing with renewable energy for cleaner generation, and redeveloping into other economic activity use. Each alternative has different levels of asset reutilization, thus varying costs and benefits in generation, local economy, and environment. Such trade-offs between macro decarbonization goals and local socio-economic changes are not well captured in the energy system planning.

This study aims to co-optimize goals in reducing GHG emissions while achieving societal benefits in local communities by exploring the future role of coal in a regional energy system. Through an agent-based model, which simulates the interaction between coal agent and power system environment, the study identifies the optimal decarbonization strategy for existing coal assets at both plant and system level. With the locational information on socioeconomics, this analysis framework incorporates societal impacts from coal power’s decisions in the regional electricity planning, which provides valuable implications for a just energy transition. As a comparison, the study further explores the performance differences between an agent-based model and a generalized multi-objective optimization. The methodology is applied in China and South Africa for case study illustration, where coal is a major electricity source.

3 - Supply Security Under Institutional Constraints and the Low-Carbon Energy Transition in China

Ming Wei, University of California San Diego, San Diego, CA, United States, Michael Davidson

In the context of meeting China's climate change targets, a massive scale up of low-carbon energy is required while meeting growing demand, presenting critical challenges for maintaining electric supply security. Institutionally, China’s power sector—as with many other systems—is also in a period of transition from central planning toward market liberalization. This study presents a retrospective analysis of the power shortages that plagued China from 2020 to 2022, examining their causes, commonalities, impacts, and governmental responses. Modeling simulations using unit commitment and economic dispatch models are then conducted to investigate the underlying operational and institutional factors. These analyses rely on extensive collection of publicly available datasets, ensuring transparency and reproducibility. The results highlight the inflexibilities of existing market mechanisms and institutional arrangements in adapting to the demands of a decarbonizing energy system. The study also explores forward-looking scenarios through 21 simulations incorporating extreme weather conditions, electricity and thermal coal pricing dynamics, and different dispatch mechanisms. These scenarios reveal critical market and institutional vulnerabilities, suggesting that reforms to improve supply security must consider a system-wide perspective beyond standard approaches such as increasing capacity. The results contribute to the ongoing discourse on effective strategies for advancing China's energy transition.

4 - Planar location-allocation problems for spatial planning of decentralized energy systems

Beste Akbaş, Imperial College London, London, United Kingdom, Ayse Selin Kocaman

One major impediment to developing countries’ economic growth is the lack of access to affordable, sustainable, and reliable modern energy systems. Hundreds of millions of people live in rural areas and do not have access to essential electricity services. In this study, we present a planar facility location–allocation problem for planning decentralized energy systems in rural development. We consider nano-grid and micro-grid systems to electrify rural households. While micro-grids serve multiple households with a common generation facility, nano-grids are small-scale systems serving individual consumers. The households served by micro-grids are connected to the generation facilities with low-voltage cables, for which we employ a distance limit constraint due to technical concerns, including power loss and allowable voltage levels. In this problem, we minimize the total investment cost that consists of the facility opening and the low-voltage cable costs. In order to capture the diversity of cost structures in renewable energy investments, we consider three versions of the objective function where we incorporate different combinations of fixed and variable cost components for facilities. For this problem, we provide mixed-integer quadratically constrained problem formulations and propose model-based and clustering-based heuristic approaches. Model-based approaches are multi-stage, in which we solve the discrete counterparts of the problem and employ alternative selection methods for the candidate facility locations. Clustering-based approaches utilize faster clustering techniques to identify the type and location of the facilities. We conduct computational experiments on real-life instances from villages in Sub-Saharan Africa and perform a comparative analysis of the suggested heuristic approaches.

Navigating Challenges in Statistical Inference and Decision-Making: Adaptive Experiments Design, Testing Complex Hypotheses, Policy Optimization, and Robust Mendelian Randomization

Invited Session

Data Mining

Chair: Mengxin Yu, University of Pennsylvania, Philadelphia, PA, 19104, United States

1 - An Online Optimization Approach to Designing Adaptive Experiments

Christopher Harshaw, MIT / UC Berkeley, Cambridge, MA, United States

From clinical trials to development economics, randomized experiments are increasingly adopted to estimate causal effects. Adaptive experiment designs – where experimental subjects arrive sequentially and the probability of treatment assignment can depend on previously observed outcomes – are becoming an increasingly popular method for causal inference, as they offer the possibility of improved precision over their non-adaptive counterparts. However, in simple settings (e.g. two treatments) the extent to which adaptive designs can improve precision is not sufficiently well understood. In this talk, I present my recent work on the problem of Adaptive Neyman Allocation, where the experimenter seeks to construct an adaptive design which is nearly as efficient as the optimal (but infeasible) non-adaptive Neyman design which has access to all potential outcomes. I will show that the experimental design problem is equivalent to an adversarial online convex optimization problem, suggesting that any solution must exhibit some amount of algorithmic sophistication. Next, I present Clip-OGD, an experimental design that combines the online gradient descent principle with a new time-varying probability-clipping technique. I will show that the Neyman variance is attained in large samples by showing that the expected regret of the online optimization problem is bounded by O(\sqrt{T}), up to sub-polynomial factors. Even though the design is adaptive, we construct a consistent (conservative) estimator for the variance, which facilitates the development of valid confidence intervals. I will conclude with recent progress on extending this work to covariate-adjusted estimators and covariate-responsive designs, which is made possible through the online optimization perspective.

2 - Hunt, Test and Aggregate: a Flexible Framework for Testing Complex Hypotheses

Richard Guo, University of Washington, Seattle, WA, United States

Hypotheses arising from real-world problems can be rather complex: (1) the null hypothesis can be large so it is difficult to test directly; (2) the alternative can be large and heterogenous, so it is challenging to devise a test that has power against a variety of alternatives. However, if such a hypothesis can be represented as a conjunction of simpler hypotheses corresponding to different directions, "hunt and test" provides a useful strategy: split the data into A and B; use A to hunt for a direction that contains signal against the null; and use B to test the simpler hypothesis associated with that direction. Nevertheless, applying "hunt and test" alone can suffer from non-replicability and low power. To remedy these problems, we demonstrate that by properly aggregating and calibrating a large number of hunt-and-tests, we can obtain an ensemble procedure that is reliable, replicable, and highly powerful. We demonstrate how to use this framework to construct tests for a variety of problems, including detecting subtypes of cancer and testing specification of regression models.

3 - Policy Learning "Without" Overlap: Pessimism and Generalized Empirical Bernstein's Inequality

Ying Jin, Data Science Institute, Harvard University, Cambridge, MA, United States, Zhimei Ren, Zhuoran Yang, Zhaoran Wang

Offline policy learning aims at utilizing observations collected a priori (from either fixed or adaptively evolving behavior policies) to learn an optimal individualized decision rule that achieves the best overall outcomes for a given population. Existing policy learning methods rely on a uniform overlap assumption, i.e., the propensities of exploring all actions for all individual characteristics must be lower bounded. As one has no control over the data collection process, this assumption can be unrealistic in many situations, especially when the behavior policies are allowed to evolve over time with diminishing propensities for certain actions. In this work, we propose Pessimistic Policy Learning (PPL), a new algorithm that optimizes lower confidence bounds (LCBs) -- instead of point estimates -- of the policy values. Without assuming any uniform overlap condition, we establish a data-dependent upper bound for the suboptimality of our algorithm, which only depends on (i) the overlap for the optimal policy, and (ii) the complexity of the policy class we optimize over. As an implication, for adaptively collected data, we ensure efficient policy learning as long as the propensities for optimal actions are lower bounded over time, while those for suboptimal ones are allowed to diminish arbitrarily fast. In our theoretical analysis, we develop a new self-normalized type concentration inequality for inverse-propensity-weighting estimators, generalizing the well-known empirical Bernstein's inequality to unbounded and non-i.i.d. data. We complement our theory with an efficient optimization algorithm via Majorization-Minimization and policy tree search, as well as extensive experiments that demonstrate the efficacy of PPL.

4 - Genius-Mawii: for Robust Mendelian Randomization with Many Weak Invalid Instruments

Ting Ye, University of Washignton, Seattle, WA, United States

Mendelian randomization (MR) addresses causal questions by using genetic variants as instrumental variables. We propose a new MR method, GENIUS-MAWII, which simultaneously addresses the two salient challenges in MR: many weak instruments and widespread horizontal pleiotropy. Similar to MR-GENIUS, we use heteroscedasticity of the exposure to identify the treatment effect. We derive influence functions of the treatment effect, and then we construct a continuous updating estimator and establish its asymptotic properties under many weak invalid instruments asymptotic regime by developing novel semiparametric theory. We also provide a measure of weak identification, an overidentification test, and a graphical diagnostic tool.

Bayesian Optimization

Invited Session

Data Mining

Chair: Raul Astudillo, California Institute of Technology, Pasadena, CA, United States

Co-Chair: Peter Frazier, Cornell / Uber, Ithaca, NY, 14850, United States

Co-Chair: Chong Liu, State University of New York at Albany, Albany, NY, 12222, United States

1 - Bayesian Optimization for Scientific Discovery: the Value of Function Networks and Partial Evaluations

Poompol Buathong, Cornell University, Ithaca, NY, United States, Jiayue Wan, Samuel Daulton, Raul Astudillo, Maximilian Balandat, Peter Frazier

Scientific discovery, including the search for new materials, drugs, and technologies, presents exciting growth opportunities for operations research and management science methods. Bayesian optimization of function networks (BOFN) has emerged as a new grey-box BO framework, offering an attractive paradigm for guiding experiments in scientific discovery. BOFN models the objective of an application as a function network and leverages the intermediate information obtained from evaluating each node in the network to improve the sampling efficiency. Similar to standard BO, BOFN can handle expensive, noisy and non-convex objective functions and constraints where derivatives are not typically available. In this talk, we introduce a significant advancement in this area – guiding so-called partial evaluations in which only a part of the function network can be evaluated. This is critical for state of the art performance in many scientific discovery applications. We demonstrate the uses of the framework in two applications, namely, designing new catalysts for hydrogen fuel cells and optimizing experimental conditions for protein encapsulation. Our numerical results show that BOFN with partial evaluations outperformed existing methods, providing a better solution while spending less evaluation budget.

2 - Parametric Function Approximation for Black-Box Optimization: A New Perspective

Chong Liu, State University of New York at Albany, Albany, NY, United States, CHUANHAO LI, Yu-Xiang Wang

To discover strong materials, materials scientists need to sequentially select processing parameters and conduct long-time experiments to observe performances. To train a deep neural network, computer scientists need to run computationally expensive hyperparameter tuning experiments on validation sets. In both cases, scientists are solving black-box optimization problems. Existing work like Bayesian optimization usually assumes objective function is drawn from some Gaussian process (GP) which unfortunately usually suffers from the curse of dimensionality. In this talk, we provide a new perspective of solving such problems without GP but instead with parametric function approximation. Common acquisition functions like upper confidence bound (UCB) can still be constructed in parameter space to help us select next data points. Both regret bounds and empirical results will be shown. In the end, I'll show our recent progress of extension to federated optimization settings.

3 - Bayesian Deep Kernel Learning for Bayesian Optimization

Christopher Yeh, California Institute of Technology, Pasadena, CA, United States, James Bowden, Raul Astudillo, Yisong Yue

Bayesian optimization is a framework for optimizing functions with time-consuming evaluations. It has been successful in a broad range of applications, from hyperparameter tuning to chemical design. Bayesian optimization methods use a probabilistic surrogate model of the objective function, most commonly Gaussian processes. However, using a Gaussian process requires specifying a kernel. The choice of the kernel is critical for achieving good performance, but this choice is often challenging for practitioners. In this work, we propose using Bayesian deep kernel learning to automatically learn a kernel "on the fly". Intuitively, this approach learns a distribution over embeddings over which a simpler kernel (such as a linear kernel) can be used effectively. We show that our method outperforms standard approaches using RBF and Matern kernels as well as a non-Bayesian deep kernel learning approach in several synthetic and real-world test problems, including protein and nanophotonics design problems. We also show that Thompson sampling under this probabilistic model enjoys a sublinear regret guarantee.

4 - Bayesian Optimization of Conditional Gaussian Process Trees

Mengrui(Mina) Jiang, Arizona State University, Tempe, AZ, United States, Giulia Pedrielli

Bayesian optimization algorithms are used in many complex problems to solve expensive black-box functions without using any information about the structure or properties of the function. In some cases additional information about the system might be available, for example, the trajectory of a dynamic system, the intermediate execution of discrete states, etc. While Bayesian optimization has been successfully applied to many problems, there is no standard way to incorporate known structure. In this work, we specifically consider extending Bayesian optimization to loss functions whose heterogeneity structure can be encoded by a tree. In particular, the response function is a finite set of functions, and constraints at the edges are imposed on intermediate output associated with the non-leaf nodes to define which path the sample is assigned to. Such response function can be modeled through a conditional Gaussian process tree (CGPT). In this work, we propose for the first time a Bayesian optimization algorithm that designs a novel acquisition function in addition to the CGPT model as the surrogate, and investigate its performance in synthetic and industrial experiments. We call the resulting algorithm the Bayesian Optimization with Conditional Gaussian Process Trees (BOCGPT).

Scaling ML applications with Federated Learning

Invited Session

Data Mining

Chair: Brianna Mueller, University of Iowa, Iowa City

Co-Chair: Zhenyu Sun, Northwestern University, Evanston, 60201, United States

1 - Dynamic Ensemble Selection for Personalized Federated Learning

Brianna Mueller, University of Iowa, Iowa City, IA, United States

Federated learning (FL) enables multiple clients with distributed data sources to collaboratively train a shared model without compromising data privacy. However, existing FL paradigms face challenges due to heterogeneity in client data distributions and system capabilities. Personalized federated learning (pFL) has been proposed to mitigate these problems, but often requires a shared model architecture and a central entity for parameter aggregation, resulting in scalability and communication issues. In this context, we introduce a novel approach that leverages dynamic ensemble selection (DES), which not only offers personalized models for individual clients but also delivers unique solutions for each test sample. Our proposed framework is based on peer-to-peer model sharing, where clients maintain a collection of models from all participants in the network. The key to DES is adaptive model aggregation, where the most competent classifiers are selected to make a prediction on a specific test sample. This presentation will discuss the advantages of DES for personalized federated learning and provide comparisons with existing methods.

2 - Generalization of Federated Learning under Different Heterogeneity Levels

Zhenyu Sun, Northwestern University, Evanston, IL, United States

Generalization performance is a key metric in evaluating machine learning models when applied to real-world applications. Good generalization indicates the model can predict unseen data correctly when trained under a limited number of data. Federated learning (FL), which has emerged as a popular distributed learning framework, allows multiple devices or clients to train a shared model without violating privacy requirements. While the existing literature has studied extensively the generalization performances of centralized machine learning algorithms, similar analysis in the federated settings is either absent or with very restrictive assumptions. Here, we aim to analyze the generalization performances of federated learning from a theoretical perspective. We utilize the notion of algorithmic stability to analyze three widely used algorithms, FedAvg, SCAFFOLD, and FedProx, under convex and non-convex loss functions. Our analysis shows that the generalization performances of models trained by these three algorithms are closely related to the heterogeneity of clients' datasets as well as the convergence behaviors of the algorithms.

Net-Zero Emissions Energy Systems: Multi-objective Optimization

Invited Session

ENRE: Energy-Climate

Chair: Jacqueline Dowling, Carnegie Science, 260 Panama St., Providence, 94305, United States

Co-Chair: Aleksander Grochowicz, University of Oslo, Oslo, Norway

Co-Chair: Henry Ssembatya, NC State University, RALEIGH, NC, United States

1 - Multi-Objective Optimization for Balancing Techno-Economic and Environmental Considerations in African Hydropower Development

Angelo Carlino, Carnegie Institution for Science, Stanford, CA, United States, Rafael Schmitt, Anna Clark, Andrea Castelletti

In continental Africa, 300 hydropower projects totaling approximately 100 GW of additional capacity have been proposed to meet the growing power demand. Yet, expanding hydropower fragments river reducing the fluvial connectivity and releases greenhouse gas emissions from reservoirs where biomass is digested. Increasingly competitive alternative renewable electricity technologies can be leveraged as alternatives to reduce these impacts with little impact on cost metrics.

Here, we use multi-objective optimization to find Pareto-optimal dam portfolios maximizing hydropower generation while minimizing impacts on river connectivity and emissions from hydropower. We then use these Pareto-optimal solutions to constrain the capacity expansion in a energy system model combining techno-economic and environmental objectives.

Compared to planning for least-cost energy systems, when capacity expansion strategies are designed to balance environmental and techno-economic objectives, electricity prices and total discounted costs increase by at most 1.4% and 0.2%, respectively, while impacts on annual hydropower emissions and river fragmentation are reduced by at least 50%.

These results show that techno-economic analysis can be revised in light of global and local environmental objectives to help policymakers reduce the impacts associated with hydropower development with marginal increases in energy costs.

2 - Targeted power sector decarbonization for improving climate and health benefits of electric vehicles in comparison to efficient gasoline hybrids

Madalsa Singh, Stanford University, Stanford, CA, United States, Inês Azevedo

Electric vehicles and efficient gasoline hybrid vehicles that satisfies the most stringent emissions standards (currently Tier-3 in the US) have emerged as two possible technologies to reduce greenhouse gas emissions and air pollution. Using a spatially resolved emissions inventory, air quality modeling, and temperature and drive-cycle dependent vehicle operations data, we compare electric and Tier-3 vehicles for their climate (greenhouse gas emissions) and health ($PM_{2.5}$ emissions) benefits. In majority of the United States, particularly in metropolitan areas, electric vehicles have higher climate and health benefits that Tier-3 vehicles. However, in certain geographies, Tier-3 hybrids fare better. In these regions, targeted power sector interventions can be deployed to maximize the environmental benefits of transport electrification. We identify 50 high emitting power plants that can be retired as well as regions where natural gas as marginal generator would be sufficient for electric vehicles to have higher climate and health benefits than Tier-3 gas vehicles. Using a modeling approach that combines lifecycle accounting and air quality analysis helps identify solutions that provide climate and health co-benefits.

3 - Land costs impact solar technology choices and carbon mitigation in China

Shi Chen, Carnegie Science, Stanford, CA, United States, Xi Lu, Jiming Hao, Edgar Virgüez, Ken Caldeira, Steven Davis

China has been at the forefront in recent solar photovoltaics deployment. However, only 12% of its utility-scale solar farms use tracking technology, versus 80% in the US. Here, we use a spatially-explicit model of solar electricity costs to explore this disparity. We find that single-axis photovoltaics generate ~20% more electricity than fixed-tilt systems in China, but single-axis systems require 118% more land (national averages). Consequently, electricity from single-axis systems is more expensive when land costs exceed CN¥10.2/m^2 ($1.48/$m^2$, with current average land costs in China at CN¥19.3/m^2 ($2.79/$m^2$)). The decision to deploy fixed-tilt saves land costs but lowers electricity generation per panel, leading to lower CO_2 mitigation- 0.23 tCO_2 less per additional square meter required by tracking. This suggests that countervailing land policies could avoid CO_2 emissions at CN¥166/ton ($24/ton). Our findings may thus have important implications for land-use and energy policy, quantifying fundamental trade-offs related to different solar technologies.

Energy Justice I: Building Back Better, Perspectives on Energy Equity in the Just Transition

Invited Session

ENRE: Other Energy

Chair: Kester Wade, Carnegie Mellon University, Pittsburgh, 15232

Co-Chair: Jordan Joseph, Carnegie Mellon University, Pittsburgh, PA, 15217, United States

Co-Chair: Destenie Nock, Carnegie Mellon University, Pittsburgh, PA, United States

1 - Rebates and Grid Decarbonization from the Inflation Reduction Act Promote Equitable Adoption of Energy Efficiency Retrofits

Jordan Joseph, Carnegie Mellon University, Pittsburgh, PA, United States

Residential and commercial buildings consume 75% of the electricity and 40% of the total energy used in the United States, an annual expense of over $400 billion. Furthermore, household energy decisions (personal transportation, space heating, water heating, and other end-uses) account for over 40% of U.S. energy-related emissions which has made residential decarbonization a priority research area. The ability to shift these energy services from fossil fuel to clean electricity has made electrification and other residential energy efficiency retrofits a viable decarbonization pathway. Around half of U.S. homes were built before most building codes and are often occupied by low-to-moderate-income (LMI) families. Equitable electrification provides a unique opportunity to significantly reduce emissions in communities where energy bill savings have the most impact on household finances. We developed the Tradeoff Analysis of Residential retrofits for Energy equity (TARE) model to address the need for holistic approaches that consider unique housing characteristics, the intensity of existing regional grid emissions and fuel prices, health outcomes, and socioeconomic factors. We estimate national baseline and post-retrofit consumption and use an adoption rate metric that considers both public (i.e., climate and health-related emissions impacts) and private (i.e., lifecycle costs and savings) benefits and costs associated with energy efficiency retrofits for space heating, water heating, cooking, and clothes drying, using the National Renewable Energy Laboratory’s End-Use Savings Shapes database.

2 - Heat, Cold, and Costs: Evaluating equity and resilience in household energy use

Kester Wade, Carnegie Mellon University, Pittsburgh, PA, United States

Energy poverty involves excessive spending on energy bills, disconnections, and sacrificing essential services like heating and cooling to limit costs. A 2022 study found 16% of households experience energy poverty due to disproportionate spending. Despite the importance of energy efficiency and conservation for climate goals, barriers especially leave low-income households behind. However, there's a lack of understanding regarding how energy efficiency programs impact different demographics, such as income levels. This study considers ~8,000 households in the mid-Atlantic region and examines the impacts of energy assistance programs on household heating and cooling behaviors over a 3-year period. We focus on the outdoor temperatures at which households turn on heating or air conditioning systems to understand whether low-income households tolerate extreme indoor temperatures to reduce financial stress. Regression analysis helps us estimate the relationship between income and energy use spikes during heatwaves or extreme cold. Energy assistance programs have massive potential to improve physical and financial well-being. This especially affects households that might engage in risky behaviors to mitigate their energy needs. We advance the scientific understanding of whether, why, and how different energy, assistance, efficiency, and conservation programs work in different households. Our framework can help evaluate and refine more than 900 similar programs offered by U.S. utilities.

3 - Near-Term Heat Pump Penetration Given Grid Constraints Under Different Scenarios

Arnav Gautam, Carnegie Mellon University, Pittsburgh, PA, United States

Heating, Ventilation, and Air Conditioning (HVAC) systems (particularly in the residential sector) are getting more critical for human well-being as climate change continues, and in their current form are substantial contributors of CO2 emissions in the United States. Electrifying residential HVAC will be an important part of decarbonization and protecting people from temperature-related health risks. HVAC electrification will occur alongside electrifying other residential energy end-uses, and within established but evolving electrical distribution infrastructure. We perform an upper bound analysis to find the maximum penetration of electrified residential heating and cooling systems that can be expected across the U.S., given existing distribution infrastructure and household electrical capabilities. To answer this, we first alter and run the NREL ResStock model to quantify the impacts of realistic electrified HVAC technologies when installed in residential buildings of different types across different climate zones. This analysis yields insight into 1) how technologies may operate in specific locations, and 2) the electrical load profiles of residential buildings outfitted with them. ResStock outputs inform our estimate of region-specific electrified HVAC technology adoption, which we get by running the Tradeoff Analysis of Residential Retrofits for Energy Equity (TARE) model. We then test the distribution grid's ability to handle the changed electricity load caused by these region-specific adoption targets, using the PNNL Gridlab-D model for power system analysis. The result of this work is region-specific insight into which heat pump technologies may realistically be adopted in the near term.

Online and Adaptive Optimization

Invited Session

Computing Society

Chair: Michael Lingzhi Li, Harvard Business School, Boston, MA, 02163, United States

1 - Learning to Cover: Online Learning and Optimization with Irreversible Decisions

Alexandre Jacquillat, MIT Sloan School of Management, Cambridge, MA, United States, Michael Li

We define an online learning and optimization problem that aims to achieve a target coverage within a finite horizon. At each period, a decision-maker opens facilities, receives information on the success of each one, and updates a machine learning model to guide future decisions in order to minimize costs under a chance constraint reflecting target coverage. Irreversible facility location decisions give rise to an exploration-exploitation trade-off with commitment. We derive an optimal algorithm and a tight lower bound in an asymptotic regime characterized by a large target number of facilities but a finite horizon. We find that the regret grows at a sub-linear rate that converges exponentially as the horizon becomes increasingly long. This result is robust to the learning environment (with offline data, imperfect learning, and continuous uncertainty), and to the optimization environment (with heterogeneous facilities characterized via a facility-customer graph). These results underscore the benefits of even limited learning, in that even a few rounds of online learning and optimization can provide significant benefits as compared to a no-learning baseline. We conclude with a case study in sustainable infrastructure planning using real-world data to show the benefits of the proposed online learning and optimization approach in practice.

2 - Speed up the Cold-Start Learning in Two-Sided Bandits with Many Arms

Wanning Chen, University of Washington, Seattle, WA, United States, Mohsen Bayati, Junyu Cao

Multi-armed bandit (MAB) algorithms are efficient approaches to reduce the opportunity cost of online experimentation and are used by companies to find the best product from periodically refreshed product catalogs. However, these algorithms face the so-called cold-start at the onset of the experiment due to a lack of knowledge of customer preferences for new products, requiring an initial data collection phase known as the burn-in period. During this period, MAB algorithms operate like randomized experiments, incurring large burn-in costs which scale with the large number of products. We attempt to reduce the burn-in by identifying that many products can be cast into two-sided products, and then naturally model the rewards of the products with a matrix, whose rows and columns represent the two sides respectively. Next, we design two-phase bandit algorithms that first use subsampling and low-rank matrix estimation to obtain a substantially smaller targeted set of products and then apply a UCB procedure on the target products to find the best one. We theoretically show that the proposed algorithms lower costs and expedite the experiment in cases when there is limited experimentation time along with a large product set. Our analysis also reveals three regimes of long, short, and ultra-short horizon experiments, depending on dimensions of the matrix. Empirical evidence from both synthetic data and a real-world dataset on music streaming services validates this superior performance.

3 - Semi-Bandit Learning for Monotone Stochastic Optimization

Viswanath Nagarajan, University of Michigan, Ann Arbor, MI, United States, Arpit Agarwal, Rohan Ghuge

Stochastic optimization is a widely used approach for optimization under uncertainty, where uncertain input parameters are modeled by random variables. Exact or approximation algorithms have been obtained for several fundamental problems in this area. However, a significant limitation of this approach is that it requires full knowledge of the underlying probability distributions. Can we still get good (approximation) algorithms if these distributions are unknown, and the algorithm needs to learn them through repeated interactions? In this paper, we resolve this question for a large class of ``monotone" stochastic problems, by providing a generic online learning algorithm with $\sqrt{(T \log T)}$ regret relative to the best approximation algorithm (under known distributions). Importantly, our online algorithm works in a semi-bandit setting, where in each period, the algorithm only observes samples from the random variables that were actually probed. Our framework applies to several fundamental problems in stochastic optimization such as prophet inequality, Pandora's box, stochastic knapsack, stochastic matchings and stochastic submodular optimization.

4 - Data-Driven Robust Sequential Search

Cagin Uru, Duke University, Durham, NC, United States, David Brown

Models of sequential search arise in a variety of problems, including organizations hiring new employees, firms developing novel technologies, and individuals seeking housing or other investment opportunities. The classical papers in the sequential search literature rely on the assumption that the decision maker (DM) fully knows (or has some prior belief about) the underlying distribution of alternative values. In many applications, however, the DM explores alternatives with limited (if any) prior information on the alternative value distribution. For example, we can consider a seller searching for the best price among several buyers without any access to the distribution of buyers' valuation or any historical data for guidance. Motivated by this consideration, we study a generalization of the classical Pandora's problem in which the alternative value distribution is unknown prior to the search. In each period, the DM can either explore an alternative at a cost to continue the search or select and acquire any previously explored alternative to end the search. The goal is to find a stopping rule that maximizes the worst-case ratio of the expected reward compared with an oracle with full knowledge of the alternative value distribution. We consider several variations of this problem. For each variation, we design simple policies that perform competitively with the oracle policy.

Furthermore, we develop upper bounds on the relative performance of any feasible policy with respect to the oracle benchmark. The resulting upper bounds show that our policies provide nearly optimal performance.

Optimization Modeling Software I

Invited Session

Computing Society

Chair: Susanne Heipcke, FICO, Xpress Optimization, Birmingham, United Kingdom

Co-Chair: Bob Fourer, AMPL Optimization Inc., Evanston, IL, 60201, United States

1 - Gamspy: a Pipeline Friendly General Algebraic Modeling Language

Steven Dirkse, GAMS Development Corporation, Fairfax, VA, United States, Adam Christensen, Muhammet Soyturk, Michael Bussieck

Algebraic modeling languages (AMLs) such as GAMS, AMPL and more recently Julia/JuMP have been a cornerstone in the fields of optimization and economics. These tools are popular because they are able to effortlessly link the worlds of algebra and computer science -- that is, the syntax of the AML closely approximates that of handwritten algebra but its execution is automated and scalable. This pedagogical link supports the developer during all phases of software development from original model formulation to performance debugging and final output. The syntax is also important when transferring modeling knowledge between parties (i.e., external code review, developer transitions, etc.). Recent years have seen sophisticated computing tools enter the mainstream. Open source software languages/packages such as Anaconda, Python, Numpy, and Pandas make it easy to work with large data structures efficiently in deployable environments. All of these compute resources mean that data assets are arriving at optimization model instances from an ever diversifying number of start points. All of this creative data pipelining requires new and creative technical solutions from AML developers. In this work we present a Python package called GAMSPy that leverages the flexible nature of Python to construct a true Python-AML. The GAMSPy design philosophy rests on the original benefits of AML languages, specifically that the syntax mirrors algebra. Its set-driven nature, a common element among AMLs, is accomplished with extensive Python operator overloading. Execution of the algebra relies on a GAMS subsystem to avoid the performance and pedagogical pitfalls of object-oriented frameworks.

2 - Modeling Consensus Admm for Progressive Hedging

David Woodruff, University of California-Davis, Davis, CA, United States

A recent paper in Operations Research by Eckstein et al demonstrated that the Progressive Hedging (PH) algorithm can be developed from the same operator splitting framework as the alternating direction method of multipliers (ADMM). In this talk, we look at software constructs to describe the model and pass it to a PH algorithm.

3 - From Algorithms to Applications: Developing and Deploying Analytical and Optimization Models with Fico Xpress Insight

Bruno Vieira, FICO, Spain, Spain

Xpress Insight provides a flexible environment for creating powerful business applications with user interfaces that facilitate the utilization of advanced analytical solutions implemented in Python or Xpress Mosel. The Insight application interface is designed for both technical and non-technical users, enabling experimentation by running several scenarios and comparing outcomes to understand sensitivities implicit to an optimization model. In this talk, we will demonstrate how an Xpress Insight application can seamlessly be built from a standard Python or Mosel optimization model with intuitive drag and drop of front-end visualization components, including multi-scenario charts and tables. Furthermore, we will demo the latest advancements for interacting with the solver during an optimization run via the new Custom Progress Reporting functionalities.

4 - Ampl: Advances in Python Integration, Cloud Deployment, and Generative AI

Filipe Brandão, AMPL Optimization Inc., Mountain View, CA, United States

Python and its vast ecosystem are great for data pre-processing, solution analysis, and visualization, but Python's design as a general-purpose programming language makes it less than ideal for expressing the complex optimization problems typical of prescriptive analytics. AMPL is a declarative language that is designed for describing optimization problems and that integrates naturally with Python.

In this presentation, you'll learn how the combination of AMPL modeling with Python environments and tools has made optimization software more natural to use, faster to run, and easier to integrate with enterprise systems. We will show how AMPL and Python work together in a range of contexts:

- Installing AMPL and solvers as Python packages anywhere

- Fast data transfer from/to Python data structures such as Pandas and Polars dataframes

- Deploying models to the cloud quickly and easily

You'll also see how Generative AI technology is enabling a rapid development process for both AMPL and Python, reducing the time and effort to produce a working application that's ready for end-users.

Optimization Algorithms and Applications in Manufacturing

Contributed Session

Chair: Megan Peitz, Numerious Inc., 8139 Brophy Rd, HOWELL, MI, 48855, United States

1 - Variable aggregation for pre-processing non-linear programs

Sakshi Naik, Carnegie Mellon University, Pittsburgh, PA, United States, Robert Parker, Russell Bent, Lorenz Biegler

Large scale nonlinear optimization problems are frequently encountered in several applications such as energy systems, process optimization, etc. Reliable online optimization of these systems is crucial for continuous operation under different conditions. Optimization of these problems using state of the art non-linear solvers can face difficulties in convergence for certain challenging applications. It is therefore, important to develop solution strategies that can reliably solve these systems and are efficient.

In this work we focus on pre-processing of non-linear programs using variable aggregation for better convergence reliability. Variable aggregation involves replacing variables with their constraint expressions which results in a reduced order model with fewer variables and constraints. Variable aggregation has played a crucial role in convergence and efficiency of linear and mixed integer optimization solvers. In NLPs, it has been shown that eliminating equality constraints that define variables can help in convergence[1]. In this talk, we present a new approximate-maximum algorithm for variable aggregation. Problem size, solve-times and problem densities are compared across different aggregation strategies. We demonstrate that variable aggregation in general and particularly the approximate-maximum strategy has the potential to increase convergence reliability in challenging nonlinear programs.

In this talk, we describe our variable aggregation framework developed in Pyomo, give details on the approximate-maximum aggregation and demonstrate that variable aggregation leads to better convergence reliability on various test problems.

1. Parker, R., Nicholson, B., Siirola, J., Laird, C. & Biegler, L. An implicit function formulation for optimization of discretized index-1 differential algebraic systems. *Computers & Chemical Engineering* **168**, 108042 (2022).

2 - Integrated Learning and Optimization for Optimal Economic Dispatch of Power Generation Sources

Imran Pervez, King Abdullah University of Science and Technology, Thuwal, Saudi Arabia, Ricardo M. Pinto De Lima, Omar M. Knio

In this work, we propose to use integrated learning and optimization (ILO) to solve economic dispatch (ED) problems. The ED is an optimization problem in power systems solved to obtain power dispatch decisions of electric generators to supply a consumer power demand at minimum operating cost. We consider that the power demand in the ED formulation is unknown and learned using learning algorithms. In the literature, ED has been solved mainly using sequential learning and optimization (SLO), which focuses on accurately training the power demand forecast and then solving the ED problem. However, an accurately trained power demand forecast does not guarantee that the optimal ED decisions are feasible or optimal for the actual demand. To minimize this deviation and the cost of dispatch, an ILO approach is used. Unlike SLO, ILO trains the power demand by minimizing a regret function, designed to minimize the penalties due to supply and demand mismatch, which is evaluated after solving the ED problem within the training phase. The regret function and its gradient are relevant components of this approach, and their derivation is described in detail. After the training phase, the ED problem is solved and the regret function value is consequently determined. The results show that ILO leads to lower regret functions than SLO, thus illustrating its efficacy in minimizing penalties due to supply and demand mismatch.

3 - Building Designs for Individual-Level Estimation: Considerations, Implications and New Tools for Choice-Based Conjoint

Megan Peitz, Numerious Inc, Howell, MI, United States, Trevor Olsen

Choice-based conjoint (CBC) experiments are widely used to understand consumer preferences and willingness to pay for different product features. One important consideration in designing CBC experiments is the balance of attribute levels across the design. This strategy seeks to give every level an equal chance to influence the respondent’s decision in the conjoint design and can work in the majority of cases. However, this work revisits the work of Huber and Zwerina (1996) to determine if utility balanced designs, a design strategy that trades off on level balance while optimizing which alternatives are paired against each other within tasks, could result in better predictions at the individual level. This presentation sets out to explore several different methods of optimizing designs and offers an open-source solution, built in Julia by the Numerious team, to leverage these different design strategies in the future.

The results from this paper show that utility balanced designs perform well in predicting data from both utility balanced and non-utility balanced designs, and that respondents do not seem to be fatigued by utility balanced designs. This would suggest that utility balanced designs could be a successful strategy depending on the attributes and levels being tested. However, we must caution the user of utility balanced designs as some design strategies may result in sparse data at the interaction level. We also believe that further research is needed to understand the differences in willingness to pay estimates between utility balanced designs and traditional, level balanced designs.

Summit - Ballroom 1

Reimagining a Healthier Future with Sustainable Supply Chains

Plenary/Keynote Session

Plenary

Chair: Polly Mitchell-Guthrie, Kinaxis, Scottsdale, AZ, United States

1 - Reimagining a Healthier Future with Sustainable Supply Chains

Ann Tracy, Colgate-Palmolive, New York, NY, United States

Sustainability is rising as a priority on the corporate agenda, with increasing attention on supply chain, since this is where key contributions of a company's carbon emissions occur including a focus on the upstream supply chain. Colgate-Palmolive is ranked as one of the best supply chains in the world, and that leadership extends to their innovation in sustainability. They developed the world's first recyclable toothpaste tube and then shared the design with competitors in order to increase adoption. Join this plenary to hear how they are leading the way and learn about the real on-the-ground challenges they are tackling.

Summit - 320

Platform-Based Innovation in Service Operations

Invited Session

Service Science

Chair: Ruijie Zhang, ShanghaiTech University, Shanghai, N/A

1 - Does Kol Matter in Live Ecommerce: An Empirical Study on Tiktok

Kai Tian, Singapore Management University, Singapore, Singapore, Ruijie Zhang, Kejia Hu

The utilization of live-streaming advertising on social media platforms has garnered significant popularity across various industries due to its potential to significantly enhance the performance of advertisements. In this paper, we adopt PSM (Propensity Score Matching) and auto-regressive linear models to investigate the impact of targeting audiences of KOL (Key Opinion Leaders) followers on advertising outcomes. Based on marketing theories and PSM criteria, we incorporate matching variables into the PSM and identified three categories of marketing outcomes: traffic, purchase intention, and engagement. Our empirical results indicate that KOL-targeting reduces traffic, enhances purchase intention but has no effect on engagement. Specifically, KOL-based targeting reduces advertisement clicks and live streaming room entrances by 0.552 and 0.490, respectively. Nevertheless, it has effectively augmented slidecart interactions by 0.147 clicks, order creation by 0.027, and order payment by 0.024. To optimize targeting, we conduct a counterfactual analysis, identifying critical parameters for specific outcomes and fine-tuning non-critical parameters to improve overall marketing effectiveness without additional costs. This comprehensive optimization strategy maximizes desired outcomes and enhances marketing performance.

2 - Allow or Forbid Returns: Online Resale of Functional Collectibles with Authentication and Speculation

Baolong Liu, ShanghaiTech University, Shanghai, China, People's Republic of, Ellen Jin Jiang, Hongyang Zhuang, Yanlu Zhao, Shouyang Wang

Functional collectibles, such as co-branded sneakers and limited-edition handbags, possess dual attributes as both collectibles and usable items. Often found in the resale market due to their scarcity, these items can achieve surprisingly high price premiums. Resale platforms, aiming to prevent counterfeits, offer authentication services before shipping ordered items to consumers. However, this process introduces delays and the risk of price drops while buyers await authentication and delivery. Meanwhile, major platform StockX in the U.S. forbids buyers from returning products after purchasing. However, others like Poizon in China allow returns to protect buyers' rights and control speculation, leading to potential revenue loss for platforms. Motivated by thes observations between platforms in the two countries, this paper investigates the speculation-controlling effects of the return policy and explores operational innovations to enhance platform revenue. We analyze resale data of Yeezy Boost 350 V2 sneakers to understand the economic, behavioral, cultural, and operational factors influencing price premiums. Subsequently, we develop queueing game models based on key operational strategies, namely the matched/returned model and the speculation/collection model. Our findings reveal that while a return policy decreases platform revenue, it effectively controls speculation and stabilizes buyer welfare in schemes with a low cultural intensity towards certain functional collectibles. Conversely, in high cultural intensity schemes, speculation can be self-discouraged. Additionally, to enhance platform revenue, we propose an *order-based prioritization* design that prioritizes authenticating matched orders over returned orders, and we also explore the implementation of *hassle-free after return* strategies.

3 - The Impact of Financial Incentives in Instant Retail: An Empirical Investigation

Ruijie Zhang, ShanghaiTech University, Shanghai, China, People's Republic of

In instant retail, financial incentives are used to address supply-demand imbalances, but their effects in this context are unclear due to platforms bearing the costs and dense store networks. This study investigates the direct and spillover effects of platform-borne financial incentives on order acceptance speed using data from a major Chinese instant retail firm. Regression discontinuity design shows incentives reduce order acceptance time by 23.66%. Network analysis via propensity score matching reveals opposing spillover effects: incentives at focal stores prolong acceptance time at nearby non-incentivized stores but shorten it at incentivized ones. This is explained by siphon and clustering effects. Optimizing incentives considering network effects could reduce costs by 22.69% and total order acceptance duration by 1.55%. Managers should extend incentives to surrounding stores to leverage clustering effects while mitigating siphon effects, and consider store type and distance when designing incentive strategies to enhance efficiency and cost-effectiveness.

4 - Motivating the Drivers with Income-Targeting Behavior: Innovation of Surge Pricing Strategies in Ridesharing Market

Yuelong Zou, Shanghai Jiao Tong University, Shanghai , China, People's Republic of, Xiaowei Mei, Liangfei Qiu, Lai Wei

With the higher level of uncertainties from the supply side in the context of the gig economy, online platforms operating in the ride-hailing business have designed various surge pricing strategies to address the increasing flexibility of the labor force, ensuring a relatively stable level of service. Although the reference-dependent theory has been widely adopted to explain the negativity of short-term wage elasticity, fewer studies have explored how drivers' irrational behaviors, especially the income targeting issue, can reshape the surge pricing mechanisms.

We developed a Stackelberg game model to examine the platform's optimal pricing strategies and the social welfare dynamics, taking into account the drivers' behavioral issues. Our findings indicate that: (1) The optimal solutions can help platforms switch incentive strategies and avoid falling into the circumstance where surge pricing is ineffective due to negative wage elasticity of the labor. (2) The reference-dependent behavior of irrational drivers widens the pricing gaps of both passengers and drivers between peak and off-peak market conditions. In milder market conditions, the platform captures the increased revenue when demand grows, leaving driver wages unchanged. (3) When the driver's income target level is within a certain range, the welfare for the both demand and supply side increases concurrently with the rise in drivers' income target.

Co-Chair: Jaesung Lee, Texas A&M University, College Station, TX, 77845, United States

1 - Den-Hmm: Deep Emission Network Based Hidden Markov Model with TIME-Evolving Multivariate Observations

Vipul Bansal, University of Wisconsin-Madison, Madison, WI, United States, Shiyu Zhou

A Hidden Markov Model (HMM) is a popular statistical modeling technique for system health state estimation, monitoring, and prognosis. However, most existing HMMs adopted some simple parametric probability distribution as the distribution of observations for a given state and thus cannot capture the intricate dependency of observations on state and possibly other covariates such as time. To address this, we propose a Deep Emission Network-based Hidden Markov Model (DEN-HMM) to capture the complex evolution of multivariate observations with respect to state and time. We also address the challenging issue of state nondiscrimination in DEN-HMM. To overcome this, we propose a regularized loss function that can prevent certain approximate solutions and enhance the state discriminative capabilities of DEN-HMM. The study further demonstrates extensive numerical studies to show the effectiveness of the proposed DEN-HMM, including a case study on steady-state estimation in ultrasonic cavitation-based dispersion processes.

2 - A General Framework for Robust Monitoring of Multivariate Processes

Xiulin Xie, Florida State University, Tallahassee, FL, United States

Statistical process control (SPC) charts provide an important analytic tool for online monitoring of sequential processes. Conventional SPC charts are designed for cases when in-control (IC) process observations are independent and identically distributed at different observation times and the IC process distribution belongs to a parametric (e.g., normal) family. In practice, however, these model assumptions are rarely valid. To address this issue, there have been some existing discussions in the SPC literature for handling cases when the IC process distribution cannot be described well by a parametric form, and some nonparametric SPC charts have been developed based on data ranking and/or data categorization. However, both data ranking and data categorization would lose information in the original process observations. Consequently, the effectiveness of the nonparametric SPC charts would be compromised. In this article, we make another research effort to handle this problem by developing a general process monitoring framework that is robust to the IC process distribution and short-ranged serial correlation. The new method tries to preserve as much information in the original process observations as possible. Instead of using data ranking and/or data categorization, it is based on intensive data pre-processing, including data decorrelation, data transformation, and data integration. Because the distribution of the pre-processed data can be approximated well by a parametric distribution, the design and implementation of the new method is relatively simple. Numerical studies show that it is indeed robust to the IC process distribution and effective for online monitoring of multivariate processes with short-ranged serial correlation.

3 - Vision System Using Mdp-Based Tracking to Create Body-in-White Dimension Control Charts in Automotive Quality

Ramiro Rodriguez Buno, The Ohio State University, Columbus, OH, United States, Yifei Zhang, Yuan Ke Tsai, Chih-Yin Lin

The traditional way to measure gap and flush are still operated manually in an assembly line with specific instrument, such as feeler gauges or dial gauges, which is not easy to obtain continuous data and it requires considerable labor cost and inspection time.

The aim of this project is to develop a vision system capable of automatically and non-invasively measuring dimensions on Body-in-white, including gaps and flushes, thereby reducing the labor costs associated with manual measurement.

The vision measurement system consists of a single camera positioned to face the inspection line. As a vehicle moves through the line, the camera swiftly captures approximately 30 images, ensuring comprehensive coverage of the vehicle's details.

We developed a vision measurement system to measure the dimensions of gaps and flushes for Body- in-white in the assembly line. This system can accurately detect the measurement area and generate dimensional values in real-time with GPU acceleration. We employ Bayesian optimization methods to optimize the parameters of image processing, thereby enhancing the accuracy of edge detection and measure accuracy.

The current detection and tracking method are still based on exhaustive search with a hierarchical level. We are going to model the tracking as a Markov Chain Process to reduce the searching cost by leveraging the historical trajectory.

To predict the gap and flush, a promising direction for future exploration is the application of sequence models like RNN (or LSTM) or Transformers.

4 - Sample-averaged variance-constrained Risk-sensitive Deep RL

Saunak Kumar Panda, University of Houston, Houston, TX, United States, Yisha Xiang

While deep reinforcement learning (DRL) has shown remarkable success in solving complex decision-making problems. However, existing DRL algorithms often lack explicit risk sensitivity mechanisms, due to their focus on maximizing the expected total return value. This has led to suboptimal performance in environments where risk management is crucial. While risk-sensitive RL methods have mostly been limited to tabular and linear methods, risk-neutral RL methods have exploited DRL infrastructure. In this work, we make an attempt to study risk-sensitive DRL with the variance risk criteria involving a sample-averaged version of the total return. Our focus is to find a policy that maximizes the sample-averaged version of total return, subject to a variance constraint bounded by some threshold. We transform the above problem to an unconstrained policy optimization problem and propose an actor-critic algorithm that efficiently updates the policy and other parameters. Finally, we provide numerical studies of our proposed algorithm on several gym environments.

5 - Knowledge Constrained Deep Clustering for Melt Pool Anomaly Detection in Laser Powder Bed Fusion

Erfan Ziad, Arizona State University, Tempe, AZ, United States, Feng Ju, Zhuo Yang, Yan Lu

The rapid expansion of the manufacturing sector has brought laser-based metal additive manufacturing, like laser powder bed fusion, to the forefront of innovation. Yet, its widespread acceptance hinges on overcoming numerous obstacles, including uncertainties regarding part quality when employing standardized materials in additive manufacturing procedures. Clustering techniques are essential in uncovering patterns within data sets, particularly in the field of additive manufacturing, where understanding the behavior of meltpool images is crucial for process optimization. Traditional hierarchical clustering methods often lack the ability to incorporate domain-specific knowledge, limiting their effectiveness in this field. In this study, we propose a novel approach that integrates prior knowledge-constrained hierarchical clustering with encoded meltpool image sequences. By incorporating domain-specific constraints, our approach aims to enhance clustering accuracy and provide more interpretable cluster assignments. Our approach improves clustering performance and provides insights into melt pool image sequences, enabling us to evaluate printed parts' quality.

1 - Domain-Informed Automated Surface Patch Extraction for 3D Printing Qualification

Weizhi Lin, University of Southern California, Los Angeles, CA, United States, Qiang Huang

In the qualification of shape quality of three-dimensional (3D) freeform products, actual products are compared to their intended designs to ensure geometric accuracy, fit, and functionality. To efficiently quantify shape differences of complex designs, surface patches are typically prespecified and used as the fundamental elements for comparison. However, as manufacturing shifts from mass production to personalization, the increasing variety of designs makes predetermining an infinite variety of surface patches impractical. Additionally, extracting these patches often relies on potentially unavailable prior knowledge, such as the number of surface patches. Moreover, verifying the validity of extracted surface patches can be challenging for unknown types. This work proposes a dimension-reduction framework that includes domain-informed representation, automated extraction, and adaptive verification of surface patches. We identify surface patches as finite primitive elements capable of reconstructing a shape’s deviation patterns. These patches capture distinct deviation patterns in local regions, determined by changes in geometric attributes rather than the original design. We characterize these changes through their smoothness, measured using the Laplacian-Beltrami (LB) operator, and through patterns of change identified by various types of critical points. To automatically extract these patches, we identify critical points as patch centroids through active landmark selection. Expanding from these centroids, we automatically define boundaries to ensure homogeneous LB operators via changepoint detection. We then design verification processes to assess the identifiability of deviation patterns across various surface patches. This framework is demonstrated through case studies in 3D printing.

2 - Physics-Guided Reinforcement Learning for Automatic Fixture Layout Design in Manufacturing Systems

Yinan Wang, Rensselaer Polytechnic Institute, Troy, NY, United States, Tim Lutz, Juan Du, Xiaowei Yue

Fixture layout design is a critical problem in the assembly process of large-scale sheet metal or composite parts. It directly influences the shape deformation of each individual sheet and the quality of the assembled product. The existing research works mainly follow the scheme of developing mathematical-optimization (MO)-based methods to generate the optimal fixture layout via interaction with physical models, finite element analysis (FEA)-based simulations, or its surrogate models. The limitations of MO-based methods can be summarized as that they are memoryless and lack scalability. Memoryless indicates that the experience in designing the fixture layout for one part is usually not transferable to others. Scalability becomes an issue for MO-based methods when the design space of fixtures is large. Furthermore, the usage of surrogate models might also hinder scalability as they might have variations in prediction accuracy when modeling high-fidelity simulations. To address these limitations, we propose a learning-based framework, SmartFixture, to design the fixture layout by training a Reinforcement learning (RL) agent through direct interaction with the FEA-based simulations. The advantages of the proposed framework include: (1) the properties of the learning-based method enable it to generalize to design fixture layouts for unseen scenarios after offline training; (2) the proposed framework has the ability to find the optimal fixture layout over a massive search space; (3) it can be extended to solve other design optimization problems in the manufacturing process. Experiments demonstrate that the proposed framework consistently outperforms the benchmark methods in designing the fixture layouts.

3 - A Personalized Federated Data Analytics Model for Rul Prediction

Yuhan Hu, North Carolina State University, Raleigh, NC, United States, Xiaolei Fang

Federated prognostics enable users to collaboratively develop a failure time prediction model using their combined data while keeping each user's data local and confidential. However, traditional federated models often assume homogeneity in the degradation processes across users, an assumption that may not hold in many industrial settings. To overcome this, our talk introduces a personalized federated prognostic model designed to accommodate users with heterogeneous degradation processes, allowing them to build tailored prognostic models. Numerical studies are presented to demonstrate the effectiveness of our approach.

4 - Privacy-Preserving Process Data Sharing for Metal-Based Additive Manufacturing via Generative Diffusion Modeling

Hugo Rodriguez, Mississippi State University, Starkville, MS, United States, Durant Fullington, Emmanuel Yangue, Chenang Liu, Wenmeng Tian

The objective of this research is to develop a de-identification mechanism for metal-based additive manufacturing (AM) process data, utilizing a generative diffusion modeling framework. The need for AM process data privacy stems from the growth of collaborative data sharing framework, used to develop robust *in-situ* anomaly detection models. However, these data sharing frameworks can compromise the confidential design information within the AM process data. The proposed diffusion modeling approach provides a novel methodology by infusing print path de-identification measures into image augmentation, resulting a surrogate image with design information masked. This allows for more precise data de-identification and the ability to maintain data usability for process anomaly detection, as the surrogate thermal history maintain similarity with the prior data distribution.

1 - Binary Factorization of Symmetric Integer Matrices via Integer Programming

Mohsen Mohammadi, Northwestern University, Evanston, IL, United States, Sanjay Mehrotra

Non-negative matrix factorization (NMF) is a fundamental problem in AL/ML, with a wide range of applications across various disciplines. Over the years, numerous variants of NMF have been explored in the literature. Herein, we study the problem of factorizing symmetric integer matrices into binary basis and its transpose. We propose several types of valid inequalities for the problem within its original variable space. We also present a branch and cut scheme to solve the problem, followed by comprehensive computational experiments to showcase the efficiency of our approach.

2 - How Useful Could the Subdominant Eigenvalue be to Estimating Convergence Rate Toward Equilibrium in Queueing Systems

Javad Tavakoli, University of British Columbia-Okanagan, Kelowna, BC, Canada, Winfried Grassmann

For estimating the speed of convergence of stochastic systems toward their equilibrium one often uses the subdominant eigenvalue. In queueing systems, this may not be appropriate. We show this both experimentally through Jensen`s method, as well as theoretically by using diagonalization. We also introduce an interpretation of the diagonalization that is helpful for deciding whether the subdominant eigenvalue should be used. Moreover, we show what model properties lead to complex eigenvalues. This is important because complex eigenvalues complicate the analysis. The theoretical analysis is bolstered by simple examples where the eigenvalues can be expressed analytically, such as the M/M/1/N queue.

3 - Minimax Rate Optimal Algorithms for High-Dimensional Stochastic Linear Bandits

Jingyu Liu, Queen's University, Kingston, ON, Canada, Yanglei Song

We consider the stochastic linear bandit problem with multi-arms over T rounds, where the dimension d of the covariate vectors is potentially larger than T, however each arm-specific parameter vector has at most s non-zero components. First, we study the single-arm case, focusing on the cumulative estimation error of the parameter vector. We show that Lasso has a sub-optimal dependence on d,T in terms of worst-case error in the online estimation setup. Further, we establish the minimax optimality of the OLS post Lasso, which first estimates the support of the parameter vector by thresholding the Lasso estimator and then runs least squares on the selected support. Second, we consider the bandit setup, using the OLS post Lasso as the main estimation method. We propose a three-stage algorithm for arm selection and derive an upper bound of order $s (\log s) (\log d + \log T)$ on its cumulative regret. Finally, we establish a matching lower bound up to a $(\log s)$ multiplicative term, which shows the near minimax optimality of the proposed method. We note that our analysis avoids the restrictive "beta-min" condition.

Advanced Methods in Optimization and Prediction

Contributed Session

Chair: Johnson Phosavanh, The University of Sydney, Sydney, 2006, Australia

1 - Guaranteed Bicluster Recovery via Semidefinite Programming

Abiodun Sumonu, The University of Alabama, Tuscaloosa, AL, United States, Brendan Ames

Unlike traditional clustering, in biclustering the goal is grouping both the object and feature sets concurrently into subgroups, called biclusters, based on their expression levels. We consider the densest k-disjoint-biclique problem in which a given weighted complete bipartite graph is partitioned into k disjoint subgraphs such that the sum of their densities is maximized as a model for the biclustering problem. We show that the optimal solution of a semidefinite relaxation of the densest k-disjoint-biclique problem recovers the correct object-feature partitions with high probability whenever the input graph is sampled from a distribution of clusterable bipartite graphs. We discuss necessary and sufficient conditions for exact recovery and empirically investigate how parameters like sparsity, distribution properties, block sizes, and outliers affect recovery through numerical simulations. Our findings highlight theoretical phase transitions, underscoring the existence of critical points for exact recovery of the bicluster structure

2 - Inert Zones in L1 Regression

Botan Citil, University of Nebraska-Lincoln, Lincoln, NE, United States

This work investigates inert zones in online L1 regression, focusing on their role in computational time savings and their relative size with respect to data space. Inert zones, both above and below the regression hyperplane, are regions where additional data points do not affect regression parameters. Characterized as convex, polyhedral shapes, inert zones share the dimensionality of the data set and are defined by intersecting pairs of simplexes with the same barycenter. Our study aims to analyze the computational time savings achieved by identifying inert arrivals and to examine how data set parameters, including cardinality, dimension, and variance, impact these savings and the size of inert zones. Empirical evidence suggests that inert zones can be relatively voluminous, further highlighting their significance in L1 regression. By presenting results on the function and geometry of these novel regions, this paper contributes to a deeper understanding of inert zones in online L1 regression and their practical implications.

3 - Expected Bipartite Matching Distance in A *D*-dimensional L^p Space: Approximate Closed-form Formulas and Applications to Mobility Services

Shiyu Shen, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Yuhui Zhai, Yanfeng Ouyang

The bipartite matching problem has been at the core of many theoretical or practical challenges. Although many well-known algorithms can solve each bipartite matching problem instance efficiently, it remains an open question how one could estimate the expected optimal matching distance for arbitrary numbers of randomly distributed vertices in a D-dimensional L^p space (referred to as a random bipartite matching problem, or RBMP). This paper proposes an analytical model with closed-form formulas (without statistical curve-fitting) that estimate both the probability distribution and expectation of the optimal matching distance of RBMP. Simpler asymptotic approximations of the formulas are also developed for some special cases. These proposed distance estimates could be key for strategic performance evaluation and resource planning in a wide variety of application contexts. To illustrate their usefulness, we focus on mobility service systems where matches must be made between customers and service vehicles that are randomly distributed over time and space. We show how the proposed distance formulas not only provide a theoretical explanation on the conditions under which empirically assumed Cobb-Douglas matching functions can be suitable for taxi systems, but can also be easily incorporated into optimization models to determine taxi operational strategies (e.g., duration of the demand pooling period). A series of simulation experiments are conducted to verify the accuracy and applicability of the proposed formulas under varying numbers of bipartite vertices, varying number of dimensions, and varying L^p distance metrics.

4 - Minimizing the number of late jobs and total late work with step-learning

Johnson Phosavanh, The University of Sydney, Sydney, Australia, Daniel Oron

We study single-machine scheduling problems with step-learning, where an improvement in processing time is experienced if a job is started at, or after, a job-dependent learning-date. We consider minimizing two functions: the number of late jobs and the total late work, and we show that when at least a common due-date or common learning-date is assumed, the problem is NP-hard in the ordinary sense; however, when both are arbitrary, the problem becomes strongly NP-hard. For each problem where at least one of the dates is assumed to be common, we analyze the structure of an optimal job schedule with and without idle time and propose pseudo-polynomial time dynamic programming algorithms. We also show that the problem of minimizing the weighted number of late jobs with step-learning can be solved with a minor change to the algorithms for the unweighted case. In addition, we show that when a common due-date is assumed and no idle time is allowed, the problem of minimizing the total late work is equivalent to minimizing the makespan. Furthermore, we provide a more efficient algorithm to minimize makespan under the assumption of a common learning-date than the one in the existing literature. Lastly, we show that our analysis can also be applied to the case of step-deterioration, where, instead, the processing times of jobs increase at a given date.

Strategies in Revenue and Payment Management

Contributed Session

Chair: Darius Walczak, PROS Inc., 3200 Kirby Drive, Suite 600, Houston, TX, 77098, United States

1 - Optimal content-selling strategy with quality-dependent preference consumer

Pengjie Guo, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of

Digital content product is a form of content product widely accepted after the vigorous development of new media, including E-journals, streaming media, digital albums and so on. Such products usually come in the form of content collections, such as multiple articles in an issue of an e-journal or ten songs in an album. They have inherent temporal and experiential features that distinguish them from normal products.

For example, the sequence of content will affect the overall experiential utility of customers and further influence repeat purchase behavior; consumers may be uncertain about the valuation of a content.

An effective way of marketing such a product turns out to be letting consumers to experience a portion of it at a low cost, or even for free, which provide an opportunity for consumers to resolve some (or all) of their uncertainty before buying. Meanwhile, Free trial of partial content products also naturally forms a quality reference point which in turn affects overall customer satisfaction and subsequent repeat purchase behavior.

This literature discusses the case of content products provided by monopoly or duopoly that consumers purchase repeatedly over two periods. We will demonstrate how, depending on these market features, the content provider's optimal sales strategy and intertemporal sequence so as to maximize the total revenue of content provider when consumers are quality reference-dependent.

2 - Buy now pay later: Endogeneity, Heterogeneity, and Intertemporal Preferences in Installment Loan Choices

Jessie Jiang, Cornell University, Ithaca, NY, United States, Christopher Anderson

Buy now pay later (BNPL) is a payment arrangement that enables consumers to make immediate purchases while spreading the payment through fixed monthly installments over time. It has gained rapid adoption across diverse markets including fashion, electronics, and travel. BNPL providers like Afterpay, Affirm and Klarna often present the purchase amount in the form of small monthly payments to attract consumers. We focus on BNPL use in services, where product consumption and payment periods may not be the same – e.g. immediate travel with delayed payment versus (partial) payment in advance of service use. We consider the role of endogeneity, heterogeneity, and intertemporal preferences in BNPL loan choices. Credit score, an essential variable for the loan underwriting process, dictates the loan amount, duration, and interest rates available to the applicants. On the other hand, as credit scores could reflect consumers' risk perceptions and spending habits, they might be also associated with the heterogenous preferences in consumers' loan choices. Additionally, when products are not readily available, such as reserving a trip, consumers would need to balance future consumption with future payments. We introduce three types of temporal elements into the choice model: (1) anticipation utility derived from the total order amount and the time to service use, (2) time discounting for future monthly payments, and (3) present bias owing to the size of down payments. Utilizing a consumer purchase dataset from a BNPL loan provider, we compare a baseline multinomial logit model with models that address endogeneity, heterogeneity and intertemporal preferences.

3 - Huge-Scale Network Revenue Management with Customer Choice: A Primal-Dual Approach

DONGHAO ZHU, The Institute of Statistical Mathematics, Tachikawa, Japan, Hanzhang Qin, Ching-pei Lee, kenji fukumizu

We consider network revenue management with customer choice on a huge scale, which is a central question for many industries including transportation, retailing, and healthcare. The solution to a choice-based linear program usually can be used to guide managers in determining sales volumes to different types of customers to maximize revenue. However, traditional methods typically fail to solve such a linear program at a huge scale due to a lack of tailoring the algorithm to consider the extremely big scale. To address the computational issue, we introduce a first-order primal-dual method SPFOM. Our algorithm requires only a small computational cost in each iteration and enjoys a provably near-optimal convergence rate. This feature is further verified through numerical simulations in comparison to state-of-the-art commercial solvers.

4 - Aspects of Network Revenue Management Control

Darius Walczak, PROS Inc., Houston, TX, United States

Abstract: We analyze several popular control methodologies for network revenue management (network RM) considering their relevance to real-life revenue management and pricing applications. Comparing advantages and disadvantages of both established and novel methods such as network decomposition (resource or product-based), iterative proration or heuristic dynamic programming methods, we point out ways to improve their performance in practice as well as user adoption. Within this context we report on recent machine learning techniques being introduced in the field.

1 - Target-Following Online Resource Allocation

Chamsi Hssaine, University of Southern California, Marshall School of Business, Los Angeles, CA, United States, Garrett van Ryzin, Huseyin Topaloglu

We consider a problem in which a decision-maker faces a sequence of requests to be assigned to a set of resources over time. Contrary to classical online resource allocation problems in which there is a fixed budget constraint on the number of resources consumed at the end of the horizon, we assume the time horizon is partitioned into a fixed number of epochs, each associated with a vector of target consumption rates for the resources. The objective is to simultaneously minimize total assignment costs and a convex deviation cost incurred at the end of each epoch which penalizes the difference between the running average consumption of resources and their respective targets. We design a primal-dual algorithm that attains sublinear regret with respect to the hindsight optimal solution, when arrivals are drawn i.i.d. from an unknown distribution. We demonstrate the effectiveness of our algorithm via extensive numerical experiments on a real-world dataset.

2 - Improving Utilization in Deceased Donor Kidney Allocation

Grace Guan, Stanford University, Stanford, CA, United States, Itai Ashlagi, Philipp Strack, Felipe Subiabre

While there are around 100,000 patients waiting for a deceased donor kidney in the U.S., over 25% of recovered kidneys are not placed. We assess the impact of incorporating learning into allocation policies to reduce inefficiencies in the system. Using simulations, we evaluate alternative allocation policies that take advantage of knowing a patient's probability of acceptance against the current sequential offering process. We quantify the reduction in waiting times and increase in utility with alternative allocation policies.

3 - Learning to Rank Under Strategic "Brush Wars"

Yifan Feng, National University of Singapore, Singapore, Singapore, Qinzhen Li, Kevin Chen

We consider a dynamic learning and ranking problem of a digital platform. Uninformed of the products' intrinsic qualities, the platform strives to design a ranking rule that learns from historical traffic data while accounting for sellers' potential manipulation through "brushing" activities, such as fake orders or sales. We study a simple Experiment-Then-Commit (ETC) policy framework and characterize the sellers' strategic responses as a "brushing war" game. We find that in the limit with a long time horizon and many sellers, there is a "self-reinforcing" market equilibrium. That is, the sellers' brushing amounts increase in the product's qualities, thus helping with the platform's complete learning.

4 - Interpretable Data-Driven Policy for Index-Based Yield Protection

Kehan Lu, Duke University, Durham, NC, United States, Jing-Sheng Song, Can Zhang

Index-based yield protection is a novel government subsidy to safeguard smallholder farmers from crop yield loss, utilizing a predefined index such as rainfall rather than the traditional method of actual yield assessments to calculate subsidy payments. In this research, we propose a data-driven framework to determine the optimal subsidy payment amount for a government-issued index-based yield protection policy. Our approach makes minimal adjustments to one widely adopted policy yet significantly improves its effectiveness. It overcomes two main limitations of the existing policy: First, it accounts for the distinct impact of yield prediction errors on risk-averse farmers across different yield levels, enhancing the model's robustness against errors in misspecification. Second, it systematically considers the accuracy of the index when determining the payment to farmers. In addition, we provide high-probability convergence guarantees for the parameters of our algorithm and extend them to performance guarantees in terms of net benefit (i.e., total farmer surplus minus expenditure). Finally, we implement our framework using real-world agricultural, climate, and remote-sensing data to illustrate its advantages.

1 - Robust Dynamic Staffing with Predictions

Yiding Feng, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Vahideh Manshadi, Rad Niazadeh, Saba Neyshabouri

We consider a natural dynamic staffing problem in which a decision-maker sequentially hires staff over a finite-time horizon to meet an unknown target demand at the end. The decision-maker also receives a sequence of predictions about the demand that become increasingly more accurate over time. Consequently, the decision-maker prefers to delay hiring decisions to avoid overstaffing. However, workers' availability decreases over time, resulting in a fundamental trade-off between securing staff early (thus risking overstaffing) versus hiring later based on more accurate predictions (but risking understaffing). This problem is primarily motivated by the staffing challenges that arise in last-mile delivery operations. A company such as Amazon has access to flexible gig economy workers whose availability decreases closer to the target operating day, but they can be hired at any time before that day if they are available.

We study the above problem when predictions take the form of uncertainty intervals that encompass the true demand. The goal of the decision-maker is to minimize the staffing imbalance cost at the end of the horizon against any sequence of prediction intervals being chosen by an adversary. Our main result is the characterization of a simple and computationally efficient online algorithm that obtains the optimal worst-case imbalance cost, aka., minimax optimal. Our base model considers staffing for one target demand. We also consider generalizations to multiple target demands with either an egalitarian cost objective or a utilitarian cost objective, and to the case where the hiring decisions can be reversed at given discharging costs.

2 - Approximating Optimum Online for Online Capacitated Allocation

Tristan Pollner, Stanford University, Stanford, CA, United States, Alexander Braun, Thomas Kesselheim, Amin Saberi

We study online capacitated resource allocation, a natural generalization of online stochastic max-weight bipartite matching. This problem is motivated by ride-sharing and Internet advertising applications, where online arrivals may have the capacity to serve multiple offline users.

Our main result is a polynomial-time online algorithm which is (0.5+c)-approximate to the optimal online algorithm for c=0.011. This can be contrasted to the (tight) 0.5-competitive algorithms to the optimum offline benchmark from the prophet inequality literature. Optimum online is a recently popular benchmark for online Bayesian problems which can use unbounded computation, but not "prophetic" knowledge of future inputs.

Our algorithm (which also works for the case of stochastic rewards) rounds a generalized LP relaxation from the unit-capacity case via a two-proposal algorithm, as in previous works in the online matching literature. A key technical challenge in deriving our guarantee is bounding the positive correlation among users introduced when rounding our LP relaxation online. Unlike in the case of unit capacities, this positive correlation is unavoidable for guarantees beyond 0.5. Conceptually, our results show that the study of optimum online as a benchmark can reveal problem-specific insights that are irrelevant to competitive analysis.

3 - Approximating Maximum Matching Requires Almost Quadratic TIME

Mohammad Roghani, Stanford University, Stanford, CA, United States, Soheil Behnezhad, Aviad Rubinstein

We study algorithms for estimating the size of maximum matching. This problem has been subject to extensive research. For n-vertex graphs, Bhattacharya, Kiss, and Saranurak [FOCS'23] (BKS) showed that an estimate that is within ϵn of the optimal solution can be achieved in $n^{2-\Omega_\epsilon(1)}$ time, where n is the number of vertices. While this is subquadratic in n for any fixed $\epsilon > 0$, it gets closer and closer to the trivial $\Theta(n^2)$ time algorithm that reads the entire input as ϵ is made smaller and smaller.

In this work, we close this gap and show that the algorithm of BKS is close to optimal. In particular, we prove that for any fixed $\delta > 0$, there is another fixed $\epsilon = \epsilon(\delta) > 0$ such that estimating the size of maximum matching within an additive error of ϵn requires $\Omega(n^{2-\delta})$ time in the adjacency list model.

4 - Online Advertising Strategy for Long-Term Good via IV-Q-Learning with Noisy Instruments

Yueyang Zhong, London Business School, London, United Kingdom

This paper examines how an online advertising system can optimize ad placement to maximize long-term expected revenue, when observed feedback is biased. We develop an advertising strategy by integrating robust causal inference with reinforcement learning. Our proposed strategy is tested in the auction simulator of our partner firm, showing a significant increase in total revenue over the test period compared to baseline strategies.

Optimization of Storage and Warehouse Operations

Contributed Session

Contributed

Chair: Marc Goessling, Afresh Technologies, Jersey City, NJ, United States

1 - Path optimization of multiple robots in robotic mobile fulfillment system

ahmad kokhahi, Clemson university, Central, SC, United States, Mary Beth Kurz

The emergence of robotic technology has led to increased attention on automated warehouses, particularly robotic mobile fulfillment systems (RMFS). These systems leverage robots for their efficiency and speed, often incorporating Automated Guided Vehicles (AGVs) to enhance integration. However, a notable challenge in robotic deployment is the potential for collisions, necessitating priority rules for collision management. While existing priority rules, such as task priority or prioritizing based on starting points, have demonstrated efficacy, they do not account for robot downtime and overall system running time. Addressing this gap, this study introduces a novel priority rule, Minimizing Wasting Time (MWT), which prioritizes based on total time wasted due to collisions. Furthermore, in cases where collisions significantly impact vehicle efficiency, task rescheduling is proposed to mitigate collisions and enhance system efficiency. This approach aims to optimize warehouse operations by minimizing downtime and improving overall productivity.

2 - Efficient Selection of Inventory Counts for Perishable Items

Marc Goessling, Afresh Technologies, Jersey City, NJ, United States, Clement Micol, Emily Meigs, Aaron Stern

Automatic ordering systems for perishable inventory optimize the tradeoff between over-ordering and under-ordering. Such systems can only be effective if they have access to accurate inventory estimates. However, frequent inventory counting is expensive in terms of labor cost. The information gain from a manual count varies depending on the accumulated uncertainty in the inventory estimate, which itself depends on factors like shelf life of the item, and reliability of corresponding shipment and sales data. Inventory targeting algorithms aim to find the right balance between information gain and labor cost.

In this talk we propose a targeting solution to select which grocery items are to be counted by a store associate. We implemented a tunable algorithm that can be controlled by setting a few intuitive parameters, including daily counting limits, counting frequency caps and, critically, a lever to trade off effort vs information gain.

In order to optimize these hyper-parameters based on business requirements, we built a backtesting framework that supports offline evaluation of candidate targeting algorithms with different settings. We share practical lessons learned after launching our solution and describe the adjustments we’ve made to the algorithm in response. Finally, we discuss the challenge of measuring inventory estimate accuracy in a system where targeting itself is dependent on inventory accuracy. To this end, we propose a random sampling extension, applicable to any targeting algorithm, that yields unbiased accuracy readings.

Blockchain Innovations in Supply Chain Management

Contributed Session

Chair: Yongle Tian, Shanghai Jiao Tong University, Shanghai, N/A

1 - The effect of blockchain implementation on supply chain conflict

Xiaoqi Lyu, Tianjin University, Tianjin, China, People's Republic of, Min Tian, Baofeng Huo

Existing researches underscore the advantages of blockchain technology in enhancing the efficiency and transparency of supply chain management. This study examines the impact of blockchain implementation on supply chain conflicts, revealing the dark side of blockchain application. By enhancing the orientation of technology for social good and reducing dependence on suppliers, the negative impact of adopting blockchain technology can be alleviated. These insights deepen our understanding of the practical applications and strategic significance of blockchain technology in supply chain management.

2 - Blockchain Adoption in the Low-Carbon Supply Chain: A Comparative Analysis of Different Adoption Modes

Yongle Tian, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Chunguang Bai

Companies can reduce their carbon footprint through both direct emission reduction efforts and indirect offset in emissions trading. Blockchain plays a vital role in addressing the challenges faced by companies in reducing their carbon footprint and has been increasingly adopted across industries. There are mainly three blockchain adoption modes—government adoption, manufacturer adoption, and retailer adoption—yet the optimal mode remains unclear both in practice and in the literature. By fully incorporating blockchain's three benefits (reducing emission reduction cost, reducing transaction cost in emissions trading, and enhancing consumers' green trust) and three costs (setup cost, operational cost, and usage fees), we compare the three blockchain adoption modes in terms of LCSC's sustainability, profitability, and social welfare. Key findings are as follows. First, regarding sustainability, LCSC may rely more on indirect offset after blockchain adoption, highlighting the trade-off between direct and indirect methods of reducing the carbon footprint. Second, regarding profitability, greater efficiency improvement in emission reduction through blockchain always benefits users, whereas it is not true for the investor. Third, retailer adoption is most effective in encouraging LCSC's direct emission reduction efforts and maximizing the manufacturer's profit and social welfare; the retailer's profit will also be highest if the setup cost coefficient and total carbon footprint per unit of product are low. Finally, blockchain's impacts on companies' direct emission reduction efforts and profitability are different across supply chains with different carbon footprint levels. We also provide valuable managerial insights for LCSC and policymakers on driving sustainable development and enhancing social welfare.

1 - Understanding the Dynamics of Deal-of-the-Day Platforms: a Multi-Level Analysis

Behrooz Davazdahemami, University of Wisconsin-Whitewater, Whitewater, WI, United States, Elham Rasouli Dezfouli

Daily deal platforms like Groupon have experienced rapid growth in E-commerce over the last decade. Numerous studies have explored what influences consumer purchasing behaviors on these platforms, but they often overlook the impact of deal types (whether they are hedonic or utilitarian). Furthermore, existing research fails to fully account for the effects of time-variant factors such as remaining sales time and previous sales.

In this study, drawing on the theory of duality modes, we examine how deal type moderates the influence of various time-variant and static factors on sales within Deal-of-the-Day (DoD) platforms. Leveraging a substantial dataset from an actual DoD website, we utilize a hybrid within-between panel regression approach to reveal the evolving dynamics of each determinant factor within and across deals over time.

2 - Beyond the Checkout Lines: An Empirical Analysis of Self-Service Technologies in Retail Stores

Jeongha Kim, Korea University, Seoul, Korea, Republic of, Hyeokkoo Eric Kwon, Dongwon Lee, Hyunseok Lee, Kyuhan Lee

Technological progress and changes in consumer habits are significantly reshaping the retail industry, with self-service technologies (SSTs) playing a pivotal role in modernizing the shopping experience. Despite their widespread use, there is still a significant gap in understanding how SSTs impact essential business metrics such as sales and labor productivity, particularly in traditional retail environments. Existing studies on customer segmentation often focus on basic demographics (e.g., age and service usage duration). Against this backdrop, this study examines the effects of SSTs on sales dynamics, labor productivity, and customer segmentation in the retail context. The result of our study based on the difference-in-differences method identifies the reduction in traditional Point of Sale (POS) transactions, suggesting a shift toward fewer but larger purchases. We also observe fewer cashiers and a lower transaction workload, indicating increased efficiency at POS counters. Additionally, there is a notable decrease in unregistered customers after SST implementation, suggesting a shift toward a more identifiable and engaged customer base. This is vital for retailers looking to implement more focused marketing strategies and improve operational efficiency. The research provides detailed insights into how different types of customers and operational timings are affected by SSTs, offering valuable perspectives for future retail strategies and technology integrations. Overall, this study not only expands the existing body of literature on the effects of SST but also guides retailers in optimizing the use of technology to enhance both customer experiences and operational effectiveness in the digitalized retail landscape.

3 - Will Providing Return-Freight-Insurances Do More Good than Harm to Dual-Channel E-Commerce Retailers?

Jiaxin Lin, The University of Hong Kong, Hong Kong, China, People's Republic of, Tsan-Ming Choi, Yong-Hong Kuo

Today, e-commerce retailers commonly operate in a dual-channel mode. Return freight insurance (RFI) is an emerging measure to resolve online shopping disputes with product returns. In practice, some dual-channel e-commerce retailers offer RFI to consumers, while others do not. We build consumer-utility-based analytical models to study the retailer's optimal pricing decisions and values of RFI. In the basic models, we examine three cases, namely Case N (RFIs are not provided), Case R (retailer purchases RFI for consumers), and Case C (consumers pay for RFI). Comparing these three cases, we uncover that the retailer who purchases RFI for consumers does not necessarily charge a higher price. We show that if the RFI premium is sufficiently (moderately) low, it is more beneficial for consumers (the retailer) to pay for the RFI. We analytically prove that (i) when the product's salvage value is polarized or the return freight cost is low, using RFI can help increase consumer surplus (CS), (ii) when the salvage value is sufficiently high, the social welfare (SW) with RFI is higher than the case without RFI. In the extended models, we explore the situation in which consumers can decide whether to purchase RFI as well as the channel to buy the products. We find that (i) the retailer should provide RFI only when the product's cost, salvage value, and return freight cost are all high, and (ii) offering RFI can increase CS but hurt SW. We also consider various extended models to prove the robustness of the research findings.

4 - Modeling the Growth of Unorganized Pharmaceutical Retail Sector: A Critical Review Based on Indian Pharmaceutical Industry

Koushik Mondal, Indian Institute of Technology Kharagpur, Kharagpur, India, Balagopal G Menon

Retail industry serves as the final member of the supply chain that directly faces customer demand fluctuations and, by fulfilling them, generates cash flow which is the lifeline of all supply chain members. Presently, organized, unorganized and e-commerce retailers are fiercely competing for market share in the emerging countries for last two decades. Surprisingly, unorganized retailers have demonstrated remarkable resilience in the face of this competition. The literature on this 'competition' among different retail formats in emerging economies is limited and mostly empirical in nature. Most of the researches are survey or data based and analyzes the retail market dynamics from a model-free perspective. Empirical studies can capture the immediate effect of retail competition when a new organized retailer enters into the market, which initiates dynamic changes in consumer purchasing behavior, infrastructure, and public policy, particularly in emerging economies. It is pertinent to analyze how the retail landscape will become stable in long run and predict the equilibrium state especially in a developing economy like India. Moreover, big retail chains and e-commerce players are offering low prices, customer loyalty programs and extensive product variety that the unorganized sector is struggling to compete with. Presently, the unorganized sector has seen a drastic decline in market share due to high competition from organized and e-commerce, and demonetization; and Indian pharmaceutical industry is no exception to it. In this backdrop, present critical review discusses the existing researches towards understanding the unorganized pharmaceutical retail supply chain dynamics in general and specifically with Indian context.

5 - How Technology-Enabled Price Discrimination Interacts with Upstream Encroachment

Yu Jiang, University of Science and Technology of China, Hefei, China, People's Republic of, Jie Wu, Xiang Ji

With the rapid growth of the platform economy, an increasing number of online platforms and firms are using information technology to price discriminate based on the browsing and purchase histories of consumers. Meanwhile, in addition to selling through the large retail platforms, increasing numbers of firms from a variety of industries are establishing their own direct channels. This study examines the interaction between an upstream firm's encroachment decision and a downstream online platform's technology-enabled price discrimination (TPD) strategy. We find that an upstream firm has less incentive to encroach if the platform commits to adopting TPD than if it does not and prefers to enter if wholesale-TPD is allowed. Our research, thus, is the first to suggest that TPD can critically affect a firm's decision to encroach. On the platform side, we show that, in anticipation of a firm's encroachment, the platform is more likely to use TPD when the technology investment cost is low. We further identify the conditions under which a firm offers direct-TPD or wholesale-TPD. Our results show that a firm prefers to not adopt TPD in the direct channel, and the firm would adopt wholesale-TPD when it is not encroaching.

Neha Sharma, The Wharton School, University of Pennsylvania, Philadelphia, PA, United States

Analyzing reservation platforms

2 - Data Sharing and Website Competition: The Role of Dark Patterns

Chiara Farronato, Harvard Business School, Boston, MA, United States

Companies often obfuscate cookie preference policies and consent forms in order to nudge users to share their data more than they would otherwise do. These practices, known as "dark patterns," are pervasive despite their effects being poorly understood. With the use of Webmunk, a browser extension developed for research studies of this type, we explore the effects of dark patterns on consumers' privacy choices. We are particularly interested in exploring the role of limiting and emphasizing options in order to increase data sharing. We find that dark patterns are effective, particularly for less popular websites, for which the baseline willingness to share data is lower than for popular websites. Given that the effects of dark patterns differ across large and small companies, the ensuing firms' competitive advantages in consumer data are affected by regulation forbidding them.

3 - Online Matching with Heterogeneous Supply and Minimum Allocation Guarantees

Raghav Singal, Tuck School of Business at Dartmouth, Hanover, NH, United States, Garud Iyengar

Motivated by our interaction with a labor marketplace, we focus on matching jobs to workers with heterogeneous preferences. In each period, jobs arrive sequentially and need to be matched to a worker in an online manner. Each worker has three parameters: her work quality, capacity, and the minimum number of jobs she desires. The platform wishes to maximize the quality of matches via its online matching policy. We use our model to understand the limitations of simple policies and propose an optimal index-based policy. We supplement our theory with extensive numerics.

4 - Designing Effective Fundraising Campaigns

Pramit Ghosh, The University of Texas at Dallas, Richardson, TX, United States, Ignacio Rios, Anyan Qi

Charitable donations are a vital source of funding for non-profit organizations, enabling them to carry out their mission of addressing social issues and providing support to those in need. To enhance donations, fundraisers employ various designs aimed at increasing donations. However, budgets are often limited, and fundraisers must strategically decide on the optimal design choice that maximizes overall donations. This paper investigates the effectiveness of two design choices in the context of fundraising: (i) the incentive mechanism focusing on matching and gift unlock programs; and (ii) the solicitation mechanism, i.e., whether donations arrive simultaneously or sequentially. Our research findings highlight the importance of design choices in fundraising and provide insights to maximize donation outcomes.

Implications of Uncertainties and Market Power in Electricity Market Pricing

Invited Session

Revenue Management and Pricing

Chair: Cheng Guo, Clemson University, Clemson, SC, United States

Co-Chair: Bolun Xu, Columbia University, New York, NY, United States

1 - Endogenous Entry in Networked Markets

Cheng Guo, Clemson University, Clemson, SC, United States, Ozan Candogan, Jiayi Wang

We propose a competitive equilibrium model which allows price to form endogenously on a networked market with profit-maximizing firms. Our model considers a general topology, and studies the effect of various factors on pricing, such as demand levels and network structures. Our findings shed light on market entry incentives.

2 - Economic Capacity Withholding Bounds of Competitive Energy Storage Bidders

Bolun Xu, Columbia University, New York, NY, United States, Xin Qin, Ioannis Lestas

Economic withholding in electricity markets refers to generators bidding higher than their true marginal fuel cost, and is a typical approach to exercising market power. However, existing market designs require storage to design bids strategically based on their own future price predictions, motivating storage to conduct economic withholding without assuming market power. As energy storage takes up more significant roles in wholesale electricity markets, understanding its motivations for economic withholding and the consequent effects on social welfare becomes increasingly vital. This paper derives a theoretical framework to study the economic capacity withholding behavior of storage participating in competitive electricity markets and validate our results in simulations based on the ISO New England system. We demonstrate that storage bids can reach unbounded high levels under conditions where future price predictions show bounded expectations but unbounded deviations. Conversely, in scenarios with peak price limitations, we show the upper bounds of storage bids are grounded in bounded price expectations. Most importantly, we show that storage capacity withholding can potentially lower the overall system cost when price models account for system uncertainties. Our paper reveals energy storage is not a market manipulator but an honest player contributing to the social welfare. It helps electricity market researchers and operators better understand the economic withholding behavior of storage and reform market policies to maximize storage contributing to a cost-efficient decolonization.

3 - Pricing Stochastic Rolling-Window Dispatch

Cong Chen, Cornell University, Ithaca, NY, United States, Lang Tong

Integrating renewables, battery energy storage systems, and electric vehicles into power grids is crucial for decarbonization, yet it poses challenges to real-time grid operations due to uncertainties and intertemporal correlations. Rolling-window dispatch enables the power system operator to centrally schedule generations and demands akin to Model Predictive Control. By anticipating future time horizons, optimizing system dynamics, and accounting for stochastic renewables and demands, rolling-window dispatch proves effective in real-time operation under uncertainty. However, it can lead to a "missing-money problem," wherein market participants may be under-compensated due to imperfect forecasts and limited lookahead horizons.

In this presentation, we will demonstrate the inadequacy of uniform pricing mechanisms in providing dispatch-following incentives in rolling-window dispatch. Consequently, discriminative out-of-market uplifts are required to address the "missing-money problem." To tackle this issue, we propose a non-uniform pricing mechanism that incorporates discriminative intertemporal constraint-induced opportunity costs. Our approach eliminates the missing money problem and ensures dispatch-following incentives independent of forecast accuracy in stochastic rolling-window dispatch.

4 - Prequalifying Residential Distributed Energy Resources (Ders) for Providing Flexibility to Power Markets

Yijiao Wang, Johns Hopkins University, Baltimore, MD, United States, Benjamin Hobbs, Elina Spyrou, Michael Blonsky

With increasing amounts of intermittent renewables in the electricity mix, managing the high variability and uncertainty of these renewables is a growing challenge for grid operators. Flexibility from residential DERs can be used to hedge system reliability risks (supply-demand imbalances). We develop an advanced prequalification and validation technique for demand-based DERs to select aggregated small-scale residential customers for flexibility provision in day-ahead markets based on user characteristics of interest. Specifically, a set of indices depicting the reliability and responsiveness of DERs are developed and demonstrated focusing on the control of HVAC systems and water heaters. Based on the reliability indices, grid operators can identify the most cost-effective small-scale aggregation for various power market applications.

Innovative Platform Strategies

Invited Session

Revenue Management and Pricing

Chair: Yao Cui, Cornell University, Ithaca, NY, United States

Co-Chair: Wee Kiat Lee, Nanyang Technological University, Singapore, Singapore

1 - Voice Chatbot Design: Leveraging the Preemptive Prediction Algorithm

Shuai Hao, Southern University of Science and Technology, Shenzhen, China, People's Republic of, Yuqian Xu

This study delves into the design of voice chatbots, focusing specifically on leveraging prediction algorithms to enhance their creativity, and assesses the effects on different business performance metrics.

2 - Freelancers OR Employees? a Field Experiment with a Food Delivery Platform

Wee Kiat Lee, Nanyang Technological University, Singapore, Singapore, Yao Cui, Qi Li

The ongoing debate surrounding the regulation of gig platforms to classify service providers as employees rather than freelancers has generated significant industry discussions. However, the potential impact of such a transition on the operational efficiency of gig platforms is largely unknown. In this paper, we adopt an operational perspective to examine this issue. We collaborate with a food delivery platform and implement a field experiment in which orders are randomly routed to freelancers and employees. Using the experimental results, we compare the job performance between freelancers and employees, and derive insights into how a platform should adjust its operational policies when it changes the recruitment status of service providers.

3 - Information Aggregators to Transaction Facilitators: a Natural Experiment on a Trucking Platform

Vivek Choudhary, NBS, NTU, Singapore, Singapore, Zhenming Shi, Serguei Netessine

The e-commerce platforms can be broadly segmented into two primary types: information aggregators and transaction facilitators. The difference between the two types of platforms lies in integrating a transaction system within the platform. This transaction system allows parties to transact on the platform after being matched, unlike the information aggregators, where the transactions happen outside the platform. Many platforms start as information aggregators, and once they have large volumes of sellers and buyers, they transform into transaction platforms. How does this transformation impact different stakeholders? This study examines this question. Utilizing a quasi-experiment conducted by a major Chinese freight logistic platform, this research employs a Difference-in-Differences (DID) analysis of 2.6 million transportation records over five months in 2023 to empirically assess the impact of integrating transaction systems. Our findings indicate that enabling transaction functionality not only increases the weekly income of drivers by an average of 15% but also reduces the time for order acceptance and delivery costs, thereby benefiting all stakeholders involved. The analysis reveals that the increased income results from enhanced trust and better utilization of resources, where drivers are more willing to accept orders from unfamiliar requesters. However, the rate drivers earn drops, and for the same total amount, the drivers need to drive for longer distances and transport more goods.

Novel Applications of Pricing and Demand Modeling

Invited Session

Revenue Management and Pricing

Chair: Pelin Pekgun, Wake Forest University, Winston-Salem, NC, United States

Co-Chair: Sanghoon Cho, Texas Christian University, Fort Worth, TX, United States

1 - Hotel Room Category Overbooking Limits with Paid Upgrade Offers

Andrew Vakhutinsky, Oracle Labs, Burlington, MA, United States, Natalia Kosilova, Farbod Ekbatani

We describe an approach to optimizing booking limits for hotel room categories when the hotel guests are offered to pay for the upgrades to premium rooms. As is often the case, the demand for basic room categories may exceed their physical capacity while demand for premium rooms may be below the category capacity. In this situation, the hotel operators often allow excessive bookings in the basic category followed by complimentary upgrades in the premium category for the customers booking at the basic rate, which results in the loss of potential revenue. We propose a mechanism to couple overbooking of basic categories with offering basic category guests an upgrade to a premium room for a fee similar to the approach used in the Oracle Nor1 product. The optimal solution balances the marginal return rate of the basic category at the given booking limit with the expected future sales of the premium category at a certain level, which allows hotel operators to increase the booking limit and their key performance indicators such as revenue per room. We explain how this approach can be generalized to the case of multi-day stays and how to account for the cancellations of the bookings.

2 - Demand Estimation with Missing Data: Imputation-Based Approach

Sanghoon Cho, Texas Christian University, Fort Worth, TX, United States, Danhyang Lee, Andrew Vakhutinsky

Modeling demand and accurately estimating choice models based on product attributes are crucial for firms to forecast demand and optimize production and pricing strategies. Discrete choice models, such as the multinomial logit model, are popular in industries like retail, airlines, and hotels, especially with the rise of online platforms and increased pricing transparency. However, missing covariates challenge the practical application of these models. This paper addresses the issue of missing covariates in estimating discrete choice models, focusing on scenarios where essential covariate information, such as prices, is missing for unsold products. We propose a novel imputation method based on an odds ratio modeling framework, extending the exponential tilting model to handle multivariate nonignorable missing mechanisms. Additionally, we introduce a simplified dependence structure among covariates to manage severe missing problems.

3 - The Spillover Effects of Giveaways on Gaming Platforms: Evidence from a Quasi-Experiment on Steam

Campbell Clarkson, University of South Carolina, Columbia, SC, United States, Simin Li, Necati Tereyagoglu, Sriram Venkataraman

We investigate the spillover effects of competitor promotions on the Steam platform's user engagement, utilizing the introduction of a game giveaway program by Epic Games, one of Steam's competitors. We also examine whether these spillover effects are driven by increased online popularity of giveaway games using traffic data from Twitch.tv, a livestreaming platform. Finally, we assess which game- and platform-specific features may act as mechanisms for spillovers to occur.

4 - Subscription vs. Selling for Digital Goods Supply Chains in the Presence of Piracy

Hongseok Jang, Tulane University, New Orleans, LA, United States, Janice Carrillo, Kyung Sung Jung, Young Kwark

Recent press coverage of piracy and digital goods touts the practice of subscription as a “piracy killer.” However, the effectiveness of digital goods subscriptions remains controversial in terms of the profitability for different supply chain members. Specifically, the dearth of existing studies concerning business model choices in distribution channel structures indicates that the literature has yet to provide a comprehensive answer to this question. Therefore, we develop an analytical model to investigate the optimal business model choices for digital good firms with the existence of digital piracy in a centralized supply chain (CSC) or a decentralized supply chain (DSC) explicitly considering heterogeneous consumer usage rates. Unique to the current literature, we find that illegal copies serve as a substitute for a different set of consumers, depending on the business model used by the firms. There are circumstances under which the firms optimally allow high-usage consumers to adopt illegal copies in the subscription model. In contrast, illegal copies can also serve as a substitute for the low-usage consumers in the selling-ownership model. Unlike current literature, we identify situations in a CSC whereby the selling-ownership model (a) is more profitable and (b) has fewer illegal goods adopted than the subscription model when piracy is present in the market. When analyzing a DSC, we find that the existence of piracy can actually aid in the coordination of the supply chain because of the interplay between the consumer targeting effect and the inefficiency mitigation effect enabled by digital piracy.

Energy Power Systems Management

Contributed Session

Chair: Jehum Cho, Erasmus School of Economics, Rotterdam, N/A, Netherlands

1 - Assessing Zonal System Inconsistencies on Power Network Security in Real-Time Operations

Jehum Cho, Erasmus University Rotterdam, Rotterdam, Netherlands, Anthony Papavasiliou

Zonal market systems encounter numerous challenges associated with network congestion. Controlling cross-border power flows at the zonal level further exacerbates issues such as unexpected violations of capacity limits on both intra- and inter-zonal transmission lines. In day-ahead markets, re-dispatch processes can alleviate some of these problems. However, in balancing markets, there is no time to address these inconsistencies. Such discrepancies in real-time operations are directly related to the safety concerns of the network. In this talk, we introduce a method for analyzing the discrepancy between nodal and zonal systems. Nonlinear behaviors of zonal systems, due to the merit order for each zone, are captured using merit-order constraints with binary variables. This allows us to represent the true feasible region of zonal net positions that ensures security in real-time operations. By comparing this feasible region subject to merit-order constraints with the one derived from existing zonal models, one can determine the extent of system distortion in terms of feasibility. We analyze the conditions under which zonal systems can avoid congestion and evaluate the impact and usefulness of the minimum cross-border capacity policy.

2 - Bidding on Combinatorial Electricity Auctions

Thomas Hübner, ETH Zurich, Zurich, Switzerland, Gabriela Hug

Day-ahead markets are one of the core elements of a liberalized energy system and allow energy to be traded for the next 24 hours in advance. In Europe, it is designed as a combinatorial auction where agents can bid not only on power for single hours but also on bundles of power in different hours by so-called block bids. This allows agents to express their complementarities between hours caused by inter-temporal constraints or quasi-fixed costs. However, it also complicates the bidding decision as the number of bundles feasible to an agent might be exponential regarding the number of hours. As an auctioneer constrains the number of bids by an agent to ensure a tractable market clearing problem, the question arises of which bids to select. In case of a sub-optimal bid selection, agents do not achieve their maximal attainable utility, leading to an overall welfare loss. We take the agent's perspective to study the action design and give decision-support tools to place bids more effectively.

3 - Exploring “Antifragility” for power systems: concepts, applications, and call for actions

Ming Jin, Virginia Tech, Blacksburg, VA, United States

This study investigates the transformative concept of antifragility and explores computational mechanisms to enhance the resilience of power systems. Antifragile systems possess the unique ability to improve and grow stronger when exposed to challenges. To operationalize this concept, we introduce two recent computational approaches for power system resilience: (1) in-context learning with transformer architecture and weak classifiers for zero-day attack detection, and (2) a hierarchical meta-reinforcement learning framework for critical load restoration. The presentation further discusses the importance of a safety-first approach, complementing existing solutions, and leveraging computational innovations to build antifragile power systems. We aim to inspire a collective effort to lay the foundation for computational antifragility, paving the way for more resilient and self-improving infrastructure in the face of increasing uncertainties and threats.

4 - Optimizing Investments in Transmission and Storage with Stochastic Dominance

Miguel Carrion, Universidad de Castilla - La Mancha, Toledo, Spain, Ruth Domínguez, Sebastiano Vitali

Increasing intermittent renewable generation to meet climate goals requires transforming current power systems to ensure rapid and flexible responses to energy flow changes. This work addresses the investment problem faced by transmission expansion planners seeking to expand the transmission network and deploy storage units for decarbonization efforts. We propose a two-stage stochastic problem considering uncertainty in demand growth. Representative days are used to characterize demand and renewable power variability. To optimize expansion strategies while satisfying emission limits, we include second-order stochastic dominance constraints. Numerical analyses using a realistic power system show that installing storage units is vital for efficiently integrating renewable generation. Additionally, investments in the transmission system focus on lower-voltage lines. Formulating the problem with stochastic dominance constraints leads to increased second-stage investments, facilitating better adaptation to evolving demand growth.

Applications of Federated and Distributed Learning Frameworks

Invited Session

Decision Analysis Society

Chair: Michael Ibrahim, Georgia Institute of Technology, Atlanta, GA, United States

1 - Federated Anomaly Detection in Vertically Partitioned Datasets

Ayush Mohanty, Georgia Institute of Technology, ATLANTA, GA, United States, Paritosh Ramanan, Dan Li, Nagi Gebraeel

In today's industrial landscape, the proliferation of Internet of Things (IoT) technology has ushered in an era where large-scale systems generate high-dimensional data from diverse sources. These systems are characterized by multiple interconnected components, each equipped with numerous sensors, resulting in a plethora of multivariate time-series data. However, the logistics of centrally aggregating this data pose significant challenges. In this talk, we present a federated learning framework tailored to address the complexities of systems where raw time-series data are distributed across a multitude of components. Unlike traditional methods that require central aggregation of sensor data, our framework operates by capturing the inter-dependencies across components without the need for data movement. We present the theoretical underpinnings of the framework, demonstrating its performance against model-based approaches reliant on centralized data aggregation. We also showcase its practical utility by applying it to the anomaly detection problems, highlighting its ability to assess root causes in real-time, without moving the high-dimensional sensor data.

2 - A Distributed Distributionally Robust Support Vector Machine

Michael Ibrahim, Georgia Institute of Technology, Atlanta, GA, United States

We study the problem of training a distributionally robust (DR) support vector machine (SVM) in a distributed fashion over a network comprised of G clients and one central server, where the clients can only communicate with the server, and the data collected locally at the clients cannot be shared. To achieve this, we propose a novel ambiguity set that relies on local Wasserstein balls centered at the empirical distribution of the data at each client. We then demonstrate that this ambiguity set allows for the DR problem to be reformulated in a separable fashion. We then study out-of-sample performance guarantees associated with our ambiguity set, demonstrating that the probability that the true distribution $\mathbb{P}$ governing the data belongs to the ambiguity set is related to the radii of the local Wasserstein balls. Subsequently, we propose two algorithms that can be used to solve our proposed model: i) a subgradient method-based algorithm, and ii) an alternating direction method of multipliers (ADMM)-based algorithm. We derive the optimization problems to be solved by each client and closed-form expressions for the computations performed by the central server during each iteration for both algorithms. Finally, we carefully examine the performance of the proposed algorithms in a series of thorough numerical experiments utilizing both simulation data and popular real-world datasets.

3 - Federated Multilinear Principal Component Analysis with Applications in Prognostics

Yuqi Su, North Carolina State University, Raleigh, NC, United States, Chengyu Zhou, Tangbin Xia, Xiaolei Fang

Multilinear Principal Component Analysis (MPCA) is a widely utilized method for the dimension reduction of tensor data. However, the integration of MPCA into federated learning remains unexplored in existing research. To tackle this gap, we propose a Federated Multilinear Principal Component Analysis (FMPCA) method, which enables multiple users to collaboratively reduce the dimension of their tensor data while keeping each user's data local and confidential. The proposed FMPCA method is guaranteed to have the same performance as traditional MPCA. An application of the proposed FMPCA in industrial prognostics is also demonstrated. Simulated data and a real-world data set are used to validate the performance of the proposed method.

4 - Distributed Estimation of Inter-Dependencies in Multi-Component Systems

Nazal Mohamed, Georgia Institute of Technology, Atlanta, GA, United States, Ayush Mohanty, Nagi Gebraeel

The integration of sensors and IoT devices has created a network of interdependencies between different systems of an enterprise, each with its own unique data storage and computing resources. This appears in industrial applications like power plant operations, supply chain networks, and some large manufacturing enterprises. Understanding the interdependencies between components of these decentralized systems is important for improved productivity and reliability. In this presentation, we consider a stylized setting where the objective is to estimate a state matrix of a linear time-invariant (LTI) state space model in a decentralized manner without the need for data centralization. The state matrix helps us understand and quantify these interdependencies. This can be very beneficial in settings where system components generate high-dimensional data. We provide theoretical insights into system identifiability in a decentralized setting. We also examine the accuracy of our decentralized estimation approach and study its scalability.

5 - SplitVAEs: Decentralized Scenario Generation from Siloed Data for Stochastic Optimization Problems

H M Mohaimanul Islam, Oklahoma State University, Stillwater, OK, United States

Stochastic optimization problems in large-scale multi-stakeholder networked systems (e.g., power grids and supply chains) rely on data-driven scenarios to encapsulate uncertainties and complex spatiotemporal interdependencies. However, centralized aggregation of stakeholder data is challenging due to privacy, computational, and logistical bottlenecks. In this paper, we present SplitVAEs, a decentralized scenario generation framework that leverages the split learning paradigm and variational autoencoders to generate high-quality scenarios without moving stakeholder data. With the help of largescale, distributed memory-based experiments, we demonstrate the broad applicability of SplitVAEs in three distinct domain areas: power systems, industrial carbon emissions, and supply chains. Our experiments indicate that SplitVAEs can learn spatial and temporal interdependencies in large-scale networks to generate scenarios that match the joint historical distribution of stakeholder data in a decentralized manner. Our results show that SplitVAEs outperform conventional state-of-the-art methodologies and provide a superior, computationally efficient, and privacy-compliant alternative to scenario generation.

Health Care Resource Planning

Contributed Session

1 - Identifying and Understanding the Socioeconomic Factors that have an impact on Hospital Readmissions Rates

Aindrila Chakraborty, Metro State University, St Paul, MN, United States, Jaymeen Shah

Hospital readmissions is a major issue in the healthcare industry today, serving as a crucial indicator of the quality of care patients receive and the related costs. Hospitals are subject to significant penalties for exceeding the expected levels of readmissions each year. Furthermore, studies have shown that a considerable proportion of these readmissions are preventable. Therefore, identifying and understanding the factors leading to hospital readmissions and predicting future occurrences based on these factors are essential tasks for hospitals aiming to lower their readmission rates and enhance patient care quality. Significant research has been conducted to evaluate the effectiveness of programs designed to reduce hospital readmissions by penalizing hospitals for excess rates. Several other research has focused on chronic diseases as a major cause of readmissions. However, there remains a lack of comprehensive studies examining how socioeconomic status and insurance factors contribute to the readmission rates. Our research employs a data-driven approach to explore these socioeconomic drivers using a nationwide dataset. Analyzing the readmission issue from a data analytics perspective is critical as this is a complex interdisciplinary issue as shown in the literature that requires a combined efforts of data analysts besides physicians, healthcare providers, and insurance companies. The findings from our study are intended to provide valuable insights for public health authorities and policymakers, guiding the development of policies and strategies for better treatment and post-discharge care that could decrease readmission rates and associated healthcare costs.

2 - Infection Aware Nurse Staffing

Buyun Li, Kelley School of Business; Indiana University, Bloomington, IN, United States, Jonathan Helm, Pengyi Shi, Kurt Bretthauer

Problem Definition: During outbreaks of infectious diseases, hospitals encounter significant challenges in making well-informed decisions regarding nurse staffing. The crisis in nurse staffing during these outbreaks arises from a simultaneous increase in patient admissions due to the outbreaks and a notably elevated rate of nurse absenteeism caused by infections. The unobservable nature of the infection time and incubation period for these infectious diseases adds complexity to understanding when and how nurses are infected. Lack of this critical information restricts hospital managers from deploying effective and informed operational strategies and staffing plans, thereby limiting their ability to proactively address the staffing crisis.

Methodology/Results: Utilizing data from the IU-Health hospital system during the COVID-19 pandemic, we first develop a Cox proportional hazard model to identify important clinical and operational features for predicting nurse absenteeism caused by infections. Then, we extend standard random graph models to handle the hidden status of nurse infections to capture the disease transmission dynamics with specific probabilistic inference on unobservable/unknown time points of when a nurse is infected or starting to show symptoms. Our model identifies infections from different sources and locations. We gain insights from our model by evaluating mitigation and staffing policies through counterfactual analysis.

Managerial Implications: We find that hospitals can effectively lower the number of nurse infections by designating dedicated units for infectious patients, providing regular testing for infections, and promoting vaccinations. Additionally, staffing decisions play an important role in nurse infection prevention. An ideal staffing level could lower infections by almost 30%.

3 - Predicting All-Types Hospital-Acquired Conditions for Working Age Adults with Multimorbidity Patterns Accounting for Individual Disparity and Structural Racism Effects

Ajit Appari, Boston University, Boston, MA, United States

Hospital-acquired conditions (HACs) are common, costly, and national patient safety priority. Patients with multimorbidity (presence of two or more chronic conditions) require complex care during hospitalization posing significant challenges for clinicians. Prior research often focused on building machine learning models for specific or a subset of HACs among adult population with specific anchor chronic disease and/or adjusting for Charlson or Elixhauser comorbidity indexes.

In my study, I focused on building machine learning models for predicting composite risk of multiple hospital acquired conditions (MHAC) among working age adults having different multimorbidity patterns adjusting for individual disparity factors {age, sex, race/ethnicity, insurance}, structural racism factors {Neighborhood Disadvantage (e.g., poverty, unemployment, households on state income support, and higher proportion of Blacks), Neighborhood Affluence (highly educated, high income population) and Hispanic & Immigrant Concentration}, and provider factors (hospital characteristics).

I used all payer administrative data on 1,645,126 hospitalizations (age: 18-64years) during 2015Q4-2016Q4 across 642 hospitals in Texas. Patients were coded for 69 chronic condition categories (reflecting 4400+ ICD10 diagnosis-and-procedure codes) and grouped into 10 different multimorbidity patterns using unsupervised learning method- Block Clustering with Bernoulli Mixture Models that leverages block classification expectation maximization algorithm. Subsequently, patients were coded for multimorbidity pattern complexity (number of chronic conditions from each patterns) to quantify potential complexity of care needs for presence of such patterns. Finally, I build and evaluate composite risk prediction model for MHACs using Zero-Inflated Negative Binomial Regression, and XGBoost Hurdle Model accounting for multimorbidity pattern complexity, individual disparity factors, structural racism factors, and provider factors.

4 - An Extended Latent Class Choice Model for Characterizing Context-driven hospital choice

Jungwoo Kim, KAIST, Daejeon, Korea, Republic of, Taesik Lee

In the domain of healthcare systems, understanding individuals' choice-making processes is crucial for effective system design and optimization. This is especially pronounced in ambulatory care, where patients are allowed to freely choose a hospital based on their preferences. Hospital choice can be illustrated as context-driven, where explanatory variables affect choices differently depending on the context (e.g., distance's effect varies with sickness severity). To address this, we propose a novel structure of Discrete Choice Model, aiming to provide a comprehensive characterization of context-driven preferences. Our method builds upon the Latent Class Choice Model (LCCM), to better capture the diverse preferences(utility functions) among individuals, improving both interpretability and flexibility. We integrate a membership classification model into LCCM, linking contexts to latent classes of utility functions. Moreover, we propose a structure allowing distinct membership classification models with varying numbers of classes for each subject variable. This approach accommodates different specifications of heterogeneity, enriching details of context-driven preference while also addressing overfitting and data scarcity issues. To estimate this complex structure, we develop an estimation method based on the Expectation Maximization algorithm, with numerical experiments confirming the robustness of our methodology. Our extended LCCM offers comprehensive insights and reliable forecasts for systems featuring complex choice-makers. We anticipate that this capability will provide foundational knowledge when devising policies, interventions, and system modifications to tackle issues in ambulatory healthcare systems and other fields.

Energy Consumption and Decarbonization

Contributed Session

Chair: John Paul Pieper

1 - China's Coal Resource Supply-Demand Pattern and "Dual Carbon" Development Strategy Simulation

Li Feng Shi, Tianjin University, Tianjin, China, People's Republic of, Xinyan Jiang, Jiatong Ji, Meixuan Xin, Junying Liu

The energy endowment characteristics of "rich coal, poor oil, and less gas" in China determine the significant role played by the reform of coal resources on the road to achieving the "Dual Carbon" goal. This paper focuses on coal resources, analyzing the supply and demand pattern of China's coal energy products and simulating the development strategy of "Dual Carbon" to aid in achieving the "Dual Carbon" goal. Firstly, starting from the spatial heterogeneity distribution of coal resources, this paper studies the spatial and temporal evolution process of producers and consumers identities in different provinces in the field of coal resources. Secondly, this paper employs the SBM model with undesired output to measure the total factor energy efficiency of each province during the sample period, conducting a comparative analysis based on temporal evolution and regional differences. Finally, this paper selects Shanxi, Shaanxi, and Inner Mongolia, three major coal resource supply provinces of China, as the coal producers, and the Yangtze River Delta, Pearl River Delta, and Beijing-Tianjin-Hebei, three major urban agglomerations of China, as the coal consumers. Building upon this, a system dynamics model of the carbon emission system is constructed. By adjusting key variables in the system, this paper simulates the supply and demand bilateral optimization policy and investigates the impact of policy implementation on China and the Shanxi-Shaanxi-Inner Mongolia region in terms of economy and environment.

2 - Infrastructure planning for cross-border renewable electricity imports: A Stochastic Programming Approach

S Viswanathan, Nanyang Technological University, Singapore, Singapore, Haifeng Qiu , Tobias Massier, Thomas Hamacher

Cross-border renewable electricity imports based on multilateral cooperation can assist countries scarce in renewable energy resources in their roadmap to net zero carbon emissions. In this paper, we develop a two-stage stochastic programming model to determine the optimal infrastructure planning as well as scheduling of importing cross-border renewables with intrinsic short-term intermittency and long-term uncertainty, thus ensuring stable and reliable connection and synchronization of renewable importing sources with the receiving-end power grid from the perspective of technical requirements. Techno-economic evaluation of importing electricity into Singapore from several Southeast Asian countries using the five-years meteorological and load data is carried out in this research. The results indicate that importing electricity through dedicated long-distance cables might be a viable option once the country-level agreements are ironed out. We also perform sensitivity analysis on several of the strict criteria for renewable importation. A new hybrid system planning framework combining both on-site and sharing energy storages demonstrates that leveraging the complementary roles of multi-location importing renewables with a balanced capacity blend of the wind and solar generation breaks through their independent bottlenecks and improves the overall economies. Our results provide a design methodology for power system infrastructure planning for renewable electricity imports, and this could help spawn more renewable energy projects in exporting and importing countries in a win-win fashion.

3 - The Impacts of the Covid-19 Pandemic on the Macroeconomic Efficiency of the OECD Countries

Umit Saglam, East Tennessee State University, Johnson City, TN, United States

In this study, a two-stage Data Enveloped Analysis (DEA) is developed to quantitatively evaluate the impact of the Covid-19 pandemic on macroeconomic efficiencies of the OECD countries by using pre-determined inputs (population, labor, capital stock, and energy consumption) and outputs (real GDP and carbon dioxide emission) variables. The Slack-Based Model (SBM) will be applied to determine undesirable outputs and calculate each country's capital, labor, energy, and emission efficiency. Second, the Malmquist Productivity Index (MPI) is developed to compare productivity changes during the pre-pandemic and pandemic. Third, the sensitivity analysis is conducted to test the robustness of the DEA models. Finally, Tobit regression models are conducted using the second stage analysis's DEA results to investigate the effects of the pandemic. We hope this study's results shed some light on the efficiency assessments of the OECD countries and their productivity changes during the pre-pandemic and pandemic.

4 - Under the goal of carbon neutrality, regional cooperation in reducing emissions can drive economic growth? An empirical examination from the two provinces of Jiangsu and Anhui in China

Jianmin Wang, School of Economics & Management Anhui University of Science and Technology, Huainan, China, People's Republic of, Yang Li

The study proposes emerging issues in the field of carbon neutrality research, that is, whether regional cooperation in emissions reduction under carbon neutrality goals can drive economic growth. Based on the accurate description of the regional economic structure using the 2017 regional input-output table and computable general equilibrium modeling method of Jiangsu and Anhui provinces in China, an empirical investigation was conducted on the economic effects of regional cooperation in emissions reduction under carbon neutrality goals in these two regions. The study found that: (1) With the continuous advancement of regional cooperation in emissions reduction under carbon neutrality goals, multiple economic indicators have been affected and show a systematic expanding trend. (2) Jiangsu and Anhui have different capabilities in dealing with the reduction in fossil fuel use based on their existing economic structures. (3) Regional cooperation in emissions reduction under carbon neutrality goals is advantageous in reducing the economic impacts of dispersed emissions reduction and the absolute economic costs. The study concludes that: (1) Phased development plans for clean energy should be formulated to gradually reduce regional reliance on fossil fuels. (2) Carbon neutrality goals should be steadily promoted based on regional emissions reduction capacity. (3) Accelerating the construction of regional cooperation mechanisms for emissions reduction and establishing a cooperative emissions reduction mechanism under carbon neutrality goals. The research findings may provide experiential insights and policy reference for other countries or regions in the process of achieving carbon neutrality goals while promoting economic growth.

5 - Transportation Decarbonization that is Robust to Global Material Supply Concerns

John Paul Pieper, Carnegie Mellon University, Pittsburgh, PA, United States

Transportation is now the largest source of greenhouse gas (GHG) emissions as well as a major source of local air pollution in the United States, and electrifying vehicles is crucial to decarbonizing the sector. Electric vehicle (EV) batteries contain critical materials that face heterogenous supply chain vulnerabilities due to geographic constraints within up- and mid-stream production. There exists a need for responsive manufacturing to increase firm flexibility in short run EV production to minimize production costs increases due to supply disruptions of critical materials.

We study the value of firm flexibility using a case study of EV production that includes multiple options for flexibility to mitigate supply chain disruptions, including switching battery chemistries or stockpiling critical materials within "medium" run production. Our analysis builds on engineering real option and electric vehicle production model literature to provide novel perspectives of flexible options for EV firms. Using real options analysis, this work will quantify the value of flexibility under supply chain uncertainty by modeling the manufacturing costs, the change in expected consumer adoption of EVs dependent on the performance characteristics, and the risk of undesirable impacts to EV production, manufacturing workers, and U.S. households under different disruption scenarios.

Our preliminary results suggest that stockpiling strategies maintain consumer adoption rates in the presence of disruptions by giving firms options that decrease production costs. We predict battery switching strategies will both maintain EV consumer adoption rates and allow for opportunistic firm behavior by creating more flexible battery production processes.

Chair: Shi Qiu, University of Illinois Urbana-Champaign, Urbana, IL, United States

1 - Forecasting Supply Chain Disruption with Heterogeneous Time Series

chaoye pan, Ford Motor Company, Dearborn, MI, United States, Bach Viet Do, Xingyu Li

Operational disruptions have an adverse material impact on the company's performance. Ford operates 37 plants globally, utilizing 17 billion parts annually to manufacture six million cars and trucks. The company has up to 10 tiers of suppliers between itself and raw material. An extended disruption anywhere within this extensive supply chain can inflict substantial financial losses on Ford. The capacity to forecast and identify such disruptions early is crucial to maintain a seamless operation. In the modern era of Big Data, data on suppliers' past performance has increasingly become a valuable source for the analysis and prediction of disruption risks. In our work, we leverage multivariate time series data to forecast supply chain disruptions. This dataset presents significant challenges due to its complexity and vast scale, consisting of over five hundred thousand individual series. The series may exhibit similarities to a certain degree, yet they also demonstrate heterogeneity within specific subgroups. Consequently, traditional industrial and statistical models are limited in capturing the complex dynamics and managing the extensive volume of data. In this presentation, we propose a novel methodology that integrates a modified Attention Sequence to Sequence model Deep Learning Neural Architecture with a Survival Analysis model, to learn intricate data patterns pertaining operational disruptions. Our model has demonstrated a performance with 85% precision and 80% recall during the Quality Assurance (QA) phase across Ford's five North American plants.

2 - Supply Chain Risk Identification: A Practice-based View

Aaron Heinrich, Texas A&M University/Department of Information and Operations Management, College Station, TX, United States, Trevor Hale

Institutions with internalized supply chains regard the finished goods of their operations processes as raw materials they need to produce and deliver the final services and goods they provide customers. For example, a city (an institution) can enforce its laws (a service) for its citizens (its customers) only by sourcing a sustainable supply (an internalized supply chain) of credentialed police officers (both finished goods and raw material inventories) from the police academy it operates (operations process). To identify potential sources of disruption to such supply chains, we analyze empirical data collected from a U.S. nuclear utility that operates an internalized supply chain of credentialed professionals and find its disruptions to be associated with idiosyncrasies in its training programs rather than in its trainees, which upends conventional wisdom. Upon synthesizing two theories from the domains of knowledge management and educational psychology with empirical data collected across multiple industries, we hypothesize and test whether the extent to which training program instructors cognitively apprentice their trainees is related to the extent to which institutions are vulnerable to supply chain disruptions. Our findings permit us to contribute a novel, practice-based view to supply chain risk management and provide actionable insights to operations managers.

3 - Designing An Apparel Closed-Loop Supply Chain Network Using a Robust Multi-Objective Programming

Saman Hassanzadeh Amin, Toronto Metropolitan University, Toronto, ON, Canada, Samira Rouhani , Leslie Wardley

In this talk, designing and optimizing an apparel closed-loop supply chain network is discussed. Several elements such as types of returns, including commercial, end of use, and end of life returns are considered in this network. To design the network, a multi-objective mixed-integer linear programming model based on robust optimization is developed. Then, the results are discussed based on an application in Canada, and the managerial insights are provided. The results show that the proposed model can handle uncertainty under different sustainability objective functions.

4 - The Supply Chain Pressure Index (SCPI): A Predictive Analytics Tool for Agile Supply Chain Risk Management

sein kim, Kyungpook National University, DAEGU, Korea, Republic of, Sungsu Kim

The Supply Chain Pressure Index (SCPI) is an innovative analytical tool developed to measure and mitigate pressures within global supply chains for supply chain risk management, focusing particularly on potential stress factors such as supply-demand imbalances, logistical bottlenecks, and market volatility. This focus sharply contrasts with the broader scope of the Global Supply Chain Pressure Index (GSCPI), which primarily assesses traditional pressure metrics. The proposed SCPI enables more adaptive strategies to changes than the GSCPI's long-term pressure assessments. Additionally, the SCPI integrates various new data sources, including social media, sensor data, and market trends, capturing previously overlooked pressure elements within the supply chain. By incorporating advanced analytics, the SCPI would provide targeted insights that accurately identify critical vulnerabilities and guide immediate corrective actions, significantly reducing risks and enhancing quicker responses to supply chain pressures. The goal of this study is to establish the SCPI as the global standard for agile supply chain risk assessment. Its adoption is expected to lead to significant advancements in global supply chains by integrating advanced diagnostics to proactively manage and mitigate supply chain pressures.

5 - Leveraging Blockchain Technology to Mitigate the Bullwhip Effect in Supply Chains: A Theoretical Model and Empirical Analysis

Shi Qiu, University of Illinois Urbana-Champaign, Urbana, IL, United States, Sridhar Seshadri

The bullwhip effect, which manifests as increasing demand variability up the supply chain, creates significant inefficiencies in supply chain operations. This paper investigates the potential of blockchain technology to mitigate this phenomenon. We develop a theoretical model that incorporates demand uncertainty and imperfect demand prediction, examining how blockchain's attributes—such as enhanced transparency, immutability, and smart contracts—can improve information sharing and coordination among supply chain participants. The model posits that blockchain can reduce demand amplification by providing real-time, accurate data and fostering trust among parties. We empirically test our model using observational data from supply chains that have implemented blockchain solutions. The results demonstrate that blockchain adoption can significantly decrease demand variability and enhance supply chain performance. This study contributes to the Operations Management literature by offering a novel perspective on addressing the bullwhip effect through blockchain technology.

Optimizing Delivery and Logistics with AI and Crowdsourcing

Contributed Session

Chair: Yooneun Lee, University of Dayton, 300 College Park, Dayton, OH, 45469, United States

1 - A Multi-agent Reinforcement Learning-based Order Dispatching in Delivery Platforms with Diverse Strategic Couriers

Jaewon Choi, Pohang University of Science and Technology, Pohang, Korea, Republic of, Daeho Kim, Dong Gu Choi

Efficiently dispatching orders to couriers has become one of the core technologies of modern on-demand delivery platforms. Particularly, the problem of allocating dynamically occurring requests to multiple service providers has been covered in the field of management science and operations research. However, the diversity of service providers and their strategic decision-making process has not been fully considered. In a realistic delivery platform environment, couriers have the rights to reject assigned orders, and the platform operator must take this into account while dispatching orders. Also, couriers feature different performance capabilities depending on their proficiency and this heterogeneity influences their acceptance behavior. We develop a framework to intelligently dispatch orders within a delivery platform based on a multi-agent Markov decision process model considering strategic couriers. We then verify the effectiveness of our logic in a dynamic simulation environment based on real-life data.

2 - End-to-End Trip to Driver Dispatchment Timing of Scheduled Delivery: A General Decision-Making System for Crowdsourced Delivery Platforms

Soumita Saha, Walmart Global Tech India, Bangalore, India, Tao Cao, Ankit Dhokariya, Weihang Ren, Minghui Liu, Yuan Wang, Sherry Wan, Jing Huang, Mingang Fu, Prakhar Mehrotra, Chittaranjan Tripathy

Crowdsourcing delivery platforms used to face most demand from real-time on-demand requests. Recently, with increasing adoption by ecommerce retailers, we observed a shift of demand pattern from on-demand to scheduled delivery requests. The increasing reliance on crowdsourced drivers for scheduled deliveries presents a new challenge. That is, the timings through the process of dispatching trips to drivers set the foundation of the delivery journey. Despite the critical role of end-to-end dispatch timing decisions, there has been a paucity of holistic approaches to this decision-making process that ensure cost-efficient, on-time deliveries. We present a novel system designed to optimize the end-to-end driver dispatch timing decisions. The system begins by predicting time durations of segments throughout delivery journeys. It then utilizes simulation, stochastic programming, and survival regression modeling to optimally determine arrival time of drivers, start time of driver dispatch, and initialization time of surge pay. The objectives are maximizing time and cost efficiency in dispatch process while meeting promised delivery time for customers. Our novel decision-making system is adaptable to dynamic market conditions through configurable parameters, which are learned automatically via market segmentations. We have implemented this system on Walmart's proprietary crowdsourced last-mile delivery platform. Our simulation and experimentation studies indicate significant improvements in dispatch efficiency, by reducing 55% dispatch idle time compared to previous solutions while maintaining high on-time delivery rates. Our work demonstrates that the framework underlying the system has the potential to enhance delivery experiences across other crowdsourced delivery platforms, where on-time delivery promise for customers are foundational.

3 - The Multichannel Last-Mile Delivery Problem with Crowdsourcing Integration

Sang Jin Kweon, Ulsan National Institute of Science and Technology (UNIST), Ulsan, Korea, Republic of, Jaesung Kim

In recent years, crowdsourcing has gained attention in last-mile logistics. This study addresses the multichannel last-mile delivery Problem integrating crowdsourcing options. We propose a delivery pricing strategy to incorporate individual crowdsourced fleets into the platform. Our mathematical model optimizes terminal locations for delivery-dedicated and individual crowdsourced fleets, aiming to minimize total last-mile delivery costs amid fluctuating demand and pricing based on a city's floating population. Experimental findings demonstrate significant cost reductions by strategically deploying crowd workers in densely populated areas rather than merely proximity to final delivery destinations. Additionally, we examine the cost and carbon emissions implications of integrating crowdsourcing and deploying electric vehicles for last-mile deliveries.

4 - Optimizing Order Consolidation and Vehicle Routing for Multi-Warehouse Retailers: A Mixed Integer Linear Programming Approach

Yooneun Lee, University of Dayton, Dayton, OH, United States, Nikesh Chithambaram, Seokgi Lee, Hyeong-Suk Na

Order consolidation has emerged as a viable solution to address the last-mile delivery challenges faced by online retailers dealing with higher volumes and frequencies of customer orders. However, making order consolidation decisions is complex due to various order time frames, the diverse range of items managed and fulfilled by multiple warehouses, and the absence of efficient algorithms to synchronize consolidation decisions with vehicle routing and dispatching. This study presents order consolidation policies and addresses the vehicle routing problem for a retailer operating multiple warehouses, aiming to simultaneously optimize order fulfillment and shipment costs. The problem is formulated as a mixed integer linear programming (MILP) model. The proposed scenarios for solving this problem are analyzed to provide practical recommendations. Furthermore, the study compares the results with those obtained from a reinforcement learning algorithm developed in a previous study, demonstrating the efficiency of the heuristic algorithm.

Economic Strategies for a Sustainable Future

Contributed Session

Chair: Takuro Murakami, Keio University, Yokohama, N/A, Japan

1 - Forecasting the Success of International Joint Ventures

Aws Hamo Younes, Durham University , Durham, United Kingdom, Konstantinos NIKOLOPOULOS, Michel Phan

A joint venture is a business partnership where two or more companies work together on a specific project, sharing resources and risks. Each company keeps its own identity while collaborating to achieve a common goal. Partner selection can be defined as the process of seeking, evaluating, and finally choosing the right partner to achieve the firm's strategic growth objectives in a specific host country. Country Governance is defined as the traditions and institutions by which authority in a country is exercised. There are six dimensions of governance are constructed based on this definition; Voice and Accountability (VA), Political Stability (PV), Government Effectiveness (GE), Regulatory Quality (RQ), Rule of Law (RL) and Control of Corruption (CC).

In an increasingly globalized world, firms aiming to stay competitive in international business must explore foreign markets and many multinational enterprises (MNEs) from developed countries use Foreign Direct Investment (FDI) as a strategy to enter markets in developing economies, benefiting from local knowledge and connections. Due to external uncertainties and the challenges of operating in a foreign market, MNEs often prefer forming International Joint

Ventures (IJVs) with local partners rather than wholly-owned subsidiaries (WOSs) to enhance the success of their international endeavours and reduce the risk of failure. This study focuses on analysing how weak country governance influences the criteria MNEs use to select local partners and develops a forecasting model for Forecasting the success of International Joint Ventures.

2 - Assessing Combined Innovation Potential of Firms through Value-Guided Transformers: Implications for Post-M&A Outcomes

Naveenkumar Ramaraju, University of Illinois at Urbana-Champaign, Champaign, IL, United States, Gautam Pant

We propose a framework to assess the combined innovation potential of firms and validate it by evaluating its impact on the post-M&A outcomes of such firms. We leverage the "Value Innovation Theory" for the framework design, which suggests that innovation should be value-driven rather than technology-driven. Specifically, we propose value embeddings (i.e., value-based vector representations) to encode the value of firm patents in the semantic-value space. An information artifact called CoMET (Combined Maximum Embedding Total) is constructed from value embeddings of patents to measure the combined innovation potential of firm pairs. We evaluate the proposed information artifact in the context of mergers and acquisitions (M&A). We find that M&As with higher combined innovation potential of constituent firms, as measured through CoMET before mergers, have higher innovation quantity, quality, and knowledge-sharing post-merger. Heterogeneity analyses show that our framework to measure the combined innovation potential is a useful indicator of post-M&A innovation output beyond the traditional indicators such as interfirm technology similarity and complementarity.

3 - Profit sharing between differentiated firms in open innovation system

Takuro Murakami, Keio University, Yokohama, Japan, Nobuo Matsubayashi

We consider an open innovation system in which multiple third-party firms are invited to participate in a platform to create an innovative product. Our focus is on the platform's profit-sharing scheme with these participants, who may differ from each other asymmetrically in terms of complementarity and substitutability. Specifically, we compare three schemes: equal splitting, profit sharing proportional to effort level, and profit sharing proportional to effort level adjusted by the degree of complementarity and substitutability. We develop a game-theoretic model where a monopolistic platform firm offers one of these profit-sharing schemes, and the third-party participants determine their effort levels to maximize their individual profits. Our equilibrium analysis reveals that the optimal profit-sharing scheme depends on the complementarity-substitutability relationship of participants, and the cost structure of innovation.

Causal Inference and Machine Learning in OM

Invited Session

MSOM: Service Operations

Chair: Ruomeng Cui, Emory University, Amazon, Decatur, GA, United States

Co-Chair: Zhikun Lu, Emory University, Decatur, GA, United States

1 - The Long-Term Impact of Wage on Workers&Rsquo; Behaviors in Sharing Economy

Shilei Luo, Washington University in St. Louis, St. Louis, MO, United States, Xinyu Cao, Dennis Zhang

In this paper, we examine the long-term effects of hourly wages on gig workers' behavior within the sharing economy through a field experiment that randomizes gig workers' hourly pay. We analyze the dynamics of these wage impacts on the workers' decision to join the platform and the quantity of the services they supply. Our findings reveal that higher wages lead to an increase in the quantity of service supplied and conducted, with the impact on service conducted intensifying over time. This dynamic is largely attributable to the workers' reputation growth and the accumulation of repeat customers.

2 - Policy Learning Under Biased Sample Selection

Roshni Sahoo, Stanford University, Stanford, CA, United States, Lihua Lei, Stefan Wager

Practitioners often use data from a randomized controlled trial to learn a treatment assignment policy that can be deployed on a target population. A recurring concern in doing so is that, even if the randomized trial was well-executed (i.e., internal validity holds), the study participants may not represent a random sample of the target population (i.e., external validity fails)--and this may lead to policies that perform suboptimally on the target population. We consider a model where observable attributes can impact sample selection probabilities arbitrarily but the effect of unobservable attributes is bounded by a constant, and we aim to learn policies with the best possible performance guarantees that hold under any sampling bias of this type. In particular, we derive the partial identification result for the worst-case welfare in the presence of sampling bias and show that the optimal max-min, max-min gain, and minimax regret policies depend on both the conditional average treatment effect (CATE) and the conditional value-at-risk (CVaR) of potential outcomes given covariates. To avoid finite-sample inefficiencies of plug-in estimates, we further provide an end-to-end procedure for learning the optimal max-min and max-min gain policies that does not require the separate estimation of nuisance parameters.

3 - The Value of Last-Mile Delivery in Online Retail

Ruomeng Cui, Emory University, Amazon, Decatur, GA, United States, Zhikun Lu, Tianshu Sun, Lixia Wu

Last-mile delivery refers to the final leg of shipment in which packages are moved from a local transportation hub to end-customers. It is known to be the most expensive part of delivery, due to operations complexity and lack of economy of scale. Given the growing importance of last-mile delivery in online retail, companies need to decide whether to outsource this service to customers through pickup stations where they can collect packages or to offer home delivery. In this paper, we study the economic value of last-mile delivery. We conducted a quasi-experiment in collaboration with Cainiao, Alibaba's logistics subsidiary, in which home delivery service was rolled out to some pickup stations sequentially in 2021. This allowed us to comprehensively evaluate the causal impact of last-mile delivery. Using a staggered difference-in-differences identification, we found that last-mile delivery significantly increases sales and customer spending on Alibaba's retail platform. Last-mile home delivery relies heavily on physical labor and thus has capacity constraints. To optimally prioritize that capacity, we used an uplift model with causal machine learning to target the most responsive customers. Specifically, we proposed a novel capacity- and fairness-aware uplift model that builds in capacity and fairness constraints to optimize the targeting policy, thereby maximizing profits without compromising social equity.

4 - Dynamic Local Average Treatment Effects

Ravi Sojitra, Stanford University, Stanford, CA, United States, Vasilis Syrgkanis

We consider Dynamic Treatment Regimes (DTRs) with one sided non-compliance that arise in applications such as digital recommendations and adaptive medical trials. These are settings where decision makers encourage individuals to take treatments over time, but adapt encouragements based on previous encouragements, treatments, states, and outcomes. Importantly, individuals may choose to (not) comply with a treatment recommendation, whenever it is made available to them, based on unobserved confounding factors. We provide non-parametric identification, estimation, and inference for Dynamic Local Average Treatment Effects, which are expected values of multi-period treatment contrasts among appropriately defined complier subpopulations. Under standard assumptions in the Instrumental Variable and DTR literature, we show that one can identify local average effects of contrasts that correspond to offering treatment at any single time step. Under an additional cross-period effect-compliance independence assumption, which is satisfied in Staggered Adoption settings and a generalization of them, which we define as Staggered Compliance settings, we identify local average treatment effects of treating in multiple time periods.

1 - Joint Probability Estimation of Many Binary Outcomes via Localized Lasso

Yan Chen, Duke University, Durham, NC, United States, Alexandre Belloni , Matthew Harding

In this work we consider estimating the probability of many (possibly dependent) binary outcomes which is at the core of many applications, e.g., multi-treatment in causal inference, demands for bundle of products, etc. Without further conditions, the probability distribution of an M dimensional binary vector is characterized by exponentially in M coefficients which can lead to a high-dimensional problem even without the presence of covariates. Understanding the (in)dependence structure allows to substantially improve the estimation as it allows for an effective factorization of the probability distribution. In order to estimate the probability distribution of a M dimensional binary vector, We leverage a Bahadur representation that connects the sparsity of its coefficients with independence across the components. We propose to use regularized estimators to obtain an adaptive estimator with respect to the dependence structure which allow for rates of convergence to depend on this intrinsic (lower) dimension. Our main results consider the presence of (low dimensional) covariates for which we propose a locally penalized estimator. We provide point-wise and uniform rates of convergence addressing several issues in the theoretical analyzes as we strive for making a computationally tractable formulation. We apply our results in the estimation of causal effects with multiple binary treatments and show how our estimators can improve the finite sample performance when compared with non-adaptive estimators that try to estimate all the probabilities directly. We also provide simulations that are consistent with our theoretical findings.

2 - Survey Descent: a Case-Study in Amplifying OR Research with Modern ML Workflows

X.Y. Han, Chicago Booth, Chicago, IL, United States

Within the classic operations research (OR) curriculum, one learns that for strongly convex objectives that are smooth, gradient descent ensures linear convergence of iterates and objective values relative to the number of gradient evaluations. Nonsmooth objective functions are more challenging: existing solutions in the OR literature typically invoke cutting plane methods whose complexities are difficult to bound, leading to convergence guarantees that are sublinear in the cumulative number of gradient evaluations. We instead propose a multipoint generalization of the gradient descent called Survey Descent. In this method, one first leverages a one-time initialization procedure to gather a "survey" of points. Then, during each iteration of the method, the survey points are updated in parallel using a simple, four-line procedure inspired by gradient descent. Under certain regularity conditions, we prove that Survey Descent then achieves a desirable performance by converging linearly to the optimal solution in the nonsmooth setting.

Despite being an OR endeavor, we discuss how the development of Survey Descent was significantly accelerated by a frictionless computational workflow made possible by tools from modern machine learning (ML); how this model of applying new ML workflows to solve open questions in optimization and applied probability could amplify the productivity of OR research; practical computational bottlenecks that could hinder this integration; and what tools are needed to overcome those obstacles.

3 - RL Algorithm Design for Improving Post-HCT Medication Adherence via a Digital Intervention

Ziping Xu, Harvard University, Allston, MA, United States, Susan Murphy

The survival of adolescents and young adults (AYA) who undergone hematopoietic stem cell transplantation critically relies on the adherence to medication that mitigates acute graft-versus host diseases. For AYAs with cancer, self-management rarely involves the individual alone and their care-partner often plays an important role, which forms a dyadic structure. The oversight of this dyadic structure may partially explain small and heterogeneous effects of previous interventions aimed at AYA adherence. In this paper, we design RL algorithms that provide personalized and just-in-time digital interventions on AYA, care-partner and their relationship to improve AYA's medication adherence. We construct a simulation testbed from an offline dataset combined with domain experts' knowledge. The testbed is used to select a set of candidate algorithms designed for the dyadic structure. Our results indicate that the appropriate choice of RL algorithm design including pooling and algorithm model can significantly improve the cumulative rewards.

4 - Property Test on the Optimal Assortment in the Contextual Multinomial Logit Model with Adaptive Sampling

Shuting Shen, Duke University, Durham, NC, United States, Alexandre Belloni, Ethan Fang

We study the combinatorial inference of the optimal assortment within the framework of the contextual multinomial logit model, where we assume that the observed data are collected over time, with contextual information varying temporally. Moreover, the offer set provided at each time point is adaptively estimated based on history data. We propose an inferential procedure that constructs a discrete confidence set for the latent optimal assortment, enabling us to infer properties of the optimal assortment, such as the number of product categories to include in the optimal offer set. The temporal dependency in the discrete supports of the summands over the products for the Hessian matrix of the log-likelihood function brings challenges to showing its convergence. To address this, we have developed novel anti-concentration bounds for the difference of the maxima of two Gaussian random vectors. Additionally, we tackle the high dimensionality of the combinatorial inference problem by utilizing subspace projection techniques. We offer theoretical guarantees for both the validity and effectiveness of our inferential procedure and establish the information-theoretic lower bounds for the necessary signal strength.

1 - Biasness in ordering: An experiment with varying holding and backorder costs

Sourish Sarkar, Penn State Erie, Erie, PA, United States

The optimal inventory level depends on the holding and backordering costs. However, past behavioral studies considered these costs fixed, and didn’t investigate the effect of such costs on the underweighting bias. A controlled laboratory experiment allows us to explore the impact of varying these costs on the cognitive bias that contributes to the bullwhip effect.

2 - Strategic Communications in Entry to a Joint Innovation Venture

Zhenxiao Chen, Southern University of Science and Technology, Shenzhen, China, People's Republic of, Kanglin CHEN, Qiaochu He

This paper depicts a frenemy relationship between an incumbent and a potential entrant in developing an innovative product with uncertain market potential. The entrant contributes to the product development but encroaches on the monopoly of the incumbent. Regarding the market entry decision, we find that an entrant with a higher market power may be less inclined to encroach on the market. In cases where the entrant has already encroached on the market, the two parties jointly exert efforts only when the synergy efficiency is high and the two parties are comparable in terms of market power; otherwise, the party with a limited market power becomes a free-rider. To reconcile the conflicting interests between both parties, we explore how the incumbent can communicate the market potential with the entrant strategically under a framework of information design. The optimal information scheme features three different signal structures: a downplay policy that deters entry, a hype policy that facilitates entry, and a silent policy that carries no information. The specific signal structure's choice is contingent upon the value of the new entrant and the prior expectation about the market potential. From the overall market perspective, an entrant comparable in market power optimally benefits the incumbent and the entire market. In that case, the two parties are highly incentivized to develop the product by exerting considerable efforts, which fully exploits the complementary effect and reinforces the investment by the parties.

3 - Relatively Robust Multiproduct Pricing

Ru Zhang, EPFL, Lausanne, Switzerland, Thomas Weber

This study investigates the robust pricing of multiple products when demand information is limited to parameter intervals, accommodating general nonlinear demand systems. The optimal robust price is obtained by maximizing a performance index, representing the worst-case ratio of attained profit to the optimal ex-post profit achievable in the absence of model ambiguity. If the firm’s product portfolio contains at least one profitable item, the optimal performance index offers a meaningful relative performance guarantee. Computational simplification is substantial due to the "envelope property" for linear multiproduct demand systems, allowing the performance index to be expressed as a function of just two vertices in the parameter space. Indeed, the linear multiproduct demand system with interval coefficients is fundamentally compatible with any Lipschitz-continuous nonlinear demand system, as the latter can be linearized around any relevant operating point. Thus, the model can be identified using appropriate OLS confidence intervals for the coefficients of a linear demand system. Regarding optimal robust pricing, in certain symmetric settings with linear, semi-log, or log-log demand models, closed-form solutions are available. For a large sample of random instances of the multiproduct pricing problem we compare our solution, based on minimizing maximum relative regret, to solutions obtained using alternative criteria, such as maximin payoff, minimax absolute regret, and Laplacian uncertainty. The findings demonstrate superior performance of our solutions, validated also using large-scale real-world data from an online retailer.

4 - Deep Reinforcement Learning based Ensemble Approach for Inventory Optimization with multi-item news vendor problem

Tejaswini Samal, Indian Institute of Technology, Kharagpur, Kharagpur, India, Anupam Ghosh

This paper addresses a multi-item newsvendor problem with both capacity and budget constraints. While this problem has been previously studied in the literature using the classical newsvendor problem and its variations, existing solutions often rely on assumptions about demand distributions that can lead to errors in inventory optimization. However, existing solutions often relied on assumptions about demand distributions, which are often incorrect and led to errors in the inventory optimization. To address this issue, this research proposes a distribution-free and entirely data-driven approach. Utilizing sample demand data as input, the proposed approach employs a deep reinforcement learning based ensemble approach with empirical risk minimization principle to determine optimal order quantities. Additionally, a heuristic is developed using hierarchies of the retail products to perform multi-item inventory optimization under both capacity and budget constraint. The proposed approach is validated on a real-world dataset of retail products. Comparative analysis of the results against data driven max-min and empirical inventory optimization methods demonstrates the superior performance of the proposed approach. Furthermore, total inventory cost comparisons reveal a significant reduction attributable to the proposed data-driven methodology.

Vehicle Routing Problems & Co.

Invited Session

OPT: Integer and Discrete Optimization

Chair: Nicholas Parham, Air Force, 10476 Glenbrittle Ave, Las Vegas, 89166, United States

1 - Introducing a mixed-integer nonlinear program to the air tasking cycle

Nicholas Parham, Air Force, Las Vegas, NV, United States

The air tasking cycle is an iterative battle rhythm that involves creating objectives, developing targets, weaponeering targets, producing orders, executing orders, and assessing execution. Producing orders, in the form of a schedule, is a key purpose of the tasking cycle. This schedule coordinates capabilities to create desired effects in support of joint force objectives. The scheduling problem that arises can be formulated as a rich vehicle routing problem, which is a variant that incorporates multiple types of constraints to handle real-life considerations. We present a mixed-integer nonlinear program that prescribes where aircraft need to be, at what time, and with which loadout, so as to maximize support of joint force objectives. Demonstrations of this model on synthetic instances show that the total man-hours spent planning can be significantly reduced at no cost to schedule quality.

3 - A Two-Echelon Vehicle Routing Problem with Mobile Satellites and Multiple Commodities

Aria Dahimi, Eindhoven University of Technology, Eindhoven, Netherlands, Virginie Lurkin, Mehrdad Mohammadi, Tom Van Woensel

The exponential growth of e-commerce has led to a surge in last-mile delivery demands, presenting intricate challenges for logistics service providers. In this study, we introduced the Two Echelon Vehicle Routing Problem (2E-VRP) with mobile satellites, multiple depots, and multiple commodities (3M-2E-VRP). A central focus of our work is exploring direct delivery using the first echelon vehicles (mobile satellites) and the potential for exchanging goods at meeting points, which can be specific locations such as parking lots or customer locations. To tackle this problem, we develop a mixed-integer linear programming (MILP) model and a math-heuristic algorithm named Approximated Learning based Large Neighbourhood Search (AL-LNS). The AL-LNS algorithm integrates innovative approximated and exact scheduling techniques to navigate within a learning-based procedure, all set up within a Large Neighborhood Search (LNS) structure. Computational experiments evaluate the validity of the 3M-2E-VRP formulation and the effectiveness of the math-heuristic. Finally, a sensitivity analysis was conducted to investigate the impact of input parameters on the final delivery solution, providing precious insights for decision makers and logistic service providers.

4 - An iterative sample scenario approach for the dynamic dispatch waves problem

Sandjai Bhulai, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, Leon Lan, Jasper van Doorn, Niels Wouda, Arpan Rijal

Same-day delivery operations face the challenge of unknown, dynamically revealed delivery requests, necessitating a balance between immediate vehicle dispatch for timely delivery and delayed dispatch to integrate future requests. We explore the dynamic dispatch waves problem where vehicles are dispatched at predetermined times. At these times, operators must decide which requests to dispatch and their routing to minimize total costs while ensuring timely service. We introduce an iterative conditional dispatch (ICD) strategy, using a sample scenario method to categorize requests into dispatch, postpone, or undecided groups, with undecided requests diminishing each iteration until a final decision in the last. ICD comes in two forms: one uses thresholds, the other leverages similarity for decisions. Notably, ICD's simplicity, conceptually straightforward and easy to implement, does not detract from its effectiveness. Extensive numerical experiments show both ICD variants adeptly handle large decision spaces and quickly reach high-quality solutions.

1 - Online Heavy-tailed Estimation and Change-point Detection

Abishek Sankararaman, Amazon, Seattle, WA, United States

Motivated by anomaly detection applications in cloud computing, this talk considers two theoretical questions on online change-point detection and mean estimation and shows that clipped-Stochastic Gradient Descent (clipped-SGD) is both a practical algorithm that enjoys good theoretical guarantees. Both of these problems are common sub-routines in variety of cloud computing applications ranging from monitoring, anomaly detection to control. The online change-point detection (OCPD) problem is one in which samples that are potentially heavy-tailed, are presented one at a time and a change in the underlying mean must be detected as early as possible. For this OCPD problem, we show that clipped-SGD enjoys finite sample guarantees on False positives and negatives and an upper bound on the worst case detection delay. This is the first bound for OCPD that works simultaneously across all settings - high-dimensional data that is either heavy-tailed, light-tailed or discrete distribution. The online estimation problem is one where a certain parameter of interest needs to be estimated from a high-dimensional, heavy-tailed and corrupted data-streams. For online estimation tasks that can be cast as minimizing a strongly convex loss function, we prove that an appropriately tuned version of the clipped-SGD is simultaneously {(i)} adaptive to drift, { (ii)} robust to heavy-tailed inliers and arbitrary corruptions, {(iii)} requires no distributional knowledge and {(iv)} can be implemented in an online streaming fashion. All prior estimation algorithms have only been proven to posses a subset of these practical desiderata. The talk is based in part on the following three papers

2 - High-dimensional scaling limits and fluctuations of online least-squares SGD with smooth covariance

Krishnakumar Balasubramanian, University of California, Davis, Davis, CA, United States

We derive high-dimensional scaling limits and fluctuations for the online least-squares Stochastic Gradient Descent (SGD) algorithm by taking the properties of the data generating model explicitly into consideration. Our approach treats the SGD iterates as an interacting particle system, where the expected interaction is characterized by the covariance structure of the input. Assuming smoothness conditions on moments of order up to eight orders, and without explicitly assuming Gaussianity, we establish the high-dimensional scaling limits and fluctuations in the form of infinite-dimensional Ordinary Differential Equations (ODEs) or Stochastic Differential Equations (SDEs). Our results reveal a precise three-step phase transition of the iterates; it goes from being ballistic, to diffusive, and finally to purely random behavior, as the noise variance goes from low, to moderate and finally to very-high noise setting. In the low-noise setting, we further characterize the precise fluctuations of the (scaled) iterates as infinite-dimensional SDEs. We also show the existence and uniqueness of solutions to the derived limiting ODEs and SDEs. Our results have several applications, including characterization of the limiting mean-square estimation or prediction errors and their fluctuations, which can be obtained by analytically or numerically solving the limiting equations.

3 - Moderate deviation principles for Join-the-Shortest-Queue-d system

Ruoyu Wu, Iowa State University, Ames, IA, United States, Zhenhua Wang

We consider the large-scale load balancing queueing system under the Join-the-Shortest-Queue-d policy. The system consists of one dispatcher and n servers. When a task arrives at the dispatcher, d servers are chosen uniformly at random, and then the task is routed to the one with the shortest queue length. We establish moderate deviation principles for the system occupancy process and average queue length process, formulated in terms of large deviation principles for the centered and scaled processes with an appropriate speed function. Proofs rely on certain variational representations for exponential functionals of Poisson random measures and weak convergence arguments. This is joint work with Zhenhua Wang.

4 - Reflected Brownian Motion with Drift in a Wedge and the Submartingale Problem

Ziran Liu, New York University, New York, NY, United States, Peter Lakner, Josh Reed

We study reflecting Brownian motion with drift constrained to a wedge in the plane. Our first set of results provides necessary and sufficient conditions for existence and uniqueness of a solution to the corresponding submartingale problem with drift, and show that its solution possesses the Markov and Feller properties. Next, we study a version of the problem with absorption at the vertex of the wedge. In this case, we provide a condition for existence and uniqueness of a solution to the problem and some results on the probability of the vertex being reached.

Learning for Contextual Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Ian Zhu, NUS Business School, Singapore, Singapore

1 - Multiproduct Inventory and Pricing with Contextual Robust Optimization

Qinshen Tang, Nanyang Techonological University, Singapore, Singapore, Xun Zhang, Zhi Chen, LI CHEN

Traditionally, multiproduct inventory and pricing problems are approached by initially estimating parameters for a presumed "sufficiently accurate" demand model, followed by optimizing specific models to determine optimal inventory and pricing decisions. However, obtaining an accurate demand model is nearly impossible due to unobservable parameters (parameter uncertainty) and the unknown distribution of the error term in the stochastic demand model (residual ambiguity). Additionally, the predicted demand is endogenously linked with pricing, leading to decision-dependent predictions that often result in intractable bilinear optimization problems. This paper addresses these challenges by introducing a contextual robust optimization (CRO) model to tackle both issues. Despite the intractability of the CRO model, we propose a fortified affine recourse approximation to resolve the decision-dependent prediction issue, reformulating the problem as a semidefinite programming model. Our extensive numerical studies demonstrate the effectiveness of the CRO model, outperforming the conventional predict-then-optimize approach in terms of average profit in out-of-sample tests.

2 - Conformal Inverse Optimization

Timothy Chan, University of Toronto, Toronto, ON, Canada, Bo Lin, Erick Delage

Inverse optimization has been increasingly used to estimate unknown parameters in an optimization model based on decision data. We show that such a point estimation is insufficient in a prescriptive setting where the estimated parameters are used to prescribe new decisions. The prescribed decisions may be low-quality and misaligned with human intuition and thus are unlikely to be adopted. To tackle this challenge, we propose conformal inverse optimization, which seeks to learn an uncertainty set for the unknown parameters and then solve a robust optimization model to prescribe new decisions. Under mild assumptions, we show that the suggested decisions can achieve bounded out-of-sample optimality gaps, as evaluated using both the ground-truth parameters and the decision maker's perception of the unknown parameters. Our method demonstrates strong empirical performance compared to classic inverse optimization.

3 - The Perturbation Gradient Surrogate Loss

Michael Huang, CUNY Baruch College, New York, NY, United States, Vishal Gupta

We propose a novel family of decision-aware surrogate losses, called Perturbation Gradient (PG) losses, for the predict-then-optimize framework. These losses directly approximate the downstream decision loss and can be optimized using off-the-shelf gradient-based methods. Importantly, unlike existing surrogate losses, the approximation error of our PG losses vanishes as the number of samples grows. This implies that optimizing our surrogate loss yields a best-in-class policy asymptotically, even in misspecified settings. This is the first such result in misspecified settings and we provide numerical evidence confirming our PG losses substantively outperform existing proposals when the underlying model is misspecified and the noise is not centrally symmetric. Insofar as misspecification is commonplace in practice -- especially when we might prefer a simpler, more interpretable model -- PG losses offer a novel, theoretically justified, method for computationally tractable decision-aware learning.

4 - Robustness in Inverse Optimization

Honglin An, Institute of Operations Research and Analytics, Singapore, Singapore, Ian Zhu

Inverse optimization has become widely studied and has permeated into a wide variety of applications. As it has been observed in the literature, parameter estimates obtained through inverse optimization can be highly sensitive to model inputs. In this talk, we establish a subtle connection between parameter instability and the robustness of inverse optimization models. In particular, we show that parameter instability can result from a lack of robustness to model inputs, motivating a new robust inverse optimization framework.

Advances in Nonlinear Continuous Optimization

Invited Session

OPT: Nonlinear Optimization

Chair: Qi Wang, Lehigh University, Bethlehem, PA, United States

1 - Structured Non-Smooth Non-Convex Composite Optimization Without Weak Convexity

YAO YAO, The University of Iowa, Iowa City, IA, United States, Qihang Lin, Tianbao Yang

This paper explores numerical methods for solving a structured non-smooth non-convex composite optimization problem without weak convexity property, which is a composite of a differentiable mapping and a non-convex non-smooth Lipschitz function that allows a simple proximal mapping. With the Moreau Envelope technique, the composite problem can be formulated as a difference-of-convex (DC) program. Then, we introduce single loop deterministic and stochastic algorithms to solve the problem. We show the iteration complexity of the proposed methods for finding an ϵ-Goldstein-stationary point. Moreover, we show that this method can be applied to fairness problem with Wasserstein distance-based fairness metric.

2 - Inexact Sequential Quadratic Programming Method for Nonlinear Constrained Stochastic Optimization

Baoyu Zhou, Arizona State University, Tempe, AZ, United States, Frank E. Curtis, Daniel Robinson

We propose a stochastic sequential quadratic programming algorithm for solving continuous optimization problems with nonlinear constraints. It is assumed that constraint function and derivative values can be computed, but that only stochastic approximations are available for the objective function and its derivatives. Our algorithm only employs stochastic objective gradient estimates without using any objective function values or estimates, and it allows inexact subproblem solutions to be employed, which is particularly useful in large-scale settings. Conditions are imposed on the inexact subproblem solutions that account for the fact that only stochastic objective gradient estimates are employed. Convergence results are established for the method. Numerical experiments show that the proposed method vastly outperforms a stochastic subgradient method and can outperform an alternative SQP algorithm that employs highly accurate subproblem solutions in every iteration.

3 - A Study on the Two-Metric Projection Method

Yue Xie, University of Hong Kong, Pokfulam, Hong Kong, Hong Kong

The two-metric projection method is a simple yet elegant algorithm proposed by Bertsekas in 1984 to address bound/box-constrained optimization problems. The algorithm's low per-iteration cost and potential for using Hessian information makes it a favourable computation method for this problem class. However, its global convergence guarantee is not studied in the nonconvex regime. In our work, we first investigate the global complexity of such a method for finding first-order stationary solution. After properly scaling each step, we equip the algorithm with competitive complexity guarantees. Furthermore, we generalize the two-metric projection method for solving ℓ_1-norm minimization and discuss its properties via theoretical statements and numerical experiments.

Applications of Optimization in Statistics

Invited Session

OPT: Optimization Under Uncertainty

Chair: Stanislav Uryasev, Stony Brook University, Stony Brook, NY, United States

1 - EM Algorithms for Optimization Problems with Polynomial Objectives

Jun-ya Gotoh, Chuo university, Bunkyo-ku, Tokyo, Japan, Kensuke Asai

EM (Expectation-Maximization) algorithm is a popular algorithm often used in maximum likelihood estimation of statistical models when they include latent random variables. Focusing on its features as an MM (Majorization-Minimization) optimization algorithm, a new algorithmic scheme based on the EM algorithm is presented for solving general (not necessarily statistical) optimization problems by introducing certain probability distributions. We show that by choosing an appropriate distribution from the exponential family, optimization problems with polynomial objective functions, which include linear program (LP) and quadratic program (QP), can be embedded in the EM scheme. Specifically, with a normal distribution, the EM algorithm for the unconstrained minimization of a convex quadratic function turns out to be a natural gradient descent without line search. For minimizing a polynomial function over a rectangle or a simplex, the EM algorithm with a binomial or multinomial distribution, respectively, becomes an interior point algorithm which is reduced to a natural gradient descent without line search. As further extensions to the case where a natural gradient descent without line search is no longer available, new interior point algorithms are presented for polynomial optimization over a polytope, LP, and QP, based on EM and generalized EM algorithms. The presented algorithms for the extensions are somewhat conceptual in that their sub-procedures require solving a nonlinear convex optimization, and some practical strategies are discussed.

2 - Risk Quadrangle and Robust Optimization Based on phi-divergence

Cheng Peng, Stony Brook University, Stony Brook, NY, United States

Distributionally robust optimization minimizes the maximum expected loss, where the maximum is over an uncertainty set defined by φ-divergence. The maximum expected loss defines the φ-divergence risk measure. This paper studies robust and distributionally robust optimization based on the extended φ-divergence under the Fundamental Risk Quadrangle framework. The extended φ-divergence is defined for signed measures. We present the primal and dual representations of the quadrangle elements (risk, deviation, regret, error and statistic) and prove that they satisfy the characterizing definitions. The φ-divergence risk measure is studied as a special case of the risk measure. The framework provides an interpretation of portfolio optimization, classification and regression as robust optimization. We furnish illustrative examples demonstrating that many common problems are included in this framework, such as Markowitz portfolio optimization, CVaR optimization, least-squares regression, quantile regression and support vector machine. We conduct a case study to visualize the optimal solution to the inner maximization of robust optimization.

3 - Biased Mean Quadrangle and Applications

Anton Malandii, Stony Brook University, Stony Brook, NY, United States

This paper introduces a novel risk quadrangle called the biased mean quadrangle and examines its mathematical properties. The linear regression using the error function from this quadrangle, referred to as the superexpectation error, can be employed for conditional biased (shifted by a predetermined real number) mean estimation. Minimization of this error is reduced to linear programming. Specifically, when the bias equals zero, the problem of conditional mean estimation reduces to linear programming. This allows for the inclusion of cardinality constraints and reduces the regression problem to a mixed-integer linear program, which is not possible with the standard mean squared error. The reduction to linear programming also indicates the robustness of regression with the superexpectation error to outliers. The theoretical results are validated with case studies.

4 - The Conditional Value-at-Risk (CVaR) based Pickands-type Estimator for Extreme Value Index

Yizhou Li, Stony Brook University, Stony Brook, NY, United States

The Pickands estimator for the extreme value index is advantageous due to its universal consistency and its invariance to location and scale. However, it suffers from poor asymptotic efficiency. To address this, we introduce the Conditional Value-at-Risk (CVaR) into a generalized class of Pickands-type estimators and propose the CVaR-based smoothed Pickands estimator. A simulation study involving a wide range of distributions shows that the CVaR-based smoothed estimator exhibits good finite-sample performance. It outperforms other estimators by achieving a lower mean squared error (MSE) and reduced bias, providing smooth estimates, and maintaining stable performance across intermediate order statistics.

Optimized Routing and Travel Time Analysis

Contributed Session

Chair: Rishav Sen

1 - Strategic API Calls: Efficient Arc Travel Time Retrievals for Optimizing a Delivery Route

Mohammad Hesam Rashidi, University of Toronto, Toronto, ON, Canada, Mehdi Nourinejad, Matthew Roorda

Last-mile logistics planners optimize delivery routes primarily based on total travel time. Many, however, lack the extensive historical data necessary for training predictive models to estimate accurate travel times across a network. As a result, they rely on Application Programming Interfaces (APIs) to access travel time data from external sources. APIs have limitations, such as call frequency restrictions and cost per call, which can impact the scalability of data-driven solutions. To address these challenges, this study proposes a heuristic approach that optimizes API usage to determine travel times for solving the Traveling Salesman Problem (TSP). The heuristic starts with an initial TSP solution using Euclidean distances as proxies for actual travel times. This solution is refined through strategic API calls to obtain actual travel times for selected arcs. A Graph Neural Network identifies the most promising arcs to sample based on assessing the local travel time uncertainty across arcs, considering factors like arc length, proximity to arcs with known travel times, and network connectivity. Once actual travel times are sampled, they are extrapolated across the network. The heuristic refines the route using a 2-opt operation—reversing tour segments to reduce overall travel time. This iterative process continues until time or budget constraints are met, ensuring the solution is cost-effective and feasible within real-time operational limits.

2 - Incorporating Travel Time Uncertainty in Last Mile Route Planning Systems

Chhavi Choudhary, Amazon, Hyderabad, India, Zeev Lieber, Yimin Liu, Karthik Konduri

We describe a new approach of informing the route planning systems about the risk of delay using distributional forecast methods for route duration. Amazon's Last Mile operates hundreds of delivery stations worldwide that deliver packages directly to customers' doorsteps. Last Mile's Routing and Planning systems are responsible for creating sustainable routes while maintaining good customer experience. Crucial to that task is the accuracy of route time estimations, which are generated by deep learning models. Route deliveries can sometimes take longer than the planned time due to various factors such as traffic, weather, delivery attempts, and others. The proposed approach allows the planner to directly balance the risk of delay and route efficiency and utilization. Offline and preliminary online results suggest that our approach sacrifices less deliveries per paid hour than the legacy method of reducing risk of delay.

3 - Data-Driven Vehicle Routing Problem with Accident Risk Minimization

Alireza Fallahtafti, Case Western Reserve University, Cleveland, OH, United States, Fatemeh Zandieh, Armin Hamedizad

One of the crucial issues in distributing goods to customers is timely delivery, as any delay in delivering the goods can lead to customer dissatisfaction. Road accidents are among the factors that can significantly impact delivery times. This research presents a data-driven vehicle routing problem with time windows, where the goal is to minimize the vehicle's travel on links with lower accident probabilities. This approach combines optimization of the routing problem with machine learning techniques. In the proposed problem, the objective function considers minimizing accident risks, aiming to increase customer satisfaction by providing timely services.

4 - Shortest Path Problem with a Crash Risk Objective

Qiong Hu, University of Colorado Denver, Denver, CO, United States, Alexander Vinel, Fadel Megahed

With more and more data related to driving, traffic, and road conditions becoming available, there has been renewed interest in predictive modeling of traffic incident risk and corresponding risk factors. New machine learning approaches in particular have recently been proposed, with the goal of forecasting the occurrence of either actual incidents or their surrogates, or estimating driving risk over specific time intervals, road segments, or both. At the same time, as evidenced by our review, prescriptive modeling literature (e.g., routing or truck scheduling) has yet to capitalize on these advancements. Indeed, research into risk-aware modeling for driving is almost entirely focused on hazardous materials transportation (with a very distinct risk profile) and frequently assumes a fixed incident risk per mile driven. We propose a framework for developing data-driven prescriptive optimization models with risk criteria for traditional trucking applications. This approach is combined with a recently developed machine learning model to predict driving risk over a medium-term time horizon (the next 20min to an hour of driving), resulting in a biobjective shortest path problem. We further propose a solution approach based on the k-shortest path algorithm and illustrate how this can be employed.

5 - Grid-Aware Charging and Operational Optimization for Mixed-Fleet Public Transit

Rishav Sen, Vanderbilt University, Nashville, TN, United States, Amutheezan Sivagnanam, Aaron Laszka, Ayan Mukhopadhyay, Abhishek Dubey

Amidst rising urban populations and heightened environmental concerns, transitioning to electric buses has become a pivotal strategy for sustainable urban transit. Managing a mixed fleet of electric, hybrid, and diesel buses presents significant operational challenges, particularly due to the complexities of dynamic electricity pricing. This paper addresses these challenges by developing a comprehensive mixed-integer linear programming (MILP) model that optimizes both the charging schedules and trip assignments for such fleets. Our model distinctively incorporates dynamic electricity pricing and seating constraints, which are critical for adapting to fluctuations in energy costs and meeting specific service demands.

The computational challenges posed by the MILP formulation, typically intractable for large fleets, are tackled using a novel hierarchical solution approach. This approach decomposes the overall problem into more manageable sub-problems that are easier to solve, thereby enhancing the tractability and scalability of the solution. We apply our methodology to real-world data from Chattanooga Area Regional Transportation Authority (CARTA), Tennessee, demonstrating its efficacy. Our results show a 2.58% reduction in operational costs compared to the state-of-the-art model by Sivagnanam et al. (AAAI 2021), a 6.25% improvement over the current operational costs, and a significant reduction (over 800 kg of carbon dioxide daily) in tailpipe emissions currently incurred by the transit agency. Furthermore, our approach aligns with energy efficiency objectives and enhances route service quality by accommodating specific bus capacity requirements.

By systematically addressing economic and environmental factors, our research provides a scalable framework for urban transit agencies seeking to optimize their operations economically and ecologically.

Performance Modelling of Intelligent Vehicle Systems

Invited Session

TSL: Intelligent Transportation Systems

Chair: Aadya Bhattarai, University of south florida, Tampa, FL, 33617, United States

1 - Predicting Fuel Consumption for Vehicles with Different Levels of Autonomy Using Data from a Road-trip Simulator

Aadya Bhattarai, University of south florida, Tampa, FL, United States

The rapid integration of autonomy in the transportation sector significantly affects various aspects including fuel consumption, emissions, safety, and road congestion. As vehicles transition through the six levels of autonomy defined by the Society of Automotive Engineers (SAE), they exhibit differences in energy management due to changes in trip planning and execution. This paper addresses a critical gap in the literature by developing models to predict fuel consumption across different levels of autonomy in fossil fuel-driven vehicles. The research leverages a two-phase approach: firstly, constructing a sophisticated simulation model that mirrors real-world driving scenarios; secondly, applying machine learning techniques to predict fuel consumption accurately per mile for various autonomous driving scenarios. The study's findings, derived from simulating realistic vehicle interactions like car following and platooning, are critical for informing policy decisions and enhancing energy optimization in autonomous transportation. This comprehensive analysis not only advances the understanding of fuel dynamics in autonomous vehicles but also sets a foundation for future research in this rapidly evolving field.

2 - Graph-Based Optimization for Efficient Image Segmentation and Object Detection

Aaron Rassiq, University of San Francisco, San Francisco, CA, United States, Deven Varu

Graph theory-based optimization techniques have revolutionized computer vision tasks, particularly in image segmentation and object detection. By modeling pixels and their interrelationships as graphs, these methods enable precise and computationally efficient solutions to challenging problems in computer vision. Key algorithms such as graph cuts and min-cut/max-flow have emerged as powerful tools for segmenting images and detecting objects with high accuracy. Graph-based models capture the spatial dependencies between pixels, allowing for the representation of complex image structures. These models leverage optimization techniques from operations research to partition graphs efficiently, producing high-quality segmentations. The min-cut/max-flow algorithm, for instance, finds optimal boundaries by minimizing the sum of weights on edges that form a cut between the foreground and background regions. Graph cuts further extend this concept to multi-label segmentation, handling multiple object classes in a single framework. This paper provides a novel graph-based optimization method for image segmentation and object detection, illustrating its impact on improving accuracy and efficiency in computer vision applications. Case studies highlight their applications in autonomous driving and real-time surveillance, demonstrating their versatility and effectiveness.

3 - Tacit algorithmic collusion in deep reinforcement learning guided price competition: A study using EV charge pricing game

Diwas Paudel, University of South Florida, Tampa, FL, United States, Tapas Das

Players in pricing games with complex structures are increasingly adopting artificial intelligence (AI) aided learning algorithms to make pricing decisions for maximizing profits. This is raising concern for the antitrust agencies as the practice of using AI may promote tacit algorithmic collusion among otherwise independent players. In this paper, we examine the concern for tacit collusion by considering a practical game where EV charging hubs compete by dynamically varying their prices. The hubs source power from the day-ahead (DA) and real-time (RT) electricity markets as well as from in-house battery storage systems. Their goal is to maximize profits via pricing and efficiently managing the cost of power usage. To aid our examination, we develop a two-step data-driven methodology. The first step obtains the DA commitment by solving a stochastic model. The second step generates the pricing strategies by solving a competitive Markov decision process model using a multi-agent deep reinforcement learning (MADRL) framework. We evaluate the resulting pricing strategies using an index for the level of tacit algorithmic collusion and find a possibility of a low to moderate level of collusion in EV charging market place.

4 - Evaluating Advanced Air Mobility System Performance with An AnyLogic Simulation Tool

Yu Zhang, University of South Florida, Tampa, FL, United States

Early stage use case of passenger advanced air mobility (AAM) could be on-demand and shared station-based services, i.e., passengers accessing to and egressing from vertiports via ground transportation mode(s) and electric vertical take-off and landing aircraft (eVTOL) carrying passengers between vertiports. For providing such services, AAM operators may follow different operational rules, which could lead to different level of service. The authors developed an agent-based AnyLogic simulation tool to mimic the operations of this emerging passenger AAM. For an AAM network designed by the authors' previous study, the simulation tool is used to evaluate system performance with different operational rules.

5 - Managing AV Platoons and Increased AV Penetration on Multiple Lanes of Freeways

Pitu Mirchandani, Arizona State University, Tempe, AZ, United States, Kerem Demirtas, Xuesong Zhou

This study explores the impact of dedicating specific freeway lanes for the exclusive use of Connected and Autonomous Vehicles (AVs) forming platoons, focusing on middle and leftmost lanes. The primary objective is to enhance overall traffic efficiency and safety by structuring and controlling AV movements. Middle lanes are typically less affected by merging and exiting traffic, providing a stable environment for effective platoon formation and maintenance. However, dedicating middle lanes exclusively to AVs can limit access for Human-Driven Vehicles (HDVs) to adjacent lanes, potentially causing congestion. Conversely, the leftmost lane, traditionally used for faster-moving vehicles, offers relative isolation from merging traffic, potentially benefiting AV platoons. Yet, incorporating HDVs in these lanes could lead to speed conflicts and increased lane change complexity. This study compares scenarios where HDVs are either allowed or restricted in dedicated lanes, highlighting the trade-offs between traffic flow flexibility and the stability of AV platoon operations. Allowing HDVs in dedicated lanes offers flexibility but can disrupt AV platoons, whereas restricting HDVs ensures a stable environment for AVs but may cause congestion in non-dedicated lanes. The findings aim to inform traffic managers on controls to optimize lane usage to maximize traffic efficiency and safety.

Artificial Intelligence in Logistics/Towards Fair Transportation Planning Under Uncertainty

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Mohammad Moshref-Javadi, University of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States

Co-Chair: Ahmad Hemmati, University of Bergen, Bergen, Norway

Co-Chair: Yu Yang, University of Florida, 401C Weil Hall, Gainesville, 32611-6595, United States

1 - Exploring the Applicability of Machine Learning in Assessing Last Mile Delivery Route Properties

Anna Konovalenko, Molde University College, Molde, Norway, Lars Magnus Hvattum, Mohamed Kais Msakni

Last-mile delivery involves a series of complex tasks in an unpredictable environment. Decision support tools based on optimization algorithms construct efficient routes for drivers, optimizing the cost of making deliveries. However, drivers often deviate from these routes due to factors not considered in the decision-making process. This discrepancy raises the question of how to identify routes that are useable in real-world scenarios. Our research proposes using modern machine learning techniques to classify routes based on their practical usability. In a controlled environment, we demonstrate that machine learning can learn hidden factors influencing route viability by focusing on variants of the vehicle routing problem with additional constraints like time window, capacity and precedence. For each underlying constraint, we show that a machine learning model can be trained to classify routes based on whether or not they violate the constraint. Using datasets generated from well-known benchmark instances, we present computational experiments to evaluate model performance. We discuss which types of constraints are more challenging to recognize and how large a dataset must be to allow for accurate classification. This research has the potential to improve existing decision tools, enabling them to generate routes that better account for real-world complexities.

2 - A Matheuristic for feeder network design problem with optional paired demands and split delivery

Anandhu Dileep, University of Bergen, Bergen, Norway, Norway, Ahmad Hemmati, Rahul Nath, Mohammad Moshref-Javadi

In this work, we study a complex variant of the feeder network design problem from the field of maritime transportation. The problem is about designing routes for ship services between several shipping ports, to deliver cargoes between these ports based on a fixed weekly demand. In many cases, this is done using disjoint networks of ships services, called feeder networks. Each feeder network is connected to a main port by a long ship service called a mother route. Some of the paired demands are delivered by the mother routes, and the remaining demands using daughter routes, which are shorter ship services that branch off from some of the ports visited by the mother routes.

So, the problem is about designing a set of mother routes and associated daughter routes, called feeder networks, to satisfy the paired demands while also allowing split deliveries of the demands and the rejection of some of the demands with penalties. There are time constraints on the routes and also on the travel time for delivery of each cargo and costs involving ship renting, port call and fuel consumption. We develop a multi-stage matheuristic framework to tackle this very complex problem.

We use a large neighborhood search following a Simulated Annealing (SA) paradigm in the heuristic part. A deep reinforcement learning agent is trained for operator selection, based on several different characteristics of the solution and the stage of the search and compared with other approaches for operator selection, like the traditional ALNS.

3 - Congestion Pricing for Efficiency and Equity: Theory and Applications to the San Francisco Bay Area

Chinmay Maheshwari, UC Berkeley, Berkeley, CA, United States

Congestion pricing, while adopted by many cities to alleviate traffic congestion, raises concerns about widening socioeconomic disparities due to its disproportionate impact on low-income travelers. In this study, we address this concern by proposing a new class of congestion pricing schemes that not only minimize congestion levels but also incorporate an equity objective to reduce cost disparities among travelers with different willingness-to-pay. Our analysis builds on a congestion game model with heterogeneous traveler populations. We present four pricing schemes that account for practical considerations, such as the ability to charge differentiated tolls to various traveler populations and the option to toll all or only a subset of edges in the network. We evaluate our pricing schemes in the calibrated freeway network of the San Francisco Bay Area. We demonstrate that the proposed congestion pricing schemes improve both efficiency (in terms of reduced average travel time) and equity (the disparities of travel costs experienced by different populations) compared to the current pricing scheme. Moreover, our pricing schemes also generate a total revenue comparable to the current pricing scheme. Our results further show that pricing schemes charging differentiated prices to traveler populations with varying willingness-to-pay lead to a more equitable distribution of travel costs compared to those that charge a homogeneous price to all.

4 - On the Distributionally Fair Facility Location Problem

QING YE, Georgia Institute of Technology, Atlanta, GA, United States, Weijun Xie

Fairness has been considered in many facility location problems. Since location decisions can have varying impacts on different demographic groups, this paper introduces the concept of distributional fairness to facility location. It aims to minimize distributional disparities of travel costs among groups. We employ the Wasserstein distance to quantify fairness and formulate the problem as a mixed-integer program. Valid inequalities and solution methods are developed to solve the problem effectively.

5 - Fairness Quantification and Assessment in Shared Electric Micromobility Systems

Violet (Xinying) Chen, Stevens Institute of Technology, Hoboken, NJ, United States

Shared Electric Micromobility Systems (SEMSs), such as e-bikes and e-scooters, have been launched in urban centers throughout US. Most SEMSs are burdened with disparities across the service regions and populations. Fair SEMSs are necessary to promote the growth of the micromobility industry and enable multi-modal transportation networks, which are more sustainable and better connected. Motivated by the lack of consistency and comprehensiveness of current approaches to fair SEMSs, we propose a fairness assessment framework to systematically quantify the fairness performance of SEMSs and guide the design of fair geographic distribution of SEMS infrastructure. Our framework strives to be comprehensive and flexible by taking account of different types of impacts SEMSs have on various stakeholders, such as, SEMS users, local communities. Case studies using historical trip data and real-time system feed data from SEMSs in US are developed to demonstrate the proposed framework and draw fairness insights about the current systems.

Equity and Optimization in Healthcare Systems

Contributed Session

Chair: Ji-Su Lee, Korea Advanced Institute of Science and Technology, Daejon, Korea, Republic of

1 - Quantifying uncertainties using conformal prediction in predicting catastrophic health expenditure among US households

Behrad Barghi, Rochester Institute of Technology, Rochester, NY, United States, Nasibeh Azadeh-Fard

Catastrophic health expenditure (CHE) describes situations where a family's direct medical expenses are so extensive that they lead to financial struggles or necessitate significant cutbacks in other vital areas, like food or housing. Health economics identifies two primary methods for estimating CHE: budget share (BS) and capacity-to-pay (CTP). This study utilizes the medical expenditure panel survey (MEPS) to explore CHE in US households. Since MEPS omits food spending data, this research uses the budget share approach. The study applies three benchmarks: 10%, 15%, and 20%, to determine CHE. Tools like the concentration index (CI), Wagstaff index (WI), and Erreygers Index (EI) were employed to measure and break down socioeconomic disparities in CHE. Additionally, this study employed 5 machine learning techniques, including random forest (RF), artificial neural networks (ANN), xgboost (XG), support vector machine (SVM), and deep learning (DL) to find the best models to forecast, categorize, and pinpoint the key factors of CHE during the specified timeframe. Conformal prediction is a technique used to quantify the uncertainty of predictions made by machine learning models. This method is useful for assessing the reliability of predictions and ensuring that the models used can provide robust and accurate forecasts. In this paper, conformal prediction method is used to find the best significance level and robust model to predict risk of CHE on US households.

2 - Closing the Loop of Healthcare Quality Improvement: An Empirical Study of Quality Competencies

Xinyu Wei, California State University, Chico, Chico, CA, United States, Heng (John) Xie, Richard Peng, Victor Prybutok

Assessment of healthcare quality is vital for enhancing patient outcomes and achieving organizational excellence. As such, assessment is of interest to healthcare professionals and scholars. This research investigates an industry framework of healthcare quality competencies to explore relevant measurements arising from the dynamic nature of today’s healthcare quality landscape. We integrate healthcare quality practices and results to develop a research model and validate its effectiveness using survey data obtained from healthcare workers. Findings are discussed to provide insights to practitioners and researchers in the healthcare field.

3 - A Study on Quality Factors for Continuous Use of Digital Healthcare Services

Seonghyeon Han, Korea University, Seoul, Korea, Republic of, Jaeseok Yoon, Sung Yeon Kim, Jinmin Kim

The digitalized networking society is increasing the scope and quality of medical services while improving access to health information and public health education, and as a result, digital healthcare services are expected to be a high value-added service industry, showing a lot of expectations and demand. However, looking at the existing research, there were many studies claiming the discrepancy between the expected benefits and actual implementation related to digital healthcare services, and few studies were found for the continuous use of the service, focusing on the effect of technology adoption and user reliability and experience on service use. Therefore, this study aims to derive quality factors that affect the continuous use of digital healthcare services by analyzing the quality of products and services that make up digital healthcare services. This study adopted the VAM (Value-based Adoption Model) to construct a research model, and set the personal characteristics claimed in the previous study and degree of standardization as control variables to suggest quality factors to be considered when establishing a service standardization strategy for continuous use. This study is expected to provide basic data necessary for service standardization and service certification by separating and analyzing device and service quality for the continuous use of digital healthcare services, which are expected to be high value-added services, and providing priority for service quality factors by reflecting changes and prospects in the service industry.

4 - A Game Theoretic Approach to Efficient and Equitable Healthcare Quality Improvement Policies for Regional Disparity

Ji-Su Lee, KAIST, Daejeon, Korea, Republic of, Woonam Hwang, Taesik Lee

While improving the quality of healthcare is a paramount objective for any healthcare systems, regional disparities in quality must not be overlooked to preserve equity and fairness in healthcare. In this respect, South Korea faces a distinctive challenge, wherein patients residing in non-metropolitan regions often gravitate towards major hospitals located in the metropolitan area, driven by perceptions of superior quality in those facilities.

To explain this phenomenon, this study constructs a modified Salop model in which hospitals under a price regulation compete on quality to attract patients seeking maximum utility. Our game theoretic analysis reveals an equilibrium where hospitals in the metropolitan region attain a higher level of quality compared to other hospitals. This equilibrium stems from two factors: intensified competition within the metropolitan area and disparities in the respective catchment population sizes.

We then use this model to explore policy options aimed at efficiently boosting overall healthcare quality while reducing regional disparities. Under this goal, a desirable policy would disproportionately enhance the quality of underperforming rural hospitals. We cast this problem as a Stackelberg game, where the government first sets a policy, followed by hospitals determining their quality levels, and patients subsequently choosing which hospital to visit. The specific policies evaluated include fee-for-service supplemental payments, pay-for-performance schemes linking reimbursement to quality metrics, and performance-based subsidies to hospitals. Equilibrium solutions resulting from each policy are analyzed to identify the optimal approach for achieving high-quality care while promoting regional equity.

Advances in Vehicle Routing

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: John Carlsson, University of Southern California, Los Angeles, CA, United States

1 - Demand Equilibria in Spatial Service Systems

John Carlsson, University of Southern California, Los Angeles, CA, United States

A service is offered at certain locations ("facilities") in a geographical region. Customers can appear anywhere in the region, and each customer chooses a facility based on travel distance as well as expected waiting time. Customer decisions affect waiting times by increasing the load on a facility, and thus impact other customers' decisions. The service provider can also influence service quality by adjusting service rates at each facility. Using a combination of queueing models and computational geometry, we characterize demand equilibria in such spatial service systems. An equilibrium can be visualized as a partition of the region into service zones that form as a result of customer decisions. Service rates can be set in a way that achieves the best possible social welfare purely through decentralized customer behavior.

2 - Penalty functions for truck-and-drone routing

Ke Xu, University of Southern California, Los Angeles, CA, United States

This study studies efficient last-mile delivery using trucks and drones. We introduce the Pickup-and-Delivery Generalized Traveling Salesman Problem (PDGTSP), a new truck-and-drone routing variant. Our approach uses a heuristic method based on Lin-Kernighan-Helsgaun with penalty functions to solve this problem. Computational experiments validate our method's effectiveness. We also discuss potential applications to more complex scenarios like the Traveling Salesman Problem with Multiple Drones (TSP-MD) and the Vehicle Routing Problem with Drones (VRPD).

3 - Sheng Liu's (student's) session

Sheng Liu, U of Toronto, Toronto, ON, Canada

4 - A continuous approximation model for the close-enough TSP

Mingxi Wang, University of Southern California, Los Angeles, CA, United States

We give a continuous approximation analysis of the “close-enough TSP”, in which one is given a set of shapes in a service region and the goal is to find the shortest tour that visits at least one point in each region. Our analysis focuses on the case where the regions are disks in the Euclidean plane. We derive asymptotic results for the optimal tour length as the number of regions approaches infinity, while the total area covered by the regions remains approximately constant. Using techniques from geometric probability theory, we establish tight bounds on the tour length.

Strategic Behavior in Queueing and Service Systems

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Chen-An Lin, Purdue University, West Lafayette, IN, 47906, United States

1 - Adding Servers to Reinforce Facilities in A Spatially Distributed Queueing System

Monir Sabbaghtorkan, UCLA, Los Angeles, CA, United States

We study the problem of adding servers to reinforce functioning facilities modeled as spatially distributed M/M/c type queuing systems. We consider two modes, stationary and interactive. The stationary mode is for a situation in which adding new servers to functioning facilities will not change the demand distribution (e.g., hospital care or vehicle inspection). The interactive mode is for a situation in which adding servers will likely change the demand distribution (e.g., gas stations, electric vehicle charging stations). Here we use the gravity rule to model demand adjustment. A case study is presented based on the allocation of gas servers to existing gas stations in a hurricane evacuation event. Managerial insights are provided based on sensitivity analysis.

2 - Waiting Together: How to Infer Response TIME when Customers Wait in Groups

Yanting Li, University of Rochester, Rochester, NY, United States, Ricky Roet-Green

We introduce a novel model that accommodates customers arriving either individually or in pairs, who are then served in their original group configurations. Each group is demanding one unit of service, regardless of the group size. The concept of information granularity is central to our study, indicating that upon arrival, customers may possess incomplete information about the demand distribution. To analyze customer strategies in the absence of perfect information, we employ Bayesian updating process to capture customers' decision making. Through an evaluation of the value of demand ratio information, we show that the provision of additional information does not always yield optimal throughput or social welfare. Indeed, under specific conditions, less information may enhance system performances. Consequently, service providers should carefully determine the level of information sharing, taking into consideration the parameters of the system.

3 - Optimal Control of Single-Server Queues: a Wait-TIME-Based Approach

Chen-An Lin, Purdue University, West Lafayette, IN, United States

This paper studies an optimal control problem for a single-server queue in which customers arrive according to a Poisson process. The service provider determines a control policy for each arriving customer according to the system wait time. The customer, in turn, decides whether to accept the policy offer and join the queue. The objective is to maximize the average reward in an infinite horizon. The proposed model encompasses many practical service systems with customers ranging from homogeneous with a known type to heterogeneous with unknown types. We illustrate the applicability of this general model through three practical service systems: discretionary services, service operations, and make-to-order systems. The key contribution of this work is to show the existence and optimality of a stationary, wait-time-dependent policy. In addition, we characterize the structure of the optimal policy through the corresponding Hamilton-Jacobi-Bellman equation and reveal insights. The application of the make-to-order system leads to a mechanism design problem. In particular, we find that when the wait time becomes longer, the provider should admit more patient customers while offering an option with a shorter job lead time. Interestingly, the offered payment may not be monotonic in the wait time.

4 - Managing Service Systems with Overconfident Customers

Na Zhang, Wichita State University, Wichita, KS, United States

We study a service system where true service times are the manager's private information and customers exhibit the cognitive bias of being overconfident (in particular, overprecise) in their beliefs about service times—customers underestimate the variability of service times. We formulate the problem as a stylized queueing model to examine the implications of overconfidence in service systems. Our models and results generalize those in several seminal queueing-economics papers published on Econometrica. Specifically, when customer overconfidence level is zero, our models and results reduce to those in the aforementioned papers; however, when customer overconfidence level is positive, our models and results are qualitatively different. Our results also generate interesting practical implications. First, we provide overconfidence theory as a plausible explanation for the commonly observed long-queue phenomenon. Second, the manager should adopt a strictly increasing price patter w.r.t. overconfidence level in the unobservable queue, but he may need to implement a non-monotonic price pattern in the observable queue. Third, we recommend the manager to always reveal queue length information to improve revenue for both sufficiently low and sufficiently high congestion, but strategically decide whether to reveal queue length information for intermediate congestion. Additionally, customers should be wary of the ostensible benefit of queue length information as it may decrease consumer surplus. This paper unravels the role of overconfidence in service systems and its important implications on the manager's pricing decision and queue-length-information provision policy, as well as consumer surplus.

Data-Driven Healthcare Management

Contributed Session

Chair: Shirin Geranmayeh, University of Alberta, Edmonton, AB, Canada

1 - Two-Step Machine Learning Approach in Healthcare Fraud Detection

Basiru Usman, North Carolina State University, Raleigh, NC, United States

In the realm of healthcare, a multifaceted environment intertwines with political sensitivity, necessitating meticulous scrutiny of any occurrences within the industry. Concurrently, the sector grapples with escalating data volumes, fostering an environment ripe for fraudulent activities exploiting its intricacies and sensitivities. This study introduces a two-tiered machine learning framework designed to augment healthcare fraud auditors' decision-making processes, offering invaluable support in navigating this complex landscape.

2 - Physician-Patient Co-production of Healthcare Services: Leveraging Generative Artificial Intelligence (AI) for Smarter Decisions and Value Co-creation

Arvin Sahaym, Washington State University, Pullman, WA, United States, Om Sahaym, Jay Sahaym

A healthcare ecosystem is a complex and dynamic system involving multiple stakeholders. Assuming that patients in the modern era get information (or misinformation) about their symptoms on the internet, this study contributes by urging traditional healthcare ecosystems to evolve into a system of co-production rather than remaining stuck in the tradition of 'service delivery.' Building on the premise that the overall goal is to provide superior value in terms of patient-centered care *and* patient satisfaction, this study examines how patients and specialist physicians can co-produce healthcare leveraging AI for smarter decisions and value co-creation. We draw on the patient's voice and feedforward literature, decision-making, and behavioral economics to propose that 1) physicians' proactive consideration of patients' voice in clinical decisions has costs and benefits but will be associated with net gain in providing superior value, 2) patient voice is influenced by generative AI, which provides more detailed deep-learning-based information that will further enhance the above relationship, 3) the AI-influenced patient voice nudges physicians toward considering the treatment desired by the patient, and 4) AI usage increases psychological ownership of the treatment by the patient, leading to higher levels of patient-centered care *and* satisfaction. Overall, smarter decision-making and superior value will be attained by incorporating AI-enabled patient voice. We contribute to the literature on decision-making, psychology, and economics and have implications for healthcare stakeholders and policymakers.

3 - Managing the Gatekeeping System: Referral Discounts and AI-Based Diagnosis

Chenhe Pan, Renmin University of China, Beijing, China, People's Republic of, Xiaofang Wang, Yixuan Liu, Guoming Lai

Patients may suffer from high congestion and delayed treatment due to unevenly distributed healthcare resources. Without professional assistance, patients cannot accurately identify their severity and may make inappropriate choice among tiered care providers. Recently, artificial intelligence-based diagnosis is widely used to help patients to make better treatment choice in addition to traditional financial incentives. We develop a model of the two-level gatekeeping healthcare system with patient choice to study the referral incentive design and the impact of introducing such artificial intelligence-based diagnosis. Our results provide insights from the perspective of social welfare optimization.

4 - Clinical Trials Supply Chain: a Multi-Stage Stochastic Programming Approach for Inventory Control

Mustafa Gurbuz, Zaragoza Logistics Center, ZARAGOZA, Spain, Daniel Calcinaro

Clinical trial supply chains have recently become more complex due to increasing globalization of such experiments and strict regulations in the pharmaceutical industry. Managers are under pressure to secure early entry to the market (i.e., reduce completion time of the trial), reduce supply chain costs, and reduce excess inventory at the end of the trial.

We propose a multi-stage stochastic optimization model to make informed production and distribution decisions with the concerns mentioned above in mind. The clinical trial supply chain we analyze has one central warehouse, multiple country depots, and multiple sites (e.g., hospitals). Patients enrol for the new drug at the sites according to a known probability distribution. Clinical trial ends when a targeted number of patients enrol, therefore we analyze a finite horizon model without a specified completion time. Our model is different from most of the existing models in the relevant literature because it allows for multiple production runs, multiple dose, and the perishable nature of the drugs.

As expected, the optimization model requires a prohibitively large number of scenarios to be evaluated. Therefore, a novel clustering-based scenario reduction technique is proposed to quickly obtain near optimal solutions. We test our model in three clinical trials that a global major pharmaceutical company ran in recent years. The scenario reduction technique we propose works very well, and show that our model helps minimize completion time, while keeping costs under control and reducing excess inventory.

5 - Operating room planning and modelling of a network of post-op units in a paediatric tertiary teaching hospital

Shirin Geranmayeh, University of Alberta, Edmonton, AB, Canada, Armann Ingolfsson, John Doucette, Oleksandr Shlakhter

Our research explores methodologies for optimizing operating room (OR) scheduling at the Stollery Children’s Hospital - a pediatric tertiary teaching hospital in Edmonton, Alberta, Canada. We propose an approach aimed at developing a master surgery schedule to minimize post-operative bed blockages in downstream units specific to a pediatric hospital. The objective is to address the challenges of surgery cancellations due to bed shortages and the aim is to improve resource allocation efficiency. Historical data is used to estimate the patient-age-specific consumption of hospital resources, which impacts operational decision making in OR, and, bed allocation and utilization.

Information Design for Incentive-Aware Learning

Invited Session

Applied Probability Society

Chair: Kunhe Yang, UC Berkeley, Berkeley, CA, United States

Co-Chair: Nika Haghtalab

1 - Information Design for Collaborative Learning: Efficiency, Incentive-Awareness, and Robustness

Kunhe Yang, University of California, Berkeley, Berkeley, CA, United States, Nika Haghtalab, Mingda Qiao

We explore an information design perspective on promoting collaboration among strategic agents, with applications to collaborative learning. It has been shown that many traditional collaboration protocols either require efforts from certain agents that surpass what is individually rational for them, or suffer from significant inefficiency. Motivated by federated collaborative learning, we propose a framework where an informed platform that possesses more information about the relationship between agents' tasks aim to steer the agents towards collaboration outcomes that are both efficient and incentive-aware. We design information structures that achieve efficiency, incentive-awareness, and robustness to signal leakage at the same time.

2 - A Persuasive Approach to Combating Misinformation

Safwan Hossain, Harvard University, Cambridge, MA, United States, Andjela Mladenovic, Yiling Chen, Gauthier Gidel

Bayesian Persuasion is proposed as a tool for social media platforms to combat the spread of misinformation. Since platforms can use machine learning to predict the popularity and misinformation features of to-be-shared posts, and users are largely motivated to share popular content, platforms can strategically signal this informational advantage to change user beliefs and persuade them not to share misinformation. We characterize the optimal signaling scheme and utility when predictions are imperfect by framing this as a linear program and giving sufficient and necessary conditions on the classifier to ensure optimal platform utility is non-decreasing and continuous. Next, this interaction is considered under a performative model, wherein platform intervention affects the user's future behaviour. The convergence and stability of optimal signaling under this performative process are fully characterized. We also experimentally validate that our approach leads to a significant reduction in misinformation, even with weak classifiers, and comment on the broader scope of using information design to combat misinformation.

3 - Incentivizing Combinatorial Bandit Exploration

Daniel Ngo, University of Minnesota, Pittsburgh, PA, United States, Xinyan Hu, Alex Slivkins, Steven Wu

Consider a bandit algorithm that recommends actions to self-interested users in a recommendation system. The users are free to choose other actions and need to be incentivized to follow the algorithm's recommendations. While the users prefer to exploit, the algorithm can incentivize them to explore by leveraging the information collected from the previous users. All published work on this problem, known as incentivized exploration, focuses on small, unstructured action sets and mainly targets the case when the users' beliefs are independent across actions. However, realistic exploration problems often feature large, structured action sets and highly correlated beliefs. We focus on a paradigmatic exploration problem with structure: combinatorial semi-bandits. We prove that Thompson Sampling, when applied to combinatorial semi-bandits, is incentive-compatible when initialized with a sufficient number of samples of each arm (where this number is determined in advance by the Bayesian prior). Moreover, we design incentive-compatible algorithms for collecting the initial samples.

4 - Dynamic Pricing and Learning with Bayesian Persuasion

Shipra Agrawal, Columbia University, New York, NY, United States

We consider a novel dynamic pricing and learning setting where in addition to setting prices of products in sequential rounds, the seller also ex-ante commits to 'advertising schemes'. That is, in the beginning of each round the seller can decide what kind of signal they will provide to the buyer about the product's quality upon realization. Using the popular Bayesian persuasion framework to model the effect of these signals on the buyers' valuation and purchase responses, we formulate the problem of finding an optimal design of the advertising scheme along with a pricing scheme that maximizes the seller's expected revenue. Without any apriori knowledge of the buyers' demand function, our goal is to design an online algorithm that can use past purchase responses to adaptively learn the optimal pricing and advertising strategy. We study the regret of the algorithm when compared to the optimal clairvoyant price and advertising scheme. Our main result is a computationally efficient online algorithm that achieves an $O(T^{2/3}(m\log T)^{1/3})$ regret bound when the valuation function is linear in the product quality. Here m is the cardinality of the discrete product quality domain and T is the time horizon. This result requires some natural monotonicity and Lipschitz assumptions on the valuation function, but no Lipschitz or smoothness assumption on the buyers' demand function. For constant m, our result matches the regret lower bound for dynamic pricing within logarithmic factors, which is a special case of our problem. We also obtain several improved results for the widely considered special case of additive valuations, including an $\tilde{O}(T^{2/3})$ regret bound independent of m when $m\le T^{1/3}$.

5 - Bayesian Strategic Classification

Juba Ziani, Georgia Tech, Atlanta, GA, United States

In strategic classification, agents modify their features, at a cost, to obtain a positive classification from the learner's classifier. The typical response of the learner is to carefully modify their classifier to be robust to such strategic behavior. Most works rely on the strong assumption that agents fully know the exact parameters of the deployed classifier by the learner. This can be unrealistic when using complex or proprietary machine learning techniques in real-world prediction tasks.

We initiate the study of partial information release by the learner in strategic classification. We move away from the traditional assumption that agents have full knowledge of the classifier and consider agents that have a distributional prior on which classifier the learner is using. The learner can reveal truthful, yet not necessarily complete, information about the deployed classifier to the agents. The learner's goal is to release just enough information about the classifier to maximize accuracy. We show how such partial information release can, counter-intuitively, benefit the learner's accuracy, despite increasing agents' abilities to manipulate.

We show that while it is intractable to compute the best response of an agent in the general case, there exist oracle-efficient algorithms that can solve this best response problem for the class of linear classifiers, or when the agents' cost function satisfies a natural notion of submodularity. We then turn our attention to the learner's optimization problem and provide both positive and negative results on the algorithmic problem of how much information the learner should release about the classifier.

1 - Exact Random Graph Matching with Multiple Graphs

Taha Ameen, University of Illinois Urbana-Champaign, Urbana, IL, United States, Bruce Hajek

This work studies fundamental limits for recovering the underlying correspondence among multiple correlated random graphs. We identify a necessary condition for any algorithm to correctly match all nodes across all graphs, and propose two algorithms for which the same condition is also sufficient. The first algorithm employs global information to simultaneously match all the graphs, whereas the second algorithm first partially matches the graphs pairwise and then combines the partial matchings by transitivity. Remarkably, both algorithms work down to the information theoretic threshold. Our analysis reveals a scenario where exact matching between two graphs alone is impossible, but leveraging more than two graphs allows exact matching among all the graphs. Along the way, we derive independent results about the k-core of Erdos-Renyi graphs.

2 - Interplay of Network Structure and Evolutions in the Emergence of Epidemics

Mansi Sood, Carnegie Mellon University, Pittsburgh, PA, United States, Anirudh Sridhar, Rashad Eletreby, Chai Wah Wu, Simon A Levin, H. Vincent Poor, Osman Yagan

In this talk, we examine mechanisms that lead to the widespread propagation of contagions, e.g., misinformation and pathogens, and identify risk factors that can trigger widespread outbreaks. Akin to different strains of a pathogen arising through evolutionary adaptations or mutations, different variants of a piece of information may be created as the content is altered on social media platforms. The resulting variants of the information may have different propensities to be circulated on different social media platforms. However, most existing models for analyzing contagions assume a simplistic network structure with a homogeneous probability of transmission of the contagion across different types of links and contagion strains. We propose and analyze models for the spread of evolving contagions by accounting for a multi-layer network structure where each individual can participate in different network layers corresponding to different settings in which they interact with others and potentially pass on the contagion. Our results highlight that reductions to existing models that do not simultaneously account for heterogeneity in the contagion strains and network layers may lead to incorrect predictions of the likelihood of the emergence of an epidemic outbreak.

3 - Random Geometric Graph Alignment with Graph Neural Networks

Suqi Liu, Harvard University, Boston, MA, United States

We characterize the performance of graph neural networks for graph alignment problems in the presence of vertex feature information. More specifically, given two graphs that are independent perturbations of a single random geometric graph with noisy sparse features, the task is to recover an unknown one-to-one mapping between the vertices of the two graphs. We show under certain conditions on the sparsity and noise level of the feature vectors, a carefully designed one-layer graph neural network can with high probability recover the correct alignment between the vertices with the help of the graph structure. We also prove that our conditions on the noise level are tight up to logarithmic factors. Finally we compare the performance of the graph neural network to directly solving an assignment problem on the noisy vertex features. We demonstrate that when the noise level is at least constant this direct matching fails to have perfect recovery while the graph neural network can tolerate noise level growing as fast as a power of the size of the graph.

4 - Manifold Filters and Neural Networks: Geometric Graph Signal Processing in the Limit

Zhiyang Wang, University of Pennsylvania, Philadelphia, PA, United States, Luana Ruiz, Alejandro Ribeiro

Convolutional neural networks (CNNs) have achieved impressive success in a wide range of applications. When processing non-Euclidean data, graphs are commonly used as a discrete model to capture the underlying geometric structure. Convolutions can be readily extended to graph convolutions, which allows defining convolutional graph neural networks (GNNs). In graphs of moderate size, GNNs are well-backed by their expressive power and stability. However, in the large-scale regime with more practical interest, their behavior is not as well understood. My work focuses on building manifold convolutional filters and manifold neural networks (MNNs) as a limit model for convolutional filters and neural networks on large geometric graphs. A two-way connection between filters and neural networks on graphs and manifolds is proposed by showing GNNs running on graphs sampled from a manifold converge to the MNN running on the underlying manifold with non-asymptotic convergence results. The convergence allows the transferability of GNNs among different graphs sampled from the same underlying manifold, which enables us to design GNNs on small graphs and transfer them to larger graphs. MNNs, as a formal limit of GNNs provide a theoretical tool for understanding large-scale GNNs. I proceed to analyze the stability of manifold filters and MNNs to smooth deformations of the manifold. This sheds light on the behavior of large-scale graph filters and GNNs, which are prone to undergo perturbations and changes in real-world scenarios. The theoretical results are verified under wireless resource allocation, point cloud analysis, and navigation control problem settings.

1 - How do neural networks learn features from data?

Adityanarayanan Radhakrishnan, Harvard SEAS, Cambridge, MA, United States, Daniel Beaglehole, Parthe Pandit, Mikhail Belkin

Understanding how neural networks learn features, or relevant patterns in data, for prediction is necessary for their reliable use in technological and scientific applications. We propose a unifying mechanism that characterizes feature learning in neural network architectures. Namely, we show that features learned by neural networks are captured by a statistical operator known as the average gradient outer product (AGOP). Empirically, we show that the AGOP captures features across a broad class of network architectures including convolutional networks and large language models. Moreover, we use AGOP to enable feature learning in general machine learning models through an algorithm we call Recursive Feature Machine (RFM). Overall, this line of work advances our fundamental understanding of how neural networks extract features from data, leading to the development of novel, interpretable, and effective models for use in scientific applications.

2 - Moreau Envelopes, Overfitting, and Generalization Theory

Frederic Koehler, University of Chicago, Chicago, IL, United States

Memorization of the training data, in various forms, seems to be a common feature of many successful ML models. From a theoretical standpoint, understanding the interplay between partial memorization and generalization also turns out to be very interesting. We discuss some recent developments which have connected VC-style generalization theory to modern probabilistic methods in high-dimensional statistics and given some new insight into what's going on, especially in the benchmark setting of linear models.

3 - The Neural Covariance SDE and Its Limiting Spectrum

Mufan Li, Princeton University, Princeton, NJ, United States

Recent advances in neural network research have predominantly focused on infinite-width architectures, yet the complexities inherent in modelling networks with substantial depth call for a novel theoretical framework. In this presentation, we explore a unique approach to modelling neural networks using the proportional infinite-depth-and-width limit.

In fact, naively stacking non-linearities in deep networks leads to problematic degenerate behaviour at initialization. To address this challenge and achieve a well-behaved infinite-depth limit, we introduce a fundamentally novel framework: we treat neural networks as depthwise stochastic processes. Within this framework, the limit is characterized by a stochastic differential equation (SDE) that governs the feature covariance matrix. Notably, the framework we introduced leads to a very accurate model of finite size networks, and the approach yields a natural remedy for vanishing gradients in Transformers. Finally, we will also leverage the SDE structure to derive a limit spectrum result for feature covariance of linear networks.

4 - How Transformers Learn Causal Structure with Gradient Descent

Eshaan Nichani, Princeton University, Princeton, NJ, United States

The incredible success of transformers on sequence modeling tasks can be largely attributed to the self-attention mechanism, which allows information to be transferred between different parts of a sequence. Self-attention allows transformers to encode causal structure which makes them particularly suitable for sequence modeling. However, the process by which transformers learn such causal structure via gradient-based training algorithms remains poorly understood. To better understand this process, we introduce an in-context learning task that requires learning latent causal structure. We prove that gradient descent on a simplified two-layer transformer learns to solve this task by encoding the latent causal graph in the first attention layer. The key insight of our proof is that the gradient of the attention matrix encodes the mutual information between tokens. As a consequence of the data processing inequality, the largest entries of this gradient correspond to edges in the latent causal graph. As a special case, when the sequences are generated from in-context Markov chains, we prove that transformers learn an induction head (Olsson et al., 2022). We confirm our theoretical findings by showing that transformers trained on our in-context learning task are able to recover a wide variety of causal structures.

1 - A Data-Driven Optimization Framework to Improve Search Advertising Efficiency

Kerim U. Kizil, Texas A&M University, College Station, TX, United States, Rajiv Mukherjee, Bala Shetty, Chelliah Sriskandarajah, Jon Stauffer

This study proposes a data-driven optimization framework to improve search advertising efficiency in higher education marketing. We define efficiency in this context as the number of clicks per advertisement dollar spent. Using a search term dataset provided by the search engine, we investigate the case of a specific higher education institution. Social media and search term data are analyzed with natural language processing and AI tools to identify seasonal patterns in the decision-making journeys of prospective students. Based on marketing literature, we focus on four decision-making steps: *(i)* need recognition, *(ii)* information search, *(iii)* evaluation of alternatives, and *(iv)* decision/application. We subsequently categorize the search terms in our dataset into four classes: *(i)* explorative, *(ii)* navigational, *(iii)* rival-branded, and *(iv)* focal-branded. The built empirical models inform the optimization process of keyword-level bid amounts, which are subject to change temporally. We use the results of this study to argue that advertisers can achieve higher search advertising efficiency by analyzing available data (i.e., historical search terms and social media data) using machine learning and AI methods rather than relying on the proprietary and opaque algorithms of search engines for bid decisions.

2 - Strategic Product Design and Launch Strategies for Manufacturers When Selling to Time-Inconsistent Consumers

Chen Pang, Hong Kong Polytechnic University, Hong Kong, Hong Kong, Gang Li, Li Jiang

The temporal disparity between instant payments and delayed payoffs leads to the misestimation of intertemporal utilities, resulting in consumers' time-inconsistent behaviour. This paper explores how manufacturers strategically adjust their product design and product launch strategies if consumers are time-inconsistent. We develop a two-period utility-based model by employing a hyperbolic discounting scheme. Our results reveal that time inconsistency gives rise to three demand patterns to the manufacturer: demand vanishing, demand migration, and demand expansion. The extent of time inconsistency and the differentiation level between advanced and original versions interact dynamically, influencing the magnitude of demand patterns accordingly. Moreover, when the advanced-versioned product closely resembles the original-versioned product in experiential features, the manufacturer tends to accelerate its product launch schedule in the presence of time-inconsistent consumers, a phenomenon termed the assistance effect. Conversely, a deterrent effect is observed when the experiential features of the advanced-versioned product significantly diverge from those of the original-versioned product. In such case, the manufacturer is more likely to defer the implementation of the product launch strategy when time inconsistency exists.

3 - Balancing Act: The impact of ESG disclosure on customer network instability

JIA REN, The Hong Kong Polytechnic University , Hong Kong, Hong Kong, Kee-hung Lai

Environmental, social, and governance (ESG) disclosure is gaining stakeholder attention.A firm's operations may be adversely affected by excessive or insufficient disclosure of ESG, a non-financial objective. So ESG disclosure balance deserves more attention. Besides, the scope of a firm's ESG disclosure is crucial for its customers because customers are the receiving ends of ESG practices and then they will decide on whether to exit original supply and demand network based on their upstream firms' ESG disclosure. However, the impact of a firm's ESG disclosure balance on its customers network instability remains a question. Drawing on organizational ambidexterity theory, this research finds an instability-reducing effect of ESG disclosure balance on a firm's customer network from the perspective of exploitation. Using 2012-2022 panel dataset from multiple sources, we find that ESG disclosure balance is negatively related to customer network instability. Furthermore, this study identifies two boundary conditions affecting this relationship.Specifically, AI innovation, as an exploration activity, strengthens the relationship between ESG disclosure balance and customer network instability, whereas from the perspective of financial constraints, positive feedback on financial performance weakens the main effect. These findings contribute to ESG disclosure and sustainable supply chain management literature by illustrating the effect of a firm's ESG disclosure balance on its customer network instability. In addition, by elaborating on exploitation (ESG disclosure balance) and exploratory activities (AI innovation), this study contributes to organizational ambidexterity theory advancement and expansion in the context of ESG disclosure.

4 - Investigating community equity through franchised fast-food restaurants: A crowdsourcing approach using Google Map Reviews

Hongli Ye, Clemson University, CENTRAL, SC, United States, Lingyao Li, Songhua Wu, Weiwei Zhan

Franchised restaurants are expected to maintain uniformity across the nation. However, through an analysis of Google Maps reviews using large language models (LLMs) and sentiment analysis, we uncovered significant variations in service quality across different communities. Furthermore, our findings indicate that the COVID-19 pandemic has notably influenced community equity within the franchised restaurant sector.

1 - Data-Informed Changes in Prenatal Care Policies to Meet Social as Well as Medical Needs

Amy Cohn, University Of Michigan, Ann Arbor, MI, United States

The standard practice of prenatal care in the United States has seen minimal changes over the history of modern healthcare. It is arguably the antithesis of "personalized medicine," with standard pathways of in-person clinical visits with limited deviation. Arguably, these visits may not all be value-added, especially when taking into account the fact that in many parts of the country the healthcare system is at (or beyond) capacity. Furthermore, while lower-income patients often receive too little care in the US health system, arguably the modern-day prenatal pathways may provide too *much* care. For patients with limited income, transportation access, and job flexibility, additional prenatal visits can provide a high burden without significant added value. We use data-driven simulation to evaluate the impact of different prenatal care pathways on patient access and clinic capacity.

2 - Cost-Effectiveness Analysis of Reducing Exposure to Secondhand Smoke in New York City: A Cardiovascular Disease Microsimulation Study

You Zhou, Purdue University, West Lafayette, IN, United States, Nan Kong, Brandon Bellows, Yan Li

Cardiovascular disease is the leading cause of deaths in the US. To reduce its heavy burden on the healthcare system, prevention-based public health policies become the focus through promoting healthy behaviors and managing risk factors. In our paper, we adapted the well-established and validated microsimulation model for tobacco tax policy analysis in New York city with incorporation of 2 key factors: 1) illicit market and 2) secondhand smoke exposure. We simulated each individual's cardiovascular disease (e.g., stroke and coronary heart disease) progression trajectory, and estimated the associated health cost reduction and the quality-adjusted life years (QALYs) gained by implementing tax policy to reduce cigarette consumption and secondhand smoke exposure for adults in New York city. In the model, the population socioeconomical and health profiles were sampled from NYC Health and Nutrition Examination Survey dataset and the relative risk of secondhand smoke exposure on cardiovascular disease were pooled from the recent meta-analyses. Our preliminary results show that the additional tobacco tax can be cost-effective (defined as <$50,000 per QALY) even with substantial illicit market. Health benefits from nonsmokers exposed to secondhand smoke show significant contribution in the analysis which takes up over 27% of total incremental QALYs.

3 - Optimizing Surveillance Policies for Hospital-Acquired Infections: Case of Mrsa

Esma Akgun, University of Waterloo, Waterloo, ON, Canada, F. Safa Erenay, Sibel Alumur Alev, William Ciccotelli

Roommates of nosocomial methicillin-resistant \textit{Staphylococcus} aureus (MRSA) cases have a high risk of MRSA acquisition. Following infection prevention and control guidelines, these individuals are isolated and undergo surveillance screening. However, the optimal post-exposure surveillance testing and isolation strategies for contacts of MRSA cases are unknown. We develop a Markov decision process model to optimize the screening decisions for the individuals exposed to MRSA cases in hospitals to minimize loss of quality-adjusted life years. We solve the model optimally using data from clinical literature and conduct sensitivity analyses on key parameters, including disutility values and disease parameters, such as prevalence and transmission probability. The optimal screening decisions recommends varying both the frequency and timing of screenings based on initial screening results and room configurations. Particularly in cohort rooms, where the risk of transmission during isolation is increased, initiating screening early is crucial. Although implementing these optimal screening decisions may present challenges due to their complexity, they offer valuable insights for improving MRSA management in healthcare settings, potentially leading to better health outcomes and cost savings compared to current practices. We evaluate and compare the performances of several surveillance policies, including different testing schedules and modalities using the proposed modeling framework enabling us to incorporate the test sensitivities on different days. We suggest alternative screening policies that balance cost-effectiveness with clinical efficacy, aligned with decision-makers' objectives. Furthermore, the model's applicability extends beyond MRSA to other hospital-acquired infections with similar surveillance screening protocols, demonstrating its potential for infection prevention and control strategies.

4 - Political Affiliation and Mental Health During Crises: Insights from Online Communication

Saeede Eftekhari, Tulane University, New Orleans, LA, United States, Zhasmina Tacheva, Claire Senot

The world is struggling with multiple crises on a global scale: from the recent global COVID-19 pandemic and a global recession to the uncertainty of the AI revolution, multiple zones of active conflict, and growing political division. Using advanced analytical techniques, including longitudinal econometric modeling, transformer-based language model analysis, and topic modeling, this paper studies whether political affiliation plays a role in the level of mental health well-being in the period between 2019 and 2023, as manifested in the online communication of the United States-based Twitter users. We found evidence for this differential effect and showed that it depends on multiple factors, including the state in which an online user resides and the type of COVID-related policies in effect in their place. This research contributes to the emergent management science domain of building healthier information ecosystems.

1 - Data-Driven Method for Quality Monitoring in Multi-Mode Surface Topography

Jaeseung Baek, Northern Michigan University, Marquette, MI, United States, Myong Kee Jeong, Elsayed Elsayed

Recent advancements in optical measuring instruments have led to an increased utilization of surface topographic data for quality monitoring of engineered surfaces. This study introduces efficient anomaly detection methods for monitoring variations in different types of surface topography. We explore approaches for monitoring two types of surfaces: single mode and multimode surface topography. Initially, we present a residual-based surface segmentation approach to identify local surface changes in surfaces under a single in-control mode. Subsequently, we introduce a multimode surface prediction model, characterizing the typical behavior of normal surfaces with multiple in-control modes.

2 - Hlfgp-Mobo: Heterogeneous Latent Factor Gaussian Process for Multi-Objective Bayesian Optimization of Longitudinal Data

Aditya Satish Rane, Oklahoma State University, Stillwater, OK, United States, Md Shihab Shakur, Srikanthan Ramesh, Akash Deep

Fabricating functional bioprinted constructs is a time-consuming and expensive process, often involving repeated measure designs. In these designs, post-printing cellular functions, such as albumin and urea secretion, are measured temporally. The goal is to develop a design strategy that effectively models and optimizes multiple outcomes simultaneously. Multi-objective Bayesian optimization (MOBO) typically uses independent Gaussian processes as surrogate models, which assume an independent covariance structure between objectives. This difficulty in capturing correlations can lead to suboptimal results when the objectives are correlated. Additionally, classical methods for modeling panel data such as Generalized Linear Mixed-Effects Models, Structural Equation Modeling, and Latent Growth Models have limitations. These include capturing non-linear effects, computational challenges with larger sample sizes, and addressing measurement errors due to sub-group heterogeneity. To overcome the challenges associated with modeling and optimizing longitudinal data with multiple objectives, we propose HLFGP-MOBO, a hybrid integration of multi-output Gaussian process covariance structure and MOBO. Our methodology comprises of three key components: (1) Model correlated time-varying multiple outcomes by capturing auto-covariance and cross-covariance. (2) Incorporating cellular endpoint sampling noise to adapt heterogeneous noise patterns, accounting for different levels of noise variability. (3) Formulating an adaptive experimentation framework with MOBO acquisition function to iteratively design experiments based on MOGP estimates. We demonstrate the effectiveness of our approach through extensive experimentation in 3D bioprinting, where time-dependent cellular endpoints are collected to measure cell viability and functionality. By optimizing bioprinting process parameters using our methodology, we aim to enhance cell proliferation.

3 - Sequential Partial Least Squares Regression for Multi-Variate Time-Series Sensor Data.

GyeongTaek Lee, Gachon University, SeongNam, Korea, Republic of

In manufacturing environments including semiconductor manufacturing, from the equipment, a variety of sensor data are collected. Process engineers manage manufacturing quality using predictive models based on the collected data . It has been a challenging task to handle this temporally characteristic data, as it is uncertain when patterns of defects might occur. Over the past decade, deep learning has advanced, allowing for the utilization of models that can incorporate temporal characteristics in manufacturing process. However, in manufacturing process. issues such as process drift, maintenance, and changes in process techniques cause periodic changes in data characteristics, making it difficult to secure large amounts of training data. This study proposes a sequential partial Least Squares Regression that can reflect temporal characteristics to enhance the performance of defect detection models. The proposed methodology exhibited higher performance than conventional machine learning and deep learning models in situations with limited data.

4 - Fast Bayesian Support Vector Data Description

Support Vector Data Description (SVDD) is a support vector-based learning algorithm that is used to detect anomalies. It obtains a spherically shaped boundary around the target data and is a very attractive kernel method as it outperforms comparable methods in problems that involve the detection of anomalies. However, training an SVDD algorithm is computationally expensive, since it requires solving a quadratic programming problem with time complexity of order $O(N^3)$. The same problem exists for Bayesian SVDD (BSVDD) processes. In BSVDD applications that involve big and high-dimensional data, a significant disadvantage is the high computational cost since the whole training data set must be stored and evaluated. Also, speed during testing is important in a growing number of applications (e.g., edge computing). To address this problem, we propose a new Fast BSVDD procedure which significantly improves the computational time of traditional BSVDD.

1 - A Geometrically Convergent Solution to Spatial Hypercube Queueing Models for Emergency Services

Yixing Wen, Shanghai Jiao Tong University, Shanghai, China, People's Republic of

The spatial hypercube queueing model was developed 50 years ago to solve spatial queueing problems and has been widely applied to emergency services such as police and ambulance systems. We devise an alternative solution to the hypercube model, and show that it yields the same solution as the original model. We prove our algorithm converges at a geometric rate to an exact solution. While the original model was developed for homogeneous service rates, we extend our method to accommodate heterogeneous service rates and prove the conditions for convergence. Through comprehensive numerical experiments using two datasets from St. Paul, MN, and Greenville County, SC, we show that our approach is more than 80% faster than the original approach with an average percentage error of less than 0.1%. Additionally, we develop a parallel computing algorithm leveraging the convergence property of our approach and two key structural properties of the problem to further reduce its computational time, achieving more than 94% of parallelization.

2 - Wasserstein Risk-Sensitive Appointment Scheduling under Delay Constraints

Jia Zhao, University of Chinese Academy of Science, Beijing, China, People's Republic of

We consider a risk-averse appointment scheduling problem for a healthcare service delivery system with discrete appointment times and service-duration ambiguity, focusing on the tradeoff between overtime work and patient delays. We employ conditional value-at-risk (CVaR) to measure the risk, and to address the ambiguity, we develop a distributionally robust optimization (DRO) model over a type-1 Wasserstein ball centered at an empirical service-duration distribution. We show that the Wasserstein DRO model enjoys a regularized reformulation, which captures an empirical-risk effect and a position-differentiated effect on synthesized aversion to risk and ambiguity. The regularized reformulation provides an important operational insight of position-differentiated robustness for delay management under service-duration ambiguity, without incurring additional complexity. Leveraging the regularized reformulations, the optimal schedule can be determined efficiently by evaluating the empirical CVaRs with binary search for each position sequentially. We then perform sensitivity analysis, primal-dual analysis, and derive finite-sample and asymptotic performance guarantees for the optimal schedule obtained. Furthermore, we extend our model to incorporate sequence decisions for multiple types of patients, which also exploits the regularization structure and can be solved as one instance of mixed-integer linear program. Finally, numerical experiments demonstrate the insights and performance of the proposed approach.

3 - Personalized Health Check-up Decisions Using Data Analytics and Markov Decision Processes

Tianning Zhu, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Guohua Wan

Annual health check-ups are common in many countries but they may not be necessary in case of persons with good health conditions. Using a large data set of health check-ups in China, we analyze the relationships between various indices of the items in health check-ups. With these relationships we develop a partially observable Markov decision process for personalized health check-up decisions so as to maximize the person's expected quality-adjusted life years.

4 - Personalized Lung Cancer Screening Strategies: A Markov Model Approach Using Real Patient Data from China

Ting Wu, Nanjing University, Nanjing, China, People's Republic of

Lung cancer ranks first in incidence and mortality among malignant tumors both in China and globally, often being detected at an advanced stage with a five-year survival rate of 17.4%. Early definitive surgery remains the most effective treatment, highlighting the importance of early detection and screening before symptoms arise and curative treatment is possible. This study explores how to personalize lung cancer screening policies to maximize long-term patient benefits. We first establish a Markov model, utilizing real patient data to estimate parameters and simulate the outcomes of lung cancer screening and subsequent treatment. We then integrate various data, supplement different actions and their benefits, and input this information into a Partially Observable Markov Decision Process (POMDP) model to determine the optimal screening strategy.

5 - Wasserstein Risk-Sensitive Appointment Scheduling under Delay Constraints

We consider a risk-averse appointment scheduling problem for a healthcare service delivery system with discrete appointment times and service-duration ambiguity, focusing on the tradeoff between overtime work and patient delays. We employ conditional value-at-risk (CVaR) to measure the risk, and to address the ambiguity, we develop a distributionally robust optimization (DRO) model over a type-1 Wasserstein ball centered at an empirical service-duration distribution. We show that the Wasserstein DRO model enjoys a regularized reformulation, which captures an empirical-risk effect and a position-differentiated effect on synthesized aversion to risk and ambiguity. The regularized reformulation provides an important operational insight of position-differentiated robustness for delay management under service-duration ambiguity, without incurring additional complexity. Leveraging the regularized reformulations, the optimal schedule can be determined efficiently by evaluating the empirical CVaRs with binary search for each position sequentially. We then perform sensitivity analysis, primal-dual analysis, and derive finite-sample and asymptotic performance guarantees for the optimal schedule obtained. Furthermore, we extend our model to incorporate sequence decisions for multiple types of patients, which also exploits the regularization structure and can be solved as one instance of mixed-integer linear program. Finally, numerical experiments demonstrate the insights and performance of the proposed approach.

E-commerce Order Fulfillment: Matching, Inventory Replenishment and Demand Spillover

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Linwei Xin, Booth School of Business, University of Chicago, Chicago, IL, United States

1 - Balancing Demand Spillover and Lost-Sales Under Fulfillment Flexibility

Jingyuan Yang, Booth School of Business, University of Chicago, Chicago, IL, United States, Linwei Xin, Yuan Zhong

One key aspect of inventory management in online retailing is demand spillover, where a stockout at one fulfillment center (FC) leads to demand shifting to another FC. Our research challenges the widely accepted benefits of inventory pooling as described by the square-root law, a concept originally presented in the influential paper by Eppen (1979). This law advocates for efficiency gains through the reduction of system-level safety-stock by pooling inventory across multiple locations, thereby changing its order of magnitude from N to √N, where N represents the number of FCs. We demonstrate that pooling can lead to significant spillovers, with the magnitude growing linearly with N. We further investigate the trade-off between minimizing lost-sales and reducing spillover in two network designs with limited flexibility, and challenge the common wisdom regarding the effectiveness of long chain, a concept related to the design of flexible processes as proposed in the seminal paper by Jordan and Graves (1995). We argue that adopting the design of long chain can significantly increase spillover. In fact, we prove that as we approach the limit of minimizing lost-sales, each unit of reduced lost-sales can lead to as much as N − 1 units of extra spillover. Our study reevaluates both these established principles due to the implications of spillover in modern online retail contexts, and our results shed light on insights for e-retailers to strike an effective balance between spillover and lost-sales especially given the significant cost implications of spillover.

2 - Hybrid Fulfillment Network Operations: Inventory Management and Fulfillment

Nayeon Kim, Wayfair, Boston, MA, United States, Jason Chen

In e-commerce operations, oftentimes an online retailer operates its own fulfillment network as a service for suppliers or to fulfill its own inventory. Fulfillment-by-Amazon and Wayfair-Castlegate are examples of such operations. Some suppliers using the service also run dropship operations from their own or 3PL fulfillment network to complement the online retailer's fulfillment operations. Such hybrid fulfillment networks can offer benefits such as enhanced demand coverage without significant asset investment.

In the context of hybrid fulfillment networks, the optimal inventory replenishment, positioning, and fulfillment decisions require full information and control of both networks, which is often not feasible. For example, the online retailer may not have visibility into the supplier's on-hand or on-order information, or the supplier may only want to leverage a portion of the online retailer's fulfillment network. We will present different inventory replenishment and positioning strategies for hybrid fulfillment networks under different information and control levels and evaluate the pros and cons of each.

3 - A Deep-Learning Approach to High-Dimensional Impulse Control: with Applications to Inventory Management

Wouter van Eekelen, University of Chicago, Booth School of Business, Chicago, IL, United States, Baris Ata, Yuan Zhong

We consider a class of joint replenishment problems with renewal demands, in which procurement fixed costs can be saved by replenishing a group of different types of items together. So far, solving these problems numerically for a large number of items has been hindered by the dreaded "curse of dimensionality." To tackle this challenge, we introduce an approximation method via impulse control---a stochastic control problem that allows the system controller to intervene through discrete jumps in the state space. We then propose a novel deep-learning framework in order to solve this impulse control approximation to the original inventory problem. Grounded in the theory of backward stochastic differential equations (BSDEs), our framework relies crucially on probabilistic identities that highlight a deep connection between impulse control and stochastic target problems.

4 - Boosting Deep Reinforcement Learning in Practice: The "Less is More Approach"

Linwei Xin, Booth School of Business, University of Chicago, Chicago, IL, United States, Yaqi Xie, Will Ma

There is a prevailing perception that black-box deep reinforcement learning (DRL) algorithms can effectively solve OR/OM problems. However, in this talk, we present preliminary evidence that challenges this perception. We demonstrate that leveraging problem-specific structures can significantly boost the performance of DRL algorithms in the context of inventory management. Our key message is that combining black-box DRL with problem-specific structures not only improves outcomes but also highlights the tangible value of moving beyond purely black-box approaches.

Queueing Applications for Service Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Tugce Isik, Clemson University, Clemson, SC, United States

1 - Optimal Admission Control in Queues with Multiple Customer Classes and Abandonments

Runhua Wu, ISyE Georgia Tech, Atlanta, GA, United States, Hayriye Ayhan

We consider a Markovian, finite capacity queueing system with multiple customer classes and multiple servers where customers waiting in line can get impatient and leave without being served. There is a cost associated with abandonments and a holding cost associated with customers in the system. Admitted customers pay a class dependent reward at the time of arrival. Under these assumptions, our objective is to characterize the optimal admission control policy that maximizes the long-run average reward. We formulate the problem as a Markov decision process problem and prove that the optimal policy is a double threshold policy. We also identify sufficient conditions under which the optimal policy reduces to a threshold policy which is known to be optimal for systems without abandonments. After investigating how the optimal long-run average reward changes with respect to system parameters, we conclude with a comparison of the performance of the optimal threshold policy to the optimal policy.

2 - Stochastic Systems Fed by Self-Exciting Point Processes

Brian Fralix, Clemson University, Clemson, SC, United States, Jeffrey Kharoufeh, David Pittman

It is well-known that the infinite-server queue fed by a nonhomogeneous Poisson process is remarkably tractable and can be used to establish good staffing levels for multiserver queueing systems. In this talk, we present a collection of self-exciting point processes, where both infinite-server queues and shot-noise models fed by these processes possess various distributions and performance measures that are surprisingly tractable.

3 - Optimal Control in Two-Class Bass Diffusion Mode

Hojun Choi, Colorado School of Mines, Golden, CO, United States, Ohad Perry, Achal Bassamboo

We propose and consider a control problem for a clearing system in the setting of healthcare with two population classes. Each class consists of two states: susceptible and infected. Furthermore, classes transition into infected state either spontaneously (e.g., interaction with the outside system) or through interactions with the infected population. We formulate the problem as a multi-class queue-clearing model. The control is the instantaneous allocation of scarce resources such as vaccine to each class at every point in time. The objective is to find a control policy that minimizes the cumulative amount of the infected when the system clears. We first show that an optimal policy has the Bang-Bang structure, i.e., we should allocate the resources to one class completely at a given point in time. However, the explicit solution is intractable due to the nonlinear dynamics of the system. Therefore, we propose a strict priority policy and a practical policy. A strict priority policy allocates all the resources to one class until it clears before switching, while a practical policy allocates proportional to the remaining susceptible population. We numerically demonstrate the optimality gap for these two controls under reasonable parameters. Our results indicate that a strict priority policy is optimal, and a practical policy can be a compromise with a heavy penalty.

4 - Optimal Routing in Loss Systems with Flexible Servers and Customers

Tugce Isik, Clemson University, Clemson, SC, United States, Avnish Malde

We study a loss system with two classes of servers and a number of customer types. We assume that there is at least one type of flexible customers that can receive service from servers of either class. Arrival rates are dependent on customer type but service rate is identical for all customer types and classes of servers. We formulate the problem as a Markov Decision Process (MDP) with rewards that are dependent on the customer type. For small systems, we use our formulation to characterize the optimal policies. For larger systems, we study the structure of the optimal policies. Our analysis shows that the optimal policies are of threshold type. Using this policy structure, we develop heuristic routing policies for general systems and benchmark these heuristics by greedy policies that route flexible customers to servers of a particular class whenever possible. Our numerical results show that our heuristics perform well across a variety of parameter settings.

Advances in Machine Learning and Optimization

Contributed Session

Chair: Ahtesham Bakht, USF, 14306 Wedgewood Circle, Tampa, FL, 33613, United States

1 - Identification and classification of the generated adversarial samples using deep learning and machine learning methods

Ahtesham Bakht, University of South Florida, Tampa, FL, United States, Ankit Shah, Nathaniel Bastian

Intrusion Detection Systems (IDS) powered by artificial intelligence have led to enhanced effectiveness in automatically detecting cyber-attacks. However, the learning models may become cyber-attack targets through carefully crafted adversarial samples (also called evasion attacks). Recent advancements indicate that deep learning models are susceptible to adversarial samples. These samples are carefully crafted by introducing slight alterations to normal samples, which are undetectable to humans but can potentially deceive the deep learning models, leading to erroneous or desired outputs by the adversary. Such attacks enable adversaries to circumvent the IDS, leading to delayed detection of attacks and infrastructure damage.

In this study, we use five state-of-the-art adversarial generation methods such as Deep PackGen, autoencoder-based generative model, Projected Gradient Descent (PGD), Fast gradient sign method (FGSM), and Deep-Fool, on the CICIDs- 2017 dataset and after creating the adversarial samples we applied the five mainstream stream machine learning and deep learning methods to identify and classify each of the adversarial generated samples. Some of the adversarial sample generation is novel in the sense that it does not change the functionality of the packets.

The findings outlined in this paper offer valuable perspectives for designing systems geared toward identifying adversarial samples. In the larger sense, it would help us identify the source of evasion attacks. Additionally, they can serve as a blueprint for devising novel approaches to detect such samples.

2 - Sample-Efficient Agnostic Boosting

Karan Singh, Tepper School of Business, Pittsburgh, PA, United States, Udaya Ghai

The theory of boosting provides a computational framework for aggregating approximate weak learning algorithms, whose performance is marginally better than that of a random predictor, into an accurate strong learner. In the realizable case, the success of the boosting approach is underscored by a remarkable fact that the resultant sample complexity matches that of a computationally demanding alternative, namely Empirical Risk Minimization (ERM). This in particular implies that the realizable boosting methodology has the potential to offer computational relief, without compromising on sample efficiency.

Despite recent progress, in agnostic boosting, where joint distributional assumptions on the labels and feature descriptions are absent, ERM outstrips the agnostic boosting methodology in being quadratically more sample efficient than the all known agnostic boosting algorithms. In this paper, we make progress on closing this gap, and give a substantially more sample efficient agnostic boosting algorithm than those known, without compromising on the computational (or oracle) complexity. A key feature of our algorithm is that it leverages the ability to reuse samples across multiple rounds of boosting, while guaranteeing a generalization error strictly better than those obtained by blackbox applications of uniform convergence arguments. We also detail resultant implications for previously studied learning problems.

3 - Single-Attempt Hyperparameter Optimization Using Graph Neural Networks

Chanho Kim, Sungkyunkwan University, Suwon, Korea, Republic of, Dohyun Bu, Bonyoung Koo, Yulim So, Gaeun Kim, Woo-Jae Lee, Jong-Seok Lee

As deep learning has gained significant attention, selecting the best hyperparameter configuration for neural network models has become crucial for optimal performance. Consequently, hyperparameter optimization (HPO) has emerged as an important problem. Many recent advancements in methodologies and theories have been developed to address HPO. However, despite efforts to reduce the search space and find efficient paths to the optimum, they still require substantial time and computational resources due to trial-and-error processes. In this research, we approach the HPO problem as a recommendation problem, assuming that optimal hyperparameter settings are similar across similar tasks. Our goal is to achieve near-optimal settings in a single attempt. Our method combines graph neural networks to represent the relationships between tasks and hyperparameter settings, recommending the best configuration. Additionally, Bayesian optimization can be applied to further improve the recommendations and systematically update the task-hyperparameter history if necessary. Numerical experiments show that our method identifies individual optimal settings with fewer trials and infers near-optimal settings for unseen tasks in a single attempt.

4 - First-improvement or best-improvement? An in-depth local search computational study to elucidate a dominance claim

Celso Ribeiro, Universidade Federal Fluminense, Rio de Janeiro, Brazil, Robin Moine, Daniel Aloise, Jonathan Jalbert

Local search methods start from a feasible solution and improve it by successive minor modifications until a solution that cannot be further improved is encountered. They are a common component of most metaheuristics. Two fundamental local search strategies exist: first-improvement and best-improvement. In this work, we perform an in-depth computational study using consistent performance metrics and rigorous statistical tests on several classes of test problems considering different initialization strategies, neighborhood structures, and types of tested instances to evaluate whether one strategy is dominant over the other. The numerical results show that computational experiments previously reported in the literature claiming the dominance of one strategy over the other for the TSP may not be consistent, and their extrapolation to other problems is not correct, possibly due to the use of a less rigorous experimental setting. Still, our results reinforce the need for extensive experimentation to decide the most appropriate strategy for each specific problem and context.

5 - Structured Real-time bidding algorithm with ESS control: Cooperative Multiagent offline RL Approach

Wooje Seong, Kia, Seoul, Korea, Republic of, Euncheol kim, Wonjong Lee, Yoonmo Koo

As renewable energy deployments accelerate, so does the need for a Virtual Power Plant (VPP) that optimizes the operation of distributed energy resources. This study proposes a Reinforcement Learning (RL)-based bidding and operation model that maximizes the profits of VPPs given uncertain power market operations. In order to optimize resources in a structured market framework—where profit is determined both by bidding and operational decisions—this study adopts a bi-level, multi-agent RL approach and the off-line learning structure. Specifically, the model considers the sequential and cooperative decision-making of bidding and operations by reflecting the communication layer between each agent and implicitly assigning the credit of individual bidding and operational decisions to the final total reward. By implementing this Centralized Training but Decentralized Execution (CTDE) architecture, we effectively derive the cooperative decision-making of the two agents to optimize the total revenue of the VPP rather than maximize the rewards of distinct bidding and operational decisions. Moreover, in order to further exploit the practicality of the proposed model, we constructed an offline-RL structure that utilizes the expert decision data derived from the history of complete market information for training. Lastly, we conducted a case study for South Korean power market and the results produced bidding and operational revenue streams that were nearly identical to revenues derived from expert decisions made with the benefit of perfect information, despite its having been applied to an uncertain market case.

6 - Increasing operations efficiency using LLMs and GPU acceleration

Hugo Linsenmaier, NVIDIA, Santa Clara, CA, United States, Victor Miara, Alex Fender

Optimizing supply chain operations is a time-consuming process requiring deep technical expertise in mathematical modeling. Understanding the outcome of the optimized plan also relies heavily on human expertise. This process can be very costly as plans need to be updated frequently to account for disruptions. In this work, we propose an LLM agent for mathematical models that accelerates operations by transforming natural language operations queries into actionable optimized strategies. Our agent can fetch relevant historical data, solve the formulated problem using GPU solvers, and answer complex queries on potential business outcomes. The efficiency of our stack makes it possible to evaluate different scenarios in near real time on large scale problems.

Advancements in Medical Decision Support Systems

Contributed Session

Chair: Helena Müller, University of Cologne, Cologne, Germany

1 - Towards Explainable Patients Recovery Prediction in Neuro Critical Care Unit

Eleanor Belkin, Johns Hopkins University Whiting School of Engineering, Baltimore , MD, United States, Dr. Tamas Budavari, Dr. Rohan Mathur, Lin Cheng, Peter Dziedzic, Niteesh Potu, Eusebia Calvillo, Josiah Lim, Vishank Shah, Jose Suarez

Our work aims to improve triage and care for patients who underwent elective craniotomies for brain tumor resection. These patients are typically admitted to the Neurosciences Critical Care Unit (NCCU) post-operatively. However, only 15-20% of these patients develop conditions in the post-operative setting that require interventions that can only be performed in the NCCU. Given the scarcity of NCCU beds and the high costs associated with critical care, there is a need to optimize these resources. Our work focuses on statistically explainable machine learning (ML) models. We explore Bayes classifiers, boosted decision trees, logistic regression, and Generalized Additive Models (GAMs) to establish a baseline. We use pre-operative EMR data and brain scans to predict the need for NCCU care post-operatively. We integrate statistical classification methods with the optimal features extracted by the deep learning network from patients' brain scans, enabling more accurate predictions while maintaining interpretability of the model. Our approach addresses the limitations of both methods, offering a hybrid system with the advantages of each and allowing to develop a novel tool for the classification by utilizing a probabilistic outcome of the model.

2 - Posturography-Based Decision Support System for mTBI Detection

Eren Darici, Western Michigan University, Kalamazoo, MI, United States, Alessander Danna-dos-Santos, ILGIN ACAR, Kira Hamelink

A mild traumatic brain injury (mTBI) or concussion, as defined by the CDC, is the disruption of normal brain functions that can be caused by a bump, blow, or jolt to the head. This study leverages custom-made force plates to collect postural sway data from over 120 patients to create a decision support-system-like approach to the diagnosis of mTBIs using various classification models. Despite accounting for roughly 90% of all traumatic brain injuries, not all mTBIs are diagnosed or treated. If left untreated, mTBIs can lead to post-concussion syndrome and a number of long-term cognitive impairments. Another long-term effect of mTBIs is the inability to adequately control postural sway; trauma to brain centers responsible for maintaining balance and proprioception reduce the ability to stabilize when standing upright. Postural sway can be measured and assessed with posturography. Analysis of posturography results can provide insight into the physical condition of a patient's brain following an mTBI or aid in the diagnosis of previously undetected mTBIs. In a clinical setting, however, it becomes challenging and time-consuming to conduct the structural analysis of posturography manually. With a high accuracy of 88%, this study examines a novel set of methodologies for mTBI detection that are mobile, inexpensive, and less time-consuming than traditional methods. The system resulting from this study has the potential to greatly increase the diagnosis rate of mTBIs, reducing the impact of untreated mTBIs. Future work includes the use of this system for the detection of neurodegenerative diseases, such as Alzheimer's and Parkinsons.

3 - Temporal Framing Effects on Responses to Messages Promoting Social Distancing: The Moderating Role of Involvement

Giha Shin, Yonsei University, Seoul, Korea, Republic of, Jarim Kim, Jihyun Lee

This study investigated how individuals' level of involvement moderates temporal framing effects in the context of COVID-19 social distancing, which provides a unique context in which most people have high involvement. Eight hundred participants were randomly assigned to one of two conditions (temporal framing: proximal vs. distal). Participants' involvement was operationalized as high or low based on whether they had close relationships with someone with an underlying condition. When exposed to distally framed messages, participants with high involvement reported more favorable attitudes and greater intentions toward social distancing than individuals with low involvement. The effects were mediated by response efficacy, concern for others, and anticipated regret. When exposed to proximally framed messages, participants with different levels of involvement did not report different responses. The study makes theoretical contributions to health care literature and practical contributions to designing effective health communication messages.

4 - The Impact of Consecutive Working Days on Individual Nurse Fatigue: An Analysis on Neonatal Wards

Helena Müller, University of Cologne, Cologne, Germany, Michael Becker-Peth, Ludwig Kuntz

Purpose: Previous research has shown the negative impact of fatigue on different outcomes in hospital settings. Our analysis contributes to this research with a longitudinal dataset at the individual nurse level, showing empirically that the operational metric of consecutive working days is correlated with the perceived fatigue.

Methodology: The data were collected as part of the Neo-CamCare study using a combined approach of an observational study and a standardised diary questionnaire. A total of 1,191 daily questionnaires from 65 nurses across three neonatal wards were collected over six-month periods on each ward. Panel regression models with fixed effects were used for analysis. To test for endogeneity, an instrumental variable approach was employed.

Results: Initial results of the survey data indicated that a higher number of consecutive working days without breaks was significantly associated with higher individual fatigue levels. Further moderation analyses revealed that the effect of consecutive working days on fatigue was contingent upon the specific shift type.

Implications: The results showed empirically that the number of consecutive working days can be used as an objective indicator of fatigue among nurses. Thus, the analysis has implications for nurse scheduling from a managerial perspective as limiting the number of consecutive working days could reduce the perceived fatigue level. Our research highlights the importance of understanding the dynamics between fatigue and work schedules among nurses, providing valuable insights for hospital management aimed at optimizing nurse scheduling while considering the perceptions of nursing staff.

Advances in Operations Management

Invited Session

MSOM: Supply Chain

Chair: Zihao Qu, The University of Massachusetts Amherst, Belchertown, MA, United States

1 - Probabilistic Design in the Operation of Service Systems

Jiangze Han, University of British Columbia, Vancouver, BC, Canada, Christopher Ryan, Xin T. Tong

Motivated by the design and operation of service systems involving non-parametric probability distributions, we study optimization problems in the space of probability measures. We propose an implementable gradient descent method and tailor it to two applications: user profile decomposition, which is an offline constrained optimization problem, and matching spatial supply with spatial demand, an online optimization problem. We analyze the performance of our method in both settings, demonstrating that (i) it converges to a solution satisfying the proposed optimality condition in the offline application, and (ii) achieves sublinear static and dynamic regret in the online setting.

2 - Sound of Silence: when to Conceal Attribute Information? the Roles of Consumer Search, Inventory, and Channel Structure

Xingyu Fu, University of New South Wales, Sydney, Australia, Zihao Chen, Pin Gao, Ying-Ju Chen

This study examines a seller's joint information disclosure and pricing decisions when launching a new product with an easy-to-communicate objective attribute and a hard-to-describe subjective attribute. We investigate how consumer search cost, inventory level, and channel structure influence the seller's optimal information policy. For brick-and-mortar retailing, our analysis suggests that the seller should conceal (or disclose) information when the search cost is low (or high). Interestingly, when the inventory level is high, the seller conceals information to retain the diamond-in-the-rough consumers, aiming to match the abundant inventory with high demand. Conversely, when inventory is low, the seller discloses information to dissuade some consumers with low objective valuations from searching, thereby reducing demand and alleviating concerns about product unavailability. In other words, the seller uses information to balance search and stock. The structure of optimal information policy is robust after considering several extensions such as partial disclosure, efficient allocation, and atomic consumers. In addition, surprisingly, fiercer demand-side competition (e.g., larger consumer population) can reduce the seller's revenue due to potential price markdowns to ease consumer concerns about competition. For omnichannel retailing with an additional online purchasing channel, our analysis suggests that abundant inventory can lead to a contrary information policy from the offline business. Collectively, our study provides managerial insights into how demand-side factors (e.g., search cost) and supply-side factors (e.g., inventory and channel structure) impact the seller's optimal information and pricing strategy. It also reveals potential risks associated with intensified demand-side competition.

3 - Dynamic Pricing and Resource Allocation in a Multi-Server Queue

Zerui Wu, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Xu Sun, Ran LIU

We explore dynamic pricing and resource allocation policies for a multi-server queue serving heterogeneous customer classes with varying price and delay sensitivities, and class-dependent service rates. This setting is relevant to applications such as drone delivery, EV charging stations, and cloud computing, where timely response and service are essential. We consider a manager who makes real-time pricing and resource allocation decisions to maximize long-run average profit. Due to the high-dimensional system state, finding an optimal solution is intractable. We propose a tractable myopic policy that solves a single-step optimization problem at each decision epoch. We prove that this simple policy is asymptotically optimal, with an O(n^(-2/3) log n) optimality gap in both revenue and delay costs compared to the optimal fluid solution, where n is the number of servers. Notably, the policy may exhibit non-monotonic pricing with respect to congestion when queues are observable to customers. Our research provides an easy-to-implement approach for real-time operations of many-server queues while maintaining near-optimal performance.

4 - Decentralized Insurance

Baikun Leng, University of Washington Foster School of Business, Seattle, WA, United States, Rowena Gan

In the traditional insurance industry, the evaluation of claims is often biased due to the inherent interest of claim assessors in maximizing company profits. We explore the potential of decentralized insurance, powered by blockchain technology, as an alternative approach to mitigate such biases. In decentralized insurance models, claims are evaluated by a "court" of assessors who are independent of the insurance company. These assessors vote collectively to determine the outcome of a claim, with their compensation tied to their alignment with the majority decision. This mechanism incentives assessors to provide judgments that reflect the consensus of the group, rather than the financial interests of the insurance company.

5 - Flexible vs. Dedicated Technology Choice in the Presence of Multi-product Subscription Programs

Liling LU, Singapore Management University, singapore, Singapore, ONUR BOYABATLI, Sarah Yini Gao

This paper studies flexible versus dedicated technology choice and capacity investment decision of a two-product firm under demand uncertainty in the presence of subscription programs. The key feature of subscription programs is that a proportion of customers that are allocated a particular product later switch to using the other product (if available). We build a two-stage stochastic program to study the optimal decisions, and investigate how the correlation between the two subscription demands affect the profitability with each technology, and shape the optimal technology choice decision.

Environmental Sustainability and Social Responsibility in Supply Chain

Invited Session

MSOM: Sustainable Operations

Chair: Mili Mehrotra, University Of Illinois Urbana Champaign, Champaign, IL, United States

Co-Chair: Xueze Song, The University of Alabama, TUSCALOOSA, United States

1 - Does the Focus on Workplace Safety Affect Environmental Performance? Analyzing the Impact of Osha Inspections on Toxic Releases of Manufacturing Facilities

Suresh Muthulingam, The Pennsylvania State University, University Park, PA, United States, In Joon Noh

Manufacturing plays a critical role in the U.S. economy but ensuring workplace safety has been a serious concern within the sector. The Occupational Safety and Health Administration (OSHA) was created to promote safe work practices in manufacturing. Since its inception, OSHA has extensively used facility inspections to assess whether manufacturing operations adhere to safety standards. A large body of work has investigated the implications of OSHA inspections from economic and safety perspectives, but hardly any research explores the implications of OSHA inspections from an environmental perspective. We seek to bridge this gap in the literature by examining whether OSHA inspections affect the toxic releases of manufacturing facilities. We draw on the attention-based view of the firm and hypothesize that OSHA inspections will draw managerial attention towards safety-related issues, but at the same time end up diverting attention away from environmental issues. We created a dataset that spans from 1987 to 2016 and includes details on the toxic chemical releases of 33,838 manufacturing facilities across the U.S. Our dataset also includes information on the 36,583 OSHA inspections conducted on these manufacturing facilities. Our econometric analyses show that OSHA inspections lead to increased toxic chemical releases at manufacturing facilities, and that this effect is largely driven by the inspections that cite violations of safety regulations. We additionally find that facility managers undertake fewer modifications to reduce toxic chemical releases at the source when OSHA inspections identify violations, which clarifies the mechanism that drive the increases in toxic releases.

2 - Pooling Carbon Targets

Christian Blanco, Ohio State University, Columbus, OH, United States, Oznur Ozdemir, Erdinc Akyildirim

Many corporations now set voluntary direct (Scope 1) and indirect (Scope 2) carbon emissions reduction targets, but low success rates reflect that firms are not experienced in designing these targets. Does pooling Scope 1 and 2 targets increase the likelihood of success? We use ten years of data collected by the CDP (formerly the Carbon Disclosure Project) to explore our research question.

3 - Fairness in Crowdwork: Making the Human Ai Supply Chain More Humane

Martin Gonzalez Cabello, University of California, Los Angeles, Los Angeles, CA, United States, Charles Corbett, Auyon Siddiq

Digital supply chains, including those that support artificial intelligence (AI), share notable similarities with physical supply chains – including multiple levels of outsourcing, reliance on low-wage labor, and limited transparency – raising ethical concerns about upstream labor conditions. Through a survey of workers on a major digital labor (“crowdwork”) platform, this article aims to shed light on the factors that shape workers’ perceptions of fair treatment and examines how platform design can influence worker welfare. Drawing from physical supply chains, it provides guidance for managers on how to promote responsible labor practices in digital supply chains.

4 - How do Favorable and Unfavorable Audit Outcomes Impact Supplier CSR Risk?

Seb Heese, NC State, Raleigh, NC, United States, Xiaojin Liu, Rob Handfield, Tim Kraft

Imperfections can exist in the design of supplier audits; the audit score a facility receives may not reflect its true compliance ability. This difference can alter the perception of the outcome, and thus, impact a facility's motivation to improve. We examine the influence of outcome favorability, defined as the difference between the audit score a facility received (we refer to this as the reported audit score) and the audit score the facility should have received based on its compliance ability (we refer to this as the corrected audit score), on the facility’s future CSR risk. To empirically address our research question, we use Item Response Theory and a dataset consisting of historical, facility-level audits for a global apparel brand. We develop a measure for CSR risk using the severity score for audit outcomes in the subsequent round of audits. We find that higher outcome favorability helps to reduce future CSR risk. Furthermore, the analysis of our moderating factors shows that this effect is more pronounced in facilities with low compliance ability, facilities that experienced a greater positive change in outcome favorability since their previous audit, facilities that have been audited a fewer number of times, and facilities in developing countries. Buyers are increasingly being pressured to take more collaborative and developmental approaches to improve their suppliers’ CSR. However, these types of efforts can be difficult and are not always successful; we provide guidance to buyers by identifying when suppliers are more likely to be intrinsically motivated to reduce CSR risk.

Diversity and Fairness in High-stakes Decisions

Invited Session

MSOM: Service Operations

Chair: Vahideh Manshadi, Yale, Westwood, United States

Co-Chair: Faidra Monachou, Yale University, New Haven, CT, United States

1 - The Feedback Loop of Statistical Discrimination

Jackie Baek, NYU Stern School of Business, New York City, NY, United States, Ali Makhdoumi

We study a dynamic model of interactions between a firm and job applicants to identify mechanisms that can lead to long-term discrimination. In each round, the firm decides which applicants to hire, where the firm’s ability to evaluate applicants is imperfect. Each applicant belongs to a group, and central to our model is the idea that firms become better at evaluating applicants from groups in which they have hired from in the past. We establish the firm's initial evaluation ability to be a critical factor in determining long-term outcomes, and small differences in this quantity across groups can steer them towards drastically different outcomes. Even if two groups of applicants are identical in size and underlying skill distributions, a marginal difference in the firm's initial ability to evaluate applicants from each group can lead to persistent disparities that exacerbate over time through a feedback loop.

Importantly, the dynamic nature of our model allows us to assess the impact of interventions. We show that drastic short-term interventions are preferable compared to milder long-term interventions. Additionally, we find that smaller groups face inherent disadvantages, and hence, enforcing a parity constraint, such as demographic parity, can be ineffective when group sizes differ.

2 - Monoculture in Matching Markets

Kenny Peng, Cornell University, New York, NY, United States

Algorithmic monoculture arises when many decision-makers rely on the same algorithm to evaluate applicants. An emerging body of work investigates possible harms of this kind of homogeneity, but has been limited by the challenge of incorporating market effects in which the preferences and behavior of many applicants and decision-makers jointly interact to determine outcomes.

Addressing this challenge, we introduce a tractable theoretical model of algorithmic monoculture in a two-sided matching market with many participants. We use the model to analyze outcomes under monoculture (when decision-makers all evaluate applicants using a common algorithm) and under polyculture (when decision-makers evaluate applicants independently). All else equal, monoculture (1) selects less-preferred applicants when noise is well-behaved, (2) matches more applicants to their top choice, though individual applicants may be worse off depending on their value to decision-makers and risk tolerance, and (3) is more robust to disparities in the number of applications submitted.

3 - Generative Social Choice

Paul Gölz, Cornell University, Ithaca, NY, United States, Sara Fish, David Parkes, Ariel Procaccia, Gili Rusak, Itai Shapira, Manuel Wüthrich

Traditionally, social choice theory has only been applicable to choices among a few predetermined alternatives but not to more complex decisions such as collectively selecting a textual statement. We introduce *generative social choice*, a framework that combines the mathematical rigor of social choice theory with the capability of large language models to generate text and extrapolate preferences. This framework divides the design of AI-augmented democratic processes into two components: first, proving that the process satisfies rigorous representation guarantees when given access to oracle queries; second, empirically validating that these queries can be approximately implemented using a large language model. We apply this framework to the problem of generating a slate of statements that is representative of opinions expressed as free-form text; specifically, we develop a democratic process with representation guarantees and use this process to represent the opinions of participants in a survey about chatbot personalization. We find that 93 out of 100 participants feel “mostly” or “perfectly” represented by the slate of five statements we extracted.

4 - Diversity in Labor Markets: Implications of the Rooney Rule

Vahideh Manshadi, Yale University, New Haven, CT, United States, Faidra Monachou, Soonbong Lee

In 2003, in response to concerns about the low representation of African Americans in head coaching and management positions, the NFL adopted the Rooney Rule, which requires every team with a vacancy to interview at least two minority candidates. While several organizations, from the tech industry to law firms, have since adopted similar hiring policies, the Rooney Rule has seen limited success in diversifying coaching teams or C-suites. Motivated by the mixed outcomes of the Rooney Rule in practice, we consider a matching model with interviews to investigate the impact of fairness constraints, such as the Rooney Rule, at the interview stage. In our model, candidates belong to two demographic groups, and their match value distributions are symmetric across groups. However, match values are only revealed after the interview. Consequently, the firm makes interview decisions based on observable scores that provide only partial information about the match values. The score distributions are asymmetric across groups, with one group having a higher variance in score distribution. The firm has limited capacity for interviewing and hiring and aims to maximize the total match value within these capacity constraints. We show that imposing constraints like the Rooney Rule at the interview stage does not mitigate the disparity in hiring between the two groups, highlighting the limitations of such interventions. Additionally, we extend our model to a two-firm scenario to study the impact of competition.

Summit - 447

Relationship between Supply Chain Network Characteristics and its Resilience

Invited Session

Public Sector OR

Chair: Alican Yilmaz, northeastern university, Boston, United States

Co-Chair: Ozlem Ergun, Northeastern University, Newton, MA, United States

1 - Relationship between supply chain network characteristics and its resilience

Alican Yilmaz, Northeastern University, Boston, MA, United States

Supply chain networks involve complex interactions among their constituent entities.These interactions encompass not only the structural properties of the network but also the service-based characteristics of the supply chain. Inspired by this, we have demonstrated that traditional centrality metrics may prove inadequate, especially in scenarios where service characteristics are heterogeneous.Thus, modified flow-based centrality metrics tailored to the specific context can yield more robust results in identifying critical nodes in the supply chain network. In this work, we first developed a linear lost demand model and illustrated that modified flow-based centrality metrics outperform generic centrality metrics in identifying critical nodes. As second part of the work, we focused on the Defender-Attacker-Defender(DAD) models. Unlike attacker-defender(AD) models, DAD models include the defender’s decision of pre-disruption. With that capability, DAD models outperforms AD models in terms of scope and analysis. However, DAD models, owing to their complex structure, often entail long run-times to reach optimal solutions. To address this challenge, numerous exact and heuristic methods have been developed. In our work, we propose that integrating information from these centrality metrics could potentially expedite the run-time of DAD models. Initial findings suggest promising results in this regard.

2 - Supplier's Capacity Decisions and Supply Network Performance under Extreme Uncertainties

Yuhong Li, Old Dominion University, Norfolk, VA, United States, Kedong Chen, Dmitry Ivanov, Anand Nair, Long Xia

Under extreme conditions caused by events like the COVID-19 pandemic, firms require more frequent operational decision-making to adapt to the volatile business environment. Such short-term decision-making is challenging in a fast-changing environment as decision-makers have limited knowledge of potential risks. In this study, we consider the effect of suppliers' *capacity decision*, a critical firm strategy, on supply network performance. We adopt a multi-method approach. First, we conduct text analytics on news articles and demonstrate that a firm's capacity decision during the extreme conditions is positively related to its asset-based performance. Next, using insights from the analysis, we build an agent-based model and design experiments to investigate the appropriate level of capacity decision across suppliers that improves the network performance. We then examine if a focal firm can further improve network performance by nudging suppliers' risk-taking behavior based on the tier that they belong to or their centrality in the supply network. The findings suggest that network performance can further improve when tier-1 suppliers take higher capacities than tier-2 suppliers, and when suppliers with higher degree centrality take higher risk preferences than less central suppliers. These findings provide insights for addressing extreme conditions by managing risk preference.

3 - Mitigating Worst-Case Supply Chain Disruptions via Safety Stock Pre-Allocation

Carson Grose, Northeastern University, Boston, MA, United States

Engineering resilient supply chains is crucial to ensuring critical commodities such as fuel, pharmaceuticals, and emergency response supplies are available when needed. A resilient supply chain should function even in the event of a disruption, which can come in the form of natural disasters, equipment failures, or attacks by nefarious actors. One way to build resilience in a supply chain is through the pre-allocation of inventory, or safety stock to carefully chosen locations in the distribution network. Safety stock is especially effective at mitigating short term supply chain disruptions. Resilience through safety stock comes with a cost however, so it is important to optimally allocate inventory to make the most effective use of a limited budget. This work studies a protection-interdiction-operation framework applied to an n-echelon supply chain model. Our model determines a worst-case network disruption and a corresponding best-case safety stock allocation plan. This enables us to quantify the worst-case cost that a disruption could incur for given safety stock budgets. We use a column-and-constraint generation (C&CG) algorithm to exactly solve the model. Our results reveal managerial insights that quantify the relationship between levels of protection investment and resilience.

4 - Improving supply chain network resilience: A framework for diagnosing vulnerabilities and identifying adaptation strategies

Chelsey Graham, Massachusetts Institute of Technology, Cambridge, MA, United States, Jarrod Goentzel

We investigate the resilience of supply chain networks, concentrating specifically on the robustness of distribution networks and the process of diagnosing the criticality of nodes. The methodology centers on the vulnerability that nodes can induce on the network, using a three-step approach: 1) Identifying a set of Key Performance Indicators (KPIs) for gauging network vulnerability, 2) Measuring vulnerability for randomly generated supply chain networks with various degree distributions via disruption simulation, and 3) Defining adaptation strategies, through re-optimization and rewiring of the network, as well as practical measures a firm could deploy in the event of a disruption. We conclude by highlighting the pivotal role of network structures in creating and preserving network robustness and unveil potential adaptation strategies for businesses working to reinforce their supply chains against unforeseen disruptions.

Summit - 448

Solutions to Build Climate Resiliency

Contributed Session

Chair: Farzane Ezzati, University of Houston, Houston, United States

1 - Enhancing Energy Resilience in Vulnerable Communities via ES+Solar Microgrids

Farzane Ezzati, University of Houston, Houston, TX, United States, Zhijie Dong, Gino Lim

Climate change is exacerbating weather-related disruptions to electrical grids, aggravating the risk of prolonged power outages that endanger the safety and well-being of all populations, particularly vulnerable communities. While renewable energies have received great attention for their potential to meet community needs during grid failures, their adoption requires efficient investment management while prioritizing the enhancement of energy resilience.

In our study, we propose a community microgrid that combines energy storage (ES) and Solar power to bolster the energy resilience of vulnerable households. To assess the efficacy of the proposed solution, we model the ES+Solar community microgrid as a two-stage stochastic programming model, accounting for various uncertainties including power outage duration, load demand, solar power generation, and future load demand growth. Additionally, we define four energy resilience metrics including Impact Endurance, Sustained Access, Demand Assurance, and Peak Assurance to comprehensively evaluate the energy resilience benefits of the proposed solution from various perspectives. Furthermore, our study advocates for the implementation of Demand Response Programs (DRP) to further support the emergency power supply.

The model is subsequently optimized using cutting-edge optimization solvers. Our numerical analysis serves two primary objectives: firstly, to provide guidance on the installation of the ES+Solar community microgrid and assess its resilience performance; and secondly, to offer valuable informative and prescriptive managerial insights aimed at evaluating energy resilience and various factors influencing the investment decisions.

2 - Cooperation in Transmission Expansion Planning: Enhancing Grid Reliability and Efficiency Under a Changing Climate

Kerem Ziya Akdemir, Pacific Northwest National Laboratory, Richland, WA, United States, Kendall Mongird, Jordan Kern, Konstantinos Oikonomou, Nathalie Voisin, Casey Burleyson, Jennie Rice, Mengqi Zhao, Cameron Bracken, Chris Vernon

Electricity grids are challenged to maintain reliability during more intense and frequent extreme weather events due to climate change. This challenge is exacerbated by multi-sector electrification and power sector decarbonization through increased reliance on variable renewable energy, which necessitates the expansion of transmission infrastructure. However, transmission expansion planning is often complicated by intertwined planning authorities and jurisdictions, and allocation of large capital investment needs. These factors cause authorities to manage transmission investments individually (i.e., only/mostly intraregional planning), which can lead to suboptimal transmission networks. This study investigates the potential benefits of cooperative transmission expansion planning (i.e., both intraregional and interregional planning that optimizes transmission investments across the entire physical system). Using sectoral and economic optimization, and machine learning models, it analyzes the impact of different levels of cooperation among transmission planning regions within U.S. Western Interconnection in 2019 and 2059 via an iterative investment process. Furthermore, it examines the effects of future climate change on transmission cooperation by simulating historical heat waves from 2019 under conditions of 2059. The results indicate that cooperative transmission planning leads to lower wholesale electricity prices, decreased energy outages, and reduced greenhouse gas emissions. However, the advantages of collaboration diminish during widespread heat waves, despite remaining beneficial especially for regions like California Independent System Operator with substantial solar installations. The study underscores the importance of transmission cooperation in reducing costs and enhancing reliability, emphasizing the need for strategic investments in storage to address challenges posed by future extreme weather events with varying spatial scales.

3 - Grid reliability and competing claims for scarce natural gas during winter storms

Chiara Lo Prete, Pennsylvania State University, University Park, PA, United States, Ashish Radhakrishnan

The increasing dependence of the electric power sector on natural gas poses vulnerabilities caused by competition for scarce pipeline capacity that are especially pronounced when both heating and electricity needs spike. During extreme cold weather events, pipeline deliveries to distribution companies serving heating customers receive the highest priority of service, while natural gas-fired generators may have their service curtailed regardless of contractual priority. This creates grid reliability challenges and adverse consequences that tend to fall on historically overburdened and underserved communities. In this paper, we quantify the benefits of reallocating gas consumption from industrial customers that hold firm contracts but do not serve human needs to power plants. We adopt a gas-electric optimization framework that models the fuel supply delivery risk at gas-fired power plants in the Northeastern U.S., and evaluate impacts on costs, emissions and unserved energy under alternate gas allocations during the 2014 Polar Vortex.

4 - Joint Expansion of Power and Water Distribution Networks

Sai Krishna Kanth Hari, Los Alamos National Laboratory, Los Alamos, NM, United States

Power and water distribution networks are tightly coupled in their operations. However, their expansion is planned separately. A joint expansion planning can offer benefits to both networks. To understand these benefits, we formulate the joint planning problem as a Mixed Integer Nonlinear Program. Using this formulation, we will discuss the potential benefits of joint planning and the challenges to overcome to implement it at a large scale.

1 - Predicting the Number of Open Operating Rooms to Enhance Resource Allocation and Patient Quality of Care

Narges Shahraki, Mayo Clinic, Rochester, MN, United States, Nageswar Madde, Ryan Schoer, Ellory Steinbauer, Aimee Tillman, Matthew Vogt, Daryl Kor

The dynamic nature of surgical demand poses challenges in predicting the number of open Operating Rooms (ORs), which may lead to inefficient resource allocation and potential negative impacts on patient quality of care. This study introduces a novel deep learning framework with a wide and deep architecture to predict the daily maximum number of open ORs. The daily maximum number of open ORs is a crucial metric for optimal recourse allocation of personnel. The predictive framework can improve resource allocation strategies, thereby enhancing patient quality of care by minimizing delays in providing care and reducing staff burnout.

2 - Patient Level Risk Prediction and Management in ICU

Hangtian Li, Tsinghua University, Beijing, China, People's Republic of, Xiaolei Xie, Feng Ju

Intensive Care Units (ICU) are associated with substantial costs, while they generate extensive patient-level physiological monitoring data. With the development of electronic medical records and data mining technology, we can use these data to predict the development of patients' conditions and then optimize the allocation of medical resources to improve patient care quality, ICU operational efficiency, and resource utilization. Based on public critical medical databases, we propose a multimodal machine learning model to model and predict patients' disease progression and risk. The proposed predictive model not only

integrates multimodal patient data for prediction but also adeptly captures correlations between each modality. Specifically, it can effectively identify the relationship between patient physiological monitoring time series data and their diagnosis/treatment procedures, thus enhancing prediction accuracy and reliability. The predictive model is based on a graph structure and can make recommendations for subsequent clinical examinations, which increases the model's interpretability and clinical utility. To validate our model, we trained the model on a large dataset to predict changes in multiple physiological indicators at the patient level. Furthermore, through the integration of patient-level modeling and predictive analytics with operations research algorithms, we optimize ICU medical resource scheduling, ultimately enhancing ICU operation quality and efficiency.

3 - Leveraging Wearable Technology to Improve Fall Prevention: Early Lessons Learned

Emma Fortune, Mayo Clinic, Rochester, MN, United States, Terri Menser, Che Ngufor, Louis Faust, Philip Tipton

Falls account for 87% of fractures in the elderly, incurring annual costs of nearly $50 billion in the U.S. Clinical assessments of fall risk are reported to have low sensitivities, provide an incomplete picture of a patient's functional level, and introduce access barriers. Remote monitoring technologies including smart phones and watches have shown promise with real-world gait and stability measurement but are not widely adopted in healthcare settings; secure and reliable data transmission remains a main challenge.

Our goal is to develop a fall prediction tool by incorporating available objective daily physical activity (PA), stability, and/or cardiopulmonary health data from patients' existing smart phones and watches with typical clinical risk factors from the electronic health record (EHR), which can provide standalone generalizability for widescale deployment. We will recruit 200 Mayo Clinic patients aged >64 years and collect pilot data for initial model and implementation strategy development. Eligibility criteria include owning an iPhone, and able to walk >1 block unassisted.

Participants will be asked to share their daily PA, stability, and/or cardiopulmonary data from their Apple device(s) for 6-months. Falls will be tracked during those 6-months using EHR-reported falls data, weekly fall survey, and the Apple Fall Detection event log. An AI predictive model will be developed using the gait and clinical data as inputs and validated using the combined fall tracking data as ground truth. The sensitivities and specificities of our model and the STEADI survey will be compared. Our implementation strategy will be refined by early lessons learned.

4 - Optimizing Technician Staffing in Medical Services Using Two-Stage Stochastic Integer Programming

Mirui Zhang, Tsinghua University, Beijing, China, People's Republic of, Feifan Wang

The technician in medical services is an important role in supporting medical procedures running smoothly. Due to the uncertainty in technician workload, technicians may often have to work overtime. It is widely seen in procedure rooms and operating rooms and may compromise patient care quality and technician job satisfaction. In this study, we focus on technician staffing, in combination with scheduling. We develop a two-stage stochastic integer programming model to improve workload coverage. Multiple scheduling scenarios are considered to determine the optimal configuration of a technician team. The proposed method is evaluated through numerical experiments. The results show that the method can significantly reduce overtime and labor cost.

1 - Analyzing Game Play Patterns and Their Association with Health Knowledge

Rema Padman, Carnegie Mellon University, Pittsburgh, PA, United States, Rahul Ladhania, Jeong Hin Chin, Abhishek Gupta

With the widespread mobile device penetration in society and easy access, gamification can be an engaging way for children to learn about healthy lifestyle related habits early in life and improve lifelong health risks. This highlights the promise of a 'digital vaccine' framework, a subcategory of digital therapeutics, which leverage AI and mobile technology-enabled solutions to reduce disease risk and improve health and well-being. In this study, we use data from a novel, 11-week, cluster randomized controlled trial we conducted in India to evaluate the impact of regular exposure in the school setting to an artificial intelligence(AI)-enabled, educational mobile health game – a low risk, non-invasive, digital vaccine candidate with neurocognitive training and implicit learning components – on students' health related knowledge. We present results examining gameplay patterns of students who were exposed to the mHealth game, and to quantify association with their health related knowledge, comprising nutrition, physical activity, and health hygiene habits, captured from student surveys over the course of the intervention. Early results from supervised and unsupervised learning of children's play patterns and their relationship with their "health knowledge" suggests the role of gameplay features such as performance on the game (win rate) and repeated exposure (number of games played) in predicting changes in participants' learning and knowledge. Examining the patterns over time also show significant variations among participants, with two types of gameplay behavior. Ongoing analyses will provide new insights into the complex interactions between gameplay and health behavior changes for designing more impactful interventions.

2 - A Game-Theoretic Framework of Fairness Dynamics: Equilibrium, Control and Beyond

Chuwen Zhang, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of, Pengyi Shi, Amy Ward

Recidivism control is a crucial aspect of modern criminology. Recently, there is a growing interest in the use of algorithmic sentencing, where the jury uses a risk estimate to make incarceration decisions. However, this approach often incorporates attributes beyond criminal recosrds, such as race, education, and unemployment, leading to significant fairness issues. We introduce a queuing-type system to model the crime justice system that delineates the dynamics of population and evolution of offending probability, in which the recidivists are modeled as a party of antagonistic players against the system, while the latter reacts by placing control policies that both affect the incentive and deterrence for recidivists. Thereby, we introduce a utility function that mimics the tradeoff of redivists. We capitalize on the theory of the generalized Nash game to facilitate a discussion on the existence of the equilibria and convergence therein. We start by the basic existence properties under fixed control policies. The uniqueness of equilibria can be captured by a curvature condition, which indicates the sufficiency of deterrence. Based on the basic stationary controls, we discuss further investigations in algorithmic sentencing settings and extensions with multiple demographic groups, in which we discuss the issues of fairness and disparity. These results provide insights on when and nor fairness constraints may be effective.

3 - Exact Sensitivity Analysis of Markov Reward Processes via Algebraic Geometry

Muhammad Maaz, University of Toronto, Toronto, ON, Canada, Timothy Chan

Markov chains are commonly used for economic modelling, especially in health economics. The outcomes of health economic analyses are functions of the primitives of the Markov chain. As these primitives are often uncertain, it is standard to do a sensitivity analysis, which is typically performed as a grid search in the parameter space. In this work, we introduce a rigorous method for sensitivity analysis of Markov models. Our key insight is that all typical health economic analyses can be reformulated as systems of polynomial inequalities. Solving this system gives an exact characterization of the space of parameters that yield the modeller's desired outcome. The algorithm of \textit{cylindrical algebraic decomposition} (CAD) is the usual method to solve polynomial systems, but it takes doubly exponential time, which is intractable for more than a few variables. We introduce a special class of polynomial systems consisting of a single defining inequality and a series of simplex constraints. Using tools from algebraic geometry, we introduce a novel class of polynomials which we call \textit{simplex-extensible}, and show that if the defining inequality consists of such a polynomial, then we can run CAD in singly exponential time. Importantly, the polynomial systems induced by Markov modelling are instances of this special system and have the simplex-extensible property. Using our theoretical results, we implement a software package which can symbolically manipulate Markov chains and construct CADs of inequalities arising from them.

4 - Learning Adaptive Behavioral Interventions to Reduce Ascvd Risk

John Silberholz, University of Michigan Ross School of Business, Ann Arbor, MI, United States, Hamsa Bastani

Increasing patient engagement in chronic disease prevention and management behaviors is crucial to the success of population health and value-based care programs, and many behavioral interventions have been studied for this purpose. A common challenge with these interventions is that they are often static -- they do not evolve based on user engagement, success, or failure. As a result, they may allocate resources in inefficient ways, such as using significant time of personnel to contact patients who are low risk or who are unengaged and unlikely to benefit from further engagement. This can be problematic, as behavioral interventions can be associated with significant costs. In this work, we develop a dynamically adapted intervention to engage patients in preventive health behaviors for Atherosclerotic Cardiovascular Disease (ASCVD), the leading cause of mortality worldwide. A key requirement for a dynamically adaptive algorithm is that it quickly identifies an effective approach to targeting patients with an intervention. To achieve this goal, we use data from five past ASCVD behavioral interventions to “warm-start” a proposed dynamically adapted intervention. We discuss ongoing work to pilot the proposed intervention.

1 - Approximate Global Convergence of Independent Learning in Multi-Agent Systems

Zaiwei Chen, Purdue University, West Lafayette, IN, United States, Ruiyang Jin, Yiheng Lin, Jie Song, Adam Wierman

Independent learning (IL), despite being a popular approach in practice to achieve scalability in large-scale multi-agent systems, usually lacks global convergence guarantees. In this paper, we study two representative algorithms, independent Q-learning and independent natural actor-critic, within value-based and policy-based frameworks, and provide the first finite-sample analysis for approximate global convergence. The results imply a sample complexity of $\tilde{\mathcal{O}}(\epsilon^{-2})$ up to an error term that captures the dependence among agents and characterizes the fundamental limit of IL in achieving global convergence. To establish the result, we develop a novel approach for analyzing IL by constructing a separable Markov decision process (MDP) for convergence analysis and then bounding the gap due to model difference between the separable MDP and the original one. Moreover, we conduct numerical experiments using a synthetic MDP and an electric vehicle charging example to demonstrate our results and the practical applicability of IL.

2 - Rectangularity and Duality of Distributionally Robust Markov Decision Processes

Yan Li, ISyE Georgia Tech, Atlanta, GA, United States, Alexander Shapiro

The main goal of this paper is to discuss several approaches to the formulation of distributionally robust counterparts of Markov Decision Processes, where the transition kernels are not specified exactly but rather are assumed to be elements of the corresponding ambiguity sets. The intent is to clarify some connections between the game and static formulations of distributionally robust MDPs, and delineate the role of rectangularity associated with ambiguity sets in determining these connections.

3 - Distributionally Robust Reinforcement Learning with Interactive Data Collection: Fundamental Hardness and Near-Optimal Algorithm

Miao Lu, Stanford University, Stanford, CA, United States, Han Zhong, Tong Zhang, Jose Blanchet

The sim-to-real gap, which represents the disparity between training and testing environments, poses a significant challenge in reinforcement learning (RL). A promising approach to addressing this challenge is distributionally robust RL, often framed as a robust Markov decision process (RMDP). In this framework, the objective is to find a robust policy that achieves good performance under the worst-case scenario among all environments within a pre-specified uncertainty set centered around the training environment. Unlike previous work, which relies on a generative model or a pre-collected offline dataset enjoying good coverage of the deployment environment, we tackle robust RL via interactive data collection, where the learner interacts with the training environment only and refines the policy through trial and error. In this robust RL paradigm, two main challenges emerge: managing distributional robustness while striking a balance between exploration and exploitation during data collection. Initially, we establish that sample-efficient learning without additional assumptions is unattainable owing to the curse of support shift. To circumvent such a hardness result, we introduce the vanishing minimal value assumption to RMDPs with a total-variation (TV) distance robust set, postulating that the minimal value of the optimal robust value function is zero. We prove that such an assumption effectively eliminates the support shift issue for RMDPs with a TV distance robust set, and present an algorithm with a provable sample complexity guarantee. Our work makes the initial step to uncovering the inherent difficulty of robust RL via interactive data collection and sufficient conditions for designing a sample-efficient algorithm.

4 - Value-Incentivized Preference Optimization: A Unified Approach to Online and Offline RLHF

Shicong Cen, Carnegie Mellon University, Pittsburgh, PA, United States, Jincheng Mei, Katayoon Goshvadi, Hanjun Dai, Tong Yang, Sherry Yang, Dale Schuurmans, Yuejie Chi, Bo Dai

We demonstrate that principled exploration for reinforcement learning (RL) can be achieved for general policy parameterizations, including large language models (LLMs), without requiring explicit uncertainty modeling. Avoiding explicit uncertainty modeling is critical in real world RL applications, such as preference alignment of LLMs using reinforcement learning from human feedback (RLHF) or direct preference optimization (DPO), since conducting uncertainty calculations over arbitrary nonlinear models is intractable. Our proposed solution, Value-Incentivized Preference Optimization (VIPO), utilizes an easy to calculate objective that admits theoretical guarantees. Experiments on text summarization and dialog verify the practicality and effectiveness of the proposed approach.

Recent Development in Revenue Management and Supply Chain Management

Invited Session

Revenue Management and Pricing

Chair: Anyan Qi, The University of Texas at Dallas, Richardson, TX, United States

1 - Component Pricing with a Bundle Size Discount

Zechao Li, Tsinghua University, Beijing, China, People's Republic of, Ningyuan Chen, Xiaobo Li, Chun Wang

Firms selling multiple products usually adopt bundle pricing in their marketing strategy for the purpose of extracting large consumer surplus. In this paper, we propose and analyze a bundling mechanism, referred to as component pricing with a bundle size discount (CPBSD), which sells bundles for the summed prices of the included products (component pricing) minus a discount based on the number of products purchased (bundle size discount). CPBSD is conceptually simple and has been widely used in real-world business. Theoretically, we show that CPBSD subsumes several well-studied bundling mechanisms as special cases. Moreover, we find instances in which other common mechanisms only generate a fraction of the optimal profit of CPBSD. We further prove that, under a general condition, CPBSD attains the optimal profit asymptotically for a large number of products among all bundle pricing mechanisms. Practically, we formulate a mixed-integer linear program for the optimal pricing scheme of CPBSD, and we also develop an approximation algorithm for efficiently solving CPBSD in large-scale problems. Through comprehensive numerical experiments, we show that CPBSD demonstrates superior performance in contrast to other bundling mechanisms. In particular, compared to bundle size pricing whose outstanding empirical performance has been extensively tested in the literature, CPBSD performs especially well when products are heterogeneous and the production costs are high. Furthermore, the outstanding performance of CPBSD is most pronounced when the potential surplus provided by products are negatively correlated with the product valuations.

2 - A Prior-Free, Asymptotically Efficient Mechanism for Two-Sided Platforms with Dynamic Arrivals

Arun Kumar Rout, The University of Texas at Dallas, Richardson, TX, United States, Milind Dawande, Ganesh Janakiraman

We consider a platform that operates a two-sided market in which unit-demand buyers with private valuations and unit-supply sellers with private costs arrive dynamically over time -- the arrival processes of the agents (buyers and sellers) and their value/cost distributions can be quite general in that these inputs are allowed to be Markov-modulated. The platform incurs a waiting cost per agent per unit time for unmatched agents waiting in the market. The platform wishes to design a mechanism that specifies how and when agents are matched or dismissed, subject to a budget-balance constraint. The platform's objective is to maximize the efficiency of the mechanism, defined as the difference of the aggregate valuation of the matched buyers and the aggregate cost of the matched sellers, less the waiting cost. For this problem, we develop a prior-free and dominant-strategy incentive compatible mechanism. For any choice of problem parameters, we derive a closed-form upper bound on the absolute efficiency gap of this mechanism. In addition, we show that this mechanism is asymptotically efficient (i.e., the relative efficiency gap of our mechanism approaches zero as the market size increases). More generally, our analysis offers a sophisticated yet intuitive framework that accepts as input a static mechanism (where all information is static) with some desirable properties and outputs a dynamic mechanism that retains these properties and is also prior-free and asymptotically efficient.

3 - Beyond One-Size-Fits-All: Personalized Delivery and Fulfillment Optimization

Quan Zhou, McGill University, Montreal, QC, Canada, Mehmet Gumus, Sentao Miao

Problem definition: Motivated by our collaboration with an online platform operating in North America, we explore the joint optimization of the order fulfillment process with personalized delivery options in the context of ecommerce. Each customer can choose from a personalized set of fulfillment options to proceed with the purchase or leave with no purchase. Fulfillment assignments of purchased orders are determined periodically. **Methodology**: We model customer behavior with a general discrete choice model and formulate the joint optimization as a stochastic dynamic program. We propose a tractable deterministic approximation and develop a computationally-efficient heuristic with a provable performance guarantee. We also extend the proposed our heuristic to the price-sensitive customer case. **Managerial implications**: By using both synthetic and real datasets collected from our industrial partner, we demonstrate the value of personalizing fulfillment options for the customers and jointly optimizing the options with fulfillment assignments. Our results show that demand management via personalized fulfillment options is prominent when customers favor quicker fulfillment and/or the fulfillment capacity is limited. However, an optimized fulfillment operation is more pivotal when customers are more willing to wait.

4 - Why Perfect Machine May Not be Perfect: Incentivizing Human-Machine Collaboration

Xiaotong Guan, Fudan University, Shanghai, China, People's Republic of, Anyan Qi, Shouqiang Wang

Humans and machines need to work collaboratively to make operational decisions such as demand forecasts. In this paper, we study how the machine should be designed to incentivize human-machine collaboration and obtain a rich set of results.

5 - Inventory Allocation Under the Greedy Fulfillment Policy: the (Potential) Perils of the Hindsight Approach

Sheng Liu, University of Toronto, Toronto, ON, Canada, Stefanus Jasin, Jinglong Zhao

We consider an online retailer with multiple warehouses and multiple demand locations. We assume that the retailer uses the greedy fulfillment policy (i.e., ship from the closest and/or cheapest warehouse) and consider the performance of the initial inventory allocation given by the hindsight or the stochastic programming approach, under which the retailer can first observe all the realized demands before simultaneously making the fulfillment decisions to minimize the total cost. The hindsight approach has been proposed by recent works in the literature and is practically appealing. While this approach has its merits, its limitations are not well understood. In this work, we first show that the hindsight solution is equivalent to the optimal inventory allocation under the greedy fulfillment policy but on a misspecified (more optimistic) demand arrival distribution. This optimism is sometimes benign but can also backfire. We provide necessary and sufficient conditions for the hindsight solution to be asymptotically optimal (as the unit lost sale cost grows large) under the greedy fulfillment policy. If any of these conditions are violated, we show that the expected total cost under the hindsight solution and the greedy fulfillment policy can be arbitrarily bad compared to the optimal expected total cost under the greedy fulfillment policy. Finally, we show that even if we allow the retailer to use the best fulfillment policy once the hindsight solution has been computed, in general, its expected total cost can still be arbitrarily bad compared to the optimal expected total cost under the greedy fulfillment policy.
